SUPPLEMENT

TO THE THIRD EDITION OF THE

ENCYCLOPÆDIA BRITANNICA;

OR, A

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE.

IN TWO VOLUMES.

Illustrated with Fifty Copperplates.

By GEORGE GLEIG, LL.D. F.R.S. Edin.

NON IGNORO, QUÆ BONA SINT, FIERI MELIORA POSSE DOCTRINA, ET QUÆ NON OPTIMA, ALIQUO MODO ACUI TAMEN, ET CORRIGI POSSE.——*Cicero.*

VOL. II.

THE SECOND EDITION, WITH IMPROVEMENTS.

Edinburgh:
PRINTED FOR THOMSON BONAR, PARLIAMENT-SQUARE;
BY *JOHN BROWN*, ANCHOR CLOSE, EDINBURGH.

1803.

[Entered in Stationers Hall.]

ADVERTISEMENT.

It would ill become me to difmifs thefe Volumes from my hands without acknowledging that, from many of the moft valuable difquifitions which they contain, I can claim no other merit than that of having ufhered them into the world.

Those who have read, and who underftand, the articles in the Encyclopædia Britannica, which were furnifhed by Profeffor Robifon of Edinburgh, can hardly need to be informed, that to the fame eminent philofopher I am indebted for the valuable articles Arch, Astronomy, Carpentry, Centre, Dynamics, Electricity, Impulsion, Involution *and* Evolution *of Curves*, Machinery, Magnetism, Mechanics, Percussion, Piano-*Forte*, *Centre of* Position, Temperament *in Mufic*, Thunder, *Mufical* Trumpet, Tschirnhaus, and Watchwork, in this Supplement. Of a friend and co-adjutor, whofe reputation is fo well eftablifhed as Dr Robifon's, I am proud to fay, that, while I looked up to him, during the progrefs of this Work, as to my mafter in mathematical and phyfical fcience, I found him ever ready to fupport, with all his abilities, thofe great principles of religion, morality, and focial order, which I felt it my own duty to maintain.

To Thomas Thomfon, M. D. of Edinburgh, a man of like principles, I am indebted for the beautiful articles Chemistry, Mineralogy, and *Vegetable*, *Animal*, and *Dyeing* Substances; of which it is needlefs for me to fay any thing, fince the Public feems to be fully fatisfied that they prove their author eminently qualified to teach the fcience of Chemiftry.

The account of the French Revolution, and of the wars which it has occafioned, has been continued in this Supplement by the fame Gentlemen by whom that account was begun in the Encyclopædia; and, owing to the caufe affigned in the article, probably with the fame merits and the fame defects.

My thanks are due to Dr William Wright for his continued kindnefs in communicating much curious botanical information: and to Mr Profeffor Playfair of the univerfity of Edinburgh, for lending his affiftance, occafionally, in the mathematical department; and for writing one beautiful article in that fcience, which is noticed as his in the order of the alphabet.

In compiling this Supplement, I have made very liberal ufe of the moft refpectable literary and fcientific journals, both foreign and domeftic; of all the late accounts of travels and voyages of difcovery, which have obtained, or feem indeed to deferve, the regard of the Public; of different and oppofite works on the French revolution, and what are emphatically called *French principles;* and even of the moft approved Dictionaries, fcientific and biographical. From no Dictionary, however, have I taken, without acknowledgment, any articles, except fuch as are floating everywhere on the furface of fcience, and are the property, therefore, of no living author.

After

After all my labour and induftry, which, whatever be thought of my other merits, I am confcious have been great, no man can be more fenfible than myfelf, that the Encyclopædia Britannica, even with the addition of this Supplement, is ftill imperfect. It would continue to be fo, were another Supplement added to this by the moft learned and laborious man on earth; for perfection feems to be incompatible with the nature of works conftructed on fuch a plan, and embracing fuch a variety of fubjects.

No candid reader will fuppofe that, by expreffing myfelf thus, I mean to cenfure the plan of the Encyclopædia Britannica in particular; for, to the general excellence of that plan I have elfewhere borne my teftimony, which I have yet feen no reafon to retract. Experience has indeed led me to think, that it is fufceptible of fuch improvements as would enable the principal Editor to carry the work *nearer* to perfection, even with lefs trouble to himfelf; but the purchafers of the third edition and this Supplement need not regret the want of thofe improvements, for they are fuch as few would difcern, who have not paid the fame attention that I have done to dictionaries of arts, fciences, and literature.

Before I take leave of the reader, I muft account for the omiffion of one or two articles (chiefly biographical) which I had given him reafon to expect in thefe volumes. It was my intention at firft to introduce into the Supplement articles on every fubject which had been admitted into the Encyclopædia itfelf; and hence in the firft fupplementary volume will be found biographical fketches of men whofe characters, though in fome refpects remarkable, have very little connection with fcience, arts, or literature. From this part of the original plan I was foon obliged to deviate. So many applications were made to me to infert accounts of perfons who, whatever may have been their private virtues, were never heard of in the republic of letters, that I was under the neceffity of excluding from the fecond volume the lives of *all* fuch as had not either been themfelves eminent in literature, or in fome liberal art or fcience, or been confpicuous as the *patrons* of fcience, arts, and literature, in others. Hence the omiffion of the life referred to from Aubigne in the firft volume, and of one or two others to which references are made in the fame way. The life of Mr James Hay Beattie of Aberdeen, whofe originality of genius, ardent love of virtue, and early and extenfive attainments in fcience and literature, raife him almoft to the eminence of Barretier, of whom we have fo pathetic an account from the pen of Johnfon, I omitted with regret; but I thought not myfelf authorized to publifh what his father had then only diftributed among a few particular friends. For the omiffion of the life of Soame Jenyns I can make no apology: it was the confequence of forgetfulnefs.

For the *errors* of thefe two volumes, whether typographical or of a nature more important, I have perhaps no occafion to folicit greater indulgence than will be voluntarily extended to me by a generous Public. Some errors I have corrected in this fecond impreffion, and fome deficiencies I have fupplied; but I was reftrained by thofe who are now Proprietors of the Work from making any *addition* to the firft volume, or any confiderable *alteration* in the firft part of the fecond. Hence the different conclufions which the reader will obferve in the articles Galvanism and Torpedo, refpecting the nature of the *Galvanic* power. Of thefe articles, the former was furnifhed by a friend, whofe name I am not at liberty to publifh; but whofe reafonings appeared to me too worthy of attention to be either omitted or abridged, though they lead to a conclufion which facts more recently afcertained feem to fet afide. Thefe facts I felt it my duty to ftate to the public; and, under the title Torpedo, I have been enabled to ftate them with the precifion and regularity of arrangement which characterife the writings of Dr Thomfon.

SUPPLEMENT

TO THE

ENCYCLOPÆDIA BRITANNICA.

INCREMENT, is the fmall increafe of a variable quantity. Newton, in his Treatife on Fluxions, calls thefe by the name *Moments;* and obferves, that they are proportional to the velocity or rate of increafe of the flowing or variable quantities in an indefinitely fmall time. He denotes them by fubjoining a cypher o to the flowing quantity whofe moment or increment it is; thus, xo the moment of x. In the doctrine of Increments, by Dr Brooke Taylor and Mr Emerfon, they are denoted by points below the variable quantities; as $\underset{.}{x}$. Some have alfo denoted them by accents underneath the letter, as $\underset{'}{x}$; but it is now more ufual to exprefs them by accents over the fame letter, as x'.

METHOD OF INCREMENTS, a branch of Analytics, in which a calculus is founded on the properties of the fucceffive values of variable quantities, and their differences or increments.

The inventor of the method of increments was the learned Dr Taylor, who, in the year 1715, publifhed a treatife upon it; and afterwards gave fome farther account and explication of it in the Philof. Tranf. as applied to the finding of the fums of feries. And another ingenious and eafy treatife on the fame, was publifhed by Mr Emerfon, in the year 1763. The method is nearly allied to Newton's Doctrine of Fluxions, and arifes out of it. Alfo the Differential method of Mr Stirling, which he applies to the fummation and interpolation of feries, is of the fame nature as the method of increments, but not fo general and extenfive.

INDETERMINATE PROBLEM. See ALGEBRA, Part I. Chap. VI. *Encycl.*

Diophantus was the firft writer on indeterminate problems, which, after the publication of his work in 1621 by Bachet, employed much of the time of the moft celebrated mathematicians in Europe. Afterwards fuch problems were neglected as ufelefs, till the public attention was again drawn to them by Euler and La Grange. The example of fuch men was followed by Mr John Leflie, a very eminent and felf-taught mathematician; who, in the fecond volume of the Tranfactions of the Royal Society of Edinburgh, has publifhed an ingenious paper on indeterminate problems, refolving them by a new and general principle. "The doctrine of indeterminate equations (fays Mr Leflie) has been feldom treated in a form equally fyftematic with the other parts of algebra. The folutions commonly given are devoid of uniformity, and often require a variety of affumptions. The object of this paper is to refolve the complicated expreffions which we obtain in the folotion of indeterminate problems, into fimple equations, and to do fo, without framing a number of affumptions, by help of a fingle principle, which, though extremely fimple, admits of a very extenfive application.

"Let $A \times B$ be any compound quantity equal to another, $C \times D$, and let m be any rational number affumed at pleafure; it is manifeft that, taking equimultiples, $A \times m B = C \times m D$. If, therefore, we fuppofe that $A = m D$, it muft follow that $m B = C$, or $B = \frac{C}{m}$. Thus two equations of a lower dimenfion are obtained. If thefe be capable of farther decompofition, we may affume the multiples n and p, and form four equations ftill more fimple. By the repeated application of this principle, an higher equation, admitting of divifors, will be refolved into thofe of the firft order, the number of which will be one greater than that of the multiples affumed."

For example, refuming the problem at firft given, viz. to find two rational numbers, the difference of the fquares of which fhall be a given number. Let the given number be the product of a and b; then by hypothefis, $x^2 - y^2 = ab$; but thefe compound quantities admit of an eafy refolution, for $\overline{x+y} \times \overline{x-y} = a \times b$. If, therefore, we fuppofe $x + y = ma$, we fhall obtain $x - y = \frac{b}{m}$; where m is arbitrary, and if rational, x and y muft alfo be rational. Hence the refolution of thefe two equations gives the values of x and y, the numbers fought, in terms of m; viz.
$x = \frac{m^2 a + b}{2m}$, and $y = \frac{m^2 a - b}{2m}$.

INDUCTION, in logic, is that procefs of the underftanding by which, from a number of *particular* truths perceived by fimple apprehenfion, and diligently compared together, we infer another truth, which is always *general* and fometimes *univerfal.* It is perhaps needlefs to obferve, that in the procefs of induction the truths to be compared muft be of the fame kind, or relate to objects having a fimilar nature; for the mereft tyro

tyro in ſcience knows that phyſical truths cannot be compared with moral truths, nor the truths of pure mathematics with either.

That the method of induction is a juſt logic has been ſufficiently evinced elſewhere (ſee Logic, Part III. chap. V. and Philosophy, n° 73—78, *Encycl.*), and is now indeed generally admitted. It is even admitted by Britiſh philoſophers to be the only method of reaſoning by which any progreſs can be made in the phyſical ſcinces; for the laws of Nature can be diſcovered only by accurate experiments, and by carefully noting the agreements and the differences, however minute, which are thus found among the phenomena apparently ſimilar. It is not, however, commonly ſaid that *induction* is the method of reaſoning employed by the mathematicians; and the writer of this article long thought, with others, that in pure geometry the reaſoning is ſtrictly *ſyllogiſtical*. Mature reflection, however, has led him to doubt, with Dr Reid*, the truth of the generally received opinion, to doubt even whether by categorical ſyllogiſms any thing whatever can be proved.

* Appendix to Vol. III. of *Sketches of the Hiſtory of Man.*

To the idolaters of Ariſtotle we are perfectly aware that this will appear an extravagant paradox; but to the votaries of truth, we do not deſpair of making it very evident, that for ſuch doubts there is ſome foundation.

We are led into this diſquiſition to counteract, in ſome degree, what we think the pernicious tendency of the philoſophy of Kant, which attempts have been lately made to introduce into this country. Of this philoſophy we ſhall endeavour to give ſomething like a diſtinct view in the proper place. It is ſufficient to obſerve here, that it reſts upon the hypotheſis, that "we are in poſſeſſion of certain notions *à priori*, which are abſolutely *independent of all experience*, although the *objects of experience* correſpond with them; and which are diſtinguiſhed by *neceſſity* and ſtrict *univerſality*." Theſe innate and univerſal notions, Kant conſiders as a ſet of *categories*, from which is to be deduced all ſuch knowledge as deſerves the name of ſcience; and he talks, of courſe, or at leaſt his Engliſh tranſlators repreſent him talking, with great contempt, of inductive reaſoning, and ſubſtituting ſyllogiſtic demonſtration in its ſtead.

As his categories are not familiar to our readers, we ſhall, in this place, examine ſyllogiſms connected with the categories of Ariſtotle, which are at leaſt more intelligible than thoſe of Kant, and which, being likewiſe general notions, muſt, in argument, be managed in the ſame way. Now the fundamental axiom upon which every categorical ſyllogiſm reſts, is the well known propoſition, which affirms, that "whatever may be predicated of a whole *genus*, may be predicated of every *ſpecies* and of every *individual* comprehended under that genus." This is indeed an undoubted truth; but it cannot conſtitute a foundation for reaſoning from the *genus* to the *ſpecies* or the *individual;* becauſe we cannot poſſibly know what can be predicated of the *genus* till we know what can be predicated of all the *individuals* ranged under it. Indeed it is only by aſcertaining, through the medium of induction, what can be predicated, and what not, of a number of individuals, that we come to form ſuch notions as thoſe of *genera* and *ſpecies;* and therefore, in a ſyllogiſm ſtrictly categorical, the propoſitions which conſtitute the *premiſſes*, and are taken for granted, are thoſe alone which are capable of proof; whilſt the concluſion, which the logician pretends to demonſtrate, muſt be evident to intuition or experience, otherwiſe the premiſſes could not be known to be true. The analyſis of a few ſyllogiſms will make this apparent to every reader.

Dr Wallis, who, to an intimate acquaintance with the Ariſtotelian logic, added much mathematical and phyſical knowledge, gives the following ſyllogiſm as a perfect example of this mode of reaſoning in the firſt figure, to which it is known that all the other figures may be reduced:—

> *Omne animal* eſt *ſenſu præditum.*
> *Socrates* eſt *animal.* Ergo
> *Socrates* eſt *ſenſu præditus.*

Here the propoſition to be demonſtrated is, that Socrates is endowed with ſenſe; and the propoſitions aſſumed as ſelf-evident truths, upon which the demonſtration is to be built, are, that "every animal is endowed with ſenſe;" and that "Socrates is an animal." But how comes the demonſtrator to know that "every animal is endowed with ſenſe?" To this queſtion we are not aware of any anſwer which can be given, except this, that mankind have agreed to call every being, which they perceive to be endowed with ſenſe, an *animal.* Let this then be ſuppoſed the true anſwer: The next queſtion to be put to the demonſtrator is, How he comes to know that *Socrates* is an *animal?* If we have anſwered the former queſtion properly, or, in other words, if it be eſſential to this genus of beings to be endowed with ſenſe, it is obvious that he can know that Socrates is an *animal* only by perceiving him to be *endowed with ſenſe;* and therefore, in this ſyllogiſm, the propoſition to be proved is the very firſt of the three of which the truth is perceived; and it is perceived intuitively, and not inferred from others by a proceſs of reaſoning.

Though there are ten categories and five predicables, there are but two kinds of categorical propoſitions; viz. Thoſe in which the property or accident is predicated of the ſubſtance to which it belongs, and thoſe in which the *genus* is predicated of the *ſpecies* or *individual.* Of the former kind is the propoſition pretended to be proved by the ſyllogiſm which we have conſidered; of the latter, is that which is proved by the following:

> Quicquid ſenſu præditum, eſt animal.
> Socrates eſt ſenſu præditus. Ergo
> Socrates eſt animal.

That this is a categorical ſyllogiſm, legitimate in mode and figure, will be denied by no man who is not an abſolute ſtranger to the very firſt principles of the Ariſtotelian logic; but it requires little attention indeed to perceive that it proves nothing. The impoſition of names is a thing ſo perfectly arbitrary, that the being, or claſs of beings, which in Latin and Engliſh is called *animal*, is with equal propriety in Greek called ζωον, and in Hebrew נפש. To a native of Greece, therefore, and to an ancient Hebrew, the major propoſition of this ſyllogiſm would have been wholly unintelligible; but had either of thoſe perſons been told by a man of known veracity, and acquainted with the Latin tongue, that every thing endowed with ſenſe was, by the Romans, called *animal*, he would then have underſtood the propoſition, admitted its truth without heſitation, and have henceforth

henceforth known that Socrates and Mofes, and every thing elfe which he perceived to be endowed with fenfe, would at Rome be called *animal*. This knowledge, however, would not have refted upon demonftrative reafoning of any kind, but upon the credibility of his informer, and the intuitive evidence of his own fenfes.

It will perhaps be faid, that the two fyllogifms which we have examined are improper examples, becaufe the truth to be proved by the former is felf-evident, whilft that which is meant to be eftablifhed by the latter is merely verbal, and therefore arbitrary. But the following is liable to neither of thefe objections:

All animals are *mortal*.
Man is *an animal*; therefore
Man is *mortal*.

Here it would be proper to afk the demonftrator, Upon what grounds he fo confidently pronounces all animals to be mortal? The propofition is fo far from expreffing a felf-evident truth, that, previous to the entrance of fin and death into the world, the firft man had furely no conception of mortality. He acquired the notion, however, by experience, when he faw the animals die in fucceffion around him; and when he obferved that no animal with which he was acquainted, not even his own fon, efcaped death, he would conclude that all animals, without exception, are mortal. This conclufion, however, could not be built upon fyllogiftic reafoning, nor yet upon intuition, but partly upon experience and partly on analogy. As far as his experience went, the proof, by induction, of the mortality of all animals was complete; but there are many animals in the ocean, and perhaps on the earth, which he never faw, and of whofe mortality therefore he could affirm nothing but from analogy, *i. e.* from concluding, as the conftitution of the human mind compels us to conclude, that Nature is uniform throughout the univerfe, and that fimilar caufes, whether known or unknown, will, in fimilar circumftances, produce, at all times, fimilar effects. It is to be obferved of this fyllogifm, as of the firft which we have confidered, that the propofition, which it pretends to demonftrate, is one of thofe truths known by experience, from which, by the procefs of induction, we infer the major of the premiffes to be true; and that therefore the reafoning, if reafoning it can be called, runs in a circle.

Yet by a concatenation of fyllogifms have logicians pretended that a long feries of important truths may be difcovered and demonftrated; and even Wallis himfelf feems to think, that this is the inftrument by which the mathematicians have deduced, from a few poftulates, accurate definitions, and undeniable axioms, all the truths of their demonftrative fcience. Let us try the truth of this opinion, by analyfing fome of Euclid's demonftrations.

In the fhort article Principle (*Encycl.*), it has been fhewn, that all our *firft* truths are *particular*, and that it is by applying to them the rules of induction that we form general truths or axioms—even the axioms of pure geometry. As this fcience treats not of real external things, but merely of *ideas* or *conceptions*, the creatures of our minds, it is obvious, that its definitions may be perfectly accurate, the induction by which its axioms are formed complete, and therefore the axioms themfelves *univerfal* propofitions. The ufe of thefe axioms is merely to fhorten the different proceffes of geometrical reafoning, and not, as has fometimes been abfurdly fuppofed, to be made the *parents* or *caufes* of *particular* truths. No truth, whether general or particular, can, in any fenfe of the word, be the caufe of another truth. If it were not true that all individual figures, of whatever form, comprehending a portion of fpace equal to a portion comprehended by any other individual figure, whether of the fame form with fome of them, or of a form different from them all, are equal to one another, it would not be true that "things in *general*, which are equal to the fame thing, or that magnitudes which coincide, or exactly fill the fame fpace," are refpectively equal to one another; and therefore the firft and eight of Euclid's axioms would be falfe. So far are thefe axioms, or general truths, from being the parents of particular truths, that, as conceived by us, they may, with greater propriety, be termed their *offspring*. They are indeed nothing more than general expreffions, comprehending all particular truths of the fame kind. When a mathematical propofition therefore is enounced, if the terms, of which it is compofed, or the figures, of which a certain relation is predicated, can be brought together and immediately compared, no demonftration is neceffary to point out its truth or falfehood. It is indeed intuitively perceived to be either comprehended under, or contrary to fome known *axiom* of the fcience; but it has the evidence of truth or falfehood in itfelf, and not in *confequence* of that axiom. When the figures or fymbols cannot be immediately compared together, it is then, and only then, that recourfe is had to demonftration; which proceeds, not in a feries of fyllogifms, but by a procefs of ideal menfuration or induction. A figure or fymbol is conceived, which may be compared with each of the principal figures or fymbols, or, if that cannot be, with one of them, and then another, which may be compared with it, till through a feries of well known intermediate relations, a comparifon is made between the terms of the original propofition, of which the truth or falfehood is then perceived.

Thus, in the 47th propofition of the firft book of Euclid's Elements, the author propofes to demonftrate the equality between the fquare of the hypothenufe of a right angled triangle, and the fum of the fquares defcribed on the other two fides; but he does not proceed in the way of categorical fyllogifms, by raifing his demonftration on fome univerfal truth relating to the *genus* of *fquares*. On the contrary, he proceeds to *meafure* the three fquares, of which he has affirmed a certain relation; but as they cannot be immediately compared together, he directs the largeft of them to be divided into two parallelograms, according to a rule which he had formerly afcertained to be juft; and as thefe parallelograms can, as little as the fquare of which they are the conftituent parts, be compared with the fquares of the other two fides of the triangle, he thinks of fome intermediate figure which may be applied as a common meafure to the fquares and the parallelograms. Accordingly having before found that a parallelogram, or fquare, is exactly double of a triangle ftanding on the fame bafe and between the fame parallels with it, he conftructs triangles upon the fame bafe, and between the fame parallels with his parallelograms, and the fquares of the fides containing the right angle of the original triangle; and finding, by a procefs formerly fhewn to be juft, that the triangles on the bases of the parallelograms are precisely equal to the triangles on the bases of the squares, he perceives at once that the two parallelograms, of which the largest square is composed, must be equal to the sum of the two lesser squares; and the truth of the proposition is demonstrated.

In the course of this demonstration, there is not so much as one truth *inferred* from another by *syllogism*, but all are perceived in succession by a series of simple apprehensions. Euclid, indeed, after finding the triangle constructed on the base of one of the parallelograms to be equal to the triangle constructed on the base of one of the squares, introduces an *axiom*, and says, "but the doubles of equals are equal to one another; *therefore* the parallelogram is equal to the square" But if from this mode of expression any man conceive the axiom or universal truth to be the *cause* of the truth more particular, or suppose that the *latter* could not be apprehended without a *previous* knowledge of the former, he is a stranger to the nature of evidence, and to the process of *generalization*, by which axioms are formed.

If we examine the problems of this ancient geometrician, we shall find that the truth of them is proved by the very same means which he makes use of to point out the truth of his theorems. Thus, the first problem of his immortal work is, "to describe an equilateral triangle on a given finite straight line; and not only is this to be done, but the method by which it is done must be such as can be shewn to be incontrovertibly just. The sides of a triangle, however, cannot be applied to each other so as to be immediately compared; for they are conceived to be immoveable among themselves. A common measure, therefore, or something equivalent to a common measure, must be found, by which the triangle may be constructed, and the equality of its three sides afterwards evinced; and this equivalent Euclid finds in the *circle*.

By contemplating the properties of the circle, it was easy to perceive that all its *radii* must be equal to one another. He therefore directs two circles to be described from the opposite extremities of the given finite straight line, so as that it may be the radius of each of them; and from the point in which the circles intersect one another, he orders lines to be drawn to the extreme points of the given line, affirming that these three lines constitute an equilateral triangle. To convince his reader of the truth of this affirmation, he has only to put him in mind, that from the properties of the circle, the lines which he has drawn must be each equal to the given line, and of course all the three equal to one another; and this mutual equality is perceived by simple apprehension, and not inferred by syllogistic reasoning. Euclid, indeed, by introducing into the demonstration his first axiom, gives to it the form of a syllogism: but that syllogism proves nothing; for if the equality of the three sides of the triangle were not intuitively perceived in their position and the properties of the circle, the first axiom would itself be a falsehood. So true it is that categorical syllogisms have no place in geometrical reasoning; which is as strictly experimental and inductive as the reasoning employed in the various branches of physics.

But if this be so, how come the truths of pure geometry to be necessary, so that the contrary of any one of them is clearly perceived to be impossible; whilst physical truths are all contingent, so that there is not one of them of which the direct contrary may not easily be conceived?

That there is not one physical truth, of which the contrary may not be conceived, is not perhaps so certain as has generally been imagined; but admitting the fact to be as it has commonly been stated, the apparent difference between this class of truths and those of pure geometry, may be easily accounted for, without supposing that the former rests upon a kind of evidence totally different from that which supports the fabric of the latter.

The objects of pure geometry, as we have already observed, are the creatures of our own minds, which contain in them nothing concealed from our view. As the mathematician treats them merely as measurable quantities, he knows, with the utmost precision, upon what particular properties the relation affirmed to subsist between any two or more of them must absolutely depend; and he cannot possibly entertain a doubt but it will be found to have place among all quantities having the same properties, because it depends upon them, and upon them alone. His process of induction, therefore, by a series of ideal measurements, is always complete, and exhausts the subject; but in physical inquiries the case is widely different. The subjects which employ the physical inquirer are not his own ideas, and their various relations, but the properties, powers, and relations of the bodies which compose the universe; and of those bodies he knows neither the substance, internal structure, nor all the qualities: so that he can very seldom discover with certainty upon what particular property or properties the phenomena of the corporeal world, or the relations which subsist among different bodies, depend. He expects, indeed, with confidence, not inferior to that with which he admits a mathematical demonstration, that any corporeal phenomenon, which he has observed in certain circumstances, will be always observed in circumstances exactly similar; but the misfortune is, that he can very seldom be ascertained of this similarity. He does not know any one piece of matter *as it is in itself*; he cannot separate its various properties; and of course cannot attribute to any one property the effects or apparent effects which proceed exclusively from it. Indeed, the properties of bodies are so closely interwoven, that by human means they cannot be completely separated; and hence the most cautious investigator is apt to attribute to some one or two properties, an event which in reality results perhaps from many. (See PHILOSOPHY and PHYSICS, *Encycl.*) This the geometrician never does. He knows perfectly that the relation of equality which subsists between the three angles of a plain triangle and two right angles, depends not upon the size of the triangles, the matter of which they are conceived to be made, the particular place which they occupy in the universe, or upon any one circumstance whatever besides their triangularity, and the angles of their corrolets being exactly right angles; and it is upon this power of discrimination which we have in the conceptions of pure geometry, and have not in the objects of physics, that the truths of the one science are perceived to be necessary, while those

Inertia, Inflammation.

those of the other appear to be contingent; though the mode of demonstration is the same in both, or at least equally removed from categorical syllogisms.

INERTIA. See DYNAMICS and IMPULSION in this *Supplement*.

INFLAMMATION has been sufficiently explained in the *Encyclopædia*, and in the article CHEMISTRY in this *Supplement;* but it cannot be improper, in this place, to give an account of some remarkable

Spontaneous INFLAMMATIONS, which, as different substances are liable to them, have been, and may again be, the cause of many and great misfortunes.

The spontaneous inflammation of essential oils, and that of some fat oils, when mixed with nitrous acid, are well known to philosophers; so also is that of powdered charcoal with the same acid (lately discovered by M. Proust), and those of phosphorus, of pyrophorus, and of fulminating gold. These substances are generally to be found only in the laboratories of chemists, who are perfectly well acquainted with the precautions which it is necessary to take to prevent the unhappy accidents which may be occasioned by them.

The burning of a store-house of sails, which happened at Brest in the year 1757, was caused by the spontaneous inflammation of some oiled cloths, which, after having been painted on one side, and dried in the sun, were stowed away while yet warm; as was shewn by subsequent experiments*.

* See *Memoires de l'Academie de Paris*, 1760.

Vegetables boiled in oil or fat, and left to themselves, after having been pressed, inflame in the open air. This inflammation always takes place when the vegetables retain a certain degree of humidity; if they are first thoroughly dried, they are reduced to ashes, without the appearance of flame. We owe the observation of these facts to MM. Saladin and Carette†.

† *Journal de Physique*, 1784.

The heaps of linen rags which are thrown together in paper manufactories, the preparation of which is hastened by means of fermentation, often take fire, if not carefully attended to.

The spontaneous inflammation of hay has been known for many centuries; by its means houses, barns, &c. have been often reduced to ashes. When the hay is laid up damp, the inflammation often happens; for the fermentation is then very great. This accident very seldom occurs to the first hay (according to the observation of M. de Bomare), but is much more common to the second; and if, through inattention, a piece of iron should be left in a stalk of hay in fermentation, the inflammation of that stalk is almost a certain consequence. Corn heaped up has also sometimes produced inflammations of this nature. Vanieri, in his *Prædium Rusticum*, says,

> *Quæ vero (gramina) nondum satis insolata recondens*
> *Imprudens, subitis pariunt incendia flammis.*

Dung also, under certain circumstances, inflames spontaneously.

In a paper, published in the *Repertory of Arts and Manufactories*, by the Rev. William Tooke, F. R. S. &c. we have the following remarkable instances of spontaneous inflammation. "A person of the name of Rüde, an apothecary at Bautzen, had prepared a pyrophorus from rye-bran and alum. Not long after he had made the discovery, there broke out, in the next village of Nauslitz, a great fire, which did much mischief, and was said to have been occasioned by the treating of a sick cow in the cow-house. Mr Rüde knew, that the countrymen were used to lay an application of parched rye-bran to their cattle for curing the thick neck; he knew also that alum and rye-bran, by a proper process, yielded a pyrophorus; and now he wished to try whether parched rye-bran alone would have the same effect. Accordingly, he roasted a quantity of rye-bran by the fire, till it had acquired the colour of roasted coffee. This roasted bran he wrapped up in a linen cloth; in the space of a few minutes there arose a strong smoke through the cloth, accompanied by a smell of burning. Not long afterwards the rag grew as black as tinder, and the bran, now become hot, fell through it on the ground in little balls. Mr Rüde repeated the experiment at various times, and always with the same result. Who now will any longer doubt, that the frequency of fires in cow-houses, which in those parts are mostly wooden buildings, may not be occasioned by this common practice, of binding roasted bran about the necks of the cattle? The fire, after consuming the cattle and the shed, communicates itself to the adjoining buildings; great damage ensues; and the ignorant look for the cause in wilful and malicious firing, consequently in a capital crime."

The same author informs us, that in the spring of the year 1780, a fire was discovered on board a Russian frigate lying in the road of Cronstadt; which, if it had not been timely extinguished, would have endangered the whole fleet. After the severest scrutiny, no cause of the fire was to be found; and the matter was forced to remain without explanation, but with strong surmises of some wicked incendiary being at the bottom of it. In the month of August, in the same year, a fire broke out at the hemp-magazine at St Petersburgh, by which several hundred thousand poods* of hemp and flax were consumed. The walls of the magazine were of brick, the floors of stone, and the rafters and covering of iron; it stands alone on an island in the Neva, on which, as well as on board the ships lying in the Neva, no fire is permitted. In St Petersburgh, in the same year, a fire was discovered in the vaulted shop of a furrier. In these shops, which are all vaults, neither fire nor candle is allowed, and the doors of them are all of iron. At length the probable cause was found to be, that the furrier, the evening before the fire, had got a roll of new cere-cloth (much in use here for covering tables, counters, &c. being easily wiped and kept clean), and had left it in his vault, where it was found almost consumed.

* A pood consists of 40 pounds Russ, or 36 English.

In the night between the 20th and 21st of April 1781, a fire was seen on board the frigate Maria, which lay at anchor, with several other ships, in the road off the island of Cronstadt; the fire was, however, soon extinguished; and, by the severest examination, little or nothing could be extorted concerning the manner in which it had arisen. The garrison was threatened with a scrutiny that should cost them dear; and while they were in this cruel state of suspence, an order came from the sovereign, which quieted their minds, and gave rise to some very satisfactory experiments.

It having been found, upon juridical examination, as well as private inquiry, that in the ship's cabin, when the smoke appeared, there lay a bundle of matting, containing Russian lamp-black prepared from fir-soot, moistened with hemp oil varnish, which was perceived

to

Inflammation. to have ſparks of fire in it at the time of the extinction, the Ruſſian admiralty gave orders to make various experiments, in order to ſee whether a mixture of hemp-oil varniſh and the forementioned Ruſſian black, folded up in a mat and bound together, would kindle of itſelf.

They ſhook 40 pounds of fir-wood ſoot into a tub, and poured about 35 pounds of hemp-oil varniſh upon it; this they let ſtand for an hour, after which they poured off the oil. The remaining mixture they now wrapped up in a mat, and the bundle was laid cloſe to the cabin, where the midſhipmen had their birth. To avoid all ſuſpicion of treachery, two officers ſealed both the mat and the door with their own ſeals, and ſtationed a watch of four ſea-officers, to take notice of all that paſſed the whole night through; and as ſoon as any ſmoke ſhould appear, immediately to give information to the commandant of the port.

The experiment was made the 26th of April, about 11 o'clock A. M. in preſence of all the officers named in the commiſſion. Early on the following day, about ſix o'clock A. M. a ſmoke appeared, of which the chief commandant was immediately informed by an officer: he came with all poſſible ſpeed, and through a ſmall hole in the door ſaw the mat ſmoking. Without opening the door, he diſpatched a meſſenger to the members of the commiſſion; but as the ſmoke became ſtronger, and fire began to appear, the chief commandant found it neceſſary, without waiting for the members of the commiſſion, to break the ſeals and open the door. No ſooner was the air thus admitted, than the mat began to burn with greater force, and preſently it burſt into a flame.

The Ruſſian admiralty, being now fully convinced of the ſelf-enkindling property of this compoſition, tranſmitted their experiment to the Imperial Academy of Sciences; who appointed Mr Georgi, a very learned and able adjunct of the academy, to make farther experiments on the ſubject. Previous to the relation of theſe experiments, it is neceſſary to obſerve, that the Ruſſian fir-black is three or four times more heavy, thick, and unctuous, than that kind of painters black which the Germans call *kien-rahm*. The former is gathered at Ochta, near St Peterſburgh, at Moſco, at Archangel, and other places, in little wooden huts, from reſinous fir-wood, and the unctuous bark of birch, by means of an apparatus uncommonly ſimple, conſiſting of pots without bottoms ſet one upon the other; and is ſold very cheap. The famous fine German *kien-rahm* is called in Ruſſia *Holland's black*. In what follows, when raw oil is ſpoken of, it is to be underſtood of linſeed-oil or hemp oil; but moſt commonly the latter. The varniſh is made of five pounds of hemp-oil boiled with two ounces and a half of minium. For wrapping up the compoſition, Mr Georgi made uſe of coarſe hemp-linen, and always ſingle, never double. The impregnations and commixtures were made in a large wooden bowl, in which they ſtood open till they were wrapped up in linen.

Three pounds of Ruſſian fir-black were ſlowly impregnated with five pounds of hemp-oil varniſh; and when the mixture had ſtood open five hours, it was bound up in linen. By this proceſs it became clotted; but ſome of the black remained dry. When the bundle had lain ſixteen hours in a cheſt, it was obſerved to emit a very nauſeous, and rather putrid, ſmell, not quite unlike that of boiling oil. Some parts of it became warm, and ſteamed much; this ſteam was watery, and by no means inflammable. Eighteen hours after the mixture was wrapped up, one place became brown, emitted ſmoke, and directly afterwards glowing fire appeared. The ſame thing happened in a ſecond and a third place, though other places were ſcarcely warm. The fire crept ſlowly around, and gave a thick, grey, ſtinking ſmoke. Mr Georgi took the bundle out of the cheſt, and laid it on a ſtone pavement; when, on being expoſed to the free air, there aroſe a ſlow burning flame, a ſpan high, with a ſtrong body of ſmoke. Not long afterwards there appeared, here and there, ſeveral chaps or clefts, as from a little volcano, the vapour iſſuing from which burſt into flame. On his breaking the lump, it burſt into a very violent flame, full three feet high, which ſoon grew leſs, and then went out. The ſmoking and glowing fire laſted for the ſpace of ſix hours; and afterwards the remainder continued to glow without ſmoke for two hours longer. The grey earthy aſhes, when cold, weighed five ounces and a half.

In another experiment, perfectly ſimilar to the foregoing, as far as relates to the compoſition and quantities, the enkindling did not enſue till 41 hours after the impregnation: the heat kept increaſing for three hours, and then the accenſion followed. It is worthy of remark, that theſe experiments ſucceeded better on bright days than on ſuch as were rainy; and the accenſion came on more rapidly.

In another experiment, three pounds of Ruſſian fir-black were ſlowly impregnated with three pounds of raw hemp-oil; and the accenſion enſued after nine hours.

Three quarters of a pound of German *rahm* were ſlowly impregnated with a pound and a half of hemp-oil varniſh. The mixture remained 72 hours before it became hot and reeking: it then gradually became hotter, and emitted a ſtrong exhalation; the effluvia were moiſt, and not inflammable. The reaction laſted 36 hours; during which the heat was one while ſtronger, and then weaker, and at length quite ceaſed.

Stove or chimney ſoot, moſtly formed from birch-wood ſmoke, was mingled with the above-mentioned ſubſtances, and tied up; the compound remained cold and quiet.

Ruſſian fir-black, mixed with equal parts of oil of turpentine, and bound up, exhibited not the leaſt reaction or warmth.

Birch oil, mixed with equal parts of Ruſſian fir-black, and bound up, began to grow warm and to emit a volatile ſmell; but the warmth ſoon went off again.

The inſtances of ſpontaneous inflammation hitherto mentioned have been only of vegetable ſubſtances; but we have examples of the ſame thing in the animal kingdom. Pieces of woollen cloth, which had not been ſcoured, took fire in a warehouſe. The ſame thing happened to ſome heaps of woollen yarn; and ſome pieces of cloth took fire in the road, as they were going to the fuller. Theſe inflammations always take place where the matters heaped up preſerve a certain degree of humidity, which is neceſſary to excite a fermentation; the heat reſulting from which, by drying the oil, leads them inſenſibly to a ſtate of ignition; and the quality of the oil, being more or leſs deſiccative, very much contributes thereto.

The

The woollen ftuff prepared at Sevennes, which bears the name of Emperor's ftuff, has kindled of itfelf, and burnt to a coal. It is not unufual for this to happen to woollen ftuffs, when in hot fummers they are laid in a heap in a room but little aired.

In June 1781, the fame thing happened at a woolcomber's in a manufacturing town in Germany, where a heap of wool-combings, piled up in a clofe warehoufe feldom aired, took fire of itfelf. This wool had been by little and little brought into the warehoufe; and, for want of room, piled up very high, and trodden down, that more might be added to it. That this combed wool, to which, as is well known, rape-oil mixed with butter is ufed in the combing, burnt of itfelf, was fworn by feveral witneffes. One of them affirmed that, ten years before, a fimilar fire happened among the flocks of wool at a clothier's, who had put them into a cafk, where they were rammed hard, for their eafier conveyance. This wool burnt from within outwards, and became quite a coal; it was very certain that neither fire nor light had been ufed at the packing, confequently the above fires arofe from fimilar caufes. In like manner, very credible cloth-workers have certified, that, after they have brought wool that was become wet, and packed it clofe in their warehoufe, this wool has burnt of itfelf; and very ferious confequences might have followed, if it had not been difcovered in time.

Nay, there are inftances, though they be but rare, of human bodies being confumed by fpontaneous inflammation. In the Philofophical Tranfactions, and in the Memoirs of the Academies of Paris and Copenhagen, it is related that an Italian lady (the Countefs Cornelia Bandi) was entirely reduced to afhes, except her legs; that an Englifh woman, called Grace Pitt, was almoft entirely confumed by a fpontaneous inflammation of her vifcera; and, laftly, that a prieft of Bergamo was confumed in the fame manner. Thefe fpontaneous inflammations have been attributed to the abufe of fpirituous liquors; but though the victims of intemperance are indeed very numerous, thefe certainly do not belong to that number.

The mineral kingdom alfo often affords inftances of fpontaneous inflammation. Pyrites heaped up, if wetted and expofed to the air, take fire. Pitcoal alfo, laid in heaps, under certain circumftances, inflames fpontaneoufly. M. Duhamel has defcribed two inflammations of this nature, which happened in the magazines of Breft, in the years 1741 and 1757. Cuttings of iron, which had been left in water, and were afterwards expofed to the open air, gave fparks, and fet fire to the neighbouring bodies. For this obfervation we are obliged to M. de Charpentier.

The caufes of thefe phenomena the chemift will affign; but they are here recorded as a warning to tradefmen and others. It is evident, from the facts which have been related, that fpontaneous inflammations being very frequent, and their caufes very various, too much attention and vigilance cannot be ufed to prevent their dreadful effects. And confequently it is impoffible to be too careful in watching over public magazines and ftorehoufes, particularly thofe belonging to the ordnance, or thofe in which are kept hemp, cordage, lampblack, pitch, tar, oiled cloths, &c. which fubftances ought never to be left heaped up, particularly if they have any moifture in them. In order to prevent any accident from them, it would be proper to examine them often, to take notice if any heat is to be obferved in them, and, in that cafe, to apply a remedy immediately. Thefe examinations fhould be made by day, it not being advifable to carry a light into the magazines; for when the fermentation is fufficiently advanced, the vapours which are difengaged by it are in an inflammable ftate, and the approach of a light might, by their means, fet fire to the fubftances whence they proceed. Ignorance of the fore-mentioned circumftances, and a culpable negligence of thofe precautions which ought to be taken, have often caufed more misfortunes and lofs than the moft contriving malice: it is therefore of great importance that thefe facts fhould be univerfally known, that public untility may reap from them every poffible advantage.

INFORMED Stars, or Informes Stellæ, are fuch ftars as have not been reduced into any conftellation; otherwife called Sporades.—There was a great number of this kind left by the ancient aftronomers; but Hevelius, and fome others of the moderns, have provided for the greater part of them, by making new conftellations.

Sympathetic INK is an old invention. Among the methods by which Ovid teaches young women to deceive their guardians, when they write to their lovers, he mentions that of writing with new milk, and of making the writing legible by coal-duft or foot.

Tuta quoque eft, fallitque oculos, e lacte recenti
Litera: carbonis pulvere tange, leges.

It is obvious, that any other colourlefs and glutinous juice, which will hold faft the black powder ftrewed over it, will anfwer the purpofe as well as milk; and therefore Pliny recommends the milky juice of certain plants to be ufed.

There are feveral metallic folutions perfectly colourlefs, or, at leaft, without any ftrong tint, which being wrote with, the letters will not appear until the paper be wafhed over with another colourlefs folution, or expofed to the vapour of it; but among all thefe there is none which excites more aftonifhment, or from which naturalifts can draw more conclufions, than that which confifts of a folution of lead in vegetable acid, and which by the vapour of arfenical liver of fulphur becomes black, even at a confiderable diftance. This ink, which may be ufed by conjurors, proves the fubtlety of vapour, and the porofity of bodies; as the change or colouring takes place even when the writing is placed on the other fide of a thin wall.

We knew before, that a folution of lead, treated in this manner, would anfwer the purpofe of a fympathetic ink (fee that article *Encycl.*); but we did not know, nor do we yet believe, that the fulphuric vapours will act upon the writing through *a wall*. Such, however, is the affirmation of Profeffor Beckmann, who gives an account of a ftill more wonderful ink from Peter Borel. This author, in a book called *Hiftoriarum et obfervationum medico-phyfic. centuriæ quatuor*, printed at Paris, firft in 1653, and afterwards in 1657, gives a receipt for making this ink, which he calls *magnetic waters which act at a diftance*. The receipt is as follows:

"Let quick lime be quenched in common water, and, while quenching, let fome orpiment be added to it (this, however, ought to be done by placing warm afhes under it for a whole day), and let the liquor be filtered, and.

Ink.

and preferved in a glafs bottle well corked. Then boil litharge of gold, well pounded, for half an hour with vinegar, in a brafs veffel, and filter the whole through paper, and preferve it alfo in a bottle clofely corked. If you write any thing with this laft water, with a clean pen, the writing will be invifible when dry; but if it be wafhed over with the firft water it will become inftantly black. In this, however, there is nothing aftonifhing; but this is wonderful, that though fheets of paper without number, and even a board, be placed between the invifible writing and the fecond liquid, it will have the fame effect, and turn the writing black, penetrating the wood and paper without leaving any traces of its action, which is certainly furprifing; but a fetid fmell, occafioned by the mutual action of the liquids, deters many from making the experiment. I am, however, of opinion, that I could improve this fecret by a more refined chemical preparation, fo as that it fhould perform its effect through a wall. This fecret (fays Borel) I received, in exchange for others, from J. Broffon, a learned and ingenious apothecary of Montpelier."

For making a fympathetic ink of the fifth clafs mentioned in the *Encyclopædia*, the following procefs by M. Meyer may be worthy of the reader's notice. It was entered upon in confequence of a receipt for rofe-coloured fympathetic ink fhewn to him by a traveller. In that receipt cobalt was the principal ingredient, and therefore the firft object was to procure cobalt; but M. Meyer, being unwilling to facrifice pure pieces of cobalt of any confiderable fize, made choice of one, which was vifibly mixed with bifmuth, iron, and quartz. He endeavoured to feparate the bifmuth as much as poffible, and alfo the arfenic, if it fhould contain any, by bringing it flowly to a red heat; and he fucceeded pretty well, as the bifmuth flowed from it in abundance; and the arfenic, the quantity of which was fmall, was volatilifed: many globules of bifmuth ftill adhered to it. By bringing it repeatedly to a red heat, and then quenching it in water, it was reduced to fuch a ftate as to be eafily pulverifed. Having poured nitrous acid upon the powder, he obtained by digeftion a beautiful rofe red folution; the filiceous earth was feparated in the form of a white flime, and by diluting it with water there was depofited a white powder, which was oxyd of bifmuth. The folution being filtered, he added to it a folution of potafh, and obtained a precipitate inclining more to a yellow than to a red colour. He again poured over it a little of the nitrous acid, by which a part of the oxyd was re-diffolved of a red colour: the remaining part, which had a dark brown colour, was oxyd of iron. From the folution, by the addition of potafh, a precipitate was formed, which was now reddifh. Having by this procefs obtained it pure, that he might now prepare from it the wifhed-for red ink, he diffolved the wafhen pure oxyd of cobalt in different acids. That diffolved in the nitrous acid with a mixture of nitre, gave a green ink like the common: that diffolved in the fulphurous acid, without the addition of falts, gave a reddifh ink, which remained after it was expofed to heat, and would not again difappear, even when a folution of nitre was applied; and that diffolved in the muriatic acid, gave a green ink, darker and more beautiful than the common. By diffolving it, however, in the acetous acid, and adding a little nitre, he obtained what he had in view; for it gave, on the application of heat, an ink of a red colour, like that of the *rofa centifolia*, which again difappeared when the paper became cold.

Inordinate, Infects.

INORDINATE PROPORTION, is where the order of the terms compared is difturbed or irregular. As, for example, in two ranks of numbers, three in each rank, viz. in one rank, - - - 2, 3, 9, and in the other rank, - - - 8, 24, 36, which are proportional, the former to the latter, but in a different order, viz. - - 2 : 3 : : 24 : 36,
and - - 3 : 9 : : 8 : 24.
then, cafting out the mean terms in each rank, it is concluded that - - - - 2 : 9 : : 8 : 36,
that is, the firft is to the 3d in the firft rank,
as the firft is to the 3d in the 2d rank.

INSECTS (See *Encycl.*). A number of non-defcript little animals was difcovered by La Martiniere the naturalift when accompanying Peroufe on his celebrated voyage of difcovery. Thefe animals he called *infects*, and to many of them he gave particular names. Of thefe we fhall give his defcription in this place, leaving our readers, as he has left his, to arrange them properly according to the Linnæan claffification.

"The infect, which is figured N° 1. inhabits a fmall prifmatic triangular cell, pointed at the two extremities, of the confiftence and colour of clear brittle ice; the body of the infect is of a green colour, fpotted with fmall bluifh points, among which are fome of a golden tinge; it is fixed by a ligament to the lower part of its fmall habitation: its neck is terminated by a fmall blackifh head compofed of three converging fcales, in the form of a hat, and enclofed between three fins, two of them large and channelled in the upper part (A) and one fmall femicircular (B). When it is difturbed, it immediately withdraws its fins and its head into its cell, and gradually finks into the water by its own fpecific gravity. Fig. 2. reprefents the under fide of the prifm, fhewing in what manner it is channelled, in order to allow free paffage to the animal when it wifhes to fhut itfelf up in it. Fig. 3 reprefents the profile of the fame. The movement carried on by the two larger fins, which are of a foftifh cartilaginous fubftance, may be compared to that which would be produced by the two hands joined together in the ftate of pronation, and forming, alternately, two inclined planes and one horizontal plane: it is by means of this motion that it fupports itfelf on the top of the water, where it probably feeds on fat and oily fubftances on the furface of the fea." Our author found it near Nootka, on the north-weft coaft of America, during a calm.

Plate XXX.

Fig. 4. reprefents a collection of infects, as our author calls them, confifting only of oval bodies, fimilar to a foap-bubble, arranged in parties of three, five, fix, and nine: among them are alfo fome folitary ones. Thefe collections of globules, being put into a glafs filled with fea-water, defcribed a rapid circle round the glafs by a common movement, to which each individual contributed by fimple compreffion of the fides of its body, probably the effect of the re-action of the air with which they were filled. It is not, however, eafy to conceive how thefe diftinct animals (for they may be readily feparated without deranging their economy) are capable of concurring in a common motion. "Thefe confiderations (fays our author), together with the form of the animal, recalled to my mind, with much fatisfaction, the ingenious fyftem of M. de Buffon; and I endeavoured to perfuade myfelf, that I was about to be witnefs

Insects, Institute.

ness to one of the most wonderful phenomena of Nature, supposing that these molecules, which were now employed in increasing or diminishing their number, or performing their revolutions in the glass, would soon assume the form of a new animal of which they were the living materials. My impatience led me to detach two from the most numerous group, imagining that this number might perhaps be more favourable to the expected metamorphosis. I was, however, mistaken. These I examined with more attention than the rest; and the following account is of their proceedings alone. Like two strong and active wrestlers, they immediately rushed together, and attacked each other on every side: sometimes one would dive, leaving its adversary at the surface of the water; one would describe a circular movement, while the other remained at rest in the centre; their motions at length became so rapid as no longer to allow me to distinguish one from the other. Having quitted them for a short time, on my return I found them reunited as before, and amicably moving round the edge of the glass by their common exertions."

Fig. 5. represents a singular animal, which has a considerable resemblance to a little lizard; its body is of a firm, gelatinous consistence; its head is furnished on each side with two small gelatinous horns, of which the two hindermost are situate the furthest inward: its body is provided with four open fan-like paws, and some appendages near the insertion of the tail, and terminates like that of a lizard; the ridge of the back is divided the whole way down by a band of a deep blue; the rest of the body, as well as the inside of its paws, is of a bright silvery white. It appears to be very sluggish in its motions; and when disturbed by the finger, merely turned itself belly upwards, soon afterwards resuming its former position. Fig. 6. represents it reversed. Martiniere caught it during a calm at the landing place on the Bashee Islands.

INSTITUTE is a name which has lately been substituted for *school* or *academy*. Formerly *institution*, in the propriety of the English language, was sometimes used as a word of the same import with *instruction*; and now *institute* is employed, especially by the admirers of French innovations, to denote what had hitherto been called an academy. When royalty was abolished in France, it would have been absurd to continue the titles *Royal* Academy of Sciences, *Royal* Academy of Inscriptions, &c.; but instead of merely abolishing the word *royal*, and substituting *national* in its stead, it occurred to the fertile brain of Condorcet, to abolish the seven academies themselves, or rather to melt them all down into one great academy; to which was given the appellation of the

National INSTITUTE, or *New Academy of Arts and Sciences*. This academy, founded on a decree of the new constitution, was opened on the 7th of December 1795, when BENEZECH, the then minister for the home department, attended, and the decree of foundation was read; which was to the following purport:

"The Academy of Arts and Sciences belongs to the whole republic, and Paris is its place of residence. Its employment is to aim at bringing all arts and sciences to the utmost perfection of which they are capable. It is to notice every new attempt, and all new discoveries, and to keep up a correspondence with all foreign literary societies. And by the particular orders of the Executive Directory, its first studies are to be directed to those subjects which more immediately tend to the reputation and advantage of the French republic."

The academy is to consist of 288 members, half of whom are to reside in Paris, the other half in the departments; and to them is to be added a certain number of foreigners, as honorary members, confined at present to twenty-four.

The academy is divided into three classes, each class into sections, each section to contain twelve members.

1st class. Mathematics and natural philosophy. This class is divided into ten sections 1. Mathematics. 2. Mechanical arts. 3. Astronomy. 4. Experimental philosophy. 5. Chemistry. 6. Natural history. 7. Botany. 8. Anatomy and animal history. 9. Medicine and surgery. 10. Animal œconomy, and the veterinary science.

2d class. Morality and politics. This class consists of six sections. 1. Analysis of sensations and ideas. 2. Morals. 3. Legislature. 4. Political economy. 5. History. 6. Geography.

3d class. Literature and the fine arts. This class consists of eight sections. 1. Universal grammar. 2. Ancient languages. 3. Poetry. 4. Antiquities. 5. Painting. 6. Sculpture. 7. Architecture. 8. Music.

For each class a particular room in the Louvre is appropriated. No one can be a member of two classes at the same time, but a member of one class may be present at the meetings of any other. Each class is to print, yearly, an account of its transactions.

Four times a-year there are to be public meetings. On these occasions, the three classes meet together. At the end of each year, they are to give a circumstantial account to the legislative body of the progress made in that year in the arts and sciences. The prizes given yearly by each class are to be publicly notified at certain times. The sums requisite for the support of the institution are to be decreed yearly by the legislative body, upon a requisition made by the Executive Directory.

The first forty-eight members were chosen by the Executive Directory, to whom the choice of the remaining members was confided. To the members, residentiary in Paris, is reserved the choice both of the department and the foreign members. On a vacancy in any class, three candidates are named by the class for the choice of the body at large.

Each class is to have, as its place of meeting, a collection of the products, both of nature and art, and a library, according to its particular wants.

The regulations of the institution, with respect to the times of meeting, and its employments, are to be drawn up by the body at large, and laid before the legislative assembly.

The hall in which the body at large holds its meetings, forms part of the west wing of the Old Louvre, at present called the Museum. It formerly went by the appellation of the Hall of Antiques (*Salle des Antiques*); and as long as the kings inhabited this part of the palace was occupied by their guards, from which circumstance it obtained the name of the Hall *de Cent Suisses*. It was likewise appropriated to banquets and entertainments, given by the court on gala days; and it was to this place that Henry IV. was conveyed, on his assassination by Ravaillac, in the *Rue de la Ferronnerie*.

It was built at the same time with the rest of this part

part of the Louvre, about the year 1528, after the designs of Pierre Lescot, abbot of Clagny. It is 144 feet in length, and 40 in breadth, and holds from 1000 to 1200 persons. In order to adapt it to its new destination the floor has been sunk, which gives a greater air of lightness to the roof. In the centre stands a double table, in the form of a horse-shoe, supported by sphinxes, at which the members of the institute take their seats. This table is surrounded by two tiers of benches, which are raised for the accommodation of spectators, who have likewise seats provided for them in the vast embrasures of the windows, and at each extremity of the hall.

Whether science will be advanced by the seven royal academies having been melted into one, time must determine; but candour compels us to acknowledge, that the proceedings of the national institute have hitherto been abundantly interesting. Intimately connected with the national institute is the French system of

National Instruction, which is likewise novel, and therefore sufficiently curious to deserve notice in a Work of this kind. When the Christian religion was abolished in France, it was impossible to continue the universities and other seminaries which were founded by Christians, and obliged by their constitution to teach, whether pure or not, the doctrines of Christianity. They were accordingly all swept away, and a new system of education planned, which was to be carried on in what they call

The primary Schools.
The Central Schools.
The School of Health.
The School of Oriental Languages.

The Jury of Public Instruction.
The Commission of Public Instruction.
The Legislative Committee of Instruction. And various other national establishments for the improvement of particular sciences.

The first degree of public instruction is to be met with in the *Ecoles Primarées*, established by a decree of the convention of the second *Pluvoise*, in the second year of the republic (A). Every district is furnished with one of these schools; the professors or masters in which are paid from the national treasury; and to which every head of a family, without exception, is compelled by law to send its children for instruction. The subjects taught in these primary or elementary schools are divided into nine classes:

1st, Instructions connected with the physical and moral situation of children, prior to their entering into these schools. *2d*, Similar instructions as a guide to teachers in the national schools. *3d*, The arts of reading and writing. *4th*, The elements of French grammar. *5th*, Elements of arithmetic and geometry, with the theory of the new mensuration. *6th*, The elements of geography. *7th*, Explanations of the principal phenomena and productions of nature. *8th*, Elements of agriculture. *9th*, Elements of republican morals.

Next to the primary schools in rank and consequence are the *Ecoles Centrales*, which were established by a decree of the Convention of the seventh *Ventose* in the third year. They are situated in the capital of every department, bearing the proportion of one central school to 300,000 inhabitants. In these schools the republican youths are taught the sciences, and their application in real life. In each of them are professors for the following branches:

1. For mathematics. 2. Experimental philosophy and chemistry. 3. Natural history. 4. Agriculture and commerce. 5. Logic and metaphysics. 6. Political economy and legislation. 7. The Philosophical history of nations. 8. The art of healing. 9. Arts and manufactures. 10. Universal grammar. 11. The belles lettres. 12. The ancient languages. 13. The modern languages. 14. The fine arts.

Each central school is furnished with an extensive public library—a botanic garden—a cabinet of natural history—an apparatus for experimental philosophy—and a collection of machines and models connected with the arts and manufactures.

The professors of each school hold, every month, a public sitting, in which conferences are held relative to subjects connected with the improvement of letters, the sciences, and the arts, which are the most beneficial to society.

The object in the establishment of the primary and central schools was, the general instruction of all classes of the citizens; and it being incompatible with the perfect completion of that important purpose, to expect from them the propagation of particular branches of science, it became necessary to establish other literary and scientific academies.

Accordingly, the French government have founded, *1st*, Schools of health (*les ecoles de sante*), in Paris, Strasburgh, and Montpelier, where medicine and surgery are studied; which schools are affirmed, by those who find nothing wrong in France, to be the most perfect of their kind, as well as new and unparalleled models for such institutions.

2d, Two schools for Oriental languages, in the national library, and in the college of France.

3d, The Polytechnic school in Paris, or central school for the direction of public works. This establishment is very generally admired and considered as a model for imitation. It contains more than 400 young persons, previously educated in the mathematics, and the majority of them intended for engineers in various lines; and they labour under the immediate direction of their tutors nine hours every day. It occupies the principal part of the *Palais de Bourbon* in Paris, and is furnished with a large collection of instruments and models. The journal of the Polytechnic school, which is published by the booksellers Regent and Bertrand at Paris, is a perfectly original work, and admirably calculated to convey useful information.

Of

(A) We would translate this chronological jargon into the language of Christian Europe, were we not persuaded that the French kalendar, the French constitution, and the French institutes, will have the same duration: we trust in God not a long duration. For *Pluvoise*, and the other fantastical names of months introduced into this article, see Revolution, *Encycl.* n° 184.

Of the national institute, a sufficient account has been given in the preceding article. We proceed therefore to the jury of public instruction *(Le Jury Central d'Instruction)*, of which the principal business is to superintend the primary and central schools. It appoints the professors in these schools, and examines into their conduct. Like the legislative body, it is renewed by a third every half year. When they have chosen a professor for a central school, they submit their choice to the department; and, in case of disapprobation, they make another appointment. To this jury of public instruction, the professors in the central schools are amenable for all misconduct connected with their offices; it may expel them, but all its decisions must be submitted for confirmation to the tribunal of the department.

There is also established at Paris a supreme council, called the Commission of Public Instruction, to which is entrusted the whole executive department. The preservation of the national monuments, of public libraries, museums, cabinets, and valuable collections; the superintendence of all the schools and the modes of instruction; all new inventions and scientific discoveries; the regulation of weights and measures; national statistics and political economy, are all placed under the authority of this supreme commission. For the commodious and regular execution of so many complicated branches of business, there is a large office, called *Le Secretariat*, which is divided into three departments.

1. For the regulation of the different kinds of instruction; of the modes of education in the schools; and for the choice of elementary books. 2. For weights and measures; inventions and discoveries; libraries and bibliography; museums, works of art, and literary rewards and encouragements. 3. For theatres, national feasts, republican institutions, and the erection of monuments.

As all public establishments require the superintendance and occasional correction of the legislature, in addition to that of their own immediate executive authority, it has been deemed necessary to appoint a permanent committee of instruction in the legislative body, to provide such sums as may be necessary for the preservation and improvement of this system of instruction. This legislative committee are invested with due authority for these purposes. Their objects are precisely the same as those of the commission of public instruction above described, only with this difference, that the latter superintends the execution of existing laws, whilst the former recives and improves them, or proposes new ones. This committee is divided into three departments, as is the commission, with exactly the same arrangement of their respective labours. The committee being charged with the enaction of all new laws, its members, with a view to obtain accurately all the requisite information relative to the numerous branches of the arts, have procured from the legislative body the appointment of a *commission temporaire des arts* to be annexed to them, and to meet in the same house with them; which temporary commission is divided into sixteen classes: viz. 1. For Zoology; 2. Botany; 3. Mineralogy; 4. Physics; 5. Chemistry; 6. Anatomy; 7. Machinery; 8. Geography; 9. Artillery and Fortification; 10. Medals and Antiquities; 11. Bibliography; 12. Painting; 13. Architecture; 14. Sculpture; 15. Bridges and Causeways; and, 16. Musical Instruments.

The improvements of the national literary and scientific establishments are numerous and important.

1st, By a decree of the convention of the 11th *Prairial*, in the second year, it was enacted that means should be adopted by which every possible advantage might be derived from the botanic gardens of the republic, in Turkey and other foreign countries. This politic decree clearly tended to render France, in the language of the reporter, *L'abregé de tous les climats, et l'entrepôt de l'Europe.* "The epitome of every climate, and the magazine of Europe." Those plants which thrive between the tropics may be cultivated in the south of France; and those which are the produce of northern climates, may be cultivated in the northern departments; by which means France will be in possession of all foreign plants and drugs, without the exportation of specie.

2d, The National Bibliography was decreed in the sitting of 22d *Germinal*, in the second year. It consists of a complete catalogue of books of all descriptions, the property of the nation; it was then ascertained that the republic possessed more than ten millions of books. The titles of them were to be adjusted by actual comparisons; the manuscripts to be registered separately; anonymous productions were to be arranged according to their subjects; and those of known authors in the alphabetical order of the names. The several editions to be classed according to their dates; and what may be deemed more important, this French National Bibliography will contain a dictionary of anonymous books, as well as those published under fictitious names, a desideratum in the republic of letters.

3d, The annihilation of all *patois*, or dialects, decreed in the sitting of the 16th *Prairial*, in the second year. Notwithstanding the universality of the French language, and that it was exclusively spoken in the majority of the inland departments, yet there existed thirty various dialects in France. It is more astonishing that Rozier had remarked, that between one neighbouring village and another, there was so considerable a difference in the dialect, that the inhabitants could not understand each other; and the vinestock had thirty different names. The naturalist Villars has stated, that in the nomenclature of vegetables, in the departments, he had only met with an hundred which had a common appellation.

4th, The establishment of the *Conservatoire des Arts et Métiers*, was decreed in the sitting of the 8th of *Vendemiaire*, in the third year. This consists of a spacious hall, in the form of an amphitheatre, and contains the instruments and the models of machinery connected with the arts, and a description of their uses, with every book relating to them. Annexed to this establishment are three expositors and a draughtsman, who explain to the students the use of each instrument, and who register every new discovery, which is presented to the *Bureau de Consultation*, to the lyceum of arts, the *cidevant* academy of sciences, or to the board of commerce.

5th, The establishment of the board of longitude was decreed in the sitting of the 7th of *Messidor*, third year. It was certainly a disgrace under the monarchy, that an astronomical and nautical establishment, which had already proved so beneficial to Great Britain, should not have been adopted in France. In consequence of this decree, the French board is now as complete as the

 English.

Institute. English. It consists of ten members, and has under its jurisdiction the national observatory at Paris, and all the astronomical instruments belonging to the republic. It corresponds with foreign astronomers; delivers public lectures on astronomy and navigation; and its proceedings are annually recited in a public sitting.

6*th*, The general school of the Oriental languages was established by a decree of the 10th of *Germinal*, in the fourth year. This school adjoins to the national library, and all the books and manuscripts relative to Oriental literature are deposited in it.

7*th*, The national museum of antiquities was decreed in the sitting of 20th of *Prairial*, fourth year. A school of this description was succesfsully established at Vienna, by Eckel; at Gottingen, by Heyne; at Leipsick, by Ernest; and even at Strasburgh, by the celebrated Obeilin; Paris was, however, without one. This national archeology, or science of antiquity, is divided into nine different classes: inscriptions, characters, statues, *bas reliefs*, sculptures, paintings, mosaics, medals, civil, religious, and military instruments. This extensive establishment is under the direction of two principal professors; *le Conservateur Professeur, et le Conservateur Bibliothecaire.* The province of the former is to deliver public lectures on the several branches of antiquities, to teach the theory of medals and engravings, the history of the arts among the ancients, &c. The duties of the latter are merely of a bibliographical nature.

8*th*, The new modelling of the Grand National Library, was decreed in the sitting of 25th *Vendemiare*, in the fourth year. By virtue of this decree, the place of librarian in chief was suppressed, and the whole establishment placed under a *conservatoire* of eight members; of whom two were appointed for the superintendence of printed books; two for manuscripts; two for antiquities; and two for engravings. From these a temporary director is annually chosen, who superintends the whole acts occasionally as president of this assembly, and maintains a regular correspondence with the constituted authorities relative to the concerns of the library.

9*th*, The augmentation of the Museum of Natural History, formerly called *Le Jardin Royal des Plantes*, This establishment was decreed the 15th *Brumaire*, third year, upon a report of Thibadeau, in the name of the committee of Public Instruction. Besides the addition of large rooms, and various other buildings, there are new collections of natural curiosities and productions; and the library is much increased. It is open to the public three times a week. At stated periods all the naturalists in Paris deliver courses of lectures in the various branches of natural history. The museum is said to have received greater improvements from this augmentation than from all the labours of Buffon, or from its foundation, since the time of Tournefort.

10*th*, The *Ecole des Mines* was established in the *Hotel des Monnaies*, and has for its direction the naturalist Le Sage. This institution is unrivalled in Europe; and the collection of mineralogical curiosities surpasses whatever can be conceived.

11*th*, The society of natural history in Paris, deservedly classes among those which have rendered the greatest services to the cause of science since the revolution. A lecture of public instruction is held every ten days, which is generally given by one of the members, and which is open to all the lovers of natural history. Premiums are proposed for dissertations; one of which, by the late C. Herman, junior (whose early decease was a great loss to the republic of letters), on the *apterous* class of insects, may be said to constitute an epocha in the annals of natural history. The society has published a volume of memoirs, in folio, entitled, "*Transactions of the Society of Natural History.*" It has likewise erected a statue to the great Linnæus, in the national garden of plants; and, at the period when every public instruction was suspended, gave lectures on the different branches of science belonging to its department. Several intelligent and skilful navigators, among others those sent in search of the unfortunate La Perouse, as well as those which accompanied Buonaparte on his romantic expedition to Egypt, were members of this society.

This statement of facts relative to the present state of public instruction, the sciences, the arts, and the progress of national literature in France, has been taken from a miscellany, of which the principal writers are well acquainted with what is doing in that distracted country. They call it a sublime system; and seem to consider the increase of the national library, the improvement of the botanic gardens, and the discoveries that have been made by the different schools or institutes, as furnishing a demonstration that the republican government is more favourable to the advancement of science, than the monarchical, whether absolute or limited. But it should not be forgotten, that this system is yet in its infancy; and that in prosecuting new schemes, all men, and more especially Frenchmen, are actuated by an enthusiasm which gradually cools as their pursuits become familiar. We shall therefore venture to predict, that the different schools will not display such ardour seven years hence as they do at present; and that if the republican government continue a dozen of years in France, the progress of science in that country will not be more rapid than it was under the monarchy. We must remember, too, that the French libraries, museums, and picture galleries, have been improved by means which the morals of other governments do not employ —by rapine and robbery.

That something may be learned from this system to improve the modes of education in other countries, we admit; and it is for that reason that we have inserted an account of it. But if it contains something worthy of imitation, it contains likewise much to be shunned. We do not think it consistent with the *rights of man* to *compel* parents to send their children to be educated in *particular* schools; especially in schools where not only religious instruction is omitted, but where, there is reason to believe, that the professors are at pains to raze all religious impressions from the youthful mind. In a nation denying the truth of Christianity, it is not to be supposed that the Christian religion will be publicly taught; but in a nation of philosophers, as the French call themselves, it might have been expected that the laws of religious toleration would have been so far regarded, that Christian parents would not have been *compelled* to send their children to *antichristian* schools! But it is not Christianity alone that is neglected in this *sublime* system of education. Though the legislative body has some time ago decreed that there is a God, there

there is not in any one of thofe fchools the fmalleft care taken to inftruct the republican youth in the principles even of natural religion! We might indeed have looked for it under the title *Metaphyfics*, had not the conftitution of the National Inftitute taught us, that French metaphyfics attend to nothing but the analyfis of fenfations and ideas. Yet the legiflators might have liftened on this fubject to a republican as found as themfelves, and who was likewife no friend to fuperftition. "Nam et Majorum inftituta tueri facris, ceremoniifque retinendis fapientis eft. Non folum ad religionem pertinet, fed etiam ad *civitatis* ftatum, ut fine iis, qui facris publice præfunt, religioni privatæ fatisfacere non poffint." *Cicero de Nat. Deorum.*

INSURANCE, in law and commerce, though an excellent inftitution, is not of high antiquity. The oldeft laws and regulations concerning infurance, with which the indefatigable Beckmann is acquainted, are the following:

On the 28th of January 1523, five perfons appointed for that purpofe drew up at Florence fome articles which are ftill employed on the exchange at Leghorn. Thefe important regulations, together with the prefcribed form of policies, which may be confidered as the oldeft, have been inferted, in Italian and German, by Magens, in his Treatife on Infurance, average, and bottomry, publifhed at Hamburgh in 1753.

There is ftill preferved a fhort regulation of the 25th May 1537, by the Emperor Charles V. refpecting bills of exchange and infurance, in which the ftrictly fulfilling only of an agreement of infurance is commanded.

In the year 1556, Philip II. king of Spain gave to the Spanifh merchants certain regulations refpecting infurance, which are inferted by Magens, with a German tranflation, in his work before mentioned. They contain fome forms of policies on fhips going to the Indies.

In the year 1598, the *Kamer von affurantie*, chamber of infurance, was eftablifhed at Amfterdam. An account of the firft regulations of this infurance office may be feen in Pontanus's Hiftory of the city of Amfterdam, and in other works.

In the year 1600, regulations refpecting infurance were formed by the city of Middleburg in Zealand.

It appears that the firft regulations refpecting infurances in England, which may be feen in *Anderfon's Hiftory of Commerce*, were made in the year 1601. We find by them, that infurers had before that period conducted themfelves in fuch a manner, that the utmoft confidence was repofed in their honefty, and that on this account few or no difputes had arifen.

Of the various policies for infurance in England, a pretty accurate account will be found in the *Encyclopædia*; but there is one of them of which our account muft be acknowledged to be now defective. This is,

Insurance on Lives; which is a policy that has greatly increafed, in confequence of its utility being more generally underftood. Of the two offices for life affurances, noticed in that article, the former, entitled the *Amicable Society*, has extended the number of its fhares to 4000; but, as we have already obferved, the nature of the inftitution is too limited to become of general importance. The latter, entitled, the *Society for equitable Affurances on Lives and Survivorfhip*, is undoubtedly one of the moft important inftitutions of the kind, as will appear by the following account, with which we have been favoured by an obliging correfpondent, and upon the accuracy of which our readers may depend.

The members of the Equitable Society, finding, in June 1777, that their affairs were in a flourifhing fituation, refolved to reduce their annual premiums one-tenth; and in 1782 adopted new tables, agreeable to the probabilities of life at Northampton, in lieu of thofe they had hitherto ufed, formed from the London bills of mortality. But though it was evident that the new tables were much better adapted for affuring promifcuoufly perfons refiding in the country, or in large towns, it was thought proper, for greater fecurity, to make an addition of 15 per cent. to the real value of the affurances, as computed from the table of mortality at Northampton; and with the view of making an adequate compenfation to the affured for their former payments, which had been fo much higher than would be required by the new rates, an addition was made to their claims of L. 1, 10s. per cent. for every premium they had paid. The confequence of thefe meafures proved highly favourable to the Society; for its bufinefs increafed fo faft, that in 1785 it was nearly doubled; the fums affured amounting to upwards of L. 720,000. At this period, the favourable refult of a minute and very laborious inveftigation of the ftate of the Society, induced them to take off the 15 per cent. charged upon the premiums in 1782, and make a further addition to the claims of L. 1 per cent. for every payment made prior to the 1ft January 1786. A ftill greater increafe of fuccefsful bufinefs determined them, in 1791, to make another addition of L. 1 per cent. to the claims; and in the following year, a further addition of L. 2 per cent.; by which the claims upon affurances of the year 1770 were more than doubled; and thofe of an earlier date increafed in a ftill higher proportion. By thefe advantages to its members, and the honourable and truly equitable manner in which the concerns of the Society are tranfacted, the augmentation of their bufinefs has been fo great, that on the 31ft December 1792, the fums affured (without including the additions made to them) amounted to upwards of L. 3,000,000; and on the 31ft December 1795, to about L. 4,000,000.

The rates of affurance, as reduced to their real values in 1786, and according to which the Society now tranfact bufinefs, are as follows:

Sum Affured £. 100.

Age.	One Year.	Seven Years.	Whole Life
15	£. 0 17 11	£. 1 2 11	£. 1 18 7
20	1 7 3	1 9 5	2 3 7
25	1 10 7	1 12 1	2 8 1
30	1 13 3	1 14 11	2 13 4
35	1 16 4	1 18 10	2 19 10
40	2 0 8	2 4 1	3 7 11
45	2 6 8	2 10 10	3 17 11
50	2 15 1	3 0 8	4 10 10
55	3 5 0	3 12 0	5 6 4
60	3 18 1	4 7 1	6 7 4
65	4 15 2	5 10 10	7 16 9

The

The other offices in London for the aſſurance of lives are, the *Royal Exchange Aſſurance*, the *Weſtminſter Society*, and the *Pelican Life Office*.

The corporation of the *Royal Exchange Aſſurance* was empowered to aſſure lives by its ſecond charter, dated 29th April 1721; but the original object of the company being ſea aſſurances, and the true principles of aſſuring on lives being at that time little underſtood, this branch of their buſineſs was at firſt comparatively ſmall: they generally required a premium of five or ſix guineas per cent. without any regard to the age; and the aſſurance, which was uſually for a ſmall ſum, was ſeldom for a greater term than one year. In this manner they continued to aſſure upon lives till the end of the year 1783, when the increaſing importance of this part of their buſineſs, which they had ſome years felt, induced them to adopt a regular table of rates of aſſurance, according to the Northampton regiſters of mortality, but with a greater addition to the real values than had been made by the "Society for Equitable Aſſurances on Lives and Survivorſhip." This was thought proper, from the conſideration that the aſſurers with the Royal Exchange Company are not in any caſe liable to a call upon them beyond the premium they engage to pay, and have the ſecurity of the capital and funds of the company ariſing from the other branches of their buſineſs; however, the company, finding themſelves ſucceſsful in their life aſſurances, determined, in 1790, to reduce their premiums; and in 1797 made a ſtill greater reduction, by which they are brought very near to thoſe above ſtated. This company have agents in all the principal towns of Great Britain, and are impowered to aſſure lives in all parts of the world.

The *Weſtminſter Society* was eſtabliſhed in 1792, for aſſuring lives, and granting annuities. Their terms are nearly the ſame as thoſe of the Royal Exchange Aſſurance; but not being a corporate body, every perſon aſſuring ſigns a declaration, that he accepts the joint ſtock of the ſociety as his ſecurity.

The *Pelican Life Office* was inſtituted in 1797, by ſome of the principal proprietors of the Phœnix Fire Office. The rates which they have publiſhed vary conſiderably from thoſe of the other offices: but whether they are founded on more juſt principles, time and experience muſt determine. This ſociety alſo makes a new ſpecies of aſſurance, by way of endowment for daughters, or for children generally, when they ſhall attain the age of twenty-one years.

INTEGRAL calculus, in the new analyſis, is the reverſe of the differential calculus, and is the finding of the integral from a given differential; being ſimilar to the inverſe method of fluxions, or the finding the fluent to a given fluxion. See Fluxions, *Encycl.*

INTEREST, is the allowance given for the uſe of money by the borrower to the lender, and is either *ſimple* or *compound*. The method of computing both intereſts is explained in the article Algebra (*Encycl.*), page 427, &c.; and the ſubject of ſimple intereſt is again reſumed in Arithmetic (*Encycl.*), n° 20. The application of the canons for the computation of compound intereſt, to the value of annuities, the only caſe in which that intereſt is allowed by the laws of this country, may be ſeen in the articles Annuity and Survivorship (*Encycl.*); where various tables are given to facilitate the different computations. Some of our readers, however, have expreſſed a wiſh to have the rule for computing compound intereſt ſo ſtated, as to be underſtood by thoſe who are unacquainted with algebraic ſymbols. Their wiſh may be eaſily gratified.

The general formula $S = p\,R^t$ anſwers for the amount of any ſum, whether the intereſt be payable yearly, half-yearly, quarterly, or daily. Let R denote the amount of one pound for the firſt payment, and t the number of payments, the unit being from the commencement till the firſt payment is due; alſo, let l denote the logarithm of any quantity before which it is wrote; then, from the known property of logarithms, the theorem may be expreſſed thus, $l.\,S = l.\,p + l.\,R \times t$.

Required the amount of L. 250 at 5 per cent. compound intereſt, for 12 years, reckoning the intereſt payable yearly, half-yearly, quarterly, and daily?

Yearly, $p = 250$, $R = 1{\cdot}05$, $t = 12$.

$$\begin{array}{rl}
0{\cdot}0211893 & = l.\,R \\
12 & \\ \hline
{\cdot}2542716 & = l.\,R \times t \\
2{\cdot}3979400 & = l.\,p \\ \hline
l.\,S = 2{\cdot}6522116 & \text{— L. } 448 : 19 : 3\tfrac{1}{4} = \text{Amount.} \\
 & \quad\;\; 250 \\ \hline
 & \quad\;\; 198 : 19 : 3\tfrac{1}{4} = \text{Comp. Int.}
\end{array}$$

Half-yearly, $p = 250$, $R = 1{\cdot}025$, $t = 24$.

$$\begin{array}{rl}
0{\cdot}0107239 & = l.\,R \\
24 & \\ \hline
428956 & \\
214478 & \\ \hline
{\cdot}2573736 & = l.\,R \times t \\
2{\cdot}3979400 & = l.\,p \\ \hline
l.\,S = 2{\cdot}6553136 & \text{— L. } 452 : 3 : 7\tfrac{1}{4} = \text{Amount.} \\
 & \quad\;\; 250 \\ \hline
 & \quad\;\; 202 : 3 : 7\tfrac{1}{4} = \text{Intereſt.}
\end{array}$$

Quarterly, $p = 250$, $R = 1{\cdot}0125$, $t = 48$.

$$\begin{array}{rl}
0{\cdot}0053950 & = l.\,R \\
48 & \\ \hline
431600 & \\
215800 & \\ \hline
{\cdot}2589600 & = l.\,R \times t \\
2{\cdot}3979400 & = l.\,p \\ \hline
l.\,S = 2{\cdot}6569000 & \text{— L. } 453 : 16 : 8\tfrac{1}{4} = \text{Amount.} \\
 & \quad\;\; 250 \\ \hline
 & \quad\;\; 203 : 16 : 8\tfrac{1}{4} = \text{Intereſt.}
\end{array}$$

Daily. $p = 250,\ R = 1 + \frac{\cdot05}{365} = \frac{365\cdot05}{365},\ t = 365 \times 12.$

$$\begin{array}{l} 2\cdot5623524 \\ 2\cdot5622929 \\ \hline \cdot0000595 = l.\ R \\ \quad 4380 \\ \hline \quad 47600 \\ \quad 1785 \\ \quad 2380 \\ \hline \cdot2606100 = l.\ R \times t \\ 2\cdot3979400 = l.\ p. \\ \hline \end{array}$$

$l.\ S = 2\cdot6585500$ — L.455 : 11 : $3\frac{1}{2}$ = Amount.
250

205 : 11 : $3\frac{1}{2}$ = Intereft.

INTERPOLATION, in the modern algebra, is ufed for finding an intermediate term of a feries, its place in the feries being given. See ALGEBRA and SERIES, *Encycl.*

The method of interpolation was firft invented by Mr Briggs, and applied by him to the calculation of logarithms, &c. in his Arithmetica Logarithmica, and his Trigonometria Britannica; where he explains, and fully applies, the method of interpolation by differences. His principles were followed by Reginal and Mouton in France, and by Cotes and others in England. Wallis made ufe of the method of interpolation in various parts of his works: as his arithmetic of infinites, and his algebra, for quadratures, &c. The fame was alfo happily applied by Newton in various ways: by it he inveftigated his binomial theorem, and quadratures of the circle, ellipfe, and hyperbola. See Wallis's Algebra, chap. 85. &c. Newton alfo, in lemma 5. lib. 3. Princip. gave a moft elegant folution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the fubfequent propofition, applied the folution of this problem to that of finding, from certain obferved places of a comet, its place at any given intermediate time. And Dr Waring, who adds, that a folution ftill more elegant, on fome accounts, has been fince difcovered by Meff. Nichol and Stirling, has alfo refolved the fame problem, and rendered it more general, without having recourfe to finding the fucceffive differences. *Philof. Tranf.* vol. 69. part 1. art. 7.

INTERSCENDENT, in algebra, is applied to quantities, when the exponents of their powers are radical quantities. Thus $x^{\sqrt{2}}$, $x^{\sqrt{a}}$, &c. are interfcendent quantities.

INTERSTELLER, a word ufed by fome authors to exprefs thofe parts of the univerfe that are without and beyond the limits of our folar fyftem.

INTRADOS, the interior and lower fide, or curve, of the arch of a bridge, &c. In contradiftinction from the extrados, or exterior curve, or line on the upper fide of the arch. See ARCH in this *Suppl.*

INVOLUTION and EVOLUTION, are terms introduced into geometry by the celebrated Mr Huyghens, to exprefs a particular manner of defcribing curvilineal fpaces which occurred to him when occupied in the improvement of his noble invention of pendulum clocks. Although he was even aftonifhed at the accuracy of their motion, and they foon fuperfeded all balance clocks, he knew that the wide vibrations were fomewhat flower than the narrow ones, and that a circle was not fufficiently incurvated at the fides to render all the vibrations ifochronous. The proper curve for this purpofe became an interefting object. By a moft accurate inveftigation of the motions of heavy bodies in curved paths, he difcovered that the cycloid was the line required. Lord Brouncker had difcovered the fame thing, as alfo Dr Wallis. But we do not imagine that Huyghens knew of this; at any rate, he has the full claim to the difcovery of the way of making a pendulum ofcillate in a cycloidal arch. It eafily occurred to him, that if the thread by which the pendulum hangs be fufpended between two curved cheeks, it would alternately lap on each of them in its vibrations, and would thus be raifed out of the circle which it defcribes when fufpended from a point. But the difficulty was to find the proper form of thefe cheeks. Mr Huyghens was a moft excellent geometer, and was poffeffed of methods unknown to others, by which he got over almoft every difficulty. In the prefent cafe there was fortunately no difficulty, the means of folution offering themfelves almoft without thought. He almoft immediately difcovered that the curve in queftion was the fame cycloid. That is, he found, that while a thread unwinds from an arch of a cycloid, beginning at the vertex, its extremity defcribes the complementary arch of an equal cycloid.

Thus he added to this curve, already fo remarkable for its geometrical properties, another no lefs curious, and infinitely exceeding all the others in importance.

The fteps by which this property was difcovered are fuch direct emanations from general principles, that they immediately excited the mind of Mr Huyghens, which delighted in geometry, to profecute this method of defcribing or transforming curve lines by evolution. It is furprifing that it had not ere this time occurred to the ancient geometers of the laft century; and particularly to Dr Barrow, who feems to have racked his fancy for almoft every kind of motion by which curve lines can be generated. Evolution of a thread from a curve is a much more obvious and conceivable genefis than that of the cycloid invented by Merfennus, or that of the conchoid by Nicodemes, or thofe of the conic fections by Vieta. But except fome vague expreffions by Ptolemy and Gaffendus, about defcribing fpirals by a thread unlapped from a cylinder, we do not recollect any thing of the kind among the writings of the mathematicians; and it is to Huyghens alone that we are indebted for this very beautiful and important branch of geometry. It well deferves both of thefe epithets. The theorems which conftitute the doctrines of evolution are remarkable for their perfpicuity and neatnefs. Nothing has fo much contributed to give us clear notions of a very delicate fubject of mathematical difcuffion, namely curvature, and the meafure and variations of curvature. It had become the fubject of very keen debate; and the notions entertained of it were by no means diftinct. But nothing can give fuch a precife conception of the difference of curvature, in the different parts of a cycloid or other curve, as the beholding its defcription by a radius continually varying in length. This doctrine is peculiarly valuable to the fpeculator

Involution. culator in the higher mechanics. The intensity of a deflecting force is estimated by the curvature which it induces on any rectilineal motion; and the variations of this intensity, which is the characteristic of the force, or what we call its nature, is inferred from the variations of this curvature. The evolution and involution of curve lines have therefore great claim to our attention. But a Work like ours can only propose to exhibit an outline of the subject; and we must refer our readers to those eminent authors who have treated it in detail. Varignon, in the Memoirs of the French Academy for 1706, has been at immense pains to present it in every form; James Bernoulli has also treated the subject in a very general and systematic manner. Some account is given of it in every treatise of fluxions. We recommend the original work of Mr Huyghens in particular; and do not hesitate to say, that it is the finest specimen (of its extent) of physico-mathematical discussion that has ever appeared. Huyghens was the most elegant of all modern geometers; and both in the geometrical and physical part of this work, *De Horologio Oscillatorio*, he has preserved the utmost rigour of demonstration, without taking one step in which Euclid or Apollonius would not have followed him.

——— *juvat integros accedere fontes*
Atque haurire.

Such authors form the taste of the young mathematician, and help to preserve him from the almost mechanical procedure of the expert symbolical analyst, who arrives at his conclusion without knowing how he gets thither, or having any notions at all of the magnitudes of which he is treating.

There are two principal problems in his doctrine.

I. To ascertain the nature of the figure generated by the evolution of a given curve.

II. To determine the nature of the curve by whose evolution a given curve may be generated.—We shall consider each of these in order, and then take the opportunity which this subject gives of explaining a little the abstruse nature of curvature, and its measures and variations, and take notice of the opinions of mathematicians about the precise nature of the angle of contact.

Plate XXXI. The curve line ABCDEF (fig. 1.) may be considered as the edge of a crooked ruler or mould; a thread may be supposed attached to it at F, and then lapped along it from F to A. If the thread be now led away from A, keeping it always tight, it is plain that the extremity A must describe a curve line A b c d e f, and that the detached parts of the thread will always be tangents to the curve ABCDEF. In like manner will the curve line F d' c' b' A' be described by keeping the thread fast at A, and unlapping it from the other end of the mould.

This process was called by Mr Huyghens the Evolution of the curve ADF. ADF is called the Evolute. A d f was named by him the Curve by Evolution. It has been since more briefly termed the Evolutrix, or unlapper. It has also been called the Involute; because, by performing the process in the opposite direction f d A, the thread is lapped up on the mould, and the whole space ADF f d A is folded up like a fan. The detached parts C c, D d, or C c', D d', &c. of the thread, are called Radii of the Evolute; perhaps with some impropriety, because they rather resemble the momentary radii of the evolutrix. We may name them the evolved radii. The beginning A of evolution may be considered as the vertex of the curves, and the ends F and f may be called the terms.

There is another way in which this description of curve lines may be conceived. Instead of a thread F f gradually lapped up on the mould, we may conceive F f to be a straight edged ruler applied to the mould, and gradually rolled along it without sliding, so as to touch it in succession in all its points. It is evident, that by this process the point f will describe the curve f d A, while the point F describes the other curve F d' a. This way of conceiving it gives a great extension to the doctrine, and homologates it with that genesis of curve lines by which cycloids of all kinds are described, and which we may distinguish by the name of Provolution. For it is plain that the relative motions of the points A and b are the same, whether the ruler b B b' roll on the mould ABF, or the mould roll on the ruler: but there will be a great difference in the form of the line traced by the describing point, if we suppose the plane on which it is traced to be attached to the rolling figure. Thus, when a circle rolls on a straight line, a point in its circumference traces a cycloid on the plane attached to the straight line, while the point of the straight line which quitted the circle describes on the plane attached to the circle another line; namely, the involute of the circle. This mode of description allows us to employ a curved ruler in place of the straight one b B b'; and thus gives a vast extension to the theory. But at present we shall confine ourselves to the employment of the straight line b B b', only keeping in mind, that there is an intimate connection between the lines of evolution and of provolution.

By the description now given of this process of evolution and involution, it is plain,

1. That the evolution is always made from the convex side of the evolute.

2. That the evolved radii B b, C c, D d, &c. are respectively equal to the arches BA, CA, DA, &c. of the evolute which they have quitted; and that b B b', c C c, d D d', &c. are always equal to the whole arch ADF.

3. That any point B of the lapped up thread describes during its evolution a curve line B γ δ ϵ φ parallel to b c d e f; because these curves are always equidistant from each other.

4. That if the thread extend beyond the mould as a tangent to it, the extremity α will describe a parallel or equidistant curve α β γ δ ϵ φ, lying without A b c d e f. From this it appears that B γ δ ϵ φ is the complete evolutrix of FEDCB, while b d c e f is the evolutrix of that arch, and the added tangent B b. In like manner, the lapped up thread ADF, with the added part F φ', describes the evolutrix φ' ϵ' δ' γ' β' A'.

5. If from any point C of the evolute there be drawn lines C b, C c, C d, C e, &c. to the evolutrix, those which are more remote from the vertex are greater than those which are nearer. Draw B b, c C, d D, e E, touching the evolute. C b is less than CB + B b; that is (2), than C c. Again, DC + C c is equal to D d, which is less than DC + C d. Therefore C c is less than C d. Now let C e cut D d in r. Then e r + r DE is greater than e E. But e E is equal to d r + r DE. Therefore e r is greater than d r; and e r + r C

Involution. rC is greater than $dr + r$C, which is greater than cC. Therefore eC is greater than cC.

6. Hence it follows, that a circle defcribed round any point of the evolute, with a radius reaching to any point of the evolutrix, will cut the evolutrix in that point, and be wholly within it on the fide remote from the vertex, and without it on the fide next the vertex.

7. The evolved radius cuts every arch of the evolutrix perpendicularly, or a right line drawn through the interfection at right angles touches the evolutrix in that point. Through any point d draw the line $m\,d\,t$ at right angles to dD. The part of it $m\,d$ next to the vertex is wholly without the curve, becaufe it is without the circle defcribed round the centre D; and this circle is without the evolutrix on that fide of d which is next the vertex (6). Any point t on the other fide of d is alfo without the curve. For let $t\,e$E be another evolved radius, cutting Dd in n: then $n\,d$ is lefs than $n\,t$, becaufe $n\,d\,t$ is a right angle by conftruction; and therefore $n\,t\,d$ is acute. But becaufe En + nD are greater than ED, En + $n\,d$ are greater than ED + Dd, that is, than Ee, and $n\,d$ is greater than $n\,e$. Therefore, fince it is lefs than $n\,t$, it follows that $n\,e$ is much lefs than $n\,t$, and t lies without the curve. Therefore the whole line $m\,d\,t$ is without the curve, except in the point d. It therefore touches the curve in d, and the radius Dd cuts it at right angles in that point. By the fame reafoning, it is demonftrated that all the curves A$b\,d\,f$, $\alpha\beta\delta\varsigma$, A$'b'd'f'$, $\alpha'\beta'\delta'\varsigma'$, are cut perpendicularly by the tangents to the evolute. Alfo all thefe curves interfect the evolute at right angles in their vertexes.

It follows from this propofition, that from every point, fuch as s, or i, or o, &c. in the fpace AOF comprehended by the evolute and its extreme tangents AO, FO, two perpendiculars may be drawn to the evolutrix A$d\,f$; and that from any point in the fpace within the angle A$o\,f$ only one perpendicular can be drawn; and that no perpendicular can be drawn from any point on the other fide of ADF. Apollonius had obferved thefe circumftances in the conic fections, but had not thought of marking the boundary formed by the evolute ADF. Had he noticed this, he would certainly have difcovered the whole theory of evolution, and its importance in fpeculative geometry.

It alfo follows from this propofition, that if a curve A$b\,c\,d\,e\,f$ is cut by the tangents of ABCDEF at right angles in every point, it will be defcribed by the evolution of that curve: For if the evolutrix, whofe vertex is A, be really defcribed, it will coincide with A$b\,c\,d$ in A, and have the fame tangent; it therefore does not deviate from it, otherwife their tangents would feparate, and would not both be at right angles with the lines touching the evolute. They muft therefore coincide throughout.

8. The arches $b\,c\,d$ and $\beta\gamma\delta$, intercepted by fome radii Bb and Dd, may be called *concentric;* and the angles contained between the tangents drawn through their extremities are equal. Thus the angle $\lambda\pi o$ is equal to $l\,p\,o$: but although equidiftant, parallel, and containing the fame angle between their tangents and between their radii, they are not fimilar. Thus, the arch $\alpha\beta$ has a curvature at α that is the fame with that of any circle whofe radius is equal to Aα; but the curvature at A is incomparable with it, and unmeafurable. The fame may be faid of the curvatures at β and at B.

9. If a circle $u\,d\,z$ be defcribed round the centre D with the radius Dd, it both touches and cuts the evolutrix in the point d, and no circle can be defcribed touching the curve in that point, and paffing between it and the circle $u\,d\,z$: For fince it touches the curve in d, its centre muft be fomewhere in the line dD perpendicular to $m\,d\,t$. It cannot be in any point n more remote from d than D is; for it would pafs without the arch $d\,u$, and be more remote than $d\,u$ from the arch $d\,c$ of the evolutrix. On the other fide, it would indeed pafs without the arch $d\,z$, which lies within the arch $d\,e$ of the evolutrix: but it would alfo pafs without the curve. For it has been already demonftrated (7) that $n\,d$ is greater than $n\,e$; and the curve would lie between it and the circle $d\,z$.

Thus it appears, that a circle defcribed with the evolved radius approaches nearer to the curve, or touches it more clofely, than any other circle; all other circles either interfect it in meafurable angles, or are within or without the curve on both fides of the point of contact. This circle $u\,d\,z$ has therefore the fame curvature with the curve in the point of contact and coalefcence. It is the EQUICURVE CIRCLE, the circle of equal curvature, the OSCULATING CIRCLE (a name given it by Leibnitz). The evolved radius of the evolute is the RADIUS OF CURVATURE of the evolutrix, and the point of the evolute is the CENTRE OF CURVATURE at the point of contact with the evolutrix. The evolute is the geometrical locus of all the centres of curvature of the evolutrix.

This is the moft important circumftance of the whole doctrine of the involution and evolution of curve lines. It is affumed as a felf-evident truth by the precipitant writers of elements. It is indeed very like truth: For the extremity of the thread is a momentary radius during the procefs of evolution; and any minute arch of the evolute nearer the vertex muft be conceived as more incurvated than the arch at the point of contact, becaufe defcribed with fhorter radii: for the fame reafon, all beyond the contact muft be lefs incurvated, by reafon of the greater radii. The curvature at the contact muft be neither greater nor lefs than that of the circle. But we thought it better to follow the example of Huyghens, and to eftablifh this leading propofition on the ftricteft geometrical reafoning, acknowledging the fingular obligation which mathematicians are under to him for giving them fo palpable a method of fixing their notions on this fubject. When the evolute of a curve is given, we have not only a clear view of the genefis of the curve, with a neat and accurate mechanical method of defcribing it, but alfo a diftinct comprehenfion of the whole curvature, and a connected view of its gradual variations.

We fpeak of curvature that is greater and leffer; and every perfon has a general knowledge or conception of the difference, and will fay that an ellipfis is more curve at the extremities of the tranfverfe axis than any where elfe. But before we can inftitute a comparifon between them with a precifion that leads to any thing, we muft agree about a meafure of curvature, and fay what it is we mean by a double or a triple curvature. Now there are two ways in which we may confider curvature, or a want of rectitude: We may call that a double curvature which, in a given fpace, carries us twice as far from the ftraight line; or we may call that a double curvature by which we deviate twice as much from

from the fame direction. Both of thefe meafures have been adopted; and if we would rigidly adhere to them, there would be no room for complaint: but mathematicians have not been fteady in this refpect, and by mixing and confounding thefe meafures, have frequently puzzled their readers. All agree, however, in their firft and fimple meafures of curvature, and fay that the curvature of an arch of a circle is as the arch directly, and as the radius inverfely. This is plainly meafuring curvature by the deflection from the firft direction. In an arch of an inch long, there is twice as much deflection from the firft direction when the radius of the circle is of half the length. If the radius is about $57\frac{1}{4}$th inches, an arch of one inch in length produces a final direction one degree different from the firft. If the radius is $114\frac{1}{2}$ inches, the deviation is but half of a degree. The linear deflection from the ftraight path is alfo one half. In the cafe of circles, therefore, both meafures agree: but in by far the greateft number of cafes they may differ exceedingly, and the changes of direction may be greateft when the linear deviation is leaft. Flexure, or change of direction, is, in general, the moft fenfible and the moft important character of curvature, and is underftood to be its criterion in all cafes. But our proceffes for difcovering its quantity are generally by firft difcovering the linear deviation; and, in many cafes, particularly in our philofophical inquiries, this linear deviation is our principal object. Hence it has happened, that the mathematician has frequently ftopped fhort at this refult, and has adapted his theorems chiefly to this determination. Thefe differences of object have caufed great confufion in the methods of confidering curvature, and led to many difputes about its nature, and about the angle of contact; to which difputes there will be no end, till mathematicians have agreed in their manner of expreffing the meafures of curvature. At prefent we abide by the meafure already given, and we mean to exprefs by curvature or flexure the change of direction.

This being premifed, we obferve, that the curvature of all thefe curves of evolution where they feparate from their evolutes, is incomparable with the curvature in any other place. In this point the radius has no magnitude; and therefore the curvature is faid to be infinitely great. On the other hand, if the evolved curve has an afymptote, the curvature of the evolutrix of the adjacent branch is faid to be infinitely fmall. Thefe expreffions becoming familiar, have occafioned fome very intricate queftions and erroneous notions. There can be little doubt of their impropriety: For when we fay, that the curvature at A is infinitely greater than at α, we do not recollect that the flexure of the whole arch A b is equal to that of the whole arch $\alpha\,\beta$, and the flexure at A muft either make a part of the whole flexure, or it muft be fomething difparate.

The evolutrix A $b\,c\,d\,e\,f$ (fig. 2.) of the common equilateral hyperbola exhibits every poffible magnitude of curvature in a very fmall fpace. At the vertex A of the hyperbola it is perpendicular to the curve; and therefore has the tranfverfe axis A τ A″ for its tangent. The curvature of the evolutrix at A is called infinitely great. As the thread unlaps from the branch ABC, its extremity defcribes A $b\,c$. It is plain that the evolutrix muft cut the affymptote φ H at right angles in fome point G, where the curvature will be what is called infinitely fmall; becaufe the centre of curvature has removed to an infinite diftance along the branch AF of the hyperbola. This evolutrix may be continued to the vertex of the hyperbola on the other fide of the affymptote, by caufing the thread to lap upon it, in the fame way that Mr Huyghens completed his cycloidal ofcillation. Or we may form another evolutrix $\alpha\,\beta\,\gamma\,\delta\,\varphi\,\gamma'\,\delta'\,\beta'$ A″, by lengthening the thread from G to τ, the centre of the hyperbola, and fuppofing that, as foon as the curve A $\delta\,\varphi$ is completed, by unlapping the thread from the branch ABC, another thread laps upon the hyperbola A″ F″. This laft is confidered as a more geometrical revolution than the other: For the mathematicians, extending the doctrine of evolution beyond Mr Huyghens's reftriction to curves which had their convexity turned one way, have agreed to confider as one continued evolution whatever will complete the curve expreffed by one equation. Now the fame equation expreffes both the curves AF and A″F″, which occupy the fame axis AA″. The cycloid employed by Huyghens is, in like manner, but one continuous curve, defcribed by the continued provolution of the circle along the ftraight line, although it appears as two branches of a *repeated* curve. We fhall meet with many inftances of this feemingly compounded evolution when treating of the fecond queftion.

Since the arch A $b\,d$ G contains every magnitude of curvature, it appears that every kind of curvature may be produced by evolution. We can have no conception of a flexure that is greater than what we fee at A, or lefs than what we fee at G; yet there are cafes which feem to fhew the contrary, and are familiarly faid, by the greateft mathematicians, to exhibit curvatures infinitely fmaller ftill. Thus, let ABC (fig. 3) be a conical parabola, whofe parameter is AP. Let AEF be a cubical parabola, whofe parameter is AQ. If we make AQ to AD as the cube of AP to the cube of AQ, the two parabolas will interfect each other in the ordinate DB. For, making AP $= p$, and AQ $= q$, and calling the ordinate of the conic parabola y, that of the cubic parabola z, and the indeterminate abfciffa AD x, we have

$$p^3 : q^3 = q : x, = q^3 : z^3, \text{ and } p : q = q : z;$$

but $q : p = q : p$; therefore, by compofition,

$$p^2 : q^2 = q^2 : p\,x = q^2 : y^2, \text{ and } p : q = q : y;$$

therefore $z = y$, and the parabolas interfect in B.

Now, becaufe in all parabolas the ordinates drawn at the extremity of the parameters are equal to the parameters, the interfections q and p will be in a line A $q\,p$, which makes half a right angle with the axis AP. Therefore, when AQ is greater than AP, the point q is without the conical parabola, and the whole arch of the cubical parabola cut off by the ordinate DB is alfo without it; but when AQ is lefs than AP, q is within the conical parabola, as is alfo the arch q B. Therefore the remaining arch BEA is without it, and is therefore lefs incurvated at A. An endlefs number of conical parabolas of fmaller curvature may be drawn by enlarging AP; yet there will ftill be an arch AEB of the cubical parabola which is without it, and therefore lefs incurvated. Therefore the curvature of a cubical parabola of lefs than that of any conical parabola: It is faid to be infinitely lefs, becaufe an infinity of cubical parabolas of *fmaller curvature* than AEB may be drawn by enlarging AQ.

It

It may be demonſtrated in the ſame manner, that a paraboloid, whoſe ordinates are in the ſubſiquuadrate ratio of the abſciſſæ, has an infinitely ſmaller curvature at the vertex than the cubical parabola. And the curvature of the paraboloid of the next degree is infinitely leſs than this; and ſo on continually. Nay, Sir Iſaac Newton, who firſt took notice of this remarkable circumſtance, demonſtrates the ſame thing of an endleſs ſucceſſion of paraboloids interpoſed between any two degrees of this ſeries. *Neque novit* (ſays he) *natura limitem.*

If this be the caſe, all curves cannot be deſcribed by evolution; for we have no conception of a radius of curvature that is greater than a line without limit. The theory of curvilineal motions delivered in the article Dynamics muſt be imperfect, or there muſt be curve lines which bodies cannot deſcribe by any powers of nature. The theory there delivered profeſſes to teach how a body can be made to deſcribe the cubical parabola, and many other curves which have theſe infiniteſimal curvatures; and yet its demonſtrations employ the radius of curvature, and cannot proceed without it. We profeſs ourſelves obliged to an attentive reader (who has not favoured us with his name) for making this obſervation. It merits attention.

There muſt be ſome paralogiſm or miſconception in all this language of the mathematicians. It does not neceſſarily follow from the arch AEB lying without the arch AIB, that it is leſs incurvated at A; it may be more incurvated between A and B. Accordingly we ſee, that the tangent BT of the conical parabola is leſs inclined to the common tangent AV than the tangent B*t* of the cubical parabola is; and therefore the flexure of the whole arch AEB is greater than that of the whole arch AIB; and we ſhall ſee afterwards, that there is a part of AEB that is more incurvated than any part of AIB. There is nothing correſponding to this unmeaning and inconceivable ſucceſſion of ſerieſes of magnitudes of one kind, each of which contains an endleſs variety of individuals, and the greateſt of one ſeries infinitely leſs than the ſmalleſt of the next, &c.; there is nothing like this demonſtrated by all our arguments. In none of theſe do we ever treat of the curvature at A, but of a curvature which is *not* at A. At A we have none of the lines which are indiſpenſably neceſſary for the demonſtration. Beſides, in the very ſame manner that we can deſcribe a cubical parabola, and prove that it has an arch lying without the conical parabola, we can deſcribe a circle, and demonſtrate that it has alſo an arch lying without the parabola. Theſe infiniteſimal curvatures, therefore, are not warranted by our arguments, nor does it yet appear that there are curves which cannot be deſcribed by evolution. We are always puzzled when we ſpeak of infinites and infiniteſimals as of ſomething preciſe and determinate; whereas the very denomination precludes all determination. We take the diſtinguiſhing circumſtance of thoſe different orders for a thing clearly underſtood; for we build much on the diſtinction. We conceive the curvature of the cubical parabola as verging on that of the common parabola, and the one ſeries of curvatures as beginning where the other ends. But Newton has ſhewn, that between theſe two ſerieſes an endleſs number of ſimilar ſerieſes may be interpoſed. The very names given to the curvature at the extremities of the hyperbolic evolutrix have no conceptions annexed to them. At the vertex of the hyperbola there is no line, and at the interſection with the aſſymptote there is no curvature. Theſe unguarded expreſſions, therefore, ſhould not make us doubt whether all curves may be deſcribed by evolution. If a line be incurvated, it is not ſtraight. If ſo, two perpendiculars to it muſt diverge on one ſide, and muſt converge and meet on the other in ſome point. This point will lie between two other points, in which the two perpendiculars touch that curve by the evolution, of which the given arch of the curve may be deſcribed. Finally (which ſhould decide the queſtion), we ſhall ſee by and bye, that the cubic, and all higher orders of paraboloids, may be ſo deſcribed by evolution from curves having aſſymptotic branches of determinable forms.

Such are the general affections of lines generated by evolution. They are not, properly ſpeaking, peculiar properties; for the evolutrixes may be any curve lines whatever. They only ſerve to mark the mutual relations of the evolutes with their evolutrixes, and enable us to conſtruct the one, and to diſcover its properties by means of our knowledge of the other. We proceed to ſhew how the properties of the evolutrix may be determined by our knowledge of the evolute.

This problem will not long occupy attention, being much limited by the conditions. One of the firſt is, that the length of the thread evolved muſt be known in every poſition: Therefore the length of the evolved arch muſt, in like manner, be known; and this, not only *in toto*, but every portion of it. Now this is not univerſally, or even generally the caſe. The length of a circular, parabolic, hyperbolic, arch has not yet been determined by any finite equation, or geometrical conſtruction. Therefore their evolutrixes cannot be determined otherwiſe than by approximation, or by compariſon with other magnitudes equally undetermined. Yet it ſometimes happens, that a curve is diſcovered to evolve into another of known properties, although we have not previouſly diſcovered the length of the evolved arch. Such a diſcovery evidently brings along with it the rectification of the evolute. Of this we have an inſtance in the very evolution which gave occaſion to the whole of this doctrine; namely, that of the cycloid; which we ſhall therefore take as our firſt example.

Let ABC (fig. 5.) be a cycloid, of which AD is the axis, and AHD the generating circle, and AG a tangent to the cycloid at A, and equal to DC. Let BKE touch the cycloid in B, and cut AG in K. It is required to find the ſituation of that point of the line BE which had unfolded from A?

Draw BH parallel to the baſe DC of the cycloid, cutting the generating circle in H, and join HA. Deſcribe a circle KEM equal to the generating circle AHD, touching AG in K, and cutting BK in ſome point E. It is known, by the properties of the cycloid, that BK is equal and parallel to HA, and that BH is equal to the arch A*h*H. Becauſe the circles AHD and KEM are equal, and the angles HAK and AKE are equal, the chords AH and KE cut off equal arches, and are themſelves equal. Becauſe BHAK is a parallelogram, AK is equal to HB; that is, to the arch A*h*H, that is, to the arch K*m*E. But if the circle KEM had been placed on A, and had rolled from A to K, the arch diſengaged would have been equal to AK, Involution. AK, and the point which was in contact with A would now be in E, in the circumference of a cycloid AEF, equal to CBA, having the line AG, equal and parallel to DC, for its base, and GF, equal and parallel to DA, for its axis. And if the diameter KM be drawn, and EM be joined, EM touches the cycloid AEF.

Cor. The arch BA of the cycloid is equal to twice the parallel chord HA of the generating circle: For this arch is equal to the evolved line BKE; and it has been shewn that EK is equal to KB, and BE is therefore equal to twice BK, or to twice HA. This property had indeed been demonstrated before by Sir Christopher Wren, quite independent of the doctrine of evolution; but it is given here as a legitimate result of this doctrine, and an example of the use which may be made of it. Whenever a curve can be evolved into another which is susceptible of accurate determination, the arch of the evolved curve is determined in length; for it always makes a part of the thread whose extremity describes the evolutrix, and its length is found by taking from the whole length of the thread that part which only touches the curve at its vertex.

This genesis of the cycloid AEF, by evolution of the cycloid ABC, also gives the most palpable and satisfactory determination of the area of the cycloid. For since BE is always parallel to AH, AH will sweep over the whole surface of the semicircle AHD, while BE sweeps over the whole space CBAEF; and since BE is always double of the simultaneous AH, the space CBAEF is quadruple of the semicircle AHD. But the space described in any moment by BK is also one-fourth part of that described by BE. Therefore the area GAEF is three times the semicircle AHD; and the space DHABC is double of it; and the space CBAG is equal to it.

Sir Isaac Newton has extended this remarkable property of evolving into another curve of the same kind to the whole class of epicycloids, that is, cycloids formed by a point in the circumference of a circle, while the circle rolls on the circumference of another circle, either on the convex or concave side; and he has demonstrated, that they also may all be rectified, and a space assigned which is equal to their area (See *Principia*, B. I. prop. 48. &c.) He demonstrates, that the whole arch is to four times the diameter of the generating circle as the radius of the base is to the sum or difference of those of the base and the generating circle. We recommend these propositions to the attention of the young reader who wishes to form a good taste in mathematical researches; he will there see the geometrical principles of evolution elegantly exemplified.

We may just observe, before quitting this class of curves, that many writers, even of some eminence, in their compilations of elements, give a very faulty proof of the position of the tangent of a curve described by rolling. They say, for example, that the tangent of the cycloid at E is perpendicular to KE; because the line KE is, at the moment of description, turning round K as a momentary centre. This, to be sure, greatly shortens investigation; and the inference is a truth, not only when the rolling figure is a circle rolling on a straight line, but even when any one figure rolls on another. Every point of the rolling figure really *begins* to move perpendicularly to the line joining it with the point of contact. But this genesis of the arch Ee, by the evolution of the arch Bb, shews that K is by no means the centre of motion, nor HK the radius of curvature. Nor is it, in the case of epicycloids, trochoids, and many curves of this kind, a very easy matter to find the momentary centre. The circle KEM is both advancing and turning round its centre; and these two motions are equal, because the circle does not slide but roll, the detached arch being always equal to the portion of the base which it quits. Therefore, drawing the tangents Eg, Mg, and completing the parallelogram Ef Mg, Ef will represent the progressive motion of the centre, and Eg the motion of rotation. EM, the motion compounded of these, must be perpendicular to the chord EK.

The investigation that we have given of the evolutrix of the cycloid has been somewhat peculiar, being that which offered itself to Mr Huyghens at the time when he and many other eminent mathematicians were much occupied with the singular properties of this curve. It does not serve, however, so well for exemplifying the general process. For this purpose, it is proper to avail ourselves of all that we know of the cycloid, and particularly the equality of its arch BA to the double of the parallel chord HA. This being known, nothing can be more simple than the determination of the evolutrix, either by availing ourselves of every property of the cycloid, or by adhering to the general process of referring every point to an abscissa by means of perpendicular ordinates. In the first method, knowing that BE is double of BK, and therefore KE equal to HA, and KA = BH, = HbA, = KmE, we find E to be the describing point of the circle, which has rolled from A to K. In the other method, we must draw EN perpendicular to AG; then, because the point E moves, during evolution, at right angles to BE, EK is the normal to the curve described, and NK the subnormal, and is equal to the corresponding ordinate H′I′ of the generating circle of the cycloid ABC. This being a characteristic property of a cycloid, E is a point in the circumference of a cycloid equal to the cycloid ABC.

Or, lastly, in accommodation to cases where we are supposed to know few of the properties of the evolute, or, at least, not to attend to them, we may make use of the fluxionary equation of the evolute to obtain the fluxionary equation of the evolutrix. For this purpose, take a point e very near to E, and draw the evolving radius be, cutting Ef (drawn parallel to the base DC) in o; draw en parallel to the axis of the evolute, cutting Eo in v; also draw bhi parallel to the base, and Bd perpendicular to it. If both curves be now referred to the same axis CGF, it is plain that Bb, Bd, and db are ultimately as the fluxions of the arch, abscis, and ordinate of the evolute, and that Ee, ev, and vE, are ultimately as the fluxions of the arch, abscissa, and ordinate of the evolutrix. Also the two fluxionary triangles are similar, the sides of the one being perpendicular, respectively to those of the other. If both are referred to one axis, or to parallel axes, the fluxion of the abscissa of the evolute is to that of its ordinate, as the fluxion of the ordinate of the evolutrix is to that of its abscissa. Thus, from the fluxionary equation of the one, that of the other may be obtained. In the present case, they may be referred to AD and FG, making CG equal to the cycloidal arch CBA. Call this a; AI, x; IB, y; and AB, or EB, z. In like manner, let

Ft

Ft be $= u$, $tE = v$, and $FE = w$; then, becaufe $DH^2 = DA^2 - AH^2$, and DA and AH are the halves of CF and BE, we have $DH^2 = \frac{a^2 - z^2}{4}$. Alfo $DI = \frac{DH^2}{DA} = \frac{a^2 - z^2}{4 \times \frac{1}{2} a} = \frac{a^2 - z^2}{2a}$. But $DI = Ft$. Therefore Ft, or u, $= \frac{a^2 - z^2}{2a}$. Alfo $\dot{w} = \frac{\dot{u}\dot{z}}{\dot{y}}$, by what was faid above, that is, $\dot{w} = \frac{a\dot{u}}{\sqrt{a^2 - z^2}} = \frac{a\dot{u}}{\sqrt{2au}}$. Therefore we have $\dot{w} : \dot{u}\ (= a : \sqrt{2au}) = \sqrt{\frac{1}{2}a} : \sqrt{u} = \sqrt{GF} : \sqrt{Ft}$, which is the analogy competent to a cycloid whofe axis is $GF = DA$.

It is not neceffary to infift longer on this in this place; becaufe all thefe things will come more naturally before us when we are employed in deducing the evolute from its evolutrix.

When the ordinates of a curve converge to a centre, in which cafe it is called a radiated curve, it is moft convenient to confider its evolutrix in the fame way, conceiving the ordinates of both as infifting on the circumference of a circle defcribed round the fame centre. Spirals evolve into other fpirals, and exhibit feveral properties which afford agreeable occupation to the curious geometer. The equiangular, logarithmic, or loxodromic fpiral, is a very remarkable example. Like the cycloid, it evolves into another equal and fimilar equiangular fpiral, and is itfelf the evolutrix of a third. This is evident on the flighteft infpection. Let $C\,r\,q\,p$ (fig. 6.) be an equiangular fpiral, of which S is the centre; if a radius SC be drawn to any point C, and another radius SP be drawn at right angles to it, the intercepted tangent CP is known to be equal to the whole length of the interior revolutions of the fpiral, though infinite in number. If the thread CP be now unlapped from the arch $C\,r\,q$, it is plain that the firft motion of the point P is in a direction PT, which is perpendicular to PC, and therefore cuts the radius PS in an angle SPT, equal to the angle SCP; and fince this is the cafe in every pofition of the point, it is manifeft that its path muft be a fpiral PQR, cutting the radii in the fame angle as the fpiral $C\,r\,q\,p$. James Bernoulli firft difcovered this remarkable property. He alfo remarked, that if a line PH be drawn from every point of the fpiral, making an angle with the tangent equal to that made by the radius (like an angle of reflection correfponding with the incident ray SP), thofe reflected rays would all be tangents to another fimilar and equal fpiral $I\,v\,H$; fo that $PH = PS$. S and H are conjugate foci of an infinitely flender pencil; and therefore the fpiral $I\,v\,H$ is the cauftic by reflection of RQP for rays flowing from S. If another equal and fimilar fpiral $x\,v\,y$ roll on $I\,v\,H$, its centre z will defcribe the fame fpiral in another pofition $w\,u\,z$. All thefe things flow from the principles of evolution alone: and Mr Bernoulli traces, with great ingenuity, the connection and dependence of cauftics, both by reflection and refraction, of cycloidal, and all curves of provolution, and their origin in evolution or involution. A variety of fuch repetitions of this curve (and many other fingular properties), made him call it the SPIRA MIRABILIS. He defired that it fhould be engraved on his tombftone, with the infcription EADEM MUTATA RESURGO, as expreffive of the refurrection of the dead. See his two excellent differtations in *Act* Erudit. 1692, March and May.

Another remarkable property of this fpiral is, that if, inftead of the thread evolving from the fpiral, the fpiral evolve from the ftraight line PC, the centre S will defcribe the ftraight line PS. Of this we have an example in the apparatus exhibited in courfes of experimental philofophy, in which a double cone defcends, by rolling along two rulers inclined in an angle to each other (fee *Gravefande's* Nat. Phil. I. § 210). It is pretty remarkable, that a rolling motion, feemingly round C, as a momentary centre, fhould produce a motion in the ftraight line SP; and it fhews the inconclufivenefs of the reafoning, by which many compilers of elements of geometry profefs to demonftrate, that the motion of the defcribing point S is perpendicular to the momentary radius. For here, although this feeming momentary radius may be fhorter than any line that can be named, the real radius of curvature is longer than any line that can be named.

But it is not merely an object of fpeculative geometric curiofity to mark the intimate relation between the genefis of curves by evolution and provolution; it may be applied to important purpofes both in fcience and in art. Mr M'Laurin has given a very inviting example of this in his account of the Newtonian philofophy; where he exhibits the moon's path in abfolute fpace, and from this propofes to inveftigate the deflecting forces, and *vice verfa*. We have examples of it in the arts, in the formation of the pallets of pendulums, the teeth of wheels, and a remarkable one in Meffrs Watt and Boulton's ingenious contrivance for producing the rectilineal motion of a pifton rod by the combination of circular motions. M. de la Hire, of the Academy of Sciences at Paris, has been at great pains to fhew how all motions of evolution may be converted into motions of provolution, in a memoir in 1706. But he would have done a real fervice, if, inftead of this ingenious whim, he had fhewn how all motions of provolution may be traced up to the evolution which is equivalent to them. For there is no organic genefis of a curvilineal motion fo fimple as the evolution of a thread from a curve. It is the primitive genefis of a circle; and it is in evolution alone that any curvilineal motion is comparable with circular motion. A given curve line is an individual, and therefore its primitive organical genefis muft alfo be individual. This is ftrictly true of evolution. A parabola has but one evolute. But there are infinite motions of provolution which will defcribe a parabola, or any curve line whatever; therefore thefe are not primitive organical modes of defcription. That this, however, is the cafe, may be very eafily fhewn. Thus let ABCD (fig. 7.) be a parabola, or any curve; and let $a\,b\,c\,d$ be any other curve whatever. A figure $E\,m\,l\,k\,h\,i$ may be found fuch, that while it rolls along the curve $a\,b\,c\,d$, a point in it fhall defcribe the parabola. The procefs is as follows: Let $B\,b$, $C\,c$, $D\,d$, &c. be a number of perpendiculars to the parabola, cutting the curve $a\,b\,c\,d$ in fo many points. The perpendiculars may be fo difpofed that the points a, b, c, &c. fhall be equidiftant. Now we can conftruct a triangle $E\,e\,h$ fo, that the three fides $E\,e$, $e\,h$, and $h\,E$, fhall be refpectively equal to the three lines $E\,e$, $e\,f$, $F\,f$. In like manner may the whole figure be conftructed, having the little bafes of the

 the triangles refpectively equal to the fucceffive portions of the bafe $Abcd$, and the radii equal to the perpendiculars Bb, Cc, Dd, &c. Let this figure roll on this bafe c. While the little fide ck moves from its prefent pofition, and applies itfelf to ef, the point E defcribes an arch E ϵ of a circle round the centre e, and, falling within the parabola, is fomewhere between E and F. Then continuing the provolution, while the next fide hi turns round f till i applies to g, the point E defcribes another arch ϵ F o round f, firft rifing up and reaching the parabola in F, when the line h E coincides with fF, and then falling within the parabola till the point h begin to rife again from f by the turning of the rolling figure round the point g. Reverfing the motion, the fides ih, he, ek, &c. apply themfelves in fucceffion to the portions gf, fe, ed, &c. of the bafe, and the point E defcribes an undulating line, confifting of arches of circles round the fucceffive centres g, f, e, &c. Thefe circular arches all touch the parabola in the points G, F, E, &c. and feparate from it a little internally. By diminifhing the portions of the bafe, and increafing the number of the triangular elements of the rolling figure without end, it is evident that the figure becomes ultimately curvilineal inftead of polygonal, and the point E continues in the parabola, and accurately defcribes it. It is now a curvilineal figure, having its elementary arches equal to the portions of the bafe to which they apply in fucceffion, and the radii converging to E equal to the perpendiculars intercepted between the curve ABCD and the bafe. It may therefore be accurately conftructed.

It is clear that practical mechanics may derive great advantage from a careful ftudy of this fubject. We now fee motions executed by machinery which imitate almoft every animal motion. But thefe have been the refult of many random trials of *wipers*, *fnail-pieces*, &c. of various kinds, repeatedly corrected, till the defired motion is at laft accomplifhed. But it is, as we fee, a fcientific problem, to conftruct a figure which fhall certainly produce the propofed motion; nor is the procefs by any means difficult. But how fimple, in comparifon, is the production of this motion by evolution. We have only to find the curve line which is touched by all the perpendiculars Bb, Cc, Dd, &c. This naturally leads us to the fecond problem in this doctrine, namely, to determine the evolute by our knowledge of the involute: a problem of greater difficulty and of greater importance, as it implies, and indeed teaches, the curvature of lines, its meafure, and the law of its variation in all particular cafes. The evolute of a curve is the geometrical expreffion, and exhibition to the eye, of both thefe affections of curve lines.

Since the evolved thread is always at right angles to the evolutrix and its tangent, and is itfelf always a tangent of the evolute, it follows, that all lines drawn perpendicular to the arch of any curve, touch the curve line which will generate the given curve by evolution. Were this evolved curve previoufly known to us, we could tell the precife point where every perpendicular would touch it; but this being unknown, we muft determine the points of contact by fome other method, and by this determination we afcertain fo many points of the evolute. The method purfued is this: When two perpendiculars to the propofed curve are not parallel (which we know from the known pofition of the tangents of our curve), they muft interfect each other fomewhere on that fide of the tangents where they contain an angle lefs than 180°. But when they thus interfect, one of them has already touched the evolute, and the other has not yet reached it. Thus let bs, es (fig. 1.) be the two perpendiculars: being tangents to the evolute, the points s of their interfection muft be on its convex-fide, and the unknown points of contact B and E muft be on different fides of s. Thefe are elementary truths.

Let eE approach toward bB, and now cut it in x. The contact has fhifted from E to D, and x is ftill between the contacts. When the fhifting perpendicular comes to the pofition cC, the interfection is at i, between the contacts B and C. And thus we fee, that as the perpendiculars to the involute gradually approach, their contacts with the evolute alfo approach, and their interfection is always between them. Hence it legitimately follows, that the ultimate pofition of the interfection (which alone is fufceptible of determination by the properties of the involute) is the pofition of the point of contact, and therefore determines a point of the evolute. The problem is therefore reduced to the inveftigation of this ultimate interfection of two perpendiculars to the propofed curve, when they coalefce after gradually approaching. This will be beft illuftrated by an example: Therefore let ABC (fig. 8.) be a parabola, of which A is the vertex, AH the axis, and AV one-half of the parameter; let BE and CK be two perpendiculars to the curve, cutting the axis in E and K, and interfecting each other in r; draw the ordinates BD, CV, and the tangent BT, and draw BF parallel to the axis, cutting CK in F, and CN in O.

Becaufe the perpendiculars interfect in r, we have $r\mathrm{E} : \mathrm{EB} = \mathrm{EK} : \mathrm{BF}$. If therefore we can difcover the ratio of EK to BF, we determine the interfection r. But the ratio of EK to BF is compounded of the ratio of EK to BO, and the ratio of BO to BF. The firft of thefe is the ratio of equality; for DE and VK are, each of them, equal to AV, or half the parameter. Take away the common part VE, and the remainders EK and DV are equal, and DV is equal to BO; therefore $\mathrm{EK} : \mathrm{BF} = \mathrm{BO} : \mathrm{BF}$; therefore $r\mathrm{E} : r\mathrm{B} = \mathrm{BO} : \mathrm{BF}$, (and by divifion) $\mathrm{BE} : \mathrm{E}r = \mathrm{FO} : \mathrm{OB}$. Now let the point C continually approach to B, and at laft unite with it. The interfection r will unite with a point of contact N on the evolute. The ultimate ratio of FO to OB, or of $fo : o\mathrm{B}$, is evidently that of ED to DT, or ED to 2DA; therefore $\mathrm{BE} : \mathrm{EN} = \mathrm{ED} : 2\mathrm{DA}$, or as half the parameter to twice the abfciffa. Thus have we determined a point of the evolute; and we may, in like manner, determine as many as we pleafe.

But we wifh to give a general character of this evolute, by referring it to an axis by perpendicular ordinates. It is plain that V is one point of it, becaufe the point E is always diftant from its ordinate DB by a line equal to AV; and therefore, when B is in A, E will be in V, and r will coincide with it. Now draw VP and NQ perpendicular to AH, and NM perpendicular to VP; let EB cut PV in t: then, becaufe AV and DE are equal, AD is equal to VE, and VE is equal to one-half of DT. Moreover, becaufe BD and NQ are parallel, $\mathrm{DE} : \mathrm{EQ} = \mathrm{BE} : \mathrm{EN} = \mathrm{DE} : \mathrm{DT}$; therefore $\mathrm{DT} = \mathrm{EQ}$, and $\mathrm{VE} = \frac{1}{2}\mathrm{EQ}$, and therefore

$= \frac{1}{3}$

$=\frac{1}{3}$VQ; therefore Vt is $\frac{1}{3}$ of Mt, and $\frac{1}{4}$ MV. This is a characteriſtic property of the evolute. The ſubtangent is $\frac{3}{2}$ of the abſciſſa; in like manner, as in the common parabola, it is double of the abſciſſa. We know therefore that the evolute is a paraboloid, whoſe equation is $a\,x^2=y^3$; that is, the cube of any ordinate MN is equal to the parallelopiped whoſe baſe is the ſquare of the abſciſſa VM, and altitude a certain line VP, called the parameter. To find VP, let CR be the perpendicular to the parabola in the point where it is cut by the ordinate at V; draw the ordinate RS of the paraboloid, and RG perpendicular to AH. Then it is evident, from what has been already demonſtrated, that VK is $\frac{1}{2}$ of KG, and $\frac{1}{3}$ of VG: therefore KG^2 $=4$VK^2, and (in the parabola) VC$^2=2$VK^2. Alſo, becauſe KV : VC = KG : GR, we have GR$^2=2$KG^2 $=8$VK^2; therefore VP × RG$^2=8$VP × VK^2. But VG$^3=27$VK^3, $=27$VK × VK^2; therefore, becauſe in the paraboloid, VP × VS^2 = SR^3, or VP × RG^2 = VG^3, we have 8 VP × VK^2 = 27 VK × VK^2, and 8 VP = 27 VK; or VK : VP; that is, AV : VP = 8 : 27; or VP = $\frac{27}{8}$ AV, or $\frac{27}{16}$ of the parameter of the parabola ABC. The evolute of the conical parabola is the curve called the ſemicubical parabola, and its parameter is $\frac{27}{16}$ of the conical parabola.

This inveſtigation is nearly the ſame with that given by Huyghens, which we prefer at preſent to the method generally employed, becauſe it keeps the principle of inference more cloſely in view.

Mr Huyghens has deduced a beautiful corollary from it. Since the parabola ABC is deſcribed by the evolution of the paraboloid VNR, the line RC is equal to the whole evolved arch RNV, together with the redundant tangent line AV. If therefore we take from CR a part C$\varkappa$ equal to the redundant AV, the remainder $\varkappa$ R is equal to the arch RNV of the paraboloid. We may do this for every poſition of the evolved radius, and thus obtain a ſeries of points V, β, $\varkappa$, δ, ϵ, of the evolutrix of the paraboloid. We have even an eaſier method for obtaining the length of any part of the arch of the parabaloid, without the previous deſcription of the parabola ABC. Suppoſe Py the arch of the paraboloid, and $y\,z$ the tangent; make Pz = $\frac{8}{27}$ of the parameter, and deſcribe the arch P$u\,u$ of a circle; then draw from every tangent $y\,z$ a parallel line $x\,v$, cutting the circle in u. The length of the arch y P is equal to $y\,z+u\,v$. The celebrated author congratulates himſelf, with great juſtice, on this neat exhibition of a right line equal to the arch of a curve, without the employment of any line higher than the circle. It is the ſecond curve that has been ſo rectified, the cycloid alone having been rectified by plain geometry a very few years before by Sir Chriſtopher Wren. It is very true, and he candidly admits it, that this very curve had been rectified before by Mr William Neill, a young gentleman of Oxford, and favourite pupil of Dr Wallis; as alſo by Mr Van Heuraet, a Dutch gentleman of rank, and an eminent mathematician. But both of theſe gentlemen had done it by means of the quadrature of a curve conſtructed from the paraboloid after the manner of Dr Barrow, *Lect. Geom.* XI. Nor was this a ſolitary diſcovery in the hands of Mr Huyghens, as the rectification of the cycloid had been in thoſe of Sir Chriſtopher Wren; for the method of inveſtigation furniſhed Mr Huyghens with a general rule, by which he could evolve every ſpecies of paraboloid and hyperboloid, two claſſes of curves which come in the way in almoſt every diſcuſſion in the higher geometry. He obſerves, that the ratio of Bf to Ee, being always compounded of the ratios of Bf to Bo, and of Bo, or Dd, to Ee; and the ultimate ratio of Bf to Bo being that of TE to TD, which is given by the nature of the paraboloid, we can always find the ratio of BE to BN, if we know that of Dd to Ee. In all curves, the ratio of Dd to Ee (taken indefinitely near), is that of the ſubtangent to the ſum of the ſubtangent and ordinate of a curve conſtructed on the ſame abſciſſa, having its ordinates equal to the ſubnormals DE, de, VK, &c. In the conic ſections the ratio is conſtant, becauſe the line ſo conſtructed is a ſtraight line; and, in the parabola, it is parallel to the axis. See farther properties of it in Barrow's *Lect. Geom.* XI.

From this inveſtigation, Mr Huyghens has deduced the following beautiful theorem:

Let a be the parameter of the paraboloid, x its abſciſſa, and y its ordinate; and let the equation be $a^m x^n = y^{m+n}$; let the radius of the evolute meet the tangent through the vertex A in Z. We ſhall always have BN $=\frac{n}{m}$ BE $+\frac{m+n}{m}$ BZ. Thus,

$$\left.\begin{array}{l} \text{If } a\,x = y^2 \\ a^2 x = y^3 \\ a\,x^2 = y^3 \\ a\,x^3 = y^5 \\ a\,x = y^4 \\ \quad\&c. \end{array}\right\} \text{ then BN} = \left\{\begin{array}{l} \text{BE} + 2\,\text{BZ} \\ \frac{1}{2}\,\text{BE} + \frac{3}{2}\,\text{BZ} \\ 2\,\text{BE} + 3\,\text{BZ} \\ 3\,\text{BE} + 4\,\text{BZ} \\ \frac{1}{3}\,\text{BE} + \frac{4}{3}\,\text{BZ} \\ \quad\&c. \end{array}\right.$$

This is an extremely ſimple and perſpicuous method of determining the radius of the evolute, or radius of curvature; and it, at the ſame time, gives us the rectification of many curves. It is plain that every geometrical curve may be thus examined, becauſe the ſubnormals DE, VK are determined; and therefore their differences are determined. Theſe differences are the ſame with the differences of Dd and Ee; and therefore the ratio of Dd to Ee is determined; that is, the ſubſidiary curve now mentioned can always be conſtructed.

There is a ſingular reſult from this rule, which would hardly have been noticed, if the common method for determing BN had alone been employed. The equation of the paraboloid is ſo ſimple, that the increaſe of the ordinates and diminution of curvature ſeem to keep pace together; yet we have ſeen that, in the vertex of the cubical parabola, the curvature is leſs than any circular curvature that can be named. In the legs, the curvature certainly diminiſhes as they extend farther; there muſt therefore be ſome intermediate point where the curvature is the greateſt poſſible. This is diſtinctly pointed out by Mr Huyghens's theorem. The evolute of this paraboloid (having $a^2 x = y^3$) is a curve ONRNQ (fig. 9.) conſiſting of two branches RO, and RQ, which have a common tangent in R; the branch RQ has the axis AE for its aſſymptote. The thread unfolding from OR, its extremity, deſcribes the arch BC, and then, unfolding from RQ, it deſcribes the ſmall arch CB′A. When B′ is extremely near A, the thread has a poſition B′N′E, in which B′N is very nearly $\frac{1}{2}$ BE. At C, if CE be biſected in G, GR is $\frac{1}{2}$ of CZ′. Here CR the radius of curvature is the ſhorteſt poſſible. The evolutes of all paraboloids conſiſt of two ſuch branches, if $m+n$ exceeds 2.

Such

Involution.

Such is the theory of evolution and involution as delivered by Mr Huyghens about the year 1672. It was cultivated by the geometers with ſucceſs. Newton prized it highly, and gave a beautiful ſpecimen of its application to the deſcription, rectification, and quadrature of epicycloids, trochoids, and epicycles of all kinds. But it was eclipſed by the fluxionary geometry of Newton, which included this whole theory in one propoſition, virtually the ſame with Mr Huyghens's, but more comprehenſive in its expreſſion, and much more ſimple in its application. Adopting the unqueſtionable principle of Mr Huyghens, that the evolved thread is the radius of a circle which has the ſame flexures with the curve, the point of the evolute will be obtained by finding the length of the radius of the equicurve circle. The formula for this purpoſe is given in the article Fluxions of the *Encyclopædia Britannica;* but is incorrectly ſtated $= \frac{\overline{a+4}|^{\frac{3}{2}}}{2\sqrt{a}}$, inſtead of $\frac{\overline{a+4x}|^{\frac{3}{2}}}{2\sqrt{a}}$. The theorem alſo from which it is deduced $\left(r = \frac{\dot z^3}{-\dot x \ddot y}\right)$ is incorrectly printed, and is given without any demonſtration, thereby becoming of very little ſervice to the reader. For which reaſon, it is neceſſary to ſupply the defect in this place.

Therefore let $A\,b\,c\,d\,E\,f$ (fig. 10.) be a circle, of which C is the centre, and ACE a diameter; let the points b, c, d, of the circumference be referred to this diameter by the equidiſtant perpendicular ordinates $b\,i$, $c\,g$, $d\,k$; draw the chords $b\,c$, $c\,d$, producing $d\,c$ till it meet the ordinate $b\,i$ in a, produce $c\,g$ to the circle in f, and join $b\,f$, $d\,f$; draw $b\,h$, $c\,m$, perpendicular to the ordinates; then $b\,h$, $c\,m$, $h\,c$, $m\,d$, $b\,c$, $c\,d$, are ultimately proportional to the firſt fluxions of the abſciſſa AE, the ordinate $c\,g$, and the arch $A\,c$; alſo $a\,b$, the difference between $d\,m$ and $c\,h$ is ultimately as the ſecond fluxion of the ordinate. The triangle $a\,b\,c$ is ſimilar to $b\,d\,f$; for the angle $a\,b\,c$ is equal to the alternate angle $b\,c\,f$, which is equal to $b\,d\,f$, ſtanding on the ſame ſegment. The angle $a\,c\,b$ is equal to $b\,f\,d$, ſtanding on the ſegment $b\,c\,d$; therefore the remaining angles $b\,a\,c$ and $d\,b\,f$ are equal; therefore $a\,b : b\,c = b\,d : d\,f = \frac{1}{2}\,b\,d : \frac{1}{2}\,d\,f$. Now let the ordinates $b\,i$ and $d\,k$ continually approach the ordinate $c\,g$, and at laſt unite with it; we ſhall then have $b\,c$ ultimately equal to $\frac{1}{2}\,b\,d$, and $c\,g$ ultimately equal to $\frac{1}{2}\,d\,f$. Therefore, ultimately, $a\,b : b\,c = b\,c : c\,g$, and $c\,g = \frac{b\,c^2}{a\,b}$.

Let u, v, w, repreſent the variable abſciſſa, ordinate, and arch. We have, for the fluxionary expreſſion of the ordinate of the equicurve circle, $v = \frac{\dot w}{-\ddot v}$ ($\ddot v$ muſt have the negative ſign, becauſe, as the arch increaſes, $\dot v$ diminiſhes). In the next place, it is evident that, ultimately, $b\,h : b\,c = c\,g : c\,C$, and $c\,C = \frac{c\,g \times b\,c}{b\,h}$. If r be the radius of the equicurve circle, we have $\dot u : \dot w = v : r$, and $r = \frac{v\,\dot w}{\dot u}$. But we had $v = \frac{\dot w^2}{-\ddot v}$. Subſtitute this in the preſent equation, and we obtain $r = \frac{\dot w^3}{-\dot u\,\ddot v}$. Laſtly, obſerve that $\dot w^2 = \dot u^2 + \dot v^2$, and $\dot w = \sqrt{\dot u^2 + \dot v^2} = \overline{\dot u^2 + \dot v^2}|^{\frac{1}{2}}$. Therefore $\dot w^3 = \overline{\dot u^2 + \dot v^2}|^{\frac{3}{2}}$ and we have $r = \frac{\overline{\dot u^2 + \dot v^2}|^{\frac{3}{2}}}{-\dot u\,\ddot v}$, as the moſt general fluxionary expreſſion of the radius of a circle, in terms of the ſine, coſine, and arch.

When a curve and a circle have the ſame curvature, it is not enough that the firſt fluxions of their abſciſſæ, ordinates, and arches, are the ſame. This would only indicate the poſition of their common tangent. They muſt have the ſame deflection from that tangent. This is always equal to half of the ſecond fluxion of the ordinate. Therefore the circle and curve muſt have the ſame ſecond fluxion of their ordinates. Therefore let $D\,b\,c\,d\,F$ be any curve coinciding with, or oſculated by, the circle $A\,b\,c\,d$. Let its axis be DG, parallel to the diameter AE; and let $c\,n$ be its ordinate. Let $D\,n$ be $= x$, $c\,n = y$, and $b\,c = z$. We have $\dot x$, $\dot y$, $\dot z$, reſpectively equal to $\dot u$, $\dot v$, $\dot w$. Therefore the radius of the oſculating circle is $r = \frac{\dot z^3}{-\dot x\,\ddot y}$, or $r = \frac{\overline{\dot x^2 + \dot y^2}|^{\frac{3}{2}}}{-\dot x\,\ddot y}$ for all curves whatever. (We recommend the careful peruſal of the celebrated 2d corollary of the 10th propoſition of the 2d book of Newton's *Principia*, where the firſt principles of this doctrine are laid down with great acuteneſs.)

Inſtead of ſuppoſing the ordinates equidiſtant, and conſequently $\dot x$ invariable, we might have ſuppoſed the ordinates to increaſe by equal ſteps. In this caſe y would have had no ſecond fluxion. The radius would then be $= \frac{\dot z^3}{\dot y\,\ddot x}$. Or, laſtly, we might ſuppoſe (and this is very uſual) the arch z to increaſe uniformly. In this caſe $r = \frac{\dot z\,\dot y}{\ddot x}$: For becauſe $\dot x^2 + \dot y^2 = \dot z^2$, by taking the fluxion of it, $2\,\dot x\,\ddot x + 2\,\dot y\,\ddot y = 0$, and $\ddot y = \frac{\dot x\,\ddot x}{\dot y}$; and therefore $r = \frac{\dot z^3}{\dot y\,\ddot x - \dot x\,\ddot y}, = \frac{\dot z^3}{\dot y\,\ddot x + \frac{\dot x^2\,\ddot x}{\dot y}}, = \frac{\dot y\,\dot z^3}{\overline{\dot y^2 + \dot x^2} \times \ddot x}, = \frac{\dot y\,\dot z}{\ddot x}$.

Having thus obtained the radius of curvature, and conſequently a point of the evolute, we determine its form by reference to an abſciſs, without much farther trouble: It only requires the drawing $C\,p$ perpendicular to the axis of the propoſed curve, and giving the values of $C\,p$ and $D\,p$. If we ſuppoſe $\dot x$ conſtant, then, $c\,C$ being $= \frac{\dot z^3}{-\dot x\,\ddot y}$, we have $D\,p$ $\left(= D\,n + g\,c, = D\,n + \frac{\dot y}{\dot z} \times c\,C\right) = x + \frac{\dot y\,\dot z^2}{-\dot x\,\ddot y}$; and $p\,C$ $\left(= c\,g - c\,n, = \frac{\dot x}{\dot z} \times c\,C - c\,n\right) = \frac{\dot z^2}{-\ddot y} - y$. But if we ſuppoſe $\dot y$ conſtant; then, $c\,C$ being $= \frac{\dot z^3}{\dot y\,\ddot x}$, we have $D\,p = x + \frac{\dot z^2}{\ddot x}$, and $p\,C = \frac{\dot x\,\dot z^2}{\dot y\,\ddot x} - y$. And if $\dot z$ be conſtant, Involution.

constant, then, cC being $= \frac{\dot{y}\dot{z}}{\ddot{x}}$, we shall have $Dp = x + \frac{\dot{y}^2}{\ddot{x}}$, and $pC = \frac{\dot{x}\dot{y}}{\ddot{x}} - y$.

These formulæ are so many general expressions for determining both the curvature of the proposed curve and the form of its evolute. They also give us the rectification of the evolute; because cC is equal to the evolved arch, or to that arch, together with a constant part, which was a tangent to the evolute at its vertex, in those cases where the involute has a finite curvature at its vertex; as in the common parabola.

Let us take the example of the common parabola, that we may compare the two methods. The equation of this is $ax = y^2$, or $a^{\frac{1}{2}} x^{\frac{1}{2}} = y$. This gives $\dot{y} = \frac{1}{2} a^{\frac{1}{2}} \dot{x} x^{-\frac{1}{2}}, = \frac{a^{\frac{1}{2}}\dot{x}}{2x^{\frac{1}{2}}}$, and (making $\dot{x}$ constant) $\ddot{y} = -\frac{1}{2} \times \frac{1}{2} a^{\frac{1}{2}} \dot{x}^2 x^{-\frac{3}{2}} = \frac{-a^{\frac{1}{2}}\dot{x}^2}{4x^{\frac{3}{2}}}$. Wherefore $\dot{z}\ (= \sqrt{\dot{x}^2 + \dot{y}^2}) = \frac{\dot{x}}{2}\sqrt{\frac{4x+a}{x}}$, and the radius of curvature $\left(= \frac{\dot{z}^3}{-\dot{x}\ddot{y}}\right) = \frac{\overline{a+4x}|^{\frac{3}{2}}}{2\sqrt{a}}$. At the vertex, where $x = 0$, the formula becomes $= \frac{1}{2} a$. Again, $Dp \left(= x + \frac{\dot{y}\dot{z}^2}{-\dot{x}\ddot{y}}\right)$ becomes $\frac{1}{2} a + 3x$; and therefore $Vp = 3x$, = the abscissa of our evolute. Likewise cp, its ordinate, $\left(= \frac{\dot{z}^2}{-\ddot{y}} - y\right) = \frac{4x^{\frac{3}{2}}}{\sqrt{a}}$; and $Cp^2 = \frac{16x^3}{a}$; and $Cp^2 \times a = 16x^3$. But $Vp = 3x$, and $Vp^3 = 27x^3$. Therefore $Cp^2 \times \frac{1}{16}$th $a = x^3$, $= \frac{1}{27}$th Vp^3, and $\frac{27}{16}$ths $a \times Cp^2 = Vp^3$. Therefore the evolute VC is a semicubical parabola, whose parameter is $\frac{27}{16}$ths a, as was shewn by Mr Huyghens. The arch VC is $= \frac{\overline{a+4x}|^{\frac{3}{2}}}{2\sqrt{a}} - \frac{1}{2} a$.

We shall give one other example, which comprehends the whole class of paraboloids. Their general equation is $y = ax^n$. This gives us $\dot{y} = nax^{n-1}\dot{x}$, and $\ddot{y} = n \times \overline{n-1} \times ax^{n-2}\dot{x}^2$; therefore $\dot{z}\ (= \sqrt{\dot{x}^2 + \dot{y}^2}) = \dot{x}\sqrt{1 + n^2a^2x^{2n-2}}$; $Cc \left(= \frac{\dot{z}^3}{-\dot{x}\ddot{y}}\right) = \frac{\overline{1 + n^2a^2x^{2n-2}}|^{\frac{1}{2}}}{-n \times \overline{n-1} \times ax^{n-2}}$; $Dp \left(= x + \frac{\dot{y}\dot{z}^2}{-\ddot{y}\dot{x}}\right) = x - \frac{x + n^2a^2x^{2n-1}}{n-1}$; $Cp \left(= \frac{\dot{z}^2}{\ddot{y}} - y\right) = \frac{1 + \overline{2n-1} \times na^2x^{2n-2}}{-\overline{n-1} \times nax^{n-2}}$; and $DV = -\frac{n^2a^2 0^{2n-1}}{n-1}$.

This last formula expresses the radius of curvature at the vertex D, or the redundant part of the thread, by which it exceeds the arch VC of the evolute. If $n = \frac{1}{2}$, the formula becomes $\frac{a^2}{2}$: but if n be greater than this, VC will be $= 0$; and it if it be less, VC will be infinite. Hence it appears, that the radius of curvature at the vertex of a curve is a finite quantity only in the cases where the first or nascent ordinates are in the subduplicate ratio of their abscissæ. In all other cases, the curvature is incomparable with that of any circle, being either what is called infinite (when n is greater than $\frac{1}{2}$) or nothing (when it is less).

Involution.

We scruple not to say, that the method of Mr Huyghens is more luminous, more pleasing to the imagination of a geometer, than this; and in all the cases which occurred to us in our employment of it, it suggested more ready constructions, with the additional satisfaction of exhibiting, in a continuous train, what the *symbolical* method, proceeding by the fluxionary calculus, only indicates by points. We must also observe, that the subsidiary curve employed by Huyghens, having its ordinates equal to the subnormals of the involute under examination, is the geometrical expression of that function of the involute which gives the second fluxions $\ddot{y}$ and $\ddot{x}$ of the ordinate and abscissa. The young mathematician will find no difficulty in constructing this curve *in every case;* whereas we imagine that he will not find it a light matter to construct the final equations of the symbolic method *almost in any case.* At the same time, the all-comprehending extent of the latter method, and the numberless general theorems which it suggests to the expert analyst, give it a most deserved preference, and make it almost an indispensable instrument for all who would extend our physico-mathematical sciences.

In the employment of the geometry of curve lines, especially in the doctrine of centripetal forces, it is usual to consider the ordinates, not as insisting on a rectilineal abscissa, but as diverging from a centre. This is also the usual way of conceiving all spirals and evolutrixes of curves which include space; in short, all RADIAL curves. The process for finding their evolute, or their radius of curvature, is somewhat different from that hitherto exhibited; but it is more simple. Thus, let GPM (fig. 10.) be the elliptical path of a planet, of which S is the focus. We require PC, the radius of curvature in the point P. Let Pp be a very small arch. Draw the radii SP, Sp, the tangents PT, pt; and draw ST perpendicular to PT, cutting pt in t; and Po perpendicular to Sp. Let the arch GP be $= z$, the radius SP $= y$, and the perpendicular ST $= p$. Then, it is plain, that Pp, op, Tt, are ultimately proportional to $\dot{z}$, $\dot{y}$, $\dot{p}$. The triangles PCp, and Tpt or TPt are also ultimately similar; as also the triangles PST and poP. Therefore, ultimately,

Tt : Pp = PT : PC

also Pp : po = PS : PT

therefore Tt : po = PS : PC, or, $\dot{p} : \dot{y} = y : r$, and $r = \frac{y\dot{y}}{\dot{p}}$; an expression of the radius of curvature, extremely simple, and of easy application.

The logarithmic or equiangular spiral PQR (fig. 6.) affords an easy example of the use of this formula. The angle SPT, which the ordinate makes with the curve, is is everywhere the fame. Therefore let a be our tabular radius, and b the fine of the angle SPT. We have $ST = \frac{by}{a}$; and therefore PC $\left(= \frac{y\dot{y}}{\dot{p}}\right) = \frac{ay\dot{y}}{b\dot{y}} = \frac{ay}{b}$. This is to SP or y in the conftant ratio of a to b, or of SP to ST; that is, ST : SP = SP : PC, the triangles SPT and PCS are fimilar, the angles at P and C equal, and C is a point of an equiangular fpiral $p\,y\,r$ round the centre S.

It is not meant that the conftruction pointed out by this theory of involution, expreffed in its moft general and fimple form, is always the beft for finding the centre of the equicurve circle. Our knowledge of, or attention to, many other properties of the curve under confideration, befides thofe which fimply mark its relation to an abfcefs and ordinate, muft frequently give us better conftructions. But evolution is the natural genefis of a line of varying curvature. Moreover, in the moft important employment of mathematical knowledge, namely, mechanical philofophy, it is well known, that the moft certain and comprehenfive method of folving all intricate problems is by reference of all forces and motions to three co-ordinates perpendicular to each other. Thus, without any intentional fearch, we have already in our hands the very fluxionary quantities employed in this doctrine; and the expreffion which it gives of the radius of curvature requires only a change of terms to make it a mechanical theorem.

Thus have we confidered the two chief queftions of evolution and involution. We have done it with as clofe attention to geometry as poffible, that the reader's mind may become familiar with the *ipfa corpora* while acquiring the elementary knowledge, which is to be employed more expeditioufly afterwards by the help of the fymbolical analyfis. Without fuch ideas in the mind, the occupation is oftentimes as much divefted of thought as that of an expert accountant engaged in complex calculations; the attention is wholly turned to the rules of his art.

It now remains to confider a little the nature of this curvature of which fo much has been faid, and about which fo many obfcure opinions have been entertained. We mentioned, in an early part of this article, the unwarranted ufe of the terms of infinite and infinitefimal magnitude as applicable to curvature, and fhewed its impropriety by the inconfiftences into which it leads mathematicians. Nothing threw fo much light on this fubject as Mr Huyghens's Geometry of Evolution; and we fhould have expected that all difputes would have been ended by it. But this has not been the cafe; and even the moft eminent geometers and metaphyficians, fuch as the Bernoullis and Leibnitz, have given explanations of orders of curvature that can have no exiftence, and explanations of that coalefcence which obtains between a curve line and its equicurve circle, which are not warranted by juft principles.

Thefe errors (for fuch we prefume to think them) arofe from the method employed by the geometers of laft century for obtaining a knowledge of the magnitude and variation of curvature. The fcrupulous geometers of antiquity defpaired of ever being able to compare a curve with a right line. The moderns, although taught by Des Cartes to define the nature of a curve by its equation, allowed that this only enabled them to exhibit a feries of points through which it paffed, and to draw the polygon which connects thefe points, but gave no information concerning the continuous *incurvated* arches, of which the fides of the polygon are the chords. They could not generally draw a tangent to any point, or from any point; but they could draw a chord through any two points. Des Cartes was the firft who could draw a tangent. He contrived it fo, that the equation which expreffes the interfections of the curve with a circle defcribed round a given centre fhould have two equal roots. This indicates the coalefcence of two interfections of the common chord of the circle and the curve. Therefore a perpendicular to the radius fo determined muft touch the curve in the point of their union. This was undoubtedly a great difcorery, and worthy of his genius. It naturally led the way to a much greater difcovery. A circle may cut a curve in more points than two: It may cut a conic fection in four points; all expreffed by one equation, having four roots or folutions. What if three of thefe roots fhould be equal? This not only indicates a clofer union than a mere contact, but alfo gives indication of the flexure of the intervening arch. For, before the union, the interfections were in the arch both of the curve and of the circle; and therefore the diftinction between the union of two and of three interfections muft be of the fame kind with that between a ftraight line and an arch of *this* circle. The flexure of a circle being the fame in every part, it becomes a proper index; and therefore the circle, which is determined by the coalefcence of three interfections, was taken as the meafure of the curvature in that point of the curve, and was called the CIRCLE OF CURVATURE, the EQUICURVE CIRCLE. There is a certain progrefs to this coalefcence which muft be noticed. Let ABD (fig. 4.) be a common parabola, EBF a line touching it in B, and BO a line perpendicular to EBF. Taking fome point O in the other fide of the axis for a centre, a circle may be defcribed which cuts the curve in four points a, b, c, and d. By enlarging the radius, it is plain that the points a and b muft feparate, as alfo the points c and d. Thus, the points b and c approach each other, and at laft coalefce in a point of contact B, with the parabola, and with its tangent. In the mean time, a and d have retired to A and D. If we now bring the centre O nearer to B, the new circle will fall wholly within the laft circle ABD; and therefore both A and D will again approach to each other, and to B, which ftill continues a point of contact. It is plain that A will approach fafter to B than D will do. At length, the centre being in o, the point A coalefces with B, and we obtain a circle ε B δ, touching the curve in B, and cutting it in δ: Confequently the arch B $\varepsilon\,\delta$ is wholly within, and B $\varphi\,\delta$ is wholly without the parabola; and the circle both touches and cuts the parabola in B. Here is certainly a clofer union, at leaft on the fide of a. But perhaps a farther diminution of the circle may bring it clofer on the fide of D. Join B δ. Let a fmaller circle be defcribed, touching the parabola in B, and cutting it in φ. Draw $\varphi\,c$ parallel to δ B. It may be demonftrated that the new circle cuts the parabola in c. Now the arch between c and φ being without the parabola, the arch BC muft be within it; and therefore this circle is within the parabola on both fides of of B, and is more incurvated than the parabola. We have seen, that a circle greater than ϵ B δ is without the parabola on both sides of B; and therefore is less incurvated than the parabola. Therefore the individual circle ϵ B δ is neither more nor less curve than the parabola in the point B. Therefore the circle indicated by the coalescence of three intersections is properly named the equicurve circle; and, since we measure all curvatures by that of a circle, it is *properly* the circle of curvature, and its radius is the radius of curvature.

Had B been the vertex of the axis, every intersection on one side of B would have been similar to an intersection on the other, and there would always have been two pairs of roots that are equal; and therefore when three intersections coalesce, a fourth also coalesces, and the contact is said to be still closer.

What has now been shewn with respect to a conic section is true of every curve. When two intersections coalesce, there is a common tangent; when three coalesce, there is an equal curvature, and no other circle can pass between this circle and the curve. There cannot be a coalescence of four intersections, except when the diameter is perpendicular to the ordinates, and those are bisected by the diameter.

Mr Leibnitz, who valued himself for metaphysical refinement, and never fails to claim superiority in this particular, notices the important distinction between a simple contact and this closer union, in a very well written dissertation, published in the *Acta Eruditorum*, July 1686. He calls the contact of equal curvatures an OSCULATION, and the circle of equal curvature the OSCULATING CIRCLE, and delivers several very judicious remarks with the tone of a master and instructor. He also speaks of different degrees or orders of osculation, each of which is infinitely closer than the other, as a thing not remarked by geometers. But Sir Isaac Newton had done all this before. The first twelve propositions of the *Principia* had been read to the Royal Society several years before, and were in the Registers. The *Principia* had received the imprimatur of the Society in July 1686; but was almost printed before that time. In the Scholium to the 11th Lemma, is contained the whole doctrine of contact and osculation; and in the lemma and its corollaries, is crowded a body of doctrine, which has afforded themes for volumes. The author glances with an eagle's eye over the whole prospect, and points out the prominent parts with the most compressed brevity; but with sufficient precision for marking out the more important objects, and particularly the different orders of curvature. This lemma and its corollaries are continually employed in the twelve propositions already mentioned. In 1671 he had written the first draught of his method of fluxions, where this doctrine is systematically treated; and Mr Collins had a copy of it ever since 1676. It is well known that Leibnitz, when in London, had the free perusal of the Society's records, and information at all times by his correspondence with the secretary Oldenburgh and Mr Collins. His conduct respecting the theorems concerning the elliptical motion of the planets, and the resistance of fluids, leave little room to doubt of his having availed himself in like manner of his opportunity of information on this subject. He gives a much better account of the Newtonian doctrine on this subject than in those other instances, it being more suited to his refining and paradoxical disposition.

In this and another dissertation, he considers more particularly the nature of evolution, and of that osculation which obtains between the evolutrix and the circle described by the evolved radius. He says, that it is equivalent to two simple contacts, each of which is equivalent to two intersections. An osculation produced in the evolution of a curve is therefore equivalent to four intersections. And he advises, with an air of authority, the mathematicians to attend to these remarks, as leading them into the recesses of science. He is mistaken, however; and the listening to him would prevent us from forming a just notion of osculation, and from conceiving with distinctness the singular fact of a circle both touching and cutting a curve in the same point. James Bernoulli lost his friendship, because he presumed to say that the presence of four intersections in an osculation is not warranted by the equation expressing those intersections.

Mr Leibnitz was misled by the way in which he had considered the osculation in the evolution of curves. It merits attention. From any point within the space ADFOA (fig. 1.), two perpendiculars may be drawn to the evolutrix A $b\,d\,f$; and therefore two circles may be described round that point, each touching the curve. Each contact is the union of two intersections. Therefore, as the centre approaches the evolute, the contacts approach each other, and they unite when the centre reaches the evolute. Therefore the osculation of evolution is equivalent to four intersections.

But when two such circles are described round a point s, so as that both may touch the evolutrix A $a\,f$, the point s is in the intersection of one evolved radius with the *prolongation* of another. The contact at the extremity b of the prolonged radius b B is an exterior contact, and the arch of the circle crosses the evolutrix, from without inwards, in some point more remote from A. The contact at the extremity e of the radius $\hat{e}$ E is an interior contact; and if $e\,s$ be greater than the straight line EA, the arch of this circle crosses the curve, from within outwards, in some point nearer to A. Thus each contact is accompanied by an intersection on the side next the other contact, sometimes beyond it, and sometimes between the contacts. As the contacts approach, the intersections also approach, still retaining their characters as intersections, as the contacts still continue contacts. Also the circle next to A crosses from without inwards, and that next to f crosses from within outwards. They retain this character to the last; and when the contacts coalesce, the two circles coalesce over their whole circumference, still, however, crossing the curve in the same direction as before; that is, without the curve on the side of A, and within it on the side of f. The contacts unite as contacts, and the intersections as intersections. Thus it is that the osculating circle both touches and intersects the curve in the same point.

At f the osculation is indeed closer than anywhere else. The variation of curvature is less there than anywhere else, because the radius changes more slowly. It is this circumstance that determines the closeness of contact. If a circle osculates a curve, it has the same curvature. If this curvature does not change in the vicinity of the contact, the curve and circle must coincide; and the deviation of the circle (the curvature of which is everywhere the same) from the curve must proceed entirely from the variation of its curvature.

This,

This, therefore, is the important circumſtance, and is indeed the characteriſtic of the figure as a curve line; and its other properties, by which the poſition of its different parts are determined, may be aſcertained by means of the *variation* of its curvature, as well as by its relation to co-ordinates. Of this we have a remarkable inſtance at this very time. The orbit of the newly diſcovered planet has been aſcertained with tolerable preciſion by means of obſervations made on its motions for three years. In this time it had not deſcribed the 20th part of its orbit; yet the figure of this orbit, the poſition of its tranſverſe axis, the place and time of its perihelion, were all determined within 100dth part of the truth by the *obſerved variation* of its curvature. It therefore merits our attention in the cloſe of this article. We know of no author who has treated the ſubject in ſo inſtructive a manner as Mr M'Laurin has done, by exhibiting the theorem which conſtitutes Newton's 11th lemma in a form which points this out even to the eye (ſee *M'Laurin's Fluxions*, Chap. xi. § 363, &c.). We earneſtly recommend this work to the young geometer, as containing a fund of inſtruction and agreeable exerciſe to the mathematical genius, and as greatly ſuperior in perſpicuity and in ideas which can be treaſured up and recollected, when required, to the greateſt part of the elaborate performances of the eminent analyſts of later times. By expreſſing every thing geometrically, the author furniſhes us with a ſort of picture, which the imagination readily reviews, and which exhibits in a train what mere ſymbols only give us a momentary glimpſe of.

"As, of all right lines which can be drawn through a given point in the arch of a curve, that alone is the tangent which touches the arch ſo cloſely that no right line can paſs between them; ſo, of all circles which touch a curve in a given point, that circle alone has the ſame curvature which touches it ſo cloſely that no circle can paſs between them. It cannot coincide with the arch of the curve; and therefore the above condition is ſufficient for making it equicurve. As the curve ſeparates from the tangent by its flexure or curvature, it ſeparates from the equicurve circle by its *change* of curvature; and as its curvature is greater or leſs according as it ſeparates more or leſs from its tangent, ſo the variation of its curvature is greater or leſs according as it ſeparates more or leſs from its equicurve circle. There can be but one equicurve circle at one point of a curve, otherwiſe any other circle deſcribed between them through that point will paſs between the curve and the equicurve circle.

"When two curves touch each other in ſuch a manner that no circle can paſs between them, they muſt have the ſame curvature; becauſe the arch which touches one of them ſo cloſely that no circle can paſs between them, muſt touch the other in like manner. But circles may touch the curve in this manner, and yet there may be indefinite degrees of more or leſs intimate contact between the curve and its equicurve circle." This is ſhewn by the ingenious author in a ſeries of propoſitions, of which a very ſhort abridgment muſt ſuffice in this place.

Let any curve EMH (fig. 11.), and a circle ERB, touch a right line ET on the ſame ſide at E. Let any right line TK, parallel to the chord EB of the circle, meet the tangent in T, the curve in M, and a curve BKF (which paſſes through B) in K. Then, if $MT \times TK$ be everywhere equal to TE^2, the curvature of EMH in the point E is the ſame as that of the circle ERB; and the contact of EM and ER is ſo much the cloſer the ſmaller the angle is which is contained at B between the curve BKF and the equicurve circle BQE.

Let TK meet the circle in R and Q. Then, becauſe $RT \times TQ = TE^2$, it muſt be $RT \times TQ = MT \times TK$; and $RT : MT = TK : TQ$. The line BKF may have any form. It may croſs the circle BQR in B, as in the figure. It may touch it, or touch EB, &c. Let us firſt conſider what ſituations of the point M correſpond with the poſition of K, in that part of the curve BKF which lies without the circle BRE. Let TK move toward EB, always keeping parallel to it, till it coincide with it, or even paſs it. Then, while the point K deſcribes KB, it is evident that ſince TK is greater than TQ, TM muſt be leſs than TR, and the point M muſt always be found between T and R. The arch ME of the curve muſt be nearer to the tangent than the arch RE of the circle. If any circle be now deſcribed touching TE in E, and cutting off from EB a ſmaller chord than EB, it is clear that the whole of this ſegment muſt be within the ſegment BRE; therefore this ſmaller circle does not paſs between ERB and the curve EMH. But ſince we ſee that the curve lies without the circle, in the vicinity of E, perhaps a greater circle than ERB may paſs between it and the curve. A greater circle, touching at E, muſt cut off a chord greater than EB. Let E r b be ſuch a circle, cutting EB in b, and TQ in q. T q is neceſſarily greater than TQ. For ſince b is beyond B, and the arch BKF lies in the angle QB b, the circle E r q muſt croſs the curve FKB in ſome point; ſuppoſe F. Then while K is found in the arch FB, the point q muſt be beyond K, or T q muſt be greater than TK. Now $Tr \times Tq = TE^2, = TM \times TQ$. Therefore $TM : Tr = Tq : TQ$. Therefore T q being greater than TQ, T r muſt be leſs than TM, and the point r muſt lie without the curve, and the arch E r does not paſs between EMH and the circle ERB. In like manner, on the other ſide of EB, it will appear, that when the curve BK'F falls within the circle which touches EMH in E, and cuts off the chord EB, the arch of the curve correſponding to the arch BK'F', lying within the circle, alſo lies within the circle. For T'K' being leſs than TQ', TM' is greater than TR', and the curve is within the circle. And, by ſimilar reaſoning, it is evident that a circle cutting off a greater chord falls without both the circle ER'B and the curve, and that a circle leſs than ER'B muſt neceſſarily leave ſome part of the curve BK'F' without it; and therefore TK' will be greater than T q', and the correſponding point r' muſt be without the curve. All circles therefore touching TE in E fall without both ER and EM, or within them both, according as they cut off from EB a chord greater or leſs than EB, and no circle can paſs between them when the rectangle $MT \times TK$ is always equal to ET^2, and the focus of the point K paſſes through B; that is, ERB is the equicurve circle at E.

This corroborates the ſeveral remarks that we have made on the circumſtance of a circle touching and cutting a curve in the ſame point. No other circle can be made

Involution. made to pafs between it and the curve, and it therefore has the fame curvature. This may therefore be taken as a fufficient indication of the equicurve circle; the character peculiarly affured to it by the nature of evolution. It muft be noted, however, that the curve is fuppofed to have its concavity in the vicinity of the contact turned all the fame way. For if the contact be in a point of contrary fluxure, even a ftraight line will both touch and cut it in that point.

The reader cannot but remark, that MK is always the chord of a circle touching TE in E, and paffing through m

Let E m be another curve, touching TE in E, fuch that the conjugate curve k B, which always gives T m $\times$ T k = TE^2, alfo paffes through B. Then, by what has now been demonftrated, the two curves EM and E m have the fame equicurve circle ERB, and confequently the fame curvature in E. Then, becaufe the rectangles $RT \times TQ$, $MT \times TK$, and $m T \times T k$, are equal, we have $T m : TM = TK : T k$. Therefore if the arch B k pafs between BK and BQ, the curve E m muft pafs between the curve EM and the circle ER. E m muft therefore have a clofer contact with ER than EM has with it; and the fmaller the angle QBK is which is contained between the curve and its equicurve circle, the clofer is the contact of the curve EM and its equicurve circle ER. Thus the length of the chord EB determines the *magnitude* or degree of curvature at E, when compared with another; and the angle contained between the equicurve circle and the conjugate curve BKF determines the clofenefs of the contact of the curve with its equicurve circle (the angle TEB being fuppofed the fame in both.)

It appears, from the procefs of demonftration, that the curve EMH falls without or within the equicurve circle according as its conjugate curve BKF does. Alfo when BKF cuts BQR, HME alfo cuts it. But if FQB is on the fame fide of QB on both fides of the interfection B, the curve HME is alfo on the fame fide of it on both fides of the contact E. It is alfo very clear, that the contact or approach to coalefcence between the curve and its circle of curvature, is fo much the clofer as the conjugate curve BKF comes nearer to the adjoining arch of this circle. It muft be the clofeft of all when KB touches QB, and it muft be the leaft fo when KB touches EB, or has EB for an affymptote. The fpace QBK is a fort of magnified picture of the fpace MER; and we have a fenfible proportion of TQ to TK as the reprefentation of the proportion of TM to TR, quantities which are frequently evanefcent and infenfible. When QBK is a finite angle, that is, when the tangents of BQ and BK do not coincide, the angle QBK can be meafured. But no rectilineal angle can be contained as an unit in the curvilineal angle MER. They are incommenfurable, or incomparable. Let the curve KB touch the circle QB without cutting it. This angle is equally incomparable with the former QBK; yet it has a counterpart in MER. This muft be incomparable with the former in the fame manner; for there is the fame proportion between the individuals of both pairs. Thus it appears plainly, that there are curvilineal angles incomparable with each other. Yet are they magnitudes of one kind; becaufe the fmalleft rectilineal angle muft certainly contain them both; and one of them contains the other.

But, further, there may be indefinite degrees of this coalefcence or clofenefs of contact between a curve and a circle. The firft degree is when the fame right line touches both. This is a *fimple contact*, and may obtain between any curve and any circle. The next is when EMH and ERB have the fame curvature, and when the conjugate curve FKB interfects the circle QB in any affignable angle. This is an *ofculation*. The third degree of contact, and fecond of ofculation, is when the curve KB touches the circle QB, but not fo as to ofculate. The fourth degree of contact, and third of ofculation, is when KB and QB have the fame curvature or ofculate in the firft degree of ofculation. This gradation of more and more intimate contact, or (more properly fpeaking) of approximation to coalefcence, may be continued without end, "*neque novit natura limitem*," the contact of EM and ER being always two degrees clofer than that of BK and BQ. Moreover, in each of thofe claffes of contact there may be indefinite degrees. Thus, when EM and ER have the fame curvature, the angle QBK admits of indefinite varieties, each of which afcertains a different clofenefs of contact at E. Alfo, though the angle QBK fhould be the fame, the contact at E will be fo much the clofer the greater the chord EB is.

For $TR : TM = TK : TQ$

Therefore $RM : TR = KQ : KT$

Or $RM : KQ = TR : TK$; $= TR \times TQ : TK \times TQ$, $= TE^2 : TK \times TQ$.

Therefore, when TE is given, RM (which is then the meafure of the angle of contact) is proportional to KQ directly, and to the rectangle $TK \times TQ$ inverfely; and when KQ is given, RM is lefs in proportion as $KT \times TQ$ is greater. In the very neighbourhood of E and B, it is plain that $KT \times TQ$ is very nearly equal to EB^2, and therefore ultimately $RM : KQ = ET^2 : EB^2$.

It will greatly affift our conception of this delicate fubject, if we view the origin of thefe degrees of contact as they are generated by the evolution of lines. A thread evolving from a polygon EDCBA (fig. 13.) defcribes with its extremity a a line *e d b c a*, confifting of fucceffive arches of circles united in fimple contacts. If it evolve from any continuous curve CBA, after having evolved from the lines ED, BC, the arch *c b* will be united with the circular arch *d c* by ofculation of the firft degree. If any other curve FC touch this evolute in a fimple contact, and if the two curves FCBA and DCBA are both evolved, they will touch each other in a fimple ofculation in that point where they have the fame radius. If FC touches DC in a fimple ofculation, the evolved curves will touch in an ofculation of the fecond degree; and, in general, the ofculation of the two generated curves is a degree clofer than that of their evolutes; and in each ftate of one of the ofculations, there is an indefinite variety of the other, according to the length of its radius of curvature. All this is very clear; and fhews, that thefe degrees of contact do not indicate degrees of curvature, one of which infinitely exceeds another; for they are all finite.

The reader will do well to remark, that the magnitude, which is the fubject of the above proportions, which is really of the fame kind in them all, and confidered as fufceptible of various degrees and orders of infinitefimals, is not curvature, but lineal extenfion. It is RM, the fubtenfe of the angle of contact MER. It is is the linear ſeparation from the tangent, or from the equicurve circle. It is, however, uſually conſidered as the meaſure of curvature, or the proportions of this line are given as the proportions of the curvature. This is inaccurate; for curvature is unqueſtionably a change of direction only. As this line has generally been the intereſting object in the refined ſtudy of curve lines, eſpecially in the employment of it in the diſcuſſions of mechanical philoſophy, it has attracted the whole attention, and the language is now appropriated to this conſideration. What is called, by the moſt eminent mathematicians, variation of curvature, is, in fact, variation of the ſubtenſe of the angle of contact. But it is neceſſary always to diſtinguiſh them carefully.

Variation of curvature is the remaining object of our attention.

Curvature is uniform in the circle alone. When the curvature of the arch EMH (fig. 11.) decreaſes as we recede from E, the arch, being leſs deflected from its primitive direction ET than the arch ER, muſt ſeparate leſs from the line ET, or muſt fall without the arch ER. The more rapidly its curvature decreaſes, the deſcribing point muſt be left more without the circle. It muſt be the contrary, if its curvature had increaſed from E toward M. It may change its curve equably or unequably. If equably, there muſt be a certain uniform rate, which would have produced the ſame final change of direction in a line of the ſame length, bending it into the uniformly incurvated arch of a circle. It is not ſo obvious how to eſtimate a râte of variation of curvature; and authors of eminence have differed in this eſtimation. Sir Iſaac Newton, who was much intereſted in this diſcuſſion, in his ſtudies on univerſal gravitation, ſeems to have adopted a meaſure which beſt ſuited his own views; and has been followed by the greater number. He gives a very clear conception of what he means, by ſtating what he thinks a caſe of an invariable rate of variation. This is the equiangular ſpiral, all the arches of which, comprehended in equal angles from the centre, are perfectly ſimilar. although continually varying in curvature. He calls this a curve EQUABLY VARIABLE, and makes its rate of variation (eſtimated in that ſenſe in which it is uniform) the meaſure of the rate of variation in all other curves. Let us ſee in what reſpect its variation of curvature is conſtant. It may be deſcribed by the evolution of the ſame ſpiral in another poſition (ſee fig. 6.), and the ratio between the radius of the evolute and that of the evolutrix is always the ſame; or (which amounts to the ſame thing) the arch of the evolutrix bears to the evolved arch of the evolute a conſtant ratio. The curvature of the ſpiral changes more rapidly in the ſame proportion as the ratio of the evolved arch to the arch of the evolutrix generated by it is greater, or as it cuts the radii in a more acute angle. Theſe arches may be infiniteſimal; therefore the fraction $\frac{\text{fluxion of evolute}}{\text{fluxion of evolutrix}}$ expreſſes the rate of the variation of curvature in this ſpiral. Now let *abcd* (fig. 13.) be any other curve, and ABCD its evolute; let p be the centre of curvature at the point B of the evolute, and Bo the evolved arch; draw the radii pB, po, Bm, on; join pm, and draw Bq perpendicuar to pm. It is evident that mn and Bo have the ſame ratio with Bm and Bp; and that theſe two ſmall arches may be conceived as being portions of the ſame equiangular ſpiral (perhaps in another poſition), of which q is the centre; and that p is in the curve of another of the ſame. For $qp : q\mathrm{B} = q\mathrm{B} : q\mathrm{M}, = p\mathrm{B} : \mathrm{B}m$; therefore the ratio of theſe infiniteſimal arches mn and Bo will expreſs the rate of variation in any curve. This is evidently equivalent to ſaying, that the variation of curvature is proportional to the fluxion of the radius of curvature directly, and the fluxion of the curve inverſely. For mn and Bo are ultimately as thoſe fluxions, and $\frac{\mathrm{B}o}{mn}$ is equivalent to $\frac{-\dot{r}}{\dot{z}}$, where z is the arch of the ſpiral, and r the evolved radius of the other. Accordingly, this is the enunciation of the INDEX OF VARIATION given by Newton: (See Newton's Fluxions, Prob. VI. § 3.) Therefore, what Newton calls a uniform variation of curvature, is not an increaſe or diminution by equal arithmetical differences, but by equal proportions of the curvature in every point. The variation of curvature in ſimilar points of ſimilar arches is ſuppoſed to be the ſame.

It is evident that this ratio is the ſame with that of radius to the tangent of the angle pmB, or of 1 to its tabular tangent. The tangent therefore of this angle correſponding to any point of a curve is the meaſure of the variation of curvature in that point. Now it may be ſhewn (and it will appear by and bye), that the fluxion of TK in fig. 11. or the ultimate value of KQ, is always ⅔ds of the fluxion of the radius of curvature. Therefore the tangent of the angle QBK is always ⅔ds of that of pmB; and therefore the angle QBK, which we have ſeen to be an index of the cloſeneſs of contact, is alſo the index of the variation of curvature. (See *M'Laurin*, § 386.)

Sir Iſaac Newton has given ſpecimens of the uſe of this meaſure in a variety of geometrical curves, by means of a general expreſſion of $\frac{\dot{r}}{\dot{z}}$. Thus in the curve ABC (fig. 8.), let AB be $= z$, AD $= x$, DB $= y$, BN $= r$, and BE $= p$; we have $\frac{\mathrm{N}n}{\mathrm{B}b} = \frac{\dot{r}}{\dot{z}}$. Now DB : BE $= y : p, = \mathrm{D}d : \mathrm{B}b, = \dot{x} : \dot{z}$. Therefore $\dot{z} = \frac{p\dot{x}}{y}$, and $\frac{\dot{r}}{\dot{z}} = \frac{y\dot{r}}{p\dot{x}}$. Now, in every curve which we can expreſs by an equatión, we can obtain all theſe quantities p, y, $\dot{r}$, and $\dot{z}$, and can therefore obtain the meaſure of the variation of curvature. It alſo deſerves particular notice, that this inveſtigation of $\frac{\dot{r}}{\dot{z}}$ is equivalent with finding the centre and radius of curvature of the evolute, by which the curve under conſideration is generated; or with finding the centre q (fig. 13.) of an equiangular ſpiral, which will touch our curve in m, its evolute in B, and the evolute of the evolute in p, if put into different poſitions when neceſſary. This leads to very curious ſpeculations, for which, however, we have no room. It has been ſaid, for inſtance, that the curvature at the interſection of a cycloid with its baſe is infinitely greater than that of any circle. If the evolution of the cycloid begin from this point, the curvature of its evolutrix will be infinitely greater ſtill upon the ſame principles; and we ſhall have one infinitely greater than

than this by evolving it. Yet all theſe infinites, multiplied to infinity, are contained in the central point of every equiangular ſpiral! In like manner, there are evolutrixes which coincide with a ſtraight line, and others of infinitely greater rectitude, and ſtill they are curves. Can this have any meaning? And can it be reconciled with the legitimate reaſoning from the ſame principles, that all theſe curvatures and angles of contact are producible by evolution; and that they may be, and certainly are every day deſcribed, by bodies moving in free ſpace, and acted on by accelerating forces directed to different bodies?

The parabola (conical) is the moſt ſimple of all the lines of unequably varying curvature, and becomes a very good ſtandard of compariſon. In the parabola ABC (fig. 8.) let the parameter be $2a$. The equation is then $2ax = y^2$; DE $= a$; p, or BE $= \sqrt{a^2 + y^2}$ DQ $= a + 2x$ (by what was formerly demonſtrated). Moreover, DB : BE = DQ : BN; and BN $= \frac{pa + 2px}{a}$, $= r$. Theſe equations give $2a\dot{x} = 2y\dot{y}$, $= 2p\dot{p}$; and $\frac{a\dot{p} + 2x\dot{p} + 2p\dot{x}}{a} = \dot{r}$ Now making $\dot{x} = 1$, and reducing the equations, we obtain $\dot{y} = \frac{a}{y}$; $\dot{p} = \frac{y\dot{y}}{p}$, $= \frac{a}{p}$; and $\dot{r} = \frac{a\dot{p} + 2x\dot{p} + 2p}{a}$.

With theſe values of $\dot{y}, \dot{p}, \dot{r}$, we obtain a numerical value of $\frac{y\dot{r}}{p}$ moſt readily. Thus in order to obtain the index of variation of curvature in the point where the ordinate at the focus cuts the parabola, make $a = 1$. Then $2x = y^2$; $x = \frac{1}{2}$, $y\ (= \sqrt{2x}) = 1$; $\dot{y}\left(= \frac{a}{y}\right) = 1$; $p\ (= \sqrt{a^2 + y^2}) = \sqrt{2}$; $\dot{p}\left(= \frac{a}{p}\right) = \sqrt{\tfrac{1}{2}}$, and $\dot{r}\left(= \frac{a\dot{p} + 2x\dot{p} + 2p}{a}\right) = \sqrt{2} \times 3$. Therefore $\frac{y\dot{r}}{p} = 3$, $=$ the index of variation in the point B when D is the focus of the parabola; that is to ſay, the fluxion of the radius of curvature is three times the fluxion of the curve.

The index of variation, where the ordinate is equal to the parameter, is had by making $x = 2$. This gives $y = 2$; $\dot{y} = \frac{1}{2}$; $p = \sqrt{5}$; $\dot{p} = \sqrt{\tfrac{1}{5}}$, and $\dot{r} = 3\sqrt{5}$. Wherefore $\frac{y\dot{r}}{p} = 6$, which is the index of variation. Moreover, ſince p and $\dot{r}$ are in a conſtant ratio, it appears that the index of variation of curvature in the parabola is proportional to the ordinate y. It is always $= 6\ \frac{\text{ordinate}}{\text{parameter}}$; and thus, with very little trouble, we can deſcribe the evolute of its evolute, *i. e.* of the ſemicubical parabola.

In like manner, it may be ſhewn that in all the conic ſections $\frac{\dot{r}}{\dot{z}}$ is always proportional to the rectangle of the ordinate DB and the ſubnormal DE, or to DB × DE. In the parabola, whoſe equation is $2ax = y^2$, we have $\frac{\dot{r}}{\dot{z}} = \frac{3y}{a}$. In an ellipſe, whoſe equation is $2ax - bx^2 = y^2$, we have $\frac{\dot{r}}{\dot{z}} = \frac{3 - 3b}{a} \times$ DB × DE, and in the hyperbola, whoſe equation is $2ax + bx^2$, $\frac{\dot{r}}{\dot{z}}$ is $= \frac{2 + 3b}{a} \times$ DB × DE. This ratio, in all the three ſections, is always as the tangent of the angle contained between the diameter and the normal at the point of contact. By this we may compare them with a parabola. In the cycloid at the point E (fig. 5.) $\frac{\dot{r}}{\dot{z}}$ is $=$ tan. ∠ EKM, &c. &c.

All theſe things may be traced in the obſervations made on fig. 11. and 12. When the angle BET is a right angle, the angle KBQ indicates it directly, its tangent being always $= \frac{2\dot{r}}{3\dot{z}}$. It is eaſy alſo to ſee, that when the curve EMH is a parabola, the line BKF is a ſtraight line parallel to ET. It is alſo plain, that by the ſame ſteps that we proved that no circle can paſs between this parabola and its equicurve circle ERB, ſo no other parabola can paſs between them. Indeed the ſame reaſoning will prove that no curve of the ſame kind can paſs between any curve and its oſculating circle. In many caſes, it is more eaſy to reaſon from the curvature of a curve, by comparing it with an equicurve parabola than with an equicurve circle; particularly in treating of the curvilineal motions of bodies in free ſpace, actuated by deflecting forces.

If EMH be an ellipſe or hyperbola, BKF is another ellipſe or hyperbola (*M'Laurin*, § 373).

We have thus endeavoured to introduce our readers into this curious branch of ſpeculative geometry. An introduction is all that can be expected from a work of this kind. We have enlarged on particular points, in proportion as we thought that the notions entertained on the ſubject were inadequate, or even vague and indiſtinct; and we hope that ſome may be incited to acquire clearer conceptions by going to the fountain head. We conclude, by recommending to the young geometer the peruſal of the Fluxions of Sir Iſaac Newton, after he has read M'Laurin's Chapter with care. He will probably be ſurpriſed and delighted with ſeeing the whole compreſſed by a maſter's hand into ſuch narrow compaſs with ſuch beautiful perſpicuity.

JOAN d'Arc, the maid of Orleans, has been variouſly characteriſed; but all now agree, that ſhe was worthy of a better fate than the horrid death ſhe was doomed to die. (See Joan *d'Arc*, *Encycl.*) But did ſhe actually die that death? An ingenious writer in the *Monthly Magazine* has proved, we think, that ſhe did not.

The biſhop of Beauvais (ſays he) is accuſed by all parties of treachery and trick in the conduct of the trial: it was his known propenſity to gain his ends by ſtratagem, craft, manœuvre, fraud, dexterity. He ſeeks out, and brings forward, ſuch teſtimony only as relates to eccleſiaſtical offences, and then hands over the deciſion

Joan, Jones.

fion to the fecular judges, whofe clemency he invokes. Joan fays to him publicly, "You * *promifed* to reftore me to the church, and you deliver me to my enemies." The intention of the bifhop, then, muft have been, that the fecular judges, for want of evidence, fhould fee no offence againft the ftate; as the clerical judges, notwithftanding the evidence, had declined to fee any againft the church. A fatal fentence was, however, pronounced; and the fulfilment of it entrufted to the ecclefiaftical authorities. Immediately after the *auto da fé*, one of the executioners ran to two friars, and faid, "that he had never been fo fhocked at any execution, and that the Englifh had built up † a fcaffolding of plafter (*un echafaud de platre*) fo lofty, that he could not approach the culprit, which muft have caufed her fufferings to be long and horrid." She was therefore, by fome *unufual* contrivance, kept out of the reach and obfervation even of the executioners.

* *Villaret Hiftoire de France*, tom. xv. p. 72.

† *Pafquier Hiftoire d'Orleans*, liv. vi.

Some time after, when public commiferation had fucceeded to a vindictive bigotry, a woman appeared at Metz ‡, who declared herfelf to be Joan of Arc. She was everywhere welcomed with zeal. At Orleans, efpecially, where Joan was well known, fhe was received with the honours due to the liberatrefs of the town. She was acknowledged by both her brothers, Jean and Pierre d'Arc. On their teftimony fhe was married by a gentleman of the houfe of Amboife in 1436. At their folicitation her fentence was annulled in 1456. The Parifians, indeed, long remained incredulous: they muft elfe have punifhed thofe ecclefiaftics, whofe humanity, perhaps, confpired with the bifhop of Beauvais to withdraw her from real execution down a central chimney of brick and mortar; or, as the executioner called it, a fcaffolding of plafter. The king, for the woman feems to have fhunned no confrontation, is ftated to have received her with thefe words: "*Pucelle, m'amie, foyez la tres bien revenue, au nom de Dieu.*" She is then faid to have communicated to him, kneeling, the artifice practifed. Can this woman be an impoftor? Our author thinks not, and appeals to Voltaire, who, in his profe works, feems willing to allow that fhe was not, as is too commonly imagined, one of thofe half infane enthufiafts, employed as tools to work upon the vulgar; whom the one party endeavoured to cry up as a prophetefs, and the other to cry down as a witch; but that fhe was a real heroine, fuperior to vulgar prejudice, and no lefs remarkable by force of mind than for a courage and ftrength unufual in her fex. This opinion is certainly countenanced by her behaviour in adverfity, and during her trial, which was firm without infolence, and exalted without affectation.

‡ *Hiftoire de la Pucelle par l'Abbé Lenglet.* See alfo *Mélanges Curieux Monftrelet*; and the manufcript authorities cited by the continuator of Velly.

JONES (Sir William), who was ftyled by Johnfon the moft enlightened of men, was the fon of William Jones, Efq. one of the laft of thofe genuine mathematicians, admirers, and contemporaries of Newton, who cultivated and improved the fciences in the prefent century. Our author was born on the 28th of September 1746, and received his education at Harrow fchool, under the care of Dr Robert Sumner, whom he has celebrated in an eulogium which will outlaft brafs or marble. We are told that he was a clafs-fellow with Dr Parr, and at a very early age difplayed talents which gave his tutor the moft promifing expectations, and which have fince been amply juftified. From Harrow he was fent to Univerfity college, Oxford, where the rapidity and elegance of his literary acquifitions excited general admiration; while a temper, ardently generous, and morals perfectly irreproachable, procured him teftimonies of the moft valuable efteem. The grateful affection which he always cherifhed for that venerable feat of learning, did as much honour to his fenfibility, as Oxford herfelf has received by enrolling him among the number of her fons.

In the twenty-third year of his age he travelled through France, and refided fome time at Nice, where he employed himfelf very differently from moft other young men who make what is called the tour of Europe. *Man*, and the influence of various forms of *government*, were the principal objects of his inveftigation; and in applying the refult of his inquiries to the ftate of his own country, he mingled the folicitudes of the Patriot with the honeft partialities of an Englifhman.

Mr Jones's firft literary work was a tranflation into French of a Perfian manufcript, entitled "*Hiftoire de Nadir Shah, connu fous le nom de Thahmas Kuli Khan, Empereur de Perfe*," in two vols 4to; the hiftory of which performance we fhall give in his own words: "A great northern monarch, who vifited this country a few years ago, under the name of the Prince of Travendal, brought with him an eaftern manufcript, containing the life of Nadir Shah, the late fovereign of Perfia, which he was defirous of having tranflated in England. The fecretary of ftate, with whom the Danifh minifter had converfed upon the fubject, fent the volume to me, requefting me to give a literal tranflation of it in the French language; but I wholly declined the tafk, alleging for my excufe the length of the book, the drynefs of the fubject, the difficulty of the ftyle, and chiefly my want both of leifure and ability to enter upon an undertaking fo fruitlefs and fo laborious. I mentioned, however, a gentleman, with whom I had not then the pleafure of being acquainted, but who had diftinguifhed himfelf by a tranflation of a Perfian hiftory, and was far abler than myfelf to fatisfy the king of Denmark's expectations. The learned writer, who had other works upon his hands, excufed himfelf on the account of his many engagements; and the application to me was renewed. It was hinted, that my compliance would be of no fmall advantage to me at my entrance into life; that it would procure me fome mark of diftinction which might be pleafing to me; and, above all, that it would be a reflection upon this country, if the king fhould be obliged to carry the manufcript into France. Incited by thefe motives, and principally by the laft of them, unwilling to be thought churlifh or morofe, and eager for the bubble Reputation, I undertook the work, and fent a fpecimen of it to his Danifh Majefty; who returned his approbation of the ftyle and method, but defired that the whole tranflation might be perfectly literal, and the oriental images accurately preferved. The tafk would have been far eafier to me, had I been directed to finifh it in Latin; for the acquifition of a French ftyle was infinitely more tedious; and it was neceffary to have every chapter corrected by a native of France, before it could be offered to the difcerning eye of the public, fince in every language there are certain peculiarities of idiom, Jones. idiom, and nice ſhades of meaning, which a foreigner can never learn to perfection. But the work, how arduous and unpleaſing ſoever, was completed in a year, not without repeated hints from the ſecretary's office that it was expected with great impatience by the Court of Denmark." The tranſlation of the Hiſtory of Nadir Shah was publiſhed in the ſummer of the year 1770, at the expence of the tranſlator; and forty copies upon large paper were ſent to Copenhagen; one of them bound with uncommon elegance for the king himſelf, and the others as preſents to his courtiers *.

Preface to the Hiſtory of Nadir Shah, 1773.

What marks of diſtinction our author received, or what fruits he reaped for his labour, he has not thought proper to diſcloſe; but if any dependence is to be placed on common fame, the reward beſtowed upon him for this laborious taſk conſiſted only in the thanks of his Daniſh Majeſty, and the honour of being enrolled in the Royal Society of Copenhagen. That diſtinction was indeed accompanied with a letter, recommending the learned tranſlator to the patronage of his own ſovereign; but, in the interim, his friend Lord Dartmouth, who was to have delivered it, had reſigned his office of ſecretary of ſtate, and the letter, we are told, was never preſented.

There is reaſon to think, that this early and ſevere diſappointment made a deep impreſſion on his mind, and induced him to renounce the muſes for a time, and to apply himſelf with aſſiduity to the ſtudy of juriſprudence. This we think apparent, from the ſtyle in which he writes of his return from the continent, and of the death of his beloved preceptor Dr Sumner.

"When I left Nice, (ſays he) where I had reſided near ſeven months, and after traverſing almoſt all France, returned to England, I moſt ardently deſired to paſs ſeveral years more in the ſtudy of polite literature; as then, I thought, I might enter into public life, to which my ambition had always prompted me, more mature and prepared: but with this fruit of my leiſure, either fortune, or rather Providence, the diſpoſer of all human events, would not indulge my ſloth; for on a ſudden, I was obliged to quit that very literature to which, from my childhood, I had applied myſelf; and he who had been the encourager and aſſiſtant of my ſtudies, who had inſtructed, taught, formed me ſuch as I was, or if I am any thing at all, Robert Sumner, within a year after my return, was ſnatched away by an untimely death."

In 1771 Mr Jones publiſhed *Diſſertation ſur la Literature Orientale*, 8vo, and this was followed by *Lettre à Monſieur A** Du P***, dans laquelle eſt compris l'Examen de ſa Traduction des Livres attribues à Zoroaſtre*, 8vo. The diſſertation offered a favourable ſpecimen of the author's abilities as a linguiſt and as a critic; and the letter contained a ſpirited vindication of the univerſity of Oxford, from the very ſcurrilous reproaches, in which its incompetency in Oriental literature was aſſerted by the illiberal tranſlator of the ſuppoſed works of the Perſian philoſopher.

In the ſame year he gave to the public, "A Grammar of the Perſian language," 4to, and at the ſame time propoſed to republiſh Meninſki's Dictionary, with improvements from *De Labroſſee's Gazophylacium Linguæ Perſarum*, and to add in their proper place an Appendix ſubjoined to Gehanaguire's Perſic Dictionary. The Grammar has been found extremely uſeful, and has been reprinted ſeveral times; but the deſign of the Dictionary, though an object of even national importance, for want of due encouragement was obliged to be laid aſide.

In 1772 he publiſhed "Poems; conſiſting chiefly of Tranſlations from the Aſiatic Languages. To which are added two Eſſays; 1. On the Poetry of the Eaſtern Nations. 2. On the Arts commonly called Imitative," 8vo, which in 1777 he republiſhed with the addition of ſome Latin Poems, every way worthy of their author. On the 18th June 1773, he took the degree of Maſter of Arts, and the ſame year publiſhed "The Hiſtory of the Life of Nadir Shah, King of Perſia. Extracted from an Eaſtern Manuſcript, which was tranſlated into French by order of his Majeſty the King of Denmark. With an Introduction, containing, 1. A Deſcription of Aſia according to the Oriental Geographers. 2. A ſhort Hiſtory of Perſia from the earlieſt Times to the preſent Century: And an Appendix, conſiſting of an Eſſay on Aſiatic Poetry, and the Hiſtory of the Perſian Language. To which are added Pieces relative to the French Tranſlation," 8vo. Our author having at this period determined to ſtudy the law as a profeſſion, and to relinquiſh every other purſuit, our readers will not be diſpleaſed with the following extract, relating to this reſolution, which concludes the preface to the hiſtory now under conſideration:

"To conclude; if any eſſential miſtakes be detected in this whole performance, the reader will excuſe them, when he reflects upon the great variety of dark and intricate points which are diſcuſſed in it; and if the obſcurity of the ſubject be not a ſufficient plea for the errors which may be diſcovered in the work, let it be conſidered, to uſe the words of Pope in the preface to his juvenile poems, that there are very few things in this collection which were not written under the age of five-and-twenty: moſt of them indeed were compoſed in the intervals of my leiſure in the South of France, before I had applied myſelf to a ſtudy of a very different nature, which it is now my reſolution to make the ſole object of my life. Whatever then be the fate of this production, I ſhall never be tempted to vindicate any part of it which may be thought exceptionable; but ſhall gladly reſign my own opinions, for the ſake of embracing others, which may ſeem more probable; being perſuaded, that nothing is more laudable than the love of truth, nothing more odious than the obſtinacy of perſiſting in error. Nor ſhall I eaſily be induced, when I have diſburdened myſelf of two other pieces which are now in the preſs, to begin any other work of the literary kind; but ſhall confine myſelf wholly to that branch of knowledge in which it is my chief ambition to excel. It is a painful conſideration, that the profeſſion of literature, by far the moſt laborious of any, leads to no real benefit or true glory whatſoever. Poetry, ſcience, letters, when they are not made the ſole buſineſs of life, may become its ornaments in proſperity, and its moſt pleaſing conſolation in a change of fortune; but if a man addicts himſelf entirely to learning, and hopes by that, either to raiſe a family, or to acquire, what ſo many wiſh for, and ſo few ever attain, an honourable retirement in his declining age, he will find, when it is too late, that he has miſtaken his path; that other labours, other ſtudies, are neceſſary; and that unleſs he can aſſert his own independence

 pendence in active life, it will avail him little to be favoured by the learned, esteemed by the eminent, or recommended even by kings. It is true, on the other hand, that no external advantages can make amends for the loss of virtue and integrity, which alone give a perfect comfort to him who possesses them. Let a man, therefore, who wishes to enjoy, what no fortune or honour can bestow, the blessing of self-approbation, aspire to the glory given to Pericles by a celebrated historian, of being acquainted with all useful knowledge, of expressing what he knows with copiousness and freedom, of loving his friends and country, and of disdaining the mean pursuits of lucre and interest: this is the only career on which an honest man ought to enter, or from which he can hope to gain any solid happiness."

The next year he published *Poeseos Asiaticæ Commentariorum Libri Sex, cum Appendice; subjicitur Limon, seu Miscellaneorum Liber*, 8vo; and pursuing his purpose of applying to the study of the law, we hear no more of him from the press (except the new edition of his Poems), until the year 1779. In this interval he was called to the bar, and attended Westminster-hall and the Oxford circuit, where he obtained but little business. He was however appointed a commissioner of bankrupts by Lord Bathurst, who is supposed to have intended to exert his interest to procure his nomination to the bench in the East Indies.

He published in this year, "The speeches of Iseus, in causes concerning the law of succession to property at Athens; with a preparatory discourse, notes critical and historical, and a Commentary, 4to." In this valuable work, the talents of the scholar, the critic, and the lawyer, combine to elucidate a very important part of jurisprudence; for, "though deep researches into the legal antiquities of *Greece* and *Rome* (as he observes in his Commentary) are of greater use to scholars and contemplative persons, than to lawyers and men of business; though Bracton and Lyttleton, Coke and Rolle, are the proper objects of our study; yet the ablest advocates, and wisest judges, have frequently embellished their arguments with learned allusions to antient cases; and such allusions, it must be allowed, are often useful, always ornamental; and, when they are introduced without pedantry, never fail to please." The work was dedicated in a style of respectful gratitude to his patron Lord Bathurst.

In the year 1780, we find our author a candidate to represent in parliament the university of Oxford. He had for some time resided but little in the university, and therefore laboured under some disadvantages; but he did not meanly court the support of any man. In a paper, which was circulated on that occasion, his friends, who were numerous, declare, that they have "neither openly solicited, nor intend openly to solicit, votes for Mr Jones within the University itself, because he will never become the instrument of disturbing the calm seat of the Muses, by consenting to any such solicitation for himself or for any man whatever. His own applications have been, are, and will be, confined to those only who have professed a regard for him, *and who have no votes themselves*: the Masters of Arts in a great university, whose prerogative is cool reason and impartial judgment, must never be placed on a level with the voters of a borough, or the freeholders of a county. Even in proceeding thus far, he does not set the example, but follows it; and his friends would never have printed any paper, if they had not thought themselves justified by the conduct of others.

"For the first and the last time, they beg leave to suggest, that no exertions must be spared by those who either personally or by reputation, approve the character of Mr Jones; into which, both literary and political, as well as moral, his friends desire and demand the strictest scrutiny. For his university he began early to provoke, and possibly to incur, the displeasure of great and powerful men: For his university he entered the lists with a foul-mouthed and arrogant Frenchman, who had attacked Oxford in three large volumes of misrepresentation and scurrility: For his university he resigned, for a whole year, his favourite studies and pursuits, to save Oxford the discredit of not having one of her sons ready to translate a tedious Persian manuscript. To Oxford, in short, he is known to be attached by the strongest possible ties; and only regrets the necessity of absenting himself from the place in which of all others he most delights, until the event of the present competition shall either convince him that he has toiled in vain as a man of letters, or shall confer on him the greatest reward to which he can aspire. The unavoidable disadvantage of being so late proposed, and the respectable support with which he is now honoured, will secure him in all events from the least disgrace." The application was unsuccessful, chiefly because his own college had fixed upon another candidate, from a persuasion that the immediate appointment of Mr Jones to a seat, then vacant on the bench of judges in India, was morally certain.

The riots of that year gave occasion to another publication of our author, entitled, "An Inquiry into the legal Mode of suppressing Riots; with a constitutional Plan of future Defence," 8vo; and in 1781 he published "An Essay on the Law of Bailments," 8vo, a very masterly treatise, which did great honour to his legal abilities. In this last work he inculcates the necessity of deeply exploring the grounds of the common law; and speaking of Blackstone, (he says) "his commentaries are the most correct and beautiful outline that ever was exhibited of any human science; but they alone will no more form a lawyer, than a general map of the world, how accurately and elegantly soever it may be delineated, will make a geographer."

In this year he likewise recalled his muse in an Ode on the nuptials of Lord Viscount Althorpe, who had been his pupil, to Miss Lavinia Bingham. This beautiful little poem is preserved in the European Magazine for January 1785, and we think in other periodical publications.

From many circumstances which might be collected together, it would appear that our author at this juncture did not coincide in opinion with those who had the direction of government, nor did he approve the measures at that period adopted.—With these sentiments he seems to have been selected as a proper person to be introduced as a member of the Constitutional Society. Could he have foreseen the degeneracy of such associations, there is reason to believe that he would have declined what he condescended to accept as an honour; for

Jones. for though an ardent friend to liberty, he was an enemy to theoretical innovation, and declares, in a letter to the fecretary, that by the term conftitution, he underftands, "the great fyftem of public, in contradiction to private and criminal law, which comprifes all thofe articles which Blackftone arranges, in his firft volume, under the rights of perfons, and of which he gives a perfpicuous analyfis. Whatever then relates to the rights of perfons, either abfolute rights, as the enjoyment of liberty, fecurity, and property, or relative, that is, in the public relations of magiftrates and people, makes a part of that majeftic whole, which we properly call the conftitution. This conftitutional or public law is partly unwritten, and grounded upon immemorial ufage, and partly written or enacted by the legiflative power; but the unwritten, or common law, contains the true fpirit of our conftitution: the written has often moft unjuftifiably altered the form of it; the common law is the collected wifdom of many centuries, having been ufed and approved by fucceffive generations; but the ftatutes frequently contain the whims of a few leading men, and fometimes of the mere individuals employed to draw them."

In 1782 he publifhed "The Mahomedan Law of Succeffion to the Property of Inteftates, in Arabic, with a verbal Tranflation and explanatory Notes." 4to.

At length the poft of one of the judges in the Eaft Indies, which had been kept vacant five years, was determined upon being filled up; and our author, on the 4th March 1783, was appointed to that ftation, and on the 20th received the honour of knighthood. On the 8th of April he married Mifs Shipley, eldeft daughter of the Bifhop of St Afaph, and almoft immediately embarked for the Indies. He had previoufly publifhed "The Moallakat; or, Seven Arabian Poems, which were fufpended on the Temple at Mecca, with a tranflation and Arguments," 4to. To this it was intended to add a preliminary difcourfe and notes.—The former to comprife obfervations on the antiquity of the Arabian language and letters; on the dialects and characters of Himyar and Koraifh, with accounts of fome Himyarick poets; on the manners of the Arabs in the age immediately preceding that of Mahomed; on the temple at Mecca, and the Moallakat, or pieces of poetry fufpended on its walls or gate; laftly, on the lives of the Seven Poets, with a critical hiftory of their works, and the various copies or editions of them preferved in Europe, Afia, and Africa. The latter to contain authorities and reafons for the tranflation of controverted paffages; to elucidate all the obfcure couplets, and exhibit or propofe amendments of the text; to direct the reader's attention to particular beauties, or point out remarkable defects; and to throw light on the images, figures, and allufions of the Arabian poets, by citations either from writers of their own country, or from fuch of our European travellers as beft illuftrate the ideas and cuftoms of Eaftern nations. This difcourfe and the notes have not yet appeared. At his departure for the eaftern world, he left, in manufcript, with his brother-in-law the Dean of St Afaph, a little tract, entitled "The Principles of Government, in a Dialogue between a Scholar and a Peafant." This celebrated dialogue being afterwards publifhed by the Dean; and widely circulated by the fociety for conftitutional information, the Dean was profecuted for publifhing a libel, and, if our memory deceives us not, was found guilty. Jones.

Sir William Jones now dropt for ever all concern in party politics, and applied himfelf to purfuits more worthy of his talents. During his voyage to India, he conceived the idea of the Afiatic Society, of which an account has been given under the title SOCIETIES (*Encycl.*), and of whofe refearches five volumes, replete with much curious information, are now before the public. But ardently as his mind was attached to general literature and fcience, he was by no means inattentive to the profeffional duties of his high ftation. He had indeed, to ufe his own expreffion, an "undiffembled fondnefs for the ftudy of jurifprudence *;" and in the character of a judge, difplayed the profound knowledge and irreproachable integrity, which, before his promotion, pervaded his reafonings as a lawyer, and governed his conduct as a man. Unfortunately the intenfe ardour of application, which produced his frequent contributions to the ftock of human knowledge, added to the unfavourable influence of the climate, greatly impaired his health. On this account, after a refidence of about fifteen years in India, he made preparations for returning to England; but death interpofed; and this illuftrious ornament of fcience and virtue was taken from the world on the 27th of April 1794, in the 48th year of his age. "It is to the fhame of fcepticifm (as one of his biographers well obferves), to the encouragement of hope, and to the honour of genius, that this great man was a fincere believer in the doctrines of Chriftianity, and that he was found in his clofet in the attitude of addreffing his prayer to God." We fhall give his character as it was drawn by Sir John Shore, Baronet, (now Lord Teignmouth) in a difcourfe delivered at a meeting of the Afiatic Society, held on the 22d of May 1794.

* *Law of Bailments.*

"His capacity for the acquifition of languages has never been excelled. In Greek and Roman literature, his early proficiency was the fubject of admiration and applaufe; and knowledge of whatever nature, once obtained by him, was ever afterwards progreffive. The more elegant dialects of modern Europe, the French, the Spanifh, and Italian, he fpoke and wrote with the greateft fluency and precifion; and the German and Portuguefe were familiar to him. At an early period of life his application to Oriental literature commenced; he ftudied the Hebrew with eafe and fuccefs; and many of the moft learned Afiatics have the candour to avow, that his knowledge of Arabic and Perfian was as accurate and extenfive as their own; he was alfo converfant in the Turkifh idiom, and the Chinefe had even attracted his notice fo far as to induce him to learn the radical characters of that language, with a view perhaps to farther improvements. It was to be expected, after his arrival in India, that he would eagerly embrace the opportunity of making himfelf mafter of the Sanfcrit; and the moft enlightened profeffors of the doctrines of Brahma confefs with pride, delight, and furprife, that his knowledge of their facred dialect was moft critically correct and profound. The Pandits, who were in the habit of attending him, could not, after his death, fupprefs their tears for his lofs, nor find terms to exprefs their admiration at the wonderful progrefs he had made in their fciences.

"Before the expiration of his twenty-fecond year, he had completed his Commentaries on the Poetry of

 the

the Afiatics, although a confiderable time afterwards elapfed before their publication; and this work, if no other monument of his labours exifted, would at once furnifh proofs of his confummate fkill in the Oriental dialects, of his proficiency in thofe of Rome and Greece, of tafte and erudition far beyond his years, and of talents and application without example.

" But the judgment of Sir William Jones was too difcerning to confider language in any other light than as the key of fcience, and he would have defpifed the reputation of a mere linguift. Knowledge and truth were the objects of all his ftudies, and his ambition was to be ufeful to mankind; with thefe views he extended his refearches to all languages, nations, and times.

" Such were the motives that induced him to propofe to the government of India, what he juftly denominated a work of national utility and importance, the compilation of a copious Digeft of Hindu and Mahomedan Law, from Sanfcrit and Arabic Originals, with an offer of his fervices to fuperintend the compilation, and with a promife to tranflate it. He had forefeen, previous to his departure from Europe, that without the aid of fuch a work, the wife and benevolent intentions of the legiflature of Great Britain, in leaving to a certain extent the natives of thefe provinces in poffeffion of their own laws, could not be completely fulfilled; and his experience, after a fhort refidence in India, confirmed what his fagacity had anticipated, that without principles to refer to, in a language familiar to the judges of the courts, adjudications amongft the natives muft too often be fubject to an uncertain and erroneous expofition, or wilful mifinterpretation of their laws.

" To the fuperintendance of this work, which was immediately undertaken at his fuggeftion, he affiduoufly devoted thofe hours which he could fpare from his profeffional duties. After tracing the plan of the Digeft, he prefcribed its arrangement and mode of execution, and felected from the moft learned Hindus and Mahomedans fit perfons for the tafk of compiling it: flattered by his attention, and encouraged by his applaufe, the Pandits profecuted their labours with chearful zeal to a fatisfactory conclufion. The Molavees have alfo nearly finifhed their portion of the work; but we muft ever regret, that the promifed tranflation, as well as the meditated preliminary differtation, have been fruftrated by that decree, which fo often intercepts the performance of human purpofes.

" During the courfe of this compilation, and as auxiliary to it, he was led to ftudy the works of Menu, reputed by the Hindus to be the oldeft and holieft of legiflators; and finding them to comprife a fyftem of religious and civil duties, and of law in all its branches, fo comprehenfive and minutely exact, that it might be confidered as the Inftitutes of Hindu Law, he prefented a tranflation of them to the government of Bengal. During the fame period, deeming no labour exceffive or fuperfluous that tended in any refpect to promote the welfare or happinefs of mankind, he gave the public an Englifh verfion of the Arabic Text of the Sirajiyah or Mahomedan Law of Inheritance, with a Commentary. He had already (as has been obferved) publifhed in England a tranflation of a tract on the fame fubject by another Mahomedan lawyer, containing, as his own words exprefs, ' a lively and elegant Epitome of the Law of Inheritance of Zaid.'

" To thefe learned and important works, fo far out of the road of amufement, nothing could have engaged his application but that defire which he ever profeffed, of rendering his knowledge ufeful to his nation, and beneficial to the inhabitants of thefe provinces.

" I fhould fcarcely (continues Lord Teignmouth) think it of importance to mention, that he did not difdain the office of editor of a Sanfcrit and Perfian work, if it did not afford me an opportunity of adding, that the latter was publifhed at his own expence, and was fold for the benefit of infolvent debtors. A fimilar application was made of the produce of Sirajiyah."

But nothing exhibits the large grafp of Sir William Jones's mind in fo ftriking a point of view as a paper in his own hand writing, which came into Lord Teignmouth's poffeffion after his death. It was intitled DESIDERATA, and propofed for inveftigation the following fubjects relating to the eaftern world.

India.—1. The antient geography of India, &c. from the Puranas. 2. A botanical defcription of Indian plants, from the Cofhas, &c. 3. A grammar of the Sanfcrit language, from Panini, &c. 4. A dictionary of the Sanfcrit language, from the 32 original vocabularies and Niructi. 5. On the ancient mufic of the Indians. 6. On the medical fubftances of India, and the Indian art of medicine. 7. On the philofophy of the ancient Indians. 8. A tranflation of the Veda. 9. On ancient Indian geometry, aftronomy, and algebra. 10. A tranflation of the Puranas. 11. A tranflation of the Mahabbara and Ramayan. 12. On the Indian theatre, &c. &c. 13. On the Indian conftellations, with their mythology, from the Puranas. 14. The hiftory of India before the Mahomedan conqueft, from the Sanfcrit Cafhmir Hiftories.

Arabia.—15. The hiftory of Arabia before Mahomed. 16. A tranflation of the Hamafa. 17. A tranflation of Hariri. 18. A tranflation of the Facahatul Khulafa. Of the Cafiah.

Perfia.—19. The hiftory of Perfia, from authorities in Sanfcrit, Arabic, Greek, Turkifh, Perfian ancient and modern, Firdaufi's Khrofrau nama. 20. The five poems of Nizami, tranflated in profe. 21. A dictionary of pure Perfian Je changire.

China.—22. A tranflation of Schi-cing. 23. The text of Can-fu-tfu, verbally tranflated.

Tartary.—24. A hiftory of the Tartar nations, chiefly of the Moguls and Othmans, from the Turkifh and Perfian.

" We are not authorifed (fays his Lordfhip) to conclude, that he had himfelf formed a determination to complete the works which his genius and knowledge had thus fketched; the tafk feems to require a period beyond the probable duration of any human life; but we, who had the happinefs to know Sir William Jones; who were witneffes of his indefatigable perfeverance in the purfuit of knowledge, and of his ardour to accomplifh whatever he deemed important; who faw the extent of his intellectual powers, his wonderful attainments in literature and fcience, and the facility with which all his compofitions were made—cannot doubt, if it had pleafed Providence to protract the date of his exiftence, that he would have ably executed much of what he had fo extenfively planned."

We have already enumerated attainments and works which, from their diverfity and extent, feem far beyond the

Jones. the capacity of the moſt enlarged minds; but the catalogue may yet be augmented. To a proficiency in the languages of Greece, Rome, and Aſia, he added the knowledge of the philoſophy of thoſe countries, and of every thing curious and valuable that had been taught in them. The doctrines of the Academy, the Lyceum, or the portico, were not more familiar to him than the tenets of the Vedas, the myſticiſm of the Sufis, or the religion of the ancient Perſians; and whilſt, with a kindred genius, he peruſed with rapture the heroic, lyric, or moral compoſitions of the moſt renowned poets of Greece, Rome, and Aſia, he could turn with equal delight and knowledge to the ſublime ſpeculations or mathematical calculations of Barrow and Newton. With them alſo he profeſſed his conviction of the truth of the Chriſtian religion; and he juſtly deemed it no inconſiderable advantage, that his reſearches had corroborated the multiplied evidence of Revelation, by confirming the Moſaic account of the primitive world.

In his eighth anniverſary diſcourſe to the Aſiatic Society, he thus expreſſes himſelf: "Theological inquiries are no part of my preſent ſubject; but I cannot refrain from adding, that the collection of tracts which we call, from their excellence, the Scriptures, contain, independently of a divine origin, more true ſublimity, more exquiſite beauty, purer morality, more important hiſtory, and finer ſtrains both of poetry and eloquence, than could be collected within the ſame compaſs from all other books that were ever compoſed in any age, or any idiom. The two parts, of which the Scriptures conſiſt, are connected by a chain of compoſitions, which bear no reſemblance in form or ſtyle to any that can be produced from the ſtores of Grecian, Indian, Perſian, or even Arabian learning; the antiquity of theſe compoſitions no man doubts, and the unſtrained application of them to events long ſubſequent to their publication, is a ſolid ground of belief that they were genuine predictions; and conſequently inſpired.

There were, in truth, few ſciences in which he had not acquired conſiderable proficiency; in moſt, his knowledge was profound. The theory of muſic was familiar to him; nor had he neglected to make himſelf acquainted with the intereſting diſcoveries lately made in chemiſtry; "and I have heard him (ſays Lord Teignmouth) aſſert, that his admiration of the ſtructure of the human frame had induced him to attend for a ſeaſon to a courſe of anatomical lectures, delivered by his friend the celebrated Hunter."

His laſt and favourite purſuit was the ſtudy of botany, which he originally began under the confinement of a ſevere and lingering diſorder, which with moſt minds would have proved a diſqualification from any application. It conſtituted the principal amuſement of his leiſure hours. In the arrangements of Linnæus, he diſcovered ſyſtem, truth, and ſcience, which never failed to captivate and engage his attention; and from the proofs which he has exhibited of his progreſs in botany, we may conclude that he would have extended the diſcoveries in that ſcience.

It cannot be deemed uſeleſs or ſuperfluous to inquire by what arts or method he was enabled to attain to a degree of knowledge almoſt univerſal, and apparently beyond the powers of man, during a life little exceeding 47 years.

The faculties of his mind, by nature vigorous, were improved by conſtant exerciſe; and his memory, by habitual practice, had acquired a capacity of retaining whatever had once been impreſſed upon it. To an unextinguiſhed ardour for univerſal knowledge, he joined a perſeverance in the purſuit of it which ſubdued all obſtacles; his ſtudies began with the dawn, and, during the intermiſſions of profeſſional duties, were continued throughout the day; reflection and meditation ſtrengthened and confirmed what induſtry and inveſtigation had accumulated. It was a fixed principle with him, from which he never voluntarily deviated, not to be deterred by any difficulties that were ſurmountable from proſecuting to a ſucceſsful termination what he had once deliberately undertaken.

But what appeared more particularly to have enabled him to employ his talents ſo much to his own and the public advantage, was the regular allotment of his time, and a ſcrupulous adherence to the diſtribution which he had fixed; hence all his ſtudies were purſued without interruption or confuſion. He collected information, too, from every quarter; juſtly concluding, that ſomething might be learned from the illiterate, to whom he liſtened with the utmoſt candour and complacency.

Lord Teignmouth, addreſſing himſelf to the Aſiatic Society, ſays, "Of the private and ſocial virtues of our lamented Preſident, our hearts are the beſt records. To you who knew him, it cannot be neceſſary for me to expatiate on the independence of his integrity, his humanity, probity, or benevolence, which every living creature participated; on the affability of his converſation and manners, or his modeſt, unaſſuming deportment: nor need I remark, that he was totally free from pedantry, as well as from arrogance and ſelf-ſufficiency, which ſometimes accompany and diſgrace the greateſt abilities. His preſence was the delight of every ſociety, which his converſation exhilarated and improved; and the public have not only to lament the loſs of his talents and abilities, but that of his example.

"To him, as the founder of our inſtitution, and whilſt he lived its firmeſt ſupport, our reverence is more particularly due. Inſtructed, animated, and encouraged by him, genius was called forth into exertion, and modeſt merit was excited to diſtinguiſh itſelf. Anxious for the reputation of the ſociety, he was indefatigable in his own endeavours to promote it, whilſt he cheerfully aſſiſted thoſe of others. In loſing him, we have not only been deprived of our brighteſt ornament, but of the guide and patron, on whoſe inſtructions, judgement, and candour, we could implicitly rely." Though theſe are the ſentiments, not only of Lord Teignmouth, but, we believe, of every man of letters, we truſt there is ſtill left in Bengal a ſufficient love of letters and of ſcience to carry on the plan which was formed by the genius of Sir William Jones.

JONESIA, is a very handſome middling-ſized ramous tree, found in gardens about Calcutta. In the Sanſcrit it is called *As'óca*, and in the Bengaleſe *Ruſſuck*; but the name Joneſia was given to it by the Aſiatic Society, who conſecrated it to the memory of their firſt preſident Sir Willam Jones. It is thus deſcribed by Dr Roxburgh, a member of that ſociety:

"*Calyx*, two-leaved, corol, one-petalled, piſtil-bearing, baſe of the tube impervious; ſtamens long, aſcending, inſerted into the margin of a glandulous nectaral ring, which crowns the mouth of the tube, the uppermoſt two-

two of which more distant; style declining. *Legume* turgid. *Trunk* erect, though not very straight. *Bark* dark brown, pretty smooth. *Branches* numerous, spreading in every direction, so as to form a most elegant shady head. *Leaves* alternate, abruptly feathered, sessile, generally more than a foot long; when young, pendulous and coloured. *Leaflets* opposite, from four to six pair, the lowermost broad lanced, the upper lanced; smooth, shining, firm, a little waved, from four to eight inches long. *Petiole* common, round, and smooth. *Stipule* axillary, solitary; in fact a process from the base of the common petiole, as in many of the grasses and monandrists, &c. *Umbels* terminal and axillary; between the stipule and branchlet, globular, crowded, subsessile, erect. *Bracts*, a small hearted one under each division of the umbel. *Peduncle* and pedicles smooth, coloured. *Flowers* very numerous, pretty large; when they first expand they are of a beautiful orange colour, gradually changing to red, forming a variety of lovely shades; fragrant during the night. *Calyx* perianth, below two-leaved, leaflets small, nearly opposite, coloured, hearted, bracte-like, marking the termination of the pedicle, or beginning of the tube of the corol. *Corol* one-petalled, funnel-form; tube slightly incurved, firm, and fleshy, tapering towards the base (club funnel-shaped) and there impervious; border four parted; division spreading, suborbicular; margins most slightly woolly: one third the length of the tube. *Nectary*, a stimeniferous and pistiliferous ring crowns the mouth of the tube. *Stamens*, filaments generally seven; and seven must, I think, be the natural number; viz. three on each side, and one below, above a vacancy, as if the place of an eighth filament, and is occupied on its inside by the pistil; they are equal, distinct, ascending from three to four times longer than the border of the corol. *Anthers* uniform, small, incumbent. *Pistil*, germ oblong, pediceled; pedicle inserted into the inside of the nectary, immediately below the vacant space already mentioned; style nearly as long as the stamens, declining; stigma simple. *Pericarp*, legume scimeter-formed, turgid, outside reticulated, otherwise pretty smooth; from six to ten inches long, and about two broad. *Seeds* generally from four to eight, smooth; grey, size of a large chesnut."

The Jonesia flowers at the beginning of the hot season, and its seeds ripen during the rains. The plants and seeds were originally brought to Calcutta from the interior parts of the country, where it is indigenous. *N. B.* Many of the flowers have only the rudiment of a pistil. In Plate XXX. A is a branchlet of the natural size. B, A single flower a little magnified; *a a* the calyx. C, A section of the same, exhibiting four of the stamens, 1 1 1 1 the pistil 2, and how far the tube is perforated. D, A similar section of one of the abortive flowers; 3 is the abortive fistil. E, The ripe legume opening near the base, natural size. *Note*, The space between the *b* and *c* marks the original tube of the coral. F, One of the seeds, natural size. G, The base of the common petiole, with its stipule; *aa*, the petioles of the lower pair of leaflets.

JOURNALS, the title of periodical publications. See *Encyclopædia*. The principal British Journals are: *The History of the Works of the Learned*, begun at London in 1699. *Censura Temporum*, in 1708. About the same time there appeared two new ones; the one under the title of *Memoirs of Literature*, containing little more than an English translation of some articles in the foreign Journals, by M. de la Roche; the other, a collection of loose tracts, entitled, *Bibliotheca Curiosa*, or a Miscellany. These, however, with some others, are now no more, but are succeeded by the *Annual Register*, which began in 1758; the *New Annual Register*, begun in 1780; the *Monthly Review*, which began in the year 1749, and gives a character of all English literary publications, with the most considerable of the foreign ones: the *Critical Review*, which began in 1756, and is nearly on the same plan: as also the *London Review*, by Dr Kenrick, from 1775 to 1780; *Maty's Review*, from Feb. 1782 to Aug. 1786; the *English Review*, begun in Jan. 1783; and the *Analytical Review*, begun in May 1788, dropt in 1798, and revived in 1799, under the title of the *New Analytical Review*; but again dropt after two or three months trial: the *British Critic*, begun in 1792, and still carried on with much spirit and ability: the *Anti-Jacobin Review and Magazine*, commenced in 1798, for the meritorious purpose of counteracting the pernicious tendency of French principles in politics and religion: the *New London Review*, January 1799: *A Journal of Natural Philosophy, Chemistry, and the Arts*, which was begun in 1797 by Mr Nicholson, and has been conducted in such a manner, that it is one of the most valuable works of the kind to be found in any language: the *Philosophical Magazine*, begun in 1798 by Mr Tilloch, and carried on upon much the same plan, and with much the same spirit, as Nicholson's Journal.

Besides these, we have several monthly pamphlets, called *Magazines*, which, together with a chronological series of occurrences, contain letters from correspondents, communicating extraordinary discoveries in nature and art, with controversial pieces on all subjects. Of these, the principal are those called the *Gentleman's Magazine*, which began with the year 1731; the *London Magazine*, which began a few months after, and has lately been discontinued; the *Universal Magazine*, which is nearly of as old a date; the *Scotch Magazine*, which began in 1739, and is still continued; the *European Magazine*; and the *Monthly Magazine*, a miscellany of much information, but not of good principles.

JOYST or JEYST, the second month of the Bengal year.

IRELAND has been so fully described, and its history so amply detailed, in the Encyclopædia, that it is introduced here only to notice its legislative union with Great Britain. Such a measure had been often wished for by the more intelligent Irish, who could not but hope, from a union, advantages to their country similar to those which Scotland had reaped from her union with England; but it was at all times dreaded by the city of Dublin, and by those individuals who preferred the empty and unmeaning sound of national independence to future prosperity. The rebellion, however, which raged in Ireland during the year 1798, and the danger which was then apprehended of its final separation from Britain, and union with France, made the wiser statesmen in both islands think seriously of a legislative union. The measure, after much opposition from the pretended patriots of both countries, who made it a rule to oppose whatever originated with administration, was finally accomplished, and the royal assent given

ven to the act of union on the 2d of July 1800. By that act, the Irish are admitted to a share of all the trade of Great Britain, except such as is confined to chartered companies, and is of course not free to the inhabitants of Britain at large. The Irish commons are represented by a hundred members in the house of commons at Westminster; the Irish peerage, spiritual and temporal, by four bishops and twenty-eight lay-lords, chosen by the bishops and peers of Ireland, to hold their seats for life: and the sovereign is now styled King of the United Kingdom of Great Britain and Ireland; having, with proper dignity, dropt the empty title of King of France. Ireland still retains her own laws and courts of justice, not excepting even the court of chancery; and his majesty is represented in Dublin by a lord lieutenant, as when the two islands were two kingdoms. Ireland is likewise exempted from all concern with the debt of Great Britain contracted before the union; in which respect the terms granted to her are preferable to those which had been granted by England to Scotland; and her contribution to the imperial expences is as 1 to $7\frac{1}{2}$. This article, however, from the probable increase of her trade, might in time prove extravagantly favourable; it is therefore subject to revisal by the imperial parliament in the course of twenty years. There is one singular clause in this act of union, of which the propriety has been questioned by men of the first-rate abilities who were friendly to the measure: Such Irish peers as are not elected into the house of lords may be chosen as representatives of British towns and counties in the house of commons, provided that, while they are members of that house, they relinquish all the privileges of the peerage.

IRON is by much the most useful of all the metals, as has been sufficiently proved under the article IRON, *Encycl.* and under CHEMISTRY in this *Supplement*. The word is again introduced here, because it affords us an opportunity of laying before our readers some valuable observations by Chaptal on the use of the *oxides* of iron in dyeing cotton.

" The oxide of iron has such an affinity for cotton thread, that if the latter be plunged in a saturated solution of iron in any acid whatever, it immediately assumes a chamoy yellow colour, more or less dark, according to the strength of the liquors. It is both a curious and easy experiment, that when cotton is made to pass through a solution of the sulphat of iron, rendered turbid by the oxide which remains suspended in the liquor, it will be sufficient to dip the cotton in the bath to catch the last particle of the oxide, and to restore to the liquor the transparency it has lost. The solution then, which before had a yellowish appearance, becomes more or less green, according as it is more or less charged.

" The colour given to cotton by the oxide of iron becomes darker merely by exposure to the air; and this colour, soft and agreeable when taken from the bath, becomes harsh and ochry by the progressive oxidation of the metal. The colour of the oxide of iron is very fast: it resists not only the air and water, but also alkaline leys, and soap gives it splendour without sensibly diminishing its intensity. It is on account of these properties that the oxide of iron has been introduced into the art of dyeing, and been made a colouring principle of the utmost value.

" In order that the oxide of iron may be conveniently applied to the cotton thread, it is necessary to begin by effecting its solution; and, in this case, acids are employed as the most useful solvents. Dyers almost everywhere make a mystery of the acid which they employ; but it is always the acetous, the sulphuric, the nitric, or the muriatic. Some of them ascribe great differences to the solution of iron by the one or the other acid; but, in general, they give the preference to the acetous. This predilection appears to be founded much less on the difference of the colours that may be communicated by the one or the other salt, than on the different degrees of corrosive power which each exercises on the stuff. That of the sulphat and muriat is so great, that if the stuff be not washed when it comes from the bath, it will certainly be burnt; whereas solutions by the acetous, or any other vegetable acid, are not attended with the like inconvenience.

" Iron appears to be at the same degree of oxydation in the different acids, since it produces the same shade of colour when precipitated; and any acid solvent may be employed indiscriminately, provided the nature of the salt, and the degree of the saturation of the acid, be sufficiently known; for the subsequent operations may be then directed according to this knowledge, and the inconveniences which attend the use of some of these salts may be prevented. This, without doubt, is a great advantage which the man of science enjoys over the mere workman, who is incapable of varying his process according to the nature and state of the salts which he employs.

" 1. If the sulphat of iron, or any other martial salt, be dissolved in water, and cotton be dipped in the liquid, the cotton will assume a chamoy colour, more or less dark according as the solution is more or less charged. The affinity of the cotton to the iron is so great, that it attracts the metal, and takes it in a great measure from the acid by which it was dissoved.

" 2. If the iron of a pretty strong solution be precipitated by an alkaline liquor that shews five or six degrees (by the areometer of Baumé), the result will be a greenish blue magma. The cotton macerated in this precipitate assumes at first an unequal tint of dirty green; but mere exposure to the air makes it in a little time turn yellow, and the shade is very dark.

" It is by such, or almost similar processes, that dyers communicate what is called among workmen an *ochre* or *rust colour*. But these colours are attended with several inconveniences to the artist: 1. Strong shades burn or injure the cloth: 2. This colour is harsh, disagreeable to the eye, and cannot be easily united with the mild colours furnished by vegetables."

To avoid these inconveniences, our author made several attempts, which led him to the following practice: He treads the cotton cold in a solution of the sulphat of iron, marking three degrees; he wrings it carefully, and immediately plunges it in a ley of potash at two degrees, upon which he has previously poured to saturation a solution of the sulphat of alumine: the colour is then brightened, and becomes infinitely more delicate, soft, and agreeable. The sulphat no longer attacks the tissue of the stuff; and after the cotton has been left in the bath for four or five hours, it is taken out to be wrung, washen, and dried. In this manner we may obtain every shade that can be wished, by graduating the strength of the solutions. This simple process, cefs, the theory of which prefents itfelf to the mind of every chemift, has the advantage of furnifhing a colour very agreeable, exceedingly fixed, and, above all, extremely economical. He employs it with great advantage in dyeing nankeens, as it has the property of refifting leys. It becomes brown, however, by the action of aftringents.

M. Chaptal made feveral attempts to combine this yellow with the blue of indigo, in order to obtain a durable green; but as they were all unfuccefsful, he infers that there is not a fufficient affinity between the blue of indigo and the oxides of iron. He found that thefe oxides, on the other hand, combine very eafily with the red of madder, and produce a bright violet or plum colour, the ufe of which is as extenfive as beneficial in the cotton manufactory. But if we fhould confine ourfelves to apply thefe two colours to cotton, without having employed a mordant capable of fixing the latter, the colour would not only remain dull and difagreeable by the impoffibility of brightening it, but it would ftill be attended with the great inconvenience of not refifting leys. We muft begin, then, by preparing the cotton as if to difpofe it for receiving the Adrianople red; and when it has been brought to the operation of galling, it is to be paffed through a folution of iron, more or lefs charged, according to the nature of the violet required: it is then to be carefully wafhed, twice maddered, and brightened in a bath of foap.

When a real velvety rich violet is required, it is not to be paffed through the folution of iron till it has been previoufly galled; the iron is then precipitated in a bluifh oxide, which, combined with the red of madder, gives a moft brilliant purple, more or lefs dark according to the ftrength of the galling and of the ferruginous folution. It is very difficult to obtain an equal colour by this procefs; and in manufactories, an equal violet is confidered as a mafter-piece of art. It is generally believed, that it is only by well-directed manipulations that it is poffible to refolve this problem, of fo much importance in dyeing. But I am convinced (fays our author), that the great caufe of the inequality in this dye is, that the iron depofited on the cotton receives an oxidation merely by expofure to the air, which varies in different parts of it. The threads which are on the outfide of the hank are ftrongly oxidated, while thofe in the infide, removed from the action of the air, experience no change. It thence follows, that the infide of the hank prefents a weak fhade, while the exterior part exhibits a violet almoft black. The means to remedy this inconvenience is, to wafh the cotton when it is taken from the folution of iron, and to expofe it to the madder moift. The colour will become more equal and velvety. The folvents of iron are almoft the fame for this colour as for the yellow colour already mentioned.

The following obfervation may ferve to guide the artift in brightening the violet on his cotton. The red of madder and the oxide of iron depofited on the ftuff determine the violet colour. This colour becomes red or blue, according as either of the principles predominates. The dyer knows by experience how difficult it is to obtain a combination which produces the tone of colour defired, efpecially when it is required to be very full, lively, and durable. This object, however, may be obtained, not only by varying the proportions of the two colouring principles, but alfo by varying the procefs of brightening. The only point is to be acquainted with the two following facts: that the foda deftroys the iron, while the foap, by ftrong ebullition, feizes in preference the red of the madder. Hence it is, that the colour may be inclined to red or blue, according as you brighten with one or the other of thefe mordants. Thus, cotton taken from the madder dye, when wafhed and boiled in the brightening liquor with $\frac{1}{10}$ths of foap, will give a fuperb violet; whereas you will obtain only a plum colour in treating it with foda.

The oxide of iron precipitated on any ftuff unites alfo very advantageoufly with the fawn colour furnifhed by aftringents; and by varying the ftrength of mordants, an infinity of fhades may be produced. In this cafe, it is lefs a combination or folution of principles than the fimple mixture or juxta-pofition of the colouring bodies on the ftuff. By means of a boiling heat, we may combine, in a more intimate manner, the oxide of iron with the aftringent principle; and then it is brought to the ftate of black oxide, as has been obferved by Berthollet. It is poffible alfo to embrown thefe colours, and to give them a variety of tints, from the bright grey to the deep black, by merely paffing the cottons impregnated with the aftringent principle thro' a folution of iron. The oxide is then precipitated itfelf by the principle which is fixed on the ftuff.

An obfervation, which may become of the utmoft value for the art of dyeing, is, that the moft ufual aftringent vegetables all furnifh a yellow colour, which has not much brilliancy, but which has fufficient fixity to be employed with advantage. This yellow colour is brightened in the feries of vegetables, in proportion as the aftringent principle is diminifhed, and the vivacity of the colour is augmented in the fame proportion. It is difficult, then, to obtain yellow colours which are at the fame time durable and brilliant. Thefe two valuable qualities are to each other in an inverfe ratio; but it is poffible to unite the colouring principles in fuch a manner as to combine fplendour with fixity. Green oak bark unites perfectly with yellow weed, and fumach with green citron. It is by this mixture that we may be able to combine with the oxide of iron vegetable colours, the fplendour of which is equal to their durability.

Our author concludes his obfervations with cautioning the dyer againft fubftituting fumach and the bark of the alder tree or oak for gall when dyeing cotton red. "I can fafely affert (fays he), that it is impoffible to employ thefe as fubftitutes, in whatever dofes they may be ufed. The colour is always much paler, poorer, and lefs fixed. I know that the cafe is not the fame in regard to dyeing wool and filk, in which it may be employed with fuccefs; and in giving an account of this difference, I think the caufe of it may be found in the nature of the gall-nuts. 1. The acid which they exclufively contain, as Berthollet has proved, facilitates the decompofition of the foap with which the cottons have been impregnated, and the oil then remains fixed in their tiffue, and in a greater quantity, as well as in a more intimate combination. 2. The gall-nuts, which owe their development to animal bodies, retain a character of animalifation, which they tranfmit to the vegetable ftuff, and by thefe means augment its affinities with the colouring principle of the madder; for it

is

is well known of what utility animal ſubſtances are to facilitate this combination. This animaliſation becomes uſeleſs in operating upon woollen or ſilk."

IRRATIONAL Numbers or *Quantities*, are the ſame as *ſurds*, for which ſee Algebra, *Encycl.*

IRREDUCIBLE Case, in algebra, is uſed for that caſe of cubic equations where the root, according to Cardan's rule, appears under an impoſſible or imaginary form, and yet is real.

It is remarkable that this caſe always happens, *viz.* one root, by Cardan's rule, in an impoſſible form, whenever the equation has three real roots, and no impoſſible ones, but at no time elſe.

If we were poſſeſſed of a general rule for accurately extracting the cube root of a binomial radical quantity, it is evident we might reſolve the irreducible caſe generally, which conſiſts of two of ſuch cubic binomial roots. But the labours of the algebraiſts, from Cardan down to the preſent time, have not been able to remove this difficulty. Dr Wallis thought that he had diſcovered ſuch a rule; but, like moſt others, it is merely tentative, and can only ſucceed in certain particular circumſtances.

JUAN de Fuca, a celebrated ſtrait on the north-weſt coaſt of America, was ſurveyed by Captain Vancouvre in the Diſcovery ſloop of war, with a view to aſcertain whether it leads to any communication between the North Pacific and the North Atlantic Oceans. As they advanced within the opening of the ſtrait, their progreſs was greatly retarded by the number of inlets into which the entrance branched in every direction; and moſt of theſe were examined by the boats, which were frequently abſent from the ſhips on this ſervice for ſeveral days together. In the midſt of their labours, they were ſurpriſed by the ſight of two Spaniſh veſſels of war, employed, like themſelves, in ſurveying this inlet, the examination of which had been begun by them in the preceding year. Meaſures of mutual aſſiſtance were concerted between the captains of the two nations for the proſecution of the ſurvey, in which each agreed to communicate to the other their diſcoveries. Not one of the many arms of the inlet, nor of the channels which they explored in this broken part of the coaſt, was found to extend more than 100 miles to the eaſtward of the entrance into the ſtrait. After having ſurveyed the ſouthern coaſt, on which ſide a termination was diſcovered to every opening, by following the continued line of the ſhore, they were led to the northward, and afterward towards the north-weſt, till they came into the open ſea through a different channel from the ſtrait of Juan de Fuca, by which they had commenced this inland navigation.

Thus it appeared, that the land forming the north ſide of that ſtrait is part of an iſland, or of an archipelago, extending nearly 100 leagues in length from S. E. to N. W.; and on the ſide of this land moſt diſtant from the continent is ſituated Nootka Sound. The moſt peculiar circumſtance of this navigation is the extreme depth of water, when contraſted with the narrowneſs of the channels. The veſſels were ſometimes drifted about by the currents during the whole of a night, cloſe to the rocks, without knowing how to help themſelves, on account of the darkneſs, and the depth being much too great to afford them anchorage.

In the courſe of this ſurvey, the voyagers had frequent communications with the natives, whom they met ſometimes in canoes and ſometimes at their villages. In their tranſactions with Europeans, they are deſcribed as "well verſed in the principles of trade, which they carried on in a very fair and honourable manner." In other reſpects they were leſs honeſt. At one village 200 ſea otter ſkins were purchaſed of them by the crews of the veſſels in the courſe of a day; and they had many more to ſell in the ſame place, as alſo ſkins of bears, deer, and other animals. One party of Indians whom they met had the ſkin of a young lioneſs; and theſe ſpoke a language different from that uſed in Nootka Sound. Veniſon was ſometimes brought for ſale; and a piece of copper, not more than a foot ſquare, purchaſed one whole deer and part of another. Among other articles of traffic, two children, ſix or ſeven years of age, were offered for ſale. The commodities moſt prized by the natives were fire-arms, copper, and great coats. Beads and trinkets they would only receive as preſents, and not as articles of exchange. Many of them were poſſeſſed of fire arms. In one part it is related, that after a chief had received ſome preſents, "he, with moſt of his companions, returned to the ſhore; and, on landing, fired ſeveral muſkets, to ſhew, in all probability, with what dexterity they could uſe theſe weapons, to which they ſeemed as familiarized as if they had been accuſtomed to fire-arms from their earlieſt infancy."

The dreſſes of theſe people, beſides ſkins, are a kind of woollen garments; the materials compoſing which are explained in the following extract:

"The dogs belonging to this tribe of Indians were numerous, and much reſembled thoſe of Pomerania, though, in general, ſomewhat larger. They were all ſhorn as cloſe to the ſkin as ſheep are in England; and ſo compact were their fleeces, that large portions could be lifted up by a corner without cauſing any ſeparation. They were compoſed of a mixture of a coarſe kind of wool, with very fine long hair, capable of being ſpun into yarn. This gave Captain Vancouver reaſon to believe, that their woollen clothing might in part be compoſed of this material mixed with a finer kind of wool from ſome other animal, as their garments were all too fine to be manufactured from the coarſe coating of the dog alone."

Of other animals alive, deer only were ſeen in any abundance by our people.

The number of inhabitants computed to be in the largeſt of the villages or towns that were diſcovered, did not exceed 600. Captain Vancouver conjectured the ſmall-pox to be a diſeaſe common and very fatal among them. Many were much marked; and moſt of theſe had loſt their right eye. Their method of diſpoſing of their dead is very ſingular.

"Baſkets were found ſuſpended on high trees, each containing the ſkeleton of a young child; in ſome of which were alſo ſmall ſquare boxes filled with a kind of white paſte, reſembling (ſays our author) ſuch as I had ſeen the natives eat, ſuppoſed to be made of the ſaranne root; ſome of theſe boxes were quite full, others were nearly empty, eaten probably by the mice, ſquirrels, or birds. On the next low point ſouth of our encampment, where the gunners were airing the powder, they met with ſeveral holes in which human bodies were interred, ſlightly covered over, and in different ſtates of decay, Juan, Jugglers.

some appearing to have been very recently deposited. About half a mile to the northward of our tents, where the land is nearly level with high water mark, a few paces within the skirting of the wood, a canoe was found suspended between two trees, in which were three human skeletons.

"On each point of the harbour, which, in honour of a particular friend, I called *Penn's Cove*, was a deserted village; in one of which were found several sepulchres, formed exactly like a centry box. Some of them were open, and contained the skeletons of many young children tied up in baskets: the smaller bones of adults were likewise noticed, but not one of the limb bones could here be found; which gave rise to an opinion, that these, by the living inhabitants of the neighbourhood, were appropriated to useful purposes; such as pointing their arrows, spears, or other weapons."

However honourable these people have been represented in their conduct as traders, it appeared on several occasions that it was unsafe to depend on their good-will alone: and some instances occurred, of their making every preparation for an attack, from which they desisted only on being doubtful of the event; yet immediately on relinquishing their purpose, they would come with the greatest confidence to trade, appearing perfectly regardless of what had before been in agitation. The boats, as already noticed, were frequently at a great distance from the ships; and on such occasions, when large parties of Indians have first seen them, they generally held long conferences among themselves before they approached the boats; probably for the purpose of determining the mode of conduct which they judged it most prudent to observe. Captain Vancouver places the entrance of the strait of Juan de Fuca in 48° 20′ N. Lat. and 124° W. Long.

JUGGLERS are a kind of people whose profession has not been often deemed either respectable or useful. Professor Beckmann, however, has undertaken their defence; and in a long and learned chapter in the third volume of his *History of Inventions*, pleads the cause of the practisers of legerdemain; rope-dancers; persons who place their bodies in positions apparently dangerous; and of those who exhibit feats of uncommnn strength. All these men he places under the general denomination of *Jugglers;* and taking it for granted (surely upon no good grounds) that every useful employment is full, he contends, that there would not be room on the earth for all its present inhabitants did not some of them practise the arts of *Juggling*.

"These arts (says he) are indeed not unprofitable, for they afford a comfortable subsistence to those who practise them; but their gain is acquired by too little labour to be hoarded up; and, in general, these roving people spend on the spot the fruits of their ingenuity; which is an additional reason why their stay in a place should be encouraged. But farther, it often happens, that what ignorant persons first employ, merely as a show, for amusement or deception, is afterwards ennobled by being applied to a more important purpose. The machine with which a Savoyard, by means of shadows, amused children and the populace, was by Liberkühn converted into a solar microscope; and, to give one example more, the art of making ice in summer, or in a heated oven, enables guests, much to the credit of their hostess, to cool the most expensive dishes. The Indian discovers precious stones, and the European, by polishing, gives them a lustre.

Jugglers.

"But, if the arts of juggling served no other end than to amuse the most ignorant of our citizens, it is proper that they should be encouraged for the sake of those who cannot enjoy the more expensive deceptions of an opera. They answer other purposes, however, than that of merely amusing; they convey instruction in the most acceptable manner, and serve as an agreeable antidote to superstition, and to that popular belief in miracles, exorcism, conjuration, sorcery, and witchcraft, from which our ancestors suffered so severely."

Surely this reasoning, as well as the cause in which it is brought forward, is unworthy of the learning of Beckmann It is indeed true, that jugglers spend their money freely, and that their arts afford them the means of subsistence; but it is very seldom, as our author must know, that they subsist either comfortably or innocently. Is it innocent to entice the ignorant and labouring poor, by useless deceptions, to part with their hard-earned pittance to idle vagabonds? or is the life of those vagabonds comfortable, when it is passed amidst scenes of the most grovelling dissipation? Jugglers spend indeed their money, for the most part on the spot where it is gained; but they spend it in drunkenness, and other seducing vices, which corrupt their own morals and the morals of all with whom they associate; and therefore their stay in a place should certainly *not* be encouraged. Could it be proved that the solar microscope would never have been invented, had not a Savoyard juggler contrived a similar machine to amuse children and the rabble, some stress might be laid on the service which such wretches have rendered to science: but where is the man that will suppose the philosophy of Bacon and Newton to rest upon the arts of juggling? or who considers the refinements of science as of equal value with the morals of the people? There is, at the moment in which this article is drawing up, a fellow exhibiting, before the windows of the writer's chamber, the most indecent scenes by means of puppets, and keeping the mob in a constant roar. Is he innocently employed? or will any good man say that there is not room for him in the ar- 1799.
mies which on the Continent are fighting in the cause of God and humanity!

Our author endeavours to strengthen his reasoning by proving, which he does very completely, the antiquity of juggling. "The deception (says he) of breathing out flames, which at present excites, in a particular manner, the astonishment of the ignorant, is very ancient. When the slaves in Sicily, about a century and a half before our æra, made a formidable insurrection, and avanged themselves in a cruel manner for the severities which they had suffered, there was amongst them a Syrian named Eunus, a man of great craft and courage, who, having passed through many scenes of life, had become acquainted with a variety of arts. He pretended to have immediate communication with the gods; was the oracle and leader of his fellow slaves; and, as is usual on such occasions, confirmed his divine mission by miracles. When, heated by enthusiasm, he was desirous of inspiring his followers with courage, he breathed flames or sparks among them from his mouth while he was addressing them. We are told by historians, Jugglers. tians, that for this purpofe he pierced a nut-fhell at both ends, and, having filled it with fome burning fubftance, put it into his mouth and breathed through it.

"This deception at prefent is performed much better. The juggler rolls together fome flax or hemp, fo as to form a ball about the fize of a walnut; fets it on fire; and fuffers it to burn till it is nearly confumed; he then rolls round it, while burning, fome more flax; and by thefe means the fire may be retained in it for a long time. When he wifhes to exhibit, he flips the ball unperceived into his mouth, and breathes through it; which again revives the fire, fo that a number of weak fparks proceed from it; and the performer fuftains no hurt, provided he infpire the air not through the mouth but the noftrils.

"For deceptions with fire the ancients employed alfo naphtha, a liquid mineral oil, which kindles when it only approaches a flame (fee NAPHTHA, *Encycl.*) Galen informs us, that a perfon excited great aftonifhment by extinguifhing a candle and again lighting it, without any other procefs than holding it immediately againft a wall or a ftone. The whole fecret of this confifted in having previoufly rubbed over the wall or ftone with fulphur. But as the author, a few lines before, fpeaks of a mixture of fulphur and naphtha, we have reafon to think that he alludes to the fame here. Plutarch relates how Alexander the Great was aftonifhed and delighted with the fecret effects of naphtha, which were exhibited to him at Ecbatana. The fame author, as well as Pliny, Galen, and others, has already remarked, that the fubftance with which Medea deftroyed Creufa, the daughter of Creon, was nothing elfe than this fine oil. She fent to the unfortunate princefs a drefs befmeared with it, which burft into flames as foon as fhe approached the fire of the altar. The blood of Neffus, in which the drefs of Hercules, which took fire likewife, had been dipped, was undoubtedly naphtha alfo; and this oil muft have been always employed when offerings caught fire in an imperceptible manner.

"In modern times, perfons who could walk over burning coals or red-hot iron, or who could hold red-hot iron in their hands, have often excited wonder. But laying afide the deception fometimes practifed on the fpectators, the whole of this fecret confifts in rendering the fkin of the foles of the feet and hands fo callous and infenfible, that the nerves under them are fecured from all hurt, in the fame manner as by fhoes and gloves. Such callofity will be produced if the fkin is continually compreffed, finged, pricked, or injured in any other manner. Thus do the fingers of the induftrious fempftrefs become horny by being frequently pricked; and the cafe is the fame with the hands of fire-workers, and the feet of thofe who walk bare-footed over fcorching fand.

"In the month of September 1765, when I vifited (fays our author) the copper-works at Aweftad, one of the workmen, for a little drink-money, took fome of the melted copper in his hand, and after fhewing it to us, threw it againft a wall. He then fqueezed the fingers of his horny hand clofe to each other; put it a few minutes under his arm-pit, to make it fweat, as he faid; and, taking it again out, drew it over a ladle filled with melted copper, fome of which he fkimmed off, and moved his hand backwards and forwards, very quickly, by way of oftentation. While I was viewing this performance, I remarked a fmell like that of finged horn or leather, though his hand was not burnt. It is highly probable that people who hold in their hands red hot iron, or who walk upon it, as I faw done at Amfterdam, but at a diftance, make their fkin callous before, in the like manner. This may be accomplifhed by frequently moiftening it with fpirit of vitriol: according to fome, the juice of certain plants will produce the fame effect; and we are affured by others, that the fkin muft be very frequently rubbed, for a long time, with oil, by which means, indeed, leather alfo will become horny*."

* *Haller, Elementa Phyfiolog.*

Our author then proves, in a very learned manner, that all thefe tricks were of high antiquity; that the Hirpi, who lived near Rome, jumped through burning coals; that women were accuftomed to walk over burning coals at Caftabala in Cappadocia, near the temple dedicated to Diana; that the exhibition of balls and cups (fee LEGERDEMAIN, *Encycl.*) is often mentioned in the works of the ancients; that in the third century, one Firmus or Firmius, who endeavoured to make himfelf emperor in Egypt, fuffered a fmith to forge iron on an anvil placed on his breaft; that rope dancers with balancing poles are mentioned by Petronius and others; and that the various feats of horfemanfhip exhibited in our circufes paffed, in the 13th century, from Egypt to the Byzantine court, and thence over all Europe.

JUNGLE, in Bengal, wafte land, or land covered with wood and brambles.

K.

Kaarta. KAARTA, a kingdom in Africa, through which Mr Park paffed in his route from the Gambia to the Niger. He defcribes the country as confifting either of fandy plains or rocky hills; but, from his account, the level part feems to be the moft extenfive. The natives are negroes, of whom many, though converted to the Mahomedan faith, or rather to the ceremonial part of the Mahomedan religion, retain all their ancient fuperftitions, and even drink ftrong liquors. They are called Johers or Jowers, and in Kaarta form a very numerous and powerful tribe. One of thefe men undertook to conduct our author to Kemmoo, the capital of the kingdom, and alarmed him not a little by his fuperftitious ceremonies.

 "We

Kaarta, Kabobiquas

"We had no fooner (fays Mr Park) got into a dark and lonely part of the firft wood, than he made a fign for us to ftop, and taking hold of a hollow piece of bamboo, that hung as an amulet round his neck, whiftled very loud three times. I confefs I was fomewhat ftartled, thinking it was a fignal for fome of his companions to come and attack us; but he affured me that it was done merely with a view to afcertain what fuccefs we were likely to meet with on our prefent journey. He then difmounted, laid his fpear acrofs the road, and having faid a number of fhort prayers, concluded with three loud whiftles; after which he liftened for fome time, as if in expectation of an anfwer, and receiving none, told us we might proceed without fear, for there was no danger."

White men were ftrangers in the kingdom of Kaarta; and the appearance of our author had on fome of the natives the effect which ignorant people, in this country, attribute to ghofts. "I had wandered (fays he) a little from my people, and being uncertain whether they were before or behind me, I haftened to a rifing ground to look about me. As I was proceeding towards this eminence, two negro horfemen, armed with mufkets, came galloping from among the bufhes: on feeing them I made a full ftop; the horfemen did the fame, and all three of us feemed equally furprifed and confounded at this interview. As I approached them their fears increafed, and one of them, after cafting upon me a look of horror, rode off at full fpeed; the other, in a panic of fear, put his hand over his eyes, and continued muttering prayers until his horfe, feemingly without the rider's knowledge, conveyed him flowly after his companion. About a mile to the weftward, they fell in with my attendants, to whom they related a frightful ftory: it feems their fears had dreffed me in the flowing robes of a tremendous fpirit; and one of them affirmed, that when I made my appearance, a cold blaft of wind came pouring down upon him from the fky like fo much cold water."

At Kemmoo our traveller was gracioufly received by the king; who honeftly told him, however, that he could not protect him, being then engaged in war with the king of Bambarra (fee Segó in this *Supplement*); but he gave him a guard to Jarra, the frontier town of the neighbouring kingdom of Ludamar. The origin and iffue of this war between Kaarta and Bambara, of which Mr Park gives a full account, fhews the folly of attempting to liberate the negroes from flavery till civilization and Chriftianity be introduced into Africa. Major Rennel places Kemmoo, the capital of Kaarta, in 14° 15′ N. Lat. and 7° 20′ W. Long.

KABOBIQUAS, a nation in South Africa, who had never feen a white man till 1785, that they were vifited by M. Vaillant. Intimation had been given of his approach by fome of the tribes through whofe country he had previoufly paffed; and every thing that had been faid of his colour, his fufees, and his equipage, bore the character of the moft enthufiaftic exaggeration. The curiofity of the people was wound up to the higheft pitch; and as foon as they faw his company at a diftance, the whole horde quitted the kraal, and ran with eagernefs to meet him. Not being able to believe their eyes in regard to what they faw, they endeavoured to obtain more fatisfaction by touching him. They felt his hair, hands, and almoft every part of his body. His beard, above all, aftonifhed them to an inconceivable degree. More than thirty perfons came in fucceffion, and half unbuttoned his clothes. They all imagined him to be a hairy animal; and fuppofed, without doubt, that his body was covered with hair as long as that on his chin; but finding this not to be the cafe, they were aftonifhed, and confeffed, with the opennefs of favages, that they had never feen the like in any man of their country. The little children, terrified at his appearance, hid themfelves behind their mothers. When he attempted to lay hold of any of them, in order to carefs them, they fent forth loud cries, as a child would do in Europe who fhould fee a negro for the firft time.

Kabobiquas

The grown up people, however, were foon reconciled to his appearance, and even the children were bribed by fmall bits of fugar candy. The chief of the horde fhewed him every mark of attachment. He was a man advanced in life, and of a majeftic figure. He wore a long mantle, which hung from his fhoulders to the ground, and which, formed of four jackal fkins joined together, was bordered at the fides with that of a hyæna. His left hand wanted two joints of the little finger, which, he faid, were amputated in his infancy to cure him of a fevere illnefs.

This cuftom of favages, who, to relieve a man from pain, add new fufferings to his evils, affords a vaft field for reflection. Mr Paterfon, another African traveller, tells us, that he obferved inftances of the fame practice among a horde at the mouth of Orange-river; which is not improbable. However abfurd a cuftom may be, favage tribes, when they are neighbours, may borrow it from each other; but that it fhould be common among the iflanders of the South Sea, who, fince their country was firft inhabited, had never feen ftrangers before Cook and Bougainville, is truly aftonifhing. Our author was very defirous of interrogating minutely the people of the horde on this fubject. He wifhed alfo to propofe fome queftions to them refpecting other cuftoms which appeared fingular; but difficulties increafed the more he advanced into the country. The Kabobiquas fpoke a particular language; and this dialect, though accompanied with the clapping noife of the Hottentots, was underftood only by the Koraquas, who, on account of their vicinity, kept up fome intercourfe with them. The cafe was the fame with the language of the Koraquas, in regard to their neighbours the Nimiquas; and nothing reached our author's ear till it had paffed through four different mouths. The confequence was, that when he afked any thing, the anfwer had frequently no relation to the queftion; and for this inconveniency no remedy could be found.

The fame defire for trinkets to ornament their drefs prevailed among the Kabobiquas as among the other hordes which Vaillant had vifited; and in one day he purchafed 20 oxen for things of that kind of no value. The chief, however, had fet his affections on a razor; and juft when our authur and he were treating about it, a fhot was fired near them, which was inftantly followed by the moft frightful cries. "Rufhing inftantly from my tent (fays M. Vaillant) to inquire what was the caufe of this noife, I faw a Kabobiqua flying as faft as he could from one of my hunters, while, at the diftance of a hundred paces farther, three men were making the moft lamentable clamour, and near them was a young girl lying

Kabobiquas.

lying on the ground. I made a fignal to my hunter to approach me; but the report of the fhot, and the howling of the three men, had already fpread alarm throughout the horde. Some cried out treachery ; others ran to their arms ; and I now imagined that I was about to be maffacred, with my whole company, and that I fhould be obliged to arm them in my defence. My fituation was the more critical, as neither I, nor any perfon in the kraal, knew what was the caufe of this confufion ; and if I had known, how could I have explained it ?

" Under this embarraffment, I took the chief by the hand, and advanced with him towards the horde. Fear was painted in his countenance ; tears began to drop from his eyes ; and he fpoke to me with great vivacity. He imagined, no doubt, that he was betrayed He complained to me, and accufed my people of perfidy ; yet he readily followed me.

" As I was without arms, and prefented myfelf with the chief, I was received with confidence, and my appearance feemed, in fome meafure, to calm their perturbation. My people, who had feen me direct my courfe towards the kraal, haftened thither after me, to protect me ; and their number overawed the multitude. At length the whole myftery was cleared up, and we learned what had occafioned the tumult.

" A Kabobiqua having met one of my hunters, who was returning with his fufee, wifhed to examine it, and begged him to fhew it to him. In handling it, however, he accidentally touched the trigger ; it inftantly went off ; and the favage, frightened by the unexpected explofion, threw down the fufee, and ran away as faft as he could.

" At that time, three men of the horde and a young girl happened unluckily to be ftanding, at the diftance of a hundred paces, in the direction of the piece. The latter received a fingle grain of fhot in the cheek ; and the others a few grains in the legs and thighs. The author of the misfortune confirmed this explanation ; tranquillity was foon reftored ; the favages depofited their arms ; and I was furrounded only by friends as before.

" Nothing remained but to enquire into the ftate of the wounded, and to give them every affiftance in my power. Without lofs of time, therefore, I repaired, ftill accompanied by the chief, to the place where they were. By the way we met the young girl, who was returning from the kraal, bathed in tears. The caufe of her uneafinefs was a grain of lead, which had, however, penetrated fo little, that I forced it out by only preffing the part with my fingers. With regard to the three men, they lay rolling on the ground, howling in a moft frightful manner, and exhibiting every fymptom of defpair.

" I was aftonifhed at their confternation, and could not conceive how men inured to fufferings fhould be fo much affected by a few fmall punctures, the pain of which could have fcarcely drawn tears from an infant. They at length told me the caufe of their wailings. Thefe favages, accuftomed to poifon their arrows, imagined that I had in like manner poifoned the lead with which they were wounded. They had, therefore, given themfelves up as loft, and expected in a few moments to expire."

It was with great difficulty that our author could convince them that they had nothing to fear. He fhewed them in the flefh of his own leg a dozen of fhots of lead ; but they were not fatisfied till one of the moft intelligent of his Hottentots, taking from his fhot-bag a few grains of lead, and fhewing them to the three men, immediately fwallowed them. This conclufive argument produced the defired effect. The cries of the wounded men inftantly ceafed ; ferenity again appeared in their faces ; and their wounds were no more mentioned.

The Kabobiquas have neither the flat nofe nor plump cheeks of the Hottentots. Their fkin alfo has not that baftard colour, which, being neither black nor white, renders them odious to both races ; nor do they befmear their bodies with thofe difgufting fat fubftances, on account of which one cannot approach them without being bedaubed with their filth, or acquiring an offenfive fmell. In ftature they are as tall as the Caffres, and their colour is equally black. Their hair, which is exceedingly fhort, and much curled, is ornamented with fmall copper buttons, arranged with great art and fymmetry. Inftead of that apron made of a jackal's fkin, employed by the Hottentot to cover what modefty bids him conceal, the Kabobiquas ufe a round piece of leather, the edge of which is ornamented with a fmall indented circle of copper, and which is divided into different compartments by rows of glafs beads of various colours, all proceeding from the centre, and diverging towards the circumference, like the rays in our images of the fun.

This kind of veil is made faft to the groin by means of a girdle ; but as it is only four inches in diameter, as it is deranged by the fmalleft movement, and as they give themfelves little uneafinefs refpecting fuch accidents, it is very ill fuited to the purpofe for which it is applied. During the great heats, this fmall and almoft ufelefs apron is the only covering on their bodies. Its being fo readily difplaced, enabled our author to afcertain that they do not practice circumcifion ; but it feemed to fhew alfo, that, in regard to modefty, their ideas are very different from ours.

Though they go thus almoft entirely naked, their manners, inftead of being licentious, are remarkably chafte No females can be more prudent or more referved than their women ; and whether from refinement of coquetry, or the effect of prudence, they do not tattoo their faces like their hufbands and fathers. They do not even follow their example in ornamenting their hair with copper buttons; and they always go barelegged, though moft of them wear fandals.

Their drefs confifts of an apron that reaches only half down the thigh ; a crofs which, paffing under the arm-pits, is tied on the breaft ; and a long mantle like that of the men. The mantle is made of fkins not deprived of the hair ; and the crofs of tanned leather, prepared like that ufed for gloves in Europe.

With regard to glafs beads, they wear them as bracelets. They form them alfo into necklaces, which defcend in different rows to the pit of the ftomach ; and they fufpend from their girdles feveral ftrings of them, which fall down their thighs below the apron.

Thefe ornaments being very durable, the habit of feeing them renders the women almoft indifferent to the pleafure of poffeffing them. Thofe they procured from our author afforded at firft great fatisfaction, on account of their novelty. But when he fhewed them fciffars and

and needles, they gave the preference to these articles; and this choice does honour to the good sense of the Kabobiqua ladies. Like their chief, they set a higher value on utility than ornament.

Before our author's arrival among them, the Kabobiquas were acquainted with the use of tobacco through the means of some of the tribes more contiguous to the Cape. It was, however, a luxury which they could seldom enjoy; and so indifferent were they about it, that if it were not brought to them, they would not go a step to procure it. This indifference, about an article which is eagerly sought for by all the tribes of Hottentots, seemed to shew that there are traits in the character of the Kabobiquas which distinguish them from their southern neighbours. The case was the same as to strong liquors, on which they set no great value; and though there were among them some few individuals disposed to relish them, the greater number absolutely refused them.

"If the contents of my flasks (says Vaillant) gave them little satisfaction, they were, however, much captivated with the flasks themselves. These transparent bottles excited their admiration in the highest degree. They called them *solid water*; for, notwithstanding the heat of the climate, these savages had seen ice on the summits of the mountains by which they are surrounded; and they entertained no doubt that the glass of my flasks was water, which I had rendered solid by magic, and which I prevented their fires from melting. As it was impossible for me to explain this matter, I did not attempt to undeceive them: and besides, with what advantage would it have been attended? I suffered them, therefore, to continue in their error, and contented myself with conferring on them an obligation, by giving them all the empty bottles for which I had no use.

"On their part, they vied with each other in shewing their generosity towards me; and I must indeed allow, that I never saw a nation so disinterested. Every night they brought to my camp a considerable quantity of milk; and they never came to spend the evening with my people, without bringing some sheep to regale them. I have seen many of them give away gratuitously, and without receiving any thing in return, part of their herds and their flocks; and, when I departed, there were many persons in my caravan who possessed both sheep and oxen, which they had received as a pure gift."

With this benevolent disposition, the Kabobiquas have also a martial character. Their weapons are poisoned arrows, and a lance with a long iron point, but different from the assagay of the Hottentots. In battle, their defensive armour consists of two bucklers; the one of a size sufficient to cover the whole body of the combatant; the other much smaller. They are both made of skins exceedingly thick, and proof against arrows.

The courage which the Kabobiquas display in combat is particularly exercised in their hunting excursions, and, above all, against carnivorous animals. Intrepid, however, as it may be to attack the elephant and the rhinoceros, these species of animals are not objects of their vengeance; because, living upon grass and herbs, they have nothing to apprehend from them, either for themselves or their cattle. But the tiger, lion, hyæna, and panther, being enemies of a different kind, they declare against them implacable war, and pursue them without remission.

Of the spoils of these destructive animals they form their bucklers, girdles, sandals, crosses, mantles, &c. They consider it as a mark of honour to wear them; and they set a much higher value upon them than upon the skin of the rhinoceros or of the elephant. If they sometimes hunt the latter, it is only as objects of food; and they employ to catch them those concealed pits, which are the usual snares of the Hottentots: but this method, which requires both patience and labour, is very little suited to a people so brave and enterprising as the Kabobiquas.

As they possess so bold and resolute a character, one might be induced to believe that they are ferocious and intractable. Among all the African nations, however, which our author visited, he never knew one that so much practised obedience and subordination.

The chief here is not, as in other tribes, a principal among his equals; he is a sovereign in the midst of his subjects, a master surrounded by his slaves. A word, a gesture, or a look, is sufficient to procure him obedience. Whatever be his orders, they are never contradicted; and the case is the same in every particular family. What the chief is to the horde, the father is to his children. His commands are absolute; and he exercises regal power at home, while he obeys elsewhere.

Though the tribe was very numerous, the wisdom with which it was ruled, and the good order that prevailed, announced, in the man by whom it was governed, an intelligence superior to that of all the savages our author had before seen; for he had not then visited the Houzouanas. The habitation of this chief was suited to his supreme dignity. It was, indeed, a hut only, like those of his subjects, and, like them, covered with the skins of animals; but it was much larger, as well as more elevated; and around it were six others, occupied by his family, and destined for them alone.

The natural dryness of the country inhabited by the Kabobiquas obliges them to dig wells, for their own use as well as for their cattle; but as the same cause often dries up these wells, they are then forced to remove, and to seek elsewhere a soil more abundant in springs; for Fish-river, though considerable in the rainy season, is often, during the great heats, entirely destitute of water.

The long journeys which these too frequent emigrations compel them to undertake, and the intercourse which they thence have with other nations, must necessarily inspire them with ideas unknown to the settled tribes; and it would not be unnatural to suppose, that to this extension of ideas are they indebted for that superiority of intelligence which elevates them above their neighbours.

Of the religion of the Kabobiquas, our author talks very inconsistently, and like a true philosopher of the French school. "Of all the African nations (says he), they are the only people among whom I found any idea, however confused a one, of the existence of a Deity. I do not know whether it be from their own reflection, or the communications of other tribes, that they have acquired this sublime knowledge, which would alone bring them

Kajaaga. them near to a level with poliſhed nations; but they believe, as far as I have been able to learn from my people, that beyond the ſtars there exiſts a Supreme Being, who made and who governs all things. I muſt, however, obſerve, that on this ſubject their ideas are vague, barren, and unproductive. They have no conception of the future exiſtence of the ſoul, or of rewards and puniſhments in another life; in ſhort, they have neither worſhip, ſacrifices, ceremonies, nor prieſts, and are total ſtrangers to what we call religion."

This is impoſſible. A people believing in a Supreme Being, who made and who governs all things, *may* indeed be without *ſacrifices*, *ceremonies*, and *prieſts*; but ſuch a people cannot avoid *wiſhing*, that the Being who governs all things may protect them. Such a wiſh is a prayer; and ſurely he who prays is no ſtranger to religion. M. Vaillant places the country of the Kabobiquas between 23° and 25° S. Lat. and 16° 25′ and 19° 25′ Long. eaſt from Paris.

KAJAAGA, an African kingdom, called by the French *Gallam*, is bounded on the ſouth-eaſt and ſouth by Bambouk; on the weſt, by Bondou and Foota Torra; and on the north, by the river Senegal. The air and climate (ſays Mr Park) are more pure and ſalubrious than at any of the ſettlements towards the coaſt; the face of the country is everywhere interſperſed with a pleaſing variety of hills and valleys; and the windings of the Senegal river, which deſcends from the rocky hills of the interior, make the ſcenery on its banks very picturesque and beautiful.

The inhabitants are called Serawoollies, or (as the French write it) *Seracolets*. Their complexion is a jet black: they are not to be diſtinguiſhed in this reſpect from the Jaloffs.

The government is monarchical; and the regal authority, from what I experienced of it, ſeems to be ſufficiently formidable. The people themſelves, however, complain of no oppreſſion; and ſeemed all very anxious to ſupport the king in a conteſt he was going to enter into with the ſovereign of Kaſſon. The Serawoollies are habitually a trading people; they formerly carried on a great commerce with the French in gold and ſlaves, and ſtill maintain ſome traffic in ſlaves with the Britiſh factories on the Gambia. They are reckoned tolerably fair and juſt in their dealings, but are indefatigable in their exertions to acquire wealth, and they derive conſiderable profits by the ſale of ſalt and cotton cloth in diſtant countries. When a Serawoolli merchant returns home from a trading expedition, the neighbours immediately aſſemble to congratulate him upon his arrival. On theſe occaſions the traveller diſplays his wealth and liberality, by making a few preſents to his friends; but if he has been unſucceſsful, his levee is ſoon over; and every one looks upon him as a man of no underſtanding, who could perform a long journey, and (as they expreſs it) *bring back nothing but the hair upon his head.*

Their language abounds much in gutturals, and is not ſo harmonious as that ſpoken by the Foulahs: it is, however, well worth acquiring by thoſe who travel through this part of the African continent; it being very generally underſtood in the kingdoms of Kaſſon, Kaarta, Ludamar, and the northern parts of Bambara. In all theſe countries the Serawoollies are the chief traders.

Joag, the frontier town of this kingdom as you enter it from Piſania, may be ſuppoſed, on a groſs computation, to contain two thouſand inhabitants. It is ſurrounded by a high wall, in which are a number of port holes, for muſquetry to fire through in caſe of an attack. Every man's poſſeſſion is likewiſe ſurrounded by a wall; the whole forming ſo many diſtinct citadels; and amongſt a people unacquainted with the uſe of artillery, theſe walls anſwer all the purpoſes of ſtronger fortifications. To the weſtward of the town is a ſmall river, on the banks of which the natives raiſe great plenty of tobacco and onions. Mr Park was in this town plundered of half his effects by order of the king, becauſe forſooth he had neglected to pay the accuſtomed duties before he entered the kingdom; and it required a good deal of addreſs to prevent himſelf and his attendants from being made ſlaves; a ſtate to which the law, it was ſaid, condemned them for the commiſſion of this unintended crime. He was at laſt reſcued from Joag by a nephew of the king of Kaſſon. Joag is placed by Major Rennel in 14° 25′ N. Lat. and 9° 46′ W. Long.

Kainſi. KAINSI, is the name given by the Hottentots to a particular ſpecies of antelope, of which, according to Vaillant, no author has yet given a perfect deſcription. It is called by the Dutch *klip-ſpringer*, on account of the eaſe with which it leaps from rock to rock; and indeed of all the antelopes there is no one equal to it in agility. It is about the ſize of a kid of a year old, and of a yellowiſh grey colour; but its hair has this peculiarity, that, inſtead of being round, pliable, and firm, like that of moſt other quadrupeds, it is flat, harſh, and ſo little adherent to the ſkin, that the ſlighteſt friction makes it fall off. Nothing is more eaſy, therefore, than to deprive this animal of its hair: dead or alive it is the ſame; to rub, or even to touch the animal, is ſufficient. Another peculiarity of this ſingular hair is its being extremely fragile; ſo that if you take a tuft of it between your fingers, and twiſt it with the other hand, it will break like the barbs of a feather. This property, however, belongs not excluſively to the hair of the kainſi; for our author ſays he has obſerved it in the hair of other quadrupeds, which in the ſame manner live among the rocks.

This antelope differs from the other ſpecies alſo in the ſhape of the foot, which, inſtead of being pointed like theirs, is rounded at the end; and as it is always accuſtomed, both in leaping and walking, to tread with the point of the hoof, without reſting at all on the heel, it leaves a print diſtinguiſhable from that of any other antelope in Africa. Its fleſh is exquiſitely flavoured, and much ſought after, particularly by the hunters.

The chace of the kainſi is very amuſing. It is true, it is ſcarcely poſſible to hunt it down with dogs, as it ſoon eſcapes them by means of its inconceivable agility, and gets out of their reach on the point of ſome detached rock, where it will remain whole hours ſafe from all purſuit, and ſuſpended, as it were, above the abyſs. But in this ſituation it is excellently placed for the arrow or the ball of the huntſman; who is commonly certain of ſhooting it at pleaſure, though he is not always able to come at it when killed. We ſhall give our author's account of a chace of the kainſi in his own words.

"I was hunting (ſays he) one of theſe animals, when, from the nature of the place, it found itſelf ſo preſſed preffed by my dogs, as to be on the point of being run down and taken. There were apparently no means of efcape; fince before it was a vaft perpendicular rock, by which its courfe was neceffarily ftopped. In this wall, however, which appeared to me perfectly fmooth, was a little ridge, projecting at moft not above *two inches*, which the kainfi quickly perceived, and, leaping upon it, to my great aftonifhment kept itfelf *firm* (A). I imagined that, at any rate, it muft foon tumble down; and my dogs, too, fo fully expected it, that they ran to the bottom of the rock, to be ready to catch it when it fell. To haften its fall, I endeavoured to harafs it, and make it lofe its equilibrium; and for this purpofe I pelted it with ftones. All at once, as if gueffing my defign, it collected its whole ftrength, bounded over my head, and, falling a few paces from me, darted away with the utmoft fpeed. Notwithftanding the rapidity of its flight, it would have been eafy for me to have fhot it; but its leap had fo furprifed and amufed me, that I gave it its life." This was generous, if the ftory be true.

KAMTSCHATKA is inhabited by a people, who are reprefented in the *Encyclopædia* as poffeffing almoft every quality that can difgrace human nature. We think it incumbent upon us to acknowledge, in this place, that a much more favourable picture of them is drawn by La Peroufe who vifited Kamtfchatka in September 1787. The Ruffian governor made the commodore and his officers remark the promifing appearance of feveral fmall fields of potatoes, of which the feed had been brought from Irkoutfk a few years before; and purpofed to adopt mild, though infallible means, of making farmers of the Ruffians, Coffacks, and Kamtfchadales. The fmall-pox in 1769 fwept away three-fourths of the individuals of the latter nation, which is now reduced to lefs than four thoufand perfons, fcattered over the whole of the peninfula; and which will fpeedily difappear altogether, by means of the continual mixture of the Ruffians and Kamtfchadales, who frequently intermarry. A mongrel race, more laborious than the Ruffians, who are only fit for foldiers, and much ftronger, and of a form lefs difgraceful to the hand of nature, than the Kamtfchadales, will fpring from thefe marriages, and fucceed the ancient inhabitants. The natives have already abandoned the *yourts*, in which they ufed to burrow like badgers during the whole of the winter, and where they breathed an air fo foul as to occafion a number of diforders. The moft opulent among them now build *ifbas*, or wooden houfes, in the manner of the Ruffians. They are precifely of the fame form as the cottages of our peafants; are divided into three little rooms; and are warmed by a brick ftove, that keeps up a degree of heat (B) infupportable to perfons unaccuftomed to it. The reft pafs the winter, as well as the fummer, in *balagans*, which are a kind of wooden pigeon-houfes, covered with thatch, and placed upon the top of pofts twelve or thirteen feet high, to which the women as well as the men climb by means of ladders that afford a footing very infecure. But thefe latter buildings will foon difappear; for the Kamtfchadales are of an imitative genius, and adopt almoft all the cuftoms of their conquerors. Already the women wear their hair, and are almoft entirely dreffed in the manner of the Ruffians, whofe language prevails in all the *oftrogs*; a fortunate circumftance, fince each Kamtfchadalian village fpoke a different jargon, the inhabitants of one hamlet not underftanding that of the next. It may be faid in praife of the Ruffians, that though they have eftablifhed a defpotic government in this rude climate, it is tempered by a mildnefs and equity that render its inconveniences unfelt. They have no reproaches of atrocity to make themfelves, like the Spaniards in Mexico and Peru. The taxes they levy on the Kamtfchadales are fo light, that they can only be confidered as a mark of gratitude towards the fovereign, the produce of half a day's hunting acquitting the impofts of a year. It is furprifing to fee in cottages, to all appearance more miferable than thofe of the moft wretched hamlets in our mountainous provinces, a quantity of fpecies in circulation, which appears the more confiderable, becaufe it exifts among fo fmall a number of inhabitants. They confume fo few commodities of Ruffia and China, that the balance of trade is entirely in their favour, and that it is abfolutely neceffary to pay them the difference in rubles. Furs at Kamtfchatka are at a much higher price than at Canton; which proves, that as yet the market of Kiatcha has not felt the advantageous effect of the new channel opened in China.

Our author compares Kamtfchatka, with refpect to climate and foil, to the coaft of Labrador in the vicinity of the Straits of Belle Ifle; but the men, like the animals, are there very different. The Kamtfchadales appeared to him the fame people as thofe of the bay of Caftries, upon the coaft of Tartary. Their mildnefs and their probity are the fame, and their perfons are very little different. They ought then no more to be compared to the Efquimaux Indians, than the fables of Kamtfchatka to the martins of Canada.

The Greek religion has been eftablifhed among the Kamtfchadales without perfecution or violence, and with extraordinary facility. The vicar of Paratounka is the fon of a Kamtfchadale and of a Ruffian woman. He delivers his prayers and catechifm with a tone of feeling very much to the tafte of the aborigines, who reward his cares with offerings and alms, but pay no tythes. The canons of the Greek church permitting priefts to marry, we may conclude that the morals of the country clergymen are fo much the better. "I believe them, however (fays Peroufe), to be very ignorant; and do not fuppofe that for a long time to come they will ftand in need of greater knowledge. The daughter, the wife, and the fifter of the vicar, were the beft dancers of all the women, and appeared to enjoy the beft ftate of health. The worthy prieft knew that we were good Catholics, which procured us an ample afperfion of holy water; and he alfo made us kifs the crofs that was carried by his clerk; thefe ceremonies were performed in the midft of the village. His parfonage houfe was a tent, and his altar in the open air; but his ufual abode is Paratounka, and he only came to St Peter and St Paul's to pay us a vifit."

The

(A) This we think incredible.

(B) Not lefs than thirty degrees of Reaumur's thermometer.

The people of Kamtſchatka have inured themſelves to the extremes of heat and cold. It is well known, that their cuſtom in Europe, as well as in Aſia, is to go into vapour baths, come out covered with perſpiration, and immediately roll themſelves in the ſnow. The *oſtrog* of St Peter had two of theſe public baths, into which our author went before the fires were lighted. They conſiſt of a very low room, in the middle of which is an oven conſtructed of ſtones, without cement, and heated like thoſe intended to bake bread. Its arched roofs is ſurrounded by ſeats one above another like an amphitheatre, for thoſe who wiſh to bathe, ſo that the heat is greater or leſs according as the perſon is placed upon a higher or lower bench. Water thrown upon the top of the roof, when heated red hot by the fire underneath, is converted inſtantly into vapour, and excites the moſt profuſe perſpiration. The Kamtſchatdales have borrowed this cuſtom, as well as many others, from their conquerors; and ere long the primitive character that diſtinguiſhed them ſo ſtrongly from the Ruſſians will be entirely effaced.

Our author deſcribes the bay of Avatſcha as the fineſt, the moſt convenient, and the ſafeſt, that is to be met with in any part of the world. The entrance is narrow, and ſhips would be forced to paſs under the guns of the forts that might be eaſily erected. The bottom is mud, and excellent holding ground. Two vaſt harbours, one on the eaſtern ſide, the other on the weſtern, are capable of containing all the ſhips of the French and Engliſh navy. The rivers of Avatſcha and Paratounka fall into this bay, but they are choaked up with ſand-banks, and can only be entered at the time of high water. The village of St Peter and St Paul is ſituated upon a tongue of land, which, like a jetty made by human art, forms behind the village a little port, ſhut in like an amphitheatre, in which three or four veſſels might lie up for the winter. The entrance of this fort of baſon is more than twenty-five toiſes wide; and nature can afford nothing more ſafe or commodious. On its ſhore the Governor propoſed to lay down the plan of a city, which ſome time or other will be the capital of Kamtſchatka, and perhaps the centre of an extenſive trade with China, Japan, the Phillippines, and America. A vaſt pond of freſh water is ſituated northward of the ſite of this projected city; and at only three hundred toiſes diſtance run a number of ſtreamlets, the eaſy union of which would give the ground all the advantages neceſſary to a great eſtabliſhment. Of theſe advantages Mr Kaſloff underſtood the value; "but firſt (ſaid he a thouſand times over) we muſt have bread and hands, and our ſtock of both of them is very ſmall." He had, however, given orders, which announced a ſpeedy union of the other *oſtrogs* to that of St Peter and St Paul, where it was his intention immediately to build a church. By obſervation, St Peter and St Paul was found to be in 53° 1′ N. Lat. and 156° 30′ E. Long. from Paris.

KANEM, is the name given by Adriſi to the kingdom of Bornou in Africa, of which the reader will find ſome account in the *Encyclopædia Britannica*. In ſome particulars, however, that account is incorrect. The kingdom of Bornou or Kanem muſt extend farther eaſt and farther north than it is there ſaid to do; for according to the lateſt and beſt accounts, its capital ſtands in Lat. 24° 32′, Long. 22° 57′. The empire is ſaid to

be very extenſive; and if it be true, as we learn from the proceedings of the African Aſſociation, that its ſovereign is more powerful than the Emperor of Morocco, the people cannot be ſuch abſolute brutes, as we have repreſented them in the article referred to; for the ſovereign of brutes would have no power. The truth, however is, that very little is yet known in Europe of Bornou or its inhabitants.

KANT (Immanuel), Royal Profeſſor of Morals and Metaphyſics in the Univerſity of Konigſberg, publiſhed ſome years ago a new ſyſtem of Metaphyſics, to which he gave the name of *Critical* Philosophy, which ſee in this *Supplement*.

KANTUFFA, a ſpecies of thorn peculiar to Abyſſinia, is thus deſcribed by Mr Bruce: The branches ſtand two and two upon the ſtalk; the leaves are diſpoſed two and two likewiſe, without any ſingle one at the point, whereas the branches bearing the leaves part from the ſtalk: at the immediate joining of them are two thick thorns placed perpendicular and parallel alternately; but there are alſo ſingle ones diſtributed in all the interſtices throughout the branch.

The male plant has a one-leaved perianthium, divided into five ſegments, and this falls off with the flower. The flower is compoſed of five petals, in the middle of which riſe ten ſtamina or filaments, the outer row ſhorter than thoſe of the middle, with long ſtigmata, having yellow farina upon them. The flowers grow in a branch, generally between three and four inches long, in a conical diſpoſition, that is, broader at the baſe than the point. The inſide of the leaves are a vivid green, in the outſide much lighter. It grows in form of a buſh, with a multitude of ſmall branches riſing immediately from the ground, and is generally ſeven or eight feet high. Our author ſaw it when in flower only, never when bearing fruit. It has a very ſtrong ſmell, reſembling that of the ſmall ſcented flower called mignionet, ſown in vaſes and boxes in windows, or rooms, where flowers are kept.

Our author repreſents the kantuffa as ſo very troubleſome, that it renders travelling through ſome places of Abyſſinia almoſt impoſſible. The ſoldier ſcreens himſelf from it by a goat's, a leopard's, or a lion's ſkin thrown over his ſhoulders, of which it has no hold. As his head is bare, he always cuts his hair ſhort before he goes to battle, leſt his enemy ſhould take advantage of it; but the women, wearing their hair long, and the great men, whether in the army or travelling in peace, being always clothed, it never fails to incommode them, whatever ſpecies of raiment they wear. If their cloak is fine muſlin, the leaſt motion againſt it puts it all in rags; but if it is a thick, ſoft cloth, as thoſe are with which men of rank generally travel, it buries its thorns, great and ſmall, ſo deep in it, that the wearer muſt either diſmount and appear naked, which to principal people is a great diſgrace, or elſe much time will be ſpent before he can diſengage himſelf from its thorns. In the time when one is thus employed, it rarely fails to lay hold of you by the hair, and that again brings on another operation, full as laborious, but much more painful, than the other. A proclamation is therefore iſſued, every year immediately before the king commences any march, in theſe words: "Cut down the kantuffa in the four quarters of the world; for I do not know where I am going." The wild animals, both

birds

Kaffon.

birds and beafts, efpecially the Guinea fowl, know how well it is qualified to protect them. In this fhelter, the hunter in vain could endeavour to moleft them, were it not for a hard-haired dog, or terrier of the fmalleft fize, who being defended from the thorns by the roughnefs of his coat, goes into the cover, and brings them and the partridges alive one by one to his mafter.

KASSON, a populous kingdom in North Africa, of which the capital *Kooniakary* is placed by Major Rennel in 14° 33′ N. Lat. and 8° 43′ W. Lon. The king who reigned when Mr Park was in the country was extremely kind to our traveller, though his fon plundered him unmercifully, like other rapacious chiefs of that favage country. From the top of a high hill, at fome diftance from the capital, "I had (fays Mr Park) a moft enchanting profpect of the country. The number of towns and villages, and the extenfive cultivation around them, furpaffed every thing I had yet feen in Africa. A grofs calculation may be formed of the number of inhabitants in this delightful plain, by confidering that the king of Kaffon can raife four thoufand fighting men by the found of his war drum."

At Teefee, a large unwalled town, where our author refided for fome days, he had an opportunity of obferving the cuftoms of the inhabitants, who confifted partly of Pagans and partly of Bufhreens, *i. e.* of negroes converted to Mahomedanifm. Though thefe people poffefs both cattle and corn in abundance, rats, moles, fquirrels, fnakes, locufts, &c. are eaten without fcruple by the higheft and loweft. Another cuftom ftill more extraordinary, is, that no woman is allowed *to eat an egg*. This prohibition, whether arifing from ancient fuperftition, or from the craftinefs of fome old Bufhreen who loved eggs himfelf, is rigidly adhered to; and nothing will more affront a woman of Teefee than to offer her an egg. The cuftom is the more fingular, as the men eat eggs without fcruple in the prefence of their wives, and Mr Park never obferved the fame prohibition in any other of the Mandingo countries.

Our author was prefent at a palaver held by the governor of Teefee on a very extraordinary occafion; of which we fhall give his account at full length, becaufe it fhows how free men are reduced to flavery in North Africa. The cafe was this: "A young man, a Kafir of confiderable affluence, who had recently married a young and handfome wife, applied to a very devout Bufhreen, or Muffulman prieft, of his acquaintance, to procure him faphies for his protection during the approaching war. The Bufhreen complied with the requeft; and in order, as he pretended, to render the faphies more efficacious, enjoined the young man to avoid any nuptial intercourfe with his wife for the fpace of fix weeks. Severe as the injunction was, the Kafir ftrictly obeyed; and without telling his wife the real caufe, abfented himfelf from her company. In the mean time it began to be whifpered at Teefee, that the Bufhreen, who always performed his evening devotion's at the door of the Kafir's hut, was more intimate with the young wife than he ought to be. At firft, the good hufband was unwilling to fufpect the honour of his fanctified friend, and one whole month elapfed before any jealoufy rofe in his mind; but hearing the charge repeated, he at laft interrogated his wife on the fubject, who frankly confeffed that the Bufhreen had feduced her. Hereupon the Kafir put her into confinement, and called a palaver upon the Bufhreen's conduct. The fact was clearly proved againft him; and he was fentenced to be fold into flavery, or to find two flaves for his redemption, according to the pleafure of the complainant. The injured hufband, however, was unwilling to proceed againft his friend to fuch extremity, and defired rather to have him publicly flogged before the governor's gate. This was agreed to, and the fentence was immediately executed. The culprit was tied by the hands to a ftrong ftake; and a long black rod being brought forth, the executioner, after flourifhing it round his head for fome time, applied it with fuch force and dexterity to the Bufhreen's back, as to make him roar until the woods refounded with his fcreams. The furrounding multitude, by their houting and laughing, manifefted how much they enjoyed the punifhment of this old gallant; and it is worthy of remark, that the number of ftripes was precifely the fame as are enjoined by the Mofaic law, *forty*, *fave one*."

Kaffon.

The method of converting the negro nations to the religion of the Arabian Impoftor is a very fingular one; and Mr Park faw the whole people of Teefee converted in an inftant. During his refidence in that town an embaffy of ten people belonging to Almami Abdulkader, king of Foota Torra, a country to the weft of Bondou, arrived at Teefee; and defiring Tiggity Sego the governor to call an affembly of the inhabitants, announced publicly their king's determination, to this effect: "That unlefs all the people of Kaffon would embrace the Mahomedan religion, and evince their converfion by faying eleven public prayers, he (the king of Foota Torra) could not poffibly ftand neuter in the prefent conteft, but would certainly join his arms to thofe of Kajaaga." A meffage of this nature, from fo powerful a prince, could not fail to create alarm; and the inhabitants of Teefee, after a long confultation, agreed to conform to his good pleafure, humiliating as it was to them. Accordingly, one and all publicly offered up eleven prayers, which were confidered a fufficient teftimony of their having renounced Paganifm, and embraced the doctrines of the Prophet.

Our author relates a ftory, which we cannot refufe ourfelves the pleafure of inferting, becaufe it exhibits a very pleafing picture of the affection and gratitude of the Pagan negroes. In his train was a blackfmith, who had lived fome years on the Gambia, and who now returned to his own country *Kaffon*. "Soon after we came in fight of Jumbo, his native town (fays Mr Park), his brother, who had by fome means been apprifed of his coming, came out to meet him, accompanied by a finging man: he brought a horfe for the blackfmith, that he might enter his native town in a dignified manner; and he defired each of us to put a good charge of powder into our guns. The finging man now led the way, followed by the two brothers; and we were prefently joined by a number of people from the town, all of whom demonftrated great joy at feeing their old acquaintance the blackfmith, by the moft extravagant jumping and finging. On entering the town, the finging man began an extempore fong in praife of the blackfmith, extolling his courage in having overcome fo many difficulties; and concluding with a ftrict injunction to his friends to drefs him plenty of victuals.

"When we arrived at the blackfmith's place of refidence, we difmounted and fired our mufkets. The meeting

meeting between him and his friends was very tender; for thefe rude children of nature, free from reftraint, difplay their emotions in the ftrongeft and moft impreffive manner. Amidft thefe tranfports the blackfmith's aged mother was led forth, leaning upon a ftaff. Every one made way for her; and fhe ftretched out her hand to bid her fon welcome. Being totally blind, fhe ftroked his hands, arms, and face, with great care, and feemed highly delighted that her latter days were bleffed by his return, and that her ears once more heard the mufic of his voice. From this interview I was fully convinced, that whatever difference there is between the Negro and European in the conformation of the nofe and the colour of the fkin, there is none in the genuine fympathies and characteriftic feelings of our common nature.

"During the tumult of thefe congratulations, I had feated myfelf apart, by the fide of one of the huts, being unwilling to interrupt the flow of filial and parental tendernefs; and the attention of the company was fo entirely taken up with the blackfmith, that I believe none of his friends had obferved me. When all the people prefent had feated themfelves, the blackfmith was defired by his father to give them fome account of his adventures; and filence being commanded, he began; and after repeatedly thanking God for the fuccefs that had attended him, related every material occurrence that had happened to him from his leaving Kaffon to his arrival at the Gambia; his employment and fuccefs in thofe parts; and the dangers he had efcaped in returning to his native country. In the latter part of his narration he had frequently occafion to mention me; and after many ftrong expreffions concerning my kindnefs to him, he pointed to the place where I fat, and exclaimed, *afille ibi firing*, "fee him fitting there." In a moment all eyes were turned upon me; I appeared like a being dropped from the clouds; every one was furprifed that they had not obferved me before; and a few women and children expreffed great uneafinefs at being fo near a man of fuch an uncommon appearance. By degrees, however, their apprehenfions fubfided; and when the blackfmith affured them that I was perfectly inoffenfive, and would hurt nobody, fome of them ventured fo far as to examine the texture of my clothes; but many of them were ftill very fufpicious; and when by accident I happened to move myfelf, or look at the young children, their mothers would fcamper off with them with the greateft precipitation. In a few hours, however, they all became reconciled to me." With thefe worthy people our author fpent the greater part of two days in feafting and merriment; the blackfmith accompanied him to the capital; and declared, that he would not leave him while he refided there.

KEATE (George, Efq; F. R. S.), defcended of an ancient and honourable family, was born about the year 1729 or 1730, and received his education at Kingfton fchool, under the Rev. Mr Woodefon. From thence he went to Geneva, where he refided fome years; and during his ftay there, became acquainted with Voltaire, with whom he continued to correfpond many years after he returned to England. After finifhing the tour of Europe, he fettled as a ftudent in the Inner Temple, was called to the bar, and fometimes attended Weftminfter Hall; though he did not meet with encouragement enough to induce his perfeverance in his profeffion, nor indeed does it feem probable that he had fufficient application for it. His firft literary performance was "Ancient and Modern Rome," a poem, written at Rome in the year 1755, printed in the year 1760, and received with confiderable applaufe. The next year he publifhed "A Short Account of the Ancient Hiftory, Prefent Government, and Laws, of the Republic of Geneva, 8vo." This work was compiled during the author's refidence at Geneva; is a very ufeful one; and is dedicated to Monfieur de Voltaire; to whom he fays, "When I reflect, that it was in this Republic, whofe government I have attempted to defcribe, that I was firft introduced to your acquaintance; when memory renews the hours of focial mirth and refined entertainment which your hofpitality and converfation afforded me—I cannot but rejoice in this occafion of expreffing my gratitude; proud that, as your friendfhip diftinguifhed the author of thefe pages in a foreign country, your name may at home adorn his labour." It was at one time the intention of Voltaire to tranflate this account into French, though he afterwards relinquifhed the defign.

The next year, 1762, he produced an "Epiftle from Lady Jane Gray to Lord Guildford Dudley:" and in 1763, "The Alps," a poem; the fubject of which comprehends all that chain of mountains known under the general name of the Alps, extending from Italy to Germany, and from France to Tyrol, by whatever denomination they are particularly diftinguifhed. Of all the poetical works of Mr Keate, this is intitled to the higheft praife for truth of defcription, elegance of verfification, and vigour of fancy.

Continuing to employ the prefs, in 1764 he publifhed "Netley Abbey," which he afterwards, in 1769, enlarged and reprinted: and, in 1765, produced "The Temple Student, an Epiftle to a Friend;" humouroufly rallying his own want of application to the ftudy of the law, his preference of the belles lettres, and his confequent want of fuccefs in his profeffion. The death of Mrs Cibber in 1766, of whofe merits as an actrefs he entertained the higheft opinion, gave occafion for a poem to her memory, which celebrates her excellent performances on the ftage, and laments the lofs the theatre would fuftain by her death.

In February 1769, he married Mifs Hudfon; and about the fame time publifhed "Ferney; an epiftle to M. de Voltaire." In this poem, after praifing with energy the various beauties of his friend's poetical works, he introduces the following panegyric on Shakefpeare:

Yes! jealous wits may ftill for empire ftrive,
Still keep the flames of critic rage alive:
Our Shakefpeare yet fhall all his rights maintain,
And crown the triumphs of Eliza's reign.
Above controul, above each claffic rule,
His tut'refs Nature, and the world his fchool,
On foaring pinions borne, to him was given
Th' ærial range of Fancy's brighteft heav'n;
To bid wrapt thought o'er nobleft heights afpire,
And wake each paffion with a mufe of fire.
Revere his genius. To the dead be juft,
And fpare the laurels that o'erfhade the duft.
Low fleeps the bard, *in cold obftruction laid*,
Nor afks the chaplet from a rival's head.
O'er the drear vault, Ambition's utmoft bound,
Unheard fhall Fame her airy trumpet found!

Keate.

Unheard alike; nor grief nor tranfport raife
The blaft of cenfure or the note of praife!
As Raphael's own creation grac'd his hearfe,
And fham'd the pomp of oftentatious verfe,
Shall Shakefpeare's honours by himfelf he paid,
And Nature perifh ere his pictures fade.

This eulogium on Shakefpeare, in an epiftle to Voltaire, who had laboured fo long and fo ftrenuoufly to detract from the merit of our immortal bard, fhews that Mr Keate had not given up his judgment to the fage of Ferney. How the old and envious fophifter would relifh his friend's conduct, may be eafily conceived. His feelings were certainly very different from thofe of the mayor and burgeffes of Stratford, when, in confequence of this panegyric on their townfman, they complimented Mr Keate with a ftandifh, mounted with filver, made out of the famous Mulberry tree planted by Shakefpeare.

In 1775, he publifhed "The Monument in Arcadia," a dramatic poem, built on the picture of Pouffin, mentioned by Abbé du Bos in his "Critical Reflections on Poetry and Painting."

In 1779, Mr Keate produced one of his moft fuccefsful works, entitled "Sketches from Nature; taken and coloured in a Journey to Margate;" 2 vols 12mo. This performance, allowing it to be, as it really is, an imitation of Sterne's "Sentimental Journey;" yet contains fo many pleafing delineations of life, fo many ftrokes of humour, and fo much elegance of compofition, that few will hefitate to give it the preference to any other of Sterne's imitators.

In 1781, he collected his poetical works in two vols, 12mo, and added feveral new pieces not before printed. The principal of thefe was "The Helvetiad," a fragment, written at Geneva in the year 1756. In the preface to this performance he gives the following account of it: "During a long ftay I many years fince made at Geneva, I vifited moft of the principal places in Switzerland. The many fublime fcenes with which nature hath enriched this romantic country; the tranquillity and content with which every individual enjoys his property; and, above all, that independence of mind which is ever the refult of liberty—animated me with fuch veneration for the firft authors of that freedom, whofe figures are recorded to pofterity either by fculpture or painting in the public parts of the towns thro' thofe little ftates, that my enthufiafm betrayed me into a defign of writing a poem on this fingular revolution; the argument of which I had divided into *ten cantos*, beginning the work with the oppreffions of the Houfe of Auftria, and clofing it with the battle of Mongarten; by which thofe injured people finally renounced its ufurpation, and formed among themfelves thofe various confederacies that ended in the great union and alliance of the prefent *thirteen cantons*. When I had fettled the whole plan of this work, I occafionally, as I found a difpofition in myfelf, took up any part of the poem which at the moment moft invited my thoughts: and enjoying at this time fuch an intercourfe with M. de Voltaire as afforded me a conftant accefs to him, I acquainted him with my intention, fhewing him the argument I had drawn out for the conduct of the whole defign. He kept it a few days; and, in returning it, told me, that he thought the great object of the piece, the epifodes connected with the hiftory, together with the fcenery of the country, prefented fubject matter whereon to found a fine poem; "but the time (added he) which fuch an undertaking will require, I would rather counfel you to employ on fubjects that might more engage the public attention; for fhould you devote yourfelf to the completion of your prefent defign, the Swifs would be much obliged to you, without being able to read you, and the reft of the world care little about the matter." Feeling the force and juftnefs of the remark, Mr Keate laid afide his plan, and probably never refumed it. In the fame year, 1781, he publifhed "An Epiftle to Angelica Kauffman."

A few years after, he became engaged in a long and vexatious law-fuit, in confequence of the neglect (to fay the leaft of it) of an architect who profeffed himfelf to be his friend; the particulars of which it is of no importance to detail. At the conclufion of the bufinefs, he fhewed that his good humour had not forfaken him: And in 1787 he gave to the public the principal circumftances of his cafe in a performance, entitled "The Diftreffed Poet, a ferio comic Poem, in three Cantos," 4to, with fome pleafantry, and without any acrimony.

His laft work did infinite honour to his head and his heart, as well as to the liberality of the bookfeller for whom on the title-page it was faid to be publifhed. In the year 1782, the Antelope packet was fhipwrecked on the Pelew iflands, where the commander, Captain Wilfon, and his crew lived fome time before they could get off. On his return to England, the Captain was, for fome reafon or other, refufed the command of another fhip; and, as we have been informed, he was reduced to a ftate much the reverfe of affluence. Thefe circumftances being communicated to Mr Keate, who was ftruck with admiration of the manners of the inhabitants of the Pelew iflands (fee Pelew Islands, *Encycl.*), he offered to draw up, for the benefit of Captain Wilfon, a narrative of the occurrences which took place during that officer's refidence among fo fingular a people. This he executed in "An Account of the Pelew Iflands, fituated in the Weftern Part of the Pacific Ocean: compofed from the Journals and Communications of Captain Henry Wilfon and fome of his Officers, who in Auguft 1783 were there fhipwrecked, in the Antelope, a Packet belonging to the Honourable the Eaft India Company," 4to; a work written with great elegance, compiled with much care, and which, if embellifhed (as it has been infinuated) with facts better calculated to have found a place in a novel than a genuine narrative, muft be afcribed to the mifinformation of thofe who were actors in the fcene, and muft firft have deceived before they obtained credit. We mention this report as it has come to us, without any attempt either to eftablifh or refute it. We fhall only add, that if the charge is well founded, Mr Keate (who undertook the tafk on the moft difinterefted principle, and derived no advantage whatever from the work) was too fturdy a moralift to have had any hand in the impofition.—The manufcript was offered to Mr Dodfley for 300 guineas; but he hefitated to give for it fo large a price, when another bookfeller undertook to publifh the work for the benefit of Mr Wilfon; and, we have reafon to believe, paid to that gentleman, within the compafs of a year, triple the fum for which the manufcript had been offered to Dodfley. Such conduct reflects honour on the London trade.

Befides

Besides the pieces already mentioned, Mr Keate was the author of many Prologues and Epilogues, spoken at Mr Newcomb's school at Hackney. He adapted his friend Voltaire's "Semiramis" to the stage; but this was superseded in 1777 at Drury Lane, by a worthless translation of as worthless an author, one Captain Ayscough; but neither this nor the author are deserving of any further notice.

We shall conclude by observing, that Mr Keate's life passed without any vicissitudes of fortune; he inherited an ample estate, which he did not attempt to increase otherwise than by those attentions which prudence dictated in the management of it. He was hospitable and beneficent, and possessed the good-will of mankind in a very eminent degree. For the last year or two, his health visibly declined; but on the day he died, it appeared to be somewhat mended. His death was sudden, on the 27th of June 1797. He left one daughter, married in 1796 to John Henderson, Esq; of the Adelphi. At the time of his death, Mr Keate was a Bencher of the Temple, and a very old member of the Royal and Antiquary Societies, of both of which he had been frequently elected one of the council.

KENNICOTT (Dr Benjamin) was a man of such eminence in the learned world, that every thing relating to him must be generally interesting. In the biographical sketch of him published in the *Encyclopædia*, we have acknowledged ourselves unacquainted with the rank and character of his parents; but this information has been since supplied by a very candid and well-informed writer in the Monthly Magazine; and as it is accompanied with circumstances peculiarly honourable to the Doctor, and ought therefore to be preserved, we shall insert it in this place.

"The parents of Dr Kennicott (says this writer) were honest characters: His father was the parish-clerk of Totness, and once master of a charity school in that town. At an early age young Kennicott succeeded to the same employ in the school, being recommended to it by his remarkable sobriety and premature knowledge. It was in that situation he wrote the verses to the honourable Mrs Courtney, which recommended him to her notice, and that of many neighbouring gentlemen. They, with laudable generosity, opened a subscription to send him to Oxford.

"He soon there distinguished himself, as is well known. As a testimony of the truth of the above statement, the following is a copy of an inscription written by Dr Kennicott, and engraved on the tomb of his father and mother. The writer of this article has transcribed it from the original in the church-yard of Totness. The tomb is more elegant than persons in their situation are accustomed to have erected, and was thought, perhaps, by the envious to be somewhat ostentatious. A personal knowledge of the Doctor induces the writer of this article to think, that it was rather the tribute of a good and grateful mind, and of the pious reverence and love which he entertained for the authors of his being.

As Virtue should be of good report,
sacred
be this humble Monument
to the Memory of
BENJAMIN KENNICOTT, Parish Clerk of Totness,
and ELIZABETH his Wife:
The latter
an Example of every Christian Duty;
The former,
animated with the warmest Zeal,
regulated by the best good sense,
and both constantly exerted
for the Salvation of himself and others.
Reader!
Soon shalt thou die also;
and as a Candidate for Immortality
strike thy breast and say,
Let me live the life of the Righteous,
that my last end may be like his.
Trifling are the dates of Time
where the subject is Eternity.
Erected
by their Son, B. Kennicott, D. D.
Canon of Christ-Church, Oxford.

"It is said, that when Dr Kennicott had taken orders, he came to officiate in his clerical capacity in his native town. When his father as clerk proceeded to place the surplice on his shoulders, a struggle ensued between the modesty of the son and the honest pride of the parent, who insisted on paying that respect to his son which he had been accustomed to shew to other clergymen: to this filial obedience was obliged to submit. A circumstance is added, that his mother had often declared she should never be able to support the joy of hearing her son preach; and that on her attendance at the church for the first time, she was so overcome as to be taken out in a state of temporary insensibility."

KERMES (see *Coccus Ilicis*, Encycl.) has been proved by Professor Beckmann to have been used as a dye from very remote antiquity. "All the ancient Greek and Latin writers, he says, agree, that kermes, called by the latter *coccum*, perhaps also *coccus*, and often *granum*, were found upon a low shrubby tree, with prickly leaves, which produced acorns, and belonged to the genus of the oak; and there is no reason to doubt that they mean *coccum ilicis*, and that low ever-green oak, with the prickly leaves of the holly (*aquifolium*), which is called at present in botany *quercus ilex*. This assertion appears more entitled to credit, as the ancients assign for the native country of this tree places where it is still indigenous, and produces kermes.

The use of kermes in dyeing seems to have been continued through every century. In the middle ages, as they are called, we meet with kermes under the name of *vermiculus* or *vermiculum*; and on that account cloth dyed with them was called *vermiculata*. Hence the French word *vermeil*, and its derivative *vermilion*, as is well known, had their extraction; the latter of which originally signified the red dye of kermes, but it is now used for any red paint, and also for fine pounded cinnabar.

KHAS, in Bengal, lands taken into the hands of government, opposed to the management of Zemindars or farmers. See ZEMINDAR in this *Supplement*.

KHALSA, in Bengal, sometimes with the addition of *Shereefah*, the department of land and revenues; the exchequer.

KHERAJE, in Bengal, signifies strictly the tribute paid by a conquered country: it is also used for revenue in general.

KHIDMUT,

KHIDMUT, office, attendance, employment, service.

KHIDMUTGAR, a waiting man.

KHISMUT, portion or division.

KHOMAR, or Comar, a Zemindar's demesne land.

KING-Post, or King-*Piece*, is a piece of timber set upwright in the middle, between two principal rafters, and having struts or braces going from it to the middle of each rafter. See Roof, *Encycl.*; and Carpentry, *Suppl.*

KIPPIS (Andrew, D. D. F. R and A. S.), was born at Nottingham, March 28 (O. S) 1725. His father, a respectable tradesman of that town, was descended from the Rev. Benjamin King of Oakham, Rutlandshire, an ejected minister; and his mother, Ann Ryther, was the grand-daughter of the Rev. John Ryther, who was ejected from the church of Fernby, in the county of York. In the year 1730, he lost his father, and went to reside with his grandfather, Andrew Kippis of Seaford in Lincolnshire. He received his classical education at the grammar school in that town; but what contributed most to his future eminence, was the friendship of the Rev. Mr Merrival, who was equalled by few of his contemporaries in various branches of learning, particularly in his acquaintance with the classics, his knowledge of ancient and modern history, and his refined taste in the belles lettres. Dr Kippis frequently said, that it was impossible for him to express his obligations to this friend of his youth. In 1741 he removed to Northampton, and commenced his academical studies under Dr Doddridge. After a residence of five years at the academy, he was invited by several congregations to become their minister. Though he was pressed to settle at Dorchester, and had been chosen their minister, he gave the preference to an invitation from Boston in Lincolnshire, where he went to reside in September 1746. Here he continued four years; and in November 1750, accepted the pastoral charge of a congregation at Dorking in Surry. The congregation meeting in Princes-Street, Westminster, having been without a minister about two years, he was chosen, in June 1753, to succeed the Rev. Dr Obadiah Hughes. On the 21st of September following, he married, at Boston, Miss Elizabeth Bott, one of the daughters of Mr Isaac Bott, a merchant of that place; and in the month of October fixed his residence in Westminster. In June 1767, he received the degree of D. D. from the university of Edinburgh, on the unsolicited recommendation of the late learned Professor Robertson. He was elected a member of the Society of Antiquaries on the 19th of March 1778; and on the 17th of June 1779, he was chosen a fellow of the Royal Society. In both Societies he had the honour of being in the council two years.

Dr Kippis was eminently distinguished for the virtues and accomplishments which form the chief ornaments of private life. With a suavity of manners and urbanity of behaviour peculiarly attractive, he united that knowledge of men and books which rendered his conversation uncommonly entertaining and instructive to the circle of his acquaintance and friends. As a minister, he was not less eminent for his profound acquaintance with every branch of theology than for the happy manner in which he applied it to the improvement of those who attended his ministry. His sermons were remarkable for perspicuity, elegance, and energy; and his elocution was unaffected and very impressive, particularly at the close of his discourses. But the superior powers and vigour of mind which he derived from nature, and which he had cultivated with unremitting diligence and peculiar success, were not to be confined to the narrow limits of private life and the duties of the pastoral charge, however important; they were designed for more extensive and important services to his country and to mankind. The interests of literature, science, and religion, have received from the exertion of his talents as a writer the most essential advantages. His first efforts in literature were made in the Gentleman's Magazine, a periodical publication called the Library, and the Monthly Review; to each of which he contributed many important articles, especially in the historical and philological departments of the last. He was the author of three important tracts, viz. "A Vindication of the Protestant Dissenting Ministers, &c." "Observations on the late Contests in the Royal Society;" and "Considerations on the Treaty with America, &c." His improved edition of Dr Doddridge's Lectures is a work of great value; and "The History of Knowledge, Learning, and Taste, in Great Britain," prefixed to the New Annual Register, merits, and has received, the approbation of the public. He published at different times several single sermons; among which, that on the death of his friend the Rev. Mr Laugher, is intitled to very high praise. The greater part of these he republished, with other practical discourses, in the year 1794: but the work which, next to the studies immediately connected with his office as a Christian minister, engaged his principal attention, and by which he has long been distinguished, is, the improved edition of the "*Biographia Britannica.*" In this great national publication, the comprehensiveness and powers of his mind, the correctness of his judgment, the vast extent of his information, his indefatigable researches and unremitting assiduity, his peculiar talent of appreciating the merits, and analyzing the labours of the most eminent writers, and his unshaken integrity, unbiassed fidelity, and impartial decision on the characters of the philosopher, statesman, poet, scholar, and divine, are strongly displayed, and universally acknowledged. His style, formed on the models of Sir William Temple and the classical Addison, is remarkable for its perspicuity, elegance, and purity; and gives a peculiar lustre to the rich stores of knowledge treasured in the volumes now published. This work has given him a high rank among the literati of his country, and will carry down his name with distinguished reputation to posterity. He died on the 8th October 1795.

KLIP-Springer. See Kainsi, *Suppl.*

KOL Quall, the Abyssinian name of a tree, which some botanists have supposed to be the Euphorbia *Officinarum* of Linnæus. Mr Bruce, who gives the only description of the Kol-quall that we have seen, is of a different opinion: for which he assigns two reasons; the first is, that the flower, which he says is rosaceous, is composed of several petals, and is not companiform; and the second, that it produces no sort of gum, either spontaneously or upon incision. We must acknowledge, that we entertain some doubts whether our author was at due pains to ascertain this fact; and these doubts are suggested by his own history of the tree. His

His defcription is not very perfpicuous, and therefore, left we fhould mifreprefent his meaning, we fhall give it in his own words:

"The firft thing that prefented itfelf was the firft fhoot of this extraordinary tree. It was a fingle ftalk, about fix inches meafured acrofs, in eight divifions, regularly and beautifully fcolloped and rounded at the top, joined in the centre at three feet and a half high. Upon the outfide of thefe fcollops were a fort of eyes or fmall knots, out of every one of which came five horns, four on the fides and one in the centre, fcarce half an inch long, fragil, and of no refiftance, but exceedingly fharp and pointed. Its next procefs is to put out a branch from the firft or fecond fcollop near the top, others fucceed from all directions; and this ftalk, which is foft and fucculent, of the confiftence of the aloe, turns by degrees hard and ligneous, and after a few years, by multiplying its branches, affumes the form of a tree, the lower part of which is wood, the upper part, which is fucculent, has no leaves; thefe are fupplied by the fluted, fcolloped, ferrated, thorny fides of its branches. Upon the upper extremity of thefe branches grow its flowers, which are of a golden colour, rofaceous, and formed of five round or almoft oval petala; this is fucceeded by a triangular fruit, firft of a light green with a flight caft of red, then turning to a deep crimfon, with ftreaks of white both at top and bottom. In the infide it is divided into three cells, with a feed in each of them; the cells are of a greenifh white, the feed round, and with no degree of humidity or moifture about it; yet the green leaves contain a quantity of bluifh watery milk almoft incredible.

"Upon cutting two of the fineft branches of a tree in its full vigour, a quantity of this iffued out, which I cannot compute to be lefs than four Englifh gallons; and this was fo exceedingly cauftic, that though I wafhed the fabre that cut it immediately, the ftain has not yet left it.

"When the tree grows old, the branches wither, and, in place of milk, the infide appears to be full of powder, which is fo pungent, that the fmall duft which I drew upon ftriking a withered branch, feemed to threaten to make me fneeze to death, and the touching of the milk with my fingers excoriated them as if fcalded with boiling water; yet I everywhere obferved the wood-pecker piercing the rotten branches with its beak, and eating the infects, without any impreffion upon its olfactory nerves."

If what is milk in a young tree be a dry powder in one that is old, is it not probable that the milk might by evaporation be reduced to the confiftence of gum, and that the kol-quall may be at moft but a variety of the *euphorbia officinarum?* From our author's obfervation, the kol-quall appeared to thrive beft on poor, fandy, ftony earth, at no great diftance from the fea. The Abyffinians employ the milky juice in tanning to take off the hair from the fkins, and they make no other ufe whatever of the tree.

KOONA, a fpecies of ECHITES (for which fee *Encycl.*), very common in the woods of North Africa. It is a fhrub, of which the leaves, when boiled with a fmall quantity of water, yield a thick black juice, into which the negroes dip a cotton thread. This thread they faften round the iron of their arrows, in fuch a manner that it is almoft impoffible to extract the arrow when it has funk beyond the barbs, without leaving the iron and the poifoned thread in the wound. The poifon of the koona is faid to be very deadly.—*Park's Travels.*

KORAQUAS, a tribe of Hottentots inhabiting a diftrict of South Africa, which M. Vaillant places on the confines of the Nimiqua country (See NIMIQUAS, *Suppl.*). When our author vifited them, the whole tribe was affembled for the election of a chief: and not agreeing among themfelves, fome blood had been fhed, and much more would have been fhed, had they not unanimoufly made choice of him. When he firft joined them, the whole horde paid attention to nothing but their quarrel. To fee their warmth, one might have fuppofed that their election was a matter of importance to the whole world, and that the fate of mankind was about to depend on their chief. All fpoke at the fame time; each endeavoured to drown his neighbour's voice by his own; their eyes fparkled with fury; and amidft this confufion, while they threatened each other in turns, the noife they made became truly dreadful.

Unarmed, and without any precaution, though furrounded by this enraged multitude, our author walked calmly along in the midft of them; and when he reached the kraal, he ordered his tent to be immediately formed, as if he had been furrounded by friends and relations. This appearance, raifed fuddenly, and as if by magic, before the eyes of the horde, with his fufees, horfes, and tent, objects which were all new to them, filled them with admiration. Men, women, and children, motionlefs, and with their mouths wide open, all ftood looking at them with profound filence. Anger, hatred, and every violent paffion, feemed by their countenances to be extinguifhed, and to have given place to more tranquil emotions, to ignorant furprife, and ftupid aftonifhment. Infancy is naturally curious; it is ftruck with every thing it fees; and the favage, in this refpect, is only a grown-up child. As thefe favages feemed to wifh that he would permit them to examine more clofely whatever excited their admiration, he readily condefcended to gratify their defire. They approached, furveyed, and handled every thing. But the principal object of general curiofity was his perfon. They feemed as if they would never be fatisfied with looking at his drefs. They pulled off his hat, that they might the better examine his hair and his beard, which were long. They even half unbuttoned his clothes; and furprifed to fee his fkin white, each felt it, as if defirous to afcertain that what they faw was real.

This comedy continued till the evening; and at length, when the moment of feparation arrived, M. Vaillant caufed to be hinted to the whole company, that if, two hours after fun rife next morning, they fhould not be agreed refpecting the choice of a chief, he would immediately leave them. He added, however, that if, on the other hand, they came and prefented to him a chief, elected by general confent, he would then load them all with prefents, and beftow on him a diftinction which would raife him above all his equals, and render the horde one of the moft celebrated in the whole country. "But what was my furprife (fays he) when I learned the fame evening, that on my head the burden of the crown was depofed!" He acquiefced, however; affuring them, that if they would promife to be obe-

dient,

dient, he would give them the only chief worthy of ruling them, and of making them happy.

By his interpreters he had learned, that the choice of the majority leaned towards one Haripa, a man about 40 years of age; tall, well made, exceedingly ſtrong, and conſequently formed by nature for ruling the feeble multitude. He therefore named Haripa chief; and the people appearing to approve of his choice, he commanded ſilence, and cauſing the new monarch to approach, placed on his head, with great ſolemnity, a Dutch grenadier cap, of which the copperplate on the front was ornamented with the arms of Holland. This ſymbol *viz.* a lion rampant, having in one of his fore-paws ſeven arrows, and in the other a naked ſabre, could not fail to pleaſe the ſavages, as it exhibited a repreſentation of the weapons peculiar to them, and of the moſt formidable animal of their country. They teſtified their admiration in the moſt expreſſive manner; and imagined that, ſuperior to kings, the white man during the night had by magic made this crown, merely to adorn their chief, and to afford them pleaſure. Vaillant then affixed to the ſkin, which formed Haripa's dreſs, ſeveral rows of glaſs beads; gave him a girdle made of a ſtring of very large ones; ornamented his arms with tin bracelets, and ſuſpended from his neck a ſmall padlock, ſhaped like a butterfly, the key of which had been loſt. Such padlocks, made in the form of animals of every kind, are very common at the Cape. They come from China; and are brought to Africa by the captains of the Company's ſhips which trade in the Indian ſeas.

During the ceremony of inſtallation, the whole horde, dumb and motionleſs through admiration, ſeemed loſt in ecſtacy. Haripa himſelf, though highly gratified, did not dare to make the leaſt movement, and obſerved a gravity altogether riſible. When the inauguration was finiſhed, and he was completely dreſſed, our author preſented him with a mirror, that he might enjoy the ſatisfaction of ſurveying his own figure. He then ſhewed him to the people, who expreſſed their joy by ſhouts and applauſes without end.

" Ye honeſt hearts (ſays M. Vaillant), who peruſe this account, behold what it coſt me to reſtore peace among a whole tribe, and to prevent them from deſtroying each other!" From this moment concord was reeſtabliſhed; univerſal joy prevailed through the horde; and they inſtantly began their dancings, which continued for three days and three nights without intermiſſion. They killed for this feſtival ſeveral fat ſheep, and even two oxen; an extraordinary and truly aſtoniſhing magnificence among a people who, when they barter one of their daughters for a cow, think they have made an excellent bargain.

Our author, wiſhing to purchaſe ſome oxen for his waggons, bought them at the price of a nail the ox; and thoſe who had the good fortune to make ſuch an exchange were highly ſatisfied with their bargain. Nails and ſmall bits of iron were indeed of real value to them, to point the arrows and aſſageys with which they ſhot the antelopes that abound in their country, and conſtitute much of their food. Like other ſavages, the Koraquas were ready to pilfer, and appropriate to their own uſe whatever they found pleaſing, or ſuited to their purpoſes. They attempted to carry away ſome of our author's effects, even before his face; and to prevent their rapacity, he was obliged either to watch over, or to depoſit them in ſome place of ſafety.

The Koraquas are much taller than the Hottentots of the colonies, though they appeared evidently to be deſcended from the ſame race, having the ſame language and cuſtoms with their neighbours the NIMIQUAS (ſee that article), who are certainly of Hottentot extraction.

As the exceſſive dryneſs of the country renders ſprings very rare, the Koraquas would be unable to inhabit it, had they not found the means of remedying this ſcarcity of water. For this purpoſe they dig in the earth a kind of ciſterns or rather wells, to which they deſcend gradually by ſteps; and theſe people are the only African nation among whom our author ever found the ſame mark of induſtry.

As their wells always contain little water, and as none is to be loſt, they take care to ſecure it even from the birds, by cloſing up the mouth of the hole with ſtones and the branches of trees; ſo that, unleſs one knows the ſpot, it is impoſſible to find it. They go down into it every day, to fetch up as much water as may be neceſſery for the conſumption of their people and cattle. They draw it in a kind of veſſels made of hollowed wood, and pour it into the ſkins of buffaloes or giraffes, placed in a concave form on the ground to hold it; but they diſtribute it with the utmoſt parſimony, and never draw more than they abſolutely have occaſion for.

Notwithſtanding this ſtrict economy, the wells often become dry; and in that caſe the horde is obliged to remove to ſome other place. Among all the weſtern tribes, therefore, there are none who lead ſo wandering a life as the Koraquas: the conſequence of which is, that, as they often change their abode, and acquire new neighbours, they muſt, in ſome meaſure, adopt the cuſtoms of the nations near which they fix their reſidence. Some tribes of them greaſe themſelves like the Hottentots; while others tattoo their face, breaſt, and arms, after the manner of the Caffres. It is, however, to be remarked, that the ſame colour is not employed by all the Koraquas; each has his own, according as caprice may direct him in his choice, and it generally varies every day; which renders, as one may ſay, the inhabitants of the ſome horde ſtrangers to each other, and gives them a motley appearance, as if they were dreſſed for a maſquerade.

KRISHNA or CRISNA, is an eaſtern river of conſiderable magnitude, which is very little known in Europe. We have the following account of it, and its tributary waters, and the countries through which it flows, in Mr Pennant's view of Hinduſtan:

" From Gangapatam, on the northern mouth of the Pennar, the land runs due north as far as Mottapilli, when it forms a ſtrong curve toward the eaſt; the point of which is one ſide of the great river Criſna, in about lat. 15° 43'. Its Delta, which winds round as far as Maſulipatam, is not conſiderable. This river annually overflows a vaſt tract of country, like the Indus on the weſtern ſide of this empire, and like all the other great rivers on this extenſive coaſt. The Criſna riſes from the foot of the weſtern Ghauts, and not more than 45 miles from Severndrug, on the weſtern coaſt. There is another branch to the eaſt, that riſes ſtill more northerly. On that ſide is Sattara, a ſtrong fortreſs, the capital of the Mahratta ſtate in the time of the rajahs of

Krishna. Sivaji's race. It was taken by him in 1673, and found to be the depofitory of immenfe treafure; at that time it belonged to the king of Vijapur: it was afterwards ufed by the Mahrattas as the lodgment of their riches, and alfo as a retreat for the more defencelefs inhabitants of Puna, and other open towns, in time of potent invafions.

" The river continues defcending to the eaft. In latitude 17° is Meritch, a ftrong fortrefs, with a Jaghirdar territory, conquered from its owner by Hyder. In lat. 16° 45′, a fmall river difcharges itfelf into the Crifna from the north. It would not be worth mentioning, but that Pannela, a fortrefs of vaft ftrength, was made by Sumbuji, the profligate fon of Sivaji, his refidence juft before his furprifal in 1689, betrayed by Cablis Khan, the vile inftrument of his pleafures, corrupted by Aurengzebe. His extravagant love of women brought on him ruin. Informed by Cablis that a Hindu of rank and great beauty was on the road to be delivered by her parents to her hufband, according to the cuftom of the Hindus, he inftantly put himfelf at the head of a fmall body of horfe to carry off the prize, and ordered Cablis to follow at a diftance for his protection, in cafe of accidents in that hoftile time. The traitor had given notice to Aurengzebe of this expedition, who, fending a body of cavalry, furprifed Sumbuji juft as he had difperfed the nuptial proceffion.

" Into the north fide of the Crifna, in lat. 16° 20′, falls the great river Bima, after a courfe of 350 miles. It rifes at the head of the weftern Ghauts, parallel to Chaul in the Concan, and not above 50 miles from the fea. It defcends rapidly towards the fouth-eaft. In lat. 17° 40′ it receives a fmall river from the weft, on the fouthern banks of which ftands Vijapur, the capital of the famous kingdom of the fame name, now poffeffed by the Mahrattas, but once governed by its own monarchs, till conquered by Aurengzebe in 1686. It was of great extent, and reached to the weftern fea, where it poffeffed the ports of Dabul, Vingorla, and Carapatan.

" The capital Vijapur is fome leagues in circuit, feated in a fine but naked country, well watered. It makes a fingular appearance from an adjacent eminence, filled with numbers of fmall domes, and one of a majeftic fize. It was once a city of great fplendour, and filled with palaces, mofques, maufoleums, and public and private buildings of great magnificence; many of them are fallen to ruin, and give melancholy proofs of its former fplendour. I fhall not attempt to detail them. The palaces of the kings, and accommodations for their attendants, were within a vaft fort, furrounded with a ditch 100 yards wide; the depth appeared to be great, but is now filled with rubbifh: within the fort is the citadel. Tavernier fays, that the great ditch was filled with crocodiles, by way of garrifon, to prevent all accefs by water. Lieutenant Moor has his doubts about this, imagining that there never was any water in this fofs. That fuch garrifons have exifted I doubt not. I have read in Purchas, that in Pegu the foffes of fortified places were ftocked with thofe tremendous animals, not only to keep out enemies, but to prevent defertion. This practice has certainly been of great antiquity in fome parts of India: Pliny mentions it as ufed in a fair city of the Horatæ, a people I cannot trace.

" The Crifna, above and below its conflux with the Bima, is fordable; and a few miles below its channel is 600 yards wide, made horrid with the number and rudenefs of the varioufly formed rocks, which are never covered but in the rainy feafon. Krifhna, Kuara.

" The Tungbuddra is another vaft branch of the Crifna. It falls into it in lat. 16° 25′, and originates extremely fouth, from a doubtful fountain. Towards its lower part it divides into three or four fmall branches, which rife remote from each other; the moft fouthern is the Curga Nair's country; the moft northern from the head of the Ghauts oppofite to Onor, and fcarcely 20 miles from the fea. What muft give this river great celebrity, is its having had on its banks, in lat. 15° 22′, the fplendid city of Vijanagar. Ferifhta fays, that it was founded in 1344 by Belaldeo king of the Carnatic, which in thofe days included the whole peninfula. It was vifited by Cæfar Frederick a Venetian travellar, in 1565, and found deferted and ruinous, having been facked by four confederated Mahomedan princes two years before, on which its monarch had retired to Penuconda. Frederick fays that its circumference was 24 miles. Mr Rennel has given us a view of its prefent ftate from Lieutenant Emitt, who vifited it in 1792.

" The ruins of Vijanagar are in the little Sircar of Anagundi, which does not extend above 20 miles around this vaft city. It is very fingular that that little Sircar is now poffeffed by a lineal defcendant of Rama Rajah, the laft great monarch of Vijanagar, and its attendant nations Canarine and Malabar, united 700 years before under the rule of Crifna Deva. Tippu wifhed to referve this little tract to himfelf, for the fatisfaction of generoufly reftoring to the defcendant the fmall relique of the great empire of his anceftors. He is denied the title of Rajah; inftead of which he has the diminutive Rail beftowed on him. This is fuitable to his revenues, which do not exceed two lacs of rupees, or 25,000 *per annum*, with the empty regality of a mint at Anagundi." In the remainder of its courfe the Crifna offers nothing remarkable.

KUARA, is a beautiful tree, which grows in the fouth and fouth-weft parts of Abyffinia. With the ebony it is almoft the only wood of the province of Kuara, of which it bears the name; but Mr Bruce affures us, that it is very frequent in all the countries where there is gold. " It is (fays he) what naturalifts call *a Corallodendron*, probably from the colour of its flowers or of its fruit, both equal in colour to coral. Its fruit is a red bean, with a black fpot in the middle of it, which is inclofed in a round capfula or covering, of a woody nature, very tough and hard. This bean feems to have been in the earlieft ages ufed for a weight of gold among the Shangalla, and, where that metal is found, all over Africa; and by repeated experiments, I have found that, from the time of its being gathered, it varies very little in weight, and may perhaps have been the very beft choice that therefore could have been made between the collectors and buyers of gold.

" I have faid this tree is called kuara, which fignifies the fun. The bean is called *carat*, from which is derived the manner of efteeming gold as fo many carats fine. From the gold country in Africa it paffed to India, and there came to be the weight of precious ftones, efpecially diamonds; fo that to this day in India we hear it commonly fpoken of gold or diamonds, that they are of fo many carats fine or weight. I have feen

Kumi.

these beans likewife from the Weft-Indian iflands. They are juft the fame fize, but, as far as I know, are not yet applied to any ufe there."

This is a very different account from the origin of the term Carat from what we have given in the *Encyclopædia*; but the reader will judge for himfelf between the two.

KUMI, the name of an ifland between Japan and China, of which Peroufe writes in the following terms: "On the 5th of May, at one o'clock in the morning, we made an ifland, which bore north north-eaft of us; we paffed the reft of the night, ftanding off and on, under an eafy fail, and at day-break I fhaped my courfe fo as to run along the weft coaft of this ifland, at the diftance of half a league. We founded feveral times without finding bottom. We were foon fatisfied that this ifland was inhabited, for we faw fires in feveral places, and herds of oxen grazing on the fea-fhore. When we had doubled its weft point, which is the moft beautiful and beft inhabited fide, feveral canoes put off from the fhore in order to obferve us. They feemed to be extremely in fear of us; their curiofity caufed them to advance within mufket fhot, and their diftruft made them immediately flee away with fpeed. Our fhouts, geftures, figns of peace, and the fight of fome ftuffs, at length determined two of the canoes to come alongfide of us. I made each of them a prefent of a piece of nankeen and fome medals. It was evident that thefe iflanders had not left the coaft with any intention of trafficking with us, for they had nothing to offer in exchange for our prefents; they only faftened to a rope a bucket of frefh water, making figns to us, that they ftill thought themfelves in our debt, but that they were going afhore to fetch provifion, which they expreffed by putting their hand into their mouth. Before coming alongfide the frigate, they placed their hands upon their breaft, and raifed their arms towards the fky: thefe geftures were repeated by us, and then they refolved to come on board; but it was with a want of confidence, which was ftrongly expreffed in their countenance during the whole time. They neverthelefs invited us to approach the land, giving us to underftand, that we fhould there want for nothing. Thefe iflanders are neither Japanefe nor Chinefe, but, fituate between thefe two empires, they feem to partake of both people. Their covering was a fhirt and a pair of cotton drawers. Their hair, tucked up on the crown of the head, was rolled round a needle, which feemed to us to be gold: each of them had a dagger, the handle of which wes gold alfo. Their canoes were made out of hollowed trees, and they managed them very indifferently. I could have wifhed to land upon this ifland; but as we had brought the fhip to, in order to wait for thefe canoes, and as the current fet to the northward with extreme rapidity, we had drifted a great way to leeward, and our efforts to reach it would perhaps have been in vain: befides, we had not a moment to lofe, and it was of the higheft importance to us to get out of the Japan feas before the month of June; a period of ftorms and hurricanes, which render thefe feas the moft dangerous in the whole world.

"It is clear, that veffels which might be in want would readily provide themfelves with provifion, wood, and water, in this ifland, and perhaps even carry on a little trade; but as it is not more than three or four leagues in circumference, there is no great probability that its population exceeds four or five hundred perfons; and a few gold needles are not of themfelves a proof of wealth." Our author, by obfervation, found the latitude of Kumi to be 24° 33′ north; its longitude 120° 56′ eaft from Paris.

Kuriles.

KURILES, are a clufter of iflands, of which fome account has been given under the word Kuril, in the *Encyclopædia*. In addition to that article, the following particulars are worthy of notice: Of the 21 iflands belonging to Ruffia, which are diftinguifhed from each other, not by names but by numbers, four only are inhabited, viz. thofe which are called the firft, the fecond, the thirteenth, and the fourteenth. The laft two may indeed be counted only as one, becaufe the inhabitants all pafs the winter upon N° 14, and return to N° 13 to pafs the fummer months. The others are entirely uninhabited, the iflanders only landing there occafionally from their canoes for the fake of hunting foxes and otters. Several of thefe laft mentioned iflands are no better than large rocks, and there is not a tree on any one of them. The currents are very violent between the iflands, particularly at the entrance of the channels, feveral of which are blocked up by rocks on a level with the fea. The population of the four inhabited iflands amounts at moft to 1400 fouls. The inhabitants are very hairy, wear long beards, and live entirely upon feals, fifh, and the produce of the chace. When vifited by M. Peroufe, they had juft been exempted for ten years from the tribute ufually paid to Ruffia, becaufe the number of otters on their iflands is very much diminifhed. Thefe poor people are good, hofpitable, and docile, and have all embraced the Chriftian religion. The more fouthern and independant iflanders fometimes pafs in canoes the channels that feparate them from the Ruffian Kuriles, in order to give fome of the commodities of Japan in exchange for peltries.

L.

Labdaffeba.

LABDASSEBA, a tribe of favage Arabs who inhabit the defart of Sahara in Africa. They are the moft powerful of all thofe tribes except the Ouadelims; and they refemble thefe fo much in every thing, that we fhall give an account of the manners of both under the title Ouadelims, and of their country under that of Sahara.

Laboratory.

LABORATORY, is an apparatus fo neceffary to the

Laboratory.

the chemift, that every contrivance to render it more convenient, or to leffen the expence of it, muft contribute greatly to the advancement of fcience. The abilities of *Morveau* alias *Guyton*, and the fuccefs with which he has profecuted the ftudy of chemiftry, are well known; and therefore his different methods of faving time and expence in making chemical experiments muft be worthy of the notice of younger chemifts.

In the fecond volume of the memoirs of the Ancient Academy of Dijon, we have a defcription by him of a box containing a kind of portable laboratory, compofed of a lamp with three wicks, difpofed in the figure of an equilateral triangle, to form an internal current of air, with fupports for the different veffels of digeftion, diftillation, evaporation, &c. He made a folution of filver with common aqua fortis and the metal in an alloyed ftate, which anfwered very well as a re-agent, without having occafion for any other utenfils but this box and apothecary's phials, which are everywhere to be found.

This apparatus, however, was confined in its application, and he foon thought of improving it. He conftructed a lamp, on the principles of Argand, with three concentric circular wicks, each having an interior and exterior current of air. The effect furpaffed his expectations with regard to the intenfity of the heat; but it was difficult to prevent the deftruction of the hard folder round the wicks; and the glafs retorts were frequently melted at the bottom, and disfigured. It was attended with other inconveniences, and the quantity of oil confumed was great.

A fhort time afterwards, it occurred to him to fubftitute, inftead of the glafs chimney of Argand's lamp, a cylinder of copper with an indented part or ledge a few millimetres (fee Revolution, *Encycl.* n° 183.) above the flame, to perform the office of the indented chimney of glafs, and by that means to render it practicable to raife the wick to a certain height without fmoaking. This cylinder has three branches like a chaffing-difh. By this apparatus two or three decilitres of water (about half an Englifh wine pint) may be brought to boil in a copper or glafs veffel in about fix or feven minutes. It has ferved for a number of operations; but it was not till after he had obferved the degree of heat obtained from the lamp in its ordinary ftate, and particularly fince he had fubftituted inftead of the metallic tube a chimney of glafs cut off at the length of three centimetres (rather more than one Englifh inch) above the contraction, that he perceived all the advantages it was capable of affording; and that by means of a moveable fupport for the reception of the different veffels, which may be fixed at pleafure by a thumb-fcrew, this lamp furnace, at the fame time that it gives light, and confequently without any additional expence, may with facility be ufed for almoft every one of the operations of chemiftry; fuch as digeftions, folutions, cryftallizations, concentrations; the rectification of acids; diftillations on the fand-bath, or by the naked fire; incinerations of the moft refractory refidues; analyfes with the pneumatic apparatus, or of minerals by the faline fufion, &c. "I have not (fays he) hitherto met with any exception but for complete vitrifications and cupellations; for even the diftillations to drynefs may be performed with fome precautions, fuch as that of transferring the matter into a fmall retort blown by the enameller's lamp, and placing its bottom on a little fand-bath in a thin metallic difh." The fupport here mentioned is fimply a copper ring eight centimetres (3,15 inch.) in diameter, which is raifed or lowered by fliding on a ftem of the fame metal. Nothing more was required but to adapt it to the fquare iron ftem which paffes through the refervoir of the lamp. The connection is made by a piece of wood, in order that lefs of the heat might be difperfed. As the lamp itfelf is capable of being moved on its ftem, it is eafy to bring it nearer or remove it at pleafure from the veffels, which remain fixed; a circumftance which, independent of the elevation or depreffion of the wick, affords the means of heating the retorts by degrees, of moderating or fuppreffing the fire inftantly, or of maintaining it for feveral hours at a conftant or determinate intenfity, from the almoft infenfible evaporation of cryftallizable folutions to the ebullition of acids; properties never poffeffed by the athanor, of which chemifts have boafted fo much The advantage of thefe will be properly valued by thofe operators who know that the moft experienced and the moft attentive chemifts meet with frequent accidents, by which both their veffels and the products of their operations are loft for want of power in the management of the fire."

For the analyfis of ftones, fuch as the cryftals of tin, the fhortened chimney of glafs is to be ufed; and the procefs is to be begun by placing the mixture in a capfule of platina or filver $2\frac{1}{4}$ inches in diameter. This capfule is to be placed on the fupport, and the heat regulated in fuch a manner, that ebullition fhall take place without throwing any portion of the matter out of the veffel. As foon as its contents are perfectly dry, they are to be transferred into a very thin crucible of platina, of which the weight is about $252\frac{1}{2}$ grains Englifh, and its diameter one inch and three-fourths. This crucible refts on a fmall fupport of iron-wire, which ferves to contract the ring; and the wick being at its greateft elevation, with the ring lowered to the diftance of $9\frac{1}{2}$ inches from the upper rim of the chimney, Guyton produced, in lefs than twenty minutes, the faline fufion to a fuch a degree, that from the commencement of the operation the decompofition proceeded as far as to 0.70 of the mineral. The fame apparatus, that is to fay, with the fhortened chimney, ferves for oxidations, incinerations, torrefactions, and diftillations to drynefs.

In fuch operations as require a lefs heat, he leaves the lamp with its large chimney abfolutely in the fame ftate as when it is ufed for illumination; and by raifing and lowering either the ring which fupports the veffel, or the body of the lamp if the veffels be fixed in communication with others, he graduates the heat at pleafure. Vinegar diftils without interruption at $2\frac{1}{7}$ inches Englifh from the upper termination of the chimney, that is to fay, $7\frac{1}{7}$ inches Englifh from the flame. Water is made to boil in eight minutes, at the fame height, in a glafs veffel containing one wine pint Englifh, and is uniformly maintained at the diftance of $8\frac{1}{7}$ inches from the flame.

"I muft not in this place (fays our author) omit to mention a flight obfervation which this procefs has afforded, becaufe it may lead to ufeful applications, and tends to point out one great advantage of this method of operating; namely, that an infinity of circumftances may be perceived, which might not even be fufpected when the whole procefs is carried on within a furnace. I have remarked, as did likewife feveral of my colleagues

Laboratory.

who were then prefent, that a column of bubbles conftantly rofe from a fixed point of the retort on one fide of the bottom. We were of opinion, that fome particle of matter was in that place incorporated with the glafs, which had a different capacity for heat from that of the reft of the glafs. In order to verify this conjecture, I endeavoured the following day to diftil the fame quantity of the fame water in the fame retort, after having introduced a button of cupelled filver, weighing nine decigrammes ($29\frac{1}{2}$ grains). At the commencement of the operation there was a fmall ftream of bubbles from the fame point as before; but a fhort time afterwards, and during the whole remaining time of operating, the largeft and moft inceffant ftream of bubbles rofe from the circumference of the button, which was often difplaced by the motion; and in proportion to the time the product of the diftillation was fenfibly greater. Whence we may conclude, that metallic wires or rods, diftributed through a mafs of water, required to be kept in a ftate of ebullition, and placed a little below its furface, would produce, without any greater expence of fuel, nearly the fame effect as thofe cylinders filled with ignited matter which are made to pafs through the boilers."

We have related this fact in Guyton's own words, or at leaft in a faithful tranflation of them; and we are far from calling it in queftion, for it is a fact which has been often obferved: but we think his inference from it too haftily drawn. It is not conceivable that heat can be more rapidly conveyed through a mafs of liquid by the conducting power of metal, than by a free circulation; but we agree with what feems to be Mr Nicholfon's opinion *, that the thin ftratum of water beneath the button becomes more fuddenly and violently elaftic than elfewhere, and therefore rifes regularly to the furface. The whole of this phenomenon the reader will find explained in our article STEAM, *Encycl.* n° 10. But this is a digreffion.

* *Journal*, Auguft 1798, note, page 212.

We return, therefore, to Guyton's laboratory, of which the reader will form a diftinct notion from plate XXXIII. where fig. 1. reprefents the whole apparatus ready mounted for diftillation, with the tube of fafety and a pneumatic receiver. A is the body or refervoir of the ufual lamp of Argand, with its fhade and glafs chimney. The lamp may be raifed or lowered at pleafure by means of the thumb fcrew B, and the wick rifes and falls by the motion of the fmall toothed wheel placed over the wafte cup. This conftruction is moft convenient, becaufe it affords the facility of altering the pofition of the flame with regard to the veffels, which remain fixed; and the troublefome management of bended wires above the flame for the fupport of the veffels is avoided, at the fame time that the flame itfelf can be brought nearer to the matter on which it is intended to act. D, a fupport confifting of a round ftem of brafs, formed of two pieces which fcrew together at about two thirds of its height. Upon this the circular ring E, the arm F, and the nut G flide, and are fixable each by its refpective thumb-fcrew. The arm alfo carries a moveable piece H, which ferves to fufpend the veffels in a convenient fituation, or to fecure their pofition. The whole fupport is attached to the fquare iron ftem of the lamp by a piece of hard wood I, which may be fixed at any required fituation by its fcrew. K reprefents a ftand for the receivers. Its moveable tablet L is fixed at any required elevation by the wooden fcrew M. The piece which forms the foot of this ftand is fixed on the board N; but its relative pofition with regard to the lamp may be changed by fliding the foot of the latter between the pieces OO. P, another ftand for the pneumatic trough. It is raifed or lowered, and fixed to its place, by a ftrong wooden fcrew Q. R is a tube of fafety, or reverfed fyphon, which ferves, in a great meafure, to prevent the bad effects of having the veffels either perfectly clofed, or perfectly open. Suppofe the upper bell-fhaped veffel to be nearly of the fame magnitude as the bulb at the lower end of the tube, and that a quantity of water, or other fuitable fluid, fomewhat lefs than the contents of that veffel, be poured into the apparatus: In this fituation, if the elafticity of the contents of the veffels be lefs than that of the external air, the fluid will defcend in the bulb, and atmofpheric air will follow and pafs through the fluid into the veffels: but, on the contrary, if the elafticity of the contents be greater, the fluid will be either fuftained in the tube, or driven into the bell-fhaped veffel; and if the force be ftrong enough, the gafeous matter will pafs through the fluid, and in part efcape.

Laboratory, || Lacfha.

Fig. 2. Shews the lamp furnace difpofed to produce the faline fufion; the chimney of glafs fhortened; the fupport D turned down; the capfule of platina or filver S placed on the ring very near the flame.

Fig. 3. The fame part of the apparatus, in which, inftead of the capfule, a very thin and fmall crucible of platina T is fubftituted, and refts upon a triangle of iron wire placed on the ring.

Fig. 4. Exhibits the plan of this laft difpofition.

LACERTA, in aftronomy. See ASTRONOMY, n° 406. *Encycl.*

LACMUS, a dye ftuff prepared by the Dutch from the LICHEN ROCELLA, which fee in this *Supplement*.

LACSHA, the Indian name of the lac infect, which has been defcribed in the *Encyclopædia* under the title COCCUS, *Species* 5. Since that article was publifhed, a defcription of that infect, which is more to be depended upon, has been given to the world in the fecond volume of the Afiatic Refearches. It is by Mr Roxburgh, furgeon on the Madras eftablifhment, and was communicated to the Society by Dr James Anderfon phyfician at Fort St George, who obferves, that Mr Roxburgh's difcovery will bring the lacfha as a genus into the clafs *Hemiptera* of Linnæus.

" Some pieces of very frefh-looking lac (fays Mr Roxburgh), adhering to fmall branches of mimofa cinerea, were brought me from the mountains on the 20th of November 1789. I kept them carefully, and today, the 4th of December, fourteen days from the time they came from the hills, myriads of exceedingly minute animals were obferved creeping about the lac, and branches it adhered to, and more ftill iffuing from fmall holes over the furface of the cells: other fmall and perforated excrefcences were obferved with a glafs amongft the perforations, from which the minute infects iffued, regularly two to each hole, and crowned with fome very fine white hairs. When the hairs were rubbed off, two white fpots appeared. The animals, when fingle, ran about pretty brifkly, but, in general, they were fo numerous as to be crowded over one another. The body is oblong, tapering moft towards the tail, below plain, above convex, with a double or flat margin: laterally

Laccha. terally on the back part of the thorax are two fmall tubercles, which may be the eyes: the body behind the thorax is croffed with twelve rings: legs fix; feelers (antennæ) half the length of the body, jointed, hairy, each ending in two hairs as long as the antennæ: rump, a white point between two terminal hairs, which are as long as the body of the animal. The mouth I could not fee. On opening the cells, the fubftance that they were formed of cannot be better defcribed, with refpect to appearance, than by faying it is like the tranfparent amber that beads are made of: the external covering of the cells may be about half a line thick, is remarkably ftrong, and able to refift injuries: the partitions are much thinner: the cells are in general irregular fquares, pentagons and hexagons, about an eighth of an inch in diameter, and one quarter deep: they have no communication with each other. All thofe I opened during the time the animals were iffuing, contained in one half, a fmall bag filled with a thick red jelly-like liquor, replete with what I take to be eggs: thefe bags, or utriculi, adhere to the bottom of the cells, and have each two necks, which pafs through perforations in the external coat of the cells, forming the fore-mentioned excrefcences, and ending in fome very fine hairs. The other half of the cells have a diftinct opening, and contain a white fubftance, like fome few filaments of cotton rolled together, and numbers of the infects themfelves ready to make their exit. Several of the fame infects I obferved to have drawn up their legs, and to lie flat: they did not move on being touched, nor did they fhew any figns of life with the greateft irritation.

"*December* 5. The fame minute hexapedes continue iffuing from their cells in numbers: they are more lively, of a deepened red colour, and fewer of the motionlefs fort. To-day I faw the mouth: it is a flattened point about the middle of the breaft, which the little animal projects on being compreffed.

"*December* 6. The male infects I have found to-day: a few of them are conftantly running among the females moft actively: as yet they are fcarce more, I imagine, than one to 5000 females, but twice their fize. The head is obtufe; eyes black, very large; antennæ clavated, feathered, about $\frac{2}{3}$ds the length of the body: below the middle an articulation, fuch as thofe in the legs: colour betwen the eyes a beautiful fhining green: neck very fhort; body oval, brown: abdomen oblong, the length of body and head: legs fix: wings membranaceous, four, longer than the body, fixed to the fides of the thorax, narrow at their infertions, growing broader for $\frac{2}{3}$ds of their length, then rounded; the anterior pair is twice the fize of the pofterior: a ftrong fibre runs along their anterior margins: they lie flat, like the wings of a common fly when it walks or refts: no hairs from the rump: it fprings moft actively to a confiderable diftance on being touched; mouth in the under part of the head: maxillæ tranfverfe. To-day the female infects continue iffuing in great numbers, and move about as on the 4th.

"*December* 7. The fmall red infects ftill more numerous, and move about as before: winged infects, ftill very few, continue active. There have been frefh leaves and bits of the branches of both *Mimofa Cinerea* and *Corinda* put into the wide mouthed bottle with them: they walk over them indifferently, without fhewing any preference, or inclination to work or copulate. I opened a cell whence I thought the winged flies had come, and found feveral, eight or ten, more in it, ftruggling to fhake off their incumbrances; they were in one of thofe utriculi mentioned on the 4th, which ends in two mouths, fhut up with fine white hairs, but one of them was open for the exit of the flies; the other would no doubt have opened in due time: this utriculus I found now perfectly dry, and divided into cells by exceeding thin partitions. I imagine, before any of the flies made their efcape, it might have contained about twenty. In thefe minute cells with the living flies, or whence they had made their efcape, were fmall dry dark-coloured compreffed grains, which may be the dried excrements of the flies."

Lamanon. LAMANON (Robert Paul), of the Academy at Turin, correfpondent of the Academy of Sciences at Paris, and member of the Mufeum in the fame city, was born at Salon in Provence, in 1752, of an old and refpectable family. Being a younger fon, he was deftined for the church, and fent to Paris to complete his theological ftudies; but getting acquainted with the philofophers (as they called themfelves), he foon loft all relifh for the ftudy of theology, and devoted himfelf to the phyfical fciences, efpecially thofe of chemiftry and mineralogy. Into the church, however, he got, and rofe to the dignity of canon; but by the death of his father and elder brother, having acquired the right of directing his own future exertions, he haftened to quit a profeffion, towards which he felt no partiality.

A prelate, then in high favour at court, hearing of Lamanon's intention of quitting his office of canon, offered him a confiderable fum, to induce him to refign in favour of one of his dependents. The chapter of Arles, replied our young ecclefiaftic, did not fell me my benefice; I fhall therefore reftore it in the fame manner that I received it. This conduct was certainly meritorious; and his eulogift *Ponce* mentions another trait of his character, which fets him in a very amiable point of view; he refufed to accept of his paternal inheritance, otherwife than as an equal fharer with his brothers and fifters.

Thus liberated from the trammels of his former profeffion, Lamanon applied himfelf with uncommon ardour to ftudy. Eager to raife the awful veil that conceals from our eyes the fecrets of Nature; perfuaded, that even the greateft genius only amufes itfelf with falfe fyftems in the filence of a cabinet; convinced of the neceffity of much and various obfervation, and of furprifing Nature as it were in the very fact, in order to penetrate into the fublimity of her operations; — our young philofopher travelled through Provence and Dauphine, and fcaled the Alps and Pyrenees. At the fight of thefe vaft natural laboratories the bent of his mind burft forth inftantaneoufly: he climbed to the fummit of rocks, and explored the abyfs of caverns, weighed the air, analyfed fpecimens, and, in his ardent fancy, having attained the fecrets of creation, he formed a new fyftem of the world. On his return home, he applied with additional intereft to the ftudy of meteorology, mineralogy, natural philofophy, and the other branches of the hiftory of nature.

Whilft he was meditating a vifit to Paris for the purpofe, as his eulogift expreffes himfelf, of converfing with the luminaries of fcience, the inhabitants of the commune of Salon, having loft a caufe againft their lord, unani-

Lamanon. unanimoufly elected Lamanon, with whofe integrity and abilities they were well acquainted, to go and folicit of the council the repeal of an unjuft decree that had been obtained by partiality. The reply of the young philofopher on this occafion is an additional proof of his uncommon difinterefteduefs. "As I intend (faid he) to go to Paris on bufinefs of my own, I cannot think of accepting your offer of 24 livres daily pay: a twelfth of this fum will cover the extraordinary expences of the journeys that I fhall be obliged to make to Verfailles on your account." He had the fatisfaction of complete fuccefs in the bufinefs thus undertaken.

Having fatisfied his curiofity in Paris, he went over to England. During the paffage, though much incommoded by fea-ficknefs, and in imminent hazard of being overwhelmed by the tumbling waves of a very ftormy fea, he caufed himfelf to be tied to the main-maft, in order to contemplate at leifure fo grand and fearful a fpectacle. The burfts of thunder, the howling of the wind, the brilliancy of the lightning, the glancing of the fpray which covered him every moment, thefe objects, fo terrible to an ordinary man, threw him into a kind of mental intoxication, and he has often declared that this day was the moft exquifite of his whole life.

Convinced that the friendfhip of an eminent man elevates the foul, excites generous emulation, and becomes an additional ftimulus to one whofe delight is ftudy, and whofe moft preffing want is an object on which to place his affection, Lamanon anxioufly endeavoured to merit the regard of Condorcet, fo well known by his talents, his impieties, his rebellion, and his misfortunes. This academician, juftly confidering that an apoftate prieft would be ready to join the confpiracy of the philofophifts againft the altar and the throne, received Lamanon with diftinction, and at length admitted him to his moft intimate friendfhip.

During the three fucceffive years that Lamanon fpent at Paris, he followed with care the track of thofe learned focieties, of which he had been elected a member. He became at this period, together with Count de Gebelin, and fome other philofophers and artifts, one of the founders of the Mufeum, the greater part of the members of which are now reunited in the open fociety of fciences, letters, and arts, at Paris. Among the different papers of his that were read at various meetings of thefe focieties, Ponce mentions with particular approbation what he calls *a notice* of Adam de Crapone, an eminent hydraulic engineer; a memoir on the Cretins; a memoir on the theory of the winds; a treatife on the alteration in the courfe of rivers, particularly the Rhone; and another on an enormous bone belonging to fome cetaceous fifh, that was dug up at Paris, in laying the foundations of a houfe in the *Rue Dauphine*. We have not feen thefe memoirs; but as their author was the friend of Condorcet, and fancied that he had attained the fecrets of creation, we can eafily conceive their tendency.

Having refolved again to revifit Switzerland and Italy, Lamanon firft went to Turin, where he allied himfelf to the learned of that country. During his ftay there, the brilliant novelty difcovered by Montgolfier was occupying the attention of all the philofophers of Europe. Lamanon, defirous of making fome experiments of this kind himfelf, afcended in a balloon from the city of Turin; but not perceiving in this difcovery, which had at firft highly interefted him, an object of public utility; not forefeeing, that one day, on the plains of Fleurus, it would be the caufe of rallying and eftablifhing victory under the ftandards of France, he returned to his favourite occupations. Purfuing his route from Piedmont, he vifited Italy, and returned by Switzerland, where he explored the Alps and afcended the fummit of Mont Blanc: thence returning, loaden with the fpoils of the countries which he had traverfed, to Provence, he employed himfelf in the arrangement of the interefting fruits of his journey. Lamanon.

Of the fcrupulous exactnefs of his obfervations, his eulogift gives the following inftance: "Being convinced that the plain of Crau, divided by the channel of the Durance, had formerly been a lake, he wifhed to be abfolutely affured of it. For this purpofe he collected a fpecimen of each of the ftones that are to be found in this vaft plain; the number of thefe he found to amount to nineteen; then tracing the courfe of the river towards its head, near the frontiers of Savoy, he obferved, that above each junction of the tributary ftreams with the Durance, the variety of pebbles diminifhed. Afterwards afcending the current of each of thefe fmaller ftreams, he difcovered on their banks the original rock of every pebble that overfpreads the plain of Crau; thus inconteftably proving, that this plain was anciently a lake formed by the waters of the Durance, and the ftreams that fall into it. If all philofophers (fays our author) would conduct their examinations with equal precifion, certain hypothefes, more brilliant than folid, would not find fo many admirers; the charm of imagination, and the graces of ftyle, would not fo often encroach upon the imprefcriptable rights of nature and truth."

To citizen Ponce this appears a demonftration of Lamanon's theory; but we cannot fay that it does fo to us. It may be a kind of proof, though not a demonftration, that in fome convulfion of nature ftones had been rolled from the rock, and the plain of Crau, for a time, overflowed by the Durance; but it furely furnifhes no evidence of that plain's having ever been *a permanent lake*. It *may* have been fo; but fuch inveftigations as this will not guard philofophers againft the delufions of favourite hypothefes.

It was at the time when Lamanon was preparing for the prefs his great work on the *Theory of the Earth*, that the French government conceived the vaft project of completing the difcoveries of Captain Cook: the academy of fciences was entrufted with the care of felecting men capable of rectifying our notions of the fouthern hemifphere, of improving hydrography, and advancing the progrefs of natural hiftory. Condorcet, not knowing any one better qualified for this laft department than Lamanon, wrote to him an invitation to fhare the danger and glory of this great enterprize. He accepted with eager tranfport a propofal that fulfilled his higheft expectations, haftened to Paris, refufed in a conference with the minifter the falary that was offered, took a hafty leave of his friends, and departed for Breft.

On the 1ft of Auguft 1785, the armament fet fail under the orders of La Peroufe, an experienced commander, whofe patriotifm and fcientific zeal were equal to his courage and good fenfe, and who had already merited the public confidence. The philofophers of all Europe

Lamanon, Lamp.

Europe were in expectation of thofe ufeful difcoveries, the probable fruit of the zeal and talents employed in the expedition. The beginning of the voyage was profperous. After various delays, and a multitude of obfervations, the two veffels arrived at the ifland of Maouna, one of the fouthern Archipelago. The impatient Lamanon, eager to affure himfelf of the truth of the publifhed accounts of that country, debarked with Langle, the fecond in command. At the moment of their return, the natives, in hopes of booty, which had been excited by the number of prefents that they had received, feized upon the boats, and attacked the party. The French were obliged to have recourfe to arms for felf-defence, and a defperate combat enfued. Lamanon, Langle, and ten of the two boats crews, fell a facrifice to the fury of thefe barbarians.

Thus perifhed Lamanon, a young man ardent in the purfuits of fcience, to a high degree difinterefted, and a zealot in what he thought the caufe of liberty. He refufed the falary which was allotted to him when he was appointed to this unfortunate expedition; for "if I do not feel fatisfied (faid he) on board the veffel; if my inclination or curiofity lead me to quit the fhip, — I fhould be unhappy if any power in the world had acquired the right of preventing me."

According to M. Ponce, Lamanon feemed born to bring about a revolution in fcience: the depth of his ideas, the energy of his character, the fagacity of his mind, united to that lively curiofity that can draw inftruction out of any thing, and leaves nothing unexplored, would have led him to the moft valuable difcoveries. In perfon he was tall; and to great vivacity and expreffion of feature added prodigious ftrength and activity; in a word, Nature formed him with fuch care, as if fhe had intended him for one of thofe few who are deftined to great exploits. His ftyle was nervous, often poetical, without lofing fight of propriety, and the language of fentiment might frequently be difcovered in the midft of ftrong and ftriking expreffions; and if he wanted the exquifitely dazzling polifh of diction, he was eminently gifted with the precifion of logical reafoning, which commands attention and enforces perfuafion.

LAMP (fee *Encycl.*) is an inftrument comprifing three articles which demand our attention, *viz.* the oil, the wick, and the fupply of air. It is required that the oil fhould be readily inflammable, without containing any fetid fubftance which may prove offenfive, or mucilage, or other matter, to obftruct the channels of the wick. Mr Nicholfon fays*, that he knows of no procefs by which oils can be meliorated for this purpofe, except that of wafhing with water containing acid or alkali. Either of thefe is faid to render the mucilage of animal oils more foluble in water; but acid is to be preferred, becaufe it is lefs difpofed to combine with the oil itfelf. Perhaps oil might be deprived of all fetid fmell in burning, by being made to pafs through Collier's filtering apparatus, defcribed under the word FILTER in this *Suppl.*

* *Journal*, i. 2.

The office of the wick appears to be chiefly, if not folely, to convey the oil by capillary attraction to the place of combuftion. As the oil is confumed and flies off, other oil fucceeds, and in this way a continued current of oil and maintenance of the flame are effected. But as the wicks of lamps are commonly formed of combuftible matter, it appears to be of fome confequence what the nature and ftructure of this material may be. It is certain that the flame afforded by a wick of rufh differs very confiderably from that afforded by cotton; though perhaps this difference may, in a great meafure, depend on the relative dimenfions of each. And if we may judge from the different odour in blowing out a candle of each fort, there is fome reafon to fufpect that the decompofition of the oil is not effected precifely in the fame manner in each. We have alfo fome obfcure accounts of prepared wicks for lamps, which are ftated to poffefs the property of facilitating the combuftion of very impure oils, fo that they fhall burn for many hours without fmoke or fmell.

Lamp.

The economical wicks of M. Leger, concerning which a report was prefented to the Academy at Paris in 1782 by Condorcet, Lavoifier, and De Milly, were compofed of cotton of different fizes and forms, namely, round and flat, according to the ufe they were intended to ferve. They were covered with a fat fubftance, of a fmell not difagreeable, but feebly aromatic. From the trials of thefe commiffaries it was afcertained: 1. That they afforded a clearer flame, with lefs undulation. 2. That they confumed fomewhat lefs oil; and, 3. That they poffeffed the remarkable property of affording neither fmell nor fmoke, however common the oil made ufe of. When ufing a lamp with a flat wick, we have ourfelves found a piece of clean cotton ftocking anfwer the purpofe better than the cotton wicks which are fold in the fhops.

The accefs of air is of the laft importance in every procefs of combuftion. When a lamp is fitted up with a very flender wick, the flame is fmall, and of a brilliant white colour: if the wick be larger, the combuftion is lefs perfect, and the flame is brown: a ftill larger wick not only exhibits a brown flame, but the lower internal part appears dark, and is occupied by a portion of volatilifed matter, which does not become ignited until it has afcended towards the point. When the wick is either very large or very long, part of this matter efcapes combuftion, and fhews itfelf in the form of coal or fmoke. The different intenfity of the ignition of flame, according to the greater or lefs fupply of air, is remarkably feen by placing a lamp with a fmall wick beneath a fhade of glafs not perfectly clofed below, and more or lefs covered above. While the current of air through the glafs fhade is perfectly free, the flame is white; but in proportion as the aperture above is diminifhed, the flame becomes brown, long, wavering, and fmoky; it inftantly recovers its original whitenefs when the opening is again enlarged. The inconvenience of a thick wick has been long fince obferved, and attempts made to remove it; in fome inftances, by fubftituting a number of fmall wicks inftead of a larger; and in others, by making the wick flat inftead of cylindrical. The moft fcientific improvement of this kind, though perhaps lefs fimple than the ordinary purpofes of life demand, is the well known lamp of Argand, defcribed in the *Encyclopædia*.

Much has been faid of this lamp, and great praife lavifhed on the inventor. It cannot indeed be denied that it was a very pretty invention, nor have we the flighteft wifh to detract from the merit of M. Argand; but truth compels us to fay, that the fame thought had occurred to others as early as to him, and that lamps had

Lamp. had been constructed on his principles long before he had published an account of his lamp to the world (A).

Many ingenious men have endeavoured to determine the most economical method of lighting up large halls and workhouses by means of different lamps and candles; and when the expence of tallow and oil is considered, it will be admitted that they could not employ their time in a manner more beneficial to the poor and the industrious. Among others, Count Rumford and M. Hassenfratz have turned their attention to this subject; and the results of their investigations are worthy of notice. To the Count, a method occurred for measuring the relative quantities of light emitted by lamps of different constructions, which is at once simple and accurate. It is as follows:

Let the two burning lamps, or other lights to be compared, be called A and B; and let them be placed at equal heights upon two light tables, or moveable stands, in a darkened room; let a sheet of clean white paper be equally spread out, and fastened upon the wainscot, or side of the room, at the same height from the floor as the lights; and let the lights be placed overagainst this sheet of paper, at the distance of six or eight feet from it, and six or eight feet from each other, in such a manner, that a line drawn from the centre of the paper, perpendicular to its surface, shall bisect the angle formed by lines drawn from the lights to that centre; in which case, considering the sheet of paper as a plane speculum, the one light will be precisely in the line of reflection of the other.

This may be easily performed, by actually laying a piece of a looking-glass, six or eight inches square, flat upon the paper, in the middle of it; and observing, by means of it, the real lines of reflection of the lights from that plane, removing it afterwards, as soon as the lights are properly arranged. When this is done, a small cylinder of wood, about one-fourth of an inch in diameter, and six inches long, must be held in a vertical position, about two or three inches before the centre of the sheet of paper, and in such a manner, that the two shadows of the cylinder, corresponding to the two lights, may be distinctly seen upon the paper.

If these shadows should be found to be of unequal densities, which will almost always be the case, then that light whose correspording shadow is the densest must be removed farther off, or the other must be brought nearer to the paper, till the densities of the shadows appear to be exactly equal; or, in other words, till the densities of the rays from the two lights are equal *at the surface of the paper;* when, the distances of the lights from the centre of the paper being measured, the squares of those distances will be to each other as the real intensities of the lights in question at their sources.

If, for example, the weaker light being placed at the distance of four feet from the centre of the paper, it should be found necessary, in order that the shadows may be of the same density, to remove the stronger light to the distance of eight feet from that centre, in that case, the real intensity of the stronger light will be to that of the weaker as 8^2 to 4^2; or as 64 to 16; or 4 to 1; and so for any other distances.

It is well known, that when any quality proceeds from a centre in straight lines in all directions, like the light emitted by a luminous body, its intensity at any given distance from that centre will be as the square of that distance inversely; and hence it is clear, that the intensities of the lights in question, at their sources, must be to each other as the squares of their distances from that given point *where their rays uniting are found to be of equal density.* For, putting $x =$ the intensity of B, if P represents the point where the rays from A and from B meeting are found to be of equal density or strength, and if the distance of A from P be $= m$, and the distance of B from the same point P $= n$; then, as the intensity of the light of A at P is $= \frac{x}{m^2}$, and the intensity of the light of B at the same place $= \frac{y}{n^2}$, and as it is $\frac{x}{m^2} = \frac{y}{n^2}$ by the supposition, it will be $x : y :: m^2 : n^2$.

That the shadows being of equal density at any given point, the intensities of the illuminating rays must of necessity be equal at that point also, is hence evident that the total absence of light being perfect blackness, and the shadow corresponding to one of the lights in question being deeper or fainter, according as it is more or less enlightened by the other, when the shadows are equal, the intensities of the illuminating rays must be equal likewise.

In removing the lights, in order to bring the shadows to be of the same density, care must be taken to recede from, or advance towards, the centre of the paper in a straight line, so that the one light may always be found exactly in the line of reflection of the other; otherwise the rays from the different lights falling upon the paper, and consequently upon the shadows, at different angles, will render the experiment fallacious.

When the intensity of one strong light is compared with the intensities of several smaller lights taken together, the smaller lights should be placed in a line perpendicular to a line drawn to the centre of the paper, and as near to each other as possible; and it is likewise necessary to place them at a greater distance from the paper than when only single lights are compared.

In all cases, it is absolutely necessary to take the greatest care that the lights compared be properly trimmed, and that they burn clear and equally, otherwise the results of the experiments will be extremely irregular and inconclusive. It is astonishing what a difference there is in the quantities of light emitted by the same candle, when it burns with its greatest brilliancy, and when it has grown dim for want of snuffing. But as this diminution of light is progressive, and as the eye insensibly conforms to the quantity of light actually present, it is not always taken notice of by the spectators; it is nevertheless very considerable, in fact, as will be apparent to any one who will take the trouble to make the experiment; and so great is the fluctuation in the quantity of light emitted by burning bodies, lamps, or candles, in all cases, even under the most favourable circumstances, that this is the source of the greatest difficulties which our author met with in determing the relative

(A) One of these was employed in the college of Glasgow, by the lecturer on chemistry, so long ago as 1766.

Lamp. relative intenſities of lights by the method here propoſed.

To aſcertain by this method the comparative denſities, or intenſities, of the light of the moon and of that of a candle, the moon's direct rays muſt be received upon a plane white ſurface, at an angle of incidence of about 60°, and the candle placed in the line of the reflection of the moon's rays from this ſurface; when the ſhadows of the cylinder, correſponding to the moon's light and to that of the candle, being brought to be of equal denſity, by removing the candle farther off, or bringing it nearer to the centre of the white plane, as the occaſion may require, the intenſity of the moon's light will be equal to that of the candle *at the given diſtance of the candle from the plane.*

To aſcertain the intenſity of the light of the heavens, by day or by night, this light muſt be let into a darkened room through a long tube blackened on the inſide, when its intenſity may be compared with that of a candle or lamp by the method above deſcribed.

The Count, however, has contrived an apparatus for aſcertaining the intenſity of the ſun's light, compared with the light emitted by any artificial illuminator, with much greater accuracy than it can be done by this ſimple method. That apparatus we ſhall deſcribe under the title PHOTOMETER in this *Supplement*; and in the mean time we proceed to lay before our readers the reſults of his experiments as they relate to economy in the production of artificial light.

1
Of the relative quantities of oil conſumed, and of light emitted, by an Argand's lamp, and by a lamp in the common conſtruction, with a riband wick.

The brilliancy of Argand's lamp is not only unrivalled, but the invention is in the higheſt degree ingenious, and the inſtrument uſeful for many purpoſes; but ſtill, to judge of its real merits as an illuminator, it was neceſſary to know whether it gives more light than another lamp *in proportion to the oil conſumed.* This point he determined in the following manner:

Having placed an Argand's lamp, well trimmed, and burning with its greateſt brilliancy, before his *photometer*, and over againſt it a very excellent common lamp, with a riband wick about an inch wide, and which burnt with a clear bright flame, without the leaſt appearance of ſmoke, he found the intenſities of the light emitted by the two lamps to be to each other as 17956 to 9063; the denſities of the ſhadows being equal when, the Argand's being placed at the diſtance of 134 inches, the common lamp was placed at the diſtance of 95,2 inches, from the field of the photometer.

Both lamps having been very exactly weighed when they were lighted, they were now (without being removed from their places before the photometer) cauſed to burn with the ſame brilliancy juſt 30 minutes; they were then extinguiſhed and weighed again, and were found to have conſumed of oil, the Argand's lamp $\frac{253}{8192}$, and the common lamp $\frac{163}{8192}$, of a Bavarian pound.

Now, as the quantity of light produced by the Argand's lamp, in this experiment, is to the quantity produced by the common lamp as 17956 to 9063, or as 187 to 100, while the quantity of oil conſumed by the former is to that conſumed by the latter only in the ratio of 253 to 163, or as 155 to 100, it is evident that the quantity of light produced by the combuſtion of a given quantity of oil in an Argand's lamp is greater than that produced by burning the ſame quantity in a common lamp, in the ratio of 187 to 155, or as 100 to 85.

The ſaving, therefore, of oil which ariſes from making uſe of an Argand's lamp inſtead of a common lamp, in the production of light, is evident; and it appears, from this experiment, that that ſaving cannot amount to leſs than fifteen *per cent.* How far the advantage of this ſaving may, under certain circumſtances, be counterbalanced by inconveniences that may attend the making uſe of this improved lamp, our author does not pretend to determine.

2
Of the relative quantities of light emitted by an Argand's lamp and by a common wax candle.

The Count made a conſiderable number of experiments to determine the relative quantities of light emitted by an Argand's lamp and a common wax-candle; and the general reſult of them is, that a common Argand's lamp, burning with its uſual brightneſs, gives about as much light as nine good wax-candles; but the ſizes and qualities of candles are ſo various, and the light produced by the ſame candle ſo fluctuating, that it is very difficult to aſcertain, with any kind of preciſion, what a common wax-candle is, or how much light it ought to give. He once found that his Argand's lamp, when it was burning with its greateſt brilliancy, gave twelve times as much light as a good wax-candle $\frac{3}{4}$ths of an inch in diameter, but never more.

3
Of the fluctuations of the light emitted by candles.

To determine to what the ordinary variations in the quantity of light emitted by a common wax-candle might amount, he took ſuch a candle, and, lighting it, placed it before the photometer, and over againſt it an Argand's lamp, which was burning with a very ſteady flame; and meaſuring the intenſity of the light emitted by the candle from time to time, during an hour, the candle being occaſionally ſnuffed when it appeared to ſtand in need of it, its light was found to vary from 100 to about 60. The light of a wax-candle of an inferior quality was ſtill more unequal; but even this was but trifling, compared to the inequalities of the light of a tallow-candle.

An ordinary tallow-candle, of rather an inferior quality, having been juſt ſnuffed, and burning with its greateſt brilliancy, its light was as 100; in eleven minutes it was but 39; after eight minutes more had elapſed, its light was reduced to 23; and in ten minutes more, or twenty-nine minutes after it had been laſt ſnuffed, its light was reduced to 16. Upon being again ſnuffed, it recovered its original brilliancy, 100.

4
Of the relative quantities of bees-wax, tallow, olive-oil, rape-oil, and linſeed-oil, conſumed in the production of light.

In order to aſcertain the relative quantities of bees wax and of olive-oil conſumed, in the production of light, the Count proceeded in the following manner: Having provided an end of a wax-candle of the beſt quality, ,68 of an inch in diameter, and about four inches in length, and a lamp with five ſmall wicks, which he had found upon trial to give the ſame quantity of light as the candle, he weighed very exactly the candle and the lamp filled with oil, and then, placing them at equal diſtances (forty inches) before the field of the photometer, he lighted them both at the ſame time; and, after having cauſed them to burn with preciſely the ſame degree of brightneſs *juſt one complete hour*, he extinguiſhed them both, and, weighing them a ſecond time, he found that 100 parts of wax and 129 parts of oil had been conſumed.

Hence it appears, that the conſumption of bees-wax is to the conſumption of olive-oil, in the produc-

tion

Lamp. tion of the fame given quantity of light, as 100 is to 129.

In this experiment no circumftance was neglected that could tend to render the refult of it conclufive; care was taken to fnuff the candle very often with a pair of fharp fciffars, in order to make it burn conftantly with the fame degree of brilliancy; and the light of the lamp was, during the whole time, kept in the moft exact equilibrium with the light of the candle, which was eafily done by occafionally drawing out, a little more or lefs, one or more of its five equal wicks. Thefe wicks, which were placed in a right line, perpendicular to a line drawn from the middle wick to the middle of the field of the photometer, were about $\frac{1}{10}$th of an inch in diameter each, and $\frac{1}{4}$th of an inch from each other; and, when they were lighted, their flames united into one broad, thin, and very clear, white flame, without the leaft appearance of fmoke.

In order to afcertain the relative confumption of olive-oil and rape-oil, in the production of light, two lamps, like that juft defcribed, were made ufe of; and, the experiment being made with all poffible care, the confumption of olive-oil appeared to be to that of rape-oil, in the production of the fame quantity of light, as 129 is to 125.

The experiment being afterwards repeated with olive-oil and very pure linfeed oil, the confumption of olive-oil appeared to be to that of linfeed oil as 129 to 120.

The experiment being twice made with olive-oil and with a tallow-candle; once when the candle, by being often fnuffed, was made to burn conftantly with the greateft poffible brilliancy, and once when it was fnuffed to burn the whole time with a very dim light, owing to the want of fnuffing; the refults of thefe experiments were very remarkable.

When the candle burnt with a clear bright flame, the confumption of the olive-oil was to the confumption of the tallow as 129 is to 101; but when the candle burnt with a dim light, the confumption of the olive-oil was to the confumption of the tallow as 129 is to 229. So that it appeared, from this laft experiment, that the tallow, inftead of being nearly as productive of light in its combuftion as bees-wax, as it appeared to be when the candle was kept conftantly well fnuffed, was now, when the candle was fuffered to burn with a dim light, by far lefs fo than oil.

But this is not all; what is ftill more extraordinary is, that the very fame candle, burning with a long wick, and a dim light, actually confumed *more tallow* than when, being properly fnuffed, it burnt with a clear bright flame, and gave near *threee times as much light.*

To be enabled to judge of the relative quantities of light actually produced by the candle in the two experiments, it will fuffice to know, that in order to counterbalance this light at the field of the *photometer*, it required, in the former experiment, the confumption of 141 parts, but in the latter only the confumption of 64 parts, of olive oil. But in the former experiment 110, and in the latter 114, parts of tallow were actually found to be confumed. Thefe parts were 8192ths of a Bavarian pound.

From the refults of all the foregoing experiments, it appears that the relative expence of the undermentioned inflammable fubftances, in the production of light, is as follows:

		Equal Parts in Weight.
Bees-wax.	A good wax-candle, kept well fnuffed, and burning with a clear bright flame, . . .	100
Tallow.	A good tallow-candle, kept well fnuffed, and burning with a bright flame, ...	101
	The fame tallow-candle, burning very dim for want of fnuffing,	229
Olive-oil.	Burnt in an Argand's lamp, . .	110
	The fame burnt in a common lamp, with a clear bright flame, without fmoke, ...	129
Rape oil.	Burnt in the fame manner, . .	125
Linfeed-oil.	Likewife burnt in the fame manner, ...	120

With the foregoing table, and the prices current of the therein mentioned articles, the relative prices of light produced by thofe different materials may very readily be computed.

In the year 1795, Mr J. H. Haffenfratz was employed by the French government to make a feries of experiments to determine the moft economical method of procuring light from the different combuftible fubftances ufually employed for that purpofe. The materials of his experiments were, wax, fpermaceti, and tallow-candles, fifh-oil, oil of colefeed, and of poppy-feeds. In ufing thefe oils, both the Argand and common lamps were employed. The wicks of the latter were round, containing thirty-fix cotton threads. The tallow and fpermaceti candles were mould, fix to the pound. The wax-candles five to the pound. Mr Haffenfratz ufed the fame method with Count Rumford for determining the comparative intenfity of the lights.

Count Rumford, as we have feen, ufed the Argand lamp as a ftandard for comparifon; but as the intenfity of its light varies according to the height of the wick, Mr Haffenfratz preferred a wax-candle, making ufe of it foon after it was lighted. When two luminous bodies, of different intenfities, are put in comparifon with each other, the fhadows are of two colours. That from the weakeft light is blue, and from the ftrongeft, red. When the lights of two different combuftible bodies are compared, they are either red or blue in a compound ratio of the colour and intenfity. Thus in comparing the fhadows from different luminous bodies, they will be red or blue refpectively, in the following order:

Light of the fun,
—— of the moon,
—— of Argand lamps,
—— of tallow-candles,
—— of wax ditto,
—— of fpermaceti ditto,
—— of common lamps.

That is to fay, when a body is illuminated by the fun and by any other luminous fubftance, the fhadow of the former is red, and of the latter, blue. In like manner, the fhadow from an Argand lamp is red, when placed by that of a tallow-candle, which is blue.

The following table will fhew, according to Mr Haffenfratz, the proportional diftance that different luminous bodies fhould be placed at to produce an equally intenfe fhadow from the fame object. The fecond column gives

gives the proportional intenfity of each light, which is known to be in proportion to the fquares of the diftances of luminous bodies giving the fame depth of fhadow. The third column fhews the quantity of combuftible matter confumed in the hour by each mode of giving light, which Mr Haffenfratz calculates from the average of many repeated experiments.

	Diftance.	Intenfity.	Quantity confumed per hour.	Quantity required for equal intenfities.
Argand lamps with oil of poppyfeed	10	10.000	23	23
— of fifhes	10	10.000	23.77	23.77
— of colefeed	9.246	8.549	14.18	16.59
Common lamps with oil of colefeed	6.774	4.588	8.81	19.2
— of fifhes	6.524	4.556	9.14	20.06
— of poppyfeed	5.917	3.501	7.05	20.14
Spermaceti candle	5.917	3.501	9.23	26.37
Old tallow candle	5.473	2.995	[illegible].54	25.17
New ditto	5.473	2.995	8.23	27.48
Wax candle	4.275	1.827	9.54	53

The relative quantity of combuftible matter required to produce *equal* lights at equal diftances, may be obtained by a fimple rule of proportion from the above data. Thus, if a given intenfity of light, expreffed by 3.501, has been produced by a confumption of 9.23 of fpermaceti in the hour, the fame luminous body will produce a light of 10.000, by confuming in the fame time a quantity of fpermaceti $= \frac{10.000 \times 9.23}{3.501} = 26.37$. Therefore we may add to the table a fourth column, expreffing the quantity of combuftible which each body muft confume to produce a light of 10.000.

From what has been laid down, it will alfo appear that the number of lights required to produce a given light, will be as follows: To produce a light equal to 100 Argand lamps, burning poppyfeed oil, it will require

100 Argand lamps with fifh-oil
117 Ditto do. with colefeed oil
218 Common lamps with colefeed oil
219 Ditto do. with fifh oil
285 Ditto do. with poppyfeed oil
285 Spermaceti candles
333 Tallow ditto
546 Wax ditto.

Mr Haffenfratz next takes notice of the comparative price of thefe articles; by which he finds, that in Paris the moft expenfive light is that produced from wax-candles; and the moft *economical* that from oil of colefeed burned in Argand lamps.

The chief difference between the Argand and common lamp is, that in the latter much of the oil is volatilized without combuftion, and hence the unpleafant fmell which it produces; whereas in the former, the heat is fo great at the top of the wick, that all the oil is decompofed in paffing through, the difpofition of the wick allowing the free accefs of air to affift combuftion. It fhould therefore follow, that the Argand lamp confumes lefs fuel to produce a given light than the common lamp, and this, as we have feen, is the opinion of Count Rumford. Yet (Mr Haffenfratz obferves) there are two circumftances that prevent the full effect of the complete combuftion in the Argand lamp. The one is, that the glafs cylinder abforbs a part of the rays of light as they pafs through; the other, that the column of light proceeding from the inner furface of the wick, is, in part, loft, by being obliged to pafs through that from the outer furface. Count Rumford allows the firft caufe of diminution of light, and eftimates it at .1854, but not the latter. The author of this memoir, in repeating Count Rumford's experiments, afferts, that when two candles are placed fo that the light of the one is obliged to pafs through that of the other, the fum of the light fo produced is not fo ftrong as when they are placed fide by fide; for in the firft cafe, a part of the hindmoft light is abforbed by the foremoft.

LANCASHIRE. In the account which we have given of that county in the *Encyclopædia*, an obliging correfpondent has pointed out to us fome miftakes. He affures us that the fea-coaft, where we underftood the atmofphere to be loaded with fuch exhalations as produce malignant and intermitting fevers, is remarkably healthy; and he fpeaks from experience, having lived on that coaft for forty years. He affures us likewife, that the Duke of Bridgewater's inland navigation was begun foon after, if not before, the year 1736, and that he (the writer), fo early as 1764, was one of a party who failed up the fough or edit a confiderable way to fee how the coals were worked. The fame correfpondent has pointed out a few miftakes in our account of

LANCASTER, the capital of the county. "That town (he fays) carries on no trade whatever with North America, but a very confiderable one with Jamaica and the other Weft India iflands, in veffels of from 100 to 500 tons burthen. It exports to thefe iflands all fuch Britifh manufactures as they have occafion for, Irifh linens, and falted provifions of all kinds, fuch as Irifh beef, pork, butter, &c. It trades alfo to the Baltic, Portugal, Hamburgh, &c. to a large amount; and fome of its fhips with their cargoes have of late been worth from L.60 to L.80,000 fterling. It has, however, no communication by water with the rivers Merfey, Dee, &c. as we have faid; the canal reaching as yet no farther than to near Prefton in Lancafhire." The communication with thefe rivers is indeed intended to be completed; but whether the fcheme be practicable is, according to our correfpondent, very uncertain.

LANTERN. See *Encycl.*—Sir George Staunton informs us, that of the Chinefe lanterns, fome were fuch as we have defcribed, viz. compofed of thin filk gauze, painted or wrought in needlework with figures of birds, infects, flowers, or fruit, and ftretched on neat frames of wood. Others, however, were very different, being entirely made of horn. Thefe were fo thin and tranfparent, that they were taken at firft for glafs; a material to which, for this purpofe, the horn is preferred by the Chinefe, as cheaper, lighter, lefs liable to accident, and, in cafe of accident, more eafily repaired; many of them were about two feet in the diameter, and in the form of a cylinder, with the ends rounded off, and the edges meeting in the point to which the fufpending cords were tied. Each lantern confifted of an uniform piece of horn, the joints, or feams, being rendered invifible

Lantern. visible by an art found out by the Chinese; among whom, the vast number of such lanterns used in their dwelling houses and temples, as well as on the occasions of their festivals and processions, have led to many trials for improving their construction. The horns generally employed are those of sheep and goats. The usual method of managing them, according to the information obtained upon the spot, is to bend them by immersion in boiling water, after which they are cut open and flattened; they then easily scale, or are separated into two or three thin laminæ or plates. In order that these plates should be made to join, they are exposed to the penetrating effect of steam, by which they are rendered almost perfectly soft. In this state the edges of the pieces to be joined are carefully scraped and slanted off, so as that the pieces overlapping each other shall not together exceed the thickness of the plate in any other part. By applying the edges, thus prepared, immediately to each other, and pressing them with pincers, they intimately adhere, and, incorporating, form one substance, similar in every respect to the other parts; and thus uniform pieces of horn may be prepared to almost any extent. It is a contrivance little known elsewhere, however simple the process appears to be; and perhaps some minute precautions are omitted in the general description, which may be essential to its complete success.

Such lanterns as these would be very proper for military store-houses; and Rochon of *the National Institute* was employed, since the commencement of the present war, to make them, if he could, for the marine store-houses of France. While he was thus engaged, however, it occurred to him that he might supply the pressing wants of the navy without horn, merely by filling up the interstices of wirecloth with fine transparent glue. In carrying this thought into execution, he at first tinned the iron wires of the sieve-cloth he made use of; but afterwards found it more convenient, in every respect, to give it a slight coating of oil paint to preserve it from rust. The glue he made use of was afforded by boiling the clippings of parchment with the air-bladders and membranes of sea-fish; materials which he used, not from any notion that they were preferable to isinglass, but because they were the cheapest he could procure. He added the juice of garlic and cyder to his composition, in such proportions as he found to communicate great tenacity, and somewhat more of transparence than it would have possessed without them. Into this transparent and very pure glue or size he plunged his wire-cloth, which came out with its interstices filled with the compound. It is requisite that the size should possess a determinate heat and consistence, concerning which experience alone must guide the operator.

When this prepared wire-cloth is fixed in the lantern, it must be defended from moisture by a coating of pure drying linseed oil; but even in this state it is not fit to be exposed to the weather. The ease with which these lanterns are repaired in case of accident, by a slight coating of glue, is pointed out as a great advantage by the inventor; who likewise informs us, that they were used in the expedition to Ireland as signal-lanterns, though contrary to his wishes.

LAPIS Fungifer, a species of earth found near Rome, Naples, and Florence, of which the following account is taken from the *New Transactions of the Royal Academy of Sciences at Stockholm* for the year 1797: Near Naples the lapis fungifer is found in the chalk-hills like a white stalactites, intermixed with a great many fine roots of shrubs; and near Florence there is a species of it, consisting of hardened turf, which is dug up near volcanoes. The author made experiments with a piece procured from Italy, and found that 100 parts contain from 45 to 46 siliceous earth, 23 argillaceous earth, 7 calcareous earth, and 20 calx of iron, with some white magnesia and vegetable alkali. It is well known, that when this friable species of stone is preserved in cellars and moistened with water, it produces abundance of eatable mushrooms, which in Italy are highly esteemed and brought to the first tables. Hence the origin of its name.

Lardizabala.

LARDIZABALA, a new genus of plants belonging to the *diœcia hexandria* of Linnæus. It is a native of Chili, and is thus described in Perouse's Voyage, from drawings sent to France by La Martiniere. The leaves are alternate, on footstalks inflated at their base. Each leaf is biternate, that is to say, it is divided into three leaflets, each of which is again subdivided into three oval sharp-pointed folioles, which, when young, are entire, but afterwards become obscurely lobed The flowers, disposed in simple and pendent clusters, grow towards the top of the stem and of the branches, in the axillæ of the leaves. The plant is diœcius. At the base of each cluster of blossoms are two small, rounded, oval, floral leaves.

Male Flower.—*Calyx* formed of six expanding leaves, oblong oval, and obtuse, of which the three outermost are the largest. *Corolla* composed of six sharp lanceolated petals, opposite to, and shorter than, the leaves of the calyx. A cylinder rises from the centre of the flower of the length of the petals, terminated by six oblong bilocular anthers, which open from below.

Female Flower.—*Calyx*, similar to that of the male flower, but larger. *Corolla* inserted beneath the pistil, composed of six petals, rarely entire, but generally bifid or trifid at their summit: shorter than the leaves of the calyx. *Stamina* six, having the same insertion as the corolla; filaments distinct, broad, very short, surrounding the pistil; *anthers*, six, upright, oblong, acuminated, barren. *Seed bud*, cells, from three to six, oblong, gibbous on the outside, of nearly the length of the corolla; styles none; stigmata, sitting, oblong, permanent. *Berries*, equal in number to the cells, oblong, acuminated (divided into six cells, containing several angular seeds. *Flora Peruviana*).

The general character of the lardizabala evidently places this new genus among the family of the *menispermæ*, to which it is related by its climbing stalk, its bunches of diœcious flowers, by its six petals, stamina, and leaves of its calyx, by its pistil, composed of from three to six cells, which contain as many seeds. It differs from the known genera of this order only in its fruit, which, instead of being monospermous, contains several seeds. This character, which requires the introduction of a new section into the *menispermæ*, strengthens the relation of this family to the next order of the *anonæ*. In fact, the greater part of the genera of the anonæ, as they have in the same flower several fruits, with numerous seeds, differ in this particular from all the genera of the menispermæ; and by placing between them the lardizabala, we establish a natural transition.

tranſition. In order to confirm theſe reſemblances, it only remains to examine the inſide of the fruit, and particularly the ſtructure of the ſeeds. Thoſe of the meniſpermæ are reniform, at leaſt on the inſide, incloſed in a hinged pericarpium, and containing in their upper part a very ſmall dicotyledonus embryo. The characters that we have given of the lardizabala render probable a ſimilar ſtructure in its ſeeds.

LARMIER, in architecture, a flat ſquare member of the cornice below the cimaſium, and jets out fartheſt; being ſo called from its uſe, which is to diſperſe the water, and cauſe it to fall at a diſtance from the wall, drop by drop, or, as it were, by tears, *larme* in French ſignifying a tear.

LATUS Primarium, a right line drawn through the vertex of the ſection of a cone, within the ſame, and parallel to the baſe.

Latus Rectum. See *Conic Sections*. Encycl.

Latus Tranſverſum of the hyperbola, is the right line between the vertices of the two oppoſite ſections, or that part of their common axis lying between the two oppoſite cones.

LAVA. In addition to the obſervations of Sir William Hamilton, Bergman, Formes, and Dalmieu, on the compoſition of different lavas, which have been given in the *Encyclopædia*, we cannot refuſe ourſelves the pleaſure of noticing, in this place, thoſe of Sir James Hall. From a number of well-deviſed experiments, Sir James thinks himſelf warranted to conclude, that lava and whinſtone are intrinſically the ſame ſubſtance; and that their apparent differences ariſe wholly from the circumſtances under which they have paſſed from a liquid to a ſolid ſtate. The lavas, it is well known, have been cooled rapidly in the open air, and the whins (according to Dr Hutton's theory, which Sir James ſeems willing to adopt) ſlowly in the bowels of the earth.

Though we are far from adopting that theory in all its parts, to which we think inſuperable objections may be made (ſee Earth, *Encycl.* n° 120), we admit, that the experiments of Sir James Hall go far to eſtabliſh the identity of lava and whinſtone. Theſe experiments were made upon ſeven different ſpecies of whinſtone and ſix lavas, of which four were broken from the currents of Etna and Veſuvius by Sir James himſelf. Each of the original whinſtones was reduced, by fuſion and ſubſequent rapid cooling, to a ſtate of perfect glaſs. This glaſs, being again placed in the furnace, was ſubjected to a ſecond fuſion. The heat, being then reduced to a temperature generally about 28° of Wedgewood, was maintained ſtationary for ſome hours; when the crucible was either immediately removed, or allowed to cool with the furnace. The conſequence was, that in every caſe the ſubſtance had loſt the character of glaſs, and by cryſtallization had aſſumed in all reſpects that of an original whinſtone. It muſt be owned, that in moſt caſes the new production did not exactly reſemble the particular original from which it was formed, but ſome other original of the ſame claſs; owing to accidental varieties in the mode of refrigeration, and to chemical changes which unavoidably took place during the proceſs. In the caſe, however, of the rock of Edinburgh caſtle, and of that of the baſaltic columns of Staffa, the artificial ſubſtances bear a complete reſemblance to their originals, both in colour and texture.

The lavas were now treated in the ſame way, and were each, by fuſion and rapid cooling, reduced, as the whinſtones had been, to glaſs. This glaſs, when fuſed again and cooled ſlowly, yielded the ſame kind of cryſtallized, ſtony, or earthy maſſes, completely reſembling an original whin or lava.

Although the internal ſtructure of lava was thus accounted for, yet Sir James was embarraſſed with the ſtate of its external ſurface; which, though cooled in contact with the open air, is ſeldom or never vitreous, holding an intermediate ſtation between glaſs and ſtone; but this difficulty was removed by a circumſtance which took place in the courſe of theſe experiments. It was found that a ſmall piece of glaſs of any of the lavas, or of ſeveral of the whins being introduced into a muffle, the temperature of which was at any point between the 20th and the 22d degree of Wedgewood's ſcale, the glaſs became quite ſoft in the ſpace of one minute; but, being allowed to remain till the end of a ſecond minute, it was found to have become hard throughout in conſequence of a rapid cryſtallization, to have loſt its character of glaſs, and to have become by 12 or 14 degrees more infuſible, being unaffected by any heat under 30, though the glaſs had been fuſible at 18° or at 16°. This accounted for the ſcoria on the ſurface of lavas; for the ſubſtance even at the ſurface, being in contact with the flowing ſtream, and ſurrounded with heated air, could not cool with exceſſive rapidity: and the experiment ſhews, that ſhould any part of the maſs, in deſcending heat, employ more than one or two minutes in cooling from 22 to 20, it would infallibly loſe its vitreous character.

Independently of any alluſion to ſyſtem or to general theory, Sir James Hall flatters himſelf that theſe experiments may be of ſome importance, by ſimplifying the hiſtory of volcanoes; and, above all, by ſuperſeding ſome very extraordinary, and, he conceives, unphiloſophical opinions advanced with regard to volcanic heat, which has been ſtated as poſſeſſing very little intenſity, and as acting by ſome ocult and inconceivable influence, or with the help of ſome inviſible agent, ſo as to produce liquidity without fuſion. Theſe ſuppoſitions, which have been maintained ſeriouſly by ſome of the moſt celebrated naturaliſts in Europe, have originated from the difficulty of accounting for the ſtony character of lavas when compared with that of glaſs, which they aſſume in conſequence of fuſion in our furnaces. But now he hopes we may be relieved from the neceſſity of ſuch violent efforts of imagination, ſince the phenomena have been fully accounted for by the ſimple, though unnoticed, principle of refrigeration, and have been repeated again and again with eaſe and certainty in a ſmall chamber furnace.

LAVOISIER (Antoine Laurent), was born in Paris on the 26th of Auguſt 1743. His father, who directed his education, was opulent, and ſpared no coſt for his improvement. The youth ſhewed a decided taſte for the phyſical ſciences. In 1764, government having propoſed an extraordinary premium for the beſt and cheapeſt mode of lighting the ſtreets of a large city, Lavoiſier obtained the gold medal; and his memoir, full of nice inveſtigation, was printed by the Academy. Into that body he was received on the 13th May 1768, in ſpite of a formidable oppoſition; and to its ſervice he ever after devoted his labours, and became one of its moſt uſeful aſſociates and coadjutors.

His

Lavoifier. His attention was fucceffively occupied with every branch of phyfical and mathematical fcience. The pretended converfion of water into earth, the analyfis of gypfum in the neighbourhood of Paris, the cryftallization of falts, the effects produced by the *grande de loupe* of the garden of the Infanta, the project of bringing water from l'Yvette to Paris, the congelation of water, and the phenomena of thunder and the aurora borealis—all occupied his attention.

Journeys, undertaken in concert with Guettard into every diftrict of France, enabled him to procure numberlefs materials towards a defcription of the lithological and mineralogical empire; thefe he arranged into a kind of chart, which wanted little of being completed. They ferved alfo as a foundation for a more laborious work of his on the revolutions of the globe, and the formation of *Couches de la Terre;* a work of which two beautiful fketches are to be feen in the Memoirs of the French Academy for 1772 and 1787. All the fortune and all the time of Lavoifier were devoted to the culture of the fciences; nor did he feem to have a preponderating inclination for any one in particular, until an event, fuch as feldom occurs in the annals of the human mind, decided his choice, and attached him thenceforth exclufively to chemiftry—a purfuit which has fince rendered his name immortal.

The important difcovery of gafes was juft announced to the philofophical world. Black, Prieftley, Scheele, Cavendifh, and Macbride, had opened to phyfiologifts a fort of new creation; they had commenced a new era in the annals of genius, which was to become equally memorable with thofe of the compafs, printing, electricity, &c.

It was about the year 1770 that Lavoifier, ftruck with the importance and grandeur of this difcovery, turned his attention to this inexhauftible fountain of truths, and inftantly perceived, by a kind of inftinct, the glorious career which lay before him, and the influence which this new fcience would neceffarily have over the whole train of phyfical refearches. Of thofe who had preceded him, the moft indefatigable experimenter was Prieftley: but facts the moft brilliant remained frequently unproductive in his hands: on every occafion he was ready to frame fome crude hypothefis, which as haftily he abandoned. Lavoifier was imbued with the true fpirit of inductive philofophy; his obfervations, eminently precife and luminous, always pointed to general views. In 1774, he publifhed his chemical opufcules, which contained a very neat hiftory of all that had been done with refpect to gafes, and concluded with the author's capital experiments, by which it was proved, that metals, in calcination, derive their augmentation of weight from the abforption of air. Soon afterward, he fhewed, in oppofition to Prieftley, that nitrous acid is compofed of air; a remark, of which the importance appeared in the fequel. His ingenuity as a chemift was now fo well known, that in 1776 Turgot employed him to infpect the manufacture of gun-powder. He introduced fome valuable improvements, and, fuppreffing the odious vifits in queft of the materials of faltpetre, he yet quintupled its produce. The gun-powder would now carry 120 toifes, when formerly it would not reach 90. This fuperiority was indeed acknowledged in the laft war.

It had been alledged, that by frequent diftillation water is converted into earth. This queftion Lavoifier refolved in 1778, having fhewn that the earthy fediment was owing to the continual erofion of the internal furface of the retort. In that fame year he made a more interefting difcovery; namely, that the refpirable portion of the atmofphere is a conftituent principle of all acids, and which he therefore denominated *oxygen:* a moft important fact, and the firft great ftep towards the new chemiftry; which the compofition of water, afcertained in 1783, triumphantly completed.

Lavoifier poffeffed decifive advantages over his contemporaries; he ftudied a geometrical accuracy of inveftigation; and his wealth enabled him to make experiments on a large fcale, and to ufe inftruments of the moft perfect conftruction. He was able to hold in his houfe, twice every week, affemblies, to which he invited every literary character that was moft celebrated in geometrical, phyfical, and chemical ftudies; in thefe inftructive *converfationes*, difcuffions, not unlike fuch as preceded the firft eftablifhment of academies, regularly took place. Here the opinions of the moft eminent literati in Europe were canvaffed; paffages the moft ftriking and novel, out of foreign writers, were recited and animadverted on; and theories were compared with experiments. Here learned men of all nations found eafy admiffion; Prieftley, Fontana, Blagden, Ingenhoufz, Landriani, Jacquin, Watt, Bolton, and other illuftrious phyfiologifts and chemifts of England, Germany, and Italy, found themfelves mixed in the fame company with La Place, La Grange, Borda, Coufin, Meunier, Vandermonde, Monge, Morveau, and Berthollet. Happy hours paffed in thefe learned interviews, wherein no fubject was left uninveftigated that could poffibly contribute to the progrefs of the fciences, and the amelioration and happinefs of man. One of the greateft benefits refulting from thefe affemblages, and the influence of which was foon afterwards felt in the academy itfelf, and confequently in all the phyfical and chemical works that have been publifhed for the laft twenty years in France, was the agreement eftablifhed in the methods of reafoning between the natural philofophers and the geometricians. The precifion, the feverity of ftyle, the philofophical method of the latter, was infenfibly transfufed into the minds of the former; the philofophers became difciplined in the tactics of the geometricians, and were gradually moulded into their refemblance.

It was in the affemblage of thefe talents that Lavoifier embellifhed and improved his own. When any new refult from fome important experiment prefented itfelf, a refult which threatened to influence the whole theory of the fcience, or which contradicted theories till then adopted, he repeated it before this felect fociety. Many times fucceffively he invited the fevereft objections of his critical friends; and it was not till after he had furmounted their objections, to the conviction and entire perfuafion of the fociety; it was not till after he had removed from it all myftery and obfcurity, that he ventured to announce to the world any difcovery of his own.

At length he combined his philofophical views into a confiftent body, which he publifhed in 1789, under the title of *Elements of Chemiftry;* a book which is a moft beautiful model of fcientific compofition, clear, logical, and elegant. It would be foreign to our purpofe to attempt an expofition of the principles, or to expatiate

tiate on the merits, of this celebrated syftem; which, within the fpace of a very few years, has been almoft univerfally adopted, and which, if not the genuine interpretation of nature, approaches as near to it as the prefent ftate of knowledge will permit. See CHEMISTRY in this *Supplement*.

The laft, but not the leaft ufeful, of Lavoifier's philofophical refearches, on the Perfpiration of Animals, was read to the Academy on the 4th May 1791, and of which part was publifhed in the volume for 1790. He found, by fome delicate experiments, made in conjunction with Seguin, that a man in 24 hours perfpires 45 ounces; that he confumes 33 ounces of vital air; that he difcharges from the lungs 8 cubic feet of carbonic acid gas, of which one-third is carbon and two-thirds are oxygen; that the weight of water difcharged from the lungs amounts to 23 ounces, of which 3 are hydrogen and 20 oxygen, exclufive of 6 ounces of water already formed, loft in pulmonary perfpiration. Thefe difcoveries were directed to the improvement of medicine.

We have mentioned the affiftance which Lavoifier received while he was digefting his new fyftem of chemiftry; but we muft add, that to him pertains exclufively the honour of a founder. His own genius was his fole conductor, and the talents of his affociates were chiefly ufeful in illuftrating difcoveries he himfelf had made; he firft traced the plan of the revolution he had been a long time conceiving; and his colleagues had only to purfue and execute his ideas.

In the twenty volumes of the Academy of Sciences, from 1772 to 1793, are 40 memoirs of Lavoifier, replete with all the grand phenomena of the fcience; the doctrine of combuftion, general and particular; the nature and analyfis of atmofpherical air; the formation and fixation of elaftic fluids; the properties of the matter of heat; the compofition of acids; the augmentation of the ponderofity of burnt bodies; the decompofition and recompofition of water; the diffolution of metals; vegetation, fermentation, and animalization. For more than 15 years confecutive, Lavoifier purfued, with unfhaken conftancy, the route he had marked out for himfelf, without making a fingle falfe ftep, or fuffering his ardour to be damped by the numerous and increafing obftacles which conftantly befet him.

Many were the fervices rendered by Lavoifier, in a public and private capacity, to manufactures, to the fciences, and to artifts. He was treafurer to the Academy after Buffon and Tillet, and introduced economy and order into the accounts. He was alfo a member of the Board of Confultation, and took an active fhare in whatever was going forwards. When the new fyftem of meafures was agitated, and it was propofed to determine a degree of the meridian, he made accurate experiments on the expanfion of metals, and conftructed a metalline thermometer. By the National Convention he was confulted on the means of improving the manufacture of affignats, and of increafing the difficulties of forging them.

Like a good citizen, Lavoifier turned his thoughts to political economy. Between the years 1778 and 1785, he allotted 240 *arpents* in the Vendômois to experimental agriculture, and increafed the ufual produce by one-half. In 1791, he was invited by the Conftituent Affembly to digeft a plan for fimplifying the collection of the taxes. This gave occafion to an excellent report, afterwards printed with the title of *Territorial Riches of France*. At this time, alfo, he was appointed commiffionary of the national treafury, in which he effected fome beneficial reforms.

During the horrors of the Robefpierrean dictatorfhip, Lavoifier told La Lande that he forefaw he fhould be ftripped of his property, but that he would work for his bread. The profeffion of apothecary would have fuited him the beft. But his doom was already fixed. On the 8th of May 1794, confounded with 28 farmers-general, he fuffered on the fcaffold, merely becaufe he was rich!

Lavoifier was tall, and of a graceful fprightly appearance. He was mild, fociable, obliging, and extremely active; and in his manners he was unaffectedly plain and fimple. Many young men, not bleffed with the gifts of fortune, but incited by their genius to woo the fciences, have confeffed their obligations to him for pecuniary aid; many, alfo, were the unfortunate whom he relieved in filence, and without the oftentation of virtue. In the communes of the department of the *Loir* and *Char*, where he poffeffed confiderable eftates, he would frequently vifit the cottages of indigence and diftrefs; and long will his memory be cherifhed there. But his reputation, influence, virtues, and wealth, gave him a great preponderance, which unfortunately prevoked the jealoufy of a crew of homicides, who made a fport of facrificing the lives of the beft of men to a fanguinary idol.

This great and good man married, in 1771, Marie-Anni-Pierette Paulze, daughter of a farmer-general; a woman whofe wit and accomplifhments conftituted the charm of his life; who affifted him in his labours, and even engraved the figures of his laft work.

LEAD. See that article, *Encycl*, and CHEMISTRY-*Index* in this *Supplement*. It is well known that lead generally contains a portion of filver, and fometimes of gold; and that there are occafions, particularly in affaying, when it is of importance to have it freed from thefe metals. For accomplifhing thefe purpofes different proceffes have been propofed; but the following, by Pet. Jac. Hjelm, as it is the leaft expenfive, promifes to be the moft ufeful:

LITHARGE (fee *Encycl.*) was the fubftance on which this chemift made his experiments, and his principal object was to free it from all mixture of filver. This was accomplifhed in the following manner: He placed a crucible, in which half a pound of litharge found good room, and which was fitted with a clofe cover, in a wind furnace filled with dead coals. He then put into the crucible a mixture of four ounces of potafh and the fame quantity of powder of flint. When the whole was well melted by ftrengthening the draught, and making the coals glow, he took off the cover, and laid hold of the crucible with a pair of tongs, in order to take it out, and to fuffer this very fufible glafs to cover the infide of the crucible, to fecure it from the glafs of the lead which he meant to melt in it. The fuperfluous glafs was poured out; the crucible again placed on its foot, and half a pound of litharge thrown into it with a fhovel. The cover was placed upon it while the litharge was melting; and when it was thoroughly glowing

Lead, Ledyard.

glowing with fluid, charcoal dust was sifted into the uncovered crucible through a sieve, so that the surface of the litharge was completely covered with it. This immediately produced an effervescence, and the rising of bubbles, by means of the separation of the air occasioned by the reduction of the lead. During this process, the cover was put on, and a few coals thrown into the furnace: when these were burnt, every thing in the crucible was quiet, and the melted mass was poured into a warm conical mould. The crucible was then again filled with half a pound of the same kind of litharge, and put into the furnace, and charcoal dust was several times sifted over the melted surface, till it was well covered before the mass was thrown out, a sufficient space being every time left for the effervescence. The first mass had, in the mean time, become cool, and, on examination, contained four ounces of lead at the bottom, and litharge at the top. When this litharge was reduced with potashes and wine stone, the lead thence obtained, which weighed 23 ounces, was found to contain less than one-half grain of silver in the pound. In the second mass there was found somewhat more than six ounces of lead, which contained all the silver that had been before mixed with the litharge, because in the lead which had been reduced from the litharge in the above manner, there were no perceptible traces of silver. This lead was then melted over a slow fire, and cast into bars, which were rolled smooth, and formed into masses of a known weight, to be used for assaying gold and silver, and for other purposes of the same kind. All these meltings were made in one crucible, which, according to every appearance, remained unhurt. If the same experiments were made with red lead, the like result would infallibly follow.

With the same view of obtaining lead free from silver, he melted, in the like manner, half a pound of white lead, which produced half an ounce of lead. When the litharge standing over it was revived, the lead obtained was still found to contain too much silver. He therefore precipitated another half pound of white lead by charcoal powder, after the lead that fell from it had been separated; and then it produced, by reviving, a mass of lead without any mixture of silver.

LEDYARD (———), the celebrated, though unfortunate, traveller, was a native of North America, but of what province we have not learned. We are equally ignorant of the year of his birth, and the rank of his parents; but have no reason to think that they were opulent. From his early youth he displayed a strong propensity to visit unknown and savage countries; and to gratify that propensity, he lived for several years with the American Indians, whose manners and habits he seemed in some degree to have acquired. Afterwards he sailed round the world with Captain Cook in the humble station of a corporal of marines; and on his return, he determined to traverse the vast continent of America, from the Pacific to the Atlantic Ocean.

This design being frustrated by his not obtaining a passage to Nootka Sound, he determined to travel over land to Kamschatka. With this view he went over to Ostend, with only ten guineas in his pocket, and proceeded by the way of Denmark and the Sound to the capital of Sweden, and endeavoured to cross the Gulph of Bothnia on the ice; but finding, when he came to the middle, that the water was not frozen, he walked round the gulph to Petersburgh. Here he found himself without stockings or shoes; but procured relief from the Portuguese ambassador, and obtained leave to proceed with a detachment of stores to Yakutz. He made this journey of six thousand miles, and there met Mr Billengs, an Englishman, whom he had known on board Captain Cook's ship. From thence he went to Oczakow, on the coast of the Kamschatka Sea; but being too late to embark that year, returned to Yakutz to winter. Here he was, on some suspicion, seized, conveyed on a sledge through Northern Tartary, and left on the frontiers of the Polish dominions. In the midst of poverty, rags, and disease, he however reached Koningsburgh, where he found friends that enabled him to reach England.

Ledyard.

On his arrival in London, he waited on Sir Joseph Banks, on whose credit he had, in his distress, received at different times 25 guineas. Sir Joseph communicated to him the views of the African Association, and pointed out the route in which they wished Africa to be explored. On his engaging at once in the enterprise, Sir Joseph asked him when he would be able to set out. "To-morrow morning," replied Ledyard, without hesitation. At this interview the president of the Royal Society declares, that he was struck with the figure of the man, the breadth of his chest, the openness of his countenance, and the rolling of his eye. Though scarcely exceeding the middle size, his figure indicated great strength and activity. Despising the accidental distinctions of society, he seemed to regard no man as his superior; but his manners, though coarse, were not disagreeable. His uncultivated genius was original and comprehensive. From the native energy of his mind, he was adventurous, curious, and unappalled by dangers; while the strength of his judgment united caution with energy. The track pointed out to him was from Cairo to Senaar, and thence westward in the latitude and supposed direction of the Niger.

He was not ignorant that the task assigned him was arduous and big with danger; but instead of shrinking from it, he said, on the day of his departure, "I am accustomed to hardships; I have known both hunger and nakedness to the utmost extremity of human suffering; I have known what it is to have food given me as charity to a madman; and I have at times been obliged to shelter myself under the miseries of that character to avoid a heavier calamity. My distresses have been greater than I ever owned, or ever will own to any man. Such evils are terrible to bear, but they never yet had power to turn me from my purpose. If I live, I will faithfully perform, in its utmost extent, my engagement to the Society: and if I perish in the attempt, my honour will be safe; for death cancels all bonds."

After receiving his instructions and letters of recommendation, this intrepid traveller sailed from London on the 30th of June 1788; and in 36 days arrived at Alexandria. Proceeding to Cairo, where he arrived August the 17th, he visited the slave markets, and conversed with the travelling merchants of the caravans. These sources of information, generally neglected by travellers, enabled him to obtain, at a very small expence, more correct information concerning the African nations and their trade, the position of places, the nature of the country, the manner of travelling, &c. than could have been easily obtained by any other method. He thus

Ledyard. thus learned, that the Arabs of the desert have an invincible attachment to liberty, though it is singular that they have no word to express liberty in their language. The Mahomedans of Africa are a trading, superstitious, and warlike set of vagabonds. He saw near 200 black slaves exposed to sale, who had been brought from the interior parts of Africa; their appearance savage, but not like prisoners of war; they had head ornaments, and their hair plaited in detached plaits of great length. Another parcel, which had come from Darfoor, were mostly women; and the beads, and some other ornaments which they wore, were Venetian. They were well formed, quite black, had the true Guinea face, and curled hair. Mr Ledyard was informed, that the king of Senaar was a merchant, and concerned in the caravans; that 20,000 negro slaves are imported into Egypt annually. Among some Senaar slaves, he saw three of a bright olive colour, but their heads uncommonly formed, the forehead the narrowest, longest, and most protuberant he ever saw.

The Senaar caravan is the most rich; that of Darfoor is not equally so, though it trades with almost the same commodities. Besides slaves, these are gum, elephants teeth, camels, and ostrich-feathers; for which are received in exchange trinkets, soap, antimony, red linen, razors, sciffars, mirrors, and beads. Wangara, to which the caravans also trade, was represented to Mr Ledyard as a kingdom producing much gold; but the king seems to intermiddle with commerce as well as the potentate of Senaar; for in order to deceive strangers. and prevent them from guessing at the extent of his riches, he was reported to vary continually the gold used in barter, which it is his province to regulate, and of which he issues at one time a great quantity, and at others little or none. A caravan goes from Cairo to Fezzan, which they call a journey of fifty days; and as the caravans travel about 20 miles a day, the distance must be about 1000 miles; from Fezzan to Tombuctoo is 1800 miles; from Cairo to Senaar about 600 miles.

Such was the information which Mr Ledyard derived from the merchants of the caravans in Egypt; but when he was about to verify it by his own observations, and had announced to the Association that his next dispatch would be dated from Senaar, he was seized with a bilious complaint, which frustrated the skill of the most eminent physicians, and put a period to his travels and his life at Cairo. It is needless to say how much his death was regretted, or how well he was qualified for the arduous enterprise in which he had engaged. The person who, with such scanty funds, could penetrate the frozen regions of Tartary, subsist among their churlish inhabitants, and ingratiate himself with the ferocious Moors of Egypt, could hardly have failed to obtain a kind reception from the gentle and hospitable Negro, had no untoward circumstance intervened. At Senaar, indeed, his risk would have been great; and Mr Bruce was decidedly of opinion, that a man so poorly attended as Mr Ledyard, could never have made his escape from that treacherous and ferocious people.

The observations of this accurate observer on the female character, though they have been repeatedly quoted in other works, are well entitled to a place here; and with them we shall conclude this sketch of his life: "I have always (says he) remarked, that women in all countries are civil and obliging, tender and humane; that they are ever enclined to be gay and cheerful, timorous and modest; and that they do not hesitate, like man, to perform a generous action. Not haughty, not arrogant, not supercilious; they are full of courtesy, and fond of society; more liable, in general, to err than man; but in general also more virtuous, and performing more good actions than he. To a woman, whether civilized or savage, I never addressed myself, in the language of decency and friendship, without receiving a decent and friendly answer. With man it has often been otherwise. In wandering over the barren plains of inhospitable Denmark, through honest Sweden, and frozen Lapland, rude and churlish Finland, unprincipled Russia, and the wide spread regions of the wandering Tartar; if hungry, dry, cold, wet, or sick, the women have ever been friendly to me, and uniformly so. And to add to this virtue (so worthy the appellation of benevolence), these actions have been performed in so free and kind a manner, that if I was dry, I drank the sweetest draught; and if hungry, I eat the coarsest morsel with a double relish." For a fuller account of *Ledyard*, see *The Transactions of the African Association*, or *A View of the Late Discoveries in Africa*

Ledyard ‖ Lemyngton

Hyperbolic LEGS, are the ends of a curve line that partakes of the nature of the hyperbola, or having asymptots.

LEMINGTON Priors, is a village two miles east of the town of Warwick, famous for its mineral waters. One salt spring, which rises near the church yard, has been long known, as well as another which rises in the bed of the river; but the most remarkable spring was discovered in the year 1790. The waters of both springs have been analyzed with great accuracy by William Lambe, M. A. late Fellow of St John's colledge, Cambridge, who has given us the following synoptical table of the substances contained in them:

Gaseous Fluids contained in a Wine-gallon in Cubic inches.

	Water of the new spring.	Water of the old spring.
Hepatic gas -	*Too small to be measured.*	*Too small to be measured.*
Azotic gas -	3.5	3
Carbonic acid gas	.5	—

Solid contents of a Wine-gallon in Grains.

	Water of the new spring.	Water of the old spring.
Carbonat of iron	.75	
Oxyds of iron and manganese -	—	*Too small to be weighed.*
Oxygenated muriat of iron and manganese - -	*Unknown, but very small.*	*Unknown, but very small.*
Sulphur - -	*Unknown, but very small.*	——
Muriat of magnesia	11.5	58
Muriat of soda	430	350
Sulphat of Soda	152	62
Sulphat of lime	112	146

In the course of his experiments, for which we must refer to the original memoir, in Transactions of the Manchester Society, Mr Lambe thinks he discovered the origin of the *muriatic acid*. He found a coincidence, very unexpected, between the hepatised solution of iron and the oxygenated muriat of iron. "I had almost concluded (says he), from the resemblance between the properties of this salt and the phenomena of the water, that the water contains this very salt. Now, I conclude, that they contain a matter, be it what it may, produced by the action of hepatic gas on iron. But they are the very same facts which form the basis, upon which each separate inference is built. Does it not follow, then, as a necessary consequence, that the hepatised solution itself contains a muriat of iron highly oxygenated, and that therefore *in this process muriatic acid is generated?* This conclusion seemed authorised by reason, and experiment has confirmed it."

LEMNISCATE, the name of a curve in the form of the figure of 8.

LEMON Juice, is an article of such harmless luxury, and in some cases of such real utility, that many of our readers will be pleased to know a simple method by which they may obtain it in great purity. In the article Chemistry (*Suppl.*), n° 476, we have shewn from Scheele and Dizé, how to obtain the citric acid perfectly pure, and in the form of crystals; but here we mean nothing more than to shew how it may be completely separated from that slimy substance with which it is always mixed in the lemon, without allowing it time to spoil or to acquire any disagreeable taste during the separation. This we are enabled to do by M. Brugnatelli, who, in the second volume of the *Annali de Chimia*, informs us, that he expressed in the common manner the juice of perfectly ripe lemons, and strained it through a piece of linen. In half an hour he strained it again, to free it from a little slimy matter which had settled at the bottom of the vessel. He then added to the juice a certain quantity of the strongest spirit of wine, and preserved the mixture for some days in a well-corked bottle. During that time there was a considerable deposit, which to all appearance was of a slimy nature, and which he separated by filtering paper. If the fluid was too thick to pass through the filter, he diluted it again with spirit of wine. After this operation, the deposit remained on the paper, which was entirely covered with it; and he obtained, in the vessel placed below, the purest acid of lemons combined with spirit of wine.

If it be required to obtain the acid perfectly pure, nothing is necessary but to separate from it the spirit of wine, which can be best effected by evaporation. The acid of the lemons assumes, after it has been freed from the spirit of wine and the moisture combined with it, a yellowish colour, and becomes so strong, that by its taste it may be considered as a mineral acid.

It is not necessary to evaporate the spirit of wine in a close vessel, if the experiment is made only on a small scale; nor is there any danger that in open vessels any of the acid will be lost, as it is too fixed to be votalitised by the same degree of heat at which spirit of wine evaporates. This acid has peculiar properties, which deserve farther examination.

LENSES (see Lens and Dioptrics, *Encycl.*), are either blown or ground.

Blown Lenses are used only in the single microscope; and the usual method of making them has been to draw out a fine thread of the soft white glass called *crystal*, and to convert the extremity of this into a spherule by melting it at the flame of a candle. But this glass contains lead, which is disposed to become opake by partial reduction, unless the management be very carefully attended to. We are informed, however, by Mr Nicholson, that the hard glass used for windows seldom fails to afford excellent spherules. This glass is of a clear bright green colour when seen edgewise. A thin piece was cut from the edge of a pane of glass less than one-tenth of an inch broad. This was held perpendicularly by the upper end, and the flame of a candle was directed upon it by the blow-pipe at the distance of about an inch from the lower end. The glass became soft, and the lower piece descended by its own weight to the distance of about two feet, where it remained suspended by a thin thread of glass about one five-hundreth of an inch in diameter. A part of this thread was applied endwise to the lower blue part of the flame of the candle without the use of the blow-pipe. The extremity immediately became white-hot, and formed a globule. The glass was then gradually and regularly thrust towards the flame, but never into it, until the globule was sufficiently large. A number of these were made; and being afterwards examined, by viewing their focal images with a deep magnifier, proved very bright, perfect, and round. This, as the ingenious author observes, may prove an acceptable piece of information to those eminent men (and there are many such), whose narrow circumstances, or remote situations, are obliged to have recourse to their own skill and ingenuity for experimental implements.

Ground Lenses, are such as are ground or rubbed into the desired shape, and then polished. Different shapes have been proposed for lenses; but in the article Optics, n° 251 (*Encycl.*), it has been shewn that, after all, the spherical is the most practically useful. By many of the methods of grinding, however, the artificer, with his utmost care, can only produce an approximation to a truly spherical figure; and, indeed, gentlemen have, for the most part, nothing to depend on for the sphericity of the lenses of their telescopes, but the care and integrity of the workmen. In the 41st volume of the Transactions of the Royal Society of London, a machine is described by Mr Samuel Jenkins, which, as it is contrived to turn a sphere at one and the same time on two axes, cutting each other at right angles, will produce the segment of a true sphere merely by turning round the wheels, and that without any care or skill in the workmen. The following description of this machine will enable our readers fully to comprehend its construction, and the mode of using it: Plate
A is a globe covered with cement, in which are fixed XXXII.
the pieces of glass to be ground. This globe is fastened to the axis, and turns with the wheel B. C is the brass cup which polishes the glass: this is fastened to the axis, and turns with the wheel D. The motion of the cup C, therefore, is at right angles with the motion of the globe A; whence it follows demonstrably, that the pieces of glass ground by this double motion must be formed into the segments of spheres.

LEO X. is a pontiff to whom learning, and art, and science, are so deeply indebted, that not to give a sketch of his life and character, in a Work of this kind, would be an unpardonable omission. A character of him is indeed given in the *Encyclopædia*; but it is so far from the truth, Leo. truth, that it is difficult to conceive the prejudices under which he must have laboured by whom such a libel was drawn up.

Leo, whose name, before his elevation to the pontificate, was *Giovanni de Medici*, was the second son of Lorenzo de Medici, justly styled the Magnificent. In the life of that great man published in this *Supplement*, the reader will see by what means, and for what purpose, he got Giovanni raised to the dignity of cardinal at so early a period of life; and in the elegant work of Roscoe, to which we there refer, he will find such instructions of Lorenzo to the cardinal as must have made a deep impression on his youthful mind.

Speaking of his promotion, Lorenzo says, "The first thing that I would suggest to you is, that you ought to be grateful to God, and continually to recollect that it is not through your merits, your prudence, or your solicitude, that this event has taken place, but through his favour which you can repay only by a *pious*, *chaste*, and *exemplary life*; and that your obligations to the performance of these duties are so much the greater, as in your *early years* you have given some *reasonable expectation* that your riper age may produce such fruits. It would indeed be highly disgraceful, and as contrary to your duty as to my *hopes*, if at a time when others display a greater share of reason, and adopt a better mode of life, you should forget the *precepts of your youth*, and forsake the path in which you have *hitherto trodden*."—"I well know (continues Lorenzo), that as you are now to reside at Rome, that sink of all iniquity, the difficulty of conducting yourself by these admonitions will be increased. The influence of example is itself prevalent; but you will probably meet with those, who will particularly endeavour to corrupt and incite you to vice; because, as you yourself may perceive, your early attainment of so great a dignity is not observed without envy, and those who could not prevent your receiving that honour, will secretly endeavour to diminish it, by inducing you to forfeit the good estimation of the public."—"You are not unacquainted with the great importance of the character which you have to sustain; for you well know, that all the Christian world would prosper if the cardinals were what they ought to be; because in such a case there would always be a good pope, upon which the tranquillity of Christendom so materially depends."

As this was a confidential letter from Lorenzo to his son, the first of these extracts furnishes very sufficient evidence, that Giovanni had been at least a well behaved boy, diligent in his studies, and regular in his conduct; and without supposing him remarkably religious, the admonitions of such a father, aided by his own ambition and love of letters, would surely guard him against such gross licenciousness as that of which he is accused in the *Encyclopædia*. How much he revered his father, is apparent from the letter which he wrote to his brother immediately after Lorenzo's death. "What a father (says he) have we lost! How indulgent to his children! Wonder not, then, that I grieve, that I lament, that I find no rest. Yet, my brother, I have some consolation in reflecting that I have thee, whom I shall always regard in the place of a father," Surely this is not the language of a gross sensualist, or of one who could soon forget the salutary admonitions of such a parent as Lorenzo de Medici. But it is needless to infer the decency of his character by such reasonings as these. The story published in the *Encyclopædia*, of the manner in which the Cardinal de Medici obtained the tiara, cannot possibly be true. The reader, who shall turn to the article POPE in that Work, will find that the conclave, when fitted up for an election, is so large a place, that we may safely affirm, that had the cardinal's ulcer discharged matter so fetid as to *poison all the cells*, the assertion of the physicians would have been verified, and that in the then state of the healing art, the new pope could not have survived a month. Let it be remembered, too, that Leo, at his accession, was not 30, but 37 years of age, and that he had long ruled in Florence with sovereign sway by the same means which had upheld the authority of his father. The follies of youth, therefore, had he ever been remarkable for such follies, must have been over with him; and in such a state as Florence he could not have maintained the authority of Lorenzo, without exhibiting not only Lorenzo's liberality, but likewise his decency of manners.

The next charge brought against Leo in the *Encyclopædia*, is, that he published general indulgencies throughout Europe; and this is so expressed as to lead the ill informed reader to suppose, either that no such indulgencies had ever been published by any of his predecessors, or that there was something peculiarly scandalous in Leo's mode of publishing them. Both suppositions, however, are erroneous. The historian of the council of Trent, who certainly was not partial to the court of Rome, or to the dispensing power of the pope, has shewn, that the practice of raising money, by the publication of indulgencies, had prevailed ever since the year 1100; that many former popes had raised money in this manner for purposes much less laudable than those which Leo had in his eye; and that the real cause of Luther's attack upon Leo's indulgencies was, that they were preached through Saxony by the Dominican friars; whereas the preaching of former indulgencies had been committed to the hermits of St Augustine, the order to which Luther himself belonged!

Leo is likewise accused in the *Encyclopædia* of being a professed infidel, and of having called Christianity "a fable very profitable for him and his predecessors." But of the truth of this accusation there seems not to be the shadow of evidence. Leo had too much sense to utter expressions of this kind, even had he been an unbeliever in his heart; for he could not possibly expect that his indulgencies and pardons would be purchased, had he declared in such strong terms that they were of no value. Father Paul indeed says, that he was not a deep divine, or so pious as some of his predecessors; but he affirms, that he *adorned the papacy* with many admirable qualities; that he was learned, affable, liberal, *good*; that he delighted in healing differences, and that his equal had not, for many years, filled the chair of St Peter. Surely this is not the character of a profane infidel!

Leo has been charged with raising his own family to grandeur at the expence of justice; and of dealing treacherously, in order to effect this purpose, both with the Emperor and with the French king. But the charge is either false or greatly exaggerated. He lost no opportunity indeed of aggrandizing his relations, well knowing, that in order to secure to them any lasting benefit, it was necessary that they should be powerful enough to defend themselves, after his death, from the

Leo, Leslie.

rapacious aims of succeeding pontiffs; but, in prosecuting this plan, he was so far from acting tyrannically or injuriously to others, that during his pontificate, the papal dominions enjoyed a degree of tranquillity superior to any other Italian state. During the contests that took place between the emperor and the French king, so far from acting treacherously, he distinguished himself by his moderation, his vigilance, and his political address; on which account he is justly celebrated by an eminent historian of our own*, as "the only prince of the age who observed the motions of the two contending monarchs with a prudent attention, or who discovered a proper solicitude for the public safety."

* Dr Robertson.

We trust that no zealous Protestant will think we have employed our time ill, in vindicating the character of this splendid pontiff; for good learning, and, of course, true religion, are more indebted to Leo X. than to any other individual of the age in which he lived, his father Lorenzo alone excepted.

Leo Minor, the *Little Lion*, a constellation of the northern hemisphere, and one of the new ones that were formed out of what were left by the ancients, under the name of *Stellæ Informes*, or unformed stars. See ASTRONOMY, n° 406. *Encycl.*

LESLIE (Charles), was a man so eminent for his learning, his talents, and his piety, that a fuller account of him than that which is given in the *Encyclopædia* must be acceptable to our Christian readers. He was the second son of Dr John Leslie bishop of Clogher in Ireland, who was descended from an ancient family in the north of Scotland, and being an admirable scholar, rose to the dignity of bishop of Orkney in his own country, whence he was translated, in 1633, to Raphoe in Ireland, and afterwards, in 1661, to the see of Clogher.

Our author was born in Ireland, but in what year we have not learned. A ludicrous story goes indeed of his having been begotten in prison, and of his father having said that he hoped he would in consequence become the greatest scourge of the covenanters that Great Britain or Ireland had ever seen. This story, with all its circumstances as told to us, can hardly be true; but we think it could not have been fabricated, had not Charles Leslie been born within a year of Cromwell's conquest of Ireland, when the good bishop, having sustained a siege in his castle of Raphoe against that arch rebel, was some time kept in close confinement.

We are equally ignorant of the school where he was educated as of the year of his birth; but we know that he had his academical education in Trinity College, Dublin, where he took the degree of master of arts. In the year 1671, he lost his father, when he came over to England, and, entering himself in the Temple, studied law for some years, but afterwards relinquished it for the study of divinity. In 1680, he was admitted into holy orders; and, in 1687, was made chancellor of Connor.

About this period he rendered himself particularly obnoxious to the Popish party in Ireland, by his zealous opposition to them, which was thus called forth. Roger Boyle, bishop of Clogher, dying in 1687, Patrick Tyrrel was made titular Popish bishop, and had the revenues of the see assigned him by king James. He set up a convent of friars in Monaghan: and, fixing his habitation there, held a public visitation of his clergy with great solemnity; when, some subtile logicians attending him, he was so insolent as to challenge the Protestant clergy to a public disputation. Leslie undertook the task, and performed it to the satisfaction of the Protestants; though it happened, as it generally does at such contests, that both sides claimed the victory. He afterwards held another public disputation with two celebrated Popish divines, in the church of Tynan, in the diocese of Armagh, before a very numerous assembly of persons of both religions; the issue of which was, that Mr John Stewart, a Popish gentleman, solemnly renounced the errors of the church of Rome.

Biographical Dictionary.

As the Papists had got possession of an Episcopal see, they engrossed other offices too; and a Popish high-sheriff was appointed for the county of Monaghan. This proceeding alarmed the gentlemen in that county; who, depending much on Leslie's knowledge as a justice of peace, repaired to him, then confined by the gout to his house. He told them, that it would be as illegal in them to permit the sheriff to act as it would be in him to attempt it. But they insisting that he should appear himself on the bench at the next quarter sessions, and all promising to stand by him, he was carried thither with much difficulty and in great pain. When the sheriff appeared, and was taking his place, he was asked whether he was legally qualified; to which he answered pertly, "That he was of the king's own religion, and it was his Majesty's will that he should be sheriff." Leslie replied, "That they were not inquiring into his Majesty's religion, but whether he (the pretended sheriff) had qualified himself according to law, for acting as a proper officer; that the law was the king's will, and nothing else to be deemed such; that his subjects had no other way of knowing his will, but as it is revealed to them in his laws; and it must always be thought to continue so, till the contrary is notified to them in the same authentic manner." Upon this, the bench unanimously agreed to commit the pretended sheriff, for his intrusion and arrogant contempt of the court. Leslie also committed some officers of that tumultuous army which the Lord Tyrconnel raised for robbing the country.

In this spirited conduct Leslie acted like a sound divine and an upright magistrate; but though he thought himself authorised to resist the illegal mandates of his sovereign, like many other great and good men, he distinguished between active and passive obedience, and felt not himself at liberty to transfer his allegiance from that sovereign to another. Refusing therefore to take the oaths to king William and queen Mary, he was deprived of all his preferments; and in 1689 he removed with his family to England, where he published the following works, besides those already noticed in the *Encyclopædia*: 1, Answer to Archbishop King's State of the Protestants in Ireland. 2. Cassandra, concerning the new Associations, &c. 1703, 4to. 3. Rehearsals; at first a weekly paper, published afterwards twice a-week in a half-sheet, by way of dialogue on the affairs of the times; begun in 1704, and continued for six or seven years. 4. The Wolf stripped of his Shepherd's Clothing, in Answer to Moderation a Virtue, 1704, 4to. The pamphlet it answers was written by James Owen. 5. The Bishop of Sarum's [Burnet's] proper Defence, from a speech said to be spoken by him against occasional conformity, 1704, 4to. 6. The new Association

Aſſociation of thoſe called Moderate Churchmen, &c. occaſioned by a pamphlet, entitled, The Danger of Prieſtcraft, 1705, 4to. 7. The new Aſſociation, part 2d, 1705, 4to. 8. The Principles of Diſſenters concerning Toleration and occaſional Conformity, 1705, 4to. 9. A warning for the Church of England, 1706, 4to. Some have doubted whether theſe two pieces were his. 10. The good old Cauſe, or Lying in Truth; being a ſecond Defence of the Biſhop of Sarum from a ſecond Speech, &c. 1710. For this a warrant was iſſued out againſt Leſlie. 11. A Letter to the Biſhop of Sarum, in Anſwer to his Sermon after the Queen's Death, in Defence of the Revolution, 1715. 12. Salt for the Leech. 13. The Anatomy of a Jacobite. 14. Gallienus redivivus. 15. Delenda Carthago. 16. A Letter to Mr William Molyneux, on his Caſe of Ireland's being bound by the Engliſh Acts of Parliament. 17. A Letter to Julian Johnſon. 18. Several Tracts againſt Dr Higden and Mr Hoadly. 19. A Diſcourſe, ſhewing who they are that are now qualified to adminiſter Baptiſm. 20. The Hiſtory of Sin and Hereſy, &c. 1698, 8vo. 21. The Truth of Chriſtianity demonſtrated, in a Dialogue between a Chriſtian and a Deiſt, 1711, 8vo.—Againſt the Papiſts: 22. Of private Judgment and Authority in Matters of Faith. 23. The Caſe ſtated between the Church of Rome and the Church of England, &c. 1713. 24. The true notion of the Catholic Church, in Anſwer to the Biſhop of Meaux's Letter to Mr Nelſon, &c.

Beſides theſe, he publiſhed the four following Tracts: 25. A Sermon preached in Cheſter, againſt Marriages in different Communions, 1702, 8vo. This ſermon occaſioned Mr Dodwell's diſcourſe upon the ſame ſubject. 26. A Diſſertation concerning the Uſe and Authority of Eccleſiaſtical Hiſtory. 27. The Caſe of the Regal and the Pontificate. 28. A Supplement, in Anſwer to a Book, entitled, The regal Supremacy in Eccleſiaſtical Affairs aſſerted, &c. Theſe two laſt pieces were occaſioned by the diſpute about the rights of convocation, between Wake, &c. on one ſide, and Atterbury and his friends, among whom was Leſlie, on the other.

It is ſaid by the authors of the Biographical Dictionary, that, in conſequence of a publication of his, entitled, "The hereditary right of the crown of England aſſerted," he was under the neceſſity of leaving the kingdom; and that he repaired to the Pretender at *Bar le duc*, where he was allowed to officiate, in a private chapel, after the rites of the church of England; and where he endeavoured, though in vain, to convert the Pretender to the Proteſtant religion.

That he repaired to *Bar le duc*, and endeavoured to convert to the church of England him whom he conſidered as the rightful ſovereign of England, is indeed true; but we have reaſon to believe that this was not in conſequence of his being obliged to leave the kingdom. There is, in the firſt place, ſome grounds to believe, that "The hereditary right of the crown of England aſſerted" was not written by him; and there is ſtill in exiſtence undoubted evidence, that, in conſequence of his great fame as a polemic, he was ſent to *Bar le duc* for the expreſs purpoſe of endeavouring to convert the ſon of James II. by ſome gentlemen of fortune in England, who wiſhed to ſee that prince on the throne of his anceſtors. The writer of this article had the honour, 16 or 17 years ago, to be known to the granddaughter of one of thoſe gentlemen—a lady of the ſtricteſt veracity; and from her he received many anecdotes of Leſlie and his aſſociates, which, as he did not then foreſee that he ſhould have the preſent occaſion for them, he has ſuffered to ſlip from his memory. That lady is ſtill alive, and we have reaſon to believe is in poſſeſſion of many letters by Leſlie, written in confidence to her grandfather, both from *Bar le duc* and from St Germains; and by the account which ſhe gave of theſe letters, Leſlie appears to have conſidered his prince as a weak and incorrigible bigot, though, in every thing but religion, an amiable and accompliſhed man. This may have been his genuine character; for we all know that it was the character of his father: but it is not of him that we are writing.

Mr Leſlie having remained abroad from the year 1709 till 1721, returned that year to England, reſolving, whatever the conſequences might be, to die in his own country. Some of his friends acquainting Lord Sunderland with his purpoſes, implored his protection for the good old man, which his Lordſhip readily and generouſly promiſed. Mr Leſlie had no ſooner arrived in London, than a member of the houſe of commons officiouſly waited on Lord Sunderland with the news, but met with ſuch a reception from his Lordſhip as the malice of his errand deſerved. Our author then went over to Ireland, where he died April 13. 1722, at his own houſe at Glaſlough in the county of Monaghan.

His character may be ſummed up in a few words. Conſummate learning, attended by the loweſt humility, the ſtricteſt piety without the leaſt tincture of moroſeneſs, a converſation to the laſt degree lively and ſpirited, yet to the laſt degree innocent, made him the delight of mankind, and leaves what Dr Hickes ſays of him unqueſtionable, that he made more converts to a ſound faith and holy life than any other man of our times.

A charge, however, has been lately brought againſt him of ſuch a nature, as, if well founded, muſt detract not only from his literary fame, but alſo from his integrity. "The ſhort and eaſy method with the Deiſts" is unqueſtionably his moſt valuable, and apparently his moſt original work; yet this tract is publiſhed in French among the works of the Abbé St Real, who died in 1692; and therefore it has been ſaid, that unleſs it was publiſhed in Engliſh prior to that period, Charles Leſlie muſt be conſidered as a ſhameleſs plagiary.

The Engliſh work was certainly not publiſhed prior to the death of Abbé St Real; for the firſt edition bears date July 17th 1697; and yet many reaſons conſpire to convince us, that our countryman was no plagiary. There is indeed a ſtriking ſimilarity between the Engliſh and the French works; but this is no complete proof that the one was copied from the other. The article Philology in the *Encyclopædia Britannica*, of which Dr Doig is the author, was publiſhed the very ſame week with Dr Vincent's diſſertation on the Greek verb. It was therefore impoſſible that either of theſe learned men, who were till then ſtrangers to each others names, could have ſtolen aught from the other; and yet Dr Vincent's derivation of the Greek verb bears as ſtriking a reſemblance to Dr Doig's as the Abbé St Real's work does to Charles Leſlie's. In the article Miracle (*Encycl.*), the credibility of the goſpel miracles is eſtabliſhed by an argument, which the author certainly borrowed from no man, and which the late Principal

Campbell

Campbell considered as original; yet within half-a-year of the publication of that article, the credibility of the gospel-miracles was treated in the very same manner by F. Sayers, M. D. though there is in his dissertation complete internal evidence that he had not seen the article in the *Encyclopædia*. Not many months ago, the author of this sketch reviewed, in one of the journals, the work of a friend, which was at the same time reviewed in another journal, that at this moment he has never seen. Yet he has been told by a friend, who is much versant in that kind of reading, and knows nothing of his concern with either review, that the book in question must, in both journals, have been reviewed by the same hand; because in both the same character is given of it in almost the very same words!

After these instances of apparent plagiarism, which we know to be *only* apparent, has any man a right to say that Charles Leslie and the Abbé St Real might not have treated their subject in the way that they have done, without either borrowing from the other? The coincidence of arrangement and reasoning in the two works is indeed very surprising; but it is by no means so surprising as the coincidence of etymological deductions which appears in the works of the Doctors Doig and Vincent. The divines reason from the acknowledged laws of human thought; the reasonings of the grammarians, with all due deference to their superior learning, we cannot help considering as sometimes fanciful.

But this is not all that we have to urge on the subject. If there be plagiarism in the case, and the identity of titles looks very like it, it is infinitely more probable that the editor of St Real's works stole from Leslie, than that Leslie stole from St Real, unless it can be proved that the works of the Abbé, and this work in particular, were published before the year 1697. At that period, the English language was very little read or understood on the continent; whilst in Britain the French language was, by *scholars*, as generally understood as at present. Hence it is, that so many Frenchmen, and indeed foreigners of different nations, thought themselves safe in pilfering science from the British philosophers*; whilst there is not, that we know, one well authenticated instance of a British philosopher appropriating to himself the discoveries of a foreigner. If, then, such men as LEIBNITZ, John BERNOULLI, and Des CARTES, trusting to the improbability of detection, condescended to pilfer the discoveries of HOOKE, NEWTON, and HARRIOT, is it improbable that the editor of the works of St Real would claim to his friend a celebrated tract, of which he knew the real author to be obnoxious to the government of his own country, and therefore not likely to have powerful friends to maintain his right?

* See *Quantity* (Encycl.), *Astronomy*, *Dynamics*, *Impulsion*, and *Harriot*, in this Suppl.

But farther, Burnet, bishop of Sarum, was an excellent scholar, and well read, as every one knows, in the works of foreign divines. Is it conceivable, that this prelate, when smarting under the lash of Leslie, would have let slip so good an opportunity of covering with disgrace his most formidable antagonist, had he known that antagonist to be guilty of plagiarism from the writings of the Abbé St Real? Let it be granted, however, that Burnet was a stranger to these writings and to this plagiarism; it can hardly be supposed that *Le Clarc* was a stranger to them likewise. Yet this author, when, for reasons best known to himself, he chose (1706) to depreciate the argument of *the short method*, and to traduce its author as ignorant of ancient history, and as having brought forward his four marks for no other purpose than to put the deceitful traditions of Popery on the same footing with the most authentic doctrines of the gospel, does not so much as insinuate that he borrowed these marks from a Popish abbé, though such a charge, could he have established it, would have served his purpose more than all his rude railings and invective. But there was no room for such a charge. In the second volume of the works of St Real, published in 1757, there is indeed a tract entitled *Methode Courte et Aisée pour combattre les Deistes*; and there can be little doubt but that the publisher wished it to be considered as the work of his countryman. Unfortunately, however, for his design, a catalogue of the Abbé's works is given in the first volume; and in that catalogue the *Methode Courte et Aisée* is not mentioned.

We have dwelt thus long on *The Short and Easy Method with the Deists*, because it is one of the ablest works that ever was written in proof of the Divine origin of the Jewish and Christian Scriptures; a work of which the merit is acknowledged by Lord Bolingbroke, and which, as has been observed elsewhere, (see THEOLOGY, n° 16. *Encycl.*) Dr Conyers Middleton confesses to be unanswerable. If by men of science we be thought to have spent our time well in vindicating the rights of our illustrious philosophers Hooke and Newton, to discoveries which have been unjustly claimed by the philosophers of Germany and France; we will not surely by the friends of Christianity be thought to have employed our time ill in vindicating Leslie's claim to this decisive argument in support of our holy religion.

LEVER, the first of the mechanical powers, for the properties of which see MECHANICS; and for a demonstration of its fundamental property, see STEEL YARD, both in the *Encyclopædia*.

LICENSER OF BOOKS (see LIBERTY *of the Press*, *Encycl.*), has been an officer in almost every civilized nation, till the end of the last century that the office was abolished in Great Britain. Professor Beckmann, with his usual industry*, has proved, that such an office was established not only in the Roman Empire, but even in the republic, and in the free states of ancient Greece. At Athens, the works of Protagoras were prohibited; and all the copies of them which could be collected were burnt by the public crier. At Rome, the writings of Numa, which had been found in his grave, were, by order of the senate, condemned to the fire, because they were contrary to the religion which he had introduced. As the populace of Rome were, in times of public calamity, more addicted to superstition than seemed proper to the government, an order was issued, that all superstitious and astrological books should be delivered into the hands of the prætor. This order was often repeated; and the emperor Augustus caused more than twenty thousand of these books to be burnt at one time. Under the same emperor the satirical works of Labienus were condemned to the fire, which was the first instance of this nature; and it is related as something singular, that, a few years after, the writings of the person who had been the cause of the order for that purpose shared the like fate, and were also

* *History of Inventions*, vol. 3d.

Cenfor, Lichen. alfo publicly burnt. When Cremutius Cordus, in his hiftory, called C. Caffius the laft of the Romans, the fenate, in order to flatter Tiberius, caufed the book to be burnt; but a number of copies were faved by being concealed. Antiochus Epiphanes caufed the books of the Jews to be burnt; and in the firft centuries of our æra the books of the Chriftians were treated with equal feverity, of which Arnobius bitterly complains. We are told by Eufebius, that Dioclefian caufed the facred Scriptures to be burnt. After the fpreading of the Chriftian religion the clergy exercifed, againft books that were either unfavourable or difagreeable to them, the fame feverity which they had cenfured in the heathens as foolifh and prejudicial to their own caufe.

Soon after the invention of printing, laws began to be made for fubjecting books to examination; a regulation propofed even by Plato; and which has been wifhed for by many fince. Our author gives a great deal of curious information on this important fubject, which our limits do not permit us to repeat; but it is apparent from his work, that the liberty of the prefs is but a modern privilege; and that it has not been enjoyed completely in any country but this happy ifland.

LICHEN (fee *Encycl.*), is a genus of Plants, of which the moft valuable fpecies feems to be the LICHEN ROCELLA, or *Argol*. As that fpecies has not been noticed in the article referred to, the following account of it from Profeffor Beckmann will be acceptable to many of our readers:

It is found in abundance in fome of the iflands near the African coaft, particularly in the Canaries, and in feveral of the iflands in the Archipelago. It grows up right, partly in fingle, partly in double ftems, which are about two inches in height. When it is old, thefe ftems are crowned with a button fometimes round, and fometimes of a flat form, which Tournefort, very properly, compares to the excrefcences on the arms of the fepia. Its colour is fometimes a light, and fometimes a dark grey. Of this mofs, with lime, urine, and alkaline falts, is formed a dark red pafte, which in commerce has the fame name, and which is much ufed in dyeing. That well-known fubftance called lacmus is alfo made of it.

Theophraftus, Diofcorides, and their tranfcriber Pliny, gave the name of *Phycos thalaffion*, or *pontion*, to this plant, which, notwithftanding its name, is not a fea weed but a mofs; as it grew on the rocks of different iflands, and particularly on thofe of Crete or Candia. It had, in their time, been long ufed for dyeing wool; and the colour it gave when frefh was fo beautiful, that it excelled the ancient purple, which was not red, as many fuppofe, but violet. Pliny tells us, that with this mofs dyers gave the ground or firft tint to thofe cloths which they intended to dye with the coftly purple. When it was firft employed as a dye by the moderns, is not fo certain, though the Profeffor has proved, we think completely, that it muft have been at leaft as early as the beinning of the 14th century.

"Among the oldeft and principal Florentine families (fays he), is that known under the name of the Oricellarii or Rucellarii, Rufcellai or Rucellai, feveral Lichen. of whom have diftinguifhed themfelves as ftatefmen and men of letters. This family are defcended from a German nobleman, named Ferro or Frederigo, who lived in the beginning of the twelfth century. One of his defcendants, in the year 1300, carried on a great trade in the Levant, by which he acquired confiderable riches, and returning at length to Florence, with his fortune, firft made known in Europe the art of dyeing with argol. It is faid, that a little before his return from the Levant, happening to make water on a rock covered with this mofs, he obferved, that the plant, which was there called *refpio*, or *refpo*, and in Spain *orciglia*, acquired by the urine a purple, or, as others fay, a red colour. He therefore tried feveral experiments; and when he had brought to perfection the art of dyeing wool with this plant, he made it known at Florence, where he alone practifed it for a confiderable time, to the great benefit of the ftate. From this ufeful invention, the family received the name of Oricellarii, from which, at laft, was formed Rucellai." The Profeffor, however, does not believe that this Florentine difcovered the dye by means of the above-mentioned accident, but that he learned the art in the Levant, and on his return taught it to his countrymen.

"Our dyers do not purchafe raw argol, but a pafte made of it, which the French call *orfeille en pâte*. The preparation of it was for a long time kept a fecret by the Florentines. The perfon who, as far as I know, made it firft known was Rofetti; who as he himfelf tells us, carried on the trade of dyer at Florence. Some information was afterwards publifhed concerning it by Imperati * and Micheli the botanift †. In later times this art has been much practifed in France, England, and Holland. Many druggifts, inftead of keeping this pafte in a moifte ftate with urine, as they ought, fuffer it to dry, in order to fave a little dirty work. It then has the appearance of a dark violet-coloured earth, with here and there fome white fpots in it.

* Lib. xxvii c. 96

† *Nova Plantarum genera Florenciæ*, 1719.

"The Dutch (continues our author), who have found out better methods than other nations of manufacturing many commodities, fo as to render them cheaper, and thereby to hurt the trade of their neighbours, are the inventors alfo of lacmus, a preparation of argol, called *orfeille en pierre*, which has greatly leffened the ufe of that *en pâte*, as it is more eafily tranfported and preferved, and fitter for ufe; and as it is befides, if not cheaper, at leaft not dearer. This art confifts, undoubtedly, in mixing with that commodity fome lefs valuable fubftance, which either improves or does not much impair its quality, and which, at the fame time, increafes its weight (A). Thus do they pound cinnabar and fmalt finer than other nations, and yet fell both thefe articles cheaper. Thus do they fift cochineal, and fell it cheaper than what is unfifted.

"It was for a long time believed, that the Dutch prepared their lacmus from thofe linen rags which in the fouth of France are dipped in the juice of the *croton tinctorium*; but at prefent, it is almoft certainly known, that *orfeille en pâte* is the principal ingredient in *orfeille en*

(A) As dry lacmus is much cheaper than moift, it may be readily fuppofed that it is adulterated with fand and other fubftances. *Valentini Hiftoria fimplicium*. Francf. ad Moen. 1716. fol. p. 152.

en pierre that is in lacmus; and for this curious information we are indebted to Ferber. But whence arises the smell of the lacmus, which appears so like that of the Florentine iris?" Some of the latter may, perhaps, be mixed with it; for our author thinks, that he has observed in it small indissoluble particles, which may have been bits of the roots. The addition of this substance can be of no use to improve the dye; but it may increase the weight, and give the lack more body; and perhaps it may be employed to render imperceptible some unpleasant smell, for which purpose the roots of that plant are used on many other occasions.

LIGHT, it has been observed in the article CHEMISTRY, n° 319. (*Suppl.*), consists of rays differently flexible. This was established by some well devised experiments made by Henry Brougham, Esq; of which it may be proper to give an account here.

In the first experiment, he darkened his chamber in the usual way, and let a beam of the sun's light into it through the hole of a metal plate fixed in the shutter of the window, $\frac{1}{30}$th of an inch in diameter. At the hole within the room he placed a prism of glass, of which the refracting angle was 45 degrees, and which was everywhere covered with black paper, except a small part on each side; and through this part the light was refracted so as to form a distinct spectrum on a chart at six feet distance from the window. In the rays, at two feet from the prism, he placed a black unpolished pin, of which the diameter was $\frac{1}{10}$ of an inch, parallel to the chart, and in a vertical position. The shadow of the pin was found in the spectrum; and this shadow had a considerable penumbra, which was broadest and most distinct in the violet part, narrowest and most confused in the red, and of an intermediate thickness and distinctness in the intermediate colours. The penumbra was bounded by curvilinear sides, convex towards the axis to which they approached as to an asymptote, so as to be nearest to it in the place of the least refrangible rays. By moving the prism on its axis, and causing the colours to ascend and descend on any bodies that were used instead of the pin; the red, wherever they fell, made the least, and the violet the greatest, shadow.

In the next experiment, a screen was substituted in the place of the pin; and this screen had a large hole, on which was a brass plate, pierced with a small hole $\frac{1}{31}$d of an inch in diameter. While an assistant moved the prism slowly on its axis, the author observed the round image made by the different rays passing through the hole to the chart; that made by the red was greatest, that of the violet least, and that of each intermediate ray was of an intermediate size. When the sharp blade of a knife was held at the back of the hole, "so as to produce the fringes mentioned by Grimaldo and Newton, these fringes in the red were broadest and most moved inwards to the shadow, and most dilated when the knife was moved over the hole; and the hole itself on the chart was more dilated during the motion when illuminated by the red than when illuminated by any other of the rays, and least of all when illuminated by the violet."

From these two experiments, the author infers "that the rays of the sun's light differ in degree of flexibility, and that those which are least *refrangible* are *most inflexible*." From other experiments he concludes, that the *most inflexible* rays are also *most deflexible*. In the sequel of his paper, he ascertains the proportion which the angle of *inflection* bears to that of *deflection* at equal incidences, and the proportion which the different *flexibilities* of the different rays bear to one another.

LIMBERS, in artillery, a sort of advanced train, joined to the carriage of a cannon on a march. It is composed of two shafts, wide enough to receive a horse between them, called the *fillet horse*: these shafts are joined by two bars of wood, and a bolt of iron at one end, and mounted on a pair of rather small wheels. Upon the axle-tree rises a strong iron spike, which is put into a hole in the hinder part of the train of the gun carriage, to draw it by. But when a gun is in action, the limbers are taken off, and run out behind it.

LIMITED Problem, denotes a problem that has but one solution, or some determinate number of solutions: as to describe a circle through three given points that do not lie in a right line, which is limited to one solution only; to divide a parallelogram into two equal parts by a line parallel to one side, which admits of two solutions, according as the line is parallel to the length or breadth of the parallelogram; or to divide a triangle in any ratio by a line parallel to one side, which is limited to three solutions, as the line may be parallel to any of the three sides.

LOCAL PROBLEM, is one that is capable of an infinite number of different solutions; because the point, which is to solve the problem, may be indifferently taken within a certain extent; as suppose any where in such a line, within such a plane figure, &c. which is called a *geometrical Locus*.

A local problem is *simple*, when the point sought is in a right line; *plane*, when the point sought is in the circumference of a circle; *solid*, when it is in the circumference of a conic section; or *sursolid*, when the point is in the perimeter of a line of a higher kind.

LOCI, the plural of

LOCUS, a line by which a local or indeterminate problem is solved; or a line of which any point may equally solve an indeterminate problem. See ALGEBRA, *Encycl.*

LOGISTIC CURVE, the same with *LOGARITHMIC Curve*, for which see *Encycl.*

LOGISTICS, or *LOGISTICAL Arithmetic*, a name sometimes employed for the arithmetic of sexagesimal fractions, used in astronomical computations.

The same term has been used for the rules of computations in algebra, and in other species of arithmetic: witness the logistics of Vieta and other writers.

Shakerly, in his *Tabulæ Britannicæ*, has a table of logarithms adapted to sexagesimal fractions, and which he calls Logistical Logarithms; and the expeditious arithmetic, obtained by means of them, he calls Logistical Arithmetic.

LIBYAN LOTUS has been described (*Encycl.*) under the title RHAMNUS; but the following additional particulars from Mr Park will be acceptable to our botanical readers:

The lotus is very common in all the countries which our author visited, and he had an opportunity to make a drawing of a branch in flower, of which an engraving is published in his travels, that with his permission we have copied (see Plate XXX.). The lotus produces fruit which the negroes call *tomberongs*. These are small farinaceous berries, of a yellow colour and delicious

cious taſte. They are much eſteemed by the natives, who convert them into a ſort of bread, by expoſing them for ſome days to the ſun, and afterwards pounding them gently in a wooden mortar, until the farinaceous part of the berry is ſeparated from the ſtone. This meal is then mixed with a little water, and formed into cakes; which, when dried in the ſun, reſemble in colour and flavour the ſweeteſt gingerbread. The ſtones are afterwards put into a veſſel of water, and ſhaken about ſo as to ſeparate the meal which may ſtill adhere to them: this communicates a ſweet and agreeable taſte to the water, and, with the addition of a little pounded millet, forms a pleaſant gruel called *fondi*, which is the common breakfaſt in many parts of Ludamar, during the months of February and March. The fruit is collected by ſpreading a cloth upon the ground, and beating the branches with a ſtick. Our author thinks there can be little doubt of this being the lotus mentioned by Pliny, as the food of the Lybian Lotophagi. An army may very well have been fed with the bread made of the meal of the fruit, as is ſaid by Pliny to have been done in Lybia; and as the taſte of the bread is ſweet and agreeable, it is not likely that the ſoldiers would complain of it.

LOWANG, a Chineſe iſland of ſome extent in the neighbourhood of the CHUSAN-Iſles, which ſee in this *Supplement*.

LOXODROMIC CURVE, or *Spiral*, is the ſame as the rhumb-line, or path of a ſhip ſailing always on the ſame courſe in an oblique direction, or making always the ſame angle with every meridian. It is a ſpecies of logarithmic ſpiral, deſcribed on the ſurface of the ſphere, having the meridians for its radii.

LOXODROMICS, the art or method of oblique ſailing, by the loxodromic or rhumb line.

LUCIOLE, a name given in the *Annales de Chimie* to the *LAMPYRIS Italica* (See LAMPYRIS, *Encycl.*). According to Dr Carradori, the light of the luciole does not depend on the influence of any external cauſe, but merely on the will of thoſe inſects. While they fly about at freedom, their ſhining is very regular; but when they are once in our power, they ſhine very irregularly, or do not ſhine at all. When they are moleſted, they emit a frequent light, which appears to be a mark of their reſentment. When placed on their backs, they ſhine almoſt without interruption, making continual efforts to turn themſelves from that poſition. In the day-time it is neceſſary to torment them in order to make them ſhine; and thence it follows, that the day to them is the ſeaſon of repoſe. The luciole emit light at pleaſure from every point of their bellies, which proves that they can move all the parts of their viſcera independently of each other. They can alſo render their phoſphoreſcence more or leſs vivid, and continue it as long as they pleaſe.

A ſlight compreſſion deprives the luciole of their power of ceaſing to ſhine. The author is inclined to believe, that the movement by which they conceal their light is executed by drawing back their phoſphoric ſubſtance into a particular membrane or tunic. He ſuppoſes alſo, that the ſparkling conſiſts in a trembling or oſcillation of the phoſphoric maſs. He is of opinion, that there is no emanation of a phoſphoric ſubſtance, and that the whole phenomenon takes place in the interior part of the luminous viſcera. When the ſhining is at its greateſt degree of height, it is ſo ſtrong that a perſon may by it eaſily diſtinguiſh the hours on the ſmalleſt watch, and the letters of any type whatever.

The phoſphoric part of the luciole does not extend farther than to the extreme rings of the belly. It is there encloſed in a covering compoſed of two portions of membranes, one of which forms the upper, and the other the lower, part of the belly, and which are joined together. Behind this receptacle is placed the phoſphorus, which reſembles a paſte, having the ſmell of garlic, and very little taſte. The phoſphoric matter iſſues from a ſort of bag on the ſlighteſt preſſure; when ſqueezed out, this matter loſes its ſplendour in a few hours, and is converted into a white dry ſubſtance. A portion of the phoſphoric belly put into oil, ſhone only with a feeble light, and was ſoon extinguiſhed. In water, a like portion ſhone with the ſame vivacity as in the air, and for a much longer time. The author thence concludes that the phoſphoreſcence of the luciole is not the effect of ſlow inflammation, nor of the fixation of azotic gas, as the oil in which they ſhine does not contain a ſingle air-bubble: beſides, the phoſphorus of theſe inſects ſhines in a barometrical vacuum. The obſervation made by Foſter, that the luciole diffuſed a more vivid light in oxygen gas than in atmoſpheric air, does not, according to Carradori, depend upon a combuſtion more animated by the inſpiration of this gas, but on the animals feeling themſelves, while in that gas, in a better condition. "Whence, then, ariſes (ſays the author) the phoſphoric light of the luciole? I am of opinion (adds he), that the light is peculiar, and innate in theſe inſects, and ſeveral other productions are peculiar to other animals. As ſome animals have the faculty of accumulating the electric fluid, and of keeping it condenſed in particular organs, to diffuſe it afterwards at pleaſure, there may be other animals endowed with the faculty of keeping in a condenſed ſtate the fluid which conſtitutes light. It is poſſible, that by a peculiar organiſation they may have the power of extracting the light which enters into the compoſition of their food, and of tranſmitting it to the reſervoir deſtined for that purpoſe, which they have in their abdomen. It is not even impoſſible that they may have the power to extract from the atmoſpheric air the luminous fluid, as other animals have the power of extracting from the ſame air, by a chemical proceſs, the fluid of heat."

Carradori diſcovered, that the phoſphoreſcence of the luciole is a property independent of the life of theſe animals, and that it is chiefly owing to the ſoft ſtate of the phoſphoric ſubſtance. Its light is ſuſpended by drying, and it is again revived by ſoftening it in water; but only after a certain time of deſiccation. Reaumur, Beccaria, and Spallanzani, obſerved the ſame thing in regard to the *pholades* and the *meduſa*.

By plunging the luciole alternately into lukewarm and cold water, they ſhine with vivacity in the former, but their light becomes extinct in the latter; which, according to the author, depends on the alternate agreeable and diſagreeable ſenſation which they experience. In warm water their light diſappears gradually. Dr Carradori tried on the luciole and their phoſphorus the action of different ſaline and ſpirituous liquors, in which they exhibited the ſame appearances as other phoſphoric animals. Theſe laſt experiments prove that the phoſphoric

Ludamar.

phofphoric matter of the luciole is only foluble in water.

LUDAMAR, a Moorifh kingdom in the interior of Africa, of which the capital Benorm is placed by Major Rennel in 15° N. lat. and 6° 50′ W. Long. It has for its northern boundary the great defart (fee SAHARA in this *Supplement*), and is defcribed by Mr Park as little better than a defert itfelf. Our traveller was taken captive on the confines of this kingdom, and carried to the camp of the king, where he was fubjected to the cruelleft indignities that the malice of bigotted Moors could invent. He was not fuffered to travel beyond the camp; though he moved as it moved, and of courfe faw a confiderable part of the country, and had an opportunity of obferving the manners of the people. "The Moors of Ludamar fubfift chiefly on the flefh of their cattle; and are always on the extreme of either gluttony or abftinence. In confequence of the frequent and fevere fafts which their religion enjoins, and the toilfome journeys which they fometimes undertake acrofs the defert, they are enabled to bear both hunger and thirft with furprifing fortitude; but whenever opportunities occur of fatisfying their appetite, they generally devour more at one meal than would ferve an European for three. They pay but little attention to agriculture; purchafing their corn, cotton cloth, and other neceffaries, from the Negroes, in exchange for fat, which they dig from the pits in the Great Defert.

"The natural barrennefs of the country is fuch, that it furnifhes but few materials for manufacture. The Moors, however, contrive to weave a ftrong cloth, with which they cover their tents; the thread is fpun by their women from the hair of goats: and they prepare the hides of their cattle fo as to furnifh faddles, bridles, pouches, and other articles of leather. They are likewife fufficiently fkilful to convert the native iron, which they procure from the Negroes, into fpears and knives, and alfo into pots for boiling their food; but their fabres and other weapons, as well as their fire-arms and ammunition, they purchafe from the Europeans, in exchange for the Negro flaves which they obtain in their predatory excurfions. Their chief commerce of this kind is with the French traders on the Senegal river."

The Moors of this country have fingular ideas of feminine perfection. The gracefulnefs of figure and motion, and a countenance enlivened by expreffion, are by no means effential points in their ftandard; with them corpulence and beauty appear to be terms nearly fynonymous. A woman, of even moderate pretenfions, muft be one who cannot walk without a flave under each arm to fupport her; and a perfect beauty is a load for a camel. In confequence of this prevalent tafte for unwieldinefs of bulk, the Moorifh ladies take great pains to acquire it early in life; and for this purpofe many of the young girls are compelled by their mothers to devour an immenfe quantity of food, and drink a large bowl of camel's milk every morning. It is of no importance whether the girl has an appetite or not, the meat and the drink muft be fwallowed; and obedience is frequently enforced by blows. This fingular practice, inftead of producing indigeftion and difeafe, foon covers the young lady with that degree of plumpnefs, which, in the eye of a Moor, is perfection itfelf.

Ludamar ‖ Lynx.

"Although the wealth of the Moors confifts chiefly in their numerous herds of cattle; yet, as the paftoral life does not afford full employment, the majority of the people are perfectly idle, and fpend the day in trifling converfation about their horfes, or in laying fchemes of depredation on the Negro villages.

"The ufual place of rendezvous for the indolent is the king's tent, where great liberty of fpeech feems to be exercifed by the company towards each other. While in fpeaking of their chief, they exprefs but one opinion. In praife of their fovereign, they are unanimous. Songs are compofed in his honour, which the company frequently fing in concert; but they are fo loaded with grofs adulation, that no man but a Moorifh defpot could hear them without blufhing. The king is diftinguifhed by the finenefs of his drefs, which is compofed of blue cotton cloth brought from Tombuctoo, or white linen or muflin from Morocco. He has likewife a larger tent than any other perfon, with a white cloth over it; but in his ufual intercourfe with his fubjects, all diftinctions of rank are frequently forgotten. He fometimes eats out of the fame bowl with his camel-driver, and repofes himfelf, during the heat of the day, upon the fame bed.

"The military ftrength of Ludamar confifts in cavalry. They are well mounted, and appear to be very expert in fkirmifhing and attacking by furprife. Every foldier furnifhes his own horfe, and finds his accoutrements, confifting of a large fabre, a double barrelled gun, a fmall red leather bag for holding his balls, and a powder-horn flung over the fhoulder. He has no pay, nor any remuneration but what arifes from plunder. This body is not very numerous; for when Ali the king made war upon Bambara, our author was informed that his whole force did not exceed 2000 cavalry. They conftitute, however, by what he could learn, but a very fmall proportion of his Moorifh fubjects. The horfes are very beautiful, and fo highly efteemed, that the Negro princes will fometimes give from twelve to fourteen flaves for one horfe."

Cut off from all intercourfe with civilized nations, and boafting an advantage over the Negroes, by poffeffing, though in a very limited degree, the knowledge of letters, the Moors of Ludamar are at once the vaineft and proudeft, and perhaps the moft bigotted, ferocious, and intolerant of all the nations on the earth; combining in their character the blind fuperftition of the Negro with the favage cruelty and treachery of the Arab. It was with the utmoft difficulty that our author made his efcape from this inhofpitable people.

LUPUS, the *Wolf*, a fouthern conftellation, joined to the Centaur, containing together 19 ftars in Ptolomy's catalogue, but 24 in the Britannic catalogue.

LYNX, a conftellation of the northern hemifphere, compofed by Hevelius out of the unformed ftars. In his catalogue it confifts of 19 ftars, but in the Britannic 44.

MACHINERY.

THE denomination *Machine* is now vulgarly given to a great variety of fubjects, which have very little analogy by which they can be claffed with propriety under any one name. We fay a travelling machine, a bathing machine, a copying machine, a thrafhing machine, an electrical machine, &c. &c. The only circumftance in which all thefe agree feems to be, that their conftruction is more complex and artificial than the utenfils, tools, or inftruments which offer themfelves to the firft thoughts of uncultivated people. They are more artificial than the common cart, the bathing tub, or the flail. In the language of ancient Athens and Rome, the term was applied to every tool by which hard labour of any kind was performed; but in the language of modern Europe, it feems reftricted either to fuch tools or inftruments as are employed for executing fome philofophical purpofe, or of which the conftruction employs the fimple mechanical powers in a confpicuous manner, in which their operation and energy engage the attention. An electrical machine, a centrifugal machine, are of the firft clafs; a thrafhing machine, a fire machine, are of the other clafs. It is nearly fynonymous, in our language, with ENGINE; a term altogether modern, and in fome meafure honourable, being beftowed only, or chiefly, on contrivances for executing work in which ingenuity and mechanical fkill are manifeft. Perhaps, indeed, the term *engine* is limited, by careful writers, to machines of confiderable magnitude, or at leaft of confiderable art and contrivance. We fay, with propriety, fteam-engine, fire-engine, plating engine, boring engine; and a dividing machine, a copying machine, &c. Either of thefe terms, *machine* or *engine*, are applied with impropriety to contrivances in which fome piece of work is not executed on materials which are then faid to be manufactured. A travelling or bathing machine is furely a vulgarifm. A machine or engine is therefore a TOOL; but of complicated conftruction, peculiarly fitted for expediting labour, or for performing it according to certain invariable principles: And we fhould add, that the dependence of its efficacy on mechanical principles muft be apparent, and even confpicuous. The contrivance and erection of fuch works conftitute the profeffion of the engineer; a profeffion which ought by no means to be confounded with that of the mechanic, the artifan, or manufacturer. It is one of the *artes liberales;* as deferving of the title as medicine, furgery, architecture, painting, or fculpture. Nay, whether we confider the importance of it to this flourifhing nation, or the fcience that is neceffary for giving eminence to the profeffor, it is very doubtful whether it fhould not take place of the three laft named, and go *pari paffu* with furgery and medicine. The inconfiderate reader, who perufes *Cicero de Oratore* with fatisfaction, is apt to fmile at Vitruvius, who requires in his architect nearly the fame accomplifhments which Cicero requires in his orator. He has not recollected, or perhaps did not know, that the profeffion of an architect in the Auguftan age was the moft refpectable of all thofe which were not effentially connected with the management of ftate affairs. It appears that the architects were all Greeks, or the pupils of Greeks, altogether different from the members of the *Collegium Murariorum*, the corporation of builders and mafons. The architecture of temples, ftadiums, circufes, amphitheatres, feems to have been monopolifed, by ftate authority, by a fociety which had long fubfifted in Afia, connected by certain myfterious bonds, both civil and religious. We find it in Syria; and we learn that it was brought thither from Perfia in very ancient times. From thence it fpread into Ionia, where it became a very eminent and powerful affociation, under the particular protection of Bacchus, to whom the members had erected a magnificent temple at Teos, with a vaft eftablifhment of priefts and priefteffes, confifting of perfons of the firft rank in the ftate. They were the fole builders of temples and ftadiums throughout all Greece and the Leffer Afia; and the contractors for the machinery that was employed in the theatres, and in the great temples, for the celebration of the high myfteries of paganifm. By the imperfect accounts which remain of the Eleufinian and other myfteries, it appears, that this machinery muft have been immenfe and wonderful, and muft have required a great deal of mechanical fkill. This indeed appears, in the moft convincing manner, to any perfon who reflects on the magnificent ftructures which they erected, which excite to this day the wonder of the world, not only on account of their magnificence and incomparable elegance, but alfo on account of the mechanical knowledge that feems indifpenfably neceffary for their erection. This will ever remain a myftery. There are no traces of fuch knowledge to be found in the writings of antiquity. Even Vitruvius, writing exprefsly on the fubject, has given us nothing but what is in the loweft degree of elementary knowledge.

This affociation of the Dionyfiacs undoubtedly kept their mechanical fcience a profound fecret from the uninitiated, the profane. They were the engineers of antiquity, and Vitruvius was perhaps not one of the initiated. He fpeaks of Myro and other Greek architects in terms of refpect which border on veneration. Perhaps the modern affociation of free mafons is a remain of this ancient fraternity, continued to our times by the company of builders, who erected the cathedrals and great conventual churches. No one who confiders their works with fcientific attention, can doubt of their being deeply verfed in the principles of mechanics, and even its more refined branches. They appear to have carried the art of vault-roofing almoft to its acmé of perfection; far outftripping their Grecian inftructors in their knowledge of this moft delicate branch of their art.

It were greatly to be wifhed that fome fuch inftitution did yet exift, where men might be induced by the moft powerful motives to accomplifh themfelves in the knowledge neceffary for attaining eminence in their profeffion.

We have been informed (and we thought our authority good), that our gracious Sovereign has fignified his intention of patronifing an inftitution of this kind. We heard, that it was propofed to inftitute degrees fimilar to our univerfity degrees, and proceeding on fimilar conditions of a regular education or ftanding, which would enfure the *opportunities* of information, and alfo on an examination of the proficiency of the candidate. This examination, being conducted by perfons eminent in the profeffion, perhaps ftill exercifing it, would probably be ferious, becaufe the fuccefsful candidate would immediately become a rival practitioner. Such an inftitution would undoubtedly prevent many grofs impofitions by unlettered mill-wrights and pump-makers, who now feldom appear under any name but that of engineer, although they are frequently ignorant even of the elements of mechanical fcience, and are totally unacquainted with the higher mathematics; without which it is abfolutely impoffible for them to contrive a machine well fuited to the intended puropofe, or to fay with any tolerable precifion what will be the performance of the engine they have erected. Yet thefe are queftions fufceptible of accurate folution, becaufe they depend on the unalterable laws of matter and motion.

All who have a juft view of the unfpeakable advantages which this highly favoured land poffeffes in the fuperiority and activity of its manufactures, and who know how much of this fuperiority fhould be afcribed to the great improvements which have been made in practical mechanics within thefe laft thirty years, will join us in wifhing fuccefs to fome fuch inftitution as that now mentioned.

We were naturally led to thefe reflections when we turned our thoughts to machinery in general, and obferved what is done in this country by the native energy of its inhabitants, unaffifted by fuch fcientific inftructions as they might have expected from the pupils of a Newton, their countryman, under the patronage of the beft of Sovereigns, eminently knowing in thefe things, and ever ready to encourage thofe fciences and arts which have fo highly contributed to the national profperity. What might not be reafonably expected from Britifh activity, if thofe among ourfelves who have knowledge and leifure had been at the fame pains with the members of the foreign academies to cultivate the Newtonian philofophy, and particularly the more refined branches of mechanics, and to deduce from their fpeculations maxims of conftruction fitted to our fituation as a great manufacturing nation? But fuch knowledge is not attainable by thofe who are acquainted only with the imperfect elements contained in the publications read by the bulk of our practitioners. Much to this purpofe has been done on the continent by the moft eminent mathematicians; but from want of individual energy, or perhaps of general fecurity and protection, the patriotic labours of thofe gentlemen have not done the fervice to their country which might have been reafonably expected. Indeed, their differtations have generally been fo compofed, that only the learned could fee their value. They feem addreffed only, or chiefly, to fuch; but it is to thofe authors that our countrymen generally have recourfe for information concerning every thing in their profeffion that rifes above mere elementary knowledge. The books in our language which profefs to be fyftems of mechanics rarely go beyond this: they contain only the principles of equilibrium. Thefe are abfolutely neceffary for the knowledge of machines; but they are very far indeed from giving what may be called a practical knowledge of *working machinery*. This is never in a ftate of equilibrium. The machine muft move in order to work. There muft be a fuperiority of impelling power, beyond what is merely fufficient for balancing the refiftance or contrary action of the work to be performed. The reader may turn to the article Statics in the *Encyclopædia Britannica*, and he will there fee fome farther obfervations on this head. And in the article Mechanics he will find a pretty ample detail of all the ufual doctrines, and a defcription of a confiderable variety of machines or engines, accompanied by fuch obfervations as are neceffary for tracing the propagation or tranfmiffion of preffure from that part of the machine, to which the natural power is applied, to the working part of the machine. Along with thefe two articles, it will be proper to read with peculiar attention the article Rotation.

By far the greateft number of our moft ferviceable engines confift chiefly of parts which have a motion of rotation round fixed axes, and derive all their energy from levers virtually contained in them. And thefe acting parts are alfo material, requiring force to move them, over and above what is neceffary for producing the acting force at the working part of the machine. The modifications which this circumftance frequently makes of the whole motions of the machine, are indicated in the article Rotation in an elementary way; and the propofitions there inveftigated will be found almoft continually involved in the complete theory of the operation of a machine. Laftly, it will be proper to confider attentively the propofitions contained in the article *Strength of Materials*, that we may combine them with thofe which relate wholly to the working of the machine; becaufe it is from this combination only that we difcover the ftrains which are excited at the various points of fupport, and of communication, and in every member of the machine. We fuppofe all thefe things already underftood.

1 The chief queftion in mechanics.

Our object at prefent is to point out the principles which enable us to afcertain what will be the precife motion of a machine of given conftruction, when actuated by a natural power of known intenfity, applied to a given point of the machine, while it is employed to overcome a known refiftance acting at another point. To abbreviate language, we fhall call that the impelled point of the machine to which the preffure of the moving power is immediately applied; and we may call that the working point, where the refiftance arifing from the work to be performed immediately acts.

To confider this important fubject, even in its chief varieties, requires much more room than can be allowed in an undertaking like ours, and therefore we muft content ourfelves with a very limited view; but at the fame time, fuch a view as fhall give fufficient indication of the principles which fhould direct the practical reader in every important cafe. We fhall confider thofe machines which

which perform their motions round fixed axes; thefe being by far the moft numerous and important, becaufe they involve in their conftruction and operations all the leading principles.

2 The proper meafure of mechanical power explained.

That we may proceed fecurely, it is neceffary to have a precife and adequate notion of moving force, as applied to machinery, and of its meafures. We think this peculiarly neceffary. Different notions have been entertained on this fubject by Mr Leibnitz, Des Cartes, and other eminent mechanicians of the laft century; and their fucceffors have not yet come to an agreement. Nay, fome of the moft eminent practitioners of the prefent times (for we muft include Mr Smeaton in the number) have given meafures of mechanical power in machinery which we think inaccurate, and tending to erroneous conclufions and maxims.

We take for the meafure (as it is the effect) of exerted mechanical power the quantity of motion which it produces by its uniform exertion during fome given time. We fay *uniform exertion*, not becaufe this uniformity is neceffary, but only becaufe, if any variation of the exertion has taken place, it muft be known, in order to judge of the power. This would needlefsly complicate the calculations; but in whatever way the exertion may have varied, the whole accumulated exertion is ftill accurately meafured by the quantity of motion exifting at the end of the exertion. The reader muft perceive that this is the fame thing that is expreffed in the article DYNAMICS of this *Supplement*, nº 90. by the area of the figure whofe abfciffa or axis reprefents the time of exertion; and the ordinates are as the preffures in the different inftants of that time, the whole being multiplied by the number of particles (that is, by the quantity of matter), becaufe that figure reprefents the quantity of motion generated in one particle of matter only. All this is abundantly clear to perfons converfant in thefe difquifitions; but we wifh to carry along with us the diftinct conceptions of that ufeful clafs of readers whofe profeffion engages them in the conftruction and employment of machines, and to whom fuch difcuffions are not fo familiar. We muft endeavour therefore to juftify our choice of this meafure by appealing to familiar facts.

If a man, by preffing uniformly on a mafs of matter for five feconds, generates in it the velocity of eight feet per fecond, we obtain an exact notion of the proportion of this exertion to the mechanical exertion of gravity, when we fay that the man's exerted force has been precifely one-twentieth part of the action of gravity on it; for we know that the weight of that body (or, more properly, its heavinefs) would, in five feconds, have given it the velocity of 160 feet per fecond, by acting on it during its fall. But let us attend more clofely to what we mean by faying that the exerted force is one-twentieth of the exertion of gravity. The only notion we have of the exertion of gravity is what we call the weight of the body—the preffure which we feel it make on our hand. To fay that this is 20 pounds weight, does not explain it; becaufe this is only the action of gravity on another piece of matter. Both preffures are the fame. But if the body weighs 20 pounds, it will draw out the rod of a fteelyard to the mark 20. The rod is fo divided, that the 20th part of this preffure will draw it out to 1. Now the fact is, that if the man preffes on the mafs of 20 pounds weight with a fpring fteelyard during five feconds, and if during that time the rod of the fteelyard was always at the mark 1, the body will have acquired the velocity of eight feet per fecond. This is an acknowledged fact. Therefore we were right in faying, that the man's exertion is one-twentieth of the exertion of gravity. And fince we believe the weight of bodies to be proportional to their quantity of matter, all matter being equally heavy, we may fay, that the man's exertion was equal to the action of gravity on a quantity of matter whofe weight is one pound. We exprefs it much more familiarly, by faying, that the man exerted on it the preffure of one pound of matter, or the force of one pound.

In this manner, the motion communicated to a mafs of matter, by acting on it during fome time, informs us with accuracy of the real mechanical force or preffure which has been exerted. This is judged to be double when twice the velocity has been generated in the fame mafs, or where the fame velocity has been generated in twice the mafs; becaufe we know, that a double preffure would have done either the one or the other.

But farther: We know that this preffure is the exertion; we have no other notion of our own force; and our notion of gravity, of elafticity, or any other natural force, is the fame. We alfo know that the continuance of this exertion fatigues and exhaufts our ftrength as completely as the moft violent motion. A dead pull, as it is called, of a horfe, at a poft fixed in the ground, is a ufual trial of his ftrength. No man can hold out his arm horizontally for much more than a quarter of an hour; and the exertion of the laft minutes gives the moft diftreffing fatigue, and difables the fhoulder from action for a confiderable time after. This is therefore an expenditure of mechanical power, in the ftrict primitive fenfe of the word. Of this expenditure we have an exact and adequate effect and meafure in the quantity of motion produced; that is, in the product of the quantity of matter by the velocity generated in it by this exertion. And it muft be particularly noticed, that this meafure is applicable even to cafes where no motion is produced by the exertion; that is, if we know that the exertion which is juft unable to ftart a block of ftone lying on a fmooth ftone pavement, but would ftart it, if increafed by the fmalleft addition; and if we know that this would generate in a fecond 32 feet of velocity in 100 pounds of matter—we are certain that it was a preffure equal to the weight of this 100 pounds. It is a good meafure, though not immediate, and may be ufed without danger of miftake when we have no other.

3 Mr Smeaton's meafure.

The celebrated engineer Mr Smeaton, in his excellent differtation on the power of water and wind to drive machinery, and alfo in two other differtations, all publifhed in the Philofophical Tranfactions, and afterwards in a little volume, has employed another meafure, both of the expenditure of mechanical power, and of the mechanical effect produced. He fays, that the weight of a body, multiplied by the height thro' which it defcends, while driving a machine, is the only proper meafure of the power expended; and that the weight, multiplied by the height through which it is uniformly raifed, is the only proper meafure of the effect produced. And he produces a large train of accurate experiments;

riments to prove that a certain weight, deſcending through a certain ſpace, always produces the ſame effect, whether it has deſcended ſwiftly or ſlowly, employing little or much time.

Had this eminent engineer propoſed this as a popular meaſure, of eaſy comprehenſion and remembrance, and as well accommodated to the uſes of thoſe engaged in the conſtruction of machines, when reſtricted to a certain claſs of caſes, it might have anſwered very good purpoſes; but the author is at pains to recommend it to the philoſophers as a neceſſary correction of their theories, which he ſays tends to miſlead the artiſts. His own reaſonings terminate in the ſame concluſion with Mr Leibnitz's, namely, that the power of producing a mechanical effect, and the effect produced, are proportional to the ſquare of the velocity. The difference juſtly due to Mr Smeaton's authority, and the influence of his name among thoſe who are likely to make the moſt uſe of his inſtructions, render it neceſſary for us to examine this matter with ſome attention.

Mr Smeaton was led to the adoption of this meaſure by his profeſſional habits. Raiſing a weight to a height is, in one ſhape or another, the general taſk of the machines he was employed to erect; and we may add, the opportunities of expending the mechanical powers of nature which are in our command, are generally in this proportion. A certain daily ſupply of water, coming from a certain height, is our beſt opportunity, and may very properly be ſaid to be expended.

4 Examined.

This being the general caſe, the meaſure was obvious, and natural, and good. The power and effect were of the ſame kind, and *muſt* be meaſures of each other; at leaſt in thoſe circumſtances in which they were ſet in oppoſition. Yet even here Mr Smeaton was obliged to make a reſtriction of his meaſures: "The height thro' which a body *ſlowly and equably* deſcended, or to which it was raiſed." And why was this limitation neceſſary? "Becauſe in rapid or accelerated motions, the inertia of bodies occaſioned ſome variation*." But this is too vague language for philoſophical diſquiſition. Beſides, what is meant by this variation? What is the ſtandard from which the unreſtricted meaſure varies? This ſtandard, whatever it is, is the true meaſure, and it was needleſs to adopt any other. Now, the ſtandard from which Mr Smeaton eſtimates the deviation, is the very meaſure which we wiſh to employ, namely, the quantity of motion produced. Strictly ſpeaking, even this is not the immediate meaſure. The immediate meaſure is that faculty which we call preſſure. This is the intermedium perceivable in all productions of motion; and it is alſo the intermedium of mechanical effect, even when motion is not produced; as when the weight of a body bends a ſpring, or the elaſticity of a body ſupports another preſſure. How it operates in all or any of theſe caſes, we know not; but we know that all theſe meaſures of preſſure agree with each other. A double quantity of motion will bend a ſpring doubly ſtrong, will raiſe a double weight, will withſtand any double preſſure, &c. &c. In ſhort, preſſure is the immediate agent in every mechanical phenomenon. It penetrates bodies, overcoming their tenacity; it overcomes friction; it balances preſſure; it produces motion. Mr Smeaton's meaſure is only nearly true, in any caſe, and in all caſes it is far from being exact in the firſt inſtants of the motion, during its acceleration or retardation.

* Page 70.

We have already noticed the complete expenditure of animal power by continued preſſure, even when motion is not produced: the only difficulty is to connect this in a meaſurable way with the power which the ſame exertion has of generating motion in a body.

When a man ſupports a weight for a ſingle inſtant, he certainly balances the preſſure or action of gravity on that body; and he continues this action as long as he continues to ſupport it: and we know that if this body were at the end of a horizontal arm turning round a vertical axis, the ſame effort which the man exerted in merely carrying the weight, if now exerted on the body, by puſhing it horizontally round the axis, will generate in it the ſame velocity which gravity would generate by its falling freely. On this authority therefore we ſay, that the whole accumulated action of a man, when he has juſt carried a body whoſe weight is 30 pounds for one minute, is equal to the whole exertion of gravity on it during that minute; and if employed, not to counteract gravity, but to generate motion, would generate, during the minute, the ſame motion that gravity would, that is, 60×32 feet velocity per ſecond, in a maſs of 30 pounds. There would be 30 pounds of matter moving with the velocity of 1920 feet per ſecond. We would expreſs this production or effect by 30×1920, or by 57600, as the meaſure of the man's exertion during the minute.

But, according to Mr Smeaton, there is no expenditure of power, nor any production of mechanical effect, in thus carrying 30 pounds for a minute; there is no product of a weight by a height through which it is equably raiſed; yet ſuch exertion will completely exhauſt a man's ſtrength if the body be heavy enough. Here then is a caſe to which Mr Smeaton's meaſure does not readily apply; and this caſe is important, including all the actions of animals at a dead pull.

But let us conſider more narrowly what a man really does when he performs what Mr Smeaton allows to be the production of a meaſurable mechanical effect. Suppoſe this weight of 30 pounds hanging by a cord which paſſes over a pulley, and that a man, taking this cord over his ſhoulder, turns his back to the pulley, and walks away from it. We know, that a man of ordinary force will walk along, raiſing this weight, at the rate of about 60 yards in a minute, or a yard every ſecond, and that he can continue to do this for eight or ten hours from day to day; and that this is all that he can do without fatigue. Here are 30 pounds raiſed uniformly 180 feet in a minute; and Mr Smeaton would expreſs this by 30×180, or 5400, and would call this the meaſure of the mechanical effect, and alſo of the expenditure of power. This is very different from our meaſure 57600.

5 And found to be inaccurate.

But this is not an accurate and complete account of the man's *action* on the weight, and of the whole effect produced. To be convinced of this, ſuppoſe that a man A has been thus employed, while another B, walking along ſide of him at the ſame rate, ſuddenly takes the rope out of his hand, frees him of the taſk, and *continues* to raiſe the weight without the ſmalleſt change on its velocity of aſcent. What is the action of B, and whether is it the ſame with that of A or not? It is acknowledged by all, that the exertion of B againſt the load is preciſely equal to 30 pounds. If he holds the rope by a ſpring ſteelyard, it will ſtand conſtantly at the mark 30. B exerts the ſame action on the load as when

when he simply supports it from falling back into the pit. It was moving with the velocity of three feet per second when he took hold of the rope, and it would continue to move with that velocity if any thing could annihilate or counteract its gravity. If therefore there was no action when a person merely carried it, there is none at present when it is rising 180 feet in a minute. The man does indeed work more than on that occasion, but not against the load; his additional work is walking, the motion of his own body, as a thing previously necessary that he may continue to support the load, that he may continue his mechanical effort as it follows him. It appears to yield to him: but it is not to *his* efforts that it yields; its weight completely balances those efforts, and is balanced by them. It was to a *greater* effort of the man A that it yielded. It was then lying on the ground. He pulled at the cord, gradually perhaps increasing his pull till it was just equal to its weight. When this obtains, the load no longer presses on the ground, but is completely carried by the rope. But it does not move by this effort of 30 pounds; but let him exert a force of 31 pounds, and continue this for three seconds. He will put it in motion; will accelerate that motion; and at the end of three seconds the load is rising with the velocity of three feet per second. The man feels that this as much speed as he can continue in his walk; he therefore slackens his pull, reducing his action to 30 pounds, and with this action he walks on. All this would be distinctly perceived by means of a steelyard. The rod would be pulled out beyond 30, till the load acquired the uniform velocity intended, and after this it would be observed to shrink back to 30.

More is done therefore than appears by Mr Smeaton's measure. Indeed, all that appears in it is the exertion necessary for *continuing* a motion already produced, but which would be immediately extinguished by a contrary power, which must therefore be counteracted. This measure will not apply to numberless cases of the employment of machines, where there is no such opposing power, and where, notwithstanding, mechanical power must be expended, even according to Mr Smeaton's measurement. Such are corn mills, boring mills, and many others.

How then comes it that Mr Smeaton's valuable experiments concur so exactly in shewing that the same quantity of water descending from the same height, always produces the same effect (as he measured it), whatever be the velocity? In the first place, all his experiments are cases where the power expended and the work performed are of the same kind: A heavy body descends, and by its preponderancy raises another heavy body. But even this would not ensure the precise agreement observed in his experiments, if Mr Smeaton were not careful to exclude from his calculations all that motion where there is any acceleration, and all the expenditure of water during the acceleration, and to admit only those motions that are sensibly uniform. In moderate velocities, the additional pressure required for the first acceleration is but an insignificant part of the whole; and to take these accelerated motions into the account, would have embarrassed the calculations, and perhaps confused many of the readers. We see, in the instance now given, that the addition of one pound continued for three seconds only, was all that was necessary.

Mr Smeaton's measurement is therefore abundantly exact for practice; and being accommodated to the circumstances most likely to engage the attention, is very proper for the instruction of the numerous practitioners in all manufacturing countries who are employed for ordinary erections; but it is improperly proposed as an article essential to a just theory of mechanics, and therefore it was proper to notice it in this place. Besides, there frequently occur most important cases, in which the motion of a machine is, of necessity, desultory, alternately accelerated, and retarded. We should not derive all the advantages in our power from the first mover, if we did not attend particularly, and chiefly, to the *accelerating* forces. And in every case, the improvement, or the proper employment of the machine, is not attained, if we are not able to discriminate between the two parts of the mechanical exertion; one of them, by which the motion is produced and accelerated to a certain degree; and the other, by which that motion is continued. We must be able to appreciate what part of the effect belongs to each. But it is now time to proceed to the important question,

What will be the precise motion of a machine of given construction, actuated by a power of known intensity and manner of acting, and opposed by a known resistance?

6 Things to be considered in a machine at work.

In the solution of this question, much depends on the nature of both power and resistance. In the statical consideration of machines, no attention is paid to any differences. The intensity of the pressures is all that it is necessary to regard, in order to state the proportion of pressure which will be exerted in the various parts of the machine. The pressures at the impelled and working points, combined with the proportions of the machine, necessarily determine all the rest. Pressure being the sole cause of all mechanical action among bodies, any pressure may be substituted for another that is equal to it; and the pressure which is most familiar, or of easiest consideration, may be used as the representative of all others. This has occasioned the mechanical writers to make use of the pressure of gravity as the standard of comparison, and to represent all powers and resistances by weights. However proper this may be in their hands, it has hurt the progress of the science. It has rendered the usual elementary treatises of mechanics very imperfect, by limiting the experiments and illustrations to such as can be so represented with facility. This has limited them to the state of equilibrium (in which condition a working machine is never found), because illustrations by experiment out of this state are neither obvious nor easy. It has also prevented the students of mechanics from accomplishing themselves with a mathematical knowledge required for a successful prosecution of the study. The most elementary geometry is sufficient for a thorough understanding of equilibrium, or the doctrines of statics; but true mechanics, the knowledge of machines as instruments by which work is performed, requires more refined mathematics, and is inaccessible without it.

Had not Newton or others improved mathematics by the invention of the infinitesimal analysis and calculus, we must have rested contented with the discoveries (really great) of Galileo and Huyghens. But Newton,

ton, *suâ mathesi facem præferente*, opened a boundless field of investigation, and has not only given a magnificent and brilliant specimen of the discoveries to be made in it, but has also traced out the particular paths in which we are to find the solution of all questions of practical mechanics. This he has done by shewing another species of equilibrium, indicated, not by the cessation of all motion, but by the uniformity of motion; by the cessation of all acceleration or retardation. As the extinction of motion by the action of opposite forces is assumed by us as the indication of the perfect equality of those forces; so the extinction of acceleration should be received as the indication of something equal and opposite to the force which was known to have caused the acceleration; and therefore as the indication of an equilibrium between opposite forces, or else of the cessation of all force.

7 Mechanical equilibrium

This new view of things was the source of all our distinct notions of mechanical forces, and gave us our only unexceptionable marks and measures of them. The 39th proposition of the first book of Newton's Principles of Natural Philosophy, and its corollaries, contain almost the whole doctrine of active mechanical nature, and are peculiarly applicable to our present purpose, because they enable us to comprehend in this *mechanical equilibrium* (so different from the *statical*) every circumstance in which those pressures which are exerted by natural powers differ from each other, and vary in their action on the impelled and working points of a machine. Indeed, when we recollect that the operations of our machines are the same on board a ship as on shore, and that all our machines are moving with the ground on which they stand, we must acknowledge, that even ordinary statics is only an imperfect view of an equilibrium among things which are in motion; and this should have taught us that, even in those cases where nothing like equilibrium appears, an equilibrium may still be usefully traced.

8 Distinctions must be the made in the nature of the powers applied to working machines.

In the statical consideration of machines, the *quantity* of pressure is all that we need attend to. But in the mechanical discussion of their *operations*, we must attend to their distinctions in kind: and it will by no means be sufficient to represent them all by weights; for their distinction in kind is accompanied by great differences in their manner of acting on the machine. Some natural powers, in order to continue their action on the impelled point of the machine, must at the same time put into motion a quantity of matter external to the machine, in which these powers reside; and this must be made to follow the impelled point in its motion, and not only follow, but continue to press it forward; or, this matter, thus continually put into motion, must be successively applied to different points of the machine, which become impelled points in their turn. This is the case with a weight, with the action of a spring, the action of animals, the action of a stream of water or wind, and many other powers. A part of the natural mechanical powers must therefore be employed in producing this external motion. This is sometimes a very considerable part of the whole natural power. In some cases it is the whole of it. This obtains in the action of a descending weight, lying on the end of a lever and pressing it down, or hanging by a cord attached to the machine.

There is also an important distinction in the manner in which this external motion is kept up. In a weight employed as the moving power, the actuating pressure seems to reside in the matter itself; and all that is necessary for continuing this pressure is merely to continue the connection of it with the machine. But in the action of animals it may be very different: A man pushing at a capstan bar, must first of all walk as fast as the bar moves round, and this requires the expenditure of his muscular force. But this alone will not render his action an effective power: He must also *press forward* the capstan bar with as much force as he has remaining over and above what he expends in walking at that rate. The proportion of these two expenditures may be very different in different circumstances; and in the judicious selection of such circumstances as make the first of these as inconsiderable as possible, lies much of the skill and sagacity of the engineer. In the common operation of thrashing corn, much more than half of the man's power is expended in giving the necessary motion to his own body, and only the remainder is employed in urging forward the swiple with a momentum sufficient for shaking off the ripe grains from the stalk. We had sufficient proof of this, by taking off the swiple of the flail, and putting the same weight of lead on the end of the staff, and then causing the hind to perform the usual motions of thrashing with all the rapidity that he could continue during the ordinary hours of work. We never could find a man who could make three motions in the same time that he could make two in the usual manner, so as to continue this for half an hour. Hence we must conclude, that half (some will say two-thirds) of a thresher's power is expended in merely moving his own body. Such modes of animal action will therefore be avoided by a judicious engineer; but to be avoided, their inconvenience must be understood. More of this will occur hereafter. In other cases we are almost, (never wholly) free from this unprofitable expenditure of power. Thus, in the steam engine, the operation requires that the external air follow the piston down the cylinder, in order to continue its pressure. But the force necessary for sending in this rare fluid into the cylinder with the necessary velocity, is such an insignificant part of the whole force which is at our command, that it would be ridiculous affectation in any engineer to take it into account; and this is one great ground of preference to this natural power. The same thing may be said of the action of a strong and light spring, which is therefore another very eligible first mover for machinery. The ancient artillerists had discovered this, and employed it in their warlike engines.

We must also attend to the nature of the resistance which the work to be performed opposes to the motion of our machine. Sometimes the work opposes, not a simple obstruction, but a real resistance or reaction, which, if applied alone to the machine, would cause it to move the contrary way. This always obtains in cases where a heavy body is to be raised, where a spring is to be compressed, and in some other cases. Very often, however, there is no such contrary action. A flour mill, a saw mill, a boring mill, and many such engines, exhibit no reaction of this kind. But although such machines, when at rest or not impelled by the first mover, sustain no pressure in the opposite direction, yet they

they will not acquire any motion whatever, unleſs they be impelled by a power of a certain determinate intenſity. Thus in a ſaw mill, a certain force muſt be impreſſed on the teeth of the ſaw, that the coheſion of the fibres of the timber may be overcome. This requires that a certain force, determined by the proportions of the machine, be impreſſed on the impelled point. If this, and no more, be applied there, a force will be excited at the teeth of the ſaw, which will *balance* the coheſion of the wood, but will not *overcome* it. The machine will continue at reſt, and no work will be performed. Any addition of force at the impelled point, will occaſion an addition to the force excited in the teeth of the ſaw. The coheſion will be overcome, the machine will move, and work will be performed. It is only this *addition* to the impelling power that gives motion to the machine; the reſt being expended merely in balancing the coheſion of the woody fibres. While therefore the machine is in motion, performing work, we muſt conſider it as actuated by a force impreſſed on the impelled point by the natural power, and by another acting at the working point, furniſhed by or derived from the reſiſtance of the work.

Again: It not unfrequently happens, that there is not even any ſuch reſiſtance or obſtruction excited at the working point of the machine; the whole reſiſtance (if we can with propriety give it that name) ariſes from the neceſſity of giving motion to a quantity of inert and inactive matter. This happens in urging round a heavy fly, as in the coining preſs, in the punching engine, in drawing a body along a horizontal plane without friction, and a few ſimilar caſes. Here the ſmalleſt force whatever, applied at the impelled point, will begin motion in the machine; and the *whole* force ſo applied is conſumed in this ſervice. Such caſes are rare, as the ultimate performance of a machine; but occaſionally, and for a farther purpoſe, they frequently occur; and it is neceſſary to conſider them, becauſe there are many of the moſt important applications of machinery where a very conſiderable part of the force is expended in this part of the general taſk.

Such are the chief circumſtances of diſtinction among the mechanical powers of nature which muſt be attended to, in order to know the motion and performance of a machine. Theſe never occur in the ſtatical conſideration of the machine, but here they are of chief importance.

9 [e inertia / he ma[chine] / [th]e itſelf / [mu]ſt alſo / [be] conſider[ed].]

But farther: The action of the moving power is transferred to the working point through the parts of a machine, which are material, inert, and heavy. Or, to deſcribe it more accurately, before the neceſſary force can be excited at the working point of the machine, the various connecting forces muſt be exerted in the different parts of the machine; and in order that the working point may follow out the impreſſion already made, all the connecting parts or limbs of the machine muſt *be moved*, in different directions, and with different velocities. Force is neceſſary for thus changing the ſtate of all this matter, and frequently a very conſiderable force. Time muſt alſo elapſe before all this can be accompliſhed. This often conſumes, and really waſtes, a great part of the impelling power. Thus, in a crane worked by men walking in a wheel, it acquires motion by ſlow degrees; becauſe, in order to give ſufficient room for the action of the number of men or cattle that are neceſſary, a very capacious wheel muſt be employed, containing a great quantity of inert matter. All of this muſt be put in motion by a very moderate preponderance of the men. It accelerates ſlowly, and the load is raiſed. When it has attained the required height, all this matter, now in conſiderable motion, muſt be ſtopped. This cannot be done in an inſtant with a jolt, which would be very inconvenient, and even hurtful; it is therefore brought to reſt gradually. This alſo conſumes time; nay, the wheel muſt get a motion in the contrary direction, that the load may be lowered into the cart or lighter. This can only be accompliſhed by degrees. Then the tackle muſt be lowered down again for another load, which alſo muſt be done gradually. All this waſtes a great deal both of time and of force, and renders a walking wheel a very improper form for the firſt mover of a crane, or any machine whoſe uſe requires ſuch frequent changes of motion. The ſame thing obtains, although in a lower degree, in the ſteam engine, where the great beam and pump rods, ſometimes weighing very many tons, muſt be made to acquire a very briſk motion in oppoſite directions twice in every working ſtroke. It obtains, in a greater or a leſs degree, in all engines which have a reciprocating motion in any of their parts. Pump mills are of neceſſity ſubjected to this inconvenience. In the famous engine at Marly, about $\frac{19}{20}$ of the whole moving power of ſome of the water wheels is employed in giving a reciprocating motion to a ſet of rods and chains, which extend from the wheels to a ciſtern about three-fourths of a mile diſtant, where they work a ſet of pumps. This engine is, by ſuch injudicious conſtruction, a monument of magnificence, and the ſtruggle of ignorance with the unchangeable laws of Nature. In machines, all the parts of which continue the direction of their motions unchanged, the inertia of a great maſs of matter does no harm; but, on the contrary, contributes to the ſteadineſs of the motion, in ſpite of ſmall inequalities of power or reſiſtance, or unavoidable irregularities of force in the interior parts. But in all reciprocations, it is highly prejudicial to the performance; and therefore conſtructions which admit ſuch reciprocation without neceſſity, are avoided by all intelligent engineers. The mere copying artiſt, indeed, who derives all his knowledge from the common treatiſes of mechanics, will never ſuſpect ſuch imperfections, becauſe they do not occur in the ſtatical conſideration of machines. 10

Laſtly, no machine can move without a mutual rubbing of its parts, at all points of communication; ſuch as the teeth of wheelwork, the wipers and lifts, and the gudgeons of its different axes. In many machines, the ultimate taſk performed by the working point, is either friction, or very much reſembles it. This is the caſe in poliſhing mills, grinding mills, nay, in boring mills, ſaw mills, and others. A knowledge of friction, in all its varieties, ſeems therefore abſolutely neceſſary, even for a moderate acquaintance with the principles of machinery. This is a very abſtruſe ſubject; and although a good deal of attention has been paid to it by ſome ingenious men, we do not think that a great deal has been added to our knowledge of it; nor do the experiments which have been made ſeem to us well calculated to lead us to a diſtinct knowledge of its nature and modifications. It has been conſidered chiefly with a view to diminiſh it as much as poſſible in the communicating parts

And its friction.

parts of machinery, and to obtain ſome general rules for aſcertaining the quantity of what unavoidably remains. Mr Amontons, of the Royal Academy of Sciences at Paris, gave us, about the beginning of this century, the chief information that we have on the ſubject. He diſcovered, that the obſtruction which it gave to motion was very nearly proportional to the force by which the rubbing ſurfaces are preſſed together. Thus he found, that a ſmooth oaken board, laid on another ſmooth board of the ſame wood, requires a force nearly equal to one third of what preſſes the ſurfaces together. Different ſubſtances required different proportions.

11 Meaſure of it by Amontons.

He alſo found, that neither the extent of the rubbing ſurfaces, nor the velocity of the motion, made any conſiderable variation on the obſtruction to motion. Theſe were curious and unexpected reſults. Subſequent obſervations have made ſeveral corrections neceſſary in all theſe propoſitions. This ſubject will be more particularly conſidered in another place; but ſince the deviations from Mr Amontons's rule are not very conſiderable, at leaſt in the caſes which occur in this general conſideration of machines, we ſhall make uſe of it in the mean time. It gives us a very eaſy method of eſtimating the effect of friction on machines. It is a certain proportion of the mutual preſſure of the rubbing ſurfaces, and therefore muſt vary in the ſame proportion with this preſſure. Now, we learn from the principles of ſtatics, that whatever preſſures are exerted on the impelled and working point of the machine, all the preſſures on its different parts have the ſame conſtant proportion to theſe, and vary as theſe vary: Therefore the whole friction of the machine varies in the ſame proportion. But farther, ſince it is found that the friction does not ſenſibly change with the velocity, the force which is juſt ſufficient to overcome the friction, and put the loaded machine in motion, muſt be very nearly the ſame with the force expended in overcoming the friction while the machine is moving with any velocity whatever, and performing work. Therefore if we deduct from the force which juſt puts the loaded machine in motion that part of it which balances the reaction of the impelled point occaſioned by the reſiſtance of the work, or which balances the reſiſtance of the work, the remainder is the part of the impelling power which is employed in overcoming the friction. If indeed the actual reſiſting preſſure of the work varies with the velocity of the working point, all the preſſures, and all the frictions in the different communicating parts of the machine, vary in the ſame proportion. But the law of this variation of working reſiſtance being known, the friction is again aſcertained.

We can now ſtate the dynamical equilibrium of forces in the working machine in two ways. We may either conſider the efficient impelling power as diminiſhed by all that portion which is expended in overcoming the friction, and which only prepares the machine for performing work, or we may conſider the impelling power as entire, and the work as increaſed by the friction of the machine; that is, we may ſuppoſe the machine without friction, and that it is loaded with a quantity of additional reſiſtance acting at the working point. Either of theſe methods will give the ſame reſult, and each has its advantages. We took the laſt method in the ſlight view which we took of this ſubject in the *Encycl.* article ROTATION, nº 64. and ſhall therefore uſe it here.

Suppoſing now this previous knowledge of all theſe variable circumſtances which affect the motion of machines of the rotative kind, ſo that, for any momentary poſition of it while performing work, we know what are the preciſe preſſures acting at the impelled and working points, and the conſtruction of the machine, on which depend the friction, and the momentum of its inertia (expreſſed in the article ROTATION by $\int p r^2$); we are now in a condition to determine its motion, or at leaſt its momentary acceleration, competent to that poſition. Therefore,

Let there be a rotative machine, ſo conſtructed, that while it is performing work, the velocity of its impelled point is to that of its working point as m to n. It is eaſy to demonſtrate, from the common principles of ſtatics, that if a ſimple wheel and axle be ſubſtituted for it, having the radius of the wheel to that of the axle in the ſame proportion of m to n, and having the ſame momentum of friction and inertia, and actuated by the ſame preſſures at the impelled and working points, then the velocities of theſe points will be preciſely the ſame as in the given machine.

12 Compoſition of the formula expreſſing the performance of a machine.

Let p repreſent the intenſity (which may be meaſured by pounds weight) of the preſſure exerted in the moment at the impelled point; and r expreſs the preſſure exerted at the working point by the reſiſtance oppoſed by the work that is then performing. This may ariſe from the weight of a body to be raiſed, from the coheſion of timber to be ſawed, &c. Any of theſe reſiſtances may alſo be meaſured by pounds weight; becauſe we know that a certain number of pounds hung on the ſaw of a ſaw mill, will juſt overcome this coheſion, or overcome it with any degree of ſuperiority. Therefore the impelling power p, and the reſiſtance r, however differing in kind, may be compared as mere preſſures.

Let x repreſent the quantity of inert matter which muſt be urged by the impelling power p, with the ſame velocity as the impelled point, in order that this preſſure p may really continue to be exerted on that point. Thus, if the impelling power is a quantity of water in the bucket of an overſhot wheel, acting by its weight, this weight cannot impel the wheel except by impelling the water. In this way, x may be conſidered as repreſenting the inertia of the impelling power, while p repreſents its preſſure on the machine. In like manner, let y repreſent the quantity of external inert matter which is really moved with the velocity of the working point in the execution of the taſk performed by the machine.

Whatever be the momentum of the inertia of the machine, we can always aſcertain what quantity of matter, attached to the impelled point, or the working point of the wheel and axle, will require the ſame force to give the wheel the ſame angular motion; that is, which ſhall have the ſame momentum of inertia. Let the quantity a, attached to the working point, give this momentum of inertia $a n^2$.

Laſtly, ſuppoſing that the wheel and axle have no friction, let f be ſuch a reſiſtance, that if applied to the working point, it ſhall give the ſame obſtruction as the friction of the machine, or require the ſame force at the impelled point to overcome it.

Theſe

13 Angular motion of the machine.

Theſe things being thus eſtabliſhed, the angular velocity of the wheel and axle, that is, the number of turns, or the portion of a turn, which it will make in a given time, will be proportional to the fraction $\frac{pm - \overline{r+f}n}{xm^2 + \overline{a+y}n^2}$. (I.)—See ROTATION, n° 64, &c. *Encycl.*

Since the whole turns together, the velocities of the different points are as their diſtances from the axis, and may be expreſſed by multiplying the common angular velocity by theſe diſtances. Therefore the above formula, multiplied by m or n, will give the velocity of the impelled or of the working point. Therefore,

14 Velocity of the impelled point.

Velocity of impelled point $= \frac{pm^2 - \overline{r+f}mn}{xm^2 + \overline{a+y}n^2}$. (II.)

15 Velocity of the working point.

Velocity of working point $= \frac{pmn - \overline{r+f}n^2}{xm^2 + \overline{a+y}n^2}$. (III.)

In order to obtain a clear conception of theſe velocities, we muſt compare them with motions with which we are well acquainted. The propoſition being univerſally true, we may take a caſe where gravity is the ſole power and reſiſtance; where, for example, p and r are the weights of the water in the bucket of a wheel, and in the tub that is raiſed by it. In this caſe, $p = x$, and $r = y$. We may alſo, for greater ſimplicity, ſuppoſe the machine without inertia and friction. The velocity of p is now $\frac{pm^2 - rmn}{pm^2 + rn^2}$.

16 Abſolute meaſure of them.

Let g be the velocity which gravity generates in a ſecond. Then it will generate the velocity $g\dot{t}$ in the moment $\dot{t}$. Let $\dot{v}$ be the velocity generated during this moment in p, connected as it is with the wheel and axle, and with r. This connection produces a change of condition $= g\dot{t} - \dot{v}$. For, had it fallen freely, it would have acquired the velocity $g\dot{t}$, whereas it only acquires the velocity $\dot{v}$. In like manner, had r fallen freely, it would have acquired the velocity $g\dot{t}$. But, inſtead of this, it is raiſed with the velocity $\frac{n}{m}\dot{v}$. The change on it is therefore $= g\dot{t} + \frac{n}{m}\dot{v}$. Theſe changes of mechanical condition ariſe from their connection with the corporeal machine. Their preſſures on it bring into action its connecting forces, and each of the two external forces is in immediate equilibrium with the force exerted by the other. The force excited at the impelled point, by r acting at the working point, may be called the momentum or energy of r. Theſe energies are preciſely competent to the production of the changes which they really produce, and muſt therefore be conceived as having the ſame proportions. They are therefore equal and oppoſite, by the general laws *obſerved* in all actions of tangible matter; that is, they are ſuch as balance each other. Thus, and only thus, the remaining motions are what we obſerve them to be.

That is, $p \times \overline{g\dot{t} - \dot{v}} \times m = r \times \overline{g\dot{t} + \frac{n}{m}\dot{v}} \times n$

Or $pmg\dot{t} - pm\dot{v} = rng\dot{t} + r\frac{n^2}{m}\dot{v}$

Or $pm^2g\dot{t} - pm^2\dot{v} = rmng\dot{t} + rn^2\dot{v}$

Or $\overline{pm^2 - rmn} \times g\dot{t} = \overline{pm^2 + rn^2} \times \dot{v}$

That is, $pm^2 + rn^2 : pm^2 - rmn = g\dot{t} : \dot{v}$

That is, *the denominator of the fraction, expreſſing the velocity of the impelled point, is to the numerator as the velocity which a heavy body would acquire in the moment* $\dot{t}$, *by falling freely, is to the velocity which the impelled point acquires in that moment.* The ſame thing is true of the velocity of the working point.

This reaſoning ſuffers no change from the more complicated nature of the general propoſition. Here the impelling power is ſtill p, but the matter to be accelerated by it at the working point is $a + y$, while its reaction, diminiſhing the impelling power, is only r. We have only to conſider, in this caſe, the velocity with which $a + y$ would fall freely when impelled, not by $a + y$, but only by r. The reſult would be the ſame; $g\dot{t}$ would ſtill be to $\dot{v}$ as the denominator of the ſame fraction to its numerator.

Thus have we diſcovered the momentary acceleration of our machine. It is evident, that if the preſſures p and r, and the friction and inertia of the machine, and the external matter, continue the ſame, the acceleration will continue the ſame; the motion of rotation will be uniformly accelerated, and $pm^2 + \overline{a+y}n^2$ will be to $pm^2 - \overline{r+f}mn$ as the ſpace s, through which a heavy body would fall in any given time t, is to the ſpace through which the impelled point will really have moved in the ſame time. In like manner, the ſpace through which the working point moves in the ſame time is $= \frac{pmn - \overline{r+f}n^2}{pm^2 + \overline{a+y}n^2}s$.

Thus are the motions of the working machine determined. We may illuſtrate it by a very ſimple example. Suppoſe a weight p of five pounds, deſcending from a pulley, and dragging up another weight r of three pounds on the other ſide. m and n are equal, and each may be called 1. The formula becomes $\frac{p-r}{p+r}s$, or $\frac{5-3}{5+3}s$, or $\frac{2}{8} = \frac{1}{4}s$. Therefore, in a ſecond, the weight p will deſcend $\frac{1}{4}$th of 16 feet, or 4 feet; and will acquire the velocity of 8 feet per ſecond.

17 Performance of the machine.

Having obtained a knowledge of the velocity of every point of the machine, we can eaſily aſcertain its performance. This depends on a combination of the quantity of reſiſtance that is overcome at the working point, and the velocity with which it is overcome. Thus, in raiſing water, it depends on the quantity (proportional to the weight) of water in the bucket or pump, and the velocity with which it is lifted up. This will be had by multiplying the third formula by r, or by $rg\dot{t}$, or by rs. Therefore we obtain this expreſſion,

Work done $= \frac{pmrn - \overline{r+f}rn^2}{pm^2 + \overline{a+y}n^2}g\dot{t}$. (IV.)

Such is the general expreſſion of the momentary performance of the machine including every circumſtance which can affect it. But a variation of thoſe circumſtances produces great changes in the reſults. Theſe muſt be diſtinctly noticed.

Cor. 1. If $pmrn$ be equal to $\overline{r+f}rn^2$, there will be no work done, becauſe the numerator of the fraction is annihilated. There is then no unbalanced force, and the

the natural power is only able to balance the preffure propagated from the working point to the impelled point.

2 In like manner, if $n = o$, no work is done altho' the machine turns round. The working point has no motion. For the fame reafon, if m be infinitely great, although there is a great prevalence of impelling momentum, there will not be any fenfible performance during a finite time. For the velocity which p can imprefs is a finite quantity, and the impelled point cannot move fafter than x would be moved by it if detached from the machine. Now when the infinitely removed impelled point is moved through any finite fpace, the motion of the working point muft be infinitely lefs, or nothing, and no work can be done.

Remark. We fee that there are too values of n, viz. v, and $m \times \frac{p}{r}$, which give no performance. But in all other proportions of m and n fome work is done. Therefore, as we gradually vary the proportion of m to n, we obtain a feries of values expreffing the performance, which muft gradually increafe from nothing, and then decreafe to nothing. There muft therefore be fome proportion of m to n, depending on the proportion of p to $\overline{r+f}$, and of x to $\overline{a+y}$, which will give the greateft poffible value of the performance. And, on the other hand, if the proportion of m to n be already determined by the conftruction of the machine already erected, there muft be fome proportion of p to $\overline{r+f}$, and of x to $\overline{a+y}$, by which the greateft performance of the machine may be enfured. It is evident that the determination of thefe two proportions is of the utmoft importance to the improvement of machines. The well-informed reader will pardon us for endeavouring to make this appear more forcibly to thofe who are lefs inftructed, by means of fome very fimple examples of the firft principle.

Suppofe that we have a ftream of water affording three tons per minute, and that we want to drain a pit which receives one ton per minute, and that this is to be done by a wheel and axle? We wifh to know the beft proportion of their diameters m and n. Let m be taken $= 6$; and fuppofe,

1. That $n = 5$.
Then $\frac{pmrn - r^2n^2}{pm^2 + rn^2} = \frac{3.6.1.5 - 1.25}{3.36 + 1.36}, = \frac{65}{133}, = 0{,}4887$

2. Let n be $= 6$. The formula is $= 0{,}5$.

3. Let $n = 7$. The formula is $= 0{,}49045$. Hence we find, that the performance is greater when n is 6 than when it is either 5 or 7.

As an example of the fecond principle, fuppofe the machine a fimple pulley, and let p be 10.

1. Let r be $= 3$. The formula is $\frac{10 \times 3 - 9}{10 + 3} = \frac{21}{13}$, $= 1{,}6154$.

2. Let r be $= 4$. The formula is $= \frac{10 \times 4 - 16}{10 + 4}$, $= \frac{24}{14}, = 1{,}7143$.

3. Let r be $= 5$. The formula is $= \frac{10 \times 5 - 25}{10 + 5}$, $= \frac{25}{15}, = 1{,}6666$. Here it appears, that more work is done when r is 4 than when it is 5 or 3.

It muft therefore be allowed to be one of the moft important problems in practical mechanics to determine that conftruction by which a given power fhall overcome a given refiftance with the greateft advantage, and the proportion of work which fhould be given to a machine already contructed fo as to gain a fimilar end. 18

Proportion of the machine which gives the greateft work.

I. The general determination of the firft queftion has but little difficulty. We muft confider n as the variable magnitude in the formula $\frac{pmrn - \overline{r+f}\,rn^2}{pm^2 + \overline{a+y}\,n^2}$, which expreffes the work done; and find its value when the formula is a maximum. Taking this method, we fhall find that the formula IV. is a maximum when n is $= m\,\frac{\sqrt{x^2(r+f)^2 + p^2x(a+y)} - x(r+f)}{p(a+y)}$.

This expreffion of the performance, in its beft ftate, appears pretty complex; but it becomes much more fimple in all the particular applications of it, as the circumftances of the cafe occur in practice.

We have obtained a value of n expreffed in parts of m. If we fubftitute this for n in the third formula, we obtain the greateft velocity with which the refiftance r, connected with the inertia y, can be overcome by the power p, connected with the inertia x, by the intervention of a machine, whofe momentum of inertia and friction are an^2 and fn. This is $= \frac{r+f}{2\,\overline{a+y}} \times \left(\sqrt{\frac{p^2\,\overline{a+y}}{\overline{r+f}^2\,x} + 1} - 1\right) g\,t$. This expreffes the velocity of the working point in feet per fecond, and therefore the actual performance of the machine.

But the proper proportion of m to n, afcertained by this procefs, varies exceedingly, according to the nature both of the impelling power, and of the work to be performed by the machine.

1. It frequently happens that the work exerts no contrary ftrain on the machine, and confifts merely in impelling a body which refifts only by its inertia. This is the cafe in urging round a milftone or a heavy fly; in urging a body along a horizontal plane, &c. In this cafe r does not enter into the formula, which now becomes $m \times \frac{\sqrt{x^2f^2 + p^2x(a+y)} - xf}{p(a+y)}$. If the friction be infignificant, we may take $n = m\sqrt{\frac{p^2x(a+y)}{p^2(a+y)^2}}$ $= m\sqrt{\frac{x}{a+y}}$. The velocity of the working point is nearly $= \frac{p}{2\sqrt{x\,\overline{a+y}}}$. In this cafe, it will be found that the velocity acquired at the end of a given time will be nearly in the proportion of the power applied to the machine.

2. On the other hand, and more frequently, the inertia of the external matter which muft be moved in performing the work need not be regarded. Thus, in the grinding of grain, fawing of timber, boring of cylinders, &c. the quantity of motion communicated to the flour, to the faw-duft, &c. is too infignificant to be taken into the account. In this cafe, y vanifhes from the formula, which becomes extremely fimple when the friction and inertia of the machine are inconfiderable. We fhall

ſhall not be far from the truth if we make m to n as $2r$ to p, or $n = m \times \frac{p}{2r+f}$. In this caſe, the velocity of the working point is $\frac{p^2}{4x(r+f) + \frac{a p^2}{4(r+f)}}$

But it is rare that machines of this kind have a ſmall inertia. They are generally very ponderous and powerful; and the force which is neceſſary for generating even a very moderate motion in the unloaded machine (that is, unloaded with any work), bears a great proportion to the force neceſſary for overcoming the reſiſtance oppoſed by the work. The formula muſt therefore be uſed in all the terms, becauſe a is joined with y. It would have been ſimpler in this particular, had a been joined with x in the expreſſion of the angular velocity.

3. In ſome caſes we need not attend to the inertia of the power, as in the ſteam engine. In this caſe, if taken ſtrictly, n appears to have no value, becauſe x is a factor of every term of the numerator. But the formula gives this general indication, that the more inſignificant the inertia of the moving power is ſuppoſed, the larger ſhould m be in proportion to n; provided always, that the impelling power is not, by its nature, greatly diminiſhed, by giving ſo great a velocity to the impelled point. This circumſtance will be particularly conſidered afterwards.

4. If the inertia of the power and the reſiſtance be proportional to their preſſures, as when the impelling power is water lying in the buckets of an overſhot wheel, and the work is the raiſing of water, minerals, or other heavy body, acting *only* by its weight; then p and r may be ſubſtituted for x and y, and the formula expreſſing the value of n, when the performance is a maximum, becomes

$$n = m\,\frac{\sqrt{p^2 \times \overline{r+f}^2 + p^3 \times \overline{a+r}} - p \times \overline{r+f}}{p \times \overline{a+r}}$$

If, in this caſe, the inertia and friction of the machine may be diſregarded, as may often be done in pulleys, we have

$$n = m\sqrt{\frac{p}{r}+1} - 1.$$

If we make m the unit of the radii, and r the unit of force, we have

$$n = \sqrt{p+1} - 1, \text{ in parts of } m = 1.$$

Or, making $p = 1$, we have $n = \sqrt{\frac{1}{r}+1} - 1$.

Theſe very ſimple expreſſions are of conſiderable uſe, even in caſes where the inertia of the machine is very conſiderable, provided that it have no reciprocating motions. A ſimple wheel and axle, or a train of good wheelwork, have very moderate friction. The general reſults, therefore, which even very unlettered readers can deduce from theſe ſimple formulæ, will give notions that are uſeful in the caſes which they cannot ſo thoroughly comprehend. Some ſervice of this kind may be derived from the following little table of the beſt proportions of m to n, correſponding to the proportions of the power furniſhed to the engineer, and the reſiſtance which muſt be overcome by it. The quantity r is always $= 10$, and $m = 1$.

p	n	p	n
1	0,0488	10	0,4142
2	0,0954	20	0,7321
3	0,1402	30	1,
4	0,1832	40	1,2362
5	0,2246	50	1,4495
6	0,2649	60	1,6457
7	0,3038	70	1,8284
8	0,3416	80	2,
9	0,3784	90	2,1623
10	0,4142	100	2,3166

This muſt ſuffice for a very general view of the firſt problem.

II. The next queſtion is not leſs momentous, namely, to determine for a machine of a given conſtruction that proportion of the reſiſtance at the working point to the impelling power which will enſure the greateſt performance of the machine; that is, the proportion of m to n being given, to find the beſt proportion of p to r. 19 Beſt proportion of the power and work.

This is a much more complicated problem than the other; for here we have to attend to the variations both of the preſſures p and r, and alſo of the external matters x and y, which are generally connected with them. It will not be ſufficient therefore to treat the queſtion by the uſual fluxionary proceſs for determining the maximum, in which r is conſidered as the only varying quantity. We muſt, in this curſory diſcuſſion, reſt ſatisfied with a comprehenſion of the circumſtances which moſt generally prevail in practice.

It muſt either happen, that when r changes, there is no change (that is, of moment) in the maſs of external matter which muſt be moved in performing the work, or that there is alſo a change in this circumſtance. If no change happens, the denominator of the fourth formula, expreſſing the performance, remains the ſame; and then the formula attains a maximum when the numerator $p\,r\,m\,n - \overline{r+f}\,r\,n^2$ is a maximum. Alſo, we may include f without complicating the proceſs, by the conſideration, that f is always in nearly the ſame ratio to r; and therefore $r+f$ may be conſidered as a certain multiple of r, ſuch as $b\,r$. We may therefore omit f in the fluxionary equations for obtaining the maximum, and then, in computing the performance, divide the whole by b. Thus if the whole friction be $\frac{1}{20}$th of the reſiſting preſſure r, we have $r+f = \frac{21}{20}$ of r, and $b = \frac{21}{20}$. Having aſcertained the beſt value for r, we put this in its place in the fourth formula, and take $\frac{20}{21}$ of this for the performance. This will never differ much from the truth.

This proceſs gives us $p\,m\,n = 2\,n^2\,r$, and $r = \frac{p\,m\,n}{2\,n^2}$, $= \frac{p\,m}{2\,n}$; and if we farther ſimplify the proceſs, by making $p = 1$, and $m = 1$, we have $r = \frac{1}{2\,n}$; a moſt ſimple expreſſion, directing us to make the reſiſtance one half of what would balance the impelling power by the intervention of the machine.

This

This will evidently apply to many very important cafes, namely, to all thofe in which the matter put in motion by the working point is but trifling.

But it alfo happens in many important cafes, that the change is at leaft equally confiderable in the inertia of the work. In this cafe it is very difficult to obtain a general folution. But we can hardly imagine fuch a change, without fuppofing that the inertia of the work varies in the fame proportion as the preffure excited by it at the working point of the machine; for fince r continues the fame in kind, it can rarely change but by a proportional change of the matter with which it is connected. Yet fome very important cafes occur where this does not happen. Such is a machine which forces water along a long main pipe. The refiftance to motion and the quantity of water do not follow nearly the fame ratio. But in the cafes in which this ratio is obferved, we may reprefent y by any multiple $b\,r$ of r, which the cafe in hand gives us; b being a number, integer, or fractional. In the farther treatment of this cafe, we think it more convenient to free r from all other combinations; and inftead of fuppofing the force f (which we made equivalent with the friction of the machine) to be applied at the working point, we may apply it at the impelled point, making the effective power $q=p-f$. For the fame reafons, inftead of making the momentum of the machine's inertia $= a\,n^2$, we may make it $a\,m^2$, and make $a+x=z$. Now, fuppofing q, or $p-f$, $=1$, and alfo $m=1$, our formula expreffing the performance becomes $\frac{r\,n - r^2 n^2}{z + b\,r\,n^2}$. This is a maximum when $r = \frac{\sqrt{z^2 + z\,b\,n} - z}{b\,n^2}$.

Cor. 1. If the inertia of the work is always equal to its preffure, as when the work confifts wholly in raifing a weight, fuch as drawing water, &c. then $b=1$, and the formula for the maximum performance becomes $r = \frac{\sqrt{z\,n + z^2} - z}{n^2}$.

2. If the inertia of the impelling power is alfo the fame with its preffure, and if we may neglect the inertia and friction of the machine, the formula becomes $r = \frac{\sqrt{n+1} - 1}{n^2}$.

Example. Let the machine be a common pulley, fo that the radii m and n are equal, and therefore $n=1$. Then, $r = \frac{\sqrt{1+1} - 1}{1}$, $= \sqrt{2} - 1$, $= 0{,}4142$, &c. more than $\frac{2}{5}$ths of what would balance it.

Here follows a feries of the beft values of r, correfponding to different values of n. m and p are each $=1$. The numbers in the laft column have the fame proportion to 1 which r has to the refiftance which will balance p.

n	r	
$n = \frac{1}{4}$	$r =$ 1,8885	0,4724 to 1

3	0,1111	0,3333
4	0,0772	0,3088

From what has now been eftablifhed, we fee with fufficient evidence the importance of the higher mathematics to the fcience of mechanics. If the velocities of the impelled and working points of an engine are not properly adjufted to the preffures, the inertia, and the friction of the machine, we do not derive all the advantages which we might from our fituation. Hence alfo we learn the falfity of the maxim which has been received as well founded, that the augmentation of intenfity of any force, by applying it to the long arm of a lever, is always fully compenfated by a lofs of time; or, as it is ufually expreffed, "what we gain by a machine in force we lofe in time." If the proportion of m to n is well chofen, we fhall find that the work done, when it refifts by its inertia only, increafes nearly in the proportion of the power employed; whereas, when the inertia of the work is but a fmall part of the refiftance, it increafes nearly in the duplicate ratio of the power employed.

General but erroneous maxim.

It was remarked in the fetting out in the prefent problem, that the formulæ do not immediately exprefs the velocity of any point of the machine, but its momentary acceleration. But this is enough for our purpofe; becaufe, when the momentary acceleration is a maximum, the velocity acquired, and the fpace defcribed, in any given time, is alfo a maximum. We alfo fhewed how the real velocities, and the fpaces defcribed, may be afcertained in known meafures. We may fay in general, that if g reprefent the preffure of gravity on any mafs of matter w, then $\frac{g}{w}$ is to $\frac{p\,m\,n - \overline{r+f}\,n}{a\,m^2 + \overline{a+y}\,n^2}$ as 16 feet to the fpace defcribed in a fecond by the working point in a fecond, or as 32 feet per fecond is to the velocity acquired in that time.

20 Caufe why machines do not continually accelerate.

A remark now remains to be made, which is of the greateft confequence, and gives an unexpected turn to the whole of the preceding doctrines. It appears, from all that has been faid, that the motion of a machine muft be uniformly accelerated, and that any point will defcribe fpaces proportional to the fquares of the times; for while the preffures, friction, and momentum of inertia remain the fame, the momentary acceleration muft alfo be invariable. But this feems contrary to all experience. Such machines as are properly conftructed, and work without jolts, are obferved to quicken their pace for a few feconds after ftarting; but all of them, in a very moderate time, acquire a motion that is fenfibly uniform. Is our theory erroneous, or what are the circumftances which remain to be confidered, in order to make it agree with obfervation? The fcience of machines is imperfect, till we have explained the caufes of this deviation from the theory of uniform acceleration.

Thefe caufes are various.

1. Increafe of friction.

1. In fome cafes, every increafe of velocity of the machine produces an increafe of friction in all its communicating parts. By thefe means, the accelerating force, which is $p\,m - \overline{r+f}\,n$, or $\overline{p-f}\,m - r\,n$, is diminifhed, and confequently the acceleration is diminifhed. But it feldom happens that friction takes away or employs the whole accelerating force. We are not yet well inftructed in the nature of friction. Moft of the kinds of friction which obtain in the communicating parts of machines, are fuch as do not fenfibly increafe by an increafe of velocity; fome of them really diminifh. Yet even the moft accurately conftructed machines, unloaded with work, attain a motion that is fenfibly uniform. If we take off the pallets from a pendulum

dulum clock, and allow it to run down amain, it accelerates for a while, but in a very moderate time it acquires an uniform motion. So does a common kitchen jack. Thefe two machines feem to bid the faireft of any for an uniformly accelerated motion; for their impelling power acts with the utmoft uniformity. There is fomething yet unexplained in the nature of friction, which takes away fome of this acceleration.

. Refiftance of air. But the chief caufe of its ceffation in thefe two inftances, and others *of very rapid motion*, is the refiftance of the air. This arifes from the motion which is communicated to the air difplaced by the fwift moving parts of the machine. At firft it is very fmall; but it increafes nearly in the duplicate ratio of the velocity (fee *Resistance of Fluids*, Encycl.) Thus r increafes continually; and, in a certain ftate of motion, $\overline{r + f n}$ becomes equal to $p\ m$. Whenever this happens, the accelerating power is at an end. The acceleration alfo ceafes; and the machine is in a ftate of dynamical equilibrium; not at reft, but moving uniformly, and performing work.

. Increafe of refiftance very imperfectly known. Still, however, this is not one of the general caufes of the uniform motion attained by working engines. Rarely is the motion of their parts fo rapid, as to occafion any great refiftance from the air. But in the moft frequent employments of machines, every increafe of velocity is accompanied by an increafe of refiftance from the work performed. This occurs at once to the imagination; and few perfons think of inquiring farther for a reafon. But there is perhaps no part of mechanics that is more imperfectly underftood, even in our prefent improved ftate of mechanical fcience. In many kinds of work, it is very difficult to ftate what increafe of labour is required in order to perform the work with twice or thrice the fpeed. In grinding corn, for inftance, we are almoft entirely ignorant of this matter. It is very certain, that twice the force is not neceffary for making the mill grind twice as faft, nor even for making it grind twice as much grain equally well. It is not eafy to bring this operation under mathematical treatment; but we have confidered it with fome attention, and we imagine that a very great improvement may ftill be made in the conftruction of grift mills, founded on the law of variation of the refiftance to the operation of grinding, and a fcientific adjuftment of m to n, in confequence of our knowledge of this law. We may make a fimilar obfervation on many other kinds of work performed by machines. In none of thofe works where the inertia of the work is inconfiderable, are we well acquainted with the real mechanical procefs in performing it. This is the cafe in fawing mills, boring mills, rolling mills, flitting mills, and many others, where the work confifts in overcoming the ftrong cohefion of a fmall quantity of matter. In fawing timber (which is the moft eafily underftood of all thefe operations), if the faw move with a double velocity, it is very difficult to fay how much the actual refifting preffure on the teeth of the faw is increafed. Twice the number of fibres are neceffarily torn afunder during the fame time, becaufe the fame number are torn by one defcent of the faw, and it makes that ftroke in half the time. But it is very uncertain whether the refiftance is double on this account; becaufe if each fibre be fuppofed to have the fame tenacity in both cafes, it refifts with this tenacity only for half the time. The parts of bodies refift a fimilar change of condition in different manners; and there is another difference in their refiftance of different changes—the refiftance of red hot iron under the roller may vary at a very different rate from that of its refiftance to the cutting tool. The refiftance of the fpindles of a cotton mill, arifing partly from friction, partly from the inertia of the heaped bobbins, and partly from the refiftance of the air, is ftill more complicated, and it may be difficult to learn its law. The only cafe in which we can judge with fome precifion is, when the inertia of matter, or a conftant preffure like that of gravity, conftitutes the chief refiftance. Thus in a mill employed to raife water by a chain of buckets, the refiftance proceeds from the inertia only of the water. The buckets are moving with a certain velocity, and the loweft of them takes hold of a quantity of water lying at reft in the pit, and drags it into motion with its acquired velocity. The force required for generating this motion on the quiefcent water muft be double or triple, when the velocity that muft be given to it is fo. This abforbs the overplus of the impelling power, by which that power exceeds what is neceffary for balancing the weight of the water contained in all the afcending buckets. This is a certain determinate quantity which does not change; for in the fame inftant that a new bucket of water is forced into motion below, and its weight added to that of the afcending buckets, an equal bucket is emptied of its water at top. The afcending buckets require only to be balanced, and they then *continue* to afcend, with any velocity already acquired. While the machine moves flow, the motion impreffed on the new bucket of water is not fufficient to abforb all the overplus of impelling power. The quantity not abforbed accelerates the machine, and the next bucket muft produce more motion in the water which it takes up. This confumes more of the overplus. This goes on till no overplus of power is left, and the machine accelerates no more. The complete performance of the machine now is, that "a certain quantity of water, formerly at reft, is now moving with a certain velocity." Our engineers confider it differently; "as a certain *weight* of water lifted up." But while the machine is thus moving uniformly, it is really not doing fo much as before; that is, it is not exerting fuch great preffures as before the motion was rendered uniform: for at that time there was a preffure at the working point equal to the weight of all the water in the afcending buckets; and alfo an overplus of preffure, by which the whole was accelerated. In the ftate of uniform motion, the preffure is no more than juft balances the weight of the afcending chain. We fhall learn by and bye how the preffures have been diminifhing, although the mill has been accelerating; a thing that feems a paradox.

In this inftance, then, we fee clearly, why a machine muft attain a uniform motion. A pumping machine gives us the fame opportunity, but in a manner fo different as to require explanation. The pifton may be fuppofed at the very furface of the pit water, and the impelling power may be lefs than will fupport a column in the pipe as high as can be raifed by the preffure of the atmofphere. Suppofe the impelling power to be the water lying in the buckets of an overfhot wheel. Let

Let this water be laid into the buckets by a very fmall ftream. It will fill the buckets very flowly; and as this gives them a preponderance, the mill lofes its balance, the wheel begins to move, and the pifton to rife, and the water to follow it. The water may be delivered on the wheel drop by drop; the pifton will rife by infenfible degrees, always ftanding ftill again as foon as the atmofpheric preffure on it juft balances the water on the wheel. The water in the rifing pipe is always a balance to the preffure of the atmofphere on the ciftern; therefore the preffure of the atmofphere on the pifton (which is the r in our formula) is equal to the weight of this water. Our pump-makers therefore (calling themfelves engineers) fay, that the weight of water in the pipe balances the water on the wheel. It does not balance it, nor is it raifed by the wheel, but by the atmofphere; but it ferves us at prefent for a meafure of the power of the wheel. At laft, all the buckets of the wheel are full, and the water is (for example) 25 feet high in the pipe. Now let the ftream of water run its full quantity. It will only run over from bucket to bucket, and run off at the bottom of the wheel; but the mill will not move, and no work will be performed. (N. B. We are here excluding all impulfe or ftroke on the buckets, and fuppofing the water to act only by its weight.) But now let all be emptied again, and let the water be delivered on the wheel in its full quantity as at the firft. The wheel will immediately acquire a preponderancy, which will *greatly* exceed the firft fmall preffure of the atmofphere on the pifton. It will therefore accelerate the pifton, overcoming the preffure of the air with great velocity. The pifton rifes faft; the water follows it, by the preffure of the atmofphere; and when it attains the former utmoft height, it attains it with a confiderable velocity. If allowed to run off there, it will *continue* to run off with that velocity; becaufe there is the fame quantity of water preffing round the wheel as before, and therefore enough to balance the preffure of the atmofphere on the pifton. The preffure of the fame atmofphere on the water in the ciftern, raifed the water in the pipe with this velocity; therefore it will continue to do fo, and the mill will deliver water by the pump with this velocity, although there is no more preffure acting on it than before, when the water ran to wafte, doing no work whatever.

This mode of action is extremely different from the former example. The mill is not acting againft the inertia y of the water to be moved, but againft the preffure r of the atmofphere on the pifton. The preffure of the fame atmofphere on the ciftern is employed againft the inertia of the water in the pipe; and the ufe of the mill is to *give occafion*, by raifing the pifton, to the exertion of this atmofpherical preffure, which is the real raifer of the water. The maxim of conftruction, and the proper adjuftment of m to n in this cafe, are different from the former; and we fhould run the rifk of making an imperfect engine were we to confound them.

We muft mention another cafe of a pumping mill, feemingly the fame with this, but effentially different. Suppofe the pipe of this pump to reach 30 feet below the furface of the pit water, and that the pifton is at the very bottom of it. Suppofe alfo, that the wheel buckets, when filled with water, only enable it to *fupport* 25 feet of water in the rifing pipe. Let the water be delivered into the wheel drop by drop. The wheel will gradually preponderate; the pifton will gradually rife, lifting the water above it, fuftaining a preffure of water which gradually increafes. At laft, the water in the pump is 25 feet higher than that in the ciftern; the wheel is full and running to wafte; but no work is performed. Let all be emptied, and now let the water come to the wheel in its full ftream, but without impulfe. The pifton will lift the water brifkly, bring it to 25 feet high with a confiderable velocity, and the mill will now raife it with this velocity. In this example the mill is the immediate agent in raifing the water; but, in this cafe alfo, its ultimate office is not overcoming inertia, but overcoming preffure. It was the overplus of power only that was employed in overcoming inertia, while accelerating the water in the rifing pipe, in order to give it the neceffary velocity for a continued difcharge.

These and fimilar examples fhew the great difference between the ftatical and dynamical equilibrium of machines, and the neceffity of a fcientific attention by all who wifh to improve practical mechanics. Without this, and even a pretty refined attention, we cannot fee the connection between a copious fupply of water to the bucket wheel and a plentiful difcharge by the pump. We believe, that the greateft part of thofe employed in erecting machines conceive it as owing to the greater weight of water impelling the wheel with greater force; but we fee that there is no difference in the preffures on the mill at reft, and the mill doing its work fteadily and uniformly, with any velocity, however great. Without keeping the notions of that part of the impelling power which fupports diftinct from that of the part which accelerates, we fhall never have a clear conception of the operation of machines, or of mechanical power in general. We cannot derive all the advantages of our natural powers, without knowing how our machine employs the preffure excited by it at the working point; that is, without perceiving in what cafes it is oppofed to inertia, and in what to the mechanical properties of tangible matter. This only can inform us at what rate the refiftance varies by a change of velocity; and when it happens that this augmentation, neceffarily accompanied by an augmentation of all the frictions, and the refiftance of the air, is in equilibrio with the whole of the impelling power, and all acceleration is at an end. 21

The chief caufe is a real diminution of power.

Laftly, another chief caufe of the finally uniform motion of machines is, that, in moft cafes, an increafe of velocity produces a real diminution of impelling power. We hardly know any exception to this befides the employment of *one* defcending weight as a power or firft mover. Moft of the powers which we employ refide in bodies external to the machine; and thefe bodies muft be put in motion, and continued in that motion, in order to continue their preffure on the impelled point. Frequently a great part of the power is employed in giving this neceffary motion to the external matter, and the remainder only is employed in preffing forward the machine. We mentioned a remarkable inftance of this in the operation of thrafhing. Now, the power thus employed muft increafe in proportion to the motion required; that is, in proportion to the velocity of the impelled 22 pelled point; what remains, urging forward the machine, is therefore diminifhed. The acceleration is therefore diminifhed, and may ceafe. At *laft* the actual preffure is fo much diminifhed, that it is no more than what is neceffary for overcoming the increafed refiftance of the work, the increafed friction. The machine therefore accelerates no more, but moves uniformly.

[T]his caufe [v]ery gene[r]al.

This caufe of the diminution of power by an increafe of velocity, obtains in all cafes where the ftrength of animals, of fprings, the force of fired gunpowder, &c. is exerted. In fome cafes, the vifible effect is not very confiderable; as in the employment of a ftrong fpring, the force of gunpowder, and a few others. In the action of animals, this defalcation of power is very great when the velocity is confiderable. Nay, even in the action of gravity, although it acts as ftrongly on a body in rapid motion as on one at reft, yet when gravity is not the immediate agent, but acts by the intervention of a body in which it refides, the neceffity of previoufly moving this body frequently diminifhes the acceleration which it would otherwife produce. Thus, in an overfhot wheel, if the water be delivered into the bucket with a velocity (eftimated in the direction of the part of the wheel, into which it is delivered) lefs than that of the rim of the wheel, it muft retard the motion; for it muft be immediately dragged into that motion; that is, part of the accelerating overplus, already acting on the wheel, muft be employed in accelerating this new bucket of water, and this muft leffen the general acceleration of the machine. Hence we learn, that the water muft be delivered on the wheel with a velocity that is at leaft not lefs than that of the wheel's motion.

[I]t obtains [i]n all machines actuated by impulfion,

The cafe in which we fee this diminution of power on machines moft diftinctly is, when water or wind, acting by impulfe alone, is our moving power. Since the mutual impulfes of bodies depend entirely on their relative motions (fee Impulsion, *Suppl.*), it follows, that when the velocity of the impelled point is augmented, the impulfion, or effective preffure, muft be diminifhed. Nay, this velocity may be fo increafed, that there fhall be no relative motion, and therefore no impulfion. If the floats of an underfhot wheel be moving with the velocity of the ftream, they remain conjoined in their progrefs, but without any mutual action. Therefore, when an underfhot wheel is fet into a running water, the firft impulfions are ftrong, and accelerate the wheel. This diminifhes the next impulfion and acceleration: but the wheel is ftill impelled and accelerated; lefs and lefs in every fucceeding moment, as it moves fafter; by and bye, the acceleration becomes infenfible, and the wheel appears to attain a motion which is perfectly uniform. This requires a very long time, or rather it is never attained, and we only cannot difcern the very fmall additions which are ftill made to the velocity. All this happens generally after a very moderate time, by reafon of various other obftructions.

[o]r by the [fo]rce of ani[m]als.

Animal action is fubject to the fame variation. We know, that there is a certain rate at which a horfe can run, exhaufting or employing his whole ftrength. If he be made to drag any the fmalleft load after him, he muft employ part of his force on it, and his fpeed will be checked. The more he is loaded with a draught, the flower he will run, ftill employing all his ftrength. The draught may be increafed till he is reduced to a trot, to a walk, nay, till he is unable to draw it. Now, juft inverting this procefs, we fee, that there is a certain ftrain which will fufficiently tire the horfe without ftirring from the fpot, but which he could continue to exert for hours. This is greater than the load that he can juft crawl along with, employing his ftrength as much as would be prudent to continue from day to day. And, in like manner, every leffer draught has a correfponding rate at which the horfe, employing his whole working ftrength, can continue to draw at during the working hours of a day. At fetting out, he pulls harder, and accelerates it. Following his pull, he walks fafter, and therefore pulls lefs (becaufe we are ftill fuppofing him to employ his whole working ftrength). At laft he attains that fpeed which occupies his whole ftrength in merely continuing the pull. Other animals act in a fimilar manner; and it becomes a general rule, that the preffure actually exerted on the impelled point of a machine diminifhes as its velocity increafes.

23
We muft diftinguifh between the power expended and the power employed.

From the concurrence of fo many facts, we perceive that we muft be careful to diftinguifh between the quantity of power expended, and the quantity that is ufefully employed, which muft be meafured folely by the preffure exerted on the machine. When a weight of five pounds is employed to drag up a weight of three pounds by means of a thread over a pulley, it defcends, with a motion uniformly accelerated, four feet in the firft fecond. Mr Smeaton would call this an expenditure of a mechanical power 20. The weight three pounds is raifed four feet. Mr Smeaton would call this a mechanical effect 12. Therefore the effect produced is not adequate to the power expended. But the fact is, that the preffure, ftrain, or mechanical power really exerted in this experiment, is neither five nor three pounds; the five pound weight would have fallen 16 feet, but it falls only 4. A force has therefore acted on it fufficient to make it defcribe 12 feet in a fecond, with a uniformly accelerated motion; for it has counteracted fo much of its weight. The thread was ftrained with a force equal to $3\frac{3}{4}$ pounds, or $\frac{3}{4}$ths of 5 pounds. In like manner, the three pound weight would have fallen 16 feet; but it was raifed 4 feet. Here was a change precifely equal to the other. A force of $3\frac{3}{4}$ pounds, acting on a mafs whofe matter is only 3, will, in a fecond, caufe it to defcribe 20 feet with a uniformly accelerated motion. Now, 5×12, and 3×20, give the fame product 60. And thus we fee, that the quantity of motion extinguifhed or produced, and not the product of the weight and height, is the true unequivocal meafure of mechanical power really expended, or the mechanical effect really produced; and that thefe two are always equal and oppofite. At the fame time, Mr Smeaton's theorem merits the attention of engineers; becaufe it generally meafures the opportunities that we have for procuring the exertion of power. In fome fenfe Mr Smeaton may fay, that the quantity of water multiplied by the height from which it defcends in working other machines, is the meafure of the power expended; becaufe we muft raife this quantity to the dam again, in order to have the fame ufe of it. It is expended, but not employed; for the water, at leaving the wheel, is ftill able to do fomething.

It requires but little confideration to be fenfible, that 24.

the preceding account of the ceffation of accelerated motion in our principal machines, muft introduce different maxims of conftruction from thofe which were exprefsly adapted to this acceleration; or rather, which proceeded on the erroneous fuppofition of the conftancy of the impelling power and the refiftance. The examination of this point has brought into view the fundamental principle of working machines, namely, the perfect equilibrium which takes place between the impelling power and the fimultaneous refiftance. It may be expreffed thus:

First principle of working machines.

The force required for preferving a machine in uniform motion, with any velocity whatever, is that which is neceffary for balancing the refiftance then actually exerted on the working point of the machine. We faw this diftinctly in the inftance of the two weights acting againft each other by the intervention of a thread over a fixed pulley. It is equally true of every cafe of acting machinery: for if the force at the impelled point be greater than what balances the refiftance acting at the fame point, it muft accelerate that point, and therefore accelerate the whole machine; and if the impelling force be lefs than this, the machine muft immediately retard in is motion. When the machine has once acquired this degree of motion, every part of it will continue in its prefent ftate of motion, if only the two external forces are in equilibrio, but not otherwife. But when the preffure of the external power on the impelled point balances the refiftance oppofed by that point, it is, in fact, maintaining the equilibrium with the external power acting at the working point; for this is the only way that external forces can be fet in oppofition to each other by the intervention of a body. The external forces are not in immediate equilibrio with each other, but each is in equilibrio with the force exerted by the point on which it acts. This force exerted by the point is a modification of the connecting forces of the body, all of which are brought into action by means of the actions of the external forces, and each is accompanied by a force precifely equal and oppofite to it. Now, the principles of ftatics teach us the proportions of the external preffures which are thus fet in equilibrium by the intervention of a body; and therefore teach us what proportion of power and refiftance will keep a machine of a given conftruction in a ftate of uniform motion.

This propofition appears paradoxical, and contrary to common obfervation; for we find, that, in order to make a mill go fafter, we muft either diminifh the refiftance, or we muft employ more men, or more water, or water moving with greater velocity, &c. But this arifes from fome of the caufes already mentioned. Either the refiftance of the work is greater when the machine is made to move fafter, or the impulfion of the power is diminifhed, or both thefe changes obtain. Friction and refiftance of air alfo come in for their fhare, &c. The actual preffure of a given quantity of the external power is diminifhed, and therefore more of it muft be employed. When a weight is *uniformly* raifed by a machine, the preffure exerted on it by the working point is precifely equal to its weight, whatever be the velocity with which it rifes. But, even in this fimpleft cafe, more natural power muft be expended in order to raife it fafter; becaufe either more natural power muft be employed to accelerate the external matter which is to prefs forward the impelled point, or the relative motion of the preffing matter will be diminifhed.

It is well known, that, in the employment of the mechanic powers, whether in their ftate of greateft fimplicity, or any how combined in a complicated machine, if the machine be put in motion, the velocities of the extreme points (which we have called the *impelled* and *working* points) are inverfely proportional to the forces which are in equilibrio when applied to thefe points in the direction of their motion. This is an inductive propofition, and has been ufed as the foundation of fyftems of mechanics. It is unneceffary to take up time in proving what is fo familiarly known; confequently, the products of the preffures at thofe points by the velocities of the motions are equal; that is, the product of the preffure actually exerted at the impelled point of a machine working uniformly, multiplied by the velocity of that point, is equal to the product of the refiftance actually exerted at the working point, multiplied by the velocity of that point, that is, by the velocity with which the refiftance is overcome,

$$p\,m = r\,n.$$

Now, the product of the refiftance, by the velocity with which it is overcome, is evidently the meafure of the performance of the machine, or the work done. The product of the actual preffure on the impelled point, by the velocity of that point, may be called the MOMENTUM OF IMPULSE.

Hence we deduce this propofition: 25

Second principle. Momentum of impulse and the performance of the machine are equal.

In all working machines which have acquired a uniform motion, the performance of the machine is equal to the momentum of impulfe (A).

This

(A) The truth of this propofition has been long perceived in every particular inftance that happened to engage the attention; but we do not recollect any mechanician before Mr Euler confidering it as a general truth, expreffing in a few words a mechanical law. This celebrated mathematician undertook, about the year 1735 or 1736, a general and fyftematic view of machines, in order to found a complete theory immediately conducive to the improvement of practical mechanics. In 1743 he publifhed the firft propofitions of this ufeful theory in the 10th volume of the *Comment. Petropolitani*, containing the excellent dynamical theorems of which we have given the fubftance. In the 3d volume of the *Comment. Novi Petropol.* he profecuted the fubject a little farther; and in the 8th volume, he entered on what we are now engaged in, and formally announces this fundamental propofition, calling thefe two products the *momentum of impulfe*, and the *momentum of effect*. It is much to be regretted, that this confummate mathematician did not continue thefe ufeful labours; his ardent mind being carried away by more abftrufe fpeculations in all the moft refined departments of mathematics and philofophy. No man in Europe could have profecuted the fubject with more judgment and fuccefs.—See alfo *Mem. Acad. Berlin*, 1747 and 1752.

This is a propoſition of the utmoſt importance in the ſcience of machines, and leads to the fundamental maxim of their conſtruction. Since the performance of a machine is equal to the momentum of impulſe, it increaſes and diminiſhes along with it, and is a maximum when the momentum of impulſe is a maximum; therefore the fundamental maxim in the conſtruction of a machine is to faſhion it in ſuch a manner, that the momentum of impulſe ſhall be a maximum, or that the product of the preſſure actually exerted on the impelled point of the machine by the velocity with which it moves may be as great as poſſible. Then are we certain that the product of the reſiſtance, by the velocity of the working point, is as great as poſſible, provided that we take care that none of the impulſe be needleſsly waſted by the way by injudicious communications of motion, by friction, by unbalanced loads, and by reciprocal motions, which irrecoverably waſte the impelling power. This maxim holds good, whether the reſiſtance remains conſtantly the ſame, or varies by any law whatever.

26 Important deſiderata for practice.

But much remains to be done for the improvement of mechanical ſcience before we can avail ourſelves of this maxim, and apply it with ſucceſs. The chief thing, and to this we ſhould give the moſt unremitting attention, is, to learn the changes which obtain in the actual preſſure exerted by thoſe natural powers which we can command; the changes of actual preſſure produced by a change of the velocity of the impelled point of the machine. Theſe depend on the ſpecific natures of thoſe powers, and are different in almoſt every different caſe. Nothing will more contribute to the improvement of practical mechanics than a ſeries of experiments, well contrived, and accurately made, for diſcovering thoſe laws of variation, in the caſes of thoſe powers which are moſt frequently employed. Such experiments, however, would be coſtly, beyond the abilities of an individual; therefore, it were greatly to be wiſhed that public aid were given to ſome perſons of ſkill in the ſcience to inſtitute a regular train of experiments of this kind. An experimental machine might be conſtructed, to be wrought either by men or by cattle. This ſhould be loaded wirh ſome kind of work which can be very accurately meaſured, and the load varied at pleaſure. When loaded to a certain degree, the men or cattle ſhould be made to work at the rate which they can continue from day to day. The number of turns made in an hour, multiplied by the load, will give the performance correſponding to the velocities; and thus will be diſcovered the moſt advantageous rate of motion. The ſame machine ſhould alſo be fitted for grinding, for ſawing, boring, &c. and ſimilar experiments will diſcover the relation between the velocities with which theſe operations are performed, and the reſiſtances which they exert. The laws of friction may be inveſtigated by the ſame machine. It ſhould alſo be fitted with a walking wheel, and the trial ſhould be made of the ſlope and the velocity of walking which gives the greateſt momentum of impulſe. It is not unreaſonable to expect great advantages from ſuch a train of experiments.

27 A ſubſtitute for them.

Till this be done, we muſt content ourſelves with eſtabliſhing the above, in the moſt general terms, applicable to any caſe in which the law of the variation of force may hereafter be diſcovered.

There is a certain velocity of the impelled point of a machine which puts an end to the action of the moving power. Thus, if the floats of an underſhot wheel be moving with the velocity of the ſtream, no impulſe is made on them. If the arm of a gin or capſtan be moving with that velocity with which a horſe or a man can juſt move, ſo as to continue at that ſpeed from day to day, employing all his working ſtrength, but not fatiguing himſelf; in this ſtate of motion, the animal can exert no preſſure on the machine. This may be called the EXTINGUISHING VELOCITY, and we may expreſs it by the ſymbol e. Let f be that degree of force or preſſure which the animal can exert at a dead pull or thruſt, as it is called. We do not mean the utmoſt ſtrain of which the animal is capable, but that which it can continue unremittingly during the working hours of a day, fully employing but not fatiguing itſelf. And let p be the preſſure which it actually exerts on the impelled point of a machine, moving with the velocity m. Let $e - m$ be called the RELATIVE VELOCITY, and let it be expreſſed by v. And let it be ſuppoſed that it has been diſcovered, by any means whatever, that the actual preſſure varies in the proportion of v^q, or $\overline{e-m}^q$. This ſuppoſition gives us $e^q : v^q = f : p$, and $p = f \times \frac{v^q}{e^q}$. For the machine muſt be at reſt, in order that the agent may be able to exert the force f on its impelled point. But when the machine is at reſt, what we have named the relative velocity is e, the whole of the extinguiſhing velocity.

The momentum of impulſe is $p\,m$, that is $\frac{v^q}{e^q} f m$, or $f \times \frac{v^q}{e^q} \times \overline{e-v}$ (becauſe $m = e - v$). Therefore $f \times \frac{v^q}{e^q} \times \overline{e-v}$ muſt be made a maximum. But f and e^q are two quantities which ſuffer no change. Therefore the momentum of impulſe will be a maximum when $v^q \times \overline{e-v}$ is a maximum. Now $v^q \times \overline{e-v} = v^q e - v^q v, = v^q e - v^{q+1}$. The fluxion of this is $q e v^{q-1} \dot{v} - \overline{q+1}\, v^q \dot{v}$. This being ſuppoſed $= o$, we have the equation

$$q e v^{q-1} = \overline{q+1}\, v^q$$

$$\text{And } q e = \overline{q+1}\, v$$

$$\text{Therefore } v = \frac{q e}{q+1}$$

And m, which is $= e - v$, becomes $\frac{e}{q+1}$. Therefore we muſt order matters ſo, that the velocity of the impelled point of the machine may be $= \frac{e}{q+1}$. Now p is $= f \frac{v^q}{e^q}$, and therefore $= f \times \frac{q^q}{\overline{q+1}^q}$. And $p\,m$, $= f \frac{q^q}{\overline{q+1}^q} m, = f \frac{q^q}{\overline{q+1}^q} \times \frac{e}{q+1} = f \times \frac{q^q e}{\overline{q+1}^{q+1}}$, $=$ the momentum of impulſe, and therefore $=$ the momentum of effect, or the performance of the machine, when in its beſt ſtate.

28 Example in underſhot mills by Mr Parent.

Thus may the maxim of conſtruction be ſaid to be brought to a ſtate of great ſimplicity, and of moſt eaſy recollection. A particular caſe of this maxim has been long known, having been pointed out by Mr Parent. Since the action of bodies depends on their relative velocity,

locity, the impulfe of fluids muft be as the fquare of the relative velocity. From which Mr Parent deduced, that the moft advantageous velocity of the floats of an underfhot wheel is one-third of that of the ftream. This maxim is evidently included in our general propofition; for in this cafe, the index q of that function of the relative velocity v, which is proportional to the impulfe, is $= 2$. Therefore we have the maximum when $v = \frac{2e}{2+1}, = \frac{2}{3}e$, and $m = \frac{1}{3}e$. e, the extinguifhing velocity, is evidently the velocity of the ftream. Our propofition alfo gives us the precife value of the performance. The impulfe of the ftream on the float at reft being fuppofed $= f$, its impulfe on the float moving with the velocity $\frac{2}{3}e$ muft be $= \frac{4}{9}f$. This is the meafure of the actual preffure p. This being multiplied by m, or by $\frac{1}{3}e$, gives $\frac{4}{27}f$. Now f is confidered as equal to the weight of a column of water, having the furface of the floatboard for its bafe, and the depth of the fluice under the furface of the refervoir (or, more accurately, the fall required for generating the velocity of the ftream) for its height. Hence it has been concluded, that the utmoft performance of an underfhot wheel is to raife $\frac{4}{27}$ of the water which impels it, to the height from which it falls. But this is not found very agreeable to obfervation. Friction, and many imperfections of execution in the delivery of the water, the direction of its impulfe, &c. may be expected to make a defalcation from this theoretical performance. But the actual performance, even of mills of acknowledged imperfection, confiderably exceeds this, and fometimes is found nearly double of this quantity. The truth is, that the particular fact from which Mr Parent firft deduced this maxim (namely, the performance of what is called *Parent's* or *Dr Barker's mill*), is, perhaps of all that could have been felected, the leaft calculated for being the foundation of a general rule, being of a nature fo abftrufe, that the firft mathematicians of Europe are to this day doubtful whether they have a juft conception of its principles. Mr Smeaton's experiments fhew very diftinctly, that the maximum of performance of an underfhot wheel correfponds to a velocity confiderably greater than one-third of the ftream, and approaches nearly to one-half; and he affigns fome reafons for this which feem well founded. But, independent of this, the performance of Mr Smeaton's model was much greater than what correfponds with the velocity by the above mentioned eftimation of f. The theory of the impulfion of fluids is extremely imperfect; and Daniel Bernoulli fhews, from very unqueftionable principles, that the impulfe of a narrow vein of fluid on an extended furface is double of what was generally fuppofed; and his conclufions are abundantly confirmed by the experiments adduced by him.

Not accurate.

29

This fubftitute is ufeful even where it is not altogether exact.

It is by no means pretended that the maxim of conftruction is reduced to the great fimplicity enounced in the propofition now under confideration. We only fuppofed that a cafe had been obferved where the preffure exerted by fome natural agent did follow the proportions of v^q. This being admitted, the propofition is ftrictly true. But we do not know any fuch cafe; yet is the propofition of confiderable ufe: for we can affirm, on the authority of our own obfervations, that the action both of men and of draught horfes does not deviate very far from the proportions of v^2. The obfervations were made on men and horfes tracking a lighter along a canal, and working feveral days together, without having any knowledge of the purpofe of the obfervations. The force exerted was firft meafured by the curvature and weight of the track rope, and afterwards by a fpring fteelyard. This was multiplied by the number of yards per hour, and the product confidered as the momentum. We found the action of men to be very nearly as $\overline{e-m}^2$. The action of horfes, loaded fo as not to be able to trot, was nearly as $\overline{e-m}^{1,7}$.

The practitioner can eafily avail himfelf of the maxim, although the function q fhould never be reduced to any algebraic form. He has only to inftitute a train of experiments on the natural agent, and felect that velocity which gives the higheft product when multiplied by its correfponding preffure.

30

Two methods of availing ourfelves of this maxim.

When this felection has been made, we have two ways of giving our working machines the maximum of effect, having once afcertained the preffure f which our natural power exerts on the impelled point of the machine when it is not allowed to move.

1. When the refiftance arifing from the work, and from friction, is a given quantity; as when water is to be raifed to a certain height by a pifton of given dimenfions.

Since the friction in all the communicating parts of the machine vary in the fame proportion with the preffure, and fince thefe vary in the fame proportion with the refiftance, the fum of the refiftance and friction may be reprefented by $b\,r$, b being an abftract number. Let n be the undetermined velocity of the working point; or let $m : n$ be the proportion of velocities at the impelled and working points. Then, becaufe the preffures at thefe points balance each other, in the cafe of uniform motion, they are inverfely as the velocities at thofe points. Therefore we muft make $b\,r : p = m : n$, and $n = \frac{p\,m}{b\,r} = \frac{\frac{q^q}{\overline{q+1}^q} f m}{b\,r}, = m \frac{q^q f}{\overline{q+1}^q\, b r}$, or $m : n = \overline{q+1}^q \times b\,r : q^q f$.

2. On the other hand, when $m : n$ is already given, by the conftruction of the machine, but $b\,r$ is fufceptible of variation, we muft load the machine with more and more work, till we have reduced the velocity of its impelled point to $\frac{e}{q+1}$.

In either cafe, the performance is expreffed by what expreffes $p\,m$, that is, by $f e \times \frac{q^q}{\overline{q+1}^{q+1}}$. But the ufeful performance, which is really the work done, will be had by dividing the value now obtained by the number b, which expreffes the fum of the refiftance overcome by the working point and the friction of the machine.

Recapitulation.

What has been now delivered contains, we imagine, the chief principles of the theory of machines, and points out the way in which we muft proceed in applying them to every cafe. The reader, we hope, fees clearly the imperfection of a confideration

tion of machines which proceeds no farther than the ftatement of the proportions of the fimultaneous preffures which are excited in all the parts of the machine by the application of the external forces, which we are accuftomed to call the *power* and the *weight*. Unlefs we take alfo into confideration the immediate effect of mechanical force applied to body, and combine this with all the preffures which ftatical principles have enabled us to afcertain, and by this combination be able to fay what portion of unbalanced force there is acting at one and all of the preffing points of the machine, and what will be the motion of *every part* of it in confequence of this overplus, we have acquired no knowledge that can be of fervice to us. We have been contemplating, not a working machine, but a fort of balance. But, by reafoning about thefe unbalanced forces in the fame fimple manner as about the fall of heavy bodies, we were able to difcover the momentary accelerations of every part, and the fenfible motion which it would acquire in any affigned time, if all the circumftances remain the fame. We found that the refults, although deduced from unqueftionable principles, were quite unlike the obferved motions of moft working machines. Proceeding ftill on the fame principles, we confidered this deviation as the indication, and the precife meafure, of fomething which we had not yet attended to, but which the deviation brought into view, and enabled us to afcertain with accuracy. Thefe are the changes which happen in the exertions of our actuating powers by the velocity with which we find it convenient to make them act. Thus we learn more of the nature of thofe powers; and we found it neceffary to diftinguifh carefully between the apparent magnitude of our actuating power and its real exertion in doing our work. This confideration led us to a fundamental propofition concerning all working machines when they have attained an uniform motion; namely, that the power and refiftance then really exerted on the machine precifely balance each other, and that the machine is precifely in the condition of a fteelyard loaded with its balanced weights, and moved round its axis by fome external force diftinct from the power and the weight. We found that this force is the previous overplus of impelling power, before the machine had acquired the uniform motion; and on this occafion we learned to eftimate the effect produced, by the momentum (depending on the form of the machine) of the quantity of motion produced in the whole affemblage of power, refiftance, and machine.

31 Theory of machines ftill intricate, efpecially of fuch as reciprocate.

The theory of machines feemed to be now brought back to that fimplicity of equilibrium which we had faid was fo imperfect a foundation for a theory; but in the availing ourfelves of the maxim founded on this general propofition, we faw that the equilibrium is of a very different kind from a quiefcent equilibrium. It neceffarily involves in it the knowledge of the momentary accelerations and their momenta; without which we fhould not perceive that one ftate of motion is more advantageous than another, becaufe all give us the fame proportion of forces in equilibrio.

But this is not the only ufe of the previous knowledge of the momentary accelerations of machines; there are many cafes where the machine works in this very ftate. Many machines accelerate throughout while performing their work; and their efficacy depends entirely on the final acceleration. Of this kind is the coining prefs, the great forge or tilt mill, and fome other capital engines. The fteam engine, and the common pump, are neceffarily of this clafs, although their efficacy is not eftimated by their final acceleration. A great number of engines have reciprocating motions in different fubordinate parts. The theory of all fuch engines requires for its perfection an accurate knowledge of the momentary accelerations; and we muft ufe the formulæ contained in the firft part of this article.

32 Working and returning ftrokes.

Still, however, the application of this knowledge has many difficulties, which make a *good* theory of fuch machines a much more intricate and complicated matter than we have yet led the reader to fuppofe. In moft of thefe engines, the whole motion may be divided into two parts. One may be called the WORKING STROKE, and the other in which the working points are brought back to a fituation which fits them for acting again, may be called the RETURNING STROKE. This return muft be effected either by means of fome immediate application of the actuating power, or by fome other force, which is counteracted during the working ftroke, and muft be confidered as making part of the refiftance. In the fteam engine, it is generally done by a counterpoife on the outer end of the great working beam. This muft be accounted a part of the refiftance, for it muft be raifed again; and the proportions of the machine for attaining the maximum muft be computed accordingly. The quantity of this counterpoife muft be adjufted by other confiderations. It muft be fuch, that the defcent of the pump rods in the pit may *juft employ the whole time* that is neceffary for filling the cylinder with fteam. If they defcend more brifkly (which an unfkilful engineer likes to fee), this muft be done by means of a greater counterpoife, and this employs more power to raife it again. Defaguliers defcribes a very excellent machine for raifing water in a bucket by a man's ftepping into an oppofite bucket, and defcending by his preponderancy. When he comes to the bottom, he fteps out, goes up a ftair, and finds the bucket returned and ready to receive him again. This machine is extremely fimple, and perhaps the beft that can be contrived; and yet it is one of the moft likely to be a very bad one. The bucket into which the man fteps muft be brought up to its place again by a preponderancy in the machine when unloaded. It may be returned fooner or later. It fhould arrive precifely at the fame time with the man. If fooner, it is of no ufe, and waftes power in raifing a counterpoife which is needlefsly heavy: if later, time is loft: Therefore, the perfection of this very fimple machine requires the judicious combination of two maximums, each of which varies in a ratio compounded of two other ratios. Suppofe the man to employ a minute to go up ftairs 50 feet, which is very nearly what he can do from day to day as his only work, and fuppofe him to weigh 150 pounds, and that he acts by means of a fimple pulley—the maximum for a lever of equal arms would require him to raife about 60 pounds of water. But when all the other circumftances are calculated, it will be found that he muft raife 138 pounds (neglecting the inertia of the machine). He fhould raife 542 pounds 10 feet in a minute; and this is nearly the moft exact valuation of a man's work.

There is the fame neceffity of attending to a variety of of circumſtances in all machines which reciprocate in the whole or any conſiderable part of their motion. The force employed for bringing the machine into another working poſition, muſt be regulated by the time neceſſary for obtaining a new ſupply of power; and then the proportion of m to n muſt be ſo adjuſted, that the work performed, divided by the *whole* time of the working and returning ſtrokes, may give the greateſt quotient. It is ſtill a difficult thing, therefore, to conſtruct a machine in the moſt perfect manner, or even to ſay what will be the performance of a machine already conſtructed; yet we ſee that every circumſtance is ſuſceptible of accurate computation.

With reſpect to machines which acquire a ſort of uniform motion in general, although ſubject to partial reciprocations, as in a pumping, ſtamping, forging engine, it is alſo difficult to aſſign the rate even of this general uniform motion. We may, however, ſay, that it will not be greater than if it were uniform throughout. Were it entirely free from friction, it would be exactly the ſame as if uniform; becauſe the accelerations during the advantageous ſituations of the impelling power would compenſate the retardations. But friction diminiſhes the accelerations, without diminiſhing the retardations.

We may conclude this article with ſome obſervations tending to the general improvement of machines.

33 Uniformity of motion throughout is of great advantage.

Nothing contributes more to the perfection of a machine, eſpecially ſuch as is maſſive and ponderous, than great uniformity of motion. Every regularity of motion waſtes ſome of the impelling power; and it is only the greateſt of the varying velocities which is equal to that which the machine would acquire if moving uniformly throughout; for while the motion accelerates, the impelling force is greater than what balances the reſiſtance then actually oppoſed to it, and the velocity is leſs than what the machine would acquire if moving uniformly: and when the machine attains its greateſt velocity, it attains it becauſe the power is then not acting againſt the whole reſiſtance. In both of theſe ſituations, therefore, the performance of the machine is leſs than if the power and reſiſtance were exactly balanced; in which caſe it would move uniformly.

34 How to attain this.

Every attention ſhould therefore be given to this, and we ſhould endeavour to remove all cauſe of irregularity. The communications of motion ſhould be ſo contrived, that if the impelled point be moving uniformly, by the uniform preſſure of the power, the working point ſhall alſo be moving uniformly. Then we may generally be certain, that the maſſy parts of the machine will be moving uniformly. When this is not done through the whole machine, there are continual returns of ſtrains and jolts; the inertia of the different parts acting in oppoſite directions. Although the whole momenta may always balance each other, yet the general motion is hobbling, and the points of ſupport are ſtrained. A great engine ſo conſtructed, commonly cauſes the building to tremble; but when uniform motion pervades the whole machine, the inertia of each part tends to preſerve this uniformity, and all goes ſmoothly. It is alſo deſerving of remark, that when the communications are ſo contrived that the uniform motion of one part produces uniform motion on the next, the preſſures at the communicating points remain conſtant or invariable. Now the accompliſhing of this is always within the reach of mechanics.

35 Beſt form for the teeth of wheels. Plate XXXIII. fig. 1.

One of the moſt uſual communications in machinery is by means of toothed wheels acting on each other. It is of importance to have the teeth ſo formed, that the preſſure by which one of them A urges the other B round its axis ſhall be conſtantly the ſame. It can eaſily be demonſtrated, that when this is the caſe, the uniform angular motion of the one will produce a uniform angular motion of the other: or, if the motions are thus uniform, the preſſures are invariable. This is accompliſhed on this principle, that the mutual actions of ſolid bodies on each other in the way of preſſure are perpendicular to the touching ſurfaces. Therefore let the tooth a preſs on the tooth b in the point C; and draw the line FCDE perpendicular to the touching ſurfaces in the point C. Draw AF, BE perpendicular to FE, and let FE cut the line AB in D. It is plain, from the common principles of mechanics, that if the line FE, drawn in the manner now deſcribed, always paſs through the ſame point D, whatever may be the ſituation of the acting teeth, the mutual action of the wheels will always be the ſame. It will be the ſame as if the arm AD acted on the arm BD. In the treatiſes on the conſtruction of mills, and other works of this kind, are many inſtructions for the formation of the teeth of wheels; and almoſt every noted millwright has his own noſtrums. Moſt of them are egregiouſly faulty in reſpect of mechanical principle. Indeed they are little elſe than inſtructions how to make the teeth clear each other without ſticking. Mr de la Hire firſt pointed out the above-mentioned principle, and juſtly condemned the common practice of making the ſmall wheel or pinion in the form of a lantern (whence it alſo took its name), conſiſting of two round diſks, having a number of cylindrical ſpokes (fig. 2.) The ſlighteſt inſpection of this conſtruction ſhews that, in the different ſituations of the working teeth, the line FCE continually changes its interſection with AB. If the wheel B be very ſmall in compariſon of the other, and if the teeth of A take deep hold of the cylindrical pins of B, the line of action EF is ſometimes ſo diſadvantageouſly placed, that the preſſure of the one wheel has ſcarcely any tendency at all to turn the other. Mr de la Hire, or Dr Hooke, was, we think, the firſt who inveſtigated the form of tooth which procured this conſtant action between the wheels; and in a very ingenious diſſertation, publiſhed among the Memoirs of the Academy of Sciences at Paris 1668, the former of theſe gentlemen ſhews that this will be enſured by forming the teeth into epicycloids. Mr Camus of the ſame Academy has publiſhed an elaborate diſſertation on the ſame ſubject, in which he proſecutes the principle of Mr de la Hire, and applies it to all the variety of caſes which can occur in practice. There is no doubt as to the goodneſs of the principle; and it has another excellent property, "that the mutual action of the teeth is abſolutely without any friction." The one tooth only applies itſelf to the other, and rolls on it, but does not ſlide or rub in the ſmalleſt degree. This makes them laſt long, or rather does not allow them to wear in the leaſt. But the conſtruction is ſubject to a limitation which muſt not be neglected. The teeth muſt be ſo made, that the curved part of the tooth b is acted on by a flat part of the tooth a till it comes to the line AB in the courſe of its action; after which

Epicycloids recommended by De la Hire.

which the curved part of *a* acts on a flat part of *b*; or the whole action of *a* on *b* is either completed, or only begins at the line AB, joining the centres of the wheels.

36 A better form.

Another form of the teeth ſecures the perfect uniformity of action without this limitation, which requires very nice execution. Let the teeth of each wheel be formed by evolving its circumference; that is, let the acting face GCH of the tooth *a* have the form of the curve traced by the extremity of the thread FC, unlapped from the circumference. In like manner, let the acting face of the tooth *b* be formed by unlapping a thread from its circumference. It is evident, that the line FCE, which is drawn perpendicularly to the touching ſurfaces in the point C, is juſt the direction or poſition of the evolving threads by which the two acting faces are formed. This line muſt therefore be the common tangent to the two circles or circumferences of the wheels, and will therefore always cut the line AB in the ſame point D. This form allows the teeth to act on each other through the whole extent of the line FCE, and therefore will admit of ſeveral teeth to be acting at the ſame time (twice the number that can be admitted in Mr de la Hire's method). This, by dividing the preſſure among ſeveral teeth, diminiſhes its quantity on any one of them, and therefore diminiſhes the dents or impreſſions which they unavoidably make on each other. It is not altogether free from ſliding and friction, but the whole of it can hardly be ſaid to be ſenſible. The whole ſlide of a tooth three inches long, belonging to a wheel of ten feet diameter, acting on a tooth of a wheel of two feet diameter, does not amount to $\frac{1}{16}$th of an inch; a quantity altogether inſignificant.

In the formation of the teeth of wheels, a ſmall deviation from theſe perfect forms is not perhaps of very great importance, except in caſes where a very large wheel drives a very ſmall one (a thing which a good engineer will always avoid). As the conſtruction, however, is exceedingly eaſy, it would be unpardonable to omit it. Well formed teeth, and a great number of them acting at once, make the communication of motion extremely ſmooth and uniform. The machine works without noiſe, and the teeth laſt a very long time without ſenſibly changing their ſhape. But there are caſes, ſuch as the pallets of clocks and watches, where the utmoſt accuracy of form is of the greateſt importance for the perfection of the work.

37 Maxim for the conſtruction of ſtampers, &c.

When heavy ſtampers are to be raiſed, in order to drop on the matters to be pounded, the wipers by which they are lifted ſhould be made of ſuch a form, that the ſtamper may be raiſed by a uniform preſſure, or with a motion almoſt perfectly uniform. If this is not attended to, and the wiper is only a pin ſticking out from the axis, the ſtamper is forced into motion at once. This occaſions violent jolts to the machine, and great ſtrains on its moving parts and their points of ſupport; whereas, when they are gradually lifted, the inequality of deſultory motion is never felt at the impelled point of the machine. We have ſeen piſtons moved by means of a double rack on the piſton rod. A half wheel takes hold of one rack, and raiſes it to the required height. The moment the half wheel has quitted that ſide of the rack, it lays hold of the other ſide, and forces the piſton down again. This is propoſed as a great improvement; correcting the unequable motion of the piſton moved in the common way by a crank. But it is far inferior to the crank motion. It occaſions ſuch abrupt changes of motion, that the machine is ſhaken by jolts. Indeed if the movement were accurately executed, the machine would be ſhaken to pieces, if the parts did not give way by bending and yielding. Accordingly, we have always obſerved that this motion ſoon failed, and was changed for one that was more ſmooth. A judicious engineer will avoid all ſuch ſudden changes of motion, eſpecially in any ponderous part of a machine.

When ſeveral ſtampers, piſtons, or other reciprocal movers, are to be raiſed and depreſſed, common ſenſe teaches us to diſtribute their times of action in a uniform manner, ſo that the machine may always be equally loaded with work. When this is done, and the obſervations in the preceding paragraph attended to, the machine may be made to move almoſt as ſmoothly as if there were no reciprocations in it. Nothing ſhews the ingenuity of the author more than the artful yet ſimple and effectual contrivances for obviating thoſe difficulties that unavoidably ariſe from the very nature of the work that muſt be performed by the machine, and of the power employed. The inventive genius and ſound judgment of Watt and Boulton are as perceptible to a ſkilled obſerver in theſe ſubordinate parts of ſome of their great engines, as in the original diſcovery on which their patent is founded. In ſome of thoſe engines the maſs of deed matter which muſt be put into motion, and this motion deſtroyed and again reſtored in every ſtroke, is enormous, amounting to above an hundred tons. The ingenious authors have even contrived to draw ſome advantages from it, by allowing a great want of equilibrium in certain poſitions; and this has been condemned as a blunder by engineers who did not ſee the uſe made of it.

38 The unavoidable inequalities of moving power muſt be compenſated by the conſtruction.

There is alſo great room for ingenuity and good choice in the management of the moving power, when it is ſuch as cannot immediately produce the kind of motion required for effecting the purpoſe. We mentioned the converſion of the continued rotation of an axis into the reciprocating motion of a piſton, and the improvement which was thought to have been made on the common and obvious contrivance of a crank, by ſubſtituting a double rack on the piſton rod, and the inconvenience ariſing from the jolts occaſioned by this change. We have ſeen a great forge, where the engineer, in order to avoid the ſame inconvenience ariſing from the abrupt motion given to the great ſledge hammer of ſeven hundred weight, reſiſting with a five-fold momentum, formed the wipers into ſpirals, which communicated motion to the hammer almoſt without any jolt whatever; but the reſult was, that the hammer roſe no higher than it had been raiſed in contact with the wiper, and then fell on the iron bloom with very little effect. The cauſe of its inefficiency was not gueſſed at; but it was removed, and wipers of the common form were put in place of the ſpirals. In this operation, the rapid motion of the hammer is abſolutely neceſſary. It is not enough to *lift* it up; it muſt be *toſſed* up, ſo as to fly higher than the wiper lifts it, and to ſtrike with great force the ſtrong oaken ſpring which is placed in its way. It compreſſes this ſpring, and is reflected by it with a conſiderable velocity, ſo as to hit the iron as if it had fallen from a great height. Had it it been allowed to fly to that height, it would have fallen upon the iron with ſomewhat more force (becauſe no oaken ſpring is perfectly elaſtic); but this would have required more than twice the time.

38 Great inconveniences of a reciprocating power.

In employing a power which of neceſſity reciprocates, to drive machinery which requires a continuous motion (as in applying the ſteam engine to a cotton or a griſt mill), there alſo occur great difficulties. The neceſſity of reciprocation in the firſt mover waſtes much power; becauſe the inſtrument which communicates ſuch an enormous force muſt be extremely ſtrong, and be well ſupported. The impelling power is waſted in imparting, and afterwards deſtroying, a vaſt quantity of motion in the working beam. The ſkilful engineer will attend to this, and do his utmoſt to procure the neceſſary ſtrength of this firſt mover, without making it a vaſt load of inert matter. He will alſo remark, that all the ſtrains on it, and on its ſupports, are changing their directions in every ſtroke. This requires particular attention to the manner of ſupporting it. If we obſerve the ſteam engines which have been long erected, we ſee that they have uniformly ſhaken the building to pieces. This has been owing to the ignorance or inattention of the engineer in this particular. They are much more judiciouſly erected now, experience having taught the moſt ignorant that no building can withſtand their deſultory and oppoſite jolts, and that the great movements muſt be ſupported by a frame-work independent of the building of maſonry which contains it (B).

The engineer will alſo remark, that when a ſingle ſtroke ſteam engine is made to turn a mill, all the communications of motion change the direction of their preſſure twice every ſtroke. During the working ſtroke of the beam, one ſide of the teeth of the intervening wheels is preſſing the machinery forward; but during the returning ſtroke, the machinery, already in motion, is dragging the beam, and the wheels are acting with the other ſide of the teeth. This occaſions a rattling at every change, and makes it proper to faſhion both ſides of the teeth with the ſame care.

It will frequently conduce to the good performance of an engine, to make the action of the reſiſting work unequable, accommodated to the inqualities of the impelling power. This will produce a more uniform motion in machines in which the momentum of inertia is inconſiderable. There are ſome beautiful ſpecimens of this kind of adjuſtment in the mechaniſm of animal bodies.

39 Nature, operation, and uſe of a Fly.

It is very cuſtomary to add what is called a FLY to machines. This is a heavy diſk or hoop, or other maſs of matter, *balanced on its axis*, and ſo connected with the machinery as to turn briſkly round with it. This may be done with the view of rendering the motion of the whole more regular, notwithſtanding unavoidable inequalities of the accelerating forces, or of the reſiſtances occaſioned by the work. It becomes a REGULATOR. Suppoſe the reſiſtance extremely unequal, and the impelling power perfectly conſtant; as when a bucket wheel is employed to work *one* pump. When the piſton has ended its working ſtroke, and while it is going down the barrel, the power of the wheel being ſcarcely oppoſed, it accelerates the whole machine, and the piſton arrives at the bottom of the barrel with a conſiderable velocity. But in the riſing again, the wheel is oppoſed by the column of water now preſſing on the piſton. This immediately retards the wheel; and when the piſton has reached the top of the barrel, all the acceleration is undone, and is to begin again. The motion of ſuch a machine is very hobbling: but the ſuperplus of accelerating force at the beginning of a returning ſtroke will not make ſuch a change in the motion of the machine if we connect the fly with it. For the accelerating momentum is a determinate quantity. Therefore, if the radius of the fly be great, this momentum will be attained by communicating a ſmall angular motion to the machine. The momentum of the fly is as the ſquare of its radius; therefore it reſiſts acceleration in this proportion; and although the overplus of power generates the ſame momentum of rotation in the whole machine as before, it makes but a ſmall addition to its velocity. If the diameter of the fly be doubled, the augmentation of rotation will be reduced to one-fourth. Thus, by giving a rapid motion to a ſmall quantity of matter, the great acceleration, during the returning ſtroke of the piſton, is prevented. This acceleration continues, however, during the whole of the returning ſtroke, and at the end of it the machine has acquired its greateſt velocity. Now the working ſtroke begins, and the overplus of power is at an end. The machine accelerates no more; but if the power is juſt in equilibrio with the reſiſtance, it keeps the velocity which it has acquired, and is ſtill more accelerated during the *next* returning ſtroke. But now, at the beginning of the ſubſequent working ſtroke, there is an overplus of reſiſtance, and a retardation begins, and continues during the whole riſe of the piſton; but it is inconſiderable in compariſon of what it would have been without the fly; for the fly, retaining its acquired momentum, drags forward the reſt of the machine, aiding the impelling power of the wheel. It does this by all the communications taking into each other in the oppoſite direction. The teeth of the intervening wheels are heard to drop from their former contact on one ſide, to a contact on the other. By conſidering this proceſs with attention, we eaſily perceive that, in a few ſtrokes, the overplus of power during the returning ſtroke comes to be ſo adjuſted to the deficiency during the working ſtroke, that the accelerations and retardations exactly deſtroy each other, and every ſucceeding ſtroke is made with the ſame velocity, and an equal number of ſtrokes is made in every ſucceeding minute. Thus the machine acquires a general uniformity with periodical inequalities. It is plain, that by ſufficiently enlarging either the diameter or the weight

(B) The gudgeons of a water-wheel ſhould never reſt on the wall of the building. It ſhakes it; and if ſet up ſoon after the building has been erected, it prevents the mortar from taking firm bond; perhaps by ſhattering the calcareous cryſtals as they form. When the engineer is obliged to reſt the gudgeons in this way, they ſhould be ſupported by a block of oak laid a little hollow. This ſoftens all tremors, like the ſprings of a wheel carriage. This practice would be very ſerviceable in many other parts of the conſtruction.

weight of the fly, the irregularity of the motion may be rendered as ſmall as we pleaſe. It is much better to enlarge the diameter. This preſerves the friction more moderate, and the pivot wears leſs. For theſe reaſons, a fly is in general a conſiderable improvement in machinery, by equaliſing many exertions that are naturally very irregular. Thus, a man working at a common windlaſs, exerts a very irregular preſſure on the winch. In one of his poſitions in each turn he can exert a force of near 70 pounds without fatigue, but in another he cannot exert above 25; nor muſt he be loaded with much above this in general. But if a large fly be conected properly with the windlaſs, he will act with equal eaſe and ſpeed againſt 30 pounds.

40
It is a powerful regulator.

This regulating power of the fly is without bounds, and may be uſed to render uniform a motion produced by the moſt deſultory and irregular power. It is thus that the moſt regular motion is given to mills that are driven by a ſingle ſtroke ſteam engine, where for two or even three ſeconds there is no force preſſing round the mill. The communication is made through a maſſive fly of very great diameter, whirling with great rapidity. As ſoon as the impulſe ceaſes, the fly, continuing its motion, urges round the whole machinery with almoſt unabated ſpeed. At this inſtant all the teeth, and all the joints, between the fly and the firſt mover, are heard to catch in the oppoſite direction.

If any permanent change ſhould happen in the impelling power, or in the reſiſtance, the fly makes no obſtacle to its producing its full effect on the machine; and it will be obſerved to accelerate or retard uniformly, till a new general ſpeed is acquired exactly correſponding with this new power and reſiſtance.

Many machines include in their conſtruction movements which are equivalent with this intentional regulator. A flour mill, for example, cannot be better regulated than by its millſtone: but in the Albion mills, a heavy fly was added with great propriety; for if the mills had been regulated by their millſtones only, then at every change of ſtroke in the ſteam engine, the whole train of communications between the beam, which is the firſt mover, and the regulating millſtone, which is the very laſt mover, would take in the oppoſite direction. Although each drop in the teeth and joints be but a trifle, the whole, added together, would make a conſiderable jolt. This is avoided by a regulator immediately adjoining to the beam. This continually preſſes the working machinery in one direction. So judiciouſly were the movements of that noble machine contrived, and ſo nicely were they executed, that not the leaſt noiſe was heard, nor the ſlighteſt tremor felt in the building.

Mr Valoué's beautiful pile engine employed at Weſtminſter Bridge is another remarkable inſtance of the regulating power of a fly*. When the ram is dropped, and its follower diſengaged immediately after it, the horſes would inſtantly tumble down, becauſe the load, againſt which they had been ſtraining hard, is at once taken off; but the gin is connected with a very large fly, which checks any remarkable acceleration, allowing the horſes to lean on it during the deſcent of the load; after which their draught recommences immediately. The ſpindles, cards, and bobbins, of a cotton mill, are alſo a ſort of flies. Indeed all bulky machines of the rotative kind tend to preſerve their motion with ſome degree of ſteadineſs, and their great momentum of inertia is as uſeful in this reſpect as it is prejudicial to the acceleration or any reciprocation when wanted.

* See PILE-Engine, Encycl.

41
A bad conſtruction of a fly.

There is another kind of regulating fly, conſiſting of wings whirled briſkly round till the reſiſtance of the air prevents any great acceleration. This is a very bad one for a *working* machine, for it produces its effect by *really waſting* a part of the moving power. Frequently it employs a very great and unknown part of it, and robs the proprietor of much work. It ſhould never be introduced into any machine employed in manufactures.

42
A conical pendulum is the moſt perfect regulator.

Some rare caſes occur where a very different regulator is required; where a certain determined velocity is found neceſſary. In this caſe the machine is furniſhed, at its extreme mover, with a conical pendulum, conſiſting of two heavy balls hanging by rods, which move in very nice and ſteady joints at the top of a vertical axis. It is well known, that when this axis turns round, with an angular velocity ſuited to the length of thoſe pendulums, the time of a revolution is determined. Thus, if the length of each pendulum be $39\frac{1}{7}$ inches, the axis will make a revolution in two ſeconds very nearly. If we attempt to force it more ſwiftly round, the balls will recede a little from the axis, but it employs as long time for a revolution as before; and we cannot make it turn ſwifter, unleſs the impelling power be increaſed beyond all probability; in which caſe the pendulum will fly out from the centre till the rods are horizontal, after which every encreaſe of power will accelerate the machine very ſenſibly. Watt and Boulton have applied this contrivance with great ingenuity to their ſteam engines, when they are employed for driving machinery for manufactures which have a very changeable reſiſtance, and where a certain ſpeed cannot be much departed from without great inconvenience. They have connected this receſs of the balls from the axis (which gives immediate indication of an increaſe of power or a diminution of reſiſtance) with the cock which admits the ſteam to the working cylinder. The balls flying out, cauſe the cock to cloſe a little, and diminiſh the ſupply of ſteam. The impelling power diminiſhes the next moment, and the balls again approach the axis, and the rotation goes on as before, although there may have occurred a very great exceſs or deficiency of power. The ſame contrivance may be employed to raiſe or lower the feeding ſluice of a water mill employed to drive machinery.

43
A fly ſometimes collects power.

A fly is ſometimes employed for a very different purpoſe from that of a regulator of motion—it is employed as a *collector of power*. Suppoſe all reſiſtance removed from the working point of a machine furniſhed with a very large or heavy fly immediately connected with the working point When a ſmall force is applied to the impelled point of this machine, motion will begin in the machine, and the fly begin to turn. Continue to preſs uniformly, and the machine will accelerate. This may be continued till the fly has acquired a very rapid motion, If at this moment a reſiſting body be applied to the working point, it will be acted on with very great force; for the fly has now accumulated in its circumference a very great momentum. If a body were expoſed immediately to the action of this circumference, it would be violently ſtruck. Much more will it be ſo, if the body be expoſed to the action of the working

working point, which perhaps makes one turn while the fly makes a hundred. It will exert a hundred times more force there (very nearly) than at its own circumference. All the motion which has been accumulated on the fly during the whole progreſs of its acceleration is exerted in an inſtant at the working point, multiplied by the momentum depending on the proportion of the parts of the machine. It is thus that the coining preſs performs its office; nay, it is thus that the blackſmith forges a bar of iron. Swinging the great ſledge hammer round his head, and urging it with force the whole way, this accumulated motion is at once extinguiſhed by impact on the iron. It is thus we drive a nail; and it is thus that by accumulating a very moderate force exerted during four or five turns of a fly, the whole of it is exerted on a punch ſet on a thick plate of iron, ſuch as is employed for the boilers of ſteam engines. The plate is pierced as if it were a bit of cheeſe. This accumulating power of a fly has occaſioned many who think themſelves engineers to imagine, that a fly really adds power or mechanical force to an engine; and, not underſtanding on what its efficacy depends, they often place the fly in a ſituation where it only added a uſeleſs burden to the machine. It ſhould always be made to move with rapidity. If intended for a mere regulator, it ſhould be near the firſt mover. If it is intended to accumulate force in the working point, it ſhould not be far ſeparated from it. In a certain ſenſe, a fly may be ſaid to add power to a machine, becauſe by accumulating into the exertion of one moment the exertions of many, we can ſometimes overcome an obſtacle that we never could have balanced by the ſame machine unaided by the fly.

It is this accumulation of force which gives ſuch an appearance of power to ſome of our firſt movers. When a man is unfortunately catched by the teeth of a paltry country mill, he is cruſhed almoſt to mummy. The power of the ſtream is conceived to be prodigious; and yet we are certain, upon examination, that it amounts to the preſſure of no more than fifty or ſixty pounds. But it has been acting for ſome time; and there is a milſtone of a ton weight whirling twice round in a ſecond. This is the force that cruſhed the unfortunate man; and it required it all to do it, for the mill ſtopped. We ſaw a mill in the neighbourhood of Elbingroda in Hanover, where there was a contrivance which diſengaged the milſtone when any thing got entangled in the teeth of the wheels. It was tried in our ſight with a head of cabbage. It cruſhed it indeed, but not violently, and would by no means have broken a man's arm.

44 Simplicity of conſtruction recommended.

It is hardly neceſſary to recommend ſimplicity in the conſtruction of machines. This ſeems now ſufficiently underſtood. Multiplicity of motions and communications increaſes frictions; increaſes the unavoidable loſſes by bending and yielding in every part; expoſes to all the imperfections of workmanſhip; and has a great chance of being indiſtinctly conceived, and therefore conſtructed without ſcience. We think the following conſtruction of a capſtan or crab a very good example of the advantages of ſimplicity. It is the invention of an untaught but very ingenious country tradeſman.

Fig. 3. EAB is the barrel of the capſtan, ſtanding vertically in a proper frame, as uſual, and urged round by bars ſuch as EF. The upper part A of the barrel is 17 inches in diameter, and the lower B is 16. C is a ſtrong pulley 16 inches in diameter, having a hook D, which takes hold of a hawſer attached to the load. The rope ACB is wound round the barrel A, paſſes over the pulley C, and is then wound round the barrel B in the oppoſite direction. No farther deſcription is neceſſary, we think, to ſhew that, by heaving by the bar F, ſo as to wind more of the rope upon A, and unwind it from B, the pulley C muſt be brought nearer to the capſtan by about three inches for each turn of the capſtan; and that this ſimple capſtan is equivalent to an ordinary capſtan of the ſame length of bar EF, and diameter of barrel B, combined with a 16 fold tackle of pulleys; or, in ſhort, that it is 16 times more powerful than the common capſtan; free from the great loſs by friction and bending of ropes, which would abſorb a third of the power of a 16 fold tackle; and that whereas all other engines become weaker as they multiply the power to a greater degree (unleſs they are proportionally more bulky), this engine becomes really ſtronger in itſelf. Suppoſe we wanted to have it twice as powerful as at preſent; nothing is neceſſary but to cover the part B of the barrel with laths a quarter of an inch thick. In ſhort, the nearer the two barrels are to equality, the more powerful does it become. We give it to the public as an excellent capſtan, and as ſuggeſting thoughts which an intelligent engineer may employ with great effect. By this contrivance, and uſing an iron wire inſtead of a catgut, we converted a common eight day clock into one which goes for two months.

45 Example of a very ſimple and powerful capſtan.

We intended to conclude this article with ſome obſervations on the chief claſſes of powers which are employed to drive machinery; ſuch as water, wind, atmoſphoric preſſure, gunpowder, and the force of men and other animals, giving ſome notion of their abſolute magnitudes, and the effect which may be expected from them. We ſhould then have mentioned what has been diſcovered as to their variation by a variation of velocity. And we intended to conclude with an account of what knowledge has been acquired concerning friction, and the loſs of power in machinery ariſing from this cauſe, and from the ſtiffneſs of ropes, and ſome other cauſes: But we have not yet been able to bring theſe matters into a connected form, which would ſuggeſt the methods and means of farther information thereon. We muſt endeavour to find another opportunity of communicating to the public what we may yet learn on thoſe ſubjects.

We have now eſtabliſhed the principles on which machines muſt be conſtructed, in order that they may produce the greateſt effect; but it would be improper to diſmiſs the ſubject without ſtating to our readers Mr Bramah's new method of producing and applying a more conſiderable degree of power to all kinds of machinery requiring motion and force, than by any means at preſent practiſed for that purpoſe. This method, for which on the 31ſt of March 1796 he obtained a patent, conſiſts in the application of water or other denſe fluids to various engines, ſo as, in ſome inſtances, to to cauſe them to act with immenſe force; in others, to communicate the motion and powers of one part of a machine to ſome other part of the ſame machine; and, laſtly, to communicate the motion and force of one machine to another, where their local ſituations preclude the application of all other methods of connection.

The firſt and moſt material part of this invention will be clearly underſtood by an inſpection of fig. 4. where "A is a cylinder of iron, or other materials, ſufficiently ſtrong, and bored perfectly ſmooth and cylindrical; into which is fitted the piſton B, which muſt be made perfectly water-tight, by leather or other materials, as uſed in pump-making. The bottom of the cylinder muſt alſo be made ſufficiently ſtrong with the other part of the ſurface, to be capable of reſiſting the greateſt force or ſtrain that may at any time be required. In the bottom of the cylinder is inſerted the end of the tube C; the aperture of which communicates with the inſide of the cylinder, under the piſton B, where it is ſhut with the ſmall valve D, the ſame as the ſuction-pipe of a common pump. The other end of the tube C communicates with the ſmall forcing pump or injector E, by means of which water or other denſe fluids can be forced or injected into the cylinder A, under the piſton B. Now, ſuppoſe the diameter of the cylinder A to be 12 inches, and the diameter of the piſton of the ſmall pump or injector E only one quarter of an inch, the proportion between the two ſurfaces or ends of the ſaid piſtons will be as 1 to 2304; and ſuppoſing the intermediate ſpace between them to be filled with water or other denſe fluid capable of ſufficient reſiſtance, the force of one piſton will act on the other juſt in the above proportion, viz. as 1 is to 2304. Suppoſe the ſmall piſton in the injector to be forced down when in the act of pumping or injecting water into the cylinder A, with the power of 20 cwt. which could eaſily be done by the lever H; the piſton B would then be moved up with a force equal to 20 cwt. multiplied by 2304. Thus is conſtructed a hydro-mechanical engine, whereby a weight amounting to 2304 tons can be raiſed by a ſimple lever, through equal ſpace, in much leſs time than could be done by any apparatus conſtructed on the known principles of mechanics; and it may be proper to obſerve, that the effect of all other mechanical combinations is counteracted by an accumulated complication of parts, which renders them incapable of being uſefully extended beyond a certain degree; but in machines acted upon or conſtructed on this principle, every difficulty of this kind is obviated, and their power ſubject to no finite reſtraint. To prove this, it will be only neceſſary to remark, that the force of any machine acting upon this principle can be increaſed *ad infinitum*, either by extending the proportion between the diameter of the injector and the cylinder A, or by applying greater power to the lever H.

"Fig. 5. repreſents the ſection of an engine, by which very wonderful effects may be produced inſtantaneouſly by means of compreſſed air. AA is a cylinder, with the piſton B fitting air-tight, in the ſame manner as deſcribed in fig. 4. C is a globular veſſel made of copper, iron, or other ſtrong materials, capable of reſiſting immenſe force, ſimilar to thoſe of air guns. D is a ſtrong tube of ſmall bore, in which is the ſtop-cock E. One of the ends of this tube communicates with the cylinder under the piſton B, and the other with the globe C. Now, ſuppoſe the cylinder A to be the ſame diameter as that in fig. 4. and the tube D equal to one quarter of an inch diameter, which is the ſame as the injector fig. 4.: then, ſuppoſe that air is injected into the globe C (by the common method), till it preſſes againſt the cock E with a force equal to 20 cwt. which can eaſily be done; the conſequence will be, that when the cock E is opened, the piſton B will be moved in the cylinder AA with a power or force equal to 2304 tons; and it is obvious, as in the caſe fig. 4. that any other unlimited degree of force may be acquired by machines or engines thus conſtructed.

"Fig. 6. is a ſection, merely to ſhew how the power and motion of one machine may, by means of fluids, be transferred or communicated to another, let their diſtance and local ſituation be what they may. A and B are two ſmall cylinders, ſmooth and cylindrical; in the inſide of each of which is a piſton, made water and air tight, as in figs 4. and 5. CC is a tube conveyed under ground, or otherwiſe, from the bottom of one cylinder to the other, to form a communication between them, notwithſtanding their diſtance be ever ſo great; this tube being filled with water or other fluid, until it touch the bottom of each piſton; then, by depreſſing the piſton A, the piſton B will be raiſed. The ſame effect will be produced *vice verſa:* thus bells may be rung, wheels turned, or other machinery put inviſibly in motion, by a power being applied to either.

"Fig. 7. is a ſection, ſhewing another inſtance of communicating the action or force of one machine to another; and how water may be raiſed out of wells of any depth, and at any diſtance from the place where the operating power is applied. A is a cylinder of any required dimenſions, in which is the working piſton B, as in the foregoing examples: into the bottom of this cylinder is inſerted the tube C, which may be of leſs bore than the cylinder A. This tube is continued, in any required direction, down to the pump cylinder D, ſuppoſed to be fixed in the deep well EE, and forms a junction therewith above the piſton F; which piſton has a rod G, working through the ſtuffing-box, as is uſual in a common pump. To this rod G is connected, over a pulley or otherwiſe, a weight H, ſufficient to overbalance the weight of the water in the tube C, and to raiſe the piſton F when the piſton B is lifted: thus, ſuppoſe the piſton B is drawn up by its rod, there will be a vacuum made in the pump cylinder D, below the piſton F; this vacuum will be filled with water through the ſuction pipe, by the preſſure of the atmoſphere, as in all pumps fixed in air. The return of the piſton B, by being preſſed downwards in the cylinder A, will make a ſtroke of the piſton in the pump cylinder D, which may be repeated in the uſual way by the motion of the piſton B, and the action of the water in the tube C. The rod G of the piſton F, and the weight H, are not neceſſary in wells of a depth where the atmoſphere will overbalance the water in the ſuction of the pump cylinder D, and that in the tube C. The ſmall tube and cock in the ciſtern I, are for the purpoſe of charging the tube C."

That theſe contrivances are ingenious, and may occaſionally prove uſeful, we are not inclined to controvert; but we muſt confeſs, that the advantages of them appear not to us fo great as to their author. Why they do not, we need not explain to any man who, with a fufficient degree of mechanical and mathematical knowledge, has perufed this article with attention. *Mr John Lucock*, however, of Marley, near Leeds, thinks fo very differently from us on this fubject, that, on Mr Bramah's principle, he propofes to apply water or other denfe fluids, fo as to make them fupply the place of fteam in what is commonly called the *fteam engine*. He calls his engine the *paradoxical machine*; and he got a patent for it on the 28th of February 1799, though it differs in nothing from Mr Bramah's machine, reprefented by fig. 4. except that the tube C in the paradoxical machine is fupplied with water, not by means of a forcing pump, but from a ciftern elevated to fuch a height as, that the water defcending through the tube may produce its effect merely by its weight. Whether this variation, for it is no improvement, of Mr Bramah's machine, intitled its author to a patent, it is not our bufinefs to inquire.

Macpherfon.

MACPHERSON (James, Efq;), was born in the parifh of Kingufie, and county of Invernefs, in the year 1738. His father was a farmer of no great affluence; and young Macpherfon received the earlier part of his education in one of the parifh fchools in the diftrict called Badenoch. By an anonymous writer in the Edinburgh Magazine, he is faid to have been educated in the grammar fchool of Invernefs; and he may, for ought that we know to the contrary, have fpent a year in that feminary; but we rather think that he went directly from a country fchool to the univerfity of Aberdeen. At this our readers need not be furprifed; for at the period to which we refer, fome of the parochial fchoolmafters in Scotland, and more efpecially in the Highlands, were men eminent for tafte and claffical literature.

It was in the end of October or the 1ft of November 1752, that James Macpherfon entered the King's College; where he difplayed more genius than learning, entertaining the fociety of which he was a member, and even diverting the younger part of it from their ftudies, by his humorous and doggerel rhimes. About two years after his admiffion into the univerfity, the King's College added two months to the length of its annual *feffion* or *term*; which induced Macpherfon, with many other young men, to remove to the Marifchal College, where the feffion continued fhort; and it is this circumftance which leads us to fuppofe that his father was not opulent.

Soon after he left college, and perhaps before he left it, he was fchoolmafter of Ruthven, or Riven, of Badenoch; and we believe he afterwards delighted as little as his great antagonift Johnfon in the recollection of that period when he was compelled, by the narrownefs of his fortune, to teach boys in an obfcure fchool. It was during this period, we think in 1758, that he publifhed *The Highlander*, an heroic poem in fix cantos, 12mo. Of this work, as we have never feen it, we can fay nothing. By the anonymous writer already quoted, it is mentioned as a "tiffue of fuftian and abfurdity;" whilft others, and they too men of learning and character, have affured us, that it indicated confiderable genius in fo young an author.

Soon after this publication, Mr Macpherfon quitted his fchool, and was received by Mr Graham of Balgowan into his family as tutor to his fons; an employment of which he was not fond, and to which he was not long condemned. In the year 1760 he furprifed the world by the publication of *Fragments of Ancient Poetry, collected in the Highlands of Scotland, and Tranflated from the Gaelic or Erfe Language*, 8vo. Thefe fragments, which were declared to be genuine remains of ancient Scottifh poetry, at their firft appearance delighted every reader; and fome very good judges, and amongft the reft Mr Gray, were extremely warm in their praifes. Macpherfon had intended to bury them in a Scotch magazine, but was prevented from fo injudicious a ftep by the advice of a friend. He publifhed them therefore in a pamphlet by themfelves, and thus laid the foundation of his future fortune.

As other fpecimens were faid to be recoverable, a fubfcription was fet on foot by the Faculty of Advocates at Edinburgh, to enable our author to quit the family of Balgowan, perambulate the Highlands, and fecure, if he could, the precious treafure. He engaged in the undertaking, and was fuccefsful; for all who poffeffed any of the long-famed works, vied with each other in giving or fending them, to a man who had fhewn himfelf fo capable of doing them juftice.

With his collection of poems, and fragments of poems, he went to London; and tagging them together in the form which he thought beft, he publifhed, in 1762, *Fingal, an Ancient Epic Poem, in fix books*, together with feveral other poems, compofed by Offian the fon of Fingal, tranflated from the Gaelic language, 4to. The fubject of this epic poem is an invafion of Ireland by Swaran king of Lochlin. Cuchullin, general of the Irifh tribes during the minority of Cormac, king of Ireland, upon intelligence of the invafion, affembled his forces near Tura, a caftle on the coaft of Ulfter. The poem opens with the landing of Swaran; councils are held, battles fought, and Cuchullin is at laft totally defeated. In the mean time, Fingal, king of the Highlands of Scotland, whofe aid had been folicited before the enemy landed, arrived, and expelled them from the country. This war, which continued but fix days and as many nights, is, including the epifodes, the ftory of the Poem. The fcene, the heath of Lena, near a mountain called Cromleach in Ulfter. This poem alfo was received with equal applaufe as the preceding Fragments.

The next year he produced *Temora*, an ancient epic poem, in eight books; together with feveral other poems compofed by Offian fon of Fingal, 4to; which, though well received, found the public fomewhat lefs difpofed to beftow the fame meafure of applaufe. Tho' thefe poems had been examined by Dr Blair and others, and their authenticity afferted, there were not wanting fome of equal reputation for critical abilities, who either doubted or declared their difbelief of the genuinenefs of them,

them. Into this queſtion it would be ſuperfluous to enter here particularly, as we have ſaid enough on it elſewhere. See Ossian, *Encycl.*

That any man ſhould ſuppoſe Macpherſon, after his tranſlation of Homer, the *author* of the poems which he aſcribes to Oſſian, appears to us very extraordinary; and it is little leſs extraordinary, that any one ſhould, for a moment, believe in the exiſtence of *manuſcripts* of theſe poems of *very high* antiquity. Part of them he undoubtedly received in manuſcript from Macdonald of Clanronald; but we can affirm, on the beſt authority, that the ſaid manuſcript was written at different times by the Macvurichs, hereditary bards to that family. He may likewiſe have received ſhort manuſcripts elſewhere; but every Highland gentleman of learning and of candour (and none elſe have a right to decide on this queſtion), declares, that by much the greater part of the poems had been preſerved in fragments and popular ſongs from a very remote age by oral tradition. To theſe fragments Macpherſon and his aſſociates (A) gave form; and it was by uniting together fragments of different ages, that he inadvertently furniſhed Gibbon and others with the opportunity of objecting, that the poems are ſometimes inconſiſtent with the truth of hiſtory. This, however, is no ſolid objection to their authenticity; for every Weſt Highlander ſixty years of age remembers to have heard, in his youth, great part of thoſe poems repeated by old men; and is confident that, many centuries ago, the names of *Fiune Mackuil* (Fingal), and of Oſſian's other heroes and heroines, were as familiar to a Highland ear, as the names of Agamemnon, Hector, Helen, &c. were to a Grecian ear at the time when the poems of Homer were reduced into their preſent form. For the ſubſtance of the poems, this is ſuch evidence as none will reject who does not prefer his own cobweb theories to the united teſtimony of a whole people.

With reſpect to authenticity, the poems of Oſſian have indeed been compared with the poems of Rowley; but the compariſon is abſurd. The poems of the Celtic bard were not found in an old cheſt, and preſented to a people who had never before heard either of them or of their author; they were the popular ſongs and traditions of ages collected together, and reduced into form, with additions occaſionally made by the tranſlator. It is ridiculous to aſk how theſe ſongs and ſtories could be ſo long preſerved among a rude and illiterate people; for it is only among ſuch a people, whoſe objects of purſuit are too few to occupy all their attention, that the exploits of their anceſtors can be handed down by tradition; and the moſt ſerious objection which we have ever met with to the tranſlator's account of the origin of the poems, ariſes from his having pretended that he received the greater part of them in old manuſcripts.

After the publication of Oſſian's poems, by which we have reaſon to believe that he gained twelve hundred pounds, Mr Macpherſon was called to an employment which withdrew him, for ſome time, both from the muſes and from his country. Captain Johnſtone was appointed governor of Penſacola, and Mr Macpherſon accompanied him as his ſecretary, being at the ſame time made ſurveyor-general of the Floridas. If our memory does not deceive us, ſome difference aroſe between the principal and his dependant, and they parted before their return to England. Having contributed his aid to the ſettlement of the civil government of that colony, he viſited ſeveral of the Weſt India iſlands, and ſome of the provinces of North America, and returned to England in the year 1766, where he retained for life his ſalary as ſurveyor, which we believe was L. 200 a-year.

He ſoon returned to his ſtudies, and in 1771 produced *An Introduction to the Hiſtory of Great Britain and Ireland*, 4to; a work which he ſays, "without any of the ordinary incitements to literary labour, he was induced to proceed in by the ſole motive of private amuſement." The ſubject of this performance, it might reaſonably be ſuppoſed, would not excite any violent controverſial acrimony; yet neither it nor its author could eſcape from ſeveral moſt groſs and bitter invectives; for ſome of which he perhaps gave too great occaſion.

His next performance produced him neither reputation nor profit. In 1773 he publiſhed, *The Iliad of Homer*, tranſlated in two volumes 4to; a work fraught with vanity and ſelf-conſequence, and which met with the moſt mortifying reception from the public. It was condemned by the critics, ridiculed by the wits, and neglected by the world. Some of his friends, and particularly Sir John Elliott, endeavoured to reſcue it from contempt, and force it into notice. Their ſucceſs was not equal to their efforts.

About this time ſeems to be the period of Mr Macpherſon's literary mortifications. In 1773 Dr Johnſon and Mr Boſwell made the tour to the Hebrides; and in the courſe of it, the former took ſome pains to examine into the proofs of the authenticity of Oſſian. The reſult of his inquiries he gave to the public in 1775, in his narrative of the tour; and his opinion was unfavourable. "I believe they (*i. e.* the poems, ſays he), never exiſted in any other form than that which we have ſeen. The editor or author never could ſhew the original; nor can it be ſhewn by any other. To revenge reaſonable incredulity by refuſing evidence, is a degree of inſolence with which the world is not yet acquainted; and ſtubborn audacity is the laſt refuge of guilt. It would be eaſy to ſhew it if he had it. But whence could it be had? It is too long to be remembered, and the language had formerly nothing written. He has doubtleſs inſerted names that circulate in popular ſtories, and may have tranſlated ſome wandering ballads, if any can be found; and the names and ſome of the images being recollected, make an inaccurate auditor imagine that he has formerly heard the whole."

Again, he ſays, "I have yet ſuppoſed no impoſtor but in the publiſher; yet I am far from certainty, that ſome tranſlations have not been lately made, that may,

(A) We have been aſſured that he had aſſociates: and that for the deſcription of Cuchullin's chariot in particular he was indebted to Mr Macpherſon of *Stramazhie*; a man of native genius, and though not poſſeſſed of very extenſive erudition, well acquainted with Gaelic poetry.

Macpherson. may now be obtruded as parts of the original work.

"Credulity on the one part is a strong temptation to deceit on the other, especially to deceit of which no personal injury is the consequence, and which flatters the author with his own ingenuity. The Scots have something to plead for their easy reception of an improbable fiction: they are seduced by their fondness for their supposed ancestors. Neither ought the English to be much influenced by Scots authority; for of the past and present state of the whole Erse nation, the Lowlanders are at least as ignorant as ourselves. To be ignorant is painful; but it is dangerous to quiet our uneasiness by the delusive opiate of hasty persuasion."

These reasonings, if reasonings they can be called, might have been easily answered, had not Macpherson pretended to the possession of at least one manuscript which certainly never existed. He did, however, attempt to answer them; but adopted a mode of proceeding which tended only to convince the world that Johnson's opinion had some foundation, and that the editor of Ossian had more imagination than sound judgement. Prompted by his evil genius, he sent a menacing letter to his illustrious antagonist, which produced the following brief but spirited reply:

"Mr James Macpherson, No date.

"I received your foolish and impudent letter. Any violence that shall be offered to me, I will do my best to repel; and what I cannot do for myself, the law shall do for me; for I will not be hindered from exposing what I think a cheat, by the menaces of a ruffian. What! Would you have me retract? I thought your work an imposition: I think so still; and, for my opinion, I have given reasons, which I dare you to refute. Your abilities, since your *Homer*, are not so formidable; and what I hear of your morality, inclines me to believe rather what you shall prove than what you shall say."

Whether this letter shewed to Macpherson the imprudence of his conduct, or that he had been made sensible of his folly by the interposition of friends, we know not, but certain it is, we hear no more afterwards of this ridiculous affair, except that our author is supposed to have assisted Mr Macnicol in an answer to Dr Johnson's Tour, printed in 1779. This supposition we are enclined to consider as well-founded, because we have been told by a gentleman of veracity, that Mr Macnicol affirms, that the scurrility of his book, which constitutes a great part of it, was inserted, unknown to him, after the manuscript was sent for publication to London.

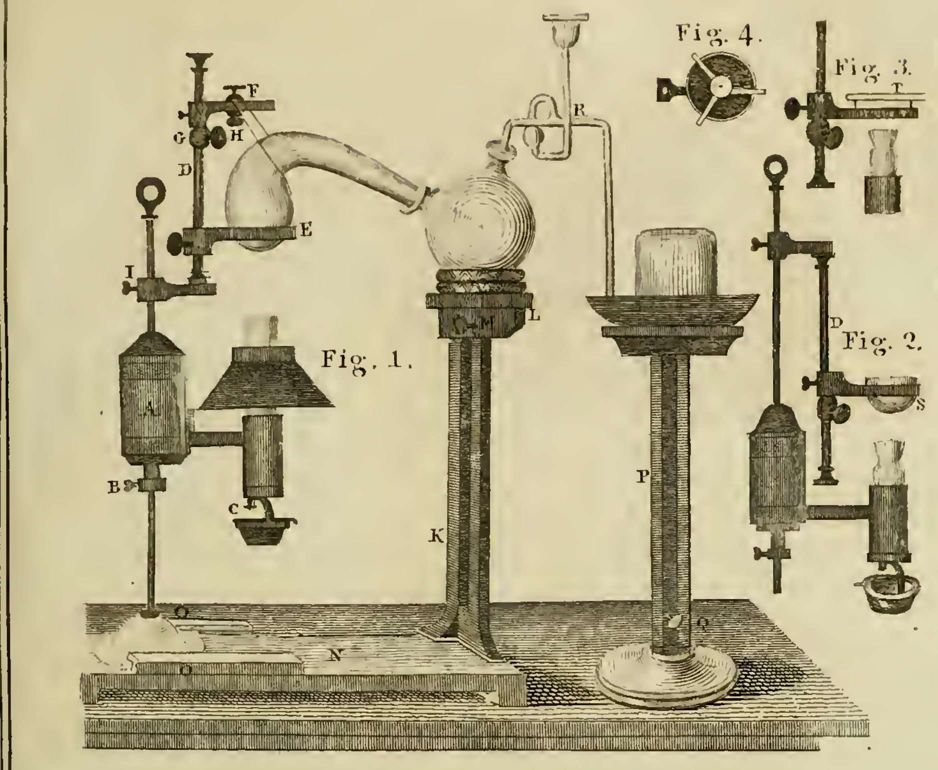
In 1775 Mr Macpherson published *The History of Great Britain from the Restoration to the Accession of the House of Hanover*, in two volumes 4to; a work in our opinion of great merit, though by one party it has been industriously, and, we are sorry to add, too successfully, decried. As an historian, our author could not indeed boast the attic elegance of a Robertson, the splendour of a Gibbon, or the philosophical profundity of a Hume; but his *style*, though it has sometimes been the avowed, was not the real, cause of the coldness with which his history was received. The writer of this sketch once saw a gentleman of rank, and of the Whig interest, turn over one of Macpherson's volumes, and heard him say, upon shutting the book, "I cannot bear that work." He was asked if he thought the narrative false? and he replied, "No! it is too true; but I cannot bear it, because it gives me a bad opinion of those great men to whom I have been accustomed to look back with reverence as to the saviours of my country."

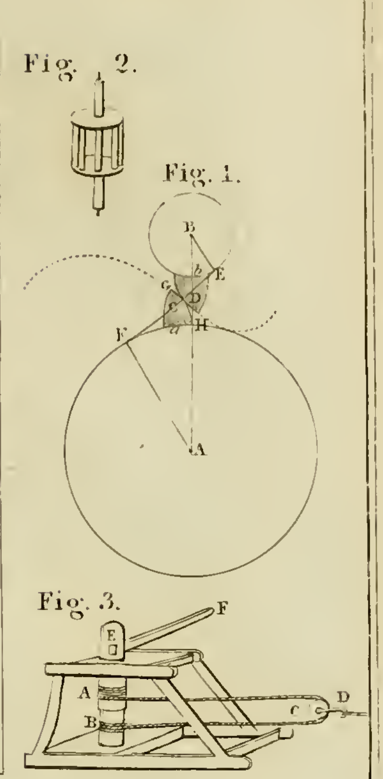
That it has been abhorred by others on the same account, we have not a doubt; and yet language has no name too contemptuous for those who will not follow Truth whithersoever she may lead them; or who, on the absurd pretence of having already made up their minds, will not study the evidence on both sides of a disputed question in our national history. A man needs not surely disapprove of the Revolution, or of the subsequent settlements, though he should find complete proofs that Danby and Sunderland were crooked politicians, that Marlborough was ungrateful, or even that King William himself was not that upright and disinterested character which from their infancy they have been taught to believe. It is no uncommon thing for Divine Providence to accomplish good ends by wicked instruments. Every Protestant surely considers the Reformation as one of the most blessed events that have taken place in the world since the first preaching of the gospel of Christ; yet he would be a hardy champion who should undertake to vindicate the motives which influenced the conduct of the first reformers—of Henry VIII. for instance, or even of Luther himself. And why may not the Revolution be considered as in the highest degree beneficial to the country, though the conduct of some of those who brought it about should be found to be such as Macpherson represents it?

That author certainly acted with great fairness; as together with the history he published the proofs upon which his facts were founded, in two quarto volumes, intitled, *Original Papers, containing the secret History of Great Britain, from the Restoration to the Accession of the House of Hanover; to which are perfixed, Extracts from the Life of James II. as written by himself.* These papers were chiefly collected by Mr Carte, but are not all of equal authority. They, however, clear up many obscurities, and set the characters of many persons in past times in a different light from that in which they have been usually viewed. On this account we have no hesitation to say, that he who is capable of sacrificing prejudice to truth, and wishes to understand the politics of the reigns of James, and William, and Anne, should study with care the volumes of Macpherson.

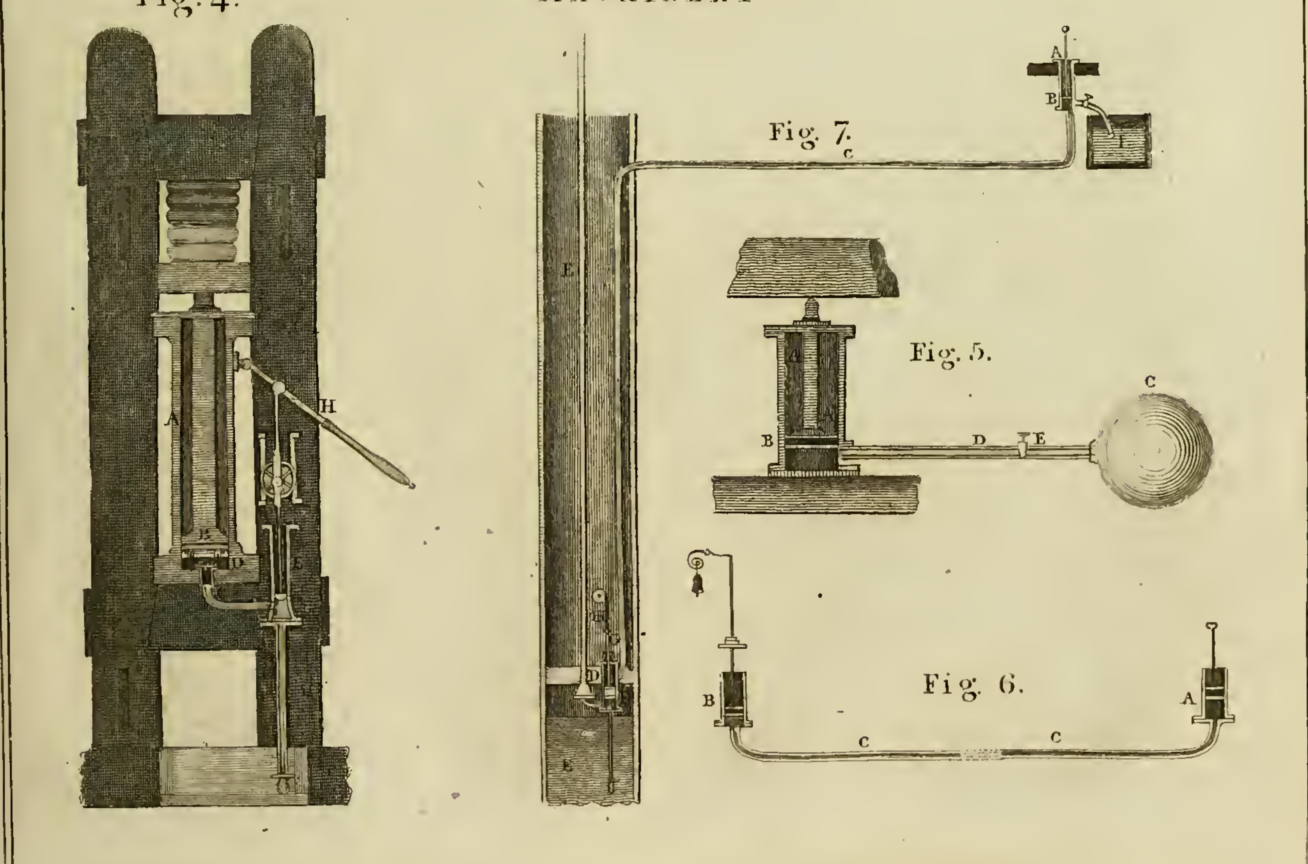
Soon after this period, the tide of fortune flowed very rapidly in Mr Macpherson's favour, and his talents and industry were amply sufficient to avail himself of every favourable circumstance which arose. The resistance of the Colonies called for the aid of a ready writer to combat the arguments of the Americans, and to give force to the reasons which influenced the conduct of government, and he was selected for the purpose. Among other things (of which we should be glad to receive a more particular account), he wrote a pamphlet, which was circulated with much industry, intitled, *The Rights of Great Britain asserted against the Claims of the Colonies; being an Answer to the Declaration of the General Congress*, 8vo, 1776, and of which many editions were published. He also was the author of *A short History of Opposition during the last Session of Parliament*,

LABORATORY. PLATE XXXIII.





MACHINERY



Macpherson.

Parliament, 8vo, 1779; a pamphlet which, on account of its merit, was by many afcribed to Mr Gibbon.

But a more lucrative employment was conferred on him about this time. He was appointed agent to the nabob of Arcot, and in that capacity exerted his talents in feveral appeals to the public in behalf of his client. Among others, he publifhed, *Letters from Mahommed Ali Chan, Nabob of Arcot, to the Court of Directors; to which is annexed, a State of Facts relative to Tanjore, with an Appendix of Original Papers*, 4to, 1777; and he was fuppofed to be the author of *The Hiftory and Management of the Eaft India Company from its Origin in* 1600 *to the prefent Times*, vol. i. containing the affairs of the Carnatic, in which the rights of the nabob are explained, and the injuftice of the Company proved, 4to, 1779.

In his capacity of agent to the nabob, it was probably thought requifite that he fhould have a feat in the Britifh Parliament. He was accordingly in 1780 chofen member for Camelford; but we do not recollect that he ever attempted to fpeak in the Houfe. He was alfo rechofen in 1784 and 1790.

He had purchafed, we think before the year 1790, an eftate in the parifh in which he was born; and changing its name from *Retz* to *Belville*, built on it a large and elegant manfion, commanding a very romantic and picturefque view; and thither he retired, when his health began to fail, in expectation of receiving benefit from the change of air. He continued, however, to decline; and after lingering fome time, died at his feat at Belville, in Invernefs, on the 17th of February 1796.

Macpherfon, Magma.

He appears to have died in very opulent circumftances; and by his will, dated June 1793, gave various annuities and legacies to feveral perfons to a great amount. He alfo bequeathed L. 1000 to John Mackenzie of Figtree Court, in the Temple, London, to defray the expence of printing and publifhing Offian in the original. He directed L. 300 to be laid out in erecting a monument to his memory in fome confpicuous fituation at Belville, and ordered that his body fhould be carried from Scotland, and interred in the Abbey Church of Weftminfter, the city in which he had paffed the beft part of his life. His remains were accordingly taken from the place where he died, and buried in the Poets Corner of Weftminfter Church.

MAGMA is properly the *refufe* of any fubftance which has been fubjected to preffure; but, in chemiftry, the term is fometimes ufed to denote a mixture of two or more bodies, reduced to the confiftence of dough or pafte.

MAGNETISM,

IN natural philofophy.—Our intention in the prefent article was principally to give a more diftinct account of the theory of Mr Æpinus than is contained in the article MAGNETISM of the *Encyclopædia Britannica*, referring for proof and illuftration to the many facts contained in that article: but, on more mature confideration, we concluded, that this method would fret and confufe the reader by continual references, and leave but a feeble impreffion at laft. We have therefore preferred the putting the whole into the form of a fhort treatife on magnetifm, fimilar to our fupplementary article of ELECTRICITY. This, we hope, will be more perfpicuous and fatisfactory; ftill leaving to the reader the full ufe of all the information contained in the article MAGNETISM of the Dictionary.

1
[...]ons the [...]nts [...] ig[...]nt of [...]ral [...]ofophy.

The knowledge which the ancient naturalifts poffeffed of this fubject was extremely imperfect, and affords, we think, the ftrongeft proof of their ignorance of the true method of philofophifing; for there can hardly be named any object of phyfical refearch that is more curious in itfelf, or more likely to engage attention, than the apparent life and activity of a piece of rude unorganifed matter. This had attracted notice in very early times; for Thales attributed the characteriftic phenomenon, the attraction of a piece of iron, to the agency of a mind or foul refiding in the magnet. Philofophers, as they were called, feem to have been contented with this lazy notice of a flight fuggeftion, unbecoming an inquirer, and rather fuch as might be expected from the moft incurious peafant. Even Ariftotle, the moft zealous and the moft fyftematic ftudent of Nature of whofe labours we have any account, has collected no information that is of any importance. We know that the general imperfection of ancient phyfics has been afcribed to the little importance that was attached to the knowledge of the material world by the philofophers of Greece and Rome, who thought human nature, the active purfuits of men, and the fcience of public affairs, the only objects deferving their attention. Moft of the great philofophers of antiquity were alfo great actors on the ftage of human life, and defpifed acquifitions which did not tend to accomplifh them for this dignified employment: but they have not given this reafon themfelves, though none was more likely to be uppermoft in their mind. Socrates diffuades from the ftudy of material nature, not becaufe it was unworthy of the attention of his pupils, but becaufe it was too difficult, and that certainty was not attainable in it. Nothing can more diftinctly prove their ignorance of what is really attainable in fcience, namely, the knowledge of the *laws of nature*, and their ignorance of the only method of acquiring this knowledge, viz. obfervation and experiment. They had entertained the hopes of difcovering the *caufes* of things, and had formed their philofophical language, and their mode of refearch, in conformity with this hopelefs project. Making little advances in the difcovery of the caufes of the phenomena of material nature, they deferted this ftudy for the ftudy of the conduct of man; not becaufe the difcovery of caufes was more eafy and frequent here, but becaufe the ftudy itfelf was more immediately interefting, and becaufe any thing like fuperior knowledge in it puts the poffeffor in the defirable fituation of an advifer, a man of fuperior wifdom; and as this ftudy was clofely connected with morals, becaufe the fear of God is truly the beginning of wifdom, the character of the philofopher acquired an eminence and dignity which was highly flattering to human vanity. Their procedure in the moral and intellectual fciences is ftrongly marked with the fame ignorance of the true method of philofophifing; for we rarely

rarely find them forming general propoſitions on copious inductions of facts in the conduct of men. They always proceed in the ſynthetic method, as if they were fully converſant in the firſt principles of human nature, and had nothing to do but to make the application, according to the eſtabliſhed forms of logic. While we admire, therefore, the ſagacity, the penetration, the candid obſervation, and the happy illuſtration, to be found in the works of the ancient moraliſts and writers on juriſprudence and politics, we cannot but lament that ſuch great men, frequently engaged in public affairs, and therefore having the fineſt opportunities for deducing general laws, have done ſo little in this way; and that their writings, however engaging and precious, cannot be conſidered as any thing more refined than the obſervations of judicious and worthy men, with all the diffuſeneſs and repetition of ordinary converſation. All this has ariſen from the want of a juſt notion of what is attainable in this department of ſcience, namely, the laws of intellectual and moral nature; and of the only poſſible method of attaining this knowledge, viz. obſervation and experiment, and the formation of general laws by the induction of particular facts.

2
Dr Gilbert was the firſt experimental inquirer about magnetiſm.

We have been led into theſe reflections by the inattention of the ancients to the curious phenomena of magnetiſm; which muſt have occurred in conſiderable and entertaining variety to any perſon who had taken to the experimental method. And we have hazarded theſe free remarks, expecting the acquieſcence of our readers, becauſe the ſuperior knowledge which we, in theſe later days, have acquired of the magnetical phenomena, were the firſt fruits of the true method of philoſophiſing. This was pointed out to the learned world in 1590 by our celebrated countryman Chancellor Bacon, in his two great works, the *Novum Organum Scientiarum*, and *De Argumentis Scientiarum*. Dr Gilbert of Colcheſter, a philoſopher of eminence in many reſpects, but chiefly becauſe he had the ſame juſt views of philoſophy with his noble countryman, publiſhed about the ſame time his *Phyſiologia Nova, ſeu Tractatus de Magnete et Corporibus Magneticis*. In the introduction, he recounts all the knowledge of the ancients on the ſubject, and their ſupine inattention to what was ſo entirely in their hands; and the impoſſibility of ever adding to the ſtock of uſeful knowledge, ſo long as men imagined themſelves to be philoſophiſing while they were only repeating a few cant words, and the unmeaning phraſes of the Ariſtotelian ſchool. It is curious to remark the almoſt perfect ſameneſs of Dr Gilbert's ſentiments and language with thoſe of Lord Bacon. They both charge, in a peremptory manner, all thoſe who pretend to inform others, to give over their dialectic labours, which are nothing but ringing changes on a few trite truths, and many unfounded conjectures, and immediately to betake themſelves to experiment. He has purſued this method on the ſubject of magnetiſm with wonderful ardour, and with equal genius and ſucceſs; for Dr Gilbert was poſſeſſed both of great ingenuity, and a mind fitted for general views of things. The work contains a prodigious number and variety of obſervations and experiments, collected with ſagacity from the writings of others, and inſtituted by himſelf with conſiderable expence and labour. It would indeed be a miracle, if all Dr Gilbert's general inferences were juſt, or all his experiments accurate. It was untrodden ground. But, on the whole, this performance contains more real information than any writing of the age in which he lived, and is ſcarcely exceeded by any that has appeared ſince. We may hold it with juſtice as the firſt fruits of the Baconian or experimental philoſophy.

This work of Dr Gilbert's relates chiefly to the loadſtone, and what we call magnets, that is, pieces of ſteel which have acquired properties ſimilar to thoſe of the loadſtone. But he extends the term *magnetiſm*, and the epithet *magnetic*, to all bodies which are affected by loadſtones and magnets in a manner ſimilar to that in which they affect each other. In the courſe of his inveſtigation, indeed, he finds that theſe bodies are only ſuch as contain iron in ſome ſtate or other: and in proving this limitation he mentions a great variety of phenomena which have a conſiderable reſemblance to thoſe which he allows to be magnetical, namely, thoſe which he called *electrical*, becauſe they were produced in the ſame way that amber is made to attract and repel light bodies. He marks with care the diſtinctions between theſe and the characteriſtic phenomena of magnets. He ſeems to have known, that all bodies may be rendered electrical, while ferruginous ſubſtances alone can be made magnetical.

3
His treatiſe contains many diſcoveries.

It is not ſaying too much of this work of Dr Gilbert's to affirm, that it contains almoſt every thing that we know about magnetiſm. His unwearied diligence in ſearching every writing on the ſubject, and in getting information from navigators, and his inceſſant occupation in experiments, have left very few facts unknown to him. We meet with many things in the writings of poſterior inquirers, ſome of them of high reputation, and of the preſent day, which are publiſhed and received as notable diſcoveries, but are contained in the rich collection of Dr Gilbert. We by no means aſcribe all this to mean plagiariſm, although we know traders in experimental knowledge who are not free from this charge. We aſcribe it to the general indolence of mankind, who do not like the trouble of conſulting originals, where things are mixed with others which they do not want, or treated in a way, and with a painful minuteneſs, which are no longer in faſhion. Dr Gilbert's book, although one of thoſe which does the higheſt honour to our country, is leſs known in Britain than on the continent. Indeed we know but of two Britiſh editions of it, which are both in Latin; and we have ſeen five editions publiſhed in Germany and Holland before 1628. We earneſtly recommend it to the peruſal of the curious reader. He will (beſides the ſound philoſophy) find more facts in it than in the two large folios of Scarella.

After this moſt deſerved eulogy on the parent of magnetical philoſophy, it is time to enter on the ſubject.

4
We can only claſs the phenomena.

In mechanical philoſophy, a phenomenon is not to be conſidered as explained, unleſs we can ſhew that it is the certain reſult of the laws of motion applied to matter. It is in this way that the general propoſitions in phyſical aſtronomy, in the theory of machines, in hydraulics, &c. are demonſtrated. But the phenomena called *magnetical* have not as yet obtained ſuch an explanation. We do not ſee their immediate cauſe, nor can we ſay with confidence that they are the effects of any

any particular kind of matter, acting on the bodies either by impulſion or preſſure.

All that can be done here is to claſs the phenomena in the moſt diſtinct manner, according to their generality. In this we obtain a two-fold advantage. We may take it for granted that the moſt general phenomenon is the neareſt allied to the general cauſe. But, farther, we obtain by this method a true theory of all the ſubordinate phenomena. For a juſt theory is only the pointing out the general fact of which the phenomenon under conſideration is a particular inſtance. Beginning therefore with the phenomenon which comprehends all the particular caſes, we explain thoſe caſes in ſhewing *in what manner* they are included in the general phenomenon, and thus we ſhall be able to predict what will be the reſult of putting the body under conſideration into any particular ſituation. And perhaps we may find, in them all, coincidences which will enable us to ſhew that they are all modifications of a fact ſtill more general. If we gain this point, we ſhall have eſtabliſhed a complete theory of them, having diſcovered the general fact in which they are all comprehended. Should we for ever remain ignorant of the cauſe of this general fact, we have nevertheleſs rendered this a complete branch of mechanical theory. Nay, we may perhaps diſcover ſuch circumſtances of reſemblance between this general fact and others, with which we are better acquainted, that we ſhall, with great probability at leaſt, be able to aſſign the cauſe of the general fact itſelf, by ſhewing the law of which it is a particular inſtance.

We ſhall attempt this method on the preſent occaſion.

5 First leading fact. Iron arranges itſelf in a particular poſition.

The leading facts in magnetiſm are the two following:

1. If any oblong piece of iron, ſuch as a bar, rod, or wire, be ſo fitted, that it can aſſume any direction, it will arrange itſelf in a certain determinate direction with reſpect to the axis of the earth. Thus, if, in any part of Briton, an iron or ſteel wire be thruſt through a piece of cork, as repreſented in fig. 1. ſo as that the whole may ſwim level in water, and if it be laid in the water nearly north-weſt and ſouth eaſt, it will ſlowly change its poſition, and finally ſettle in a direction, making an angle of about 25 degrees with the meridian. (Plate XXXIV.)

This experiment, which we owe to Dr Gilbert (ſee B. I. ch. 11.), is delicate, and requires attention to many circumſtances. The force with which the iron tends toward this final poſition is extremely weak, and will be balanced by very minute and otherwiſe inſenſible reſiſtances; but we have never found it fail when executed as here directed. An iron wire of the ſize of an ordinary quill, and about eight or ten inches long, is very fit for the purpoſe. It ſhould be thruſt through the cork at right angles to its axis; and ſo adjuſted, by repeated trials, as to ſwim level or parallel to the horizon. The experiment muſt alſo be made at a great diſtance from all iron; therefore in a baſon of ſome other metal or earthen ware. It may ſometimes require a very long while before the motion begin; and if the wire has been placed at right angles to the direction which we have mentioned as final, it will never change its poſition: therefore we have directed it to be laid in a direction not too remote, yet very ſenſibly different from the final direction.

But this is not the true poſition affected by the iron rod. If it be thruſt through a piece of wood or cork perfectly ſpherical, in ſuch a manner that it paſſes thro' its centre, and if the centre of gravity coincide with this centre, and the whole be of ſuch weight as to remain in any part of the water without either aſcending or deſcending, then it will finally ſettle in a plane inclined to the meridian about 25°, and the north end will be depreſſed about 73° below the horizon.

All this is equivalent with ſaying, that if any oblong piece of iron or ſteel be very nicely poiſed on its centre of gravity, and at perfect liberty to turn round that centre in every direction, it will finally take the poſition now mentioned.

We have farther to obſerve with regard to this experiment, that it is indifferent which end of the rod be placed toward the north in the beginning of the experiment. That end will finally ſettle toward the north; and if the experiment be repeated with the ſame rod, but with the other end north, it will finally ſettle in this new attitude. It is, however, not always that we find pieces of iron thus perfectly indifferent. Very frequently one end affects the northerly poſition, and we cannot make the other end aſſume its place: the cauſes of this difference will be clearly ſeen by and bye.

6 Magnetical poſition.

The poſition thus affected by a rod of iron is called by Dr Gilbert the MAGNETICAL POSITION or DIRECTION. It is not the ſame, nor parallel in all parts of the earth, as will be more particularly noticed afterwards.

7 Second fact. Iron attracts and repels iron.

2. The other leading facts is this: When a piece of iron, lying in the *magnetical* poſition, or nearly ſo, and at perfect liberty to move in every direction, is approached by another oblong piece of iron, held nearly in the ſame poſition, it is attracted by it; that is, the moveable piece of iron will gradually approach to the one that is preſented to it, and will at laſt come into contact with it, and may then be ſlowly drawn along by it.

This phenomenon, although not ſo delicate as the former, is ſtill very nice, becauſe the attraction is ſo weak that it is balanced by almoſt inſenſible obſtructions. But the experiment will ſcarcely fail if conducted as follows: Let a ſtrong iron wire be made to float on water by means of a piece of cork, in the manner already deſcribed, having one end under water. See fig. 1. B.

When it is nearly in the magnetical poſition, bring the end of a pretty big iron rod, ſuch as the point of a new poker, within a quarter of an inch of its ſouthern end (holding the poker in a poſition not very different from the magnetical poſition), and hold it there for ſome time, not exactly ſouthward from it, but a little to one ſide. The floating iron will be obſerved to turn towards it with an accelerated motion; will touch it, and may then be drawn by it through the water in any direction. We ſhall have the ſame reſult by approaching the northern extremity of the floating iron with the upper end of the poker.

The ſame phenomenon may be obſerved by ſuſpending the firſt piece of iron by its middle by a long and ſlender hair or thread. The ſuſpenſion muſt be long, otherwiſe the ſtiffneſs of the hair or thread may be ſufficient for balancing the very ſmall force with which the pieces of iron tend toward each other. The phenomenon

non may alfo be obferved in a piece of iron which turns freely on a fine point, like the needle of the mariner's compafs.

In this, as in the former experiment, the ends of the pieces of iron are obferved, in general, to be indifferent; that is, either end of the one will attract either end of the other. It often happens, however, that the ends are not thus indifferent, and that the end of the moveable piece of iron, inftead of approaching the other, will be obferved to recede from it, and appear to avoid it. We fhall foon learn the caufe of this difference in the ftates of iron.

8
This action mutual.

It is fcarcely neceffary to remark, that we muft infer from thefe experiments, that the action is mutual between the two pieces of iron. Either of them may be the moveable piece which approaches the other, manifefting the attraction of that other. This reciprocity of action will be abundantly verified and explained in its proper place.

9
Not peculiar to magnets or loadftone;

Thefe two facts were long thought to be peculiar to loadftones and artificial magnets, that is, pieces of iron which have acquired this property by certain treatment with loadftones; but they were difcovered by Dr Gilbert to be inherent in all iron in its metallic ftate; and were thought by him to be neceffary confequences of a general principle in the conftitution of this globe. Thefe phenomena are indeed much more confpicuous in loadftones and magnets; and it is therefore with fuch that experiments are beft made for learning their various modifications.

10
But, in iron, is indifferent, and momentary, and in loadftones it is fixed and determinate.

But there is another circumftance, befides the degree of vivacity, in which the magnetifm of common iron and fteel remarkably differs from that of a loadftone or magnet. When a loadftone or magnet is fo fupported as to be at liberty to take any pofition, it arranges itfelf in the magnetical direction, and *one determined end* of it fettles in the northern quarter; and if it be placed fo that the other end is in that fituation, it does not remain there, but gradually turns round, and, after a few ofcillations, the *fame end* ultimately fettles in the north. This is diftinctly feen in the needle of the mariner's compafs, which is juft a fmall magnet prepared in the fame way with all other magnets. The feveral ends of loadftones or magnets are thus permanently the north or the fouth ends; whereas we faid that either end of a piece of common iron being turned to the northern quarter, it finally fettles there.

It is this circumftance which has rendered magnetifm fo precious a difcovery to mankind, by furnifhing us with the compafs, an inftrument by which we learn the different quarters of the horizon, and which thus tells the direction of a fhip's courfe through the pathlefs ocean (fee COMPASS and VARIATION, *Encycl.*); and alfo fhews us the directions of the veins and workings in the deepeft mines. It was natural therefore to call thofe the north and fouth ends of the mariner's needle, or of a loadftone or magnet. Dr Gilbert called them the POLES of the loadftone or magnet. He had found it convenient for the propofed train of his experiments to form his loadftones into fpheres, which he called TERRELLÆ, from their refemblance to this globe; in which cafe the north and fouth ends of his loadftones were the poles of the terrellæ. He therefore gave the name *pole* to that part of any loadftone or magnet which thus turned to the north or fouth. The denomination was adopted by all fubfequent writers, and now makes a term in the language of magnetifm.

Alfo, when we approach either end of a piece of iron A to either end of another B, thefe ends mutually attract; or if either end of a magnet A be brought near either end of a piece of common iron, they mutually attract each other. But if we bring that end of a magnet A which turns to the north near to the *fimilar* end of another magnet B, thefe ends will not attract each other, but, on the contrary, will repel. If the two magnets are made to float on pieces of wood, and have their north poles fronting each other, the magnets will retire from each other; and in doing fo, they generally turn round their axis, till the north pole of one front the fouth pole of the other, and then they run together. This is a very notable diftinction between the magnetifm of magnets and that of common iron; and whenever we fee a piece of iron fhew this permanent diftinction of its ends, we muft confider it as a magnet, and conclude that it has met with fome peculiar treatment.

It is not, however, ftrictly true, that the poles of loadftones or magnets are fo fixed in particular parts of their fubftance, nor that the poles of the fame name fo conftantly repel each other; for if a fmall or weak magnet A have its pole brought near the fimilar pole of a large or ftrong magnet B, they are often found to attract when almoft touching, although at more confiderable diftances they repel each other. But this is not an exception to the general propofition; for when the north pole of A is thus attracted by the north pole of B, it will be found by other trials to have all the qualities of a fouth pole, while thus in the neighbourhood of the north pole of B.

The magnetic properties and phenomena are conveniently diftinguifhed into thofe of FORCE and of POLARITY. Thofe of the firft clafs only were known to the ancients, and even of them their knowledge was extremely fcanty and imperfect. They may all be claffed under the following general propofitions. 12 Magnetic FORCE and POLARITY

1. The fimilar poles of two magnets repel each other with a force decreafing as the diftances increafe. 13 Similar poles repel, and diffimilar poles attract, each other.

2. The diffimilar poles of two magnets attract each other with a force decreafing as the diftances increafe.

3. Magnets arrange themfelves in a certain determinate pofition with refpect to each other.

14
The law of attraction and repulfion is of difficult inveftigation.

The firft object of refearch in our further examination of thefe properties is the relation which is obferved to obtain between the diftances of the acting poles and their force of action. This has accordingly occupied much attention of the philofophers, and numberlefs experiments have been made in order to afcertain the law of variation, both of the attraction and the repulfion. A great number of thefe have been narrated in the article MAGNETISM of the *Encycl.* from which it appears that it has been a matter of great difficulty, and had not been afcertained with certainty or precifion when that article was publifhed. It is obvious, from the nature of the thing, that the determination is very difficult, and the inveftigation very complicated. We can only obferve the fimultaneous motion of the whole magnet; yet we know that there are four feparate actions coexifting and contributing in different directions, and with different forces, to the fenfible effect. The force which we meafure, in any way whatever, is compounded

-pounded of four different forces, which we cannot feparate and meafure apart; for the north pole of A repels the north pole of B, and attracts its fouth pole, while the fouth pole of A exerts the oppofite forces on the fame poles of B. The attraction which we obferve is the excefs of two unequal attractions above two unequal repulfions. The fame might be faid of an obferved repulfion. Nay, the matter is incomparably more complicated than this; becaufe, for any thing that we know, *every* particle of A acts on *every* particle of B, and is acted on by it; and the intenfity of thofe actions may be different at the fame diftances, and is certainly different when the diftances are fo. Thus there is a combination of an unknown number of actions, each of which is unknown individually, both in direction and intenfity. The precife determination is therefore, in all probability, impoffible. By precife determination, we mean the law of mutual action between two magnetic particles, or that precife function of the diftance which defines the intenfity of the force; fo that meafuring the diftance of the acting particles on the axis of a curve, the ordinates of the curve may have the proportions of the attractions and repulfions.

It is almoft needlefs to attempt any deduction of the law of variation from the numerous experiments which have been publifhed by different philofophers. An ample collection of them may be feen in Scarella's treatife. Mr Mufchenbroek has made a prodigious number; but all are fo anomalous, and exhibit fuch different laws of diminution by an increafe of diftance, that we may be certain that the experiments have been injudicious. Attention has not been paid to the proper objects. Magnets of moft improper fhapes have been employed, and of moft diffufe polarity. No notice has been taken of a circumftance which, one fhould think, ought to have occupied the chief attention; namely, the joint action of four poles, of which the experiment exhibits only the complex refult. A very flight reflection might have made the enquirer perceive, that the attractions or repulfions are not the moft proper phenomena for declaring the precife law of variation; becaufe what we obferve is only the excefs of a fmall difference of attractions and repulfions above another fmall difference. Mr Hawkfbee and Dr Brook Taylor employed a much better method, by obferving the deviations from the meridian which a magnet occafioned in a compafs needle at different diftances. This is occafioned by the difference of the two fums of the fame forces; and this difference may be made a hundred times greater than the other. But they employed magnets of moft improper fhapes.

15 Judicious experiments by Mr Lambert.

We muft except from this criticifm the experiments of Mr Lambert, recorded in the Memoirs of the Academy of Berlin for 1756, publifhed in 1758. This moft fagacious philofopher (for he highly merits that name) placed a mariner's needle at various diftances from a magnet, in the direction of its axis, and obferved the declination from the magnetic meridian produced by the magnet, and the obliquity of the magnet to the axis of the needle. Thus was the action of the magnet fet in oppofition and equilibrium with the natural polarity of the needle. But the difficulty was to difcover in what proportion each of thefe forces was changed by their obliquity of action on this little lever. No man excelled Mr Lambert in addrefs in devifing methods of mathematical inveftigation. He obferved, that when the obliquity of the magnet to the axis of the needle was 30°, it caufed it to decline 15°. When the obliquity was 75°, the diftance being the fame, it declined 30°. Call the obliquity o, and the declination d, and let f be that function of the angle which is proportionable to the action. Alfo let p be the natural polarity of the needle, and m the force of the magnet. It is evident that

$$p \times f,\ 15 = m \times f,\ 30$$

And $p : m = f,\ 30 : f,\ 15$; for the fame reafon

$$p : m = f,\ 75 : f,\ 30$$

Therefore $f,\ 15 : f\ 30 = f,\ 30 : f,\ 75°$.

But it is well known that

Sine 15 : Sine 30 = Sine 30 : Sine 75.

Hence Mr Lambert was led to conjecture, that the fine was that function of the angle which was proportional to the action of magnetifm on a lever. But one experiment was infufficient for determining this point. He made a fimilar comparifon of feveral other obliquities and declinations with the fame diftances of the magnet, and alfo with other diftances; and he put it paft all difpute, that his conjecture was juft.

Had Mr Lambert's experiments terminated here, it muft be granted that he has made a notable difcovery in the theory of the intimate nature of magnetifm. It completely refutes all the theories which pretend to explain the action of the magnet by the impulfion of a ftream of fluid, or by preffure arifing from the motion of fuch a ftream; for in this cafe the preffure on the needle muft have diminifhed in the duplicate ratio of the fine. The directive power with the angle 90 muft be 4 times greater than with the angle 30°; whereas it was obferved to be only twice as great. Magnetifm does not act therefore by the impulfion or preffure of a ftream of fluid, but in the manner of a fimple incitement, as we conceive attraction or repulfion to act.

Having afcertained the effect of obliquity, Mr Lambert proceeded to examine the effect of diftance; and, by a moft ingenious analyfis of his obfervations, he difcovered, that if we reprefent the force of the magnet by f, and the diftance of the neareft pole of the magnet from the centre of the needle by δ, and if a be a conftant quantity, nearly equal to two-thirds of the length of the needle, we have f proportional to $\overline{\delta - a^2}$.

Mr Lambert found this hold with very great exactnefs with magnets ten times larger, and needles twice as fhort. But he acknowledges, that it gives a very fingular refult, as if the action of a magnet were exerted from a centre beyond itfelf. He attributes this to its true caufe, the ftill great complication of the refult, arifing from the action of the remote pole of the magnet. He therefore takes another method of examination, which we fhall underftand by and bye, when we confider the *directive* power of a magnet. We have mentioned this imperfect attempt chiefly on account of the unqueftionable manner in which he has afcertained the effect of obliquity, and the importance of this determination.

We have attempted this inveftigation in a very fimple manner. We got fome magnets made, confifting of two balls connected by a flender rod. By a very particular mode of impregnation, we gave them a pretty good

 magnet-

magnetifm ; and the force of each pole feemed to refide almoft in the centre of the ball. This was our object in giving them this fhape. It reduced the examination both of the attractive and of the directive power to a very eafy computation. The refult was, that the force of each pole varied in the inverfe duplicate ratio of the diftance The error of this hypothefis in no cafe amounted to $\frac{1}{17}$th of the whole. In computing for the phenomena of the directive power, the irregularities and deviations from this ratio were much fmaller.

The previous knowledge of this function would greatly expedite and facilitate our farther inveftigation ; but we muft content ourfelves with a very imperfect approximation, and with arriving at the defired determination by degrees, and by a very circuitous route.

16 Attempt to explain the phenomena without a precife knowledge of this law.

It is a matter of experience, that when two magnets are taken, each of which is as nearly equal as poffible in the ftrength of both poles, then, if they are placed with their axes in one ftraight line, and the north pole of one fronting the fouth pole of the other, they attract each other with a force which diminifhes as the diftance increafes ; and this variation of force is regular, that is, without any fudden changes of intenfity, till it becomes infenfible. No inftance has occurred of its breaking fuddenly off when of any fenfible force, but it appears to diminifh continually like gravity. No inftance occurs in which attraction is changed into repulfion.

But it is, moreover, to be particularly remarked, that, having made this obfervation with the north pole of A fronting the fouth pole of B, if the experiment be repeated with the fouth pole of A fronting the north pole of B, the refults will be precifely the fame. And, laftly, it is a matter of unexcepted experience, that the fenfible action of A on B, meafured by the force which is neceffary for preventing the farther approach of B, is precifely equal to the action of B on A. This is the cafe, however unequal the force of the two magnets may be ; that is, although A may fupport ten pounds of iron, and B only ten ounces.

Now, the fimpleft view we can take of this experiment is, by fuppofing the whole action of one end or pole of a magnet to be exerted at one point of it. This will give us four actions of A on B, accompanied by as many equal and oppofite actions of B on A. It is plain that we may content ourfelves with the inveftigation of one only of thefe fets of actions.

What we obferve is the excefs of the attractions of the poles of A for the diffimilar poles of B above the repulfions of the fame poles of A for the fimilar poles of B. At all diftances there is fuch an excefs. The fum of the attractions exceeds the fum of the repulfions competent to every diftance.

Now this will really happen, if we fuppofe that the poles of a magnet are of equal ftrength, and that, however thefe different magnets differ in ftrength, they have the fame law of diminution by an increafe of diftance. The firft circumftance is a very poffible thing, and the laft is demonftrated by the obferved equality of action and reaction. Every thing will now appear very plain, by reprefenting (as we did in Electricity, *Suppl.* n° 44, &c.) the intenfities of attraction and repulfion by the ordinates of a curve, of which the abfciffæ reprefent the diftances of the acting poles.

Therefore let A and B (fig. 2.) reprefent the two magnets, placed with their four poles S, N, s, n, in a ftraight line. In the ftraight line O q take O m, O p, O n, O q, refpectively equal to N s, N n, S s, S n ; and let MPNQ be a curve line, having O q for its axis and affymptote ; and let the curve, in every part, be convex towards its axis. Then draw the ordinates m M, p P, n N, q Q, to the curve. Thefe ordinates will reprefent the intenfities of the forces exerted between the poles of the magnets, in fuch a manner as to fulfil all the conditions that are really obferved : For m M reprefents the attraction of the north pole N of the magnet, A for the fouth pole s of the magnet B ; p P reprefents the repulfion of N for n ; n N reprefents the repulfion of S for s ; and q Q reprefents the attraction of S for n. The diftance between m and n, or between p and q, is equal to the length of the magnet A, and m p, or n q, is equal to that of B. M m, P p, and N n, Q q, are pairs of equidiftant ordinates. It furely requires only the infpection of the figure to fee that, in whatever fituation along the axis we place thofe pairs of equidiftant ordinates, the fum of M m and Q q will always exceed the fum of P p and N n ; that is, the fum of the attractions will always exceed that of the repulfions. This will not be the cafe if the curve, whofe ordinates are proportional to the forces, have a point Z of contrary flexure, as is reprefented by the dotted curve P′ZQ′. For this curve, having O q for its affymptote (in order to correfpond with forces which diminifh continually by an increafe of diftance, but do not abruptly ceafe (muft have its convexity turned toward this affymptote in the remote parts. But there will be an arch MPZ between Z and O, which is concave toward the affymptote. In which cafe, it is impoffible that M m + Q q fhall be lefs than P p + N n ; and then the repulfions will exceed the attractions; which is contrary to the whole train of obfervation.

It may be thought, that if the repulfion exerted between two particles be always lefs than the attraction at the fame diftance, the phenomena will be accounted for, although the law of action be not reprefented by fuch a curve as has been affumed. Undoubtedly they will, while the diffimilar poles form each other. But the refults of fuch a fuppofition will not agree with the phenomena while the fimilar poles front each other : For it is an uncontradicted fact, that when two fine hard magnets, whofe poles are nearly or exactly of equal vigour, have their fimilar poles fronting each other, the repulfions fall very little fhort of the attractions at the fame diftances when their pofition is changed: When the diftances are confiderable, fcarcely any difference can be obferved in the beginning of the experiment. The differences, alfo, which are obferved at fmaller diftances, are obferved to augment by continuing the magnets in their places without changing their diftances ; and therefore feem to arife from fome change produced by each on the magnetifm of the other. And, accordingly, if we invert one of the magnets, we fhall find that the attractions have been diminifhed as much as the repulfions. Now, the confequences of magnetic repulfion, being always weaker than attraction, would be the reverfe of this. The differences would appear moft remarkable in the greater diftances, and magnets might be found which repel at fmall diftances, and attract at greater diftances ; which is contrary to all obfervation.

From all this it follows, with fufficient evidence for our

our prefent purpofe, that the function of the diftance which expreffes the law of magnetic action muft be reprefented by the ordinates of a curve of the hyperbolic kind, referred to its affymptote as an axis; and therefore always convex toward this axis. We think it alfo fufficiently clear, that the confequences which we have deduced from the fimple fuppofition of four acting points, inftead of the combined action of every particle, may be adopted with fafety. For they would be juft, if there were only thofe four particles; they would be juft with refpect to another four particles—therefore they would be juft when thefe are joined; and fo on of any number. Therefore the curve, whofe ordinates exprefs the mean action of each pole, as if exerted by its centre of effort, will have the fame general form: It will be convex toward its affymptotic axis.

It will greatly aid our conceptions of the combined actions of the four magnetic poles, if we notice fome of the primary properties of a curve of this kind, limited by no other condition.

17 Unquestionable inferences from the phenomena.

Draw the chords MQ, PN, MP, NQ. Bifect them in B, D, E, F, and join EF. Draw the ordinates E e Ff, and BDb (cutting EF in C. Draw P u parallel to the axis, cutting E e in ι. Draw alfo Q i parallel to the axis, cutting Ff in τ. Alfo draw FHL parallel to the axis, and P o t parallel to QN; and draw PL l, and P e x, cutting M m in l and x.

Let each ordinate be reprefented by the letter at its interfection with the axis. Thus, the ordinates M m and Q q may be reprefented by m and q, &c.

Becaufe MP is bifected in E, M t is double of E ι; M l is double of EL; M x is double of E e. Alfo, becaufe P t is parallel to QN, and P u to Q i, we have $t\,u = N\,i$. From thefe premifes, it is eafy to perceive, that,

1. $Bb = \frac{m+q}{2}$.
2. $Db = \frac{p+n}{2}$.
3. $BD = \frac{\overline{m+q}-\overline{p+n}}{2}$.
4. $Mu = m-p$.
5. $ut = n-q$.
6. $Mt = \overline{m-p}-\overline{n-q}$.
7. $Ee = \frac{m+p}{2}$.
8. $Ff = \frac{n+q}{2}$.
9. $Ml = \overline{m+p}-\overline{n+q}$.
10. $EL = \frac{\overline{m+p}-\overline{n+q}}{2}$.
11. $CD = \frac{\overline{m+q}-\overline{p+n}}{4}$.
12. $CH = \frac{\overline{m+p}-\overline{n+q}}{4}$.

Thefe combinations will fuggeft to the attentive reader the explanation of many modifications of the combined action of the four poles of two magnets. They are all comprehended in one propofition, which it will be convenient to render familiar to the thought; namely, if two pairs of equidiftant ordinates be taken, the fum of the two extremes exceeds that of the intermediate ones. $m+q$ is greater than $p+n$. Alfo, the difference between the pair neareft to O exceeds the difference between the remote pair.

Now, conceiving thefe ordinates to reprefent the mutual actions of the magnetic poles, we fee that their tendency to or from each other, or their fenfible attractions or repulfions, are expreffed by $\overline{m+q}-\overline{n+p}$; that is, by the excefs of the fum of the actions of the neareft and moft remote poles above the fum of the actions of the intermediate diftant poles. It will alfo be frequently convenient to confider this tendency as reprefented by $\overline{m-p}-\overline{n-q}$; that is, by the excefs of the difference of the actions of the neareft pole of A on the two poles of B, above the difference of the actions of its remote pole on the fame poles of B.

Let us now confider fome of the chief modifications of thefe actions.

1. Let the diffimilar poles front each other. It is plain that $m+q$ reprefent attractions, and that $p+n$ reprefent repulfions. Alfo $m+q$ is greater than $p+n$. Therefore the magnets will attract each other. This attraction is alfo reprefented by $\overline{m-p}-\overline{n-q}$. 18 Explanation of the observed attraction of magnets,

Now $m+q-p+n$ is evidently equal to M t, or to twice E o, or to twice BD, or to four times CD.

This action will be increafed,

1. By increafing the ftrength of either of the magnets. The action of the magnets is the combined action of each acting particle of the one on each acting particle of the other; and it is mutual. Therefore all the ordinates will increafe in the ratio of the ftrength of each magnet, and their fums and differences will increafe in the fame ratio.

2. By diminifhing the diftance between the magnets. For this brings all the ordinates nearer to O, while their diftance mp, pn, nq, remain as before. In this cafe it is plain that M u, the difference of M m and Pp, will increafe fafter than $t\,u$ or N i, the difference between N n and Q q. Therefore M t will increafe; that is, the attraction will increafe.

3. By increafing the length of A, while the diftance between them remains the fame. For O m remaining the fame, as alfo mp and nq, while nq is only removed farther from mp, it is plain M u remains the fame, and that N i and $t\,u$ are diminifhed; therefore M t muft increafe, or the attraction muft increafe.

4. By increafing the length of B, the diftance between them remaining the fame. For this increafes mp and nq; and confequently increafes M u and $t\,u$. But M u increafes more than $t\,u$; and therefore M t is increafed, and the attraction or tendency is increafed.

All thefe confequences of our original fuppofition, that the magnetic action may be reprefented by the ordinates of a curve every where convex to an affymptotic axis, are ftrictly conformable to obfervation.

19 And of their repulfions.

If we place the magnets with their fimilar poles fronting each other, it is evident that the ordinates which expreffed attractions in the former cafe, will now exprefs repulfions; and that the forces with which the magnets now repel each other, are equal to thofe with which they attracted when at the fame diftances. When the experiments are made with good loadftones, or very fine magnets, tempered extremely hard, and having the energy of their poles fenfibly refiding in a fmall fpace very near the extremities, the refults are alfo very nearly ly conformable to this mathematical theory; but there is generally a weaker action. The magnets ſeldom repel as ſtrongly as they attract at the ſame diſtance; at leaſt when theſe diſtances are ſmall. If one or both of the magnets is ſoft, or if one of them be much more vigorous than the other, there are obſerved much greater deviations from this theory. The repulſions are *conſiderably* weaker than the attractions at the ſame diſtance, and the law of variation becomes extremely different. When placed at very conſiderable diſtances, they repel. As the magnet B is brought nearer to A, the repulſion increaſes, agreeable to the theory, but not ſo faſt. Bringing them ſtill nearer, the repulſion ceaſes to increaſe, then gradually diminiſhes, and frequently vaniſhes altogether, before the magnets are in contact; and when brought ſtill nearer, it is changed into attraction.

20 Seeming exceptions obviated. But more careful obſervation ſhews, that this anomaly does not invalidate the theory. It is found that the vigour of the magnet is permanently changed by this proceſs. The magnets act on each other in ſuch a way as to weaken each other's magnetiſm. Nay, it frequently happens, that the weaker or the ſofter of the two has had its magnetiſm changed, and that the pole neareſt to the other has changed its nature. While they are lying in contact, or at ſuch a diſtance that they attract, although their ſimilar poles front each other, it is found that the pole of one of them is really changed; although it may ſometimes recover its former ſpecies again, but never ſo vigorouſly as when the other magnet is removed. In ſhort, it is obſerved, that the magnetiſm is diminiſhed in all experiments in which the magnets repel each other, and that it is improved in all experiments in which they attract.

We have hitherto ſuppoſed the magnets placed with their axes in one ſtraight line. If they are differently placed, we cannot aſcertain by this ſingle circumſtance of the law of magnetic action, whether they will attract or repel—we muſt know ſomewhat more of the variation of force by a change of diſtance.

21 Directive power explained. If the magnet B be not at liberty to approach toward A, or recede from it, but be ſo ſupported at its centre B that it can turn round it, it is very plain that it will retain the poſition in which it is drawn in the figure. For its ſouth pole s being more attracted by N than it is repelled by S, is, on the whole, attracted by the magnet A; and, by this attraction, it would vibrate like a pendulum that is ſupported at the centre B. In like manner, its north pole n is more repelled by N than it is attracted by S, and is, on the whole, repelled. The part Bn would therefore alſo vibrate like a pendulum round B. Thus each half of it is urged into the very poſition which it now has; and if this poſition be deranged a little, the attraction of sB toward A, and the repulſion of nB from it, would impel it toward the poſition s B n.

This will be very evident, if we put the magnet B into the poſition s' B n' at right angles to the line AB. The pole s' and the pole n' are urged in oppoſite, and therefore conſpiring, directions with equal forces, very nearly at right angles to $n' s'$, if the magnet B be ſmall. In any oblique poſition, the forces will be ſomewhat unequal, and account muſt be had of the obliquity of the action, in order to know the preciſe rotative momentum of the actions.

Dr Gilbert has given to this modification of the action of A on B, the name of VIS DISPONENS; which we may tranſlate by DIRECTIVE POWER OR FORCE. Alſo, that modification of the tendency of B to or from A is called by him the VERTICITAS of B. We might call it the VERTICITY of B; but we think that the name POLARITY is ſufficiently expreſſive of the phenomenon; and as it has come into general uſe, we ſhall abide by it.

It is not ſo eaſy to give a general, and at the ſame time preciſe, meaſure of the directive power of A and polarity of B. 22 Its meaſure. The magnet B muſt be conſidered as a lever; and then the force tending to bring it into its ultimate poſition $n s$ depends both on the diſtance of its poles from N and S, and alſo on the angle which the axis of B makes with the line AB. When the axis of B coincides with AB, the force acting on its poles, tending to *keep* them in that ſituation, is evidently $\overline{m+p} - \overline{n+q}$, and therefore may be repreſented by M l (in fig. 2.), or by twice EL, or by four times CH. If B has the poſition n'Bs', perpendicular to AB, let the ordinates E e and F f cut the curve on I and K; and draw KL parallel to the axis (our figure cauſes this line almoſt to coincide with QL, and in all important caſes it will be nearly the ſame). In this caſe IL will expreſs one half of this force. Either of theſe eſtimations of this modification of the mutual action of the magnets will be ſufficient for the objects we have in view.

The directive power of A, and the polarity of B, are increaſed, 23 How increaſed and diminiſhed

1. By increaſing the ſtrength of one or both of the magnets. This is evident,

2. By diminiſhing the diſtance of the magnets. For this, by increaſing the ſum of M m and P p more than the ſum of N n and Q q, muſt increaſe EL or M l.

3. By increaſing the length of A. For this, by removing n and q farther from m and p, muſt depreſs the points L and l, and increaſe EL, or IL, or M l.

4. By diminiſhing the length of B, while the diſtance N s between the magnets remains the ſame. For this, by bringing p and q nearer to m and n, muſt increaſe M m + P p more than N n + Q q. Or, by bringing E e and F f nearer to M m and N n, it muſt increaſe EL and M l.

If the diſtance N n between the pole of A and the remote pole of B remain the ſame, the directive force of A, and polarity of B, are diminiſhed by diminiſhing the length of B, as is eaſily ſeen from what has been juſt now ſaid. It is alſo diminiſhed, but in a very ſmall degree, by diminiſhing the length of B, when the diſtance between the centres of A and B remain the ſame. For, in this caſe, the ordinates I e and K f retain their places; but the points m and p approach to e; and this brings the interſection E of the ordinate and chord nearer to I, and diminiſhes EL, becauſe the point L is not ſo much depreſſed by the approach of F to K as E is depreſſed.

But in all caſes, the *ratio* of the directive power of A to its attractive force, or of the polarity of B to its tendency to A, is increaſed by diminiſhing the length of B. For it is plain that by diminiſhing $m p$ and $n q$, while I e and K f keep their places, the point o is raiſed, and the point L is depreſſed; and therefore the ratio of EL to E[illegible] or of M l to M t, is increaſed. We even ſee that, by diminiſhing the length of B continually 24 Circumſtances affecting the proportion of the attractive and directive powers.

and

and without end, the ratio of $M\,l$ to $M\,t$ may be made to exceed any ratio that can be assigned.

25 'he polarity of a nall magnet may be reat while he attraction is insensible.

Now, since diminishing the length of B increases the ratio of the directive power of A to its attractive power, while increasing the length of A increases both, and also increases the ratio of EL to E o (as is very easily seen), and since this increase may be as great as we please, it necessarily follows, that if the same very small magnet B be placed at such distances from a large and strong magnet A, and from a smaller and less vigorous one C, as to have equal polarities to both, its tendency to A will be less than its tendency to C. It may even be less in any ratio we please, by sufficiently diminishing the length of B.

Dr Gilbert observed this; and he expresses his observation by saying, that the directive power extends to greater distances than the attractive power. We must just conclude, that the last becomes *insensible* at smaller distances than the first. This will be found a very important observation. It may be of use to keep in mind, that the directive power of a magnet A on another magnet B, is the difference of the *sums* of the actions of each pole of A on both poles of B; and the attractive power of A for another magnet B, is the difference of the *differences* of these actions.

It may also be remarked just now, that the directive force of A always exceeds its attractive force by the quantity $2\ (p - q)$. For their difference may be expressed by $t\,l$, which is equal to twice o L. Now $\epsilon\,e$ is equal to $P\,p$, or to p; and ϵ L is equal to $P\,p - F\,f$, or to $P\,p - Q\,q - F\,\varphi$, or to $P\,p - Q\,q - o\,\epsilon$. Therefore $o\,L = P\,p - Q\,q$, and $t\,l = 2\,(P\,p - Q\,q)$, $= 2\ (p - q)$.

By inspecting this figure with attention, we obtain indications of many interesting particulars. If the lengths of the magnets A and B are the same, the point n in the axis of the curve will coincide with p. As the length of A increases, the part $n\,q$ is removed farther from the part $m\,p$. The line P t becomes less inclined to the axis, and is ultimately parallel to it, when n is infinitely remote. At this time L falls on e; so that the ultimate ratio of the attraction to the polarity is that of E ϵ to E e, when the magnet A is infinitely long. It is then the ratio of the difference of the actions of the nearest pole of A on the two poles of B to the sum of these actions. Hence it follows, that when A is very great and B very small, the polarity of B is vastly greater than its tendency to A. It may have a great polarity when its tendency is insensible.

The ratio of the polarity to the attraction also increases by increasing the distance of the magnets while their dimensions continue the same. This will appear, by remarking that the chords MP and NQ must intersect in some point ϖ; and that when the four points m, p, n, and q, move off from O, keeping the same distances from each other, E o will diminish faster than EL, and the ratio of EL to EO will continually increase.

Therefore when a small magnet B is placed at such a distance from a great magnet A, and from a smaller one C, as to have equal polarity to both, its tendency to C will exceed its tendency to A. For the polarities being equal, it must be farther from the great magnet; in which case the ratio of its polarity to its attraction is increased.

And this will also obtain if the magnets differ also in strength. For, to have equal polarities, B must be still farther from the great and powerful magnet.

For all these reasons, a large and powerful magnet may exert a strong directive power, while its attractive power is insensible.

We have hitherto supposed the magnet B to be placed in the direction of the axis of A, and only at liberty to turn round its centre B. But let its centre be placed on the centre of A, as in fig. 3. it must evidently take a position which may be called subcontrary to that of A, the north pole of B turning toward the south pole of A, and its south pole turning toward the north pole of A. 26 Peculiarities of oblique positions of two magnets.

The same thing must happen when the centre of B is placed in B, any where in the line AE perpendicular to NS. S attracts n with a force $n\,b$, while N repels n with a force $n\,o$, somewhat smaller than $n\,b$. These two compose the force $n\,d$. In like manner, the two forces $s\,e$ and $s\,f$, exerted by N and S on the pole s, compose the force $s\,q$. Now if the axis of the magnet B be parallel to NS, but the poles in a contrary position, and if each magnet be equally vigorous in both poles, the magnet B will retain this position; because the forces $n\,b$ and $s\,e$ are equal, as also the forces $n\,c$ and $s\,f$. These must compose two forces $n\,d$ and $s\,q$, which are equal, and equally inclined to $n\,s$; and they will therefore be in equilibrio on this lever.

Let us now place the centre of the small magnet in C, neither in the axis of the other, nor in the perpendicular AE. Let its north pole n point toward the centre of A. It cannot remain in this position; for N repels n with a force $n\,c$, while S attracts it with a force $n\,b$ (smaller than $n\,c$, because the distance is greater). These two compose a force $n\,d$ considerably different from the direction $c\,n$ of its axis. In like manner, the south pole s of the small magnet is acted on by two forces $s\,e$ and $s\,f$, exerted by the two poles of A, which compose a force $s\,q$ nearly equal and parallel to $n\,d$, but in a nearly opposite direction. It is plain that these forces must turn the small magnet round its centre C, and that it cannot rest but in a position nearly parallel to $n\,d$ or $s\,f$. Its position is better represented by fig. 4. with its south pole turned toward the north pole of the other magnet, and its north pole in the opposite direction.

What the precise position will be, depends on that function of the distance which is always proportional to the intensity of the action; on the force of each of the poles of A, and on the length of the magnet B. Nay, even when we know this function, the problem is still very intricate.

There are methods by which we may approximate to the function with success. If the magnet B be indefinitely small, so that we may consider the actions on its two poles as equal, the investigation is greatly simplified. For, in this case, each pole of the small magnet B (fig. 5.) may be conceived as coinciding with its centre. Then, drawing NB, SB, and taking B b toward N, to represent the force with which N attracts the south pole of B, and taking B c, in SB produced to represent the force with which S repels the same pole, the compound force acting on this pole is B d, the diagonal of a parallelogram B b, $d\,c$. In like manner, we must take B e, in N b produced, and equal to B b, to 27 Means of acquiring a [?] measure of the law of action.

to reprefent the repulfion of N for the north pole of B, and Bf equal to Bc, to reprefent the attraction of S for this pole. The compound force will be Bg, equal and oppofite to Bd. It follows evidently from this inveftigation, that the fmall magnet will not reft in any pofition but dg. In this fuppofition, therefore, of extreme minutenefs of the magnet B, one of the parallelograms is fufficient. We may farther remark, that we have this approximation fecure againft any error arifing from the fuppofition that all the action of each pole of B is exerted by one point. Although we fuppofe it diffufed over a confiderable portion of the magnet, ftill the extreme minutenefs of the whole makes the action, even on its extreme points, very nearly equal.

28 Law of action inveftigated—MAGNETIC CURVE.

Hence may be derived a conftruction for afcertaining the pofition of the needle, when the function m of the diftance is given, or for difcovering this function by obfervation of the pofition of the needle.

Let NS (fig. 5. n° 2.) meet the direction of the needle in K. Make BG = BN, and draw NF, GE, SH, perpendicular to BK. It is evident that Bb is to Bc, or bd, as the fine of the angle HBS to the fine of KBN. Therefore, becaufe BG and BN are equal, we have $Bb : Bc = GE : NF$.

$$\begin{array}{lll} \text{Therefore } GE : NF & = BS^m & : BN^m \\ \text{But} \quad SH : GE & = BS & : BN \\ \text{Therefore } SH : NF & = BS^{m+1} & : BN^{m+1} \\ \text{And} \quad SK : NK & = BS^{m+1} & : BN^{m+1}. \end{array}$$

If magnetic action be inverfely as the diftance, we have $SK : NK = BS^2 : BN^2$, and B is in the circumference of a circle which paffes through S and N, and has BK for a tangent, as is plain by elementary geometry. If the action be inverfely as the fquare of the diftance, we have $SK : NK = BS^3 : BN^3$, and B is in the circumference of a curve of more difficult inveftigation. But, as in the circle, the fum of the angles BSN and BNS is a conftant angle; fo, in this curve, the fum of the cofines of thofe angles is a conftant quantity. This fuggefts a very fimple conftruction of the curve. Let it pafs through the point T of the line AT, drawn from the centre of the magnet, perpendicular to its axis. Defcribe the femicircle SPQN, cutting ST and NT in P and Q. Then, in order to find the point where any line SB cuts the curve, let it cut the femicircle in p, and apply the line $Nq = SP + NQ - Sp$, and produce it till it meet the line SB in B, which is a point in the curve; for it is evident that Sp and Nq are the cofines of BSN and BNS. We hope to give, by the help of a learned friend, the complete conftruction of curves for every value of m, in an Appendix to this article. It will form a new and curious clafs, arranged by the functions of the angles at N and S.

But, in the mean time, we have determined the pofition of an indefinitely fmall needle, in refpect of a magnet of which we may conceive the polar activity concentrated in two points; and we may, on the other hand, make ufe of the obferved pofitions of fuch a needle and magnet for difcovering the value of m. For, fince $\frac{SK}{NK} = \frac{SB^{m+1}}{NB^{m+1}}$, it is plain that $m = \frac{\text{Log. } SK : NK}{\text{Log. } SB : NB} - 1$. Thus, in an obfervation which the writer of this article made on a very fmall needle, and a magnet having globular poles, and $8\frac{1}{8}$ inches between their centres, he found $SB = 5\frac{1}{3}$, $NB = \frac{1}{3}$, $SK = 11,49$, and $NK = 3,37$. This gives $m = 1,97$, which differs from 2 only $\frac{1}{60}$th part. Finding it fo very near the inverfe duplicate ratio of the diftance, a circle VUZ was defcribed, the circumference of which is the locus of $SB : BN = 8 : 5,333$. When the centre of the needle was placed anywhere in the circumference of this circle, it fcarcely deviated from the point K, except when fo far removed from the magnet that its natural polarity prevailed over the directive power of the magnet, or fo near its middle that the action of the cylindrical part became very fenfible.

It is plain that the length of the needle muft occafion fome deviation from the magnetic direction, by deftroying the perfect equality of action on its two poles. He therefore employed three needles of $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{1}{4}$ of an inch in length; and by noticing the differences of direction, he inferred what would be the direction, if the forces on each pole were precifely equal. He had the pleafure of feeing that the deviation from the inverfe duplicate ratio of the diftances was fcarcely perceptible.

Mr Lambert's experiments on the directive power of the magnet, narrated in his fecond differtation in the 22d volume of the memoirs of the Academy of Berlin, are the moft valuable of all that are on record; and the ingenious addrefs with which they are conducted, and the inferences are drawn, would have done credit to Newton himfelf. We earneftly recommend the careful perufal of that Effay, as the moft inftructive of any that we have read. The writer of this found himfelf obliged to repeat all his former experiments, mentioned above, in Mr Lambert's manner, and with his precaution of keeping the needle in its natural pofition; a circumftance to which he had not fufficiently attended before. The new refults were ftill more conformable to his conjecture as to the law of variation. Mr Lambert clofes his differtation with an hypothefis, " that the force of each tranfverfe element of a magnet is as its diftance from the centre, and its action on a particle of another magnet is inverfely as the fquare of the diftance." On this fuppofition, he calculates the pofition of a very fmall needle, and draws three of the curves to which it fhould be the tangent. Thefe are very exactly coincident with fome that he obferved. We tried this with feveral magnetic bars, and found it very conformable to obfervation in fome magnets; but deviating fo far in the cafe of other magnets, that we are convinced that there is no rule for the force of each tranfverfe element of a magnet, and that the magnetifm is differently difpofed in different magnets. It was chiefly this which induced us to form the magnets employed in this refearch of two balls united by a flender rod. Lichtenberg, in his notes on Erxleben's Natural Philofophy, fays, that there is a MS of the celebrated Tobias Mayer in the library of the Academy of Gottingen, in which he affumes the hypothefis above mentioned, and gives a conftruction of the magnetic curves founded on it, making them a kind of catenaria. The interior curves do indeed refemble the catenaria, but the exterior are totally unlike. But there is no occafion for much argument to convince us, that the firft part of this hypothefis is not only gratuitous, but unwarranted by any general phenomena. We know that a magnetical bar may have its magnetifm very differently difpofed; for it may have more than two poles, and the intermediate poles *cannot* have this difpofition of the magnetifm.

netifm. Such a difpofition is perhaps poffible; but is by no means general, or even frequent. We are difpofed to think, that permanent magnetifm muft have its intenfity diminifhing in the very extremity of the bar. The reader may guefs at our reafons from what is faid in ELECTRICITY, *Suppl.* n° 222.

29 PRIMARY and SECONDARY, or SIMPLE and COMPOUND curves.

The following very curious and inftructive phenomenon was the firft thing which greatly excited the curiofity of the writer of this article, and long puzzled him to explain it. Indeed it was his endeavours to explain it which gradually opened up to him the theory of the mutual action of magnets contained in thefe paragraphs, and firft gave him occafion to admire the fagacity of Dr Gilbert, and to fee the connecting principle of the vaft variety of obfervations and experiments which that philofopher had made. It feems owing to the want of this connecting principle, that a book fo rich in facts fhould be fo little read, and that fo many of Dr Gilbert's obfervations have been publifhed by others as new difcoveries.

Amufing himfelf in the fummer 1758 with magnetic experiments, two large and ftrong magnets A and B (fig. 6), were placed with their diffimilar poles fronting each other, and about three inches apart. A fmall needle, fupported on a point, was placed between them at D, and it arranged itfelf in the fame manner as the great magnets. Happening to fet it off to a good diftance on the table, as at F, he was furprifed to fee it immediately turn round on its pivot, and arrange itfelf nearly in the oppofite direction. Bringing it back to D reftored it to its former pofition. Carrying it gradually out along DF, perpendicular to NS, he obferved it to become fenfibly more feeble, vibrating more flowly; and when in a certain point E, it had no polarity whatever towards A and B, but retained any pofition that was given it. Carrying it farther out, it again acquired polarity to A and B, but in the oppofite direction; for it now arranged itfelf in a pofition that was parallel to NS, but its north pole was next to N, and its fouth pole to S.

This fingular appearance naturally excited his attention. The line on which the magnets A and B were placed had been marked on the table, as alfo the line DF perpendicular to the former. The point E was now marked as an important one. The experiments were interrupted by a friend coming in, to whom fuch things were no entertainment. Next day, wifhing to repeat them to fome friends, the magnets A and B were again laid on the line on which they had been placed the day before, and the needle was placed at E, expecting it to be neutral. But it was found to have a confiderable verticity, turning its north pole toward the magnet B; and it required to be taken farther out, toward F, before it became neutral. While ftanding there, fomething chanced to joggle the magnets A and B, and they inftantly rufhed together. At the fame inftant, the little magnet or needle turned itfelf brifkly, and arranged itfelf, as it had done the day before, at F, quivering very brifkly, and thus fhewing great verticity. This naturally furprifed the beholders; and we now found that, by gradually withdrawing the magnets A and B from each other, the needle became weaker—then became neutral—and then turned round on its pivot, and took the contrary pofition. It was very amufing to obferve how the fimply feparating the magnets A and B, or bringing them together, made the needle affume fuch a variety of pofitions and degrees of vivacity in each.

The needle was now put in various fituations, in refpect to the two great magnets; namely, off at a fide, and not in the perpendicular DF. In thefe fituations, it took an inconceivable variety of pofitions, which could not be reduced to any rule; and in moft of them it required only a motion of one of the great magnets for an inch or two, to make the needle turn brifkly round on its pivot, and affume a pofition nearly oppofite to what it had before.

But all this was very puzzling, and it was not till after feveral months that the writer of this article, having conceived the notion of the magnetic curves, was in a condition to explain the phenomena. With this affiftance, however, they are very clear, and very inftructive.

Nothing hinders us from fuppofing the magnets A and B perfectly equal in every refpect. Let NHM, NEL, be two magnetic curves belonging to A; that is, fuch that the needle arranges itfelf along the tangent of the curve. Then the magnet B has two curves SGK, SEI, perfectly equal, and fimilar to the other two. Let the curves NHM and SGK interfect in C and F. Let the curves NEL and SEI touch each other in E.

The needle being placed at C, would arrange itfelf in the tangent of the curve KGS, by the action of B alone, having its north pole turned toward the fouth pole S of B. But, by the action of A alone, it would be a tangent to the curve NHM, having its north pole turned away from N. Therefore, by the combined action of both magnets, it will take neither of thefe pofitions, but an intermediate one, nearly bifecting the angle formed by the two curves, having its north pole turned toward B.

But remove the needle to F. Then, by the action of the magnet A, it would be a tangent to the curve FM, having its north pole toward M. By the action of B, it would be a tangent to the curve KFG, having its north pole in the angle MFG, or turned toward A. By their joint action, it takes a pofition nearly bifecting the angle GFM, with its north pole toward A.

Let the needle be placed in E. Then, by the action of the magnet A, it would be a tangent to the curve NEL, with its north pole pointing to F. But, by the action of B, it will be a tangent to SEI, with its north pole pointing to D. Thefe actions being fuppofed equal and oppofite, it will have no verticity, or will be neutral, and retain any pofition that is given to it.

The curve SEI interfects the curve NHM in P and Q. The fame reafoning fhews, that when the needle is placed at P, it will arrange itfelf with its north pole on the angle SPH: but, when taken to Q, it will ftand with its north pole in the angle EQM.

From thefe facts and reafonings we muft infer, that, for every diftance of the magnets A and B, there will be a feries of curves, to which the indefinitely fhort needle will always be a tangent. They will rife from the adjoining poles on both fides, croffing diagonally the lozenges formed by the PRIMARY or SIMPLE curves, as in fig. 6. Thefe may be called COMPOUND or SECONDARY magnetic curves. Moreover, thefe fecondary curves will be of two kinds, according as they paſs through the firſt or ſecond interſections of the primary curves, and the needle will have oppoſite poſitions when placed on them. Theſe two ſets of curves will be ſeparated by a curve GEH, in the circumference of which the needle will be neutral. This curve paſſes through the points where the primary curves touch each other. We may call this the *line of neutrality* or inactivity.

We now ſee diſtinctly the effect of bringing the magnets A and B nearer together, or ſeparating them farther from each other. By bringing them nearer to each other, the point E, which is now a point of neutrality, may be found in the *ſecond* interſection (ſuch as F) of two magnetic curves, and the needle will take a ſubcontrary poſition. By drawing them farther from each other, E may be in the *firſt* interſection of two magnetic curves, and the needle will take a poſition ſimilar to that of C.

If the magnets A and B are not placed ſo as to form a ſtraight line with their four poles, but have their axes making an angle with each other, the contacts and interſections of their attending curves may be very different from thoſe now repreſented; and the poſitions of the needle will differ accordingly. But it is plain, from what has been ſaid, that if we knew the law of action, and conſequently the form of the primary curves, we ſhould always be able to ſay what will be the poſition of the needle. Indeed, the conſideration of the ſimple curves, although it was the mean of ſuggeſting to the writer of this article the explanation of thoſe more complicated phenomena, is by no means neceſſary for this purpoſe. Having the law of magnetic action, we muſt know each of the eight forces by which the needle is affected, both in reſpect of direction and intenſity; and are therefore able to aſcertain the ſingle force ariſing from their compoſition.

Secondary curves of repulſion. When the ſimilar poles of A and B are oppoſed to each other, it is eaſy to ſee, that the poſition of the needle muſt be extremely different from what we have been deſcribing. When placed anywhere in the line DF, between two magnets, whoſe north poles front each other in N and S, its north pole will always point away from the middle point D. There will be no neutral point E. If the needle be placed at P or Q, its north pole will be within the angle EPH, or FQI. This poſition of the magnets gives another ſet of ſecondary curves, which alſo croſs the primary curves, paſſing diagonally through the lozenges formed by their interſection. But it is the other diagonal of each lozenge which is a chord to thoſe ſecondary curves. They will, therefore, have a form totally different from the former ſpecies.

30 Remarks on this inveſtigation. The conſideration of this compound magnetiſm is important in the ſcience, both for explaining complex phenomena, and for advancing our knowledge of the great deſideratum, the law of magnetic action. It ſerves this purpoſe remarkably. By employing a very ſmall needle, the points of neutrality aſcertain very nearly where the magnetic curves have a common tangent, and ſhews the poſition of this tangent. By placing the two magnets ſo as to form various angles with each other, we can, by means of theſe neutral points, know the poſition of the tangent in every point of the curve, and thus can aſcertain the form of the curve, and the law of action, with conſiderable accuracy. The writer of this article took this method; and the reſult confirmed him in the opinion, that it was in the inverſe duplicate ratio of the diſtances. The chief (perhaps the only) ground of error ſeemed to be the difficulty of procuring large magnets, having the action of each pole very much concentrated. Large magnets muſt be employed. He attempted to make ſuch, conſiſting of two ſpherical balls, joined by a ſlender rod. But he could not give a ſtrong magnetiſm to magnets of this form, and was forced to make uſe of common bars, the poles of which are conſiderably diffuſed. This diffuſion of the pole renders it very difficult to ſelect with propriety the points from which the diſtances are to be eſtimated, in the inveſtigation of the relation between the forces and diſtances.

He tried another method for aſcertaining this ſo much deſired law, which had alſo the ſame reſult. Having made a needle conſiſting of two balls joined by a ſlender rod, and having touched it with great care, ſo that the whole ſtrength of its poles ſeemed very little removed from the centres of the balls, he counted the number of horizontal vibrations which it made in a given time by the force of terreſtrial magnetiſm. He then placed it on the middle of a very fine and large magnet, placed with its poles in the magnetic meridian, the north pole pointing ſouth. In this ſituation he counted the vibrations made in a given time. He then raiſed it up above the centre of the large magnet, till the diſtance of its poles from thoſe of the great magnet were changed in a certain proportion. In this ſituation its vibrations were again counted. It was tried in the ſame way in a third ſituation, conſiderably more remote from the great magnet. Then, having made the proper reduction of the forces correſponding to the obliquity of their action, the force of the poles of the great magnet was computed from the number of vibrations. To ſtate here the circumſtances of the experiment, the neceſſary reductions, and the whole computations, would occupy ſeveral pages, and to an intelligent reader would anſwer little purpoſe. Mr Lambert's excellent diſſertation in the 22d vol. of the *Mem. de l'Acad. de Berlin*, will ſhew the prolixity and intricacy of this inveſtigation. Suffice it to ſay, that theſe experiments were the moſt conſiſtent with each other of any made by the writer of this article, with the view of aſcertaining the law of magnetic action; and it is chiefly from their reſult that he thinks himſelf authoriſed to ſay, with ſome confidence, that it is inverſely as the ſquare of the diſtance. Theſe experiments were firſt made in a rough way in 1769 and 1770. In 1775, obſerving that Mr Æpinus ſeemed to think the action inverſely as the diſtance (ſee his *Tentam. Theor. Electr. et Magn.* § 301. &c.), they were repeated with very great care; and to theſe were added another ſet of experiments, made with the ſame magnet and the ſame needle, placed not above the magnet, but at one ſide (but always in the line through the centre, perpendicular to the axis, ſo that the actions of the two poles might be equal). This diſpoſition evidently ſimplifies the proceſs exceedingly. The reſult of the whole was ſtill more ſatisfactory. This concluſion is alſo confirmed by the experiments of Mr Coulomb in the Memoirs of the Academy of Sciences at Paris for 1786 and 1787. It would ſeem therefore to be pretty well eſtabliſhed. Another method, which ſeems ſuſceptible of

conſiderable

conſiderable accuracy, ſtill remains to be tried. It will be mentioned in due time.

Such then are the general laws obſerved in the mutual action of magnets. We think it ſcarcely neceſſary to enter into a farther detail of their conſequences, correſponding to the innumerable varieties of poſitions in which they may be placed with reſpect to each other. We are confident, that the ſenſible actions will always be found agreeable to the legitimate conſequences of the general propoſitions which we have eſtabliſhed in the preceding paragraphs. We proceed therefore to conſider ſome phyſical facts not yet taken notice of which have great influence on the phenomena, and greatly aſſiſt us in our endeavours to underſtand ſomething of their remote cauſe.

31 agnetiſm tempora- and pe- hing.

Magnetiſm, in all its modifications of attraction, repulſion, and direction, is, in general, of a temporary or periſhing nature. The beſt loadſtones and magnets, unleſs kept with care, and with attention to certain circumſtances, are obſerved to diminiſh in their power. Natural loadſtones, and magnets made of ſteel, tempered as hard as poſſible, retain their virtue with greateſt obſtinacy, and ſeldom loſe it altogether, unleſs in ſituations which our knowledge of magnetiſm teaches us to be unfavourable to its durability. Magnets of tempered ſteel, ſuch as is uſed for watch-ſprings, are much ſooner weakened, part with a greater proportion of their force by ſimple keeping, and finally retain little or none. Soft ſteel and iron loſe their magnetiſm almoſt as ſoon as its producing cauſe is removed, and cannot be made to retain any ſenſible portion of it, unleſs their metallic ſtate ſuffer ſome change.

Hurt by roper tion.

1. Nothing tends ſo much to impair the power of a magnet as the keeping it in an improper poſition. If its axis be placed in the magnetic direction, but in a contrary poſition, that is, with the north pole of it where the ſouth pole tends to ſettle, it will grow weaker from day to day; and unleſs it be a natural loadſtone, or be of hard tempered ſteel, it will, after no very long time, loſe its power altogether.

By heat; ects of nder electri-

2. This diſſipation of a ſtrong magnetic power is greatly promoted by heat. Even the heat of boiling water affects it ſenſibly; and if it be made red hot, it is entirely deſtroyed. This laſt fact has long been known. Dr Gilbert tried it with many degrees of violent heat, and found the conſequences as now ſtated; but having no thermometers in that dawn of ſcience, he could not ſay any thing preciſe. He only obſerves, that it is deſtroyed by a heat not ſufficient to make it viſible in a dark room. Mr Canton found even boiling water to weaken it; but on cooling again the greateſt part was recovered.

By vio- treat- nt.

3. What is more remarkable, magnetiſm is impaired by any rough uſage. Dr Gilbert found, that a magnet which he had impregnated very ſtrongly, was very much impaired by a ſingle fall on the floor; and it has been obſerved ſince his time, that falling on ſtones, or receiving any concuſſion which cauſes the magnet to ring or ſound, hurts it much more than beating it with any thing ſoft and yielding. Grinding a natural loadſtone with coarſe powders, to bring it into ſhape, weakens it much; and loadſtones ſhould therefore be reduced into a ſhape as little different from their natural form as poſſible; and this ſhould be done briſkly, cutting them with the thin diſks of the lapidary's wheel, cutting off only what is neceſſary for leaving their moſt active parts or poles as near their extremities as we can.

All theſe cauſes of the diminution of magnetiſm are more operative if the magnet be all the while in an improper poſition.

4. Laſtly, magnetiſm is impaired and deſtroyed by placing the magnet near another magnet, with their ſimilar poles fronting each other. We have had occaſion to remark this already, when mentioning the experiments made with magnets in this poſition, for aſcertaining the general laws or variations of their repulſion. We there obſerved, that magnets ſo ſituated always weakened each other, and that a powerful magnet often changed the ſpecies of the neareſt pole of one leſs powerful. This change is recovered, in part at leaſt, when it has taken place in a loadſtone or a magnet of hard ſteel; but in ſpring tempered ſteel the change is generally permanent, and almoſt to the full extent of its condition while the magnets are together. It is to be remarked, that this change is gradual; and is expedited by any of the other cauſes, particularly by heat or by knocking. 4. By other magnets.

32 Magnetiſm may be acquired.

On the other hand, magnetiſm is acquired by the ſame means, when ſome other circumſtances are attended to.

1. A bar of iron, which has long ſtood in the magnetic direction, or nearly ſo, will gradually acquire magnetiſm, and the ends will acquire the polarity correſponding to their ſituation. In this country, and the north of Europe, the old ſpindles of turret vanes, old bars of windows, &c. acquire a ſenſible magnetiſm; their lower extremity becoming a north pole, and the other end a ſouth pole. Gilbert ſays, that this was firſt obſerved in Mantua, in the vane ſpindle of the Auguſtine church—"*Vento flexa* (ſays he) *de prompta et apothecario cuidam conceſſa, attrahebat ferrea ramenta, vi perquam inſigni.*" The upper bar of a hand rail to a ſtair on the north ſide of the higheſt part of the ſteeple of St Giles's church in Edinburgh is very magnetical; and the upper end of it, where it is lodged in the ſtone, is a vigorous ſouth pole. It is worth notice, that the parts of ſuch old bars acquire the ſtrongeſt magnetiſm when their metallic ſtate is changed by expoſure to the air, becoming foliated and friable. It would be worth while to try, whether the æthiops martialis, produced by ſteam in the experiments for decompoſing water, will acquire magnetiſm during its production. The pipe and the wires, which are converted into the ſhining æthiops ſhould be placed in the magnetic direction. 1 By magnetical poſition;

2. If a bar of ſteel be long hammered while lying in the magnetic direction, it acquires a ſenſible magnetiſm (See Dr Gilbert's plate, repreſenting a blackſmith hammering a bar of iron in the magnetic direction). The points of drills, eſpecially the great ones, which are urged by very great preſſure; and broaches, worked by a long lever, ſo as to cut the iron very faſt, acquire a ſtrong magnetiſm, and the lower end always becomes the north pole (*Phil. Tranſ.* xx. 417.) Even driving a hard ſteel punch into a piece of iron, gives it magnetiſm by a ſingle blow. In ſhort, any very violent ſqueeze given to a piece of tempered ſteel renders it magnetic, and its polarity correſponds with its poſition during the experiment. We can ſcarcely take up a cutting or boring tool in a ſmith's ſhop that is not magnetical. Even 2. By hammering;

ſoft ſteel and iron acquire permanent magnetiſm in this way. Iron alſo acquires it by twiſting and breaking. It is therefore difficult to procure pieces of iron or ſteel totally void of determinate and permanent magnetiſm; and this frequently mars the experiments mentioned in the firſt paragraphs of this article. The way therefore to enſure ſucceſs in theſe experiments is to deprive the rods of their accidental magnetiſm, by ſome of the methods mentioned a little ago. Let them be heated red hot, and allowed to cool while lying in a direction perpendicular to the magnetic direction (nearly E. N. E. and W. S. W. in this country).

3. By heating; 3. As heat is obſerved to deſtroy magnetiſm, ſo it may alſo be employed to induce it on ſubſtances that are ſuſceptible of magnetiſm. Dr Gilbert makes this obſervation in many parts of his work. He ſays, that the ores of iron which are in that particular metallic ſtate which he conſiders as moſt ſuſceptible of magnetiſm, will acquire it by long continuance in a red heat, if laid in the magnetic direction, and that their polarity is conformable to their poſition, that end of the maſs which is next the north becoming the north pole. He alſo made many experiments on iron and ſteel bars expoſed to ſtrong heats in the magnetical direction. Such experiments have been made ſince Gilbert's time in great number. Dr Hooke, in 1684, made experiments on rods of iron and ſteel one-fifth of an inch in diameter, and ſeven inches long. He found them to acquire permanent magnetiſm by expoſure to ſtrong heat in the magnetic direction, and if allowed to cool in that direction. But the magnetiſm thus acquired by ſteel rods was much ſtronger, and more permanent, if they were ſuddenly quenched with cold water, ſo as to temper them very hard. He found, that the end which was next to the north, or the lower end of a vertical bar, was always its permanent north pole. Even quenching the upper end, while the reſt was ſuffered to cool gradually, became a very ſenſible ſouth pole. No magnetiſm was acquired if this operation was performed on a rod lying at right angles to the magnetical direction.

In theſe trials the polarity was always eſtimated by the action on a mariner's needle, and the intenſity of the magnetiſm was eſtimated by the deviation cauſed in this needle from its natural poſition. Dr Gilbert made a very remarkable obſervation, which has ſince been repeated by Mr Cavallo, and publiſhed in the Philoſophical Tranſactions as a remarkable diſcovery. Dr Gilbert ſays, p. 69. "*Bacillum ferreum, valide ignitum appone verſorio excito; ſtat verſorium, nec ad tale ferrum convertitur: ſed ſtatim ut primum de candore aliquantulum remiſerit, confluit illico.*" In ſeveral other parts of his treatiſe he repeats the ſame thing with different circumſtances. It appears, therefore, that while iron is red hot, it is not ſuſceptible of magnetiſm, and that it is during the cooling in the magnetic direction that it acquires it. Gilbert endeavoured to mark the degree of heat moſt favourable for this purpoſe; but being unprovided with thermometers, he could not determine any thing with preciſion. He ſays, that the verſorium, or mariner's needle, was moſt deranged from its natural poſition a little while after the bar of iron ceaſed to ſhine in day light, but was ſtill pretty bright in a dark room. But there are other experiments which we have made, and which will be mentioned by and bye; by which it appears, that although a bright red or a white heat makes iron unſuſceptible of magnetiſm while in that ſtate, it prediſpoſes it for becoming magnetical. When a bar of ſteel was made to acquire magnetiſm by tempering it in the magnetical direction, we found that the acquired magnetiſm was much ſtronger when the bar was made firſt of all very hot, even although allowed to come to its moſt magnetical ſtate before quenching, than if it had been heated only to that degree; nay, we always found it ſtronger when it was quenched when red hot. We offer no explanation at preſent; our ſole buſineſs juſt now being to ſtate facts, and to generalize them, in the hopes of finding ſome fact which ſhall contain all the others.

4. The moſt diſtinct acquiſitions and changes of magnetiſm are by juxtapoſition to other magnets and to iron. 4. By juxtapoſition. As the magnetiſm of a loadſtone or magnet is weakened by bringing its pole near the ſimilar pole of another magnet, it is improved by bringing it near the other pole; and it is always improved by bringing it near any piece of iron or ſoft ſteel.

But this action, and the mutual relation of magnets and common iron, being the moſt general, and the moſt curious and inſtructive of all the phenomena of magnetiſm, they merit a very particular conſideration.

Of the communication of Magnetiſm.

33 Communication of magnetiſm.

THE whole may be comprehended in one propoſition, which may be ſaid to contain a complete theory of magnetiſm.

Fundamental propoſition.

Any piece of iron, when in the neighbourhood of a magnet, is a magnet, and its polarity is ſo diſpoſed that the magnet and it mutually attract each other.

The phenomena which reſult from this fundamental principle are infinitely various, and we muſt content ourſelves with deſcribing a ſimple caſe or two, which will ſufficiently enable the reader to explain every other.

34. Attractive power communicated.

Take a large and ſtrong magnet NAS (fig. 7.), of which N is the north, and S the ſouth pole. Let it be properly ſupported in a horizontal poſition, with its poles free, and at a diſtance from iron or other bodies. Take any ſmall piece of common iron, not exceeding two or three inches in length, ſuch as a ſmall key. Take alſo another piece of iron, ſuch as another ſmaller key, or a bit of wire about the thickneſs of an ordinary quill.

1. Hold the key horizontally, near one of the poles, (as ſhewn at n° 1.), taking care not to touch the pole with it; and then bring the other piece of iron to the other end of the key (it is indifferent which pole is thus approached with the key, and which end of the key is held near the pole). The wire will hang by the key, and will continue to hang by it, when we gradually withdraw the key horizontally from the magnet, till, at a certain diſtance, the wire will drop from the key, becauſe the magnetiſm imparted from this diſtance is too weak. That this is the ſole reaſon of its dropping, will appear by taking a ſhorter, or rather a ſlenderer, bit of wire, and touch the remote end of the key with it: it will be ſupported, even though we remove the key ſtill farther from the magnet.

2. Hold the key *below* one of the poles, as at n° 2. or 3. and touch its remote end with the wire. It will be ſuſpended in like manner, till we remove the key too far from the magnet.

3. Hold

3. Hold the key *above* the poles, as at n° 4. or 5. and touch its adjacent end with the wire (taking care that the wire do not alſo touch the magnet). The wire will ſtill be ſupported by the key, till both are removed too far from the magnet.

Thus it appears that, in all theſe ſituations, the key has ſhewn the characteriſtic phenomenon of magnetiſm, namely, attraction for iron. In the experiment with the key held above the pole, the wire is in the ſame ſituation in reſpect to magnetiſm as the key is when held below the pole; but the actions are mutual. As the key attracts the wire, ſo the wire attracts the key.

If the magnet be ſupported in a vertical poſition, as in fig. 8. the phenomena will be the ſame; and when the key is held directly above or directly below the pole, it will carry rather a heavier wire than in the horizontal poſition of the magnet and key.

Inſtead of approaching the magnet with the key and wire, we may bring the magnet toward them, and the phenomena will be ſtill more palpable. Thus, if the bit of wire be lying on the table, and we touch one end of it with the key, they will ſhew no connection whatever. While we hold the key very near one end of the wire, bring down the pole of a magnet toward the key, and we ſhall then ſee the end of the wire riſe up and ſtick to the key, which will now ſupport it. In like manner, if we lay a quantity of iron filings on the table, and touch them with the key, in the abſence of the magnet, we find the key totally inactive. But, on bringing the magnet anyhow near the key, it immediately attracts the iron filings, and gathers up a heap of them.

35 Alſo a directive power.

In the next place, this vicinity of a magnet to a piece of iron gives it a directive power. Let NAS (fig. 9.) be a magnet, and BC (n° 1.) a key held near the north pole, and in the direction of the axis. Bring a very ſmall mariner's needle, ſupported on a ſharp point, near the end C of the key which is fartheſt from N. We ſhall ſee this needle immediately turn its ſouth pole towards C, and its north pole away from C. This poſition of the needle is indicated at *c*, by marking its north pole with a dart, and its ſouth with a croſs. Thus it appears that the key has got a directive power like a magnet, and that the end C is performing the office of a north pole, attracting the ſouth pole of the needle, and repelling its north pole. It may indeed be ſaid, that the needle at *c* arranges itſelf in this manner by the directive power of the magnet; for it would take the ſame poſition although the key were away. But if we place the needle at *b*, it will arrange itſelf as there repreſented, ſhewing that it is influenced by the key, and not (wholly at leaſt) by the magnet. In like manner, if we place the needle at *a*, we ſhall ſee it turn its north pole toward B, notwithſtanding the action of the magnet on it. This action evidently tends to turn its north pole quite another way: but it is influenced by B, and B is performing the office of a ſouth pole.

In like manner, if we place the key as at n° 2. we ſhall obſerve the end B attract the ſouth pole of the needle placed at *a*, and the end C attract the north pole of a needle placed in *b*. In this ſituation of the key, we ſee that B performs the office of a north pole, and C performs the office of a ſouth pole.

Thus it appears that the key in both ſituations has become a magnet, poſſeſſed of both an attractive and a directive power. It has acquired two poles.

36 The attraction of iron is owing to the diſpoſition of its own temporary magnetiſm.

Laſtly, the magnetiſm of the key is ſo diſpoſed that the two magnets NAS and BC muſt mutually attract each other; for their diſſimilar poles front each other. Now, it is a matter of uniform and uncontradicted obſervation, that when a piece of iron is thus placed near a magnet, and the diſpoſition of its magnetiſm is thus examined by means of a mariner's needle, the diſpoſition is ſuch that two permanent magnets with their poles ſo diſpoſed muſt attract each other. The piece of iron, therefore, having the ſame magnetic relation to the magnet that a ſimilar and ſimilarly diſpoſed magnet has, muſt be affected in the ſame manner. We cannot, by any knowledge yet contained in this article, give any preciſe intimation in what way the polarity of the piece of iron will be diſpoſed. This depends on its ſhape as much as on its poſition. By deſcribing two or three examples, a notion is obviouſly enough ſuggeſted, which, although extremely gratuitous, and perhaps erroneous, is of ſervice, becauſe it has a general analogy with the obſerved appearances.

If one end of a ſlender rod or wire be held near the north pole of the magnet, while the rod is held in the direction of the axis (like the key in fig. 7. n° 1.), the near end becomes a ſouth, and the remote end a north pole. Keeping this ſouth pole in its place, and turning the rod in any direction from thence, as from a centre, the remote end is always a north pole. And, in general, the end of any oblong piece of iron which is neareſt to the pole of a magnet becomes a pole of the oppoſite name, while the remote end becomes a pole of the ſame name with that of the magnet.

If the iron rod be held perpendicularly to the axis, with its middle very near the north pole of the magnet, the two extremities of the iron become north poles, and the middle is a ſouth pole.

If the north pole of a magnet be held perpendicular to the centre of a round iron plate, and very near it, this plate will have a ſouth pole in its centre, and every part of its circumference will have the virtue of a north pole.

If the plate be ſhaped with points like a ſtar, each of theſe points will be a very diſtinct and vigorous north pole.

Something like this will be obſerved in a piece of iron of any irregular ſhape. The part immediately adjoining to the north pole of the magnet will have the virtue of a ſouth pole, and all the remote protuberances will be north poles.

The notion naturally ſuggeſted by theſe appearances is, that the virtue of a north pole ſeems to reſide in ſomething that is moveable, and that is protruded by the north pole of the magnet toward the remote parts of the iron; and is thus conſtipated in all the remote edges, points, and protuberances, much in the ſame manner as electricity is obſerved to be protruded to the remote parts and protuberances of a conducting body by the preſence of an overcharged body. This notion will greatly aſſiſt the imagination; and its conſequences very much reſemble what we obſerve.

As a farther mark of the complete communication of every magnetic power by mere vicinity to a magnet, we may here obſerve that the wire D, of fig. 7. n° 2. and 3. will ſupport another wire, and this another; and ſo,

on,

on, to a number depending on the ſtrength of the magnet. The key has therefore become a true magnet in every reſpect; for it induces complete magnetiſm on the appended wire. That this is not the ſame operation of the great magnet (at leaſt not wholly ſo), appears by examining the magnetiſm of D with the needle, which will be ſeen to be more influenced by D than by A. This fact has been long known. The ancients ſpeak of it: They obſerve, that a loadſtone cauſes an iron ring to carry another ring, and that a third; and ſo on, till the ſtring of rings appears like a chain.

37 Exception explained. What has now been ſaid will explain a ſeeming exception to the univerſality of the propoſition. If the key be held in the ſituation and poſition repreſented by fig. 10. the bit of wire will not be attracted by it; and we may imagine that it has acquired no magnetiſm: But if we bring a mariner's needle, or a bit of wire, near to its remote end B, it will be ſtrongly attracted, and ſhew B to be a north pole. The needle held near to C will alſo ſhew C to be a ſouth pole. Alſo, if held near to D, it will ſhew D to be a north pole. Now the ends C, both of the key and of the wire, being ſouth poles, they cannot attract each other, but, on the contrary, they will repel; and therefore the wire will not adhere to the key. And if the key of fig. 17. n° 4. with the wire hanging to it, be gradually carried outward, beyond the north pole of the magnet, and then brought down till its lower end be level with the pole, the wire will drop off.

There is however, one exception to the propoſition. If the key in fig. 7. with its appending wire D, be gradually carried from any of the ſituations 2, 3, 4, or 5, toward the middle of the magnet, the wire will drop off whenever it arrives very near the middle. If we ſuppoſe a plane to paſs through the magnetic centre A', perpendicular to the axis (which plane is very properly called the magnetic equatorial plane by Gilbert), a ſlender piece of iron, held anywhere in this plane, acquires no ſenſible magnetiſm. It gives no indication of any polarity, *and it is not attracted by the magnet.* It is well known, that the activity of a loadſtone or magnet reſides chiefly in two parts of it, which have been called its poles; and that thoſe are the beſt magnets or loadſtones in which this activity is leaſt diffuſed; and that a certain circumference of every loadſtone or magnet is wholly inactive. When a loadſtone or magnet of any ſhape is laid among iron filings, it collects them on two parts only of its ſurface, and between theſe there is a ſpace all round, to which no filings attach themſelves.

We preſume that the reader already explains this appearance to himſelf. Many things ſhew a contrariety of action of the two poles of a magnet. We have already obſerved, that the north pole of a ſtrong magnet will produce a ſtrong northern polarity in the remote end of a ſmall ſteel bar; and if it be then applied near to that end in the oppoſite direction, it will deſtroy this polarity, and produce a ſouthern polarity. In whatever theſe actions may conſiſt, there is ſomething not only different but oppoſite. They do not blend their effects, as the yellow and blue making rays do in producing green. They oppoſe each other, like mechanical preſſures or impulſions. We have every mark of mechanical action; we have local motion, though unſeen, except in the gradual progreſſion of the magnetical faculties along the bar; but we have it diſtinctly in the ultimate effect, the approach or receſs of the magnets: and in theſe phenomena we ſee plainly, that the forces, in producing their effects, act in oppoſite directions. Whatever the internal inviſible motions may be, they are compoſed of motions whoſe equivalents are the ſame with the equivalents of the ultimate, external, ſenſible motions; therefore the internal motions are oppoſite and equal if the ſenſible motions are ſo, and converſely.

Adopting this principle, therefore, that the actions of the two poles are not only different but oppoſite, it follows, that if they are alſo equal and act ſimilarly, each muſt *prevent* the action of the other; and that there will be a mechanical equilibrium—it may even be called a magnetical equilibrium. Therefore if every part of a ſlender rod, or of a thin plate of iron, lie in the plane of the magnetic equator, the magnetic ſtate (in whatever it may conſiſt) cannot be produced in it. It will exhibit no magnetiſm; have no polar faculties; and we can ſee no reaſon why it ſhould be attracted by the magnet, or ſhould attract iron. We muſt not forget to obſerve in this place, that iron in a ſtate of incandeſcence acquires no magnetiſm by juxtapoſition. We have already remarked, that iron in this ſtate does not affect the magnet. If a bar of red hot iron be ſet near a mariner's needle, it does not affect it in the ſmalleſt degree till it almoſt ceaſes to appear red hot in day-light, as has been obſerved by Dr Gilbert. All actions that we know are accompanied by equal and oppoſite re-actions; and we ſhould expect, what really happens in the preſent caſe, namely, that red hot iron ſhould not be rendered magnetical and attractable.

38 Magnetiſm not impaired by communication. There is a very remarkable circumſtance which accompanies the whole of this communication of magnetiſm to a piece of iron. It does not impair the power of the magnet; but, on the contrary, improves it. This fact was obſerved, and particularly attended to, by Dr Gilbert. He remarks, that a magnet, in the hands of a judicious philoſopher, may be made to impart more magnetiſm than it poſſeſſes to each of ten thouſand bars of ſteel, and that it will be more vigorous than when the operations began. A magnet (ſays he) may be ſpoiled by injudicious treatment with other magnets, but never can touch a piece of common iron without being improved by it. He gives a more direct proof. Let a magnet carry as heavy a lump of iron as poſſible by its lower pole. Bring a great lump of iron cloſe to its upper pole, and it will now carry more. Let it be loaded with as much as it can carry while the lump of iron touches its upper pole. Remove this lump, and the load will inſtantly drop off. But the following experiment ſhews this truth in the moſt convincing manner:

Let NAS (fig. 11.) be a magnet, not very large, nor of extreme hardneſs. Let CD be a ſtrong iron wire, hanging perpendicularly from a hook by a ſhort thread or loop. The magnet, by its action on CD, renders D a north pole and C a ſouth pole, and the polarity of D's magnetiſm fits it for being attracted. Let it aſſume the poſition C *e*, and let this be very carefully marked. Now bring a great bar of iron *s* B *n* near to the other end of the magnet. We ſhall inſtantly perceive the wire C *e* approach to the ſouth pole of the magnet, taking a poſition C *f*. Withdraw the bar of iron, and C *f* will fall back into the poſition C *e*. As we bring the iron bar gradually nearer to the magnet, the

the wire will deviate farther from the perpendicular, and when the bar B touches the magnet CD, will ſtart a great way forward. It is alſo farther to be obſerved, that the larger the bar of iron is, the more will CD deviate from the perpendicular.

Now this muſt be aſcribed to the action of the bar on the magnet. For if the magnet be removed, the bar alone will make no ſenſible change on the poſition of the wire. We know that the bar of iron becomes magnetical by the vicinity of the magnet. If we doubt this, we need only examine it by means of a piece of iron or a mariner's needle. This will ſhew us that *s* has become a ſouth, and *n* a north pole. Here then are two magnets with their diſſimilar poles fronting each other. In conformity with the whole train of magnetical phenomena, we muſt conclude that they attract each other, and muſt improve each other's magnetiſm.

39 erefore thing is nsferred. This is a moſt important circumſtance in the theory of magnetiſm. For it ſhews us, that, in rendering a piece of iron magnetic, there is no material communication. There is no indication of the transference of any ſubſtance reſiding in the magnet into the piece of iron; nor is there even any transference of a power or quality. Were this the caſe, or if the ſubſtance or quality which was in A be now transferred to B, it can no longer be in A; and therefore the phenomena reſulting from its preſence and agency muſt be diminiſhed. We muſt ſay that the magnet has excited powers inherent, but dormant, in the iron; or is, at leaſt, the occaſion of this excitement, by diſturbing, in ſome adequate manner, the primitive condition of the iron. We muſt alſo ſay, that the competency of the magnet and of the iron to produce the phenomena, is owing to the ſame circumſtances in both; becauſe we ſee nothing in the phenomena which authoriſes us to make any diſtinction between them. Whatever therefore cauſes one magnet to attract another, is alſo the reaſon why a piece of iron in the neighbourhood of a magnet attracts another piece of iron; and we muſt ſay that the cauſe of polarity, or the origin of the directive power, is the ſame in both. Now we underſtand perfectly the directive power of a magnet, as exerted on another magnet. We ſee that it ariſes from a combination and mechanical compoſition of attractions and repulſions. It muſt be the ſame in this magnetiſm now inherent in the iron. The piece of iron directs the mariner's needle, as a magnet would direct it; therefore, as there is ſomething in a piece of iron which *now* attracts ſomething in another piece of iron, ſo there is ſomething in the firſt which repels ſomething in the laſt.

40 jections ſwered a curious t. It may indeed be ſaid that it is not a piece of iron, but a mariner's needle, or magnet, that is thus directed by our iron magnetiſed by vicinity to a magnet. This objection is completely removed by the moſt curious of all the facts which occur in this manner of producing magnetiſm. Take a piece of common iron, faſhion it, and fit it up preciſely like a mariner's needle, and carefully avoid every treatment that can make it magnetical. Set it on its pivot, and bring it near the north pole of a magnet, placing the end, made like the ſouth pole of the needle, next to the north pole of the magnet. In ſhort, place it by hand exactly as a real mariner's needle would arrange itſelf. It will retain that poſition. Now carry it round the magnet, along the circumference of a magnetic curve, or in any regular and continuous route. This piece of iron will, in every ſituation, aſſume the very ſame poſition or attitude which the real magnetical needle would aſſume if in the ſame place, and it will oſcillate preciſely in the ſame way.

Here then it is plain, that there is no diſtinction of power between the magnetiſm of the iron and of the real needle. To complete the proof: Inſtead of approaching the magnet with this iron needle, bring it into the vicinity of a piece of iron, which is itſelf magnetical only by vicinity to a magnet, it will arrange itſelf juſt as the real needle would do, with the ſole difference, that it does not indicate the *kind* of polarity exiſting in the extremities of the iron, becauſe either end of it will be attracted by them. And this circumſtance leads us to the conſideration of the only diſtinction between the magnetiſm of a loadſtone or magnet and that of common iron.

The magnetiſm of common iron is momentary, and therefore indifferent; whereas that of a magnet is permanent and determinate. When iron becomes magnetic in the way now mentioned, it remains ſo only while the magnet remains in its place; and when that is removed, the iron exhibits no ſigns of magnetiſm. Therefore when the north pole of a magnet has produced a ſouth pole in the neareſt end of an iron wire, and a north pole at its remote end, if we turn the magnet, and preſent its ſouth pole, the neareſt end of the wire inſtantly becomes a north pole, and the other a ſouth pole; and this change may be made as often, and as rapidly, as we pleaſe. This is the reaſon which made us direct the experimenter on the iron needle to begin his operation, by placing the end marked for a ſouth pole next to the north pole of the magnet. It becomes a real ſouth pole in an inſtant, and acts as ſuch during its peregrination round the magnet. But in any one of its ſituations, if we turn it half round with the finger, the end which formerly turned away from a pole of the magnet, will now turn as vigorouſly toward it. Therefore, in carrying the iron needle round the magnet, we directed the progreſs to be made in a continuous line, to avoid all chance of miſtaking the polarities. 41 Magnetiſm of iron is tranſitory and indifferent; but that of magnets is durable and determinate.

For all the reaſons now adduced, we think ourſelves obliged to ſay, that the magnetiſm produced on common iron by mere juxtapoſition to a magnet, is generated without any *communication* of ſubſtance or faculty. The power of producing magnetical phenomena is not *ſhared* between the magnet and the iron. We ſhall call it INDUCED MAGNETISM; MAGNETISM BY INDUCTION. 42 MAGNETISM OF INDUCTION.

We have ſaid that induced magnetiſm of common iron is quite momentary. This muſt be underſtood with careful limitations. It is ſtrictly true only in the caſe of the fineſt and pureſt ſoft iron, free of all knots and hard veins, and therefore in its moſt metallic ſtate. Iron is rarely found in a ſtate ſo very pure and metallic; and even this iron will acquire permanent and determinate magnetiſm by induction, if it had been twiſted or hammered violently, although not in the magnetic direction; alſo the changes produced (we imagine) on the pureſt iron by the action of the atmoſphere make it ſuſceptible of fixed magnetiſm. But the magnetiſm thus inducible on good iron is ſcarcely ſenſible, and of no duration, unleſs it has lain in the neighbourhood of a magnet for a very long while.

What has now been ſaid of common iron, is alſo true of it when in the ſtate of ſoft ſteel.

But

43 Tempered steel acquires durable magnetism.

But any degree of temper that is given to steel makes a very important change in this respect. In the first place, it acquires magnetism more slowly by induction than an equal and similar piece of common iron, and finally acquires less. These differences are easily examined by the deviations which it causes in the mariner's needle from the magnetic meridian, and by its attraction.

When the inducing magnet is removed, some magnetism remains in the steel bar, which retains the polarity which it had in the neighbourhood of the magnet.

Steel tempered to the degree fit for watch springs acquires a strong magnetism, which it exhibits immediately on the removal of the magnet. But it dissipates very fast; and, in a very few minutes, it is reduced to less than one-half of its intensity while in contact with the magnet, and not two-thirds of what it was immediately on removal from it. It continues to dissipate for some days, though the bar be kept with care; but the dissipation diminishes fast, and it retains at least one-third of its greatest power for any length of time, unless carelessly kept or injudiciously treated.

Steel tempered for strong cutting tools, such as chisels, punches, and drills for metal, acquires magnetism still more slowly by induction, and acquires less of it while in contact with the magnet: but it retains it more firmly, and finally retains a greater proportion of what it had acquired.

Steel made as hard as possible, is much longer in acquiring all the magnetism which simple juxtaposition can give to it. It acquires less than the former; but it retains it with great firmness, and finally retains a much greater proportion.

Such ores of iron as are susceptible of magnetism, are nearly like hard steel in these respects; that is, in the time necessary for their *greatest* impregnation, and in the durability of the acquired magnetism. They differ exceedingly in respect to the degree of power which they can attain by mere juxtaposition, and the varieties seem to depend on heterogeneous mixture. We must observe, that few ores of iron are susceptible of magnetism in their natural state. The ordinary ores, consisting of the metal in the state of an oxyd, and combined with sulphur, are not magnetizable while remaining in that state. Most ores require roasting, and a sort of cementation, in contact with inflammable substances. This matter is not well understood; but it would seem that complete metallization is far from being the most favourable condition, and that a certain degree of oxydation, and perhaps some other composition, yet unknown, make the best loadstones. But all this is extremely obscure. The late Dr Gowin Knight made a composition which acquired a very strong and permanent magnetism, but the secret died with him. Dr Gilbert speaks of similar compositions, in which ferrugineous clays were ingredients; but we know nothing of the state of the metal in them, nor their mode of acquiring magnetism.

44 Induction of magnetism is gradual and progressive.

It is of peculiar importance to remark that the acquisition of magnetism is gradual and progressive, and that the gradation is the more perceptible in proportion as the steel is of a harder temper. When a magnet is brought to one end of a bar of common iron, its remote extremity, unless exceedingly long, acquires its utmost magnetism immediately. But when the north pole of a magnet is applied to one end of a bar of hard steel, the part in contact immediately becomes a south pole, and the far end is not yet affected. We observe a north pole formed at some distance from the contact, and beyond this a faint south pole. These gradually advance along the bar. The remote extremity becomes first a faint south pole, and it is not till after a very long while (if ever) that it becomes a simple, vigorous, north pole. More frequently it remains a diffused and feeble north pole: nay, if the bar be very long, it often happens that we have a succession of north and south poles, which never make their way to the far end of the bar. This phenomenon was first observed (we think) by Dr Brook Taylor, who gives an account of his observations in the *Philosophical Transactions*, n° 344.

45 Iron is attracted only because it becomes magnetical.

From the account we have given of these phenomena of induced magnetism, it appears that the temporary magnetism is always so disposed that the sum of the mutual attractions of the dissimilar poles exceeds the sum of the repulsions between the similar poles, and that therefore the two magnets tend to each other. This is evidently equivalent to saying, that a piece of unmagnetic iron is always attracted by a magnet. No exception has ever been observed to this fact; for Pliny's story of a Theamedes, or loadstone, which repels iron, is allowed by all to have been a fable.

We think ourselves authorised to say that this attraction of the loadstone for iron, or this tendency of iron to the loadstone, is a secondary phenomenon, and is the *consequence* of the proper disposition of the induced magnetism. The proofs already given of the compound nature of this phenomenon, namely, that it arises from the excess of two attractions above two repulsions, need (we imagine) no addition. But the following considerations place the matter beyond doubt:

1. The magnetism of the two poles is evidently of an opposite nature; the one repelling what the other attracts. If the one attracts iron, therefore, the other should repel it. But each pole, by inducing a magnetism opposite to its own, on the nearest end of the iron, and the same with its own on the remote end, and its action diminishing with an increase of distance, there must always be an excess of attraction, and the iron must be attracted.

2. Each of the magnets A and B, in either of the positions represented in fig. 12. would alone attract the piece of common iron C. But when placed together, the south pole of A tends to render the upper end of C a north pole; while the north pole of B tends to make it a south pole. If their actions be nearly equal, the weight of C cannot be supported by the magnetism induced by any difference of action that may remain. While C is hanging by B alone, let A be gradually brought near; it gradually destroys the action of the north pole of B, so that C gradually loses its magnetism and polarity, and its weight prevails.

3. In all those cases where the induction of magnetism is slow, the attraction is weak in proportion. This is particularly remarked by Dr Gilbert. If we take pieces of common iron, and of steel of different tempers, but all of the same size and form, we shall find that the iron is much more strongly attracted than any of the rest, and that the attraction for each of them is weaker in proportion as they are harder. This diversity is so accurately observed, that when the piece is thoroughly suscep-

susceptible of magnetism, we can tell, with considerable precision, what degree will be ultimately acquired, and how much will be finally retained. Also, the attraction of the magnet for any of those pieces of steel increases exactly in proportion as their acquired magnetism increases.

4. An ore of iron incapable of acquiring magnetism is not attracted by a magnet. But we know that, by cementation with charcoal dust, they may be rendered susceptible of magnetism. In this state they are attracted. It is an universal fact, that any substance that is attracted by a magnet may be rendered magnetical, and that none else can. We have already observed that red hot iron is not attracted; nor does it acquire any directive power while in that state. From all this we must conclude, that the previous induction of magnetism is the mean of the observed attraction of magnets for iron, and that this is not a primary fact in magnetism.

These observations also complete the proof that magnetic attraction and repulsion are equal at the same distance, and follow the same law. Dr Gilbert seems to think that the repulsion is always weaker than the attraction; and this is almost the only mistake in conception into which that excellent philosopher has fallen. But it only requires a fair comparison of facts to convince a good logician, that since, *in every case*, and at every distance, either pole of a magnet attracts either end of a piece of common iron, it is impossible that one of these forces can exceed the other. It might be so, were it not that induced magnetism is durable in proper substances. And if we take magnets which have been made such by induction, and present them to each other with their similar poles fronting each other, they never fail to repel each other at considerable distances, and even at very small distances for a few moments; and this is the case whichever poles are next each other. This cannot be on any other supposition. Cases would occur of polarity without attraction, or of attraction without polarity. Such have never been seen, any more than the Theamedes, always repelling iron.

46 Phenomena of iron threads and filings.

Let a great number of small oblong pieces of iron be lying very near each other on the surface of quicksilver. Bring a strong magnet into the midst of them. It immediately renders them all magnetical by induction. The one nearest the north pole of the magnet immediately turns one end toward it, and the other end away from it. The same effect is produced on the one that is just beyond this nearest one. Thus the remote end of the first becomes a north pole, and the nearest end of the second becomes a south pole. These, being very near each other, must mutually attract. The same thing may be said of a third, a fourth, and so on. And thus it appears that not only is magnetism induced on them all, but also that the magnetism of each is so disposed, that both ends of it are in a state of attraction for the ends of some of its neighbours; and that they will therefore arrange themselves by coalescence in some particular manner. Should a parcel of them chance to be standing with their centres in a magnetic curve, with their heads and points turned in any ways whatever, the moment that the magnet is brought among them, and set in the axis of that magnetic curve, the whole pieces of this row will instantly turn towards each other, and their ends will adhere together, if they are near enough; otherwise they will only point toward each other, forming a set of tangents to the magnetic curve, reaching from one pole of the magnet to the other.

Or, suppose a vast number of small bits of iron, each shaped like a grain of barley, a little oblong. Let them be scattered over the surface of a table, so near each other as just to have room to turn round. Let a magnet be placed in the midst of them. They will all have magnetism induced on them in an instant; and such as are not already touching others, will turn round (because they rest on the table by one point only), and each will turn its ends to the ends of its neighbours; and thus they will arrange themselves in curves, which will not differ greatly from true magnetic curves (because each grain is very short), issuing from one pole of the magnet, and terminating in the other.

Does not this suggest to the reflecting reader an explanation of that curious arrangement of iron filings round a magnet, which has so long entertained and puzzled both the philosophers and the unlearned, and which has given rise to the Cartesian and other theories of magnetism? The particles of iron filings are little rags of soft iron torn off by the file, and generally a little oblong. These *must* have magnetism induced on them by a magnet, and, while falling through the air from the hand that strews them about the magnet, they are at perfect liberty to arrange themselves magnetically; and *must therefore so arrange themselves*, forming on the table curves, which differ very little indeed from the true magnetic curves. Suppose them scattered about the table before the magnet is laid on it. If we pat the table a little, so as to throw it into tremors, this will allow the particles to dance, and turn round on their points of support, till they coalesce by their ends in the manner already described.

All this is the genuine and inevitable consequence of what Dr Gilbert has taught us of induced magnetism. It must be so; and cannot be otherwise. This curious arrangement of iron filings round a magnet is therefore not a primary fact, and a foundation for a theory, but the result of principles much more general.

Most of our readers know that this disposition of iron filings has given rise to the chief mechanical theories which have been proposed by ingenious men for the explanation of all the phenomena of magnetism. An invisible fluid has been supposed to circulate through the pores of a magnet, running along its axis, issuing from one pole, streaming round the magnet, and entering again by the other pole. This is thought to be indicated by those lines formed by the filings. The stream, running also through *them*, or around them, arranges them in the direction of its motion, just as we observe a stream of water arrange the flote grass and weeds. It would require a volume to detail the different manners in which those mechanicians attempt to account for the attraction, repulsion, and polarity of magnetic bodies, by the mechanical impulsion of this fluid. Let it suffice to say, that almost every step of their theories is in contradiction to the acknowledged laws of impulsion. Nay, the whole attempt is against the first rule of all philosophical discussion, never to admit for an explanation of phenomena the agency of any cause which we do not know to exist, and to operate in the very phenomenon. We know of no such fluid; and we can demonstrate, that the genuine effects of its impulsion would be totally unlike the phenomena 47 Remarks on the theories by impulsion.

nomena of magnetiſm. But the proper refutation of theſe theories would fill volumes. Let it ſuffice (and to every logician it will abundantly ſuffice) to remark, that this phenomenon is but a ſecondary fact, depending on, and reſulting from, principles much more general, viz. the induction of magnetiſm, and the attraction of diſſimilar, and repulſion of ſimilar, poles.

The above explanation of the curious diſpoſition of iron filings round a magnet, occurred to the writer of this article while ſtudying natural philoſophy, on ſeeing the Profeſſor exhibit Mr Henſhaw's beautiful experiment in proof of terreſtrial magnetiſm*. He at that time imagined himſelf the author, and promiſed himſelf ſome credit for the thought. But having ſeen the *Phyſiologia Nova de Magnete* by Dr Gilbert, he found that it had not eſcaped the notice of that ſagacious philoſopher; as will appear paſt diſpute from the following paſſage, as well as ſome others, leſs pointed, in that work: "Magnetica fruſta (that is, ſubſtances ſuſceptible of magnetiſm) bene et convenienter intra vires poſita, mutuo cohærent. Ferramenta, preſente magnete (etiamſi magnetem non attingant), concurrunt, ſolicité ſe mutuo quærunt, et amplexantur, et, conjuncta, quaſi ferruminantur. Scobs ferrea, vel in pulverem redacta, fiſtulis impoſita chartaceis—ſupra lapidem meridionaliter locata, vel propius tantum admota, in unum coaleſcet corpus; et ſubito tam multæ partes concreſcunt et combinantur; ferrumque aliud affectat conjuratorum turma et attrahit, ac ſi unum tantum et integrum eſſet ferri baeillum; dirigiturque ſupra lapidem in ſeptemtriones et meridiem. Sed cum longius a magnete removeantur (tanquam ſoluta rurſus) ſeparantur, et diffluunt ſingula corpuſcula." B. ii. c. 23.

* See VARIATION, *Encycl.* p. 621.

Mr Æpinus alſo had taken the ſame view of the ſubject*. It is alſo very clearly conceived and expreſſed by the celebrated David Gregory, Savilian Profeſſor of aſtronomy in the Univerſity of Oxford, in a MS. volume of notes and commentaries, written by him in 1693, on Newton's *Principia*, and uſed by Newton in improving the ſecond edition. The MS. is now in the library of the univerſity of Edinburgh. Gregory's words are as follow: "Mihi ſemper dubium viſum eſt num magnetica virtus mechanicé, *i. e.* per impulſum, producatur. Mirum eſt, effluvia, quæ ferrum agitare valent, bracteas aureas *interpoſitas* ne vel minimum a loco movere. Lucretii et Carteſii theoriam, de fugato intermedio aëre, refutat experimentum infra aquam inſtitutum. *Sulci in limatura ferri, magneti in plano cujuſvis meridiani circumpoſita, non ſiunt ab effluviis ſecundum iſtos canales motis, ſed ex inde, quod ipſa ramenta, magnetice excitata, ſeſe ſecundum longitudinem et ſecundum polos diſponunt.* Ex altera vero parte exinde quod vis magnetica, interveniente flamma aut calore, interrumpatur, quod virga ferrea, vel diuturno ſitu perpendiculari, vel in eo ſitu frigeſcendo, virtutem magneticam a tellure acquirat, ut nos docet perſpicaciſſimus Gilbertus. Quod mallei ſuper incudem ictu forti ad alterum extremum, virtutem acquirat magneticam; quod ictu forti vel ſaltem fortiori ad alterum extremum poli permutantur, ut qui prius ſeptemtriones reſpiciebat nunc auſtrum reſpicit; quod ictu forti ad medium, virtutem illam prorſus amittat. Hæc inquam, et ſimilia, mechanicam ejus qualitates ortum arguunt. Hugenius, præter gravitatem, etiam magneticam, et electricam virtutem, aliaſque plures experimento novit vires naturales, ut mihi ipſi narravit hac eſtate anni 1693. Qualis ut hæc forſitan quod cymba papyracea, prope labra vaſis aquam, cui innatet, continentis, poſita, labrum viciniſſimum continuo, et cum impetu petat (A)." *Nat. MS. in Prop.* 23. ii. *Prin.*

* See § 306.

48 Filings are weakly attracted.

Not only the mere arrangement of the filings in curve lines follows of neceſſity from the properties of induced magnetiſm, but all the ſubordinate circumſtances of this phenomenon are included in the ſame explanation. By continuing to tap the table, and throw it into tremors, the filings are obſerved to approach gradually, but very ſlowly, to the poles of the magnet. Each particle is a very ſmall temporary magnet. The attractive power of the great magnet, $\overline{m-p}-\overline{n-q}$, is therefore extremely ſmall in proportion to its directive power, $\overline{m+p}-\overline{n+q}$. And we obſerve that the accumulation of the filings round the poles of the magnet is ſo much the ſlower as the filings are finer.

49 Curious fact.

If a paper be laid above the magnet, and the filings be ſprinkled on it, we obſerve them to conſtipate along its edges, while none remain immediately above its ſubſtance; they are all beyond, or on the outſide of its outline, and they are obſerved not to be lying flat on the paper, but to be ſtanding obliquely on one point. They move off from the paper immediately above the magnet, becauſe they repel each other. They ſtand obliquely from the edges, becauſe that is the direction of a magnetic meridian at its parting from the pole. If the magnet be at ſome diſtance below the paper, then tapping the paper will cauſe the filings to move away from the magnet laterally. This ſingular and unexpected appearance is owing to the combination of gravity with the magnetic action. A particle, ſuch as $n\,s$ (fig. 13.), reſts on the paper by the point n, which is a temporary north pole (S being ſuppoſed the ſouth pole of the magnet). The particle takes a poſition $n\,s$ nearer to the horizon than the poſition $n\,o$, which it would take if its centre of gravity b were ſupported. The poſition is ſuch, that its weight, acting vertically at b, is in equilibrio with the magnetic repulſion $s\,d$, exerted between S and s. When the paper is tapped, it is beaten down, or withdrawn from n, and the particle of iron is left for a moment in the air. It therefore turns quickly round b, in order to aſſume a poſition parallel to $n\,o$, and it meets the paper, as that riſes again after the ſtroke, in a point farther removed from the magnet, and again deſcends by its weight (turning round the newly ſupported point n), till it again takes a poſition parallel to $n\,s$, but farther off, as repreſented by the dotted line. Thus it travels gradually outwards from the magnet, appearing to be repelled, although it is really attracted by it. If the magnet be held above the paper, at a little diſtance, the filings, when we repeatedly pat the paper, gradually collect into a heap under it. This will appear very plainly to one who conſiders the ſituation of a particle in the manner now explained.

The

(A) Perhaps it may be proper to obſerve, that Dr Gregory expreſſes his differing in his opinion from Newton about magnetiſm. Newton, in this propoſition, thinks that the law of magnetic action approaches to the inverſe triplicate ratio of the diſtances. Dr Gregory invalidates the argument uſed by Newton.

50 ...ings ar- ...ge in ...gnetic ...ves;

The curve lines formed by very fine filings approach very nearly to the form of the primary curve which indicates the law of magnetic action in the way already explained. If the magnet be placed under water, and if filings be ſprinkled copiouſly on the ſurface of it from a gauze ſearce, held at ſome diſtance above it, the reſiſtance to their motion through the water gives them time to arrange themſelves magnetically before they reach the bottom, and the lines become more accurate. But they were ſo much deranged by any method that we could take for removing the water, and meaſuring them, that we were diſappointed in our expectations of obtaining a very near approximation to the law of action.

51 ...o in ſe- ...dary ...ves.

We took notice of ſome very ſingular phenomena of a compaſs needle in the neighbourhood of two magnets, and we obſerved that, in this caſe alſo, the needle was always a tangent to a curve of another kind, and which we called *ſecondary* and *compound magnetic curves*. Theſe are produced in the ſame way, by ſtrewing iron-filings round the magnets. Many repreſentations have been given of theſe curves by different authors, particularly by Muſchenbroeck, in his *Eſſais de Phyſique;* and by Fuſs in the *Comment. Petropolit.* Great uſe has been made of theſe arrangements of filings by two magnets in the theories of magnetiſm propoſed by thoſe who inſiſt on explaining all motion by impulſe. When the diſſimilar poles of two magnets A and B (fig. 14.) face each other, the curves formed by the filings conſiderably reſemble thoſe which ſurround a ſingle magnet, and give the whole ſomewhat of the appearance of a magnet with very diffuſed poles. The arranging fluid, which ſtreams from one pole of a magnet, is ſuppoſed to meet with no obſtruction to its entry into the adjoining pole of the other magnet, but, on the contrary, to be impelled into it; and therefore (ſay the propoſers) it circulates round both as one magnet, and by its vortex brings the magnets together; which phenomenon we call the attraction of the magnets. But when the ſimilar poles front each other; for example, the poles from which the arranging fluid iſſues, then the two ſtreams meet, obſtruct each other, accumulate, and, by this accumulation, cauſe the magnets to recede from each other; which we call the repulſion of the magnets. This is the only explanation of this kind that can make any pretenſions to probability, or indeed that can be conceived. For how the free circulation in the former caſe can bring the two magnets together, no perſon can form to himſelf any conception. We ſee nothing like this produced by any vortex that we are acquainted with. All ſuch vortices cauſe bodies to ſeparate. But even this explanation of magnetic repulſion is inadmiſſible. It will not apply to the repulſion of the receiving poles; and the phenomena of the filings are inconſiſtent with the notion of accumulation. The filings indeed accumulate, and they look not unlike two ſtreams which oppoſe each other, and deflect to the ſides (ſee fig. 15.): But, unfortunately, by tapping the paper gently, the filings do not move off from the magnets, but approach them much faſter than in any other experiment. The phenomenon receives a complete and palpable explanation from the principles we have eſtabliſhed. Both magnets concur in giving the ſame polarity to every particle of the filings. Thus, if the fronting poles are north poles, each particle has its neareſt end made a vigorous ſouth pole, and its remote end a north pole; and it is *therefore* ſtrongly attracted towards both magnets while it is arranged in the tangent to the ſecondary curve of that claſs, which croſſes the others nearly at right angles.

52 Magnets muſt affect each other.

Since it is found, that the magnetiſm, even of natural loadſtones and hard ſteel, and ſtill more thoſe of ſofter tempered ſteel, are continually tending to decay; and ſince we find that it may be induced by mere approach to a magnet; and ſince we know that magnets may oppoſe each other in producing it—it is reaſonable to ſuppoſe, that when a piece of iron has acquired a ſlight, though permanent magnetiſm, by the vicinity of a magnet, a magnet applied in the oppoſite direction will deſtroy it, and afterwards produce the oppoſite magnetiſm.

Accordingly, we may change the poles of ſoft magnets at pleaſure.

Farther; ſince we find that loadſtones and hard tempered ſteel bars are diſtinguiſhed from ſoft ones only by the *degree* of obſtinacy with which they retain their preſent condition, we ſhould alſo expect that hard magnets will even affect each other. It muſt therefore happen, that a powerful magnet applied to a weak one, ſo that their ſimilar poles are in contact, ſhall weaken, deſtroy, and even change the magnetiſm of the weaker. Dr Knight's famous magazine of magnets enabled him to change the poles of the greateſt and the ſtrongeſt natural loadſtone, or artificial magnet, that could be given him, in the ſpace of one minute.

53 Attraction muſt appear to exceed repulſion.

We now ſee clearly the reaſon why magnetic repulſion is weaker than attraction at the ſame diſtance. When magnets are placed with their ſimilar poles fronting each other, in order to make trials of their repulſion, they really do weaken each other, and are not in the ſame magnetical condition as before. For ſimilar reaſons, we ſee how experiments with magnets attracting each other rather improve them, and make their attractive powers appear greater than they are. All theſe effects muſt be moſt remarkable in ſoft magnets, eſpecially when long.

54 The obſerved law differs from the true.

We alſo ſee, that the obſerved law of attraction and repulſion between two magnets muſt be different from the real law of magnetic action. For, in the experiments made on attraction at different diſtances, beginning with the greateſt diſtance, the magnetiſm is continually increaſing, and the attraction will appear to increaſe in a higher rate than the juſt one: the contrary may happen, if we begin with the ſmaller diſtances. The reſults of experiments on repulſion muſt be ſtill more erroneous; becauſe it is eaſier to diminiſh any accumulation which required an exertion to produce it, than to puſh it ſtill farther.

55 Magnetiſm improves by inducing it on iron.

We have now a complete explanation of the remarkable fact, that the induction of magnetiſm does not weaken the magnet employed; but, on the contrary, improves it. The magnetiſm induced on the iron cauſes it to act on the magnet employed in the very ſame manner that a permanent magnet of the ſame ſhape, ſize, and ſtrength, would do. Nay, it will have even a greater effect; for as it improves the magnet, its own induced magnetiſm will improve; and will therefore ſtill farther improve the magnet.

Hence it is, that, in whatever manner a magnet touches a piece of iron, it improves by it. It may be hurt 56.

hurt by a magnet in an improper pofition; but it always puts common iron into a ftate which increafes its own magnetifm. This has been known as long as magnetifm itfelf; and the ancients conceived the notion that the magnet fomehow fed upon the iron (B).

We think that thefe obfervations authorife us to fay, that in reducing a loadftone into a convenient fhape, as much as poffible of the operation fhould be performed by grinding them with emery, in cavities made in large blocks of *hammered* iron. The magnetifm induced on the iron muft be favourable to the confervation of that in the loadftone; which, we are perfuaded, is rapidly diffipated by the tremors into which this very elaftic fubftance is thrown by the grinding with coarfe powders in any mould but iron. We imagine that the cutting off flices by the lapidaries wheel has the fame bad effect.

57. Not only will a magnet lift a greater lump of iron by its north pole, when another lump is applied to its fouth pole, but it will lift a greater piece of iron from an anvil than from a wooden table: for the magnet induces the properly difpofed polarity, not only in the iron which it lifts, but alfo in the anvil, or any piece of iron immediately beyond it. This is fo difpofed as to increafe the magnetifm of the piece of iron between them; and therefore to increafe their attraction. The magnetifm induced on the anvil is alfo in part, and perhaps chiefly, induced by the intervening iron. Thefe experiments are extremely variable in their refults.—Sometimes a fmall magnet will pull an iron wire from a large and ftrong one. Sometimes this will be done even by a piece of unmagnetic iron; and the refults appear quite capricious. But they are accurately fixed, depending on the induced compound magnetifm. Mr Æpinus has ftated fome of the more fimple cafes, in which we can tell which magnet fhall prevail. But the unfolding even of thefe cafes would take a great deal of room, and muft be omitted here. Befides, we are too imperfectly acquainted with the degree of magnetifm induced on the various parts of an iron rod, and the degree of magnetifm inherent in the various parts of the magnets, to be able to fay, with certainty, even in thofe fimple cafes, on which fide the fuperiority of attraction will remain.

58 Making of artificial magnets.

We may now proceed to deduce from this theory (for fo it may juftly be called, fince all is reduced to one fact) the procefs for communicating magnetifm to bodies fitted for receiving and retaining it; that is, the method of making artificial magnets. We fhall not employ much time on this, becaufe the moft approved methods have been delivered at length in the article Magnetism of the *Encyclopædia Britannica*; and therefore we fhall juft make fuch obfervations on them as ferve to confirm, or to perfect them by the theory. We acknowledge, that we do not know the internal procefs by which magnetifm is induced, nor even in what this magnetifm confifts. All that we know is, that the bringing the pole of a magnet near to any magnetifable matter, produces a magnetifm of the kind oppofite to that of the pole employed. We know that this is the cafe with both poles, and that it obtains at all the diftances where magnetifm is obferved. We know that the action of one pole is contrary to that of the other; that is, it counteracts the other, prevents it from producing its effect, and deftroys it when already produced: and we know that the production of thefe effects refembles, in its refult, the protrufion of fomething fluid through the pores of the body, conftipating it in all remote parts; as if the virtue of a pole refided in this moveable matter. This is nearly all that we know of it; and by thefe facts and notions we muft judge of the propriety and effect of all the proceffes for magnetifing bodies.

The moft fimple method of magnetifing a fteel bar, is to apply the north pole of a magnet to that end which we wifh to render a fouth pole. Attention to the effects of this application is very inftructive. Have in readinefs a very fmall compafs needle; turning on its pivot. It fhould not exceed half an inch in length, and fhould be as hard tempered as poffible, and ftrongly impregnated. Immediately after the application of the magnet, carry the needle along the fide of the bar. If the bar be long, and very hard, we fhall obferve a fouth polarity at the place of contact; a north polarity at a fmall diftance from it; beyond this a weak fouth polarity; then a weak and diffufed north polarity, &c.; toward the remote end the polarity will be found very uncertain. The fame thing may be difcovered by laying a ftiff paper on the bar, and fprinkling iron filings over it, and then gently tapping the paper, to make them arrange themfelves in curve lines; which will point out the various poles, and fhew whether they are diffufed or conftipated. It is very amufing and inftructive to obferve the progrefs of this impregnation. In a few minutes after the firft application of the magnet, we fhall perceive the ftate of magnetifm very fenfibly changed. The north pole will be farther from the magnet, and will be more diftinct; the fouthern polarity will alfo be protruded, and may appear for a moment at the remote extremity. The change advances; but the progrefs is more flow, and at laft is infenfible. When the bar is not harder than the temper of a cutting tool, the procefs is foon over; and if the bar is but fix or eight inches long, the remote end fhews the north polarity in a very few minutes. When the bar is very hard, the progrefs of impregnation is greatly expedited by ftriking it fo as to make it found. If it be fufpended by a ftring in a vertical pofition, and the magnet applied to its lower end, the ftriking it with a key will make it ring; and in this way make the progrefs of magnetization very quick: but it does not allow it to acquire all the magnetifm that can be given it by a very ftrong magnet.

But this is a bad way of impregnation. It is feldom that uniform magnetifm, with only two poles, and thofe of

(B) So Claudian.——" Nam ferro nurunt vitam, ferrique vigore
Vefcitur, hoc dulces epulas, hoc pabula novit
Hinc proprias renovat vires, hinc fufa per artus
Afpera fecretum fervant alimenta vigorem
Hoc abfente petit, trifti morientia torpent
Membra fame, venafque fitis confumit apertas."

Pliny fays, " Sola hæc materia (ferrum) vires ab eo lapide, accipit retinetque longo tempore, aliud apprehendens ferrum, ut annulorum catena fpectetur interdum, quod imperitum vulgus ferrum appellat vivum.

of equal ftrength, can be given. Even when there are but two, the remote pole is generally diffufed, and therefore feeble. It is much improved by employing two magnets, one at each end. And if the bar is not more than fix or eight inches long, and good magnets are employed, the magnetifm is abundantly regular. This, accordingly, is practifed for the impregnation of dipping needles, which muft not be touched, left we difturb the centre of gravity of the needle. But in all cafes, this method is tedious, and does not give ftrong magnetifm.

The method which was ufually practifed before we had obtained a pretty clear knowledge of magnetifm, was to apply the pole of a magnet to one end of the bar, and pafs it along to the other end, preffing moderately. This was repeated feveral times on both fides of the bar, always beginning the ftroke at the fame end as at firft, and, in bringing the magnet back to that end, keeping it at a diftance from the bar. The effect of this operation was to leave the end at which we began the ftroke poffeffed of the polarity of the pole employed.

A general notion of the procefs may be given as follows, obferving, however, that there occur very many great and capricious anomalies. When the north pole N (fig. 16.) of the magnet A is fet on the end C of the bar CBD, a fouth pole is produced at C, and a north pole at D, when the length of the bar is moderate. As the magnet advances flowly along the bar, the fouthern polarity at C firft increafes, then diminifhes, and vanifhes entirely when N has arrived at a certain point *a*; after which, a northern polarity appears at C, and increafes during the whole progrefs of the magnet. In the mean time, the northern polarity firft produced at D increafes till the magnet reaches a certain point *e*, then diminifhes, vanifhes when the magnet reaches a certain point *f*; after which, a fouthern polarity appears at D, which increafes till the magnet reaches D. Mr Brugmann, who firft attended minutely to thefe particulars (for Gilbert fpeaks of them pointedly), calls *a* and *f points of indifference*, and *e* the *culminating* point of the pole D, and *i* the culminating point of the pole C. Hardly can any general rule be given for the fituation of thefe points, nor even for the order in which they ftand; fo great and capricious are the anomalies in an amazing feries of experiments narrated by Brugmann and by Van Swinden. Repeating the operation, and beginning at C, the northern polarity there is weakened (fometimes deftroyed), then reftored, and continually increafed during the reft of the ftroke. The fouthern polarity at D is alfo firft weakened, and fometimes deftroyed; then reftored, and finally augmented. The points *i*, *a*, *e*, *f*, change their fituations, and frequently their order.

Van Swinden has attempted to deduce fome general laws from his immenfe lift of experiments, avoiding every confideration of a hypothefis, or the leaft conjecture by what means thefe faculties are excited. But though we have perufed his inveftigation with care and candor, we muft acknowledge, that we have not derived any knowledge which can help us to predict the refult of particular modes of treatment with any greater precifion than is fuggefted by a fort of common fenfe aided (or perhaps perverted) by a vague notion, that thefe energies refide in fomething, which avoids the pole of the fame name, carrying along with it this diftinctive energy or polarity. This conception tallies perfectly with thefe obfervations of Brugmann and Van Swinden; and admits of all the anomalies in the fituation of Bergmann's indifferent and culminating points, if we only fuppofe that this motion is obftructed by the particles of the body. We muft leave this to the reflection of the reader, who will *guefs* how, when the magnet is between C and *i*, this fubftance, avoiding the pole N of the magnet, efcapes below it, and goes toward the farther end. As the magnet advances, it drives fome of this back again, &c. &c. This is gratuitous; but it aids the fancy, which, without fome conception of this kind, has no object of fteady contemplation. We have no thought when we fpeak of the generating at C, or *a*, or *e*, a faculty of fome kind, by the exertion of the fame faculty in N. The conception is too abftracted, and much too complex. We muft content ourfelves with knowing, that N produces a fouth pole immediately under it, and a north pole everywhere elfe, or endeavours to do fo. It is unneceffary to infift longer on this method: Common fenfe fhews it to be a very judicious one.

This method was greatly improved in beginning the friction at the centre. Apply the north pole at the centre or middle of the bar, and draw it over the end intended for the fouth pole. Having done this feveral times to one end on both fides, turn the magnet, applying its fouth pole to the middle of the bar, and drawing it feveral times over the end intended for the north pole.

It was ftill more improved by employing two magnets at once, placed as in fig. 17. on the middle B of the bar, and drawing them away from each other, over the ends of it, as fhewn by the directing darts, and repeating this operation. It is plain that, as far as we underftand any thing of this matter, this procefs muft be much preferable to either of the former two. The magnets A and E certainly concur in producing a properly difpofed magnetifm on all that lies between them; and therefore on the whole bar at the end of each ftroke. The end C muft become a north, and D a fouth pole. Still, however, as the ftroke goes on to the point of indifference, each magnet tends to weaken the polarity of the parts fituated beyond it.

This method continued to be practifed till about the year 1750. Mr Canton, availing himfelf of the experiments of Mr Mitchell of Cambridge, publifhed his method by the DOUBLE TOUCH as it is called. See *Monthly Review* for 1785.

59

We need not repeat what has been detailed in the *Encyclopædia*, MAGNETISM, p. 440, &c. and fhall only make fome obfervations on the peculiar advantages of this procefs, as prefcribed by Mitchell, Canton, and improved by Mr Antheaume, in his memoir *fur les Aimans artificiels* 1766, which was crowned by the Academy of Sciences, (See alfo differtations on the fubject by *Le Maire and Du Hamel*, 1745). Method of double touch.

There is an evident propriety in the arrangement invented by Mr Mitchell, reprefented in fig. 18. The magnetifm induced on the two pieces of foft iron AD and BC is an excellent method for *fecuring* every acceffion of magnetifm to either of the bars. A good deal depends on the proper fize and length of thefe pieces; and our ignorance of the interior procefs obliges us to have recourfe to experiment alone for afcertaining this. Whatever circumftances induce the ftrongeft magnetifm on on these pieces of iron, will cause them to produce the greatest effect on the steel bars; and this will be indicated by a greater attraction. Therefore that distance will be the best which enables two bars AB and DC to lift the greatest weight hung on the piece AD or BC. When we impregnated bars whose breadth was about one tenth of their length, and their thickness about one-half of their breadth, we found, that if AD was about one fourth, or nearly one-third, of AB, they carried more than if it was either much longer or much shorter. Mr Antheaume's addition of the two great bars of iron E and F makes a sensible improvement of the *beginning* of the impregnation, when very weak magnets are employed; but did not seem to us to be of any farther service on the table. This is agreeable to any theory which can be established by what we have said hitherto.

The method of employing the magnets A and E (fig. 19), prescribed by Mitchell and Canton, is extremely judicious. The meeting of the dissimilar poles at top increases the magnetism of each. The two dissimilar poles F and G, certainly tend to give a regular and proper magnetism to the part FG of the bar which lies between them; and this is the case on whatever part of the bar they are placed. But each pole tends to destroy the present magnetism of what lies between it and the pole of the bar on that side. But mark—they tend to produce the desired magnetism on what lies between them with the *sum* of their forces; while each tends to destroy the magnetism of the part without it by the *difference* only of their forces. Therefore, on the whole, as they are moved to and fro along the bar, and the foremost one even made to pass over the end of it a little way, they always add to the magnetism already acquired. This consideration seems to enjoin setting F and G extremely near each other; for this seems to increase the sum, and to diminish the difference of their action. But it may be a question, Whether we gain more by strongly magnetising a very small part during a very short while that the magnets pass over it, or by acting on more of the bar at once, and continuing a weaker action for a longer while on this larger portion. Mr Æpinus adds another consideration depending on his notion of the internal process; but we defer this to another opportunity. The safest direction seems to be, to place them at the distance which enables them to lift the greatest weight. They are then undoubtedly acting with the greatest effect.

Mr Antheaume directs to place the touching magnets as in fig. 20. for a reason to be mentioned afterwards. Mr Æpinus also recommends it for reasons founded on his own hypothesis. We must say, that in our trials, we have found this method very sensibly superior, especially in the latter parts of the operation, when the resistance to farther impregnation becomes nearly a balance for the accumulating power of the magnets; and we consider this as no inconsiderable argument for the justice of Mr Æpinus's hypothesis.

The great advantage of this method is the regularity of the magnetism which it produces. We never find more then two poles; and when the bars are hard, and of uniform texture, the polarity is very little diffused, and seemingly confined to a very small space at the very extremities of the bar. This is indeed a prodigious advantage in point of strength. It is no less so in order to fit the magnets for experiments on the law of magnetic action; for the latitude which the diffused condition of the poles gives in the selection of the points from which the distances are to be computed, has hitherto hindered us from pronouncing on the law of magnetic action with the precision of which we think it fully susceptible. This method also is the only one by which we have been able to impregnate two bars joined end to end, considering them as one bar. We have sometimes (though very rarely) succeeded in this; so that when filings were strewed over them, the appearance could not be distinguished from a single bar.—*N. B.* Yet even in this case, in one experiment with two bars of six inches long, treated as one, when it could not be distinguished, either by the appearance of the filings, or by going round it very near with a compass needle, a very small compass needle discovered a neutral point, and a reversion of polarity similar to fig. 14. at F, shewing that it was really acting as two bars. Perhaps it must always be so; and this question is of considerable importance in the establishment of any theory of the internal process.

It deserves remark, that, in order to succeed in this attempt, a very considerable pressure is necessary. We were obliged to clean the ends of the bars very carefully, and to force the frame of bars and soft pieces of iron strongly together by wedges, in the manner of a form of types. We thought that wetting the ends of the bars with pure water aided the experiment; and we are *very certain* that oil not only greatly obstructed it, but even sensibly impeded the common process. We had put a single drop of oil on a pair of bars which we were touching in the common Cantonian method, that the magnets might be more easily drawn along them; but we were surprised at finding that we could not give a strong impregnation. The oil undoubtedly prevents the close contact. We found the finest gold leaf produce the same effect in a great degree; as also talc, of which a square inch weighed $\frac{1}{73}$th of a grain. We do not infer any thing like obstruction to the passage of something material, but rather ascribe it to mere distance; although we are of opinion, that in the impregnation of two contiguous bars, so that the magnetism (whatever it is) is disposed *precisely* as in one bar, there *is* a material transference. But we shall speak of this in its due place.

It is not unworthy of remark, that we found bars to acquire more powerful magnetism when pretty well polished than when rough. But we also found, that bars considerably rough acquired the first degrees of it much more expeditiously than those which are smooth; although we never could bring them to that high degree of magnetism that the same bars acquired after they had been polished. We think it probable, that the tremors, occasioned by the rough and harsh surfaces of the hard steel, are the causes of this phenomenon.

Some more observations on this method of the double touch will be made afterwards, when we consider the hypothesis of Mr Æpinus; and we conclude the present subject, by attempting to explain some puzzling appearances which frequently occur in making artificial magnets.

60 Difficulties explained

A bar touched by a very strong magnet has been said by Muschenbroek to be impaired by going over it with a weaker magnet. If it had been made as strong

as

as poffible, the weaker magnet, when paffed over it in the way practifed by Mufchenbroek, muft *firft* deftroy part of this magnetifm; and having done fo, it is unable to raife it anew to the fame degree of vigour.

Yet (fays Mufchenbroek with furprife) a large bar of common iron has greatly improved the magnet. A very large piece of iron *muft* do this (efpecially if fhaped like a horfefhoe, and applied with both heels), if the bar be not already at its maximum.

It was thought wonderful, that, in the method of double touch, not only was the magnetifm of the magnets employed not impaired, but, beginning with two magnets, whofe power is almoft infenfible, and repeating the operations in the precife manner defcribed by Mitchel or Canton, not only the bars intended to be made magnetical, but alfo the magnets employed, may be brought to their higheft poffible ftate of magnetifm. This is in evident conformity to the general facts of induced magnetifm, and affords the ftrongeft proof that nothing is communicated in this operation, but that powers refiding in the bars are excited, or brought into action. The manipulation merely *gives occafion* to this action, as a fpark of fire kindles a city.

61 plana- of the inning avery, ton, An- aume's cefs.

There ftill remain fome circumftances of this method, as practifed by Savery, Canton, and Antheaume, which are extremely curious and important.

Mr Savery had obferved a fmall bit of fteel acquire very fenfible magnetifm by lying long in contact with the lower end of a great window bar. Telling this to a friend, he was, for the firft time, informed, that this had been long obferved, and that Dr Gilbert had made fome curious inferences from it. Mr Savery wanted fome magnets, and was at a diftance from town. Reflecting, like a philofopher, on what he had heard and obferved, he faw here a fource of magnetifm which he could increafe, in the manner commonly practifed in making magnets. He placed the bar AB (fig. 21.) to be magnetifed between two great bars of common iron C and D, placing all the three in the magnetical direction. He took another bar EF, and put two little pieces of iron, like the armour of a loadftone, on its ends: and with thefe ends he rubbed the bar AB, rubbing the upper half of it with the end F, and the lower with the end E. The refult of this was a very brifk magnetifm in a few minutes, which, by various well devifed alternations, he brought it to its higheft degree. His numerous experiments publifhed in the philofophical Tranfactions in 1746, contain much curious information, highly deferving the attention of the philofophers. Mr Canton, proceeding on the fame principle, that bars of iron, which have been long in a vertical pofition, acquire an efficient magnetifm, begins his operations by placing his fteel bar on the head of a kitchen poker, and rubs it with the lower end of a pair of kitchen tongs. Mr Antheaume adheres more ftrictly to the inferences from the principle of terreftrial magnetifm, and repeats precifely the previous difpofition of things practifed by Mr Savery, placing his little fteel bar AB (fig. 22.) between two great bars C and D of common iron, and arranging the whole in the magnetic direction. Then, proceeding moft judicioufly on the fame principle, he greatly improves the procefs, by employing two bars EF and GH for the touch, holding them about an inch apart, inclined about 15° to the bar AB. It is plain, that the lower end of each of thefe five bars is a north pole, and the upper end a fouth pole. Therefore the poles F and G concur in giving the proper magnetifm to the portion FG of the fteel bar which is between them; and by rubbing it with thefe poles up and down, overpaffing each extremity about half an inch, he muft foon give to the bar AB a regular magnetifm; weak, perhaps, but to be afterwards increafed in the Cantonian method, on a horizontal table. In this manner did Mr Antheaume make magnets of very great ftrength in 1766. See his *Differtation* already quoted.

62 Gilbert's terreftrial magnetifm.

Thefe obfervations naturally bring us to the PHYSIOLOGIA NOVA DE MAGNET ET CORPORIBUS MAGNETICIS of Dr Gilbert; a difcovery which the fagacious Kepler claffes among the greateft in the annals of fcience.

It could not be that a phenomenon fo general, and fo interefting and important as the natural polarity of magnetic bodies, would be long known without exciting curiofity about its caufe. Accordingly the philofophers of the 16th century fpeculated much about it, and entertained a variety of opinion, if that can be called an opinion which can hardly be faid to exprefs a thought. We have in *Marfigli Ficino* a fhort notice of many of thefe opinions. Some maintained that the needle was directed by a certain point in the heavens, as if that were faying more than that it always pointed one way. Others, with more appearance of reafoning, afcribed the direction to vaft magnetic rocks. But all this was without giving themfelves the trouble of trying to afcertain what fituation of fuch rocks would produce the direction that is obferved. Fracafteri was, if we miftake not, the firft who thought this trouble at all neceffary; and he obferves very fenfibly, that if thofe rocks are fuppofed to be in any place yet vifited by navigators, and if they act as loadftones do (a circumftance which he fays muft be admitted, if we attempt to explain), the direction of the needle will be very different from what we know it to be. He therefore places them in the inacceffible polar regions, but not in the very pole. Norman, the difcoverer of the dip of the mariner's needle, or of the true magnetic direction, was naturally led by his difcovery to conceive the directing caufe as placed in the earth; becaufe the north point of the needle, in every part of Europe, points very far below the horizon. But although he calls the treatife in which he announces his difcovery the *New Attractive*, he does not exprefs himfelf as fuppofing the needle to be attracted by any point within the earth, but only that it is always directed to that point.

It is to Dr Gilbert of Colchefter that we owe the opinion now univerfally admitted, that magnetic polarity is a part of the conftitution of this globe. Norman had, not long before, difcovered, that if a fteel needle be very exactly balanced on a horizontal axis, like the beam of a common balance, fo that it would retain any pofition given it, and if it be then touched with a magnet, and placed on its axis in the magnetic merdian, it is no longer in equilibrio, but at (at London) the north point of it will dip 72 or 73 degrees below the horizon. He did not, however, publifh his difcovery till he had obtained information how it ftood in other parts of the world. The differences in the variation in different places naturally fuggefted the neceffity of this to him. Being a maker of mariners compaffes, paſſes, and teacher of navigation in London, he had the faireſt opportunities that could be deſired, by furniſhing dipping needles to ſuch of the navigators, his ſcholars, as he knew moſt able to give him good information. And the accounts which he received made his diſcovery, when announced to the world, a very complete thing; for the commanders of ſhips engaged in long voyages, and particularly to China, informed him that, in the vicinity of the equator, his dipping needles remained parallel to the horizon, but that in coming toward the north pole, the north end of the needle was depreſſed, and that the ſouth end dipped in like manner at the Cape of Good Hope, and in the Indian Ocean; that the needle gradually approached the horizontal poſition as the ſhip approached the equator, but that in coming to the north of it at Batavia, the north point again dipped, and at Canton was ſeveral degrees below the horizon.

On theſe authorities, Norman boldly ſaid that, in the equatorial regions, the needle was horizontal, and that either end dipped regularly as it approached either pole; and that in the poles of the earth, the needle was perpendicular to the horizon. He therefore announced this as a diſcovery, not only ſingularly curious, but alſo of immenſe importance; for by means of a dipping needle the latitude of a ſhip at ſea may be found without ſeeing the ſun or ſtars.

Dr Gilbert, comparing this poſition of the compaſs needle with the poſitions which he had obſerved ſmall needles aſſume in his numerous experiments in relation to a magnet, as we have deſcribed at great length, was naturally led to the notion of the earth's being a great loadſtone, or as containing one, and that this arranged the dipping, or, in general, the mariner's needle, in the ſame manner as he obſerved a great magnet arrange a ſmall needle poiſed on its pivot. He therefore compoſed his *Phiſiologia Nova de Magnete*, et *de Tellure magno Magnete*; in which he notices ſo many points of reſemblance to the directive power of a magnet, that the point ſeems no longer to admit of any doubt. Dr Gilbert's theory may be thus expreſſed:

All the phenomena of natural magnetiſm are analogous to what we ſhould obſerve, if the earth were a great magnet, having its poles near the poles of the earth's equator, the north pole not far from Baffin's Bay, and the ſouth pole nearly in the oppoſite part of the globe. A dipping needle, under the influence of this great magnet, muſt arrange itſelf in a plane which paſſes through the poles of the magnet, the poſition of which plane is indicated (at leaſt nearly) by the ordinary compaſs needle; and it will be inclined to the horizon ſo much the more as we recede from the equator of the great magnet.

This opinion of Dr Gilbert was not leſs ingenious than important; and if firmly eſtabliſhed, it furniſhes a complete theory of all the phenomena of magnetiſm. But obſervations were neither ſufficiently numerous in the time of Dr Gilbert, nor ſufficiently accurate, to enable that great genius to aſſign the poſition of this great magnet, nor the laws of its action. The theory was chiefly founded on the phenomena of the dipping needle; phenomena which might have been unknown for ages, had the firſt notice of them fallen into any other hands than Norman's. They are not, like thoſe of variation, which might be made by any ſailor. They require for their exhibition a dipping needle, and the attention to circumſtances which can occur only to a mathematician. A dipping needle is to this day, notwithſtanding all our improvements in the arts, one of the moſt delicate and difficult taſks that an inſtrument maker can take in hand, and a good one cannot be had for leſs than twenty guineas. We are confident that ſuch as even Norman could make were far inferior to what are now made, and quite unfit for uſe at ſea while the ſhip is under ſail, although they may be tolerably exact for an obſervation of the dip in any port; and we preſume that it was ſuch obſervations only that Norman confided in. Our readers will readily conceive the difficulty of poiſing a needle with ſuch a perfect coincidence of its centre of gravity and axis of motion, and perfect roundneſs of this axis, that it ſhall remain in any poſition that is given it. Add to this, that a grain of duſt, inviſible to the niceſt eye, getting under one ſide of this axis, may be ſufficient for making it aſſume another poſition. It muſt alſo be a difficult matter to preſerve this delicate thing, ſo as that no change can happen to it. Beſides, all this muſt be performed on a piece of tempered ſteel which we are certain has no magnetiſm. Where can this be got, or what can inſure us againſt magnetiſm? Nor is there leſs difficulty in making the obſervations without great riſk of error. If the needle, moveable only in a vertical plane, be not ſet in the plane of a magnetic meridian, it will always dip too much. At London, where the magnetic direction is inclined 73° to the horizon, if it be in a plane 20° from the magnetic meridian, it will ſtand almoſt perpendicular; for it is eaſy to ſee, by the mechanical reſolution of forces, that it will take the poſition which brings it neareſt to the true magnetic direction. This, we think, is confirmed by ſeveral of Norman's and other old obſervations of dip. They are much greater than they have been ſince found in the ſame places.

Mr Daniel Bernoulli has given a very ingenious principle, by which we can make a dipping needle which will give a very accurate obſervation on ſhore; and being ſo eaſily executed, it deſerves to be generally known. Let a dipping needle be made in the beſt manner that can be done by a workman of the place, and balanced with ſome care before impregnation, ſo that we may be certain that when touched it will take nearly the true dip. Touch it, and obſerve the dip. Deſtroy its magnetiſm, and then alter its balance in ſuch a manner that, without any magnetiſm, it will arrange itſelf in the inclination of the obſerved dip. Now touch it again, giving it the ſame poles as before. It is plain that it will now approach exceedingly near indeed to the true dip, becauſe its want of *perfect* equilibrium deranged it but a few degrees from the proper direction. If this ſecond obſervation of the dip ſhould differ ſeveral degrees from the firſt, by the inaccurate firſt formation of the needle, it will be proper to repeat the operation. Very rarely, indeed, will the third obſervation of the dip vary from the truth half a degree.

63 Daniel Be[r]noulli's d[ip]ping nee[dle]

Mr Bernoulli makes this ſimple contrivance anſwer the purpoſe of an univerſal inſtrument in the following ingenious manner. A very light braſs graduated circle EFG (fig. 23.) is fixed to one ſide of the needle, concentric with its axis, and the whole is balanced as nicely as poſſible before impregnation. A very light index CD

CD is then fitted on the axis, ſo as to turn rather ſtiffly on it. This will deſtroy the equilibrium of the needle. If the needle has been made with perfect accuracy, and perfectly balanced, the addition of this index would cauſe it always to ſettle with the index perpendicular to the horizon, whatever degree of the circle it may chance to point at. But as this is ſcarcely to be expected, ſet the index at various degrees of the circle, and note what inclination the unmagnetic needle takes for each place of the index, and record them all in a table. Suppoſe, for example, that when the index is at 50, the needle inclines 46° from the horizon. If in any place we obſerve that the needle (rendered magnetic by lying between two ſtrong magnets), having the index at 50, inclines 46°, we may be certain that this is the dip at that place; for the needle is not deranged by the magnetiſm from the poſition which gravity alone would give it. As we generally know ſomething of the dip that is to be expected in any place, we muſt ſet the index accordingly. If the needle does not ſhew the expected dip, alter the poſition of the index, and again obſerve the dip. See whether this ſecond poſition of the index and this dip form a pair which is in the table. If they do, we have got the true dip. If not, we muſt try another poſition of the index. Noticing whether the agreement of this laſt pair be greater or leſs than that of the former pair, we learn whether to change the poſition of the index in the ſame direction as before, or in the oppoſite. The writer of this article has a dipping needle of this kind, made by a perſon totally unacquainted with the making of philoſophical inſtruments. It has been uſed at Leith, at Cronſtadt in Ruſſia, at Scarborough, and at New York, and the dip indicated by it did not in any ſingle trial differ $1\frac{1}{2}$ degrees from other trials, or from the dip obſerved by the fineſt inſtruments. He tried it himſelf in Leith Roads, in a rough ſea; and does not think it inferior, either in certainty or diſpatch, to a needle of the moſt elaborate conſtruction. It is worthy of its moſt ingenious author, and of the public notice, becauſe it may be made for a moderate expence, and therefore may be the means of multiplying the obſervations of the dip, which are of immenſe conſequence in the theory of magnetiſm, and for giving us an accurate knowledge of the magnetical conſtitution of this globe.

64 Opinions concerning the great magnet contained in this globe.

This knowledge is ſtill very imperfect, owing to the want of a very numerous collection of obſervations of the dip. They are of more importance than thoſe of the horizontal deviations from the meridian. All that we can ſay is, that the earth acts on the mariner's needle as a great loadſtone would do. But we do not think that the appearances reſemble the effects of what we would call a good loadſtone, having the regular magnetiſm of two vigorous poles. The dips of the needle in various parts of the earth ſeem to be ſuch as would reſult from the action of an extremely irregular loadſtone, having its poles exceedingly diffuſed. The increaſe of the dip, as we recede from thoſe places where the needle is horizontal, is too rapid to agree with the ſuppoſition of two poles of conſtipated magnetiſm, whether we ſuppoſe the magnetic action in the inverſe ſimple or duplicate ratio of the diſtances, unleſs the great terreſtrial magnet be of much ſmaller dimenſions than what ſome other appearances oblige us to ſuppoſe. If there be four poles, as Dr Halley imagined, it will be next to impoſſible to aſcertain the poſitions of the dipping needle. It will be a tangent to one of the ſecondary magnetic curves, and theſe will be of a very intricate ſpecies. We cannot but conſider the diſcovery of the magnetic conſtitution of this globe as a point of very great importance, both to the philoſopher and to ſociety. We have conſidered it with ſome care; but hitherto we have not been able to form a ſyſtematic view of the appearances which gives us any ſatisfaction. The well informed reader is ſenſible, that the attempt by means of the horizontal or variation needle is extremely tedious in its application, and is very unlikely to ſucceed; at the ſame time it muſt be well underſtood. The two diſſertations by Euler, in the 13th and 22d volumes of the Memoirs of the Royal Academy at Berlin, are moſt excellent performances, and give a true notion of the difficulty of the ſubject. Yet, even in theſe, a circumſtance is overlooked, which, for any thing we know to the contrary, may have a very great effect. If the magnetic axis be far removed from the axis of revolution, as far, for example, as Mr Churchman places it, the magnetic meridians will be (generally) much inclined to the horizon; and we ſhall err very far, if we ſuppoſe (as in Euler's calculus) that the dipping needle will arrange itſelf in the verticle plane, paſſing through the direction of the horizontal or variation needle; or if we imagine that the poles of the great magnet are in that plane. We even preſume to think that Mr Euler's aſſumption of the place of his fictitious poles (namely, where the needle is vertical), in order to obtain a manageable calculus, is erroneous. The introduction of this circumſtance of inclination of the magnetic meridians to the horizon, complicates the calculation to ſuch a degree as to make it almoſt unmanageable, except in ſome ſelected ſituations. Fortunately, they are important ones for aſcertaining the places of the poles. But the inveſtigation by the poſitions of the dipping needle is incomparably more ſimple, and more likely to give us a knowledge of a multiplicity of poles. The conſideration of the magnetic curves (in the ſenſe uſed in the preſent article), teaches us that we are not to imagine the poles immediately under thoſe parts of the ſurface where the needle ſtands perpendicular to the horizon, nor the magnetic equator to be in thoſe places where the needle is horizontal; a notion commonly and plauſibly entertained. Unfortunately our moſt numerous obſervations of the dip are not in places where they are the moſt inſtructive. A ſeries ſhould be obtained, extending from New Zealand northward, acroſs the Pacific Ocean to Cape Fairweather on the weſt coaſt of North America, and continued through that part of the continent. Another ſeries ſhould extend from the Cape of Good Hope, up along the weſt coaſt of Africa to the tropic of Capricorn; from thence acroſs the interior of Africa (where it would be of great importance to mark the place of its horizontality) through Sicily, Italy, Dalmatia, the eaſt of Germany, the Gulph of Bothnia, Lapland, and the weſt point of Greenland. This would be nearly a plane paſſing through the probable ſituations of the poles. Another ſeries ſhould be made at right angles to this, forming a ſmall circle, croſſing the other near Cape Fairweather. This would paſs near Japan, through Borneo, and the weſt end of New Holland; alſo near Mexico, and a few degrees weſt of Eaſter Iſland. In this place, and at Borneo, the

See VARIATION, Encycl.

the inclination of the magnetic plane to the horizon would be confiderable, but we cannot find this out. It may, however, be difcovered in other points of this circle, where the dip is confiderable. We have not room in this fhort account to illuftrate the advantages derived from thefe feriefes; but the reflecting reader will be very fenfible of them, if he only fuppofes the great magnet to be accompanied by its magnetic curves, to which the needle is always a tangent. He will then fee that the firft feries from New Zealand to Cape Fairweather, and the fecond from Cape Fairweather round the other fide of the globe, being in one plane, and at very different diftances from the magnetic axis, muft contain very inftructive pofitions of the needle. But we ftill confefs, that when we compare the dips already known with the variations, they appear fo irreconcileable with the refults of an uniform regular magnetifm, that we defpair of fuccefs. Every thing feems to indicate a multiplicity of poles, or, what is ftill more adverfe to all calculation, an irregular magnetifm with very diffufed polarity.

Much inftruction may furely be expected from the obfervations of the Ruffian academicians and their eleves, who are employed in furveying that vaft empire; yet we do not meet with a fingle obfervation of the dip of the needle in all the bygone publications of that academy, nor indeed are there many of the variation.

65 And concerning the fituation of its poles.

For want of fuch information, philofophers are extremely divided in their opinions of the fituation of the magnetic poles of this globe. Profeffor Krufft, in the 17th volume of the Peterfburgh Commentaries, places the north pole in lat. 70° N. and long. 23° W. from London; and the fouth pole in lat. 50° S. and long. 92° E.

Wilcke of Stockholm, in his indication chart (*Swed. Mem.* tom. xxx. p. 218.), places the north pole in N. Lat. 75°, near Baffin's Bay, in the longitude of California. The fouth pole is in the Pacific Ocean, in lat. 70° S.

Churchman places the north pole in lat. 59° N. and long. 135° W. a little way inland from Cape Fairweather; and the fouth pole in lat. 59° S. Long. 165° E. due fouth from New Zealand.

A planifphere by the Academy of Sciences at Paris for 1786, places the magnetic equator fo as to interfect the earth's equator in long. 75°, and 155° from Ferro Canary Ifland, with an inclination of 12 degrees nearly, making it a great circle very nearly. But we are not informed on what authority this is done; and it does not accord with many obfervations of the dip which we have collected from the voyages of feveral Britifh navigators, and from fome voyages between Stockholm and Canton. Mr Churchman has given a fketch of a planifphere with lines, which may be called parallels of the dip. Thofe parts of each parallel that have been afcertained by obfervation are marked by dots, fo that we can judge of his authority for the whole conftruction. It is but a fketch, but gives more fynoptical information than any thing yet publifhed. The magnetic equator cuts the earth's equator in long. 15°, and 195° E. from Greenwich, in an angle of nearly 17 degrees. The circles of magnetic inclination are not parallel, being confiderably nearer to each other on the fhort meridian than on its oppofite. This circumftance, being founded on obfervation, is one of the ftrongeft arguments for the exiftence of a magnet of tolerable regularity, as the caufe of all the pofitions of the compafs needle; for fuch *muft* be the pofitions of the circles of equal dip, if the axis of this magnet is far removed from the axis of rotation, and does not interfect it.

66. Now, if the fituation of the poles be any thing near the average or medium of thefe determinations, and if we form all our notions by analogy, comparing the pofitions of the compafs needle in relation to the great terreftrial magnet, with the pofitions affumed by a fmall needle in the neighbourhood of a magnet, we muft conclude, that the magnetical conftitution of this globe has little or no reference to its regular external form. The axis of the magnet is very far removed from that of the globe (at leaft 1500 miles), and is not nearly parallel to it, nor in the fame plane. It required the fagacity and the fkill of a Euler to fubject fuch anomalous magnetifm to any rules of computation; and every perfon qualified to judge of the fubject muft allow his differtation in the 13th volume of the Berlin Memoirs to be a work of wonderful refearch. It is a very agreeable thing to fee fuch a conformity between the lines which exprefs the regular magnetifm of Euler's differtation, and the lines drawn by Dr Halley from obfervation, and which appeared to himfelf fo capricious, that he defpaired (notwithftanding his confummate fkill in geometry) of their ever being reduced to a mathematical and precife fyftem.

67 Confirmations of Dr Gilbert's phyfiology.

Without detracting from the merit of Dr Gilbert, we may prefume to fay that his notion of the earth's being a great magnet was not, in his mind, more than a fagacious conjecture, formed from a very general and even vague comparifon. Yet the comparifon was fufficiently good to give him great confidence in his opinion that the action of this great magnet, in perfect conformity to what we obferve in our experiments with magnets, is the fource of all the magnetifm that we obferve. If there was nothing elfe in proof of the juftnefs of his theory, it is abundantly proved by the beautiful experiment of Mr Henfhaw, mentioned in the article VARIATION, *Encycl.* p. 621. col. 2. An iron bar held nearly upright, attracts the fouth end of a compafs needle with its lower end; and if that end of the bar be kept in its place, and the bar turned round till it becomes the upper end, the fouth point of the needle immediately turns away from it, and the north end is now attracted. This experiment may be perfectly imitated with artificial magnetifm.

Having fupported a large magnet SAN (fig. 24.), fo that its ends are detached from furrounding bodies, place a fmall needle B (poifed on its pivot) about three inches below the north pole N of the magnet, and in fuch a fituation that its polarity to the magnet may be very weak. Take now a fmall piece of common iron, and hold it in the pofition reprefented at C. Its lower end becomes a north pole, attracting the fouth pole of the needle. Keeping this in its place, turn round the piece of iron into the pofition D; the fouth pole of B will now avoid it, and the north pole will be attracted. We directed the needle to be fo placed, that its polarity, in relation to the magnet, may be weak. If it be ftrong, it may act on the end of C or D like a magnet, and counteract the magnetifm induced on C or D by vicinity to A.

An

An anonymous writer in the Philosophical Transactions, No 177. Vol. XV. relates several observations made during a voyage to the East Indies, which are quite conformable to this. A few leagues northwest from the island Ascension, the south point of the compass needle hardly shewed any tendency to or from the lower end of an iron bar. It seemed rather to avoid the upper end; it was not in the least affected by the middle of the bar; but when the bar was laid horizontal, in the magnetic direction, its two ends affected the dissimilar ends of the compass needle very strongly; but when horizontal, and lying at right angles to the magnetic direction, its polarity was altogether indifferent.

As the other phenomena of induced artificial magnetism have the same resemblance to the phenomena of natural magnetism, a bar which has remained long in the vicinity of a magnet acquires magnetism (permanent) in the same way, and modified by the same circumstances, as in natural magnetism. Hammering a bit of common iron in the immediate vicinity of a magnet, gives it very good magnetism. Exposing a red hot bar to cool in the neighbourhood of a magnet has the same effect. Also quenching it suddenly has the same effect. Quenching a small red hot steel bar between two magnets, was found by us to communicate a much stronger magnetism than we could give it by any other method. Its form indeed was very unfavourable for the ordinary method of touching; for it consisted of two little spheres connected by a slender rod, and could scarcely be impregnated in any other way than by placing it for a very long while between magnets. In all these experiments, the polarity acquired is precisely similar to that acquired by the same treatment in relation to this supposed great terrestrial magnet. In short, in whatever manner we pursue this analogy in our experiments, we find the resemblance most perfect in the phenomena.

We cannot but think, therefore, that this new physiology of the magnet by Dr Gilbert is well established; and we think ourselves authorised to assume it as a proposition fully demonstrated, that the earth is a great magnet, or contains a great magnet, the agency of which produces the direction of the magnetic needle, and all the magnetism which iron acquires by long continuance in a proper position. It is this which made us say, in the beginning of this article, that attraction and polarity were not confined to magnets, but were properties belonging to all iron in its metallic state. We now see the reason why any piece of iron brought very near to another piece will attract it—both become magnetical, in consequence of the agency of the great magnet; and their magnetism is so disposed, that their mutual attractions exceed their repulsions. Also, why an iron rod, placed nearly in the magnetical direction, will finally arrange itself in that direction. Also, why the terrestrial polarity of common iron is indifferent, and either end of the rod will settle in the north, if it have nearly that position at first. The magnetism induced by mere momentary position is so feeble as to yield to any artificial magnetism. As a moment was sufficient for imparting it, a moment suffices for destroying it; and another moment will impart the opposite magnetism. But artificial magnetism requires more force for its production, and some of it remains when the producing cause is removed, and it does not yield at once to the contrary magnetism. That there is no farther difference appears from this, that long continued position gives determined and permanent magnetism, and that it is destroyed by an equally long continuance in the contrary position. It seems to be very generally true, that a magnet will carry more by its north than by its south pole. It should be so in this part of the world, because the terrestrial magnetism induced on the iron conspires with the magnetism induced by the north pole of a magnet, but counteracts the magnetism induced by the south pole.

The propriety of Mr Savery's, Mr Canton's, and Mr Antheaume's processes for beginning the impregnation of hard steel bars is now plain, and the superior effect of the two great bars of common iron in the proposed method of Mr Antheaume. We cannot but take this opportunity of paying the proper tribute of praise to the ingenuity of Mr Savery. Every circumstance of his process was selected in consequence of an accurate conception of magnetism, and the combination of this science with Dr Gilbert's theory. His process is the same with Antheaume's in every respect, except the circumstance of the double touch borrowed from Mitchell and Canton. These observations do not detract from the discernment of Mitchell and Canton, who saw in those experiments what had escaped the attention of hundreds of readers.

68 Seeming objection deduced from the want of sensible attraction.

But there occurs an objection to this theory of Dr Gilbert, which was urged against it with great force. We observe no tendency in the magnet or compass needle toward this supposed magnet. An iron or steel bar is not found to increase its tendency downwards, that is, is not sensibly heavier, when its south pole is uppermost in this part of the world. A needle set afloat on a piece of cork arranges itself quickly in the proper direction; but if continued ever so long afloat, it has never been observed to approach the north side of the vessel. This is quite unlike what we observe in the mutual actions of magnets, or the action of magnets on iron. This objection appears to have given Dr Gilbert some concern; and he mentions many experiments which have been tried on purpose to discover some magnetical tendency. He gets rid of it as well as he can, by saying that the directive power of a magnet extends much farther than its attractive power. He confirms this by several experiments. But Dr Gilbert had not studied the simultaneous actions of the four poles, nor explained, by the principles of compound motion, how these produced all the possible positions of the needle. Indeed, the composition of mechanical forces was by no means familiar with philosophers at the end of the 16th century. We see it now very distinctly. The polarity of the needle, or the force with which it turns itself into the magnetical position, depends on the difference between the *sums* of the actions of each pole of the magnet on both the poles of the needle; whereas its tendency towards the magnet depends on the difference of the *differences* of those actions (see n° 22, 25.) The first may thus be very great when the other is almost insensible. We see that coarse iron filings heap about the magnet very fast, and that very fine filings approach it very slowly. Now, the largest magnet that we can employ, when compared with the great magnet in the earth, is but as a particle of the finest filings that can be conceived. This surely diminishes exceedingly, if it does not entirely annihilate the objection: but as we have heard it urged by many as an improbable thing, that a long magnet, kept afloat for many months (which has been done) ſhall not ſhew the *ſmalleſt* tendency towards the pole of the terreſtrial magnet, we think it deſerves to be conſidered with accuracy, and the queſtion decided in a way which will admit of no doubt.

69 This completely anſwered.

Let the very ſmall magnet C (fig. 25.) be placed near a great magnet A, and then near a ſmaller magnet B, in ſuch a manner that its polarity to both ſhall be the ſame; and then let us determine the proportion between the attractions of A and B for the ſmall magnet C.

This will evidently depend on the law of magnetic action. For greater ſimplicity of inveſtigation, we ſhall content ourſelves with ſuppoſing the action to be inverſely as the diſtance.

Let AN, = AS, $=a$; BN $=b$; Cn $=c$, AC $=d$, BC $=\delta$; and let the abſolute force of A be to that of B at the ſame diſtance as m to 1.

The magnetic action being ſuppoſed proportional to $\frac{1}{d}$, we have,

1. Action of AN on Cs $= \frac{m}{d-a-c}$.

2. ——— AN on Cn $= -\frac{m}{d-a+c}$.

3. ——— AS on Cs $= -\frac{m}{d+a-c}$.

4. ——— AS on Cn $= \frac{m}{d+a+c}$.

5. The whole action $= \dfrac{8\,m\,a\,c\,d}{\overline{d^2-\overline{a+c}^2}\,|^2 \times \overline{d^2-\overline{a-c}^2}\,|^2}$.

6. If c be very ſmall in compariſon with a or b, the whole action of A is very nearly $= \dfrac{8\,m\,a\,c\,d}{\overline{d^2-a^2}^2}$.

7. And the tendeney of C to B is, in like manner, $= \dfrac{8\,b\,c\,\delta}{\overline{\delta^2-b^2}^2}$.

The directive powers of A and B are at their maximum ſtate when C is placed with its axis at right angles to the lines AC or BC. In which caſe we have,

8. The directive power of A $= \dfrac{4\,m\,a}{d^2-a^2}$.

9. The directive power of B $= \dfrac{4\,b}{\delta^2-b^2}$.

When theſe directive powers are made equal, by placing C at the proper diſtances from A and B, we have,

10. $4\,m\,a : 4b$, or $m\,a : b = d^2-a^2 : \delta^2-b^2$

And $m\,a\,\delta^2 - m\,a\,b^2 = b\,d^2 - b\,a^2$

$m\,a\,\delta^2 = b\,(d^2-a^2) + m\,a\,b^2$.

11. $\delta^2 = \dfrac{b}{m\,a}(d^2-a^2) + b^2$.

12. $\delta = \sqrt{\dfrac{b}{m\,a}(d^2-a^2) + b^2}$.

Let the attractions of A and B for the very ſmall magnet C, when its polarity to both is the ſame, be expreſſed by the ſymbols α and β. We have

$\alpha : \beta = \dfrac{8\,m\,a\,c\,d}{(d^2-a^2)^2} : \dfrac{8\,b\,c\,\delta}{(\delta^2-b^2)^2}$, which, by n° 10. is $= \dfrac{8\,(d^2-a^2)\,c\,d}{(d^2-a^2)^2} : \dfrac{8\,(\delta^2-b^2)\,c\,\delta}{(\delta^2-b^2)^2} = \dfrac{d}{d^2-a^2} : \dfrac{\delta}{\delta^2-b^2}$, $= b\,d : m\,a\,\delta$; that is,

13. Attr^n of A : attr^n of B $= b\,d : m\,a\,\delta$.

As an example of this compariſon, let us ſuppoſe the great terreſtrial magnet to be a thouſand times larger and ſtronger than the magnet whoſe attraction we are comparing with that of terreſtrial magnetiſm. Let us alſo ſuppoſe the diſtance from the pole of the great magnet to be ſmall, ſo that its attraction may be conſiderable. Let us make $d = 1200$, a being $= 1000$, and $b = 1$. Theſe are all very reaſonable ſuppoſitions. Subſtituting theſe values in the formula, we have attr^n of A : attr^n of B $= 1 : 1000$ very nearly; and therefore when the needle, when placed near a magnet, vibrates by its polarity as faſt as it does by natural magnetiſm, its tendency toward that magnet muſt be altogether inſenſible; for the diſproportion is incomparably greater than that of 1 to 1000, in the largeſt magnets with which we can make experiments. Obſerve alſo, that we have taken the caſe where the attractions are the ſtrongeſt, viz. when the magnet C is placed in the axis of A or B. In the oblique poſitions, tangents to the magnetic curves, the attractions are ſmaller, almoſt in any ratio.

We took the inverſe ratio of the diſtances for the law of action, only becauſe the analyſis was very ſimple. It is very evident that the diſproportion will be ſtill more remarkable, if the action be inverſely as the ſquare of the diſtance.

The objection therefore to the origin of the polarity of the compaſs needle, and of all other magnets, namely, the action of a great magnet contained in the earth, appears plainly to be of no force. We rather think that the want of all ſenſible attraction, where there is a briſk polarity, is a proof of the juſtneſs of the conjecture; for if the compaſs needle were arranged by the action of magnetic rocks, or even extenſive ſtrata, near the ſurface of the earth, the attractions would bear a greater proportion to the polarities. We have even obſerved this. A conſiderable maſs of magnetic ſtratum was found to derange the needle of a ſurveyor's theodolite at a conſiderable diſtance all around (about 140 yards). The writer placed the needle on a thin lath, which juſt floated it on water in a large wooden diſh, and ſet it in a place where it was drawn about 15 degrees from the magnetic meridian. It was left in that ſituation a whole night, well defended from the wind by a board laid on the diſh. Next morning it was found applied to that ſide of the diſh which was neareſt to the diſturbing rocks. It had moved about ſix inches. This was repeated three times, and each time it moved in the ſame direction (nearly), which differed conſiderably from the direction of the needle itſelf.

It is now plain that we may, with confidence, aſſume Dr Gilbert's theory of terreſtrial magnetiſm as ſufficiently eſtabliſhed. And, ſince we muſt certainly call that the north pole of the great magnet which is ſituated in the northern parts of the earth, and ſince thoſe poles of magnets which attract each other have oppoſite polarities, we muſt ſay, that what we call the north pole of a mariner's needle, or of any other magnet, has the ſouthern polarity.

We may now venture to go farther with Dr Gilbert, and

70 The great magnet is the source of all natural magnetism.

and to say that *all* the magnetism which we observe, whether in nature or art, is either the immediate or the remote effect of the action of the great magnet. As soft bars soon acquire a transient magnetism; as hard bars, after long exposure, acquire a sensible and permanent magnetism—we must infer, that ores of iron, which are in a state fit for impregnation, must acquire a sensible and permanent magnetism, by continuing, for a series of ages, in the bowels of the earth. And thus the magnetism of loadstones, which, till the discovery of the natural magnetism acquired by position, were the sources of all our magnetical phenomena, is now proved to be a necessary consequence of the existence and agency of a great magnet contained in the bowels of the earth.

71 Loadstones in the mine may have their poles in any position.

It seems to result from this theory, that, in these northern parts of the world, that part of every natural loadstone that is at the extremity of the line drawn through the stone in the magnetic direction should be its pole; and that the loadstone, when properly poised, should of itself assume the very position which it had in the mine. Dr Gilbert complains of the inattention of miners (*rude hominum genus, lucro potius quam physicæ consulentes*) to this important circumstance. Once, however, he had the good fortune to be advertised of a great magnetic mass lying in its matrix. He repaired quickly to the mine, examined it, and marked its points which were in the extremities of the magnetic line. When it was detached from its matrix, he had the pleasure of finding its poles in the very places he expected. The loadstone was of considerable size, weighing about 20 pounds.—Mr Wilcke gives, in the Swedish Commentaries, several instances of the same kind.

But should this always be the case? By no means. There are many circumstances which may give the magnetism of a loadstone a very different direction. We have found, that simple juxtaposition to a magnet will sometimes give a succession of poles to a long bar of hard steel. The same thing may happen to an extensive vein of magnetisable matter. The loadstone taken out of this vein may have been placed like that of a soft bar placed in the magnetic line, if lying in one part of the vein; if taken from another part of it, its polarity may be the very reverse; and in another part of it may have no magnetism, although completely fitted for acquiring it. It may have its poles placed in a direction different from all these, in consequence of the vicinity of a greater loadstone. As loadstones possessed of vigorous magnetism are always found only in small pieces, and in pieces of various sizes and force, we must expect every position of their poles. The only thing that we can expect by theory is, that adjoining loadstones will have their friendly poles turned toward each other, and a general prevalence of or tendency to a polarity symmetrical with that of the earth. The reader will find some more observations to this purpose in the article Variation, *Encycl.* p. 623. as also in Gilbert's Treatise, B. III. c. 2. p. 121.

Nor should all strata or masses of iron ore be magnetical. We know that none are susceptible of induced magnetism, but such as are, to a certain degree, in the metallic state. Such ores are not abundant. Nay, even all of such strata do not necessarily acquire magnetism by the action of the great magnet. If their principal dimensions lie nearly perpendicular to the magnetic direction, they will not acquire any sensible quantity. A stratum in this country, rising about 17° to the N. N. W. will scarcely acquire magnetism. It may also happen, that the influence of the great magnet is counteracted by that of some extensive stratum inaccessible to man, by reason of its great depth.

72 Probable cause of their great natural vigour.

Thus we see that all the appearances of the original magnetism of loadstones are perfectly consistent with the notion that they are effects of one general cosmical cause, the action of the great magnet contained in the earth; and that there is no occasion to suppose this great magnet to differ, in its constitution or manner of action, from the small masses of similar matter called loadstone. The only difficulty that presents itself is the great superiority of magnetic force observable in some loadstones over other masses of ores circumjacent, which are not distinguishable by us by any other circumstance. We acknowledge ourselves unable to solve this difficulty; for the magnetism of such pieces is sometimes incomparably stronger than what a bar of iron acquires by position; yet this bar is much more susceptible than the ores which are fit for becoming loadstones. Perhaps there is some chemical change which obtains gradually in certain masses, which aids the impregnation, in the same way that we know that being red hot destroys all magnetism, whether in a metal bar or in an ore. This seems to be confirmed by what we see in some old iron stanchions, which acquire the strongest magnetism in those parts of their substance which are combining themselves with ingredients floating in the atmosphere. That part which is cased in the stone, and exfoliates and splits with rust, being converted into something like what is called finery-cinder, becomes highly and permanently magnetic. Such peculiarities as these, operating for ages, may allow a degree of magnetical impregnation (in whatever this may consist) to take place, to which we can see no resemblance in our experiments. It would be worth while to place iron wires in a tube in the magnetic direction, which could be kept of a proper red heat, while it is converted into æthiops by steam. It is not unlikely that it would acquire a sensible and permanent magnetism in this way. It may be, that the little atoms, as they arrange themselves in a sort of crystalline or symmetrical form, may also arrange so as to favour magnetism. Were this tried in the vicinity of a strong magnet, the effect might be more remarkable and precise. Perhaps, too, while iron is precipitated in a metallic form from its solutions by another metal, something of the same kind may happen. We know that proper ores of iron, exposed to cementation in a low red heat, in the magnetic direction, becomes magnetic.

73 Natural causes of the changes of the magnetic direction.

Notice has been taken in the *Encycl.* article Variation, of the attempts of ingenious men to explain the change which is observed in all parts of the globe, on the direction of the mariner's needle, the gradual change of the variation. The hypothesis of Dr Halley, that the globe which we inhabit is hollow, and incloses a magnetic nucleus, moving round another axis, is not inconsistent with any natural law, if he did not suppose the interval filled up with some fluid. The action of the nucleus and shell on the intervening fluid would gradually bring the two to one common motion of rotation, as may be inferred from the reasonings employed by Newton in his remarks on the Cartesian vortices.

Leaving

Leaving out this circumſtance, there is only another cauſe which can affect, and muſt affect, the rotation of both; namely, the mutual action of the magnetic nucleus, and the maſſes of magnetic matter in the ſhell. If the axis of rotation of this nucleus be different from the line joining its magnetic poles, theſe poles will have a motion relative to the ſhell; and this motion may eaſily be conceived ſuch as will produce the changes of magnetic direction which we obſerve. It may even produce a motion of the northern magnetic pole in one direction, and of the ſouthern pole in the oppoſite direction, and this with the appearance of different periods of rotation, as ſuppoſed by Mr Churchman. We may here obſerve, by the way, that the change of magnetic direction in this country is not nearly ſo great as is commonly imagined. The horizontal needle has ſhifted its poſition about 35° at London ſince 1585; but the point of the dipping needle has not changed 10°. We may alſo obſerve, that when the pole of the central magnet changes its place, the magnetiſm of an extenſive ſtratum, influenced by it, may ſo alter its diſpoſition, as to change the poſition of the compaſs needle in the oppoſite direction to that of the change which the central magnet alone would induce on it.

But as motions have not yet been aſſigned to this nucleus, which quadrate with the obſerved poſitions of the needle, and as the very exiſtence of it is hypothetical, it may not be amiſs to examine whether ſuch a change of variation may not be explained by what we know of the laws of magnetiſm, and of the internal conſtitution of this earth?

1. It is pretty certain that the veins in which loadſtones are found are not parts of the great magnet. This appears from their having two poles while in the mine, and alſo from the very ſmall depth to which man has been able to penetrate. When we compare the poſitions of the dipping needle with thoſe of a ſmall needle near a magnet, we muſt infer, that the poles are very far below the ſurface.

Yet we know that there are magnetiſable ſtrata of very great extent, occupying a very conſiderable portion of the external covering. Though their bulk and abſolute power may be ſmall, when compared with thoſe of the great magnet, yet their greater vicinity to the needles on which obſervations are made, may give them a very ſenſible influence. In this way may a great deal of the obſerved irregularities of the poſitions of the needle be accounted for. In the Lagoon at Teneriffe, *Feuillée* obſerved the variation 13° 30′ weſt in 1724, while at the head of the iſland it was only 5°. The dip at the Lagoon was 63° 30′, greatly ſurpaſſing what was obſerved in the neighbourhood. Muller found, in the mountains of Bohemia, great and deſultory differences of declination, amounting ſometimes to 50°. At Mantua, the variation in 1758 was 12°; while at Bononia and Brixia it was nearly 18°. Great irregularities were obſerved by Goëte in the Gulph of Finland, eſpecially near the iſland of Suſſari, among ſome rocks: on one of theſe, the needle ſhewed no polarity. Captain Cook and Captain Phipps obſerved differences of 10°, extending to a conſiderable diſtance, on the weſt coaſts of North America. In the neighbourhood of the iſland Elba in the Mediterranean, the poſition of the needle is greatly affected by the iron ſtrata, in which that iſland ſo much abounds. In this country, there are alſo obſerved ſmall deviations, which extend over conſiderable tracts of country, indicating a great extent of ſtrata that are weakly magnetic. Since ſuch ſtrata receive their magnetiſm by induction, in a manner ſimilar to a bar of hard ſteel, and ſince we know that this receives it gradually, it may very probably happen, that a long ſeries of years may elapſe before the magnetiſm attains its ultimate diſpoſition.

Here then is a neceſſary change of the magnetic direction; and although it may be very different in different places, according to the diſpoſition and the power of thoſe ſtrata, there muſt be a general vergency of it one way.

2. It is well known that all metals, and particularly iron, are in a progreſs of continual production and demetallization. The veins of metals, and more particularly thoſe of iron, are evidently of poſterior date to that of the rocks in which they are lodged. Chemiſtry teaches us, by the very nature of the ſubſtances which compoſe them, that they are in a ſtate of continual change. This is another cauſe of change in the magnetic direction. Nay, we know that ſome of them have ſuddenly changed their ſituation by earthquakes and volcanoes. Some of the ſtreams of lava from Veſuvius and Ætna abound in iron. This has greatly changed its ſituation; and if the ſtrata from which it proceeded were magnetical, the needle in its neighbourhood muſt be affected. Nay, ſubterranean heat alone will effect a change, by changing the magnetiſm of the ſtrata. Mr Lievog, royal aſtronomer at Breſſeſtedt in Iceland, writes, that the great eruption from Hecla, in 1783, changed the direction of the needle nine degrees in the immediate neighbourhood. This change was produced at a mile's diſtance from the frozen lava; and it diminiſhed to two degrees at the diſtance of 2½ miles. He could not approach any nearer, on account of the heat ſtill remaining in the lava after an interval of 14 months.

All theſe cauſes of change in the direction of the mariner's needle muſt be partial and irregular. But there is another cauſe, which is coſmical and univerſal. Dr Halley's ſuppoſition of four poles, or, at leaſt, the ſuppoſition of irregular and diffuſed poles, ſeems the only thing that will agree with the obſervations of declination. We know that all magnetiſm of this kind (that is, diſpoſed in this manner) has a natural tendency to change. The two northern poles may have the ſame or oppoſite polarities. If they are the ſame, their action on each other tends to diminiſh the general magnetiſm, and to cauſe the centre of effort to approach the centre of the magnet. If they have oppoſite polarities, the contrary effect will be produced. The general magnetiſm of each will increaſe, and the pole (or its centre of effort) will approach to the ſurface. In either of theſe caſes, the compound magnetiſm of the whole may change exceedingly, by a change by no means conſiderable in the magnetiſm of each pair of poles. It is difficult to ſubject this to calculation; but the reader may have very convincing proof of it, by taking a ſtrong and a weaker magnet of the ſame length, and one of them, at leaſt, of ſteel not harder than ſpring temper. Lay them acroſs each other like an acute letter X; and then place a compaſs needle, ſo that its plane of rotation may be perpendicular to the plane of the X. Note exactly the poſition in which the needle ſettles. In a few minutes after, it will be found to change conſiderably,

ſiderably, although no remarkable change has yet happened to the magnets themſelves.

---

74 ecula- ns about : origin magne- n. Hy- :heſis of pinus.

We flatter ourſelves, that our readers will grant that the preceding pages contain what may juſtly be called a theory of magnetiſm, in as much as we have been able to conclude every phenomenon in one general fact, the induction of magnetiſm; and have given ſuch a deſcription of that fact and its modifications, that we can accurately predict what will be the appearances of magnets and iron put into any deſired ſituation with reſpect to each other. If our notions of philoſophical diſquiſition (delivered in art. Philosophy, *Encycl. Brit.*) be juſt, we have explained the ſubordinate phenomena, or have given a theory of magnetiſm.

But it is not eaſy to ſatiſfy human curioſity. Men have even inveſtigated, or ſought for cauſes of the perſeverance of matter in its preſent condition. We have not been contented with Newton's theory of the celeſtial motions, and have ſought for the cauſe of that mutual tendency which he called gravitation, and of which all the motions are particular inſtances.

Philoſophers have been no leſs inquiſitive after what may be the cauſe of that mutual attraction of the diſſimilar poles, and the repulſion of the ſimilar poles, and that faculty of mutual impregnation, or excitement, which ſo remarkably diſtinguiſh iron, in its various ſtates, from all other ſubſtances. The action of bodies on each other at a diſtance, has appeared to them an abſurdity, and all have had recourſe to ſome material intermedium. The phenomenon of the arrangement of iron filings is extremely curious, and naturally engages the attention. It is hardly poſſible to look at it without the thought ariſing in the mind of a ſtream iſſuing from one pole of the magnet, moving round it, entering by the other pole, and again iſſuing from the former outlet. Accordingly, this notion has been entertained from the earlieſt times, and different ſpeculatiſts have had different ways of conceiving how this ſtream operated the effects which we obſerve.

The ſimpleſt and moſt obvious was juſt to make it act like any other ſtream of fluid matter, by impulſion. Impulſion is the thing aimed at by all the ſpeculatiſts. They have a notion, that we conceive this way of communicating motion with intuitive clearneſs, and that a thing is fully explained when it can be ſhewn that it is a caſe of impulſion. We have conſidered the authority of theſe explanations in the article Impulsion of this *Supplement*, and need not repeat our reaſons for refuſing it any pre-eminence. But even when we have ſhewn the phenomena to be caſes of impulſion by ſuch a ſtream, the greateſt difficulty, the moſt curious and the moſt embarraſſing, is to aſcertain the ſources of this impulſive motion of the fluid—How, and from what cauſe does it begin? What forces bend it in curves round the magnet? Thoſe philoſophers, whoſe principle obliges them to explain gravitation alſo by impulſe, muſt have another ſtream to impel this into its curves. Acting by impulſion, this magnetic ſtream muſt loſe a quantity of motion equal to what it communicates. What is to reſtore this? What directs it in a particular courſe thro' the magnet? And what is it that can totally alter that courſe—in a moment—in all the phenomena of induced magnetiſm? How does it impel? Lucretius, either of himſelf, or ſpeaking after the Greek philoſophers, makes it impel, not the iron, but the ſurrounding air, ſweeping it out of the way; and thus giving occaſion for the ſurrounding air to ruſh around the magnet, and to hurry the bits of iron toward it. There is, perhaps, more ingenious refinement in this thought than in any of the impulſive theories adopted ſince his day by Des Cartes, Euler, and other great philoſophers: But it is ſagaciouſly remarked by D. Gregory, in his MS. notes on Newton, that this theory of Lucretius falls to the ground; becauſe the experiments ſucceed juſt as well under water as in the air. As to the explanations, or deſcriptions, of the canals and their dock gates, opening in one direction, and ſhutting in the other, conſtructions that are changed in an inſtant in a bar of iron, by changing the poſition of the magnet, we only wonder that men, who have a reputation to loſe, ſhould ever hazard ſuch crude and unmechanical dreams before the public eye. The mind of man cannot conceive the poſſibility of their formation; and if they are really formed, the effects ſhould be the very oppoſite of thoſe that are obſerved: the ſtream ſhould move thoſe bodies leaſt which afford ready channels for its paſſage. If a rag of iron filings be arranged by the impulſion of ſuch a ſtream, it ſhould be carried along by it; and if it is *impelled toward* one end of the magnet, it ſhould be impelled *from* the other end. Since we now know, that each particle of filings is a momentary magnet, we muſt allow a ſimilar ſtream whirling round each. Is that an explanation which exceeds all power of conception?

But has it ever been ſhewn that there is any impulſion at all in theſe phenomena? Where is the impelling ſubſtance? The only argument ever offered for its exiſtence is, that we are reſolved that the phenomena of magnetiſm ſhall be produced by impulſion, and the arrangement of iron filings looks ſomewhat like a ſtream. But enough of this. We truſt that we have ſhewn the way in which this arrangement obtains in the cleareſt manner. Every particle becomes magnetic by induction. This is a fact, which ſets all reaſoning at defiance. The polarity of each rag is ſo diſpoſed, that their adjoining ends turn to each other. This is another uncontrovertible fact. And theſe two facts explain the whole. The arrangement of iron filings, therefore, is a ſecondary fact, depending on principles more general; and therefore cannot, conſiſtently with juſt logic, be aſſumed as the foundation of a theory.

Had magnetiſm exhibited no phenomena beſides the attraction and repulſion of magnets, it is likely that we ſhould not have proceeded very far in our theories, and would have contented ourſelves with reducing theſe phenomena to their moſt general laws. But the communication of magnetiſm ſeems a great myſtery. The ſimple approach of a magnet communicates theſe powers to a piece of iron; and this without any diminution of its own powers. On the contrary, beginning with magnets which have hardly any ſenſible power, we can, by a proper alternation of the manipulations, communicate the ſtrongeſt magnetiſm to as many hard ſteel bars as we pleaſe; and the original magnets ſhall be brought to their higheſt degree of magnetiſm. We have no notion of powers or faculties, but as qualities of ſome ſubſtances in which they are inherent. Yet here is no appearance of ſomething abſtracted from one body, and communicated to, or ſhared with another. The proceſs is like kindling a great fire by a ſimple ſpark; here is is no communication, but only *occasion* given to the exertion of powers inherent in the combustible matter. It appears probable, that the case is the same in magnetism; and that all that is performed in making a magnet is the excitement of powers already in the steel, or the giving occasion for their exertion; as burning the thread which ties together the two ends of a bow, allows it to unbend. This notion did not escape the sagacity of Dr Gilbert; and he is at much pains to shew, that the *coitio magnetica* is a quality inherent in all magnetical bodies, and only requires the proper circumstance for its exertion. He is not very fortunate in his attempts to explain *how* it is developed by the vicinity of a magnet, and how this faculty, or actual exertion of this power, becomes permanent in one body, while in another it requires the constant presence of the magnet.

74 Magnetical hypothesis of Æpinus.

It is to Mr Æpinus, of the Imperial Academy of St Petersburgh, that we are indebted for the first really philosophical attempt to explain all these mysteries. We mentioned, in the article Electricity, *Suppl.* the circumstance which suggested the first hint of this theory to Æpinus, *viz.* the resemblance between the attractions and repulsions of the tourmaline and of a magnet. A material cause of the electric phenomena had long been thought familiar to the philosophers. They had attributed them to a fluid which they called an electric fluid, and which they conceived to be shared among bodies in different proportions, and to be transferable from one to another. Dr Franklin's theory of the Leyden phial, which led him to think that the faculty of producing the electrical phenomena depended on the deficiency as well as the redundancy of this fluid, combined with the phenomena of induced electricity, suggested to Æpinus a very perspicuous method of stating the analogy of the tourmaline and the magnet; which he published in 1758 in a paper read to the academy.

Reflecting more deeply on these things, Mr Æpinus came by degrees to perceive the perfect similarity between all the phenomena of electricity by position and those of magnetism; and this led him to account for them in the same manner. As the phenomena of the Leyden phial, explained in Franklin's manner, shews that a body may appear electrical all over, by having less than its natural quantity of the electric fluid, as well as by having more, it seemed to follow, that it may also be so in respect to different parts of the same body; and therefore a body may become electrified in opposite ways at its two extremities, merely by abstracting the fluid from one end, and condensing it in the other; and thus may be explained the phenomena of induced electricity, where nothing appears to have been communicated from one body to the other. If this be the case, the two ends of a body rendered electric by induction should exhibit the same distinctions of phenomena that are exhibited by bodies wholly redundant and wholly deficient. The redundant ends should repel each other; so should the deficient ends; and a redundant part should attract a deficient. All these results of the conjecture tally exactly with observation, and give a high degree of probability to the conjecture. The similarity of these phenomena to the attractions of the dissimilar poles of a magnet, and the repulsions of the similar poles, is so striking, that the same mode of explanation forces itself on the mind, and led Mr Æpinus to think, that the faculty of producing the magnetical phenomena belonged to a magnetical fluid, residing in all bodies susceptible of magnetism; and that the exertion of this faculty require nothing but the abstraction of the fluid from one end of the magnetic bar, and its constipation in the other. And this conjecture was confirmed by observing, that in the induction of magnetism on a piece of iron, the power of the magnet is not diminished.

All these circumstances led Mr Æpinus to frame the following hypothesis:

1. There exists a substance in all magnetic bodies, which may be called the magnetic fluid; the particles of which repel each other with a force decreasing as the distance increases.

2. The particles of magnetic fluid attract, and are attracted by the particles of iron, with a force that varies according to the same law.

3. The particles of iron repel each other according to the same law.

4. The magnetic fluid moves, without any considerable obstruction, through the pores of iron and soft steel; but is more and more obstructed in its motion as the steel is tempered harder; and in hard tempered steel, and in the ores of iron, it is moved with the greatest difficulty.

In consequence of this supposed attraction for iron, the fluid may be contained in it in a certain determinate quantity. This quantity will be such, that the accumulated attraction of a particle for all the iron balances, or is equal to, the repulsion of all the fluid which the iron contains. The quantity of fluid competent to a particle of iron is supposed to be such, that the repulsion exerted between it and the fluid competent to another particle of iron is also equal to its attraction for that particle of iron: And therefore the attraction between the fluid in an iron bar A for the iron of another bar B, is just equal to its repulsion for the fluid in B; it is also equal to the repulsion of the iron in A for the iron in B. This quantity of fluid residing in the iron may be called its natural quantity.

In consequence of the mobility through the pores of the iron, the magnetic fluid may be abstracted from one end of a bar, and condensed in the other, by the agency of a proper external force. But this is a violent state. The mutual repulsion of the particles of condensed fluid, and the attraction of the iron which it has quitted, tend to produce a more uniform distribution. If we reflect on the law of action, we shall clearly perceive, that somewhat of this tendency must obtain in every state of condensation and rarefaction, and that there can be a perfect equilibrium only when the fluid is diffused with perfect uniformity. This, therefore, may be called the natural state of the iron.

If the resistance opposed by the iron to the motion of the magnetic fluid be like that of perfect fluids to the motion of solid bodies, arising entirely from the communication of motion, there is no tendency to uniform diffusion so weak as not to overcome such resistance, and finally to produce this uniform distribution. But (as is more probable) if the obstruction resembles that of a clammy fluid, or of a soft plastic body like clay, some of the accumulation, produced by the agency of an external force, may remain when the force is removed; the diffusion will cease whenever the equalising force is just in equilibrio with the obstruction.

All the preceding circumstances of the hypothesis are

are ſo perfectly analogous to the hypotheſis of Mr Æpinus for explaining the electrical phenomena, which is given in detail in the article Electricity of this *Supplement*, that it would be ſuperfluous to enter into a minute diſcuſſion of their immediate reſults. We therefore beg the reader to peruſe that part of the article Electricity where the elements of Æpinus's hypotheſis are delivered, and the phenomena of induced electricity explained (viz. from no 11. to 60. incluſive), and to ſuppoſe the diſcourſe to relate to the *magnetical* fluid. Let N, S, *n*, *s*, be conſidered as the overcharged and undercharged parts of a magnetical body, or the poles of a magnet, and of iron rendered magnetical by induction. We ſhall confine our obſervations in this place to thoſe circumſtances in which the mechanical phenomena of magnetiſm are limited by the circumſtance that magnets always contain their natural quantity of fluid; ſo that their action on iron, and on each other, depends entirely on its unequable diſtribution; as is the caſe with induced electricity.

75 Magnetiſm how induced on iron by juxtaposition.

Let the magnet NAS (fig. 26.), having its north pole NA overcharged, be ſet near to the bar *n* B *s* of common iron, and let their axes form one ſtraight line. Then (as in the caſe of electrics) the overcharged pole NA acts on the bar B only by means of the redundant fluid which it contains. For that portion of its fluid, which is juſt ſufficient for ſaturating the iron, will repel the fluid in B, juſt as much as the iron in NA attracts it; and therefore the fluid in B ſuſtains no change from this portion of the fluid in NA. In like manner, the pole SA acts on B only in conſequence of the iron in SA, which is not ſaturated or attended by its equivalent fluid.

If the fluid in B is immoveable, even the redundant fluid in NA, and redundant iron in SA, will produce no *ſenſible* effect on it: For every particle of iron in B is accompanied by as much fluid as will balance, by its repulſions and attractions, the attractions and repulſions of the equidiſtant particle of iron. But as the magnetical fluid in B is ſuppoſed to be eaſily moveable, it will be repelled by the redundant fluid in AN toward the remote extremity *n*, till the reſiſtance that it meets with, joined to its own tendency to uniform diffuſion, juſt balances the repulſion of AN. This tendency to uniform diffuſion obtains as ſoon as any fluid quits its place; as has been ſufficiently explained in the Supplementary article Electricity, no 16, 17, &c.

But, at the ſame time, the redundant iron in AS attracts the fluid in B, and would abſtract it from B *n*, and condenſe it into B *s*. This attraction oppoſes the repulſion now mentioned. But, becauſe AS is more remote from every point of B than AN is from the ſame point, the repulſions of the redundant fluid in AN will prevail; and, on the whole, fluid will be propelled toward *n*, and will be rarefied on the part B *s*. But as to what will be the law of diſtribution, both in the redundant and deficient parts of B, it is plain that nothing can be ſaid with preciſion. This muſt depend on the diſtribution of the fluid in the magnet NAS. The more diffuſed that we ſuppoſe the redundant fluid and matter in the magnet, the farther removed will the centres of effort of its poles be from their extremities; the ſmaller will be the action of AN and AS, the ſmaller will be their difference of action; and therefore the ſmaller will be the condenſation in B *n*, and the rarefaction in B *s*. Hence we learn, in the outſet of this attempt to explanation, that the action of a magnet will be ſo much the greater as its poles are more concentrated. This is agreeable to obſervation, and gives ſome credit to the hypotheſis. We can juſt ſee, in a very general manner, that the fluid will be rarer than its natural ſtate in *s*, and denſer in *n*; and that the change of denſity is gradual, and that the denſity may be repreſented by the ordinates of ſome line *c b d* (fig. 27.), while the natural denſity is repreſented by the ordinates to the line C *b* D, parallel to *s n*. There will be ſome point B of the iron bar, where the fluid will be of its natural denſity, and the ordinate B *b* will meet the line *c b d* in the point of its interſection with CD.

All this action is internal and imperceptible. Let us inquire what will be the *ſenſible* external action. There is a ſuperiority of attraction towards the magnet: For ſince the magnetic action is ſuppoſed to diminiſh continually by an increaſe of diſtance, the curve, whoſe ordinates repreſent the forces, has its convexity toward the axis. Alſo, the force of the poles AN, AS, are equal at equal diſtances: For, by the hypotheſis the attraction and repulſion of an individual particle are equal at equal diſtances; and the condenſation in AN is equal to the deficiency in AS, by the ſame hypotheſis; becauſe NAS ſtill contains its natural quantity of fluid. Therefore the action of both poles may be expreſſed by the ordinates of the ſame curve, and they will differ only by reaſon of their diſtances. We may therefore expreſs the actions by the four ordinates M *m*, P *p*, N *n*, Q *q*, of fig. 2.; of which the property (deduced from the ſingle circumſtance of its being convex toward the axis) is, that M *m* + Q *q* is greater than P *p* + N *n*. There is therefore a ſurplus of attraction. It is only this ſurplus that is perceived. The fluid, moveable in B, but retained by it ſo as not to be allowed to eſcape, is preſſed towards its remote end *n* by the exceſs P *p* — Q *q* of the repulſion of the redundant fluid in AN, above the attraction of the redundant iron in AS. This exceſs on every particle of the fluid is tranſmitted, by the common laws of hydroſtatics, to the ſtratum immediately incumbent on the extremity *n*, and B is thus preſſed away from A. But every particle of the ſolid matter in B is attracted towards A by the exceſs M *m* — N *n* of the attraction of the redundant fluid in AN above the repulſion of the redundant iron in AS: and this exceſs is greater than the other; for $\overline{m+q}$ is greater than $\overline{p+n}$.

The piece of common iron *n* B *s* is therefore attracted, *in conſequence* of the fluid in it having been propelled towards its remote extremity, and diſtributed in a manner ſomewhat reſembling its diſtribution in NAS. Now, in this hypotheſis, magnetiſm is held to depend entirely on the diſtribution of the fluid. B has therefore become a magnet, has magnetiſm induced on it, and, only in conſequence of this induction, is attracted by A.

Had we ſuppoſed the deficient, or ſouth pole of A, to have been neareſt to B, the redundant matter in AN would have attracted the moveable fluid in B more than the remoter redundant fluid in AS repels it; and, on this account, the magnetic fluid would have been conſtipated in B *s*, and rarefied in B *n*. It would, in this caſe alſo, have been diſtributed in a manner ſimilar to its

its ſituation in the magnet. And B would therefore have been a momentary magnet, having its redundant pole fronting the deficient or diſſimilar pole of A. It is plain that there would be the ſame ſurplus of attraction in this as in the former inſtance, and B would (on the whole) be attracted in conſequence, and only in conſequence, of having had a properly diſpoſed magnetiſm induced on it by juxtapoſition. The ſenſible attraction, in this caſe, is a *conſequence* of the diſtribution now deſcribed; becauſe, ſince the fluid conſtipated in the end next to A cannot quit B, the tendency of this fluid toward A muſt preſs the ſolid matter of B in this direction (by hydroſtatical laws) more than this ſolid matter is repelled in the oppoſite direction.

Thus it appears that the hypotheſis tallies preciſely with the induction of magnetiſm, We do not call this an explanation of the phenomenon; for the fact is, that it is the hypotheſis that is explained by the phenomenon: That is, if any perſon be told that induced magnetiſm is produced by the action of a fluid, in conſequence of its ſituation being changed, he will find, that in order to agree with the attraction of diſſimilar, and the repulſion of ſimilar poles, he muſt accommodate the fluid to the phenomena, by giving it the properties aſſigned to it by Æpinus.

76 Conformity of the hypotheſis with a vaſt variety of phenomena.

But the agreement with this ſimpleſt poſſible caſe of the moſt ſimple example of induced magnetiſm, is not enough to make us adopt the hypotheſis as adequate to the explanation of all the magnetic phenomena. We muſt confront the hypotheſis with a variety of obſervations, to ſee whether the coincidence will be without exception.

When the key CB, in fig. 8. is brought below the conſtipated north pole N of the magnet SAN, its own moveable fluid is propelled from C towards B, and is diſpoſed in CB nearly after the ſame manner as in SAN. Therefore the redundant fluid in the lower end of the key repels the moveable fluid in the wire BD more than the redundant matter in the upper end C attracts it; and thus the fluid is rarefied in the upper end of the wire BD, and condenſed in its lower end D. CB and BD therefore are two temporary magnets, having their diſſimilar poles in contact, or neareſt to each other. This is all that is required for their attraction. This effect is promoted by the action of N on the wire BD, alſo propelling the fluid toward D; and thus increaſing the mutual attraction of CB and BD. In like manner, when the key CB is held above the magnet, the moveable fluid in it is more attracted by the redundant matter in SA than it is repelled by the more remote redundant fluid in AN. The ſame thing happens to the fluid in the wire BD. Therefore CB and BD muſt attract each other; and the key will carry the wire, although the magnet is below it, and alſo attracts it. This ſingularity proceeds from the almoſt perfect mobility of the fluid in the two pieces of common iron, which renders their poles extremely conſtipated; whereas the hardneſs required for the fixed magnetiſm of the magnet prevents this complete conſtipation and rarefaction. This can be ſtrictly demonſtrated in the caſe of ſlender rods of iron; but we can ſhew, and experience confirms it, that in other caſes, depending on the ſhape and the temper of the pieces, the wire will not adhere to the key, but to the magnet.

In the various ſituations and poſitions of the key and wire repreſented in fig. 7. the actions of ſome of the poles on the moveable fluid in the iron are oblique in regard to the length of the pieces; but, ſince the moveable matter is ſuppoſed to be a fluid, it will ſtill be propelled along the pieces, notwithſtanding their obliquity, in the ſame manner as gravity makes water occupy the lower end of a pipe lying obliquely. If indeed the magnetic fluid could eſcape from the iron without any obſtruction by the propulſion of the magnet, it could produce no attraction, or ſenſible motion, any more than light does in a tranſparent body. What is demonſtrated of the electric fluid in the Supplemental article Electricity, n° 133. is equally true here. Why the fluid does not eſcape when it is ſo perfectly moveable, is a queſtion of another kind, and will be conſidered afterwards; at preſent, the *hypotheſis* is, that it does not eſcape.

If the key and wire have the poſition fig. 10. n° 1. the fluid is expelled from the parts in contact, and is condenſed in the remote ends. So far from attracting each other, the key and wire muſt repel. They are temporary magnets, having their ſimilar poles fronting each other. They muſt repel each other, if preſented in a ſimilar manner to the ſouth pole of the magnet.

If they be preſented as in n° 2. fig. 10. where the actions of both poles of the magnet are equal, the ſtate of the fluid in them will not be affected. The redundant pole of the magnet repels the moveable fluid in both the key and the wire toward the upper ends; but the deficient pole acts equally on it in the oppoſite direction. It therefore remains uniformly diſtributed through their ſubſtance; and therefore they can exhibit no appearance of magnetiſm.

But if the key and wire be preſented to the *ſame* part of the magnet, but in another poſition, as ſhewn in fig. 8. n° 3. the fluid of the key will be abſtracted from C, and condenſed in B, by the joint action of both poles of the magnet. The ſame thing will happen in the wire BD. Here, therefore, we have two magnets with their diſſimilar poles touching. They will attract each other ſtrongly; and if carried gradually toward the upper or lower end of the magnet, they will ſeparate before the point B arrives abreaſt of N or S. For ſimilar reaſons, the pieces of iron preſented to the middle of the magnet, as in fig. 10. will have one ſide a weak north pole, and the other ſide a weak ſouth pole; but this will not be conſpicuous, unleſs the pieces be broad.

This experiment ſhews, in a very perſpicuous manner, the competency of the hypotheſis to the explanation of the phenomena. When the fluid is not moved, magnetiſm is not induced, even on the moſt ſuſceptible ſubſtance.

When a piece of iron A (fig. 10.), nearly as large as the magnet can carry, hangs at either pole, a large piece of iron B, brought near to the pole on the other ſide, ſhould cauſe it immediately to fall. If S be the deficient pole, it cauſes the fluid in A to aſcend to the top, and A is attracted: but, for the ſame reaſon, it cauſes the fluid in B to accumulate in its lower end. This redundant fluid muſt evidently counteract the redundant matter in S, in the induction of the magnetic ſtate on A. Being more remote from A than S is, it cannot wholly prevent the accumulation in the upper end of A; but it renders it ſo trifling, that the remaining attraction

attraction thence arising cannot support the weight of A. This is a very instructive experiment.

But if, on the contrary, we bring a large piece of iron C below the heavy key A, this piece C will have its fluid accumulated in its upper end, both by the action of A on it, and by the action of the magnet. The attraction of the magnet for A should therefore be augmented; and a magnet should carry a heavier lump of iron when a great lump is beyond it. And it is clear (we think), for similar reasons, that the magnetism of the magnet itself in fig. 11. should be increased by bringing a great lump of iron near its opposite pole: for the magnet differs from common iron only in the *degree* of the mobility of its fluid.

When a compass needle is placed opposite to the redundant pole N of a magnet AN (fig. 28.), it arranges itself magnetically. If a piece of common iron be now presented laterally to the near point of the needle, the redundant matter in the adjoining parts of the needle and the iron should make them repel; but if presented to the remote end, the redundant matter in the iron should attract the redundant fluid in that end of the needle, and that end should turn toward the iron.

A parcel of slender iron wires, carried by the pole of a magnet, as in fig. 29. should avoid each other. If N be the redundant pole, the fluid in each wire will be driven to the remote end, where it must repel the similarly situated fluid of its neighbour. The same external appearance must be exhibited by pieces of wire hanging at the deficient pole of the magnet.

The redundant pole of a magnet A (fig. 30.) being held vertically above the centre of two pieces of common iron, moveable round a slender pin, renders the middle of each deficient, and their extremities redundant; therefore they should repel each other, and spread out. The same effect should be produced by the undercharged pole of A.

The redundant pole of a magnet A being applied to one branch of the piece of forked iron NCS (fig. 31.), should drive the fluid into its remote parts C, and then the branch NC should be able to induce the magnetic state on a bit of iron D. But if the deficient pole S of another magnet B be applied to the other branch, these two actions should counteract each other at C, and the iron should remain indifferent, and fall.—Yet the magnet B alone would equally cause C to carry the piece of iron.

It is surely unnecessary to demonstrate, that the consequence of this hypothesis must be, that when a magnet puts any piece of iron into the magnetic state, its own magnetism is improved. For the induced magnetism of the iron is always so disposed as to give the fluid in the magnet a greater constipation where already condensed, and to abstract more fluid from the parts already deficient. If magnetism be produced by such a fluid, a magnet must always improve by lying any how among pieces of iron.

But the case may be very different when magnets are kept in each others neighbourhood. When the overcharged poles of two magnets are placed fronting each other, the redundant fluid in each repels that in the other more than it attracts the remoter redundant iron. The magnets must therefore repel each other. Moreover, in rendering them magnetical, the repulsion of redundant fluid, or the attraction of redundant matter of some other magnet, had been employed; and when the magnet was removed, some of the constipated fluid overcame the obstruction to its uniform diffusion, and escaped into the deficient pole; what remains is withheld by the obstruction, and the restoring forces are just in equilibrio with this obstruction. If we now add to them the repulsion of redundant fluid, directed toward the deficient pole, some more of the constipated fluid must be driven that way, and the magnet must be weakened. Nay, it may be destroyed, and even reversed, if one of the magnets be very powerful, and have its own magnetism very fixed; that is, if its fluid be very redundant, and meet with very great obstruction to its motion. Hence it also should follow, that the repulsion observed between two magnets should be weaker at the same distance than their attraction, and should follow a different law. For in the course of the experiments, the situation of the fluid in the magnets is continually changing, and approaching to a state of uniform diffusion.

77 Explanation of the directive power, and of polarity.

Let us now examine into the sensible effect of this fluid on a magnet which cannot move from its place, but can turn on its centre like a compass needle. This scarcely requires any discussion. We should only be repeating with regard to the redundant fluid and redundant matter, what we formerly said in regard of north pole and south pole; the little magnet must arrange itself nearly in the tangent of a magnetic curve. But it requires a more minute investigation to determine what the sensible phenomenon should be when the fluid of the little magnet is perfectly moveable.

Suppose therefore a particle C (fig. 32.) of magnetic fluid, at perfect liberty to move in every direction, and acted on by the redundant and deficient poles of a magnet NAS. The redundant iron in S attracts C in the direction and with the force CF, while the redundant fluid in N repels it in the direction and with the force CD. By their joint action it must be urged in the direction and with the force CE, the diagonal of the parallelogram CDEF, which must be accurately a tangent to a magnetic curve. If this particle of fluid belong to the piece of iron n C s, which lies in that very direction, it will unquestionably be pushed towards the extremity n. The same must happen to other particles. Hence it appears that a piece of common iron in this situation and position must become a magnet, and must retain this position; only the mechanical energy of the lever may change the equilibrium of the magnetic forces a little; because when the piece of iron n C s has any sensible magnitude, the action on its different points will be a little unequal, and may compose diagonals which divide a little from the tangent.

Should the iron needle chance not to have the exact position, but not deviate very far from it, it is also clear that the fluid, not being able to escape, will press on the side toward which it is impelled; and thus will cause the needle to turn on its pivot, and finally arrange itself in magnetical and mechanical equilibrium, deviating so much the less from a tangent to a magnetic curve as the piece of iron is smaller. Any piece of common iron, held in the neighbourhood of a magnet, will become more overcharged at one end and undercharged at the other, in proportion as the position of its length comes nearer to the tangent of a magnetic curve. A slender wire held perpendicular to this position, that is, is, perpendicular to the curve, ſhould not acquire any ſenſible magnetiſm, either attractive or directive.

78 Explanation of the curves formed by iron filings.

We ſurely need not now employ many words to ſhew that a parcel of iron filings, ſtrewed round a magnet, ſhould arrange themſelves in the primary magnetic curves, or that when ſtrewed round two magnets they ſhould form the ſecondary or compoſite curves.

79 Explanation of tranſitory and of permanent magnetiſm, and of indifferent and determinate magnetiſm.

Let us now enquire more particularly into the modifications of this accumulation of magnetic fluid which may reſult from the nature of the piece of iron, as it is put into the magnetic ſtate. The propelling force of A acts againſt the mutual repulſion of the particles of fluid in B, and alſo againſt the obſtruction to its motion through the pores of B. The greater this obſtruction, the ſmaller will be the accumulation which ſuffices, in conjunction with the obſtruction and the attraction of the deſerted iron, to balance the propulſive force of the redundant fluid in the overcharged pole of A. This circumſtance therefore muſt limit the accumulation that can be produced in a given time. Therefore the magnetiſm produced on ſoft ſteel or iron ſhould be greater than that produced in hard ſteel at the ſame diſtance. Hence the great advantage of ſoft poles, or of armour, or of capping, to a loadſtone, or to a bundle of hard bars. The beſt form and dimenſions of this armour is certainly determinable by mathematical principles, if we knew the law of magnetical action, and the diſpoſition of the magnetiſm in our loadſtone; but theſe are too imperfectly known in all caſes for us to pretend to give any exact rules. We muſt decide experimentally by making the caps large at firſt, and reducing them till we find the loadſtone carry leſs; then make them a ſmall matter larger. The chief things to be minded are the purity, the uniformity, and the ſoftneſs of the iron, and the cloſeſt poſſible contact.

If the obſtruction reſemble that to motion through a clammy fluid, the final accumulation in hard ſteel may be nearly equal to that in iron, but will require much longer time. Alſo, becauſe ſuch obſtruction to the motion of the fluid will nearly balance the propelling force in parts that are far removed from the magnet, the accumulation will begin thereabouts, while the bar beyond is not yet affected. A redundant pole will be formed in that place. This will operate on what is *immediately* beyond it, driving the fluid farther on, and occaſioning another accumulation at a ſmall diſtance. This may produce a ſimilar effect in a ſtill ſmaller degree farther on. Thus the ſteel bar will have the fluid alternately condenſed and rarefied, and contain alternate north and ſouth poles. This ſtate of diſtribution will not be permanent; fluid will be gradually changing its place; theſe poles will gradually advance along the bar, the remoter poles becoming gradually more diffuſe and faint; and it will not be till after a very long time that a regular magnetiſm with two poles will be produced. To ſtate mathematically the procedure of this mechaniſm would require many pages. Yet it may be done in ſome ſimple caſes, as Newton has ſtated the proceſs of aerial undulation. But we cannot enter upon the taſk in this limited diſſertation. What is ſaid in the Supplementary article Electricity (n° 217, 218.) on the diſtribution of the electric fluid in an imperfect inſulator, will aſſiſt the reader to form a notion of the ſtate of magnetiſm during its induction. That ſuch alternations proceed from ſuch mechaniſm, we have ſufficient proof in the inſtances mentioned in the former part of this article. The wave, or curl, produced on the ſurface of a clammy fluid, is a phenomenon of the ſame kind, and owing to ſimilar cauſes.

When the magnet which has produced all theſe changes is removed, it is evident that a part of this accumulation will be undone again. The repulſion of the condenſed fluid, and the attraction of the deſerted iron, will bring back ſome of the fluid. But it is very evident, that a part of the accumulation will remain, by reaſon of the obſtruction to its motion in returning; and this remainder muſt be ſo much the greater as the obſtruction to the change of ſituation is greater. In ſhort, we cannot doubt but that the magnetiſm which remains will be greater in hard than in ſpring-tempered ſteel.

80 Rationale of the proceſs for making magnets.

Thus have we traced the hypotheſis in a great variety of circumſtances and ſituations, and pointed out what ſhould be the external appearance in each. We did not, in each inſtance, mention the perfect coincidence of theſe conſequences with what is really obſerved, but left it to the recollection of the reader. The coincidence is indeed ſo complete, that it ſeems hardly poſſible to refuſe granting that nature operates in this or ſome very ſimilar manner. We get ſome confidence in the conjecture, and may even proceed to explain complicated phenomena by this hypothetical theory. We might proceed to ſhew, that the effects of all the methods practiſed by the artiſts in making artificial magnets are eaſy conſequences of the hypotheſis; but this is hardly neceſſary. We ſhall juſt mention ſome facts in thoſe proceſſes which have puzzled the naturaliſts.

1. A ſtrong magnet is known to communicate the greateſt magnetiſm to a bar of hard ſteel; but Muſchenbroek frequently found, that a weak magnet would communicate more to a ſoft than to a hard bar.

Explanation. When the magnet is ſtrong enough to impregnate both as highly as they are capable of, the hard bar muſt be the ſtrongeſt; but if it can ſaturate neither, the ſpring-tempered bar muſt be left the moſt magnetical.

2. A ſtrong magnet has ſometimes communicated no higher magnetiſm than a weaker one; both have been able to ſaturate the bar.

3. A weak magnet has often impaired a ſtrong one by ſimply paſſing along it two or three times; but a piece of iron always improves a magnet by the ſame treatment.

Explanation. When the north pole of a weak but hard magnet is ſet on the north pole of a ſtrong one, it muſt certainly repel part of the fluid towards the other end, and thus it muſt weaken the magnet. When it is carried forward, it cannot repel this back again, becauſe it is not of itſelf ſuppoſed capable of making the magnet ſo ſtrong. But the end of a piece of iron, always acquiring a magnetiſm oppoſite to that of the part which it touches, muſt increaſe the accumulation of fluid where it is already condenſed, and muſt expel more from thoſe parts which are already deficient.

4. All the parts of the proceſs of the double touch, as practiſed by Meſſrs Mitchell and Canton, are eaſily explained by this hypotheſis. A particle of fluid p (fig. 33.), ſituated in the middle between the two magnets, is repelled in the direction $p\ e$ by the redundant pole of the magnet AN, whoſe centre of effort is ſuppoſed to be

be at C. It is attracted with an equal force in the direction pd toward the centre of effort of the deficient pole of AS. By these combined actions it is impelled in the direction pf. Now it is plain that, although by increasing the distance between N and S, the forces with which these poles act on p are diminished, yet the compound force pf may increase by the diminution of the angle dpe. If the action is as $\frac{1}{x^2}$, pf will be greatest when $\frac{\text{Cos.}\, dpf}{dp^2}$ is a maximum, or (nearly) when $\text{Sin.}^2\, dpf \times \text{Cos.}\, dpf$ is a maximum: but this depends on the place of the centre of effort. We can, however, gather from this observation, that the nearer we suppose the centres of effort of the poles N and S to the extremities of the magnets, the nearer must they be placed to each other. But we must also attend to another circumstance; that by bringing the poles nearer together, although we produce a greater action on the intervening fluid, this action is exerted on a smaller quantity of it, and therefore a less effect may be produced. This makes a wider position preferable; but we have too imperfect a knowledge of the circumstances to be able to determine this with accuracy. The unfavourable action on the fluid beyond the magnets must also be considered. Yet all this may be ascertained with precision in some very simple instances, and the determination might be of service, if we had not a better method, independent of all hypotheses or theory; namely, to place the magnets at the distance where they are *observed* to lift the heaviest bar of iron; then we are certain that their action is most favourable, all circumstances being combined.

We also see a sufficient reason for preferring the position of the magnets employed by Mr Antheaume (and before him by Mr Servington Savery), in his process for making artificial magnets. The form of the parallelogram $dp'ef$ is then much more favourable, the diagonal pf being much longer.

We also see, in general, that, by the method of double touch, a much greater accumulation of fluid may be produced than by any other known process.

And, lastly, since no appearances indicate any difference between natural and artificial magnetism, this hypothesis is equally applicable to the explanation of the phenomena of natural magnetism; such as the position of the horizontal, and of the dipping needle, and the impregnation of natural loadstones.

Having such a body of evidence for the aptitude of this hypothesis for the explanation of phenomena, it will surely be agreeable to meet with any circumstances which render the hypothesis itself more probable. These are not wanting; although it must be acknowledged that nothing has yet appeared, besides the phenomena of magnetism, to give us any indication of the existence of such a fluid; but there are many particulars in their appearance which greatly resemble the mechanical properties of a fluid.

81
obabili- of the stence a mag- ical d.

Heating a rod of iron, and allowing it to cool in a position perpendicular to the magnetic direction, destroys its magnetism. Iron is expanded by heat. If the particles of the magnetic fluid are retained between those of the iron, notwithstanding the forces which tend to diffuse them uniformly, they may thus escape from between the ferruginous particles which withheld them. For similar reasons, magnetism should be acquired by heating a bar and letting it cool in the magnetic direction. But, besides this evident mechanical *opportunity* of motion, the union of fire (or whatever name the neologists may choose to give to the cause of expansion and of heat) with the particles of iron may totally change the action of those particles on the particles of fluid in immediate contact with them; nay, it may even change the sensible law of action between magnet and magnet. Of this no one can doubt who understands the application of mathematical science to corpuscular attraction (See Boscovich, *Suppl.*) A change may be produced in the action between magnets without any remarkable change happening in the actions within the magnet, and it may be just the reverse. The union of fire with the magnetic fluid may increase the mutual repulsion of its parts, as it does in all aerial fluids or gases. This alone would produce a dissipation of some magnetism. It may increase the attraction (at insensible distances) between the fluid and the iron, as it does in numberless cases in chemistry.

82
Farther grounds of belief.

It is well known that violently knocking or hammering a magnet weakens its force, and that hammering a piece of iron in the magnetic direction will give it some magnetism. By this treatment the parts of the iron are put into a tremulous motion, alternately approaching and receding from each other. In the instants of their recess, the pent-up particles of the fluid may make their escape. A quantity of small shot may be uniformly mixed with a quantity of wheat, and will remain so for ever, if nothing disturb the vessel; but continue to tap it smartly with a stick for a long time, and the grains of small shot will escape from their confinements, and will all go to the bottom. We may conceive the particles of magnetic fluid to be affected in the same way. The same effect is produced by grinding or filing magnets and loadstones. The latter are frequently made worthless by grinding them into the proper shape. This should be avoided as much as possible, and it should always be done in moulds made of soft iron and very massive; but this will not always prevent the dissipation of *strong* magnetism. As a farther reason for assigning this cause for the dissipation in such cases, it must be observed (Muschenbroek takes notice of it), that a magnet or loadstone may be ground at its neutral point without much damage. But we had the following most distinct example of the process. A very fine artificial magnet was suspended by a thread, with its south pole down. A person was employed to knock it incessantly with a piece of pebble, in such a manner as to make it ring very clearly, being extremely hard and elastic. Its magnetism was examined from time to time with a very small compass needle. In three quarters of an hour, its magnetism was not only destroyed, but the lower end shewed signs of a north pole. The same magnet was again touched, and made as strong as before, and was then wound about very tight with wetted whipcord, leaving a small part bare in the middle. It was again knocked with the pebble, but could no longer ring. At the end of three quarters of an hour its magnetism was still vigorous, and was not near gone after two hours and a quarter. We discharged a Leyden jar (coated with gold leaf) in the same way. It stood on the top of an axis; and while this was turned round, the edge was rubbed with a very dry cork filled with

with rosin, and fastened to the end of a glass rod. This made the jar sound like the glass of a harmonica. One of them was split in this operation.

A small bar of steel was heated red hot and tempered hard between two strong magnets lying in shallow boxes filled with water, and was more strongly impregnated in this way than in any other that we could think of for a bar of that shape. It has not yet been ascertained in what temperature it is most susceptible of magnetism, but it was considerably hotter than to be just visible in a dark place. It is no objection to our way of conceiving magnetism, that the fluid is immoveable or inactive when the iron is red hot. Either of these, or both of them, may result from the union with the cause of heat. Even a particular degree of expansion may so change the law of action as to make it *immoveable*; or the union with caloric may render it *inactive* at all sensible distances. We cannot but think that some very instructive facts might be obtained by experiments made on iron in the moment of its production, and changes in various chemical processes. All magnetism is gone when it is united with sulphur and arsenic in the greatest number of ores; and when it is in the state of an ochre, rust, æthiops, or solution in acids; and when united with astringent substances, such as galls. When, and in what state, does it become magnetic? And whence comes the fluid of Æpinus? It were worth while to try whether magnets have any influence in the formation or crystallization of the martial salts; and what will be their effect on iron when precipitated from its solutions by another metal, &c. &c.

83 Why magnets have always more than one pole.

There remains one remarkable fact to be taken notice of, which, in one point of view, is a confirmation of the hypothesis, but in another presents considerable difficulties. It is well known that no magnet has ever been seen which has but one pole; that is, on the hypothesis of Æpinus, which is wholly redundant, or wholly deficient. If all magnetism be either the immediate or the remote effect of the great magnet contained in the earth, and if it be produced by induction, without any communication of substance, but only by changing the disposition of the fluid already in the iron, we never should see a magnet with only one pole. It must be owned, that we never can make such a magnet by any of the processes hitherto described; but the existence of such does not seem impossible. Supposing a magnet, of the most regular magnetism, having only two poles; and that we cut it through at the neutral point, or that we cut or break off any part of it—the fact is (for the experiment has been tried ever since men began to speculate about magnetism), that each part becomes an ordinary magnet, with two poles, one of which is of the same kind as before the separation. The question now is, What should happen according to the theory maintained by Æpinus?—*Tentam. Theor. Elect. et Magnetismi*, p. 104, &c.

Let NAS (fig. 34.) be a magnet, of which N is the overcharged pole. Let the ordinates of the curve DAE express the difference between the natural density of the fluid, in a state of uniform diffusion, and its density as it is really disposed in the magnet. The area $p\,n$ND will there express the quantity of redundant fluid in the part n N, and the area q ES m expresses the fluid wanting in the part S m. The intersection A marks that part of the magnet where the fluid is of its natural density. Suppose the part N n to be separated from the rest, containing the redundant fluid ND$p\,n$. The tendency of this fluid to escape from the iron with which it is connected will be greater (Mr Æpinus thinks) than before; because its tendency to quit the magnet formerly was repressed by the attractions of the redundant matter contained in AS. This is certainly true of the extremity N; nay, perhaps of all the old external surface. Fluid will therefore escape. Suppose that so much has quitted the iron that the point n has the fluid of its natural density, as is represented in n° 3. there is still a force operating at n, tending to escape, arising from the repulsion of all the redundant fluid n DN. If this be sufficient for overcoming the obstruction, it will really escape, and the iron will be left in the state represented by n° 4. with an overcharged part f N, and an undercharged part $f\,n$.

In like manner, the tendency of the magnetic fluid surrounding the magnet to enter into its deficient pole, will be greater when it is separated from the other, not being checked by the repulsion of the redundant fluid in that other.

Mr Æpinus relates some experiments which he made on this subject. The general result of them was, that the moment the parts were separated, each had two poles, and that the neutral point of each magnet was much nearer to the place of their former union than to their other ends. In a quarter of an hour afterward, the neutral points had advanced nearer to their middle, and continued to do so, by very small steps, for some hours, and sometimes days, and finally were stationary in their middles.

84 Defects of this reasoning.

We acknowledge that this reasoning does not altogether satisfy us, and that the gradual progress of the neutral point toward the middle of each piece, although agreeable to what should result from an escape of fluid, is not a proof of it. We know already, that the induction of magnetism is a progressive thing; and we should have expected this change of the situation of the neutral point, whatever be the nature of magnetism. There is something similar to this, and perhaps equally puzzling, in the immediate recovery of magnetism which has been weakened by heat; it is partly recovered on cooling.

But our chief difficulty is this: At the point A (fig. 34.) every thing is in equilibrium before the fracture. The particle A is repelled by the redundant fluid in AN, and attracted by the redundant matter in AS; yet it does not move, for the magnetism is supposed to have permanency. Therefore the obstruction at A cannot be overcome by the united repulsion of AN and attraction of AS. Nor can the obstruction at N be overcome by the difference of these two forces. Now suppose AS annihilated. The change made on the state of things at A is surely greater than that at N, because the force abstracted is greater, the distance being less. It does not clearly appear, therefore, that the removal of AS should occasion an efflux at N. This, however, is not impossible; because the fluid may be so disposed, by great constipation near N, and no great excess of density near A, that a smaller change at N may produce an efflux there. But surely the tendency to escape at A must now be diminished, instead of being greater after the fracture. And if any escape from N, this will still more diminish that tendency to escape from

from A. It does not therefore appear a clear consequence of the general theory, that the constipated fluid should escape; and more particularly, that A should become deficient. And with respect to the entry of fluid into the other fragment, and its becoming overcharged at *m*, the reasoning seems still less convincing. The steps of the physical process in the two parts of the original magnet are by no means convertible or counterparts of each other. There is nothing in the part AS to resemble the force of repulsion really exerting itself in the corresponding point of AN. There would be, if there were a particle of fluid in that place; but there is not. The tendency therefore of external fluid to enter there, does not resemble the tendency of the internal fluid to expand and dissipate. It is true, indeed, the discourse should be confined to points of the surface. But the internal motion must also be considered; and the great objection always remains, namely, that the obstruction at A (n° 1.) or at *n* (n° 3.) is sufficient to prevent the passage of a particle of fluid from the pole AN into the pole AS, when urged by the repulsion of the fluid in the one and the attraction of the iron in the other; and yet will not prevent the escape of a particle when one of those causes of motion is removed. Add to this, that the whole hypothesis assumes as a principle, that the resistance to escape from any point is greatet than the obstruction to motion through the pores. This is readily granted; for however great we suppose the attraction, in the limits of physical contact, it will be no obstruction to motion through the pores, because the particle is equally affected by the opposite sides of the pores; whereas, in quitting the body altogether, there is nothing beyond the body to counteract the attraction by which it is retained.

There seems something wanting to accommodate this beautiful hypothesis of Mr Æpinus to this remarkable phenomenon; and the coincidence is otherwise so complete, that we are almost obliged to conclude that it is merely a deficiency, arising from our not having a sufficient knowledge of the law of magnetic action. This is quite sufficient: For it may be strictly demonstrated, that if the magnetic action decreases in higher ratio than that of the squares of the distances, the permanency of the fluid in any particular disposition has scarcely any dependence on the particles at any sensible distance, and is effected only by the *variations* of its density (See Electricity, *Suppl.* n° 217. for a case somewhat similar). Therefore, if the fluid be so disposed, that its density may be represented by the ordinates of such a curve as is drawn in fig. 34. having its two extremities concave toward the axis, and a point of contrary flexure at A, the tendency to escape at A will be the greatest possible; and when the magnet is broken at A (n° 1.), or when the fluid has taken the arrangement represented by n° 3. it *cannot* stop there, and *must* become deficient in that part. Now, it must be acknowledged, that we are not absolutely certain that the magnetic action is in the precise inverse duplicate ratio of the distance. All that we are certain of is, that it is much nearer to it than to either the inverse simple or inverse triplicate ratio. We own ourselves rather disposed to ascribe the present difficulty to our ignorance of some circumstance, purely mathematical, overlooked, or mistaken, than to think a conjecture unfounded, which tallies so accurately with such a variety of phenomena.

We may here observe, that we are not altogether satisfied with Æpinus's form of the experiment. He did not break a magnet; he set two steel bars end to end, and touched them as one bar, making the magnetism perfectly regular; he then separated them, and found that each had two poles. But was he certain that, when joined, they made but one magnet? We have sometimes succeeded in doing this, as we thought, by the curves of iron filings; but on putting the needle with which we were examining their polarity into proper situations, we sometimes found it in the second intersection of the secondary curves, shewing that the bars were really two magnets, and not one.

On the other hand, when a piece is broken off from a magnet, the succussion and elastic tremor into which the parts are thrown, and even the bending previous to the fracture, may give opportunity to a dissipation, which could not otherwise happen. The parts should be separated by corrosion in an acid, and the gradual change of magnetism should be carefully noted. The writer of this article has made some experiments of this nature, the results of which present some curious observations: but they are not yet brought to a conclusion that is fit to be laid before the public.

85 Hypothesis of Prevot.

Mr Prevôt of Geneva, in a dissertation on the origin of magnetic forces, endeavours to give a theory which obviates the only difficulty in that of Æpinus; but it is incomparably more complex, employing two fluids, which by their union compose a third, which he calls combined fluid. There is much ingenuity, and even mathematical address, in adjusting the relative properties of those fluids. But some of them are palpably incompatible; *ex. gr.* the particles of each attract each other, but those of the other kind most strongly; yet they are both elastic like air. This is surely inconceivable.— Granting this, however, he suits his different attractions, so that a strong elective attraction of the combined fluid for iron decomposes part of the fluid in the iron, and each of its ingredients occupies opposite ends of the bar; then will the bars approach or recede, according as the near ends contain a different or the same ingredient. All this is operated without repulsion.

But the whole of this is mere accommodation, like Æpinus's, but so much more complex, that it requires very intense contemplation to follow the author through the consequences. Add to this, that his attractions are operated by another fluid, infinitely more subtle than either of those already mentioned, every particle of these being, as it were, a world in comparison of those of the other. In short, he adopts all the extravagant suppositions of Le Sage of Geneva, and every thing is ultimately impulsion. Nor is the contrivance for obviating the difficulty (so often mentioned) at all clear and convincing; and it is equally gratuitous with the rest. We cannot think this hypothesis at all intitled to the name of *explanation*.

86 Remarks on hypotheses.

This must serve for an account of the hypothesis of Æpinus. The philosophical reader will see, that however exactly it may tally with every phenomenon, it cannot be called an explanation of the phenomena; because it is the phenomena which explain the hypothesis, or give us the characters of the magnetic fluid, if such

ſuch fluid exiſts. But we are not obliged to admit this exiſtence, as we admit that to be the true decyphering of a letter which makes ſenſe of it. In that caſe we know both parts of the ſubject—the characters and the ſounds; but are ignorant which correſponds to which. Did we ſee a fluid abſtracted from one part of a bar and conſtipated in another, and perceive the abſtraction and conſtipation always accompanied by the obſerved attractions and repulſions, the rules of philoſophical diſcuſſion, nay, the conſtitution of our own mind, would oblige us to aſſign the one as the cauſe or occaſion of the other. But this important circumſtance is wanting in the preſent caſe. We think, however, that it merits a cloſe attention; and we entertain great hopes of it being one day completed, by including this ſingle exception.

At the ſame time, it muſt be owned, that it gives no extenſion of knowledge; for it can have no greater extenſion than the phenomena on which it is founded, and cannot, without riſk of error, be applied to an untried caſe, of a kind diſſimilar in its nature to the phenomena on which it is founded. We doubt not but that its ingenious author would have ſaid, that a bit broken off from the north pole of a magnet would be wholly a north pole, if he had not known that the fact was otherwiſe.

But this hypotheſis greatly aids the imagination in conceiving the proceſs of the magnetical phenomena. The more we ſtudy them, the more do they appear to reſemble the protruſion of a fluid through the parts of an obſtructing body. It proceeds gradually. It may be, as it were, overdone, and regorges when the propelling cauſe is removed. The motion is aided by what we know to aid other obſtructed motions. As a fluid would be conſtipated in all protuberances, ſo the faculty of producing the phenomena is greater in all ſuch ſituations, &c. &c. This, joined to the impoſſibility of ſpeaking, with clearneſs of conception, of the propagation of powers without the protruſion of ſomething in which they inhere, gives it a hold of the imagination which is not eaſily ſhaken off.

To ſay that nothing is explained when the attraction of the fluid is not explained, and that this is the main queſtion, gives us little concern. We offer no explanation of this attraction, more than of the attraction of gravity. There is nothing contrary to the laws of human intellect, nothing inconſiſtent with the rules of reaſoning, in ſaying, that things are ſo conſtituted, that when two particles are together, they ſeparate, although we are ignorant of the immediate cauſe of their ſeparation. Thoſe who think that all motion is performed by impulſion, and who explain magnetiſm by a ſtream of fluid circulating round the magnet, muſt have another fluid to impel this fluid into its curvilineal path; for they inſiſt, that the planets are ſo impelled. Then they muſt have a third fluid to deflect the vertical motions of the ſecond, and ſo on without end. This is evident, and it is abſurd. But we have ſaid enough in the article IMPULSION, *Suppl.* to ſhew that all *hypotheſes* framed on purpoſe to explain action *e diſtanti* by impulſion are illogical; becauſe impulſion requires explanation as much as the other, and neither the one nor the other will ever be reſolved into any thing but the FIAT of the Allwiſe Author of the univerſe.

We conclude with deſiring the reader to remark, that the explanation which we have given of the magnetical phenomena is independent of the hypotheſis of Æpinus, or any hypotheſis whatever. We have narrated a variety of very diſtinguiſhable facts, and have marked their diſtinctions. We have been able to reduce them to general claſſes; and even to groupe thoſe claſſes into others ſtill more general; and at laſt, to point out one which is diſcoverable in them all. This is giving a philoſophical theory, in the ſtricteſt ſenſe of the word; becauſe we ſhew, in every caſe, the modification of the general fact which allots it this or that particular place in the claſſification. Thus we have ſhewn that the polarity or directive power of magnets is only a modification of the general fact of attraction and repulſion. Dr Gilbert's theory of *terreſtrial* magnetiſm is indeed a hypotheſis, and we enounced it as ſuch. It only claims probability, and we apprehend that a very high degree of credit will be given to it. 87 The pre- ding the is not a pothesis.

We hope that many of our readers will have their curioſity excited by the account we have given of Æpinus's theory. To ſuch we earneſtly recommend the ſerious peruſal of the book *Tentamen Theoriæ Electricitis et Magnetiſmi, Auct. F. Æpino, Petropoli*, 1759. Van Swinden has included a very good abſtract of it in his 2d volume *Sur l'Electricité*, written by profeſſor Steiglehner of Ratiſbon or Ingolſtadt. The mathematical part is greatly ſimplified, and the whole is preſented in a very clear and accurate manner. Mr Van Swinden is a profeſſed foe to all hypotheſes; but he is not moderate, and we wiſh that we could ſay that he is candid. He attacks every thing; and takes the opportunity of every analogy pointed out by Æpinus between magnetiſm and electricity to repeat the firſt ſentence of his diſſertation, namely, that magnetiſm and electricity are not the ſame; a thing that Æpinus alſo maintains. But he even charges Æpinus with a miſtake in his fundamental equations, which invalidates his whole theory. He ſays that Æpinus has omitted one of the acting forces aſſumed in his hypotheſis. This is a moſt groundleſs charge; and we own that we cannot conceive how Van Swinden could fall into ſuch a miſtake. We are unwilling to call it intentional, for the mere purpoſe of raiſing a man of ſtraw to knock him down again. Abbé Haüy of the French Acdemy has alſo publiſhed an abridgment of Æpinus's theory, with many excellent remarks, tending to clear the theory of the only defect that has been found in it. This work was much approved of, and recommended by the Academy. We have not had the good fortune to ſee a copy of it.

88 Analogy magneti and elec city.

The reader cannot but have remarked the cloſe analogy between the magnetical phenomena and thoſe of induced electricity; indeed, all the phenomena of attraction and repulſion are the ſame in both. The mechanical compoſition of thoſe actions produces a directive power and a polarity, in electrical as well as in magnetical bodies. We can make an electrical needle which will arrange itſelf, with reſpect to the overcharged and undercharged ends of a body electrified by mere poſition, juſt as a compaſs needle is arranged by a magnet. We can touch a ſtick of ſealing wax in the manner of the double touch, ſo as to give it poles of conſiderable force and durability. As a red hot ſteel bar acquires permanent poles by quenching it near a magnet, ſo melted wax acquires them by freezing in the neighbourhood of a poſitive

positive and negative electric. Some have inferred a sameness of origin of these two species of powers from those various circumstances of resemblance; but the original causes seem to be distinct on many accounts. Electricity is common to all bodies. The cause of magnetism can operate only on iron. Although lightning or an electrical shock gives polarity to a needle, we need not infer the identity of the cause, because the polarity which it gives is always the same with that given by great heat; and there is always intense heat in this operation. The phenomenon which looks the most like an indication of identity of the origin of electricity and magnetism is the direction of the rays of the aurora borealis—they converge to the same point of the heavens to which the elevated pole of the dipping needle directs itself. But this is by no means a sufficient foundation for establishing a sameness. Electricity and magnetism may, however, be related by means of some powers hitherto unknown. But we are decidedly of opinon, that the electric and magnetic fluid are totally different, although their mechanical actions are so like that there is hardly a phenomenon in the one which has not an exact counterpart in the other. But we see them both operating, with all their marks of distinction, in the same body; for iron and loadstones may be electrified, like any other body, and their magnetism suffers no change of modification. We can set these two forces in opposition or composition, just as we can oppose or compound gravity with either. While the iron filings are arranging themselves round a magnet, the mechanical action of electricity may be employed either to promote or hinder the arrangement. They are therefore distinct powers, inherent in different subjects.

S) ...ey are ...t, however, effects the same ...use.

But there are abundance of other phenomena which shew this diversity. There is nothing in magnetism like a body overcharged or undercharged *in toto*. There is nothing which indicates the presence of the fluid to the other senses—nothing like the spark, the snap, the visible dissipation; because the magnetic fluid enters into no union with air, or any thing but iron. There is nothing resembling that inconceivably rapid motion which we see in electricity; the quickest motion of magnetism seems inferior (even beyond comparison) with the slowest motion along any electric conductor. Therefore there is no possibility of discharging a magnet as we discharge a coated plate. Indeed, the resemblance between a magnet and a coated plate of glass is exceedingly slight. The only resemblance is between the magnet and an inconceivably thin stratum of the glass, which stratum is positive in one side and negative in the other. The only perfect resemblance is between the induced magnetism of common iron, and the induced electricity of a conductor.

The following seem the most instructive dissertations on magnetism, either as valuable collections of observations, or as judicious reasonings from them, or as the speculations of eminent or ingenious men concerning the nature of magnetism.

Besides these original works, we have several dissertations on magnetical vortices by Des Cartes, Bernoulli, Euler, Du Tour, &c. published in the collections of the works of those authors, and many dissertations in the memoirs of different academies; and there are many popular treatises by the traders in experimental philosophy in London and Paris. Dr Gown Knight, the person in Europe who was most eminently skilled in the knowledge of the phenomena, also published a dissertation intitled, *An attempt to explain the Phenomena of Nature by two principles, Attraction and Repulsion*, Lond. 1748, 4to, in which he has included a theory of magnetism. It is a very curious work, and should be studied by all those who have recourse without scruple to the agency of invisible fluids, when they are tired of patient thinking. They would there see what thought and combination are necessary before an invisible fluid can be really fitted for performing any office we choose to assign it. And they will get real instruction as to what services we may expect of such agents, and from what tasks they must be excluded. The Doctor's theory of magnetism is very unlike the rest of the performance; for he does not avail himself of the vast apparatus of propositions which he had established, and adopts without any nice adjustment the most common notions of an impulsive vortex. Both the production and maintenance of this vortex, and its mode of operation, are irreconcileable with the acknowledged laws of impulsion.

Si quid novisti rectius istis, candidus imperti—si non—his utere mecum.

APPENDIX.

Investigation of the magnetic curve.

We have been favoured with the following investigation of the curves, to which a needle of indefinite minuteness will be a tangent, by Mr Playfair, Professor of Mathematics in the University of Edinburgh.

Two magnetical poles being given in pofition, the force of each of which is fuppofed to be as the *m*th power of the diftance from it reciprocally, it is required to find a curve, in any point of which a needle (indefinitely fhort) being placed, its direction, when at reft, may be a tangent to the curve?

1. Let A and B (fig. 35.) be the poles of a magnet, C any point in the curve required; then we may fuppofe the one of thefe poles to act on the needle only by repulfion, and the other only by attraction, and the direction of the needle, when at reft, will be the diagonal of a parallelogram, the fides of which reprefent thefe forces. Therefore, having joined AC and BC, let AD be drawn parallel to BC, and make $\frac{1}{AC^m} : \frac{1}{BC^m} :: AC : AD$; join CD, then CDF will touch the curve in C.

2. Hence an expreffion for AF may be obtained. For, by the conftruction, $AD = \frac{AC^{m+1}}{BC^m}$, and fince $BC : AD :: BF : FA$, and $BC - AD : AD :: AB : AF$, we have $AF = \frac{AB \times AC^{m+1}}{BC^{m+1} - AC^{m+1}}$.

3. A fluxionary expreffion for AF may alfo be found in terms of the angles CAB, ABC. In CF take the indefinitely fmall part CH, draw AH, BH, and from C draw CL perpendicular to AH, and CK to BH. Draw alfo BC and AM at right angles to FH. Let the angles $CAB = \varphi$, and $CBA = \psi$; then $CAH = \dot{\varphi}$, and $CBH = -\dot{\psi}$; alfo $CL = AC \times \dot{\varphi}$, and $CK = -BC \times \dot{\psi}$. Now $HC : CL :: AC : AM = \frac{AC^2 \times \dot{\varphi}}{HC}$; and for the fame reafon $BC = -\frac{BC^2 \times \dot{\psi}}{HC}$. Therefore fince $AF : FB :: AM : BC$, $AF : FB :: \frac{AC^2 \times \dot{\varphi}}{HC} : -\frac{BC^2 \times \dot{\psi}}{HC}$, and $AF : AB ::$ fin. $\psi^2 \dot{\varphi} : -$ fin. $\psi^2 \dot{\varphi} -$ fin. $\varphi^2 \dot{\psi}$; wherefore if $AB = a$, $AF = \frac{-a \dot{\varphi} \text{ fin. } \psi^2}{\dot{\psi} \text{ fin. } \varphi^2 + \dot{\varphi} \text{ fin. } \psi^2}$.

4. If this value of AF be put equal to that already found, a fluxionary equation will be obtained, by the integration of which the curve may be constructed. Becaufe $AF = \frac{AB \times AC^{m+1}}{Bc^{m+1} - Ac^{m+1}}$; and fince $AC = \frac{a \text{ fin. } \psi}{\text{fin } (\varphi + \psi)}$, and $BC = \frac{a \text{ fin. } \varphi}{\text{fin. } (\varphi + \psi)}$, we have by fubftitution $AF = \frac{a \text{ fin. } \psi^{m+1}}{\text{fin. } \varphi^{m+1} - \text{fin. } \psi^{m+1}} = -\frac{a \dot{\varphi} \text{ fin. } \psi^2}{\dot{\psi} \text{ fin. } \varphi^2 + \dot{\varphi} \text{ fin. } \psi^2}$. Hence, fin. $\varphi^2 \times \dot{\psi}$ fin. $\psi^{m+1} + \dot{\varphi}$ fin. $\psi^{m+3} = -$ fin. $\psi^2 \times \dot{\varphi}$ fin. $\varphi^{m+1} + \dot{\varphi}$ fin. ψ^{m+3}, and therefore $\dot{\psi}$ fin. $\psi^{m-1} = -\dot{\varphi}$ fin. φ^{m-1}; and alfo, $\int \dot{\psi}$ fin. $\psi^{m-1} + \int \dot{\varphi}$ fin. $\varphi^{m-1} = C$.

5. Thefe fluents are eafily found when m is any whole pofitive number.

If $m = 1$, we have $\dot{\psi} + \dot{\varphi} = o$
$m = 2$, $\dot{\psi}$ fin. $\psi + \dot{\varphi}$ fin. $\varphi = o$
$m = 3$, $\dot{\psi}$ fin. $\psi^2 + \dot{\varphi}$ fin. $\varphi^2 = o$
$m = 4$, $\dot{\psi}$ fin. $\psi^3 + \dot{\varphi}$ fin. $\varphi^3 = o$
Therefore, &c.

Alfo if $m = 1$, $\varphi + \psi = C$
$m = 2$, cof. $\varphi +$ cof. $\psi = C$
$m = 3$, $-$ fin. $2\varphi + 2\varphi -$ fin. $2\psi + 2\psi = C$
$m = 4$, cof. $3\varphi - 9$ cof. $\varphi +$ cof. $3\psi - 9$ cof. $\psi = C$, &c. &c.

The firft of the above equations belongs to a fegment of a circle defcribed upon AB, which therefore would be the curve required if the magnetical force were inverfely as the diftances.

If the magnetical force be inverfely as the fquare of the diftance, that is, if $m = 2$, cof. $\varphi +$ cof. ψ is equal to a conftant quantity. Hence if, befide the points A and B, any other point be given in the curve, the whole may be defcribed. For inftance, let the point E (fig. 36.) be given in the curve, and in the line DE which bifects AB at right angles. Defcribe from the centre A a circle through E, viz. QER; then AD being the cofine of DAE to the radius AE, the fum of the cofines of $\varphi \times \psi$ will be everywhere (to the fame radius) $= 2\,AD = AB$. Therefore to find E′, the point in which any other line AN, making a given angle with AB, meets the curve, draw from N, the point in which it meets the circumference of the circle QER, NO, perpendicular to AB, fo that AO may be the cofine of NAO, and from O toward A take OP = AB, then AP will be the cofine of the angle ABE′; fo to find BE′, draw PQ perpendicular to AP, meeting the circle in Q; join AQ, and draw BE′ parallel to AQ, meeting AE′ in E′, the point E′ is in the curve. In this way the other points of the curve may be found.

The curve will pafs through B, and will cut AB at an angle of which the cofine = RB. If then E be fuch, that AE = AB, the curve will cut AB at right angles. If E″ be more remote from A, the curve will make with AB an obtufe angle toward D; in other cafes it will make with it an acute angle.

A conftruction fomewhat more expeditious may be had by defcribing the femicircle AFB, cutting AE in F, and AE′ in N, and defcribing a circle round A, with the diftance AL = 2 AF, cutting AE′ in *b*. If AG be applied in the femicircle AFB = N*b*, AG muft cut AN in a point E′ of the curve, becaufe AN + BG = 2 AF, and AN and GB are cofines of the angles at A and B.

As the lines AN and BG may be applied either above or below AB, there is another fituation of their interfection E′. Thus A*n* being applied above, and B*g* below, the interfection is in *e*′. The curve has a branch extending below A; and if D*e* be made = DE, and B*e* be drawn, it will be an affymptote to this branch. There is a fimilar branch below B. But thefe portions of the curve evidently fuppofe an oppofite direction of one of the two magnetic forces, and therefore have no connection with the pofition of the needle.

We omitted the inferting in its proper place, n° 65. Addition to
a hypothefis of the celebrated aftronomer Tobias Mayer n° 65.
of Gottingen, by which the direction of the mariner's needle in all parts of the earth may be determined. He fuppofes that the earth contains a very powerful magnet of inconfiderable dimenfions, which arranges the needle according to the known laws of magnetifm. The centre of this magnet was diftant from the centre of the earth about 480 Englifh miles in 1756, and a line joining thefe centres interfected the earth's furface in a point fituated in 17° N. Lat. and 183° E. Long. from London. The axis of the magnet is perpedicular to this line, and the plane in which it lies is inclined about 11° to the plane of the meridian, the north end of the axis lying on the eaft fide of that meridian. From thefe data, it will be found that the axis of this magnet cuts the furface

furface of the earth about the middle of the eaftern fhore of Baffin's Bay, and in another point about 800 miles S.S.W. of the fouthern point of New Zealand. Profeffor Lichtenberg of Gottingen, who gives this extract from the manufcript, fays, that the hypothefis is accompanied by a confiderable lift of variations and dips calculated by it, and compared with obfervations, and that the agreement is very remarkable. He gives indeed a dozen inftances in very different regions of the earth. But we fufpect that there is fome error or defect in the data given by him, becaufe the annual changes, which he alfo gives, are fuch as are inconfiftent with the data, and even with each other. He fays, that the diftance from the centre increafes about four miles annually, and that *thence* arifes an annual diminution of 8 minutes in the latitude and 14 in the longitude of that point where the ftraight line joining the centres meets the furface. It can have no fuch confequence. He fays alfo, that the above mentioned inclination of the planes increafes 8 minutes annually. The compound force of the magnet is faid to be as the fquare root of the diftance inverfely. We are at a lofs to underftand the meaning of this circumftance; becaufe Mayer's hypothefis concerning the law of magnetic action is exceedingly different, as related by Mr Lichtenberg from the fame manufcript. But it was our duty to communicate this notice, though imperfect, of the fpeculations of this celebrated mathematician. See *Exliben's Elem. of Nat. Phil.* publifhed by Lichtenberg 1784, p. 645.

Addition to n° 64.

Addition to n° 64. Let HZOF (fig. 37.) be the plane of a magnetic meridian, H n'O the plane of the horizon, and NS the pofition of the magnetic needle in any place, when it is at liberty to fettle in the true magnetic direction. The angle HON is the inclination or dip of the needle. Let Z n F be a vertical circle, in which a well conftructed dipping needle can freely play up and down. This needle cannot place itfelf in the magnetic direction, becaufe it can only move in a vertical plane. Its north point is impelled in the direction $n\,o$, and its fouth point in the direction $s\,p$, both of which are parallel to NS. By the laws of mechanical equilibrium, it cannot reft, except in fuch a pofition that the forces $n\,o$ and $s\,p$ are in a plane perpendicular to the plane Z n F. In any other pofition, there would be a force impelling the needle toward that fide on which $n\,o$ makes an acute angle with the tangent $r\,n\,t$ of the vertical circle. Therefore the fpherical triangle N n F is right angled in n, and Cof. NF n : R = Tan. n F : Tan. NF, = Tan. HN : Tan. $n'n$. Therefore

$$\text{Tan. } n'n = \frac{\text{Tan. HN}}{\text{Cof. H}\,n}, = \text{Tan. HN} \times \text{Sec. H}\,n'.$$

Therefore, in any place, the real inclination of the magnetical direction to the horizon is different from what is pointed out by a dipping needle when it is in a plane which declines from the magnetic meridian; and the tangent of the obferved dip of the needle exceeds that of the inclination of the magnetic direction in the proportion of radius to the cofine of the deviation HC n', or the proportion of the fecant of this angle to the radius. If therefore the dipping needle play in a magnetic eaft and weft circle, it will ftand perpendicular to the horizon.

Malefherbes. MALESHERBES (Chriftian William de Lamoignon) was born December the 6th 1721. At the age of 24 he became a counfellor of Parliament, and fix years afterwards chief prefident of the *cour des aides*. He remained in that important fituation during a period of 25 years, and difplayed on many occafions proofs of firmnefs, eloquence, and wifdom.

When the prince of Condé was fent by the king in 1768 to filence the magiftrates who oppofed the taxes, Malefherbes replied to him, "Truth, Sir, muft indeed be formidable, fince fo many efforts are made to prevent its approach to the throne." About the fame time that he became prefident of the *cour des aides*, he was appointed by his father, then chancellor of France, fuperintendant of the prefs; an office of the greateft importance, of which the principles which Malefherbes had imbibed from D'Alembert rendered him very ill qualified to difcharge the duties. He was what the French called a *philofopher*; a term with them of the fame import with a naturalift, who openly denies revealed religion, and has no adequate notions of the moral attributes of God. The confequence was, that when the authors of impious and immoral books were brought before him in his official capacity to undergo examination, he appeared to them as advifing, affifting, and protecting them, againft that very power which was vefted in himfelf; and they were commonly difmiffed with the fenfelefs obfervation, that all books of whatever tendency fhould be confidered merely as *objects of commerce.* Had it not been for the protecting influence of Malefherbes, the *Encyclopedie*, of which the publication was frequently fufpended (fee DIDEROT in this *Supplement*), would probably have been altogether fuppreffed; and the works of Rouffeau and Raynal, which fo powerfully contributed to that revolution in which he was overwhelmed, would certainly not have fpread fo rapidly over the kingdom of France. It was he, faid D'Alembert, who *broke the fhackles of literature.*

In vain will it be replied, that he left the fame liberty to the religious as to the impious writers; for that was not always ftrictly true. The Abbé Barruel has brought the teftimony of D'Alembert himfelf to prove, that it was much againft his will that Malefherbes fuffered works refuting the fophifters to appear; and, as he very properly obferves, what a minifter allows with reluctance, he finds abundant means of preventing.

In 1775 he refigned the office of chief prefident of the *cour des aides*, and was appointed minifter and fecretary of ftate in the place of La Vrillière. Thus placed in the centre of a frivolous yet brilliant court, Malefherbes did not in the leaft deviate from his former fimplicity of life and manners; but, defpifing the eftablifhed etiquette which required magiftrates, when they became minifters of ftate, to exchange their fable habit and head-drefs for a coloured fuit, bag-wig, and fword, he retained his black coat and magifterial *peruke!* This is recorded by a panegyrift to his honour; but we perceive not the honour which it reflects on him. It ſurely requires no great powers of abſtraction to diſcover, that a coloured coat, bag-wig, and ſword, are not in themſelves more frivolous or contrary to nature, than a black coat and enormous peruke; and if the manners of a country have appropriated theſe different dreſſes to different ſtations in life, the individual muſt be actuated by a very abſurd kind of pride, who ſets up his own caprice againſt the public opinion.

As, when inveſted with the power to reſtrain within juſt limits the freedom of the preſs, it was his chief aim to encourage and extend that freedom; ſo, when raiſed to an office which gave him the unlimited power of iſſuing *lettres de cachet*, it was their total ſuppreſſion that became the earlieſt object of his *moſt ardent* zeal. Till that time *lettres de cachet*, being conſidered as a part of the general police, as well as of the royal prerogative, were iſſued not only at the will of the miniſter, but even at the pleaſure of a common clerk, or perſons ſtill more inſignificant. Maleſherbes began by relinquiſhing himſelf this abſurd and iniquitous privilege. He delegated the right to a kind of tribunal, compoſed of the moſt upright magiſtrates, whoſe opinion was to be unanimous, and founded upon open and well eſtabliſhed facts. He had but one more object to attain, and that was to ſubſtitute a legal tribunal in the place of that which he had eſtabliſhed; and this object he was upon the point of accompliſhing, when the intrigues of the court procured the diſmiſſion of Turgot; and Maleſherbes, in conſequence, reſigned on the 12th of May 1776. For this part of his conduct he is intitled to praiſe, which we feel not ourſelves inclined to withhold from his memory. Even M. Barruel admits, that he had many moral virtues, and that he diſplayed real benevolence when alleviating the rigours of impriſonment, and remedying the abuſe of *lettres de cachet*; but France, ſays he, ſhall nevertheleſs demand of him her temples that have been deſtroyed; for it was he who, above all other miniſters, abuſed his authority to eſtabliſh in that kingdom the reign of impiety.

After this epoch he undertook ſeveral journeys into different parts of France, Holland, and Switzerland, where he collected with zeal and taſte objects of every kind intereſting to arts and ſciences. As he travelled with the ſimplicity and economy of a man of letters, who had emerged from obſcurity for the purpoſe of making obſervations and acquiring knowledge, he by that means was enabled to reſerve his fortune for important occaſions, in which it might procure him information on intereſting ſubjects. He travelled ſlowly, and frequently on foot, that his obſervations might be the more minute; and employed part of his time in ſuitably arranging them. Theſe obſervations formed a valuable collection of intereſting matter relative to the arts and ſciences, but which has been almoſt totally deſtroyed by the fury of revolutioniſts, who have done as much prejudice to the intereſts of ſcience as of humanity.

Returning from his travels, Maleſherbes for ſeveral years enjoyed a philoſophic leiſure, which he well knew how to direct to uſeful and important objects. The two treatiſes which he compoſed in the years 1785 and 1786 on the civil ſtate of the proteſtants in France are well known. The law which he propoſed in theſe, was only preparatory to a more extenſive reform; and theſe treatiſes were to have been followed up by another work, the plan of which he had already laid down, when affairs growing too difficult to be managed by thoſe who held the reigns of government, they were compelled to call him to their councils. They did not, however, aſſign him the direction of any department, and introduced him merely (as ſubſequent events have ſhewn) to cover their tranſactions under a popular name, and paſs them on the world as acts in which he had taken part. Maleſherbes accepted their overtures merely to ſatisfy the deſire he felt to reveal ſome uſeful truths; but it was not for that purpoſe that they had invited him to their councils. Thoſe who preſided at them took umbrage at his firſt efforts to call their attention to the voice of truth and wiſdom; and ſucceeded ſo well in their oppoſition, that he was reduced to the neceſſity of delivering in writing the counſel which he wiſhed to offer. Such was the origin of two treatiſes relative to the calamities of France, and the means of repairing them. He tranſmitted theſe treatiſes to the king, who never read them; nor was he ever able to obtain a private audience although a miniſter of ſtate.

Such is the account of his laſt conduct in office which is given by his friends; and as we have not read his treatiſes on the calamities of France, we have no right to controvert it. From his known principles, however, we are intitled to conclude, that his plans of reformation were ſimilar to thoſe of Neckar, the offſpring rather of a head teeming with viſionary theories, than of the enlightened mind of a practical ſtateſman, or the corrupt heart of a Jacobin conſpirator.

Perceiving the inutility of his endeavours, diſguſted with what he thought the repeated errors of the government, and deprived of every means of expoſing them, or preventing their fatal effects; after frequent ſolicitations, he at length obtained leave to retire. He repaired to his eſtate at Maleſherbes, and from that moment entirely devoted his time to thoſe occupations that had ever formed the chief pleaſure of his life. He paſſed the evenings and a great part of the night in reading and ſtudy.

In this tranquil ſtate he was paſſing the evening of his days amidſt his woods and fields, when the horrors of the Revolution brought him again to Paris. During the whole of its progreſs, he had his eyes conſtantly fixed on his unhappy ſovereign, and, ſubduing his natural fondneſs of retirement, went regularly to court every Sunday, to give him proofs of his reſpect and attachment. He impoſed it as a duty on himſelf to give the miniſters regular information of the deſigns of the regicide faction *; and when it was determined to bring the king to trial, he voluntarily offered to be the defender of his maſter, in his memorable letter of the 11th of December 1792, that eternal monument of his loyalty and affection. His offer was accepted; and he pleaded the cauſe of the monarch with a ſtrength of argument that nothing could have reſiſted but the bloodthirſty minds of a den of Jacobins. "What Frenchman (ſays a valuable writer), what virtuous man of any country, can never forget that affecting ſcene, when the reſpectable old man, penetrating, for the firſt time, into the priſon of the Temple, melted into tears, on finding himſelf preſſed in the arms of his king; and that ſtill more affecting ſcene, when, entruſted with the moſt agonizing commiſſion that a ſubject could poſſibly have to his ſovereign, he threw himſelf at the feet of the innocent victim, while, ſuffocated with his ſobs, his voice, till

Malesherbes.

till re-animated by the courage of the virtuous Louis, was inadequate to announce the fatal sentence of death*."

Having discharged this painful and hazardous duty he once more returned to his country residence, and resumed his tranquil course of life. But this tranquillity was of short duration. About a twelvemonth afterwards, in the month of December 1793, three worthy members of the Revolutionary Committee of Paris came to reside with him, his son-in-law, and his daughter, and apprehended the two latter as criminals. Left alone with his grandchildren, Malesherbes endeavoured to console the rest of his unfortunate family with the hopes which he himself was far from entertaining, when, the next day, the new formed guards arrived to apprehend him, and the whole of his family, even the youngest infants. This circumstance spread a general consternation throughout the whole department; for there was hardly a man in France, a few ex-jesuits excepted, who did not revere the mild virtues of the last friend of the unfortunate king.

In this calamity Malesherbes preserved the undisturbed equanimity of virtue. His affability and good humour never forsook him, and his conversation was as usual; so that to have beheld him (without noticing his wretched guards), it seemed that he was travelling for his pleasure with his neighbours and friends. He was conducted the same night to the prison of the Madelonette with his grandson Louis Lepelletier, at the same time that his other grandchildren were separated into different prisons. This separation proving extremely afflicting to him, he earnestly solicited against it; and at length, on his repeated entreaties, they all met together once more at Port-Libre. They remained there but a short period. The son-in-law of Malesherbes, the virtuous Lepelletier Rasambo, the first of them who was arrested, was ordered into another prison, and sacrificed a few days after. Malesherbes himself, his daughter, his grand-daughter, and her husband, were soon after all brought to the guillotine. They approached it with fortitude and serenity. It was then that his daughter addressed these pathetic words to Mademoiselle Sombreuil, who had saved the life of her own father on the 2d of September: "You have had the exalted honour to preserve *your* father—I have, at least, the consolation to die with *mine*."

Malesherbes, still the same, even to his last moments exhibited to his relations an example of fortitude. He conversed with the persons that were near him without bestowing the least attention on the brutalities of the wretches who tied his hands. As he was leaving the prison to ascend the fatal cart, he stumbled against a stone, and made a false step. "See (said he smiling), how bad an omen! A Roman in my situation would have been sent back again." He passed through Paris, ascended the scaffold, and submitted to death with the same unshaken courage. He died at the age of 72 years, 4 months, and 15 days. He had only two daughters; and the son of one of them alone remains to succeed. From this account of Malesherbes's behaviour at his last moments, we are inclined to believe that his intentions were better than some parts of his practical conduct; and we know, that having dispelled the vain illusions of philosophism, he acknowledged his past errors; exclaiming, in the accents of grief, "That false philosophy (to which I confess I was myself a dupe) has plunged us into the gulph of destruction, and, by an inconceivable magic, has fascinated the eyes of the nation, and made us sacrifice reality to a mere phantom. For the simple words *political liberty*, France has lost that *social freedom* which she possessed in every respect, in a higher degree, than any other nation! How truly great did the king appear in his last moments! All their efforts to degrade him were vain; his unshaken virtue triumphed over their wickedness. It is true, then, that religion alone transfuses sufficient courage into the mind of man, to enable him to support, with so much dignity, such dreadful trials †."

Malguzzary.

MALGUZZARY, in the language of Bengal, *payment* of revenue; the *revenue* itself.

Malphaghino.

MALPHAGHINO (John), otherwise called John de Ravenna, from the place of his birth, was born in the year 1352, of a family distinguished neither by riches nor nobility. His father, however, committed him to the care of Donatus the grammarian, an intimate friend of Petrarch, who at that time taught the Latin tongue with great applause at Venice. Donatus thought he discovered such happy dispositions in young Malphaghino, that he recommended him to Petrach, not only as an excellent assistant to facilitate his labours, by reading or transcribing for him, but as a youth of the most promising talents, and worthy of being formed under the inspection of the greatest man of the fourteenth century.

It appears from some of Petrarch's letters, for it is from these chiefly we can obtain information respecting John de Ravenna, that he fully answered the expectations formed of him; and that he even gained the favour and affection of his patron so much, that he loved him and treated him as if he had been his own son. In a letter to John de Certaldo (A), Petrarch highly extols him, not only for his genius and talents, but also for his prudent and virtuous conduct. "He possesses (says he) what is very rare in our times, a great turn for poetry, and a noble desire to become acquainted with every useful and ornamental part of knowledge. He is favoured by the Muses, and already attempts verses of his own; from which one can foretel, that, if his life be spared, and if he goes on as hitherto, something great may be expected from him."

Not long, however, after this panegyric was written, young Malphaghino conceived an insuperable desire to see the world; and, notwithstanding all Petrarch's remonstrances, persisted in his resolution of quitting him. Petrarch's paternal care and regard for his pupil appear, on this occasion, in the most favourable light, as may be seen in his letters to Donatus; and his whole behaviour, though the young man insisted on leaving him, without assigning a sufficient reason for his precipitate and ungrateful conduct, does as much honour to his head as to his heart.

The precipitation with which John de Ravenna carried his plan into execution was not likely to make it answer his expectations. He departed without taking with him letters of recommendation which Petrarch offered him to his friends. He, however, pursued his journey over the Appenines, amidst continual rain, giving out that he had been dismissed by Petrarch; but, though he experienced from many a compassion to which he was not entitled by his conduct, he now began to awaken from his dream. He proceeded therefore to Pisa,

(A) Better known under the name of *Boccaccio* or *Boccace*. Certaldo was the place of his birth.

Malphaghino.

Pisa, in order to procure a vessel to carry him back towards Pavia; but being disappointed, while his money wasted as much as his patience decreased, he suddenly resolved to travel back across the Appenines. When he descended into the Ligurian planes, he attempted to wade through a river in the district of Parma, which was much swelled by the rains; and being carried by the force of the stream into a whirlpool, he would have lost his life, had he not been saved by some people who were accidentally passing that way. After escaping this danger, he arrived, pennyless and famished, at the house of his former patron, who happened then not to be at home; but he was received and kindly entertained by his servants till their master returned.

Petrarch, by his intreaties and paternal admonitions, retained the young man at his house for about a year, and prevented him from engaging in any more romantic adventures; but, at the end of that period, his desire for rambling again returned; and as Petrarch found that all attempts to check him would be fruitless, he gave him letters of recommendation to two of his friends, Hugo de St Severino and Franciscus Brunus, at Rome. To the former of these, Petrarch says, "This youth of rare talents, but still a youth, after proposing to himself various plans, has at length embraced the noblest; and as he once travelled, he is now desirous of doing so again, in order to gratify his thirst of knowledge. He has, in particular, a strong inclination for the Greek language; and entertains a wish which Cato first conceived in his old age. This wish I have endeavoured for some years to subdue; sometimes by intreaties, at other times by admonition; sometimes by representing how much he is still deficient in the Roman language; and sometimes by laying before him the difficulties which must attend him in his journey, especially as he once before left me, and by want was obliged to return. As long as that unfortunate excursion was fresh in his memory he remained quiet, and gave me hopes that his restless spirit could be overcome and restrained. But now, since the remembrance of his misfortunes is almost obliterated, he again sighs after the world; and can be retained neither by force nor persuasion. Excited by a desire which betrays more ardour than prudence, he is resolved to leave his country, friends, and relations, his aged father, and me whom he loved as a father, and whose company he preferred to a residence at home, and to hasten to you whom he knows only by name. This precipitation even has an appearance of prudence. The young man first wished to visit Constantinople; but when I told him that Greece, at present, is as poor as it was formerly rich in learning, he gave credit to my assertion, and at any rate altered his plan, which he could not carry into execution. He is now desirous of traversing Calabria, and the whole coast of Italy, distinguished formerly by the name of Magna Græcia, because I once told him that there were in that quarter several men well skilled in the Greek language, particularly a monk, Barlaam, and one Leo, or Leontius, with whom I was intimately acquainted, and of whom the first had been some time my scholar. In consequence of this proposal, he begged me to give him a recommendatory letter to you, as you have considerable influence in that part of the country. This request I granted, in hopes that the young man, by his genius and talents, will afford you satisfaction equal to the service which you may render to him." In his letter to Brunus, Petrarch expresses himself as follows: "He is a young man who wishes to see the world as I formerly did; but I never reflect on it without horror. He is desirous of seeing Rome; and this desire I cannot condemn, as I myself have so often visited that city, and could still revisit it with pleasure. I suspect, however, that he will venture on a more extensive ocean, and that he imagines to find a fortune where he will, perhaps, meet with a shipwreck. At any rate, he is desirous, he says, of putting his fortune to a trial. I wish it may be favourable; should it be adverse, he is still at liberty to return to my peaceful, though small, haven; for I hang out a light during the day as well as the night, to guide those who quit me through youthful folly, and to enable them to find their way back. The ardour by which he is impelled must not be ascribed so much to him as to his age, and is in itself commendable. If I am not much deceived, the young man loves me and virtue in general. He is unsteady, but modest; and deserves that all good men should contribute to his prosperity as far as they can."

From the letters of Petrarch, there is reason to believe, that John de Ravenna lived with him only about three years in all; and that he had not attained to the full age of manhood when he left him. It appears also, for this circumstance is very obscure, that after he quitted him, he wandered about a considerable time before he was so fortunate as to meet with a protector and patron, at whose house, as he wrote to Petrarch, he at last found a permanent asylum. How long he remained with his patron, whom some believe to have been Cardinal Philip, and what happened to him till the death of Petrarch in 1374, and for some years after, is unknown. The literary monuments of the fourteenth and fifteenth centuries say nothing farther of him till his appearance at Padua; where, according to the testimony of Sicco (B), one of the most celebrated of his scholars, he not only taught the Roman Eloquence, but also the science of moral philosophy, with such success and applause, and improved his scholars so much by his life and example, that, according to universal opinion, he far excelled all the professors of those sciences who had ever before appeared. That he was here of considerable service in reviving the study of the Latin language, and of the works of the ancient Romans, was acknowledged by all his scholars, and is confirmed by the following testimony of Blondus (C).

"About the same period, Ravenna produced that learned

learned grammarian and rhetorician Johannes, of whom Leonardus Aretinus used to say, that he first introduced into Italy, after a long period of barbarism, the study of the latin language and eloquence, now so flourishing; a circumstance which deserves to be enlarged on in the present work. Those well acquainted with Roman literature know, that after the periods of Ambrose, Jerom, and Augustine, there were none, or very few, who wrote with any elegance, unless we add to these good writers, St Gregory, the venerable Beda, and St Bernard. Francis Petrarcha was the first who, with much genius, and still greater care, recalled from the dust the true art of poetry and of eloquence. He did not attain to the flowers of Ciceronian eloquence, with which many are adorned in the present century; but this was owing rather to a want of books than of talents. Though he boasted of having found at Vercelli Cicero's letters to Lentulus, he was unacquainted with the books of that great Roman *De Oratore*, Quintilian's Institutes, the *Orator*, the *Brutus*, and other writings of Cicero. John de Ravenna was known to Petrarch both in his youth and in his old age. He was not more conversant with the ancients than Petrarch; and, as far as I know, left no works behind him. By his excellent genius, however, and, as Leonardus Aretinus says, by the particular dispensation of God, he was the preceptor of this Leonardus, of Petrus Paulus Vergerius, of Annebonus de Padua, of Robert Rossi, of James Angeli of Florence, of Poggins and Guarino of Verona, of Victorinus, Sicco, and other men of less note, whom he incited to the study of better knowledge, and to imitate Cicero, if he could not form them or instruct them completely.

"About the same time, Manuel Chrysoloras, a man as virtuous as learned, came from Constantinople to Italy, and instructed in the Greek language, partly at Venice and partly at Florence and Rome, all the before mentioned scholars of John de Ravenna. After he had continued this instruction for some years, those unacquainted with the Greek language, and the ancient Greek writers, were considered in Italy as more ignorant than those unacquainted with the Latin. A great many young men and youths were inflamed with an enthusiastic desire for the works of the ancient Greeks and Romans. At the time of the council of Constance, in the beginning of the 15th century, many of my countrymen endeavoured, by searching the neighbouring convents and cities, to discover some of the Roman manuscripts which had been lost. Poggins first discovered a complete copy of Quintilian, which was soon followed by the letters of Cicero to Atticus. As our youth applied to the study of these works with the utmost diligence, that celebrated grammarian and rhetorician Caspanius de Bergamo, opened a school at Venice, superior to the former, and in which young persons were encouraged to study the ancient languages and writers. About the same time flourished Petris Paulus Vergerus, Leonardus Aretinus, Robert Rossi, James Angeli, Poggins, and Nicolaus de Medici, whom Aretin had long instructed. Guarinus also had begun to instruct many at Venice, and Victorinus at Mantua, when Phillip III. Duke of Milan, recalled Casparinus as his subject, from Venice to Padua and Milan. The increasing study of ancient literature was much promoted by Gerard Landriano bishop of Lodi, discovering under some ruins an old copy of Cicero, written in characters scarcely legible, which, among other rhetorical writings of that great Roman, contained the whole books *De Oratore*, with his *Brutis* and *Orator*. This saved Casparinus the trouble of supplying the books of Cicero *De Oratore*, as he had attempted to supply the works of Quintilian. As no one was found in all Milan who could read this old manuscript of Cicero, an ingenious young man of Verona, named Casmus, was so fortunate as first to transcribe the books *De Oratore*, and to fill all Italy with copies of a work which was universally sought for with the utmost avidity. I myself, in my youth, when I went to Milan on the business of my native city, transcribed, with as much ardour as speed, the *Brutus* of Cicero, and sent copies of my transcription to Guarinus at Verona, and to Leonard Justiniani at Venice; by which means this work was soon dispersed all over Italy. By these new works eloquence acquired new fire; and hence it happens, that in our age people speak and write better than in the time of Petrarch. The study of the Greek language, besides the abundance of new and useful knowledge which it disclosed, was attended with this great advantage, that many attempted to translate Greek works into Latin, and thereby improved their style much more than they could have done without that practice. After this period, schools for teaching the ancient languages increased in Italy, and flourished more and more. Most cities had schools of this kind; and it gives one pleasure to observe, that the scholars excelled their masters, not only when they left them, but even while they were under their tuition. Of the scholars of John de Ravenna, two of the oldest, Guarinus and Victorinus, the former at Venice, and the latter at Mantua, Verona, Florence, and Ferrara, instructed an immense number of pupils; and among these, the Princes of Ferrara and Mantua. George of Trebisonde, when he lectured at Rome, had for his auditors, besides Italians, many French, Spaniards, and Germans, among whom sometimes there were men of rank and eminence. Franciscus Philelphus, who had been taught at Constantinople by Chrysoloras himself, instructed a great many young men and youths in the Greek and Latin languages at Venice, Florence, Siena, Bologna, and, last of all, at Milan." In the above quotation, the share which John de Ravenna had in reviving and diffusing a knowledge, not only of the Roman, but also of the Grecian literature, is so clearly represented, that no farther testimony is necessary to establish his claim to celebrity.

After John de Ravenna had taught at Padua, he removed for the like purpose to Florence; where, as appears, he instructed young people for some time, without being expressly invited by the government, and without being publicly paid for his labours. In the beginning of his residence at Florence, he seems to have been recommended by Colucius to the learned Charles de Malatesta. "There lives here at present (says Colucius, in one of his letters) a teacher of great merit, John de Ravenna.—He is (continues he) of mature age; irreproachable in his manners, and so disposed in general, that if you receive him, as I hope and wish, among the number of your intimate friends, you will find him an agreeable and incomparable assistant to you in your labours and studies. What can be more desirable to you than to possess a man who will lucubrate and labour for you? and who, in a short time, can communicate to you what you could not obtain by your own.

own exertions without great difficulty. I do not know whether you will find his like in all Italy; and I therefore wish, that, if you confide in my judgment, you will receive John de Ravenna in the room of your late learned friend James de Alegretti." It is not known whether John de Ravenna went to reside with Malatesta or not. It is, however, certain, that the former, in 1397 (the same year in which Manuel Chrysoloras came to Florence), was invited thither by the magistrates of that city, with the promise of an annual salary, to instruct young people in the Roman language and eloquence; that John de Ravenna, at the period when he entered into this honourable engagement, was 45 years of age; and that the scholars of John de Ravenna were, at the same time, scholars of Chysoloras. Saluratus Colucius, in all probability, was the cause of this invitation, as he was acquainted with the services of John de Ravenna, and knew how to appreciate them. "We know (says he), in one of his letters to John de Ravenna), and all who respect you know also, that none of the moderns, or even ancients, approached so near to Cicero as you; and that to the most wonderful beauty and powers of speech, you join the deepest knowledge." John de Ravenna, like Chrysoloras, and most of the teachers of the Greek and Roman languages in the beginning of the fifteenth century, was, no doubt, engaged at first only for a few years; when these were elapsed, the engagement was renewed, perhaps for the last time, in 1412, and he was bound, besides teaching the Roman eloquence, to read publicly, and explain in the cathedral, on festivals, the poems of Dante. John de Ravenna did not long survive the above renewal of his engagement; for an anonymous writer, who, in 1420, finished *A Guide to Letter-writing, according to the Principles of John de Ravenna*," speaks of his preceptor as of a man not then in existence.

MALT. See BREWING (*Encycl.*), where a full account is given of Sir Robert Murray's method of malt-making, together with some valuable observations on malt by Mr Richardson of Hull. In a late edition of this latter gentleman's *Theoretic Hints on Brewing*, we are told, that Mr Edward Rigby of Norwich is of opinion, that the mere exsiccation of corn is not the only object obtainable by drying it on the kiln, but that some portion of the saccharum of malt is the effect of that process. "The operation of kiln drying the malt (says Mr Rigby) is as follows:—The grain is spread thick upon a floor made of flat bricks (*tiles*), or iron plates, which are full of perforations; immediately under this floor is the oven or furnace, in which is a large fire made of *coaks*, cinders, or, in some places, billet wood; a current of air, at the mouth of the furnace, keeps up the combustion of the coaks, and the air which is phlogisticated by their burning, and which, in a common fire-place, rises up the chimney, passes, in this instance, through the apertures in the floor, and penetrates the whole stratum of malt before it can pass into the external air. Under these circumstances, it is evident, that the interstices of the malt must be filled with phlogistic air; and as the grain usually remains in this situation about two days, it is obvious, that if it have the power of absorbing phlogiston, it certainly must do it when so long in contact with it. And that the malt does really imbibe some of this principle, is not only probable on the general ground of the truth of the preceding theory, but, I believe, it will be found, that the phlogisticated air which rises from the burning substances underneath, is corrected in passing through the malt; for without its being meliorated by this or some other cause, it is evident that the air in the kiln-chamber, more especially the lower strata of it, must be noxious, and probably even so much so as to be unfit for respiration and combustion. But so far from this being the case, I am informed, that workmen will lie and sleep many hours on the malt in this situation without suffering any inconvenience. And after mentioning this, it is scarcely necessary to add, that I find also, by experiment, that a candle will burn perfectly well in the air which is immediately on the surface of the malt.

"Were heat alone sufficient for the purpose of completing the operation of malting, it certainly might be applied in a much more cheap way than is at present done; for the floor on which the grain is laid might, unquestionably, be heated equally without there being perforations in it, as with them. In which case, one kind of fuel would be as good as another; and, consequently, the present expence of previously burning the coals, to convert them into coaks or cinders, might be saved.

"But, admitting that the application of phlogiston to the malt, as well as heat, is requisite in this operation, the necessity of these perforations becomes evident, and also the propriety of previously burning the coals in such a way, that all the water, and those other heterogeneous particles which compose smoke and soot, may be dissipated; for these, merely as such, would obviously contribute little to the phlogistication of the malt, and would evidently impart some offensive flavour, if not some obnoxious quality to it.

"Reasoning from the above premises (Mr Rigby concludes), it would seem, that as all the farinaceous parts of the barley are seldom dissolved in brewing, and the grains which are left have usually the disposition to become sour, thereby manifesting some of the acid principle to be still existing in them, it is not improbable but some further saccharine matter might be obtained from the grain by another exposure to phlogisticated air, or, in other words, by being once more laid on the kiln."

This is indeed so far from being improbable, that we think it must infallibly be the case. Sugar, it is well known, consists of oxygen, hydrogen, and carbon (see CHEMISTRY in this *Supplement*, n° 466.); but from the disposition of the grains to become sour, it is plain, that after the process of brewing they still retain much oxygen; and the azotic gas, which is here called phlogisticated air, there is every reason to believe contains both hydrogen and carbon. These, therefore, uniting with the oxygen of the grains, must make an addition to the saccharine matter. This has, indeed, been found to be the fact by Mr Richardson, who, in consequence of Mr Rigby's suggestion, was induced to brew a small brewing of malt, of ten quarters only, and stopping the process when, according to his general practice, one extract was still due, he ordered the grains to be laid upon one of his malt-kilns, and cinders to be applied the same as for drying of malt. This was continued for two days and a half, when the grains, being perfectly dried, were put into sacks, and, when cold, returned again into the mash-tun. The event, in some measure, justified Mr Rigby's

Mammalukes.

Rigby's expectation; for the produce of fermentable matter was considerably more than he had reason to conclude would have been the case, had the extract been made in immediate succession, as it would have been in the ordinary course of his practice. He attempts, indeed, to account for it in a way very different from ours; but though we have the highest confidence in Mr Richardson as an experienced brewer, we must sometimes beg leave to think for ourselves as chemists. Like a man of sense, however, and a man of science, he says, "I am so well satisfied with the event of this experiment, that I shall probably be inclined, on some future occasion, to repeat it, in various stages of the process. The fine lively froth on the surface of the wort, in the underback, added to its transparency and good flavour, are circumstances which induce me to thank Mr Rigby for the hint, which, it is not improbable, may be applied to some useful purpose, in certain situations which sometimes occur in the brewing trade."

MAMMALUKES, Mamalucs, *Mameloucs*, or *Mamluks*, were a dynasty that reigned for a considerable time in Egypt, and of which some account has been given in that article (*Encycl*) A fuller account of them must, however, be acceptable to our readers, as, since their connections with the French, they have attracted considerable attention.

Antijacobin Review, n° . and *Brown's Travels.*

They were first introduced into Egypt, as we have already observed, by Saladine, who, when he had it in contemplation to besiege Jerusalem, very naturally endeavoured to collect the most forcible means to accomplish so desirable an end; and, in consequence, observing that the ancient inhabitants of Egypt were, from their effeminate mode of education, and the quiet and tranquil habits of their lives, much fitter for those occupations in which they delighted, namely, the arts, merchandize, and mechanics, than military tactics and military toil, he resolved, as little as possible, to employ or depend upon them.

This resolution stimulating him to procure a hardier race of soldiers, he therefore commissioned agents to treat with the Circassians, by the Lake of Mæotis, near Tawrica Chersónesas, whence, about the year 1176, they purchased more than a thousand slaves. Men inured to hardship, nurtured in the lap of toil and danger, and bred from their infancy to war, which was to them rather than an instinct than a science, as the continual incursions of the Tartars rendered self-defence, in their situation, absolutely necessary.

These slaves Saladine trained to military discipline, and, at the same time that he made them renounce Christianity, had them instructed in the Mahometan religion; and although he prohibited them from marrying, he allowed them an unbounded license with respect to desultory gallantry. What progress they made in the doctrines of the Alcoran, whether the tenets of that sacred volume effectually eradicated all their first principles, is uncertain; but it is certain, that in time they became excellent soldiers, and that the military glory of Saladine, which was feebly supported by the native Egyptians, expanded in the hands of the Mamelouсs, who extended their conquests on every side, until, pervading the Holy Land, they entered in the plain of Askelon.

These Mamelouсs, who were continually adding to their numbers, in process of time became naturalized to the country; and, as it has been observed, they excelled the Egyptians in strength of body, in military discipline, in their skill in horsemanship, and in courage; so they, by the liberality of their generals, and the plunder of cities and provinces, also excelled them in wealth. In fact, their mode of education fitted them for the most dangerous and adventurous enterprises, and, from being the slaves, enabled them in time to become the masters of even the Turks, by whom they had originally been purchased.

After the death of Saladine, who left the kingdom to his brother, they rose to still greater importance than they had acquired during his reign, and continued, if not absolutely to govern, yet, like the Roman soldiers in the time of Pertinax, Alexander, and Valerian, to awe the monarch.

This influence continued through the reigns of five successive Caliphs, until that of Melachsala, the last of the posterity of Saladine, who being at war with the Arristians, and, at the same time, wishing to repress the enormous power of the Mamelouсs, purchased slaves from all the surrounding countries, whom, in imitation of his ancestor, he armed and appointed to defend his dominions. The event of this measure was exactly what might have been expected. Melachsala was, in consequence of a conspiracy betwixt his new and his old soldiers, slain; and Turquemenus, the leader of this mutiny and rebellion, hailed by the title of Great Sultan of Egypt. With him began the government of the Mamelouсs, about the year 1250; which had the next year gathered such strength, that it was thought necessary, in order to repress those exuberances to which new formed governments are liable, and bring it nearer to a system, to cause the following articles, in the form of a charter, to be subscribed to by their principal leaders, as an act of the whole people:—"1st, That the Sultan should be chosen from the body of Mamelouсs; 2dly, That none should be admitted into the order that were by birth either Jews or Turks, but only Christian captives; 3dly, That the native Egyptians should not be permitted to use, or have, any weapons, except the instruments of agriculture."

Turquemenus, as is frequently the practice with those that experience a sudden elevation, endeavoured to kick down the ladder by which he had been raised; or, in other words, his carriage was so haughty and disdainful to his former companions, that he was by them, or rather by one of them named Clotho, suddenly slain; for which the murderer was rewarded with his sceptre. After him succeeded a long race of princes, many of whom were as eminent for their talents as for their valour; among whom, the name of Caitbeius has been transmitted to us as that of the greatest statesman and general of his age; but, as every one who considers the *materials* of which the government was composed, must rather wonder that it existed so long, than that it should, through almost the whole course of its operation, be exposed to all the various evils and distresses arising from a long train of sedition and tumults, so he must lament that it should expire in the reign of one of their wisest and best monarchs: yet it is some consolation to reflect, that Campson, the last Sultan of the Mamelouсs, was not *murdered by his own subjects*, but having for many years governed the kingdoms of Egypt, Judea, and Syria, in a manner that has excited the praise of

Mammalukes.

of the hiftoric pen, he, oppreffed with age and difeafe, and encumbered with his armour, funk upon the field of battle, and, with his laft breath, yielded the victory to the fortunate Selim.

With this monarch, who expired January 20, 1516, ended the government of the Mameloucs, after it had continued 276 years; for although an attempt was made by Tomumby to get himfelf declared Sultan, in which attempt he actually fucceeded fo far as to be invefted with the title, yet he was foon after defeated by the victorious Selim. He was then forfaken by his troops, taken and executed; while the Mameloucs, broken and difperfed, it was the policy of Selim to rally, and, by offers too tempting to be by them refufed, engage in his fervice. The ufe of thefe foldiers foon became fufficiently apparent to the Turkifh Emperors, to ftimulate them to augment their number, enlarge their fphere of action, and combine them clofer to the ftate, by the allowance of ftill greater privileges and advantages than they had before enjoyed.

The Beys were ordained to be chofen from among them; and the Pafha, or chief governor for the Porte, was to fhare his power with thofe Beys, and even to continue in office no longer than fhould be agreeable to their collective will. At firft the power of the Pafha was very extenfive; but, by the intrigues and ambition of the Beys, it has been reduced almoft to a cypher. It was rather of a civil than military nature. He was always prefident of the Divan, which was held in the caftle where he refided. But that council now commonly meets in the palace of one of the chief Beys, except when a firman or mandate is received from Conftantinople, when the Beys are fummoned to the caftle, to hear the commands of the Porte. The few who attend, as foon as the reading is finifhed, anfwer, as is ufual, "*Efmana wa taana*," "We have heard, and we obey." On leaving the caftle, their general voice is "*Efmana wa awfina*," "We have heard, and fhall difobey."

In the year 1791, Salah Aga, a flave of Murad Bey, was deputed from the government of Egypt to negociate their peace with the Porte. He carried prefents of horfes, rich ftuffs, &c. A fpontaneous tribute, which the Porte was in no condition to enforce, implied obligation on the part of the latter. He was well received, and afterwards was appointed *Waquil es Sultan*, agent or attorney to the Sultan in Cairo. It is probable this office was given him to incline him to fecond the efforts of the Court in difuniting the Beys; but it was ineffectual. Thefe had formerly experienced the evils of divifion, and now were united by common intereft, grown rich, and well provided with flaves; fo that no tribute has fince that time found its way to Conftantinople.

The Mameloucs remain, as they have ever been, military flaves, imported from Georgia, Circaffia, and Mingrelia. A few have been prifoners, taken from the Auftrians and Ruffians, who have exchanged their religion for an eftablifhment. The Beys give general orders to their agents at Conftantinople to purchafe a certain number every year; and many are brought to Egypt by private merchants on fpeculation. When the fupply proves infufficient, or many have been expended, black flaves from the interior of Africa are fubftituted, and, if found docile, are armed and accoutred like the reft.

Particular attention is paid to the education of thefe favoured flaves. They are inftructed in every exercife of agility or ftrength, and are, in general, diftinguifhed by the grace and beauty of their perfons. The gratitude of the difciples is equal to the favour of their mafters, whom they never quit in the hour of danger. If they have a difpofition for learning, they are taught the ufe of letters, and fome of them are excellent fcribes; but the greater part neither can read nor write. A ftriking example of which deficiency is obfervable in Murad Bey himfelf.

The inferior Mameloucs conftantly appear in the military drefs, and are commonly armed with a pair of piftols, a fabre, and a dagger. They wear a peculiar cap of a greenifh hue, around which is wreathed a turban. The reft of their drefs refembles that of other Mahomedan citizens, and is reftricted to no particular colour; but another fingularity is, their large drawers of thick Venetian cloth, of a crimfon colour, to which are attached their flippers of red leather. On horfeback they add to their arms a pair of large horfe piftols, and the dubbus or battle-axe. In battle, many of them wear an open helmet, and the ancient ring armour of interwoven links of fteel, worn under part of their drefs, and thus concealed. Thefe are dear; fometimes cofting 500 piaftres, or about L. 40. Some of them are made at Conftantinople, others in Perfia. Their horfes are of the fineft Arabian breed, and are often purchafed at three or four purfes, L. 150 to L. 200 fterling.

They have no pay, as they eat at a table in the houfe of their mafter the Bey, Cafhef, or other officer. Any military officer may purchafe a flave, who becomes *ipfo facto* a Mamelouc. The name, from *malek*, to poffefs, implies merely a perfon who is the property of another. After a proper education, the candidate thus conftituted a Mamelouc, receives a prefent of a horfe and arms from his mafter, together with a fuit of clothes; which is renewed every year in the month Ramadan. The generofity of their mafters, and rewards or extortions from others, afford them fupplies of money, either for avarice or debauchery. Some of them, admitted to peculiar favour by the Beys, as chafnadars, or purfe-bearers, &c. acquire great wealth. They are rather gay and thoughtlefs than infolent, fond of fhow, and unprincipled in their means of acquiring it. They feldom marry till they acquire fome office.

Though born of Chriftian parents, they feem highly fatisfied with their condition, which they have been known to refufe to exchange for freedom. The majority are regarded by the Arabs as little ftrict in the principles or duties of Mohamedifm. It is worthy of remark, that though the Mameloucs, in general, be ftrong and perfonable men, yet the few who marry very feldom have children. As the fon, even of a Bey, is not honoured wirh any particular confideration, the women, perhaps, procure abortions. Of eighteen Beys, with whofe hiftory Mr Browne was well acquainted, two only had any children living.

Hardy, capable of every fatigue, of undaunted courage, and eminent fkill in horfemanfhip and the ufe of the fabre, the Mameloucs may be regarded as by far the beft troops in the Eaft. But in a regular battle, conducted by manœuvres, and large or rapid movements, they are equally inferior to European troops.

Being

Mammalukes, Man.

Being diſtinguiſhed by favouritiſm or merit, the Mameloue becomes a Caſhef, and in time a Bey. The chief cauſe of preference ariſes from political adherence to ſome powerful leader.

Before the invaſion of Egypt by the French (See *Revolution, Suppl.*), the Government of Cairo, and indeed of the whole country, was veſted in 24 Beys; but the Porte has ſince endeavoured to deprive them of all power; with what ſucceſs is not yet perfectly known.

MAN, has been conſidered in a great number of particulars under the title MAN (*Encycl*).; but a reference was made from that article to the article *Varieties of the Human Species*, which was, after all, omitted entirely.

Perhaps enough has been ſaid on the varieties of the human ſpecies in the articles COMPLEXION and NEGRO (*Encycl.*); but as infidel ignorance is perpetually pretending, that the diminutive Icelanders, the ugly Eſquimaux, the woolly-headed Negro, and the copper-coloured American, could not have deſcended from one original pair, either of European complexion or of Hindoo ſymmetry—it may not be improper, in this place, to ſhew the weakneſs of this popular objection to the Moſaic hiſtory of the origin of man. This has been done in ſo ſatisfactory a manner, by Profeſſor Blumenbach, that we ſhall content ourſelves with laying his obſervations before our readers, convinced, as we are, that they are intelligible to every capacity, and that they will carry conviction to all who are not the ſlaves of prejudice.

Phil. Mag. vol. iii. p. 284.

"Some late writers on natural hiſtory (ſays the Profeſſor) ſeem doubtful whether the numerous diſtinct races of men ought to be conſidered as mere varieties, which have ariſen from degeneration, or as ſo many ſpecies altogether different. The cauſe of this ſeems chiefly to be, that they took too narrow a view in their reſearches; ſelected, perhaps, two races the moſt different from each other poſſible, and, overlooking the intermediate races that formed the connecting links between them, compared theſe two together; or, they fixed their attention too much on man, without examining other ſpecies of animals, and comparing their varieties and degeneration with thoſe of the human ſpecies. The firſt fault is, when one, for example, places together a Senegal negro and an European Adonis, and at the ſame time forgets that there is not one of the bodily differences of theſe two beings, whether hair, colour, features, &c. which does not gradually run into the ſame thing of the other, by ſuch a variety of ſhades, that no phyſiologiſt or naturaliſt is able to eſtabliſh a certain boundary between theſe gradations, and conſequently between the extremes themſelves.

"The ſecond fault is, when people reaſon as if man were the only organiſed being in nature, and conſider the varieties in his ſpecies to be ſtrange and problematical, without reflecting that all theſe varieties are not more ſtriking or more uncommon than thoſe with which ſo many thouſands of other ſpecies of organiſed beings degenerate, as it were, before our eyes."

As what we have ſaid under the articles COMPLEXION and NEGRO may be ſufficient to warn mankind againſt the firſt error, and at the ſame time to refute it, we haſten to refute the ſecond by our author's compariſon between the human race and that of ſwine.

"More reaſons (ſays he) than one have induced me to make choice of ſwine for this compariſon; but, in particular, becauſe they have a great ſimilarity, in many reſpects, to man: not, however, in the form of their entrails, as people formerly believed, and therefore ſtudied the anatomy of the human body purpoſely in ſwine; ſo that, even in the laſt century, a celebrated diſpute, which aroſe between the phyſicians of Heidelberg and thoſe of Durlach, reſpecting the poſition of the heart in man, was determined, in conſequence of orders from government, by inſpecting a ſow, to the great triumph of the party which really was in the wrong. Nor is it becauſe in the time of Galen, according to repeated aſſertions, human fleſh was ſaid to have a taſte perfectly ſimilar to that of ſwine; nor becauſe the fat and the tanned hides of both are very like to each other; but becauſe both in regard to the œconomy of their bodily ſtructure, taken on the whole, ſhew unexpectedly, on the firſt view, as well as on cloſer examination, a very ſtriking ſimilitude.

"Both, for example, are domeſtic animals; both *omnivora*; both are diſperſed throughout all the four quarters of the world; and both conſequently are expoſed, in numerous ways, to the principal cauſes of degeneration ariſing from climate, mode of life, nouriſhment, &c.; both, for the ſame reaſon, are ſubject to many diſeaſes, and, what is particularly worthy of remark, to diſeaſes rarely found among other animals than men and ſwine, ſuch as the ſtone in the bladder; or to diſeaſes excluſively peculiar to theſe two, ſuch as the worms found in meaſled ſwine.

"Another reaſon (continues he) why I have made choice of ſwine for the preſent compariſon is, becauſe the degeneration and deſcent from the original race are far more certain in theſe animals, and can be better traced, than in the varieties of other domeſtic animals. For no naturaliſt, I believe, has carried his ſcepticiſm ſo far as to doubt the deſcent of the domeſtic ſwine from the wild boar; which is ſo much the more evident, as it is well known that wild pigs, when caught, may be eaſily rendered as tame and familiar as domeſtic ſwine: and the contrary alſo is the caſe; for if the latter by any accident get into the woods, they as readily become wild again; ſo that there are inſtances of ſuch animals being ſhot for wild ſwine; and it has not been till they were opened, and found caſtrated, that people were led to a diſcovery of their origin, and how, and at what time, they ran away. It is well aſcertained, that, before the diſcovery of America by the Spaniards, ſwine were unknown in that quarter of the world, and that they were afterwards carried thither from Europe. All the varieties, therefore, through which this animal has ſince degenerated, belong, with the original European race, to one and the ſame ſpecies; and ſince no bodily difference is found in the human race, as will preſently appear, either in regard to ſtature, colour, the form of the cranium, &c. which is not obſerved in the ſame proportion among the ſwine race, while no one, on that account, ever doubts that all theſe different kinds are merely varieties that have ariſen from degeneration through the influence of climate, &c. this compariſon, it is to be hoped, will ſilence thoſe ſceptics who have thought proper, on account of theſe varieties in the human race, to admit more than one ſpecies.

"With regard to ſtature, the Patagonians, as is well known, have afforded the greateſt employment to anthropologiſts.

thropologists. The romantic tales, however, of the old travellers who give to these inhabitants of the southern extremity of America a stature of ten feet and more, are scarcely worth notice; and even the more modest relations of later English navigators, who make their height from six to seven feet, have been doubted by other travellers, who, on the same coast, sought for such children of Enoch in vain. But we shall admit every thing said of the extraordinary size of these Patagonians by Byron, Wallis, and Carteret; the first of whom assigns to their chief, and severals of his attendants, a height of not less than seven feet, as far as could be determined by the eye; the second, who asserts that he actually measured them, gives to the greater part of them from 5 feet 10 inches to 6 feet; to some 6 feet 5 inches, and 6 feet 6; but to the tallest, 6 feet 7 inches: and this account is confirmed by the last-mentioned of the above circumnavigators. Now, allowing this to be the case, it is not near such an excess of stature as that observed in many parts of America among the swine, originally carried thither from Europe; and of these I shall mention in particular those of Cuba, which are more than double the size of the original stock in Europe.

"The natives of Guinea, Madagascar, New Holland, New Guinea, &c. are black; many American tribes are reddish brown, and the Europeans are white. An equal difference is observed among swine in different countries. In Piedmont, for example, they are black. When I passed (say our author) through that country, during the great fair for swine at Salenge, I did not see a single one of any other colour. In Bavaria, they are reddish brown; in Normandy, they are all white.

"Human hair is, indeed, somewhat different from swine's bristles; yet, in the present point of view, they may be compared with each other. Fair hair is soft, and of a silky texture; black hair is coarser, and among several tribes, such as the Abyssinians, Negroes, and the inhabitants of New Holland, it is woolly, and most so among the Hottentots. In the like manner, among the white swine in Normandy, as I was assured by an incomparable observer, Sulzer of Ronneburg, the hair on the whole body is longer and softer than among other swine; and even the bristles on the back are very little different, but lie flat, and are only longer than the hair on the other parts of the body. They cannot, therefore, be employed by the brush-makers. The difference between the hair of the wild boar and the domestic swine, particularly in regard to the softer part between the strong bristles, is, as is well known, still greater.

"The whole difference between the cranium of a Negro and that of an European, is not in the least degree greater than that equally striking difference which exists between the cranium of the wild boar and that of the domestic swine. Those who have not observed this in the animals themselves, need only to cast their eye on the figure which Daubenton has given of both.

"I shall pass over (says our author) less national varieties which may be found among swine as well as among men, and only mention, that I have been assured by Mr Sulzer, that the peculiarity of having the bone of the leg remarkably long, as is the case among the Hindoos, has been remarked with regard to the swine in Normandy. 'They stand very long on their hind legs (says he, in one of his letters); their back, therefore, is highest at the rump, forming a kind of inclined plane; and the head proceeds in the same direction, so that the snout is not far from the ground.' I shall here add, that the swine, in some countries, have degenerated into races which in singularity far exceed every thing that has been found strange in bodily variety among the human race. Swine with solid hoofs were known to the ancients, and large herds of them are found in Hungary, Sweden, &c. In the like manner, the European swine, first carried by the Spaniards, in 1509, to the island of Cuba, at that time celebrated for its pearl fishery, degenerated into a monstrous race, with hoofs which were half a span in length."

From these facts our author concludes, that it is absurd to allow the vast variety of swine to have descended from one original pair, and to contend that the varieties of men are so many distinct species.

MANDING, a large state in the interior of Africa, of which the only satisfactory account that we have is by Mr Park, who, for several months, was hospitably entertained in Kamalia, one of its towns, situated in 12° 40′ N. Lat. and 6° 40′ W. Long. The government of Manding appeared to our author to be a sort of republic, or rather an oligarchy. Every town is indeed governed by a chief magistrate called Mansa, which usually signifies king; but the chief power of the state, in the last resort, is lodged in the assembly of these mansas (A). The case, however, is different in other countries, which are occupied by people who have emigrated from Manding; for in all the Mandingo states near the Gambia, the government is monarchical, tho' the power of the sovereign is by no means unlimited.

As Mr Park's route was confined to a tract of country, bounded nearly by the 12th and 15th parallels of latitude, the climate throughout the whole was nearly the same as that of Manding, and extremely hot: Yet, where the country ascended into hills, he found it comparatively cool and pleasant; though none of the districts which he traversed could be called mountainous. About the middle of June, the hot and sultry atmosphere is agitated by violent gusts of wind (called *tornadoes*), accompanied with thunder and rain. These usher in what is denominated *the rainy season*; which continues until the month of November. During this time, the diurnal rains are very heavy; and the prevailing winds are from the south-west. The termination of the rainy season is likewise attended with violent tornadoes; after which the wind shifts to the north-east, and continues to blow from that quarter during the rest of the year.

When

(A) Mr Park, for the most part, writes with remarkable perspicuity; but we are not sure that here we have not mistaken his meaning. He says, that the chief power of the state is lodged in the assembly of that *whole body*; but we think, that by the whole body must be meant the body of *Mansas*, otherwise the government could not be called an oligarchy.

Manding.

When the wind fets in from the north-eaft, it produces a wonderful change in the face of the country. The grafs foon becomes dry and withered; the rivers fubfide very rapidily, and many of the trees fhed their leaves. About this period is commonly felt the *harmattan*, a dry and parching wind, blowing from the north eaft, and accompanied by a thick fmoky haze; through which the fun appears of a dull red colour. This wind, in paffing over the great defert of Sahara, acquires a very ftrong attraction for humidity, and parches up every thing expofed to its current. It is, however, reckoned very falutary, particularly to Europeans, who generally recover their health during its continuance. The truth of this our author experienced both at Kamalia and Pifania, when he had been brought to the very brink of the grave by ficknefs.

Whenever the grafs is fufficiently dry, the negroes fet it on fire; but in Ludamar, and other Moorifh countries, this practice is not allowed; for it is upon the withered ftubble that the Moors feed their cattle until the return of the rains. The burning of the grafs in Manding exhibits a fcene of terrific grandeur. "In the middle of the night (fays Mr Park), I could fee the plains and mountains, as far as my eye could reach, variegated with lines of fire; and the light reflected on the fky made the heavens appear in a blaze. In the day time, pillars of fmoke were feen in every direction; while the birds of prey were obferved hovering round the conflagration, and pouncing down upon the fnakes, lizards, and other reptiles, which attempted to efcape from the flames." This annual burning is foon followed by a frefh and fweet verdure, and the country is thereby rendered more healthful and pleafant.

Though many fpecies of the edible roots, which grow in the Weft India iflands, are found in Africa, yet our traveller never faw, in any part of his journey, either the fugar cane, the coffee, or the cocoa tree; nor could he learn, on inquiry, that they were known to the natives. The pine-apple, and the thoufand other delicious fruits which the induftry of civilized man (improving the bounties of nature), has brought to fo great perfection in the tropical climates of America, are here equally unknown. He obferved, indeed, a few orange and banana trees, near the mouth of the Gambia; but whether they were indigenous, or were formerly planted there by fome of the white traders, he could not pofitively learn.

Concerning property in the foil, it appeared to Mr Park, that the lands in native woods were confidered as belonging to the king, or (where the government was not monarchical) to the ftate. When any individual of free condition had the means of cultivating more land than he actually poffeffed, he applied to the chief man of the diftrict, who allowed him an extenfion of territory, on condition of forfeiture if the lands were not brought into cultivation by a given period. The condition being fulfilled, the foil became vefted in the poffeffor; and, for aught that appeared, defcended to his heirs.

The Mandingoes are a very gentle race of people; cheerful in their difpofitions, inquifitive, credulous, fimple, and fond of flattery. The men are commonly above the middle fize, well fhaped, ftrong, and capable of enduring great labour; the women are good-natured, fprightly, and agreeable. The drefs of both fexes is compofed of cotton cloth of their own manufacture; that of the men is a loofe frock, not unlike a furplice, with drawers which reach half way down the leg; and they wear fandals on their feet, and white cotton caps on their heads. The womens drefs confifts of two pieces of cloth, each of which is about fix feet long and three broad; one of thefe they wrap round the waift, which, hanging down to the ancles, anfwers the purpofe of a petticoat; the other is thrown negligently over the bofom and fhoulders. Both men and women among the Mandingoes feem to have an invincible propenfity to commit depredations on the property of unprotected ftrangers; whilft fuch is the good nature of thofe poor heathens, that they will readily fympathife in the fufferings, relieve the diftreffes, and contribute to the perfonal fafety, of the very ftrangers whom they are bent upon plundering.

Among the Mandingoes, the parental and filial affection is remarkably ftrong between the mother and her child; but not fo between the father and his children. This, as Mr Park obferves, is eafily accounted for. The fyftem of polygamy, while it weakens the father's attachment, by dividing it among the children of different wives, concentrates all the mother's jealous tendernefs to one point, the protection of her own offspring. He perceived, with great fatisfaction too, that the maternal folicitude extended, not only to the growth and fecurity of the perfon, but alfo, in a certain degree, to the improvement of the mind of the infant; for one of the firft leffons, in which the Mandingo women inftruct their children, is *the practice of truth*.

The Mandingo women fuckle their children until they are able to walk of themfelves. Three years nurfing is not uncommon; and during this period, the hufband devotes his whole attention to his other wives. To this practice it is owing, that the family of each wife is feldom very numerous. Few women have more than five or fix children. As foon as an infant is able to walk, it is permitted to run about with great freedom. The mother is not over folicitous to preferve it from flight falls, and other trifling accidents. A little practice foon enables a child to take care of itfelf, and experience acts the part of a nurfe. As they advance in life, the girls are taught to fpin cotton, and to beat corn, and are inftructed in other domeftic duties; and the boys are employed in the labours of the field. Both fexes, whether Bufhreens or Kafirs, on attaining the age of puberty, are circumcifed. This painful operation is not confidered by the Kafirs fo much in the light of a religious ceremony, as a matter of convenience and utility. They have, indeed, a fuperftitious notion, that it contributes to render the marriage ftate prolific.

When a young man takes a fancy to a young girl, and wifhes to marry her, it is by no means confidered as neceffary that he fhould make an overture to the girl herfelf. The firft object is to agree with the parents, concerning the recompence to be given them for the lofs of the company and fervices of their daughter. The value of two flaves is a common price, unlefs the girl is thought very handfome; in which cafe, the parents will raife their demand very confiderably. If the lover is rich enough, and willing to give the fum demanded, he then communicates his wifhes to the damfel: but her confent consent is by no means necessary to the match; for if the parents agree to it, and eat a few *kolla-nuts*, which are presented by the suitor as an earnest of the bargain, the young lady must either have the man of their choice, or continue unmarried, for she cannot afterwards be given to another. If the parents should attempt it, the lover is then authorised, by the laws of the country, to seize upon the girl as his slave. At the celebration of a marriage, no religious ceremony seems to be practised. A select number of people are indeed invited to the wedding, and feasted; but consummation constitutes the marriage; for towards the morning, the new married couple are always disturbed by the women, who assemble to inspect the nuptial sheet (according to the manners of the ancient Hebrews, as recorded in Scripture), and dance round it. This ceremony is thought indispensably necessary; nor is the marriage considered as valid without it.

The Madingoes, and indeed all the negro states, whether Mahomedan or Pagan, allow a plurality of wives. The consequence is, that the wives frequently quarrel among themselves. When this happens, the husband decides between them; and sometimes finds it necessary to administer a little corporal chastisement before tranquillity can be restored. But if any one of the ladies complains to the chief of the town, that her husband has unjustly punished her, and shewn an undue partiality to some other of his wives, the affair is brought to a public trial. In these *palavers*, however, which are conducted chiefly by married men, our author was informed, that the complaint of the wife is not always considered in a very serious light; and the complainant herself is sometimes convicted of strife and contention, and left without remedy. If she murmurs at the decision of the court, the magic rod of *Mumbo Jumbo* soon puts an end to the business. See Mumbo Jumbo in this *Suppl.*

A child, among them, is named when it is seven or eight days old. The ceremony commences by shaving the infant's head; and a dish called *dega*, made of pounded corn and sour milk, is prepared for the guests. If the parents are rich, a sheep or a goat is commonly added. This feast is called *ding koon lee*, "the child's head shaving." During Mr Park's stay at Kamalia, he was present at four different feasts of this kind, and the ceremony was the same in each, whether the child belonged to a Bushreen or a Kafir. The schoolmaster, who officiated as priest on those occasions, and who is necessarily a Bushreen, first said a long prayer over the *dega*; during which, every person present took hold of the brim of the calabash with his right hand. After this, the schoolmaster took the child in his arms, and said a second prayer: in which he repeatedly solicited the blessing of God upon the child, and upon all the company. When this prayer was ended, he whispered a few sentences in the child's ear, and spit three times in its face; after which he pronounced its name aloud, and returned the infant to the mother. This part of the ceremony being ended, the father of the child divided the *dega* into a number of balls, one of which he distributed to every person present. And inquiry was then made, if any person in the town was dangerously sick; it being usual, in such cases, to send the party a large portion of the *dega*, which is thought to possess great medical virtues.

The Madingoes have no artificial method of dividing time. They calculate the years by the number of *rainy seasons*. They portion the year into *moons*, and reckon the days by so many *suns*. The day they divide into morning, mid-day, and evening; and further subdivide it, when necessary, by pointing to the sun's place in the heavens. Our author frequently inquired of some of them, what became of the sun during the night, and whether we should see the same sun, or a different one in the morning? But that subject appeared to them as placed beyond the reach of human investigation; they had never indulged a conjecture, nor formed any hypothesis, about the matter. The moon, by varying her form, has more attracted their attention. On the first appearance of the new moon, which they look upon to be newly created, the Pagan natives, as well as Mahomedans, say a short prayer; and this seems to be the only visible adoration which the Kafirs offer up to the Supreme Being. This prayer is pronounced in a whisper; the party holding up his hands before his face: its purport is to return thanks to God for his kindness through the existence of the past moon, and to solicit a continuation of his favour during that of the new one. At the conclusion, they spit upon their hands and rub them over their faces. Great attention is paid to the changes of this luminary in its monthly course; and it is thought very unlucky to begin a journey, or any other work of consequence, in the last quarter. An eclipse, whether of the sun or moon, is supposed to be effected by witchcraft. The stars are very little regarded; and the whole study of astronomy appears to them as a useless pursuit, and attended to by such persons only as deal in magic.

Their notions of geography are equally puerile. They imagine that the world is an extended plain, the termination of which no eye has discovered; it being, they say, overhung with clouds and darkness. They describe the sea as a large river of salt water, on the farther shore of which is situated a country called *Tobaubo doo*; "the land of the white people." At a distance from Tobaubo doo, they describe another country, which they allege is inhabited by cannibals of gigantic size, called *Koomi*.

Mr Park says he has conversed with all ranks and conditions of negroes on the subject of their faith, and that he can pronounce, without the smallest shadow of doubt, that the belief of one God, and of a future state of reward and punishment, is entire and universal among them. It is remarkable, however, that, except on the appearance of a new moon, as before related, the Pagan natives do not think it necessary to offer up prayers and supplications to the Almighty. They represent the Deity, indeed, as the creator and preserver of all things; but in general they consider him as a Being so remote, and of so exalted a nature, that it is idle to imagine the feeble supplications of wretched mortals can reverse the decrees, and change the purposes, of unerring wisdom. The concerns of this world, they believe, are committed by the Almighty to the superintendance and direction of subordinate spirits, over whom they suppose that certain magical ceremonies have great influence. A white fowl, suspended to the branch of a particular tree, a snake's head, or a few handfuls of fruit, are offerings which ignorance and superstition frequently present, to deprecate

deprecate the wrath, or to conciliate the favour, of these tutelary agents.

The Mandingoes seldom attain extreme old age. At forty, most of them become grey haired, and covered with wrinkles; and but few of them survive the age of fifty-five, or sixty. Yet their diseases appeared but few; fevers and fluxes being the most common, and the most fatal. For these they generally apply *saphies*, i. e. charms, to different parts of the body; though sometimes, on the first attack of a fever, the patient is, with great success, placed in a sort of vapour bath. The other diseases which prevail among the negroes, are the *yaws*, the *elephantiasis*, and a *leprosy* of the very worst kind, together with the *Guinea worm*, which they attribute to bad water.

When a person of consequence dies, the relations and neighbours meet together, and manifest their sorrow by loud and dismal howlings. A bullock or goat is killed for such persons as come to assist at the funeral; which generally takes place in the evening of the same day on which the party died. The negroes have no appropriate burial places, and frequently dig the grave in the floor of the deceased's hut, or in the shade of a favourite tree. The body is dressed in white cotton, and wrapped up in a mat. It is carried to the grave, in the dusk of the evening, by the relations. If the grave is without the walls of the town, a number of prickly bushes are laid upon it, to prevent the wolves from digging up the body; but our author never observed that any stone was placed over the grave as a monument or memorial.

With respect to employment, the men cultivate the ground, or catch fish in large rivers; while the women manufacture cotton cloth. It is only the spinning and the dyeing, however, that are performed by the women; for the web, which is seldom more than four inches broad, is wove by the men in a loom made exactly upon the same principle as that of Europe. As the arts of weaving, dyeing, sewing, &c. may easily be acquired, those who exercise them are not considered in Africa as following any particular profession; for almost every slave can weave, and every boy can sew. The only artists which are distinctly acknowledged as such by the negroes, and who value themselves on exercising appropriate and peculiar trades, are the manufacturers of leather and of iron. The first of these are called *Karrankea* (or as the word is sometimes pronounced *Gaungay*). They are to be found in almost every town, and they frequently travel through the country in the exercise of their calling. They tan and dress leather with very great expedition, by steeping the hide first in a mixture of wood-ashes and water, until it parts with the hair; and afterwards by using the pounded leaves of a tree, called *goo*, as an astringent.

The manufacturers in iron are not so numerous as the *Karrankeas*; but they appear to have studied their business with equal diligence. The negroes on the coast being cheaply supplied with iron from the European traders, never attempt the manufacturing of this article themselves; but in the inland parts, the natives smelt this useful metal in such quantities, as not only to supply themselves from it with all necessary weapons and instruments, but even to make it an article of commerce with some of the neighbouring states. During our author's stay at Kamalia, there was a smelting furnace at a short distance from the hut where he lodged, and the owner and his workmen made no secret about the manner of conducting the operation; and readily allowed him to examine the furnace, and assist them in breaking the iron-stone. The process it is needless to describe; though it be proper to observe, that the mass of metal obtained by it was rather steel than iron. Most of the African blacksmiths are acquainted also with the method of smelting gold, in which process they use an alkaline salt, obtained from a ley of burnt corn-stalks evaporated to dryness. They likewise draw the gold into wire, and form it into a variety of ornaments, some of which are executed with a great deal of taste and ingenuity.

The reader will observe, that in the extracts which we have made from Mr Park's interesting travels, the terms African and Negro are frequently used as if all Africans and Negroes were Mandingoes. The reason is, that the Mandingoes were not only the most numerous tribe which he visited, but were also spread over all that tract of country which he traversed.

MANOMETER, a small glass tube two or three inches high, hermetically sealed at one end, and open at the other, and divided regularly into inches and lines. It is employed in order to ascertain the rarefaction of the air produced by working an *air-pump*. The tube previously filled with mercury, and having its open end plunged into a bason of mercury, is placed in the receiver of an air-pump. As the piston is worked, the mercury gradually sinks in the tube, and the expansion is estimated by its height; for the smaller the height at which the mercury in the tube stands above the mercury in the bason, the greater is the expansion.

MANIANA, a small negro kingdom lying between 12° and 14° North Lat. and between the meridian of Greenwich and 1° and 30′ West Long. Its inhabitants, as Mr Park was informed by a variety of people in many different kingdoms, are remarkable for cruelty and ferocity; carrying their resentment to their enemies so far as never to give quarter, and even indulging themselves with banquets of human flesh. Hence the inhabitants of Bambarra, who carried on with them a long and bloody war, and must of course be well ascertained of the fact, call them *Ma dummulo*, which signifies men-eaters.

MANURE is so essential to agriculture, that the want of it, or an improper manner of using it, is the principal cause of the sterility of a country. We have therefore treated of manures and their action at some length in the article AGRICULTURE in the *Encyclopædia*; but as the theoretical part of that disquisition rests in a great measure on the doctrine of phlogiston, which is now exploded, it may not be improper to resume the subject here. Experience however being, after all, the only guide which the farmer can safely and confidently follow, instead of amusing our readers with theories of our own, we shall lay before them the observations of a man who seems to have united theory with practice.

"The use of manures (says M. Parmentier *) has been known in all ages, but we are yet far from having any clear and precise ideas of the nature of the juices which are destined for the nourishment of vegetables, and of the manner in which they are transmitted to their organs.

* Memoirs of the Royal Society of Agriculture, Paris.

Manure. organs. The writers on agriculture, who have endeavoured to explain thefe matters, perceiving falts in moft plants, were perfuaded that thefe falts, by the help of water and heat, paffed, in a faline form, through the vegetable filter. Thefe firft philofophers did not hefitate to confider every thing that has been done by the induftry of man, to improve the nature of land, and its productions, as merely forming refervoirs of thefe falts, which they confidered as the principle of fertility. This opinion was fo well eftablifhed among the improvers of land, that, to this day, many of them have no object in view, in their operations, but to difengage falts; and, when they attempt to explain certain phenomena which take place in their fields or orchards, they talk confidently about the *nitre of the air*, *of rain*, *of fnow*, *of dew*, *and fogs*; of the *falts of the earth*, *of dung*, *of marle*, *of lime*, *of chalk*, &c. and make ufe of thofe vague terms, *oil*, *fulphur*, *fpirit*, &c. which ought henceforward to be banifhed from our elementary books on agriculture.

" Among the authors who have attacked, and combated with moft fuccefs, the opinion that the fruitfulnefs of foils, and the aliment of vegetables, refide in faline fubftances, muft be reckoned Eller and Wallerius. Thefe philofophers examined, by every means which chemiftry at that time could furnifh, the various kinds of earth proper for cultivation, and alfo thofe fubftances which have always been confidered as the moft powerful manures, without being able to obtain, from any of them, any thing more than mere atoms of falt.

" Animated with the fame zeal, and taking advantage of the inftructions found in their writings, I thought it neceffary to determine, by experience, whether, as has been afferted, there really exift neutral falts in earths; and alfo, whether thofe earths are more fertile in proportion to the quantity of fuch falts they contain. With this view, I lixiviated, by means of diftilled water, many fpecies of cultivated earths, taken in various ftates, from frefh earth to that which had been impoverifhed by the growth of feveral crops; I alfo tried dung, reduced more or lefs into the ftate of mould; and likewife the moft active manures, fuch as the offal of animal fubftances rotted by putrefaction; but in none of thefe, however carefully analyzed, were found any falts in a free ftate. They contain indeed the materials proper for forming falts; but if they contain any ready formed, it is merely by accident.

" The refearches of Kraft, and thofe of Alfton, were not attended with different refults. Having fown fome oats in afhes, not lixiviated, and in fand ftrongly impregnated with potafh and with faltpetre, and having found that the oats did not grow, they concluded that neutral falts, and alkalies, not only retarded the growth of vegetables, but that they abfolutely prevented it. It is well known that in Egypt there are diftricts where the earth is entirely covered with fea-falt, and thefe diftricts are quite barren. It is probably owing to this property of fea-falt, that the Romans were accuftomed to fcatter large quantities of it over fields where any great crime had been committed, and of which they wifhed to perpetuate the remembrance, by rendering the part barren for a certain time.

" The idea that falts had great influence in vegetation, ought to have been greatly weakened by the following fimple reflection. Suppofing that falts exifted in garden mould, they would be very foon diffolved by the rain, and carried away, towards the lower ftrata of the earth, to a depth to which the longeft roots would not reach. Indeed the famous experiment of Vanhelmont would have been fufficient to have deftroyed the above opinion, if it did not generally happen that we are no fooner fet free from one error than we fall into another not lefs extraordinary. The furprifing effects of vegetation brought about by the overflowing of water, and in the neighbourhood of falt marfhes, and the infinite number of inhaling capillary tubes obferved upon the furface of vegetables, led to an opinion that the air and water, abforbed by the roots and leaves of plants, were only vehicles loaded with faline matter, analogous to the vegetables nourifhed by them.

" To the experiment of Vanhelmont, which was repeated by many accurate obfervers, fucceeded thofe of modern philofophers; from which it clearly appeared, that plants could grow, and produce fruit, in the air of the atmofphere, and in diftilled water, alfo in pure fand, in powdered glafs, in wet mofs or fponge, in the cavity of flefhy roots, &c. and that plants which had nothing but the above-mentioned fluids for their nourifhment, gave, when fubmitted to chemical analyfis, the fame products as thofe which had undergone their procefs of vegetation in a foil perfectly well manured. It was alfo obferved, that the moft barren foils were rendered fertile when they were properly fupplied with water by canals; and the efficacy of irrigation was repeatedly evinced in different ways: from thefe obfervations was formed the following fyftem, that water rifes in plants in the form of vapour, as in diftillation; that air introduces itfelf into their pores; and that, if falts contribute to the fruitfulnefs of foils, it is only in confequence of their containing the two fluids above-mentioned in great abundance."

Our author, after making many experiments upon various foils and falts, and after attending minutely to the procefs of vegetation, thinks himfelf warranted to maintain, " that faline fubftances have no fenfible effects in promoting vegetation, excepting inafmuch as they are of a deliquefcent nature, have an earthy bafis eafily decompofed, and are ufed only in fmall quantity. In thofe circumftances they have the power of attracting, from the immenfe refervoir of the atmofphere, the vapours which circulate in it; thefe vapours they retain, along with the moifture that is produced from rain, fnow, dew, fog, &c. which moifture they prevent from running together in a mafs, or from being loft, either by exhaling into the air of the atmofphere, or by filtering itfelf through the inferior ftrata of the earth, and thereby leaving the roots of vegetables dry; they diftribute that moifture uniformly, and tranfmit it, in a ftate of great divifion, to the orifices of the tubes deftined to carry it into the texture of the plant, where it is afterwards to undergo the laws of affimilation. As every kind of vegetable manure poffeffes a vifcous kind of moifture, it thereby partakes of the property of deliquefcent falts. In fhort, the preparation of land for vegetation has no other object in view but to divide the earthy particles, to foften them, and to give them a form capable of producing the above-mentioned effects. It is fufficient, therefore, that water, by its mixture with

Manure. with the earth and the manure, be divided, and ſpread out ſo as to be applied only by its ſurface, and that it keep the root of the plant always wet, without drowning it, in order to become the eſſential principle of vegetation. But as plants which grow in the ſhade, even in the beſt ſoil, are weakly, and as the greater part of thoſe which are made to grow in a place that is perfectly dark neither give fruit nor flowers, it cannot be denied that the influence of the ſun is of great importance in vegetable economy."

Such was the opinion which our author gave of the manner in which ſalts act in vegetation, at a time when it was not known that air and water (which had been ſo long conſidered as elements), far from being ſimple ſubſtances, are capable of being decompoſed by a great variety of operations both of nature and art; and nothing was wanting to complete his theory, but to know that air and water act their part in vegetation only in a ſtate of decompoſition; and that if earth well manured is a better matrix than water itſelf, it is becauſe ſuch earth has the power of converting the water into gaſes which are eaſily abſorbed, and which, while their abſorption takes place, communicate to the plants a motion and heat which they received when taking the form of gas, and which they loſe when they enter again into combination; whence it is natural to conclude, that this motion and this heat muſt neceſſarily develope themſelves in ſeeds, and maintain the vital action in plants.

What is a vegetable, conſidered chemically, according to the preſent ſtate of our knowledge? It is, ſay the chemiſts, a compound of hydrogen, oxygen, and carbon, the proportions of which vary according to the agents which have concurred to its developement, and according to the matrix which received and aſſimilated them, in order to create thoſe combinations which are varied to infinity, by their forms and properties, and known by the generic terms of ſalt, oil, and mucilage. It appears, therefore, needleſs to ſeek theſe combinations in the different ſubſtances which are uſed for manure, when we wiſh to determine the nature of them, and explain their manner of acting in vegetation; becauſe, ſuppoſing it true that theſe ſalts, theſe oils, or theſe mucilages, exiſt in their combined ſtate, nothing but their conſtituent elements, namely, hydrogen, oxygen, and carbon, can poſſibly have any action.

The ſuperiority of animal ſubſtances, as manures, and the remarkable luxuriance of thoſe plants which are watered with putrid water, prove inconteſtibly, that the putrid ſtate is favourable to vegetation, and that every ſubſtance which is liable to enter, to a certain degree, into that ſtate, contributes very powerfully thereto. The moſt aerated waters are, in this caſe, the moſt beneficial. It is obſerved that rain, particularly in ſtormy weather, quickens vegetation ſo much, that the gardeners in the neighbourhood of Paris are often obliged to drench their plants with water taken from their wells, which, in conſequence of its rawneſs, or its want of air, retards the vegetation of the plants; either becauſe it precipitates the meteoriſed or electrified water, or becauſe, by being mixed with the other water, it diminiſhes its fertilizing quality; whereas, in ſummer, this ſame well-water, by being expoſed to the ſun for ſome days, acquires a ſmell like that of ſtale eggs, loſes its rawneſs, and becomes very fit for accelerating vegetation. An atom of vegetable or animal matter is, at that time, ſufficient to bring about more quickly this ſtate of putrefaction; while theſe ſame ſubſtances, by being employed in certain proportions, far from acting as a leaven on the liquids which hold them in ſolution, preſerve thoſe liquids, or at leaſt make them more ſlow to change. Manure.

Salts and dung, therefore, are not merely decompoſed by the power of vegetation; by furniſhing the reſults of their decompoſition, they alſo act in the manner of leavens, the action of which is ſcarcely perceptible in cold or dry weather; but when they are heated by the ſun, and ſufficiently penetrated with moiſture, they very ſoon enter into a ſort of fermentation, ſuffering the various gaſes with which they are provided to eſcape. Thus manures may be conſidered as decompoſing inſtruments, provided by nature, and prepared by art, to act upon water ſo as to bring it to a proper ſtate of attenuation. The ſubſtances which enter into the compoſition of plants, are, therefore, nothing but products of the decompoſition of air and water, and combinations of the conſtituent principles of theſe two fluids, determined by the power which preſides in the ſeed, and which thence has paſſed into the plant.

It is now eaſy to account for the effects of charcoal-powder, ſtraw, &c. which are made uſe of to cover ground during long droughts with undoubted benefit: they are mechanical means of preventing the diſſipation of moiſture, and of determining it to take the form of thoſe gaſeous fluids which have ſuch powerful effect in vegetation. As water is compoſed of hydrogen and oxygen, it is not ſurpriſing that, when aſſiſted by the influence of the ſun, and that of electricity, it is capable of forming, almoſt by itſelf, the ſolids and fluids of vegetables; taking from the atmoſphere the carbon it ſtands in need of, to give them their moſt eſſential characters. We ſay their moſt eſſential characters; for thoſe terreſtrial plants which have grown in air and water do not abound in principles; and their offspring, when they have any, is by no means vigorous. We ſee alſo, that plants which are naturally of an equatic nature, have in general but little ſmell, becauſe the medium in which they live and grow furniſhes only a ſmall quantity of carbon, in proportion to the hydrogen and oxygen, which are the conſtituent principles of water. This is the reaſon why, in cold and wet years, flowers are leſs odoriferous, fruit leſs full of flavour, and more difficult to be preſerved. The germ of their reproduction is weak; and they are, if the expreſſion may be uſed, in a ſort of dropſy; that is to ſay, they are loaded with the principles which conſtitute water, and even with water itſelf.

Theſe obſervations, to which more might be added, may ſerve to explain why vegetation is ſlow and weak in a ſoil which is too much charged with ſaline matter, while it is rendered quick and vigorous by a ſmall quantity of this ſame matter; and why earth, which is perfectly lixiviated, and watered, from time to time, with diſtilled water only, is capable of giving to bitter plants their bitterneſs, to ſweet ones their ſweetneſs, to acid ones their acidity, to aromatic ones their ſpicineſs, and to poiſonous ones their deleterious qualities; in ſhort, why the inherent characters of plants are more ſtrongly marked, in proportion as the ſoil in which they grow is furniſhed with natural or mechanical means to produce

Manure. duce a quantity of gas neceffary to the formation of the fubftances on which thofe characters depend.

If a nitrous or marine plant can, even when growing in a foil deftitute of nitre or fea-falt, occafion the production of thefe falts, it muft be allowed that fuch plants would vegetate more ftrongly, and contain more of fuch falts, if they grew in foils more abounding in materials proper to form them. Thus, the different fpecies of famphire, glaffwort, fea-wrack, &c. flourifh on the borders of the fea, fuch foils being ftrongly impregnated with the fluids neceffary to form the muriatic gas and fea-falt which enter into the compofition of thofe plants, while the fun-flower, pellitory, &c. fucceed beft in earth which is mixed with the ruins of old buildings, in which the materials for the production of nitrous gas, and even of nitre itfelf, are very abundant. In fhort, the organization of thefe plants is a real elaboratory for forming the forementioned falts.

Thofe plants which, for their vegetation, require the moft affiftance from the foil and manure, are very apt to contract a difagreeable tafte, if either the foil or manure are capable of fupplying the principles from which it is acquired. The clafs *tetradynamia*, particularly all forts of cabbages (which contain fulphur ready formed), contract a bad tafte in a foil compofed of mud and dung, becaufe thefe fubftances, as they are decompofed, furnifh a great quantity of hepatic gas, or of fulphurifed hydrogen gas; yet plants of another clafs may grow in the fame foil, clofe by the cabbages, without partaking even in the fmalleft degree of the bad tafte of the latter. The plants laft mentioned, when growing in hepatic gas, retain only fo much of it as is fufficient for the production of the fubftances of which they are formed; the overplus, which could not be affimilated, is thrown out by the excretory veffels, after undergoing thofe modifications which the digeftive juices and organization of the plant, and the ftate of the atmofphere, have produced.

Thus we fee that thofe plants which abound moft in oily, faline, and mucilaginous principles, are generally fuch as require a foil well manured. Tobacco, for inftance, gives forty pounds of alkaline falt or potafh from every hundred weight of afhes: this plant may, by being buried in the ground, be converted into a very powerful manure; while other plants, which thrive in a middling foil, and appear as vigorous, are, in general, fuch as have not fo great a quantity of principles in their compofition, and when thrown on the dunghill, and left to rot, furnifh very little manure. From fuch obfervations, it may perhaps not be impoffible hereafter to judge, by the analyfis of a plant, not only whether it requires a large or a fmall quantity of manure, but likewife what kinds of foil and manure are moft fit to promote its vegetation: wild plants alfo may ferve to fhew the nature of the foil which they feem moft to flourifh in.

Befides the phyfical action of manures, they have a very evident mechanical action. When mixed with earth, in a certain proportion, they not only render it more permeable to water, but the roots of plants can with greater eafe acquire their proper fize and form in it: in other cafes, manures tend to unite that earth which is too loofe, and, by rendering it more tenacious, they prevent the water from being loft, and the roots from becoming dry. Thofe manures which are called *warm* are fuited to cold lands, not only becaufe they render them lefs compact, but alfo becaufe they take off a part of that moifture which fuch lands always have in too great quantity. Cold manures, on the other hand, by their vifcid quality, give tenacity to dry and hot foils, attracting and retaining, for a longer time, the moifture which comes in their way. The nature of the foil muft therefore determine what kind of manure it ftands in need of, and alfo whether cultivating it by means of oxen or by horfes is preferable; for the manures produced from thefe two animals have thofe oppofite qualities which we have above defcribed. By fuch obfervations, we fhall perhaps be able to refolve a queftion, refpecting which the fentiments of cultivators in many parts of the kingdom are much divided.

It cannot, however, be denied, that the earth is able of itfelf to ferve as a bafis and fupport to plants, and that it has an action more or lefs evident upon air, upon water, and upon dung. There is a well-known method of diftinguifhing clay from other earths; by merely breathing upon it, a fmell is immediately perceived, fufficiently ftrong to fhew that a decompofition and frefh combination have taken place. In fummer, after a drought of fome days continuance, there always arifes in the fields a particular fmell during a fhower of rain; and there is no kind of vegetable manure which, when mixed with earth, does not fend forth a fmell. This proves, that the nature of the foil muft have an influence, not only upon air and upon water, but alfo upon the effect of manures; and that before we fpeak of their power, we fhould always fpecify what kind of earth they were applied to; becaufe when manures and earth are mixed together, there enfues an action and reaction more or lefs favourable to vegetation.

Having examined to what degree air and water enter, in fubftance, into the veffels of plants, and having fhewn that the principal action of earth, of falts, and of manures, confifts in preparing, elaborating, and decompofing thefe two fluids, and in giving to the products of their decompofition the forms they require, to accomplifh the purpofe of nature in vegetation, our author makes fome obfervations upon the particular effects of certain fubftances ufed for improving land, fuch as marl, lime, chalk, and wood-afhes; which are ufually applied either to an exhaufted foil, in order to reftore it, or to a drooping plant, with a view to give it ftrength. Of the efficacy of thefe fubftances no one doubts, but it does not appear that we are equally agreed refpecting their manner of acting.

Marl (a manure whofe effects are well known, and which is found to be of the greateft benefit in thofe diftricts where it can be procured in fufficient quantity) is capable of acting in the fame manner as the moft fertile foil, when the principles of which it is compofed, namely, clay, fand, calcareous earth, and magnefian earth, are juftly proportioned to each other. But it is fometimes compact and tenacious, becaufe it contains a fuperabundant portion of clay, and at other times porous and friable, becaufe it contains too much fand, and therefore is not in general fit for vegetation by itfelf. Thefe confiderations ought always to be our guide when we mean to employ marl as a manure.

It has been fuppofed that *to marl* was a fort of technical expreffion, intended to denote the bringing together

Manure. ther or dividing the earthy particles by means of clay or fand. It appears to our author, that neither of the above operations can properly be called *marling*; becaufe, in either cafe, all we do is, to put the foil into a fituation to receive and to profit by the influence of the atmofphere, and that of the manures made ufe of. The peculiar principle of marl is, that part of it which, like lime, acts very powerfully upon the different aeriform fluids, is eafily reduced to powder, effervefces with acids, and fends forth a quantity of air-bubbles when water is poured upon it. Now this matter, which in a particular manner does the office of manure, refides neither in clay nor in fand. Upon the proportion of it depends the duration of the fertility it produces; confequently it is of importance, when we make ufe of marl, to know which of its conftituent parts it contains in the greateft proportion, otherwife in fome cafes we fhould only add one common kind of earth to another. Hence our author infers, that for a chalky foil clay is the proper manure, and that in fuch a foil a clay bottom is of more value than a gold mine.

"Wood-afhes, as a manure, may be, in fome refpects, compared to marl; at leaft they contain the fame earths as thofe which generally enter into the compofition of marl, but they contain a greater quantity of faline fubftances, proceeding from the vegetables of which they are the refidue, and from the procefs made ufe of in their combuftion; a procefs which increafes their activity, and fhould render us careful in what manner and for what purpofes we employ them. Wood-afhes, when fcattered over fields, at proper times and in proper quantities, deftroy weeds, and encourage the vegetation of good plants. But do the afhes produce this effect by a fort of corrofive power? I cannot (fays our author) think it; for in that cafe all kinds of plants would indifcriminately be acted upon by them, and to a certain degree deftroyed.

"Befides, the afhes of frefh wood are feldom employed until they have been lixiviated, in which ftate they are deprived of their cauftic principle; thofe afhes which are moft commonly made ufe of for manure are produced either from wood that has been floated in water, or from turf, or from pit-coal, and contain little or no alkaline falt.

"It appears much more probable that afhes, when laid upon ground, deftroy the weeds by a well-known effect, namely, by feizing with eagernefs that moifture which ferved to produce thofe weeds, and which in a fuperabundant quantity is neceffary to their exiftence and fupport. Whereas thofe plants which have a firmer texture and a longer root, which are rendered ftrong by age and by having withftood the rigour of winter, and which are in fact the plants of which the fields are compofed, do not fuffer any damage from the application of the afhes; but, on the contrary, by being freed from the fuperfluous weeds which ftifled them, and robbed them of a part of their fuftenance, they receive a quantity of nourifhment proportioned to their wants. The ftate of relaxation and langour to which they were reduced by a fuperabundance of water, leaves them, the foil gets its proper confiftence, and the grafs, corn, &c. acquiring the ftrength and vigour which is natural to them, foon overcome the mofs, rufhes, and other weeds; thus a good crop, of whatever the field confifts of, is produced. It is in the above manner that wood-afhes act, whenever in the fpring it is neceffary to apply them to meadows, corn-fields, &c. the plants of which are ftifled and weakened by a luxuriant vegetation of weeds, the ufual confequence of mild and wet winters. Manure.

"When wood-afhes produce an effect different from what is above defcribed, it is either becaufe they happen to contain too much alkaline falt, or that they are laid on the ground in too great quantity, or that the fields to which they are applied were not fufficiently wet to reftrain their action; for when they are fcattered upon cold foils, and buried by the plough before the time of fowing, they are like lime, of great fervice. The laftmentioned fubftance is very efficacious in other circumftances; and there is a well-known method of ufing it, practifed by the Germans, as follows: A heap of lime is formed by the fide of a heap of poor earth, and water is poured upon the lime; the earth is then thrown over it, and becomes impregnated with the vapours which efcape from the lime while it is flaked. The earth, after being thus aerated, may be feparated; and although no lime remains mixed with it, is, by the operation juft defcribed, rendered capable of giving a luxuriant vegetation to whatever plants may be put into it.

"It is poffible, therefore, to aerate earth as well as fluids; for this purpofe, by mixing it with certain fubftances, during their decompofition, we muft attach to it the principles of which thofe fubftances are compofed; from which there refults a matter fo loaded with gas, as to form a more compound fubftance, and one which has acquired new properties. The Arabians, for example, who take great pains to improve their land, are accuftomed to make large pits, which they fill with animals which happen to die: thefe pits they afterwards cover with calcerous or clayey earth; and after fome time thefe earths, which of themfelves are fterile, acquire the properties of the richeft manures.

"The foregoing obfervations may at leaft be confidered as proving, that thofe fubftances which, when employed frefh and in too great quantity, are more prejudicial to vegetation, have, on the contrary, an advantageous effect, when they are previoufly made to undergo a fermentation; or when they are mixed with earth or water, in a proportion adapted to the end propofed. The grafs of fields in which cattle or poultry go to feed, after the firft or fecond crop of hay, appears to be dried by the urine and dung of thofe animals; as if fire had been applied to it; whereas thefe fame excrementitious fubftances, when combined with earth, or diluted with water, are capable, without any other preparation, of performing the office of good manure.

"But if animal fecretions, when applied in fubftance to plants, were capable of acting upon them, as is affirmed, in fuch a way as to corrode or burn them, how could feed which has been fwallowed, and efcaped the action of the digeftive powers, be prolific when thrown out by the animal, after having remained fo long in its dung? yet we often fee oats, fo circumftanced, grow and produce feed. It is not more confiftent with experience and obfervation to fuppofe, that thefe excrementitious fubftances, being ftill endowed with animal heat, and with an organic motion, diffufe round plants in vegetation a deleterious principle or inflammable gas, which deftroys them: for foon after their application, the foliage of the plant grows yellow, dries up, and the plant withers, unlefs there happens a fhower of rain

Y 2 which

Manure.

which revives it. When these substances are diluted, by being mixed with water and earth, they lose that principle which is so destructive to vegetable life, and an incipient fermentation augments their power as a manure, so that they may be immediately made use of without any apprehension of injury from their effects.

"It appears, therefore, that any operation upon excrementitious substances, by which they are dried and reduced to powder, cannot be practised without depriving those substances of a great part of such of their principles as are easily evaporated, and upon which their fluidity depends; these principles, when diluted with water, and confined by being mixed with earth, are capable of increasing the produce of the soil. Such is the way in which the husbandmen in Flanders make use of this kind of manure, in the cultivation of a kind of rape or cole seed, which is to them a very important branch of agricultural industry and commerce; and they never observe that the sap carries up any of those principles which give such manure its offensive smell; nor do they observe, that the fodder produced from fields so manured, whether eaten fresh or dry, is disagreeable to their cattle. The excrements of all animals would be injurious to plants, if applied too fresh, or in too great quantity; and a gardener could not commit a greater fault, than to put more than a certain quantity of them into the water he means to make use of to water his young plants; in short, this kind of manure is to be used in a very sparing manner; and he that is too prodigal of it will find, to his cost, that excess, even of that which is otherwise beneficial, becomes an evil.

"It must certainly be allowed, that excrementitious substances are a very advantageous manure for cold soils, and suited to most vegetable productions; a long experience of their effects over a large tract of country, and the acknowledged intelligence of the Flemish farmers, ought to be considered as sufficient to overcome the prejudice that has been raised against this sort of manure. Supposing that the bad effects which have been attributed to it, when used in the state in which it is taken out of privies, &c. are not the offspring of a prejudiced imagination, they may have arisen from its having been made use of at an improper time, or in too great quantity; or from its having been applied to a soil and for the cultivation of plants to which it was not adapted; for we know that the excess of any kind of manure changes the smell and taste of plants, and the same effect is produced by watering them too frequently. Striking examples of this change are seen in the strawberry and in the violet, when such as have grown in the woods are compared to those produced from some of our over-manured gardens; also in the lettuce, and some other plants, when those raised for sale by the gardeners about Paris are compared to those of some particular kitchen gardens. In the markets of some cities, the carrots, turnips, and potatoes of the fields, are preferred to the same kind of roots cultivated by the gardeners (A); for though the last are of a larger size, they have not got so good a flavour. Some vegetables, therefore, are like certain wild species of the animal kingdom; they resist every kind of culture, as those animals resist every effort to tame them.

"Although experience has taught the Flemish farmers, that excrementitious substances are more active in their natural state than when dried, yet it cannot be denied that drying them, and reducing them into powder, is sometimes very advantageous; because in that state they are much less offensive, are easily transported to any distance, and may be used when most convenient or most proper. In many cities the inhabitants pay to have their privies emptied: in other places, those who empty them pay for their contents; and it would astonish any one to be told how great a revenue is produced in the city of Lisle in Flanders by the sale of this kind of manure. I am, however (says our author), far from thinking that it is right, in all cases, to employ it in the above-mentioned state of concentration; it would be better, in my opinion, to follow the example of the Flemish farmers, who use it the first year for the cultivation of plants for oil, or for hemp or flax; and the second year for the best kinds of grain: thus obtaining two crops, instead of one, without any farther preparation of the land. What is said above may be applied also to the manures produced from the dung of cattle, poultry, &c. (particulary to pigeon's dung, the most powerful manure of its kind), all which, by being dried and powdered before they are used, lose a great portion of their activity. From these observations another fact may be deduced, namely, that manure should not be taken from the place where it has been thrown together until the season of the year and the state of the land are such that it may be put into the ground as soon as it is brought to it. In some districts a very injurious custom prevails of carrying the manure into the fields, and leaving it there formed into small heaps, exposed for some days to the elements; during which time, either the sun or wind dry up its natural moisture, leaving a mass which is much less active; or the rain dissolves and carries away the extractive part impregnated with the salt. This kind of brine, which is the most powerful part of the manure, penetrates the earth to a considerable depth, and shews (by the thick tufts which arise in those places, and which produce more straw than grain) that manure ought to be put into the ground as soon as it is brought to it, because it then possesses its full force and effect, and consequently would be then used to the greatest advantage.

"We have always at hand the means of composing, from a great variety of vegetable and animal substances, such manures as, when brought into a proper state, and mixed with land, contribute to its fertility. Chemistry also offers to us a number of substances, which, although when used separately they tend to diminish the fertilising quality of the earth, are yet capable, by being combined, of forming excellent manures; such, for instance, is that saponaceous combination which is produced from a mixture of potash, oil, and earth. What an advantage it would be, if, instead of being sparing of manure, the inhabitants of the country would endeavour to increase the number of these resources, and to render them more beneficial, by employing them in a more effectual manner. How many years had passed before it was known that the refuse of apples and pears, after they are pressed (and which used to be thrown away as useless),

(A) We believe they are universally preferable.

ufelefs), is capable of forming as valuable a manure, in cyder and perry countries, as the refufe of grapes does in wine countries."

From what has been obferved, our author concludes, that manures act, in many circumftances, like medicines, and confequently that the fame fort of manure cannot be adapted to every fituation, and every kind of foil; we muft therefore take care to make proper diftinctions between them. Whoever fhall pretend that any particular kind of manure may be ufed, with equal benefit, in grafs-lands corn-fields, vineyards, orchards, kitchen-gardens, &c. ought to be claffed among thofe quacks who undertake to cure all perfons with the fame remedy, without any regard to their age, conftitution, &c. It is probably from not having paid fufficient attention to the forementioned diftinctions, that fome authors have found fault with particular manures, while others have fpoken too highly in their favour. He thinks, however, and we agree with him, that we are ftill in want of a courfe of comparative experiments upon the various kinds of manures, confidered according to their influence with refpect to different foils, fituations, and productions. If this part of rural œconomy were better underftood, we fhould perhaps fee many places in a ftate of cultivation, which, on account of the bad quality of their foil, have hitherto refifted all our endeavours to render them fertile.

Perhaps it would not be proper to difmifs this fubject without noticing Mr Middleton's obfervations on various kinds of manure, which were publifhed in the Tranfactions of the Society of Arts for the year 1799. This gentleman agrees with Mr Parmentier, in recommending the *excrementitious matter of privies* as the moft powerful of all manures on fome kinds of foil; but he differs from him, and we believe from moft writers on agriculture, when he affirms, that *wood afhes*, when fpread on the grafs in February or March, are of very little fervice, and that the afhes of *coal* and even of *peat* are of none upon any kind of land. He likewife affirms *foot* to be of very little value as a manure, *foapmakers wafte* to be of none, or rather to be hurtful; and he feems to confider *malt-duft*, including the duft from the malt-kilns, to be, after the foil of privies, one of the moft powerful manures. He affirms, from his own experience, that, with refpect to fertilifing power, the foil of privies, compared with farm-yard dung, is in the proportion of five to one. See more on the fubject of Manure, under the title VEGETABLE SUBSTANCES, Chap. 2d.

MAOUANA, one of that cluftre of iflands in the South Sea which were difcovered by M. Bougainville, and by him named Navigator's Iflands. It was vifited by La Peroufe in 1787, who defcribes it as exceedingly rich in every animal and vegetable production neceffary to the fuftenance of man. The two frigates which he commanded had no fooner approached the fhore, than he difcovered at the bottom of each creek a number of villages, from whence came innumerable canoes, laden with hogs, cocoa-nuts, and other fruits, which were purchafed for glafs ware. This was in the evening; and next morning the commerce was renewed in the moft friendly manner. As early as the dawn of day, the iflanders had furrounded the two frigates with 200 canoes full of different kinds of provifion, which they would exchange only for beads—in their eftimation diamonds of the firft water. Axes, cloth, and all other articles of commerce, they difdained. Abounding in real bleffings, they were defirous of obtaining fuperfluities alone.

Two boats, filled with empty cafks, were fent afhore for frefh water; and Peroufe himfelf accompanied them in his pinnace. A line of foldiers was pofted between the beech and the Indians, who amounted to about 200, including a great many women and children. The French commander prevailed upon them all to fit down under cocoa trees, that were not more than eight toifes diftant from the fhips boats. Each of them had by him fowls, hogs, parrots, pigeons, or fruit, and all wifhed to fell them at once, which occafioned fome confufion.

The women, fome of whom were very pretty, offered their favours, as well as their fowls and fruit, to all thofe who had beads to give them; and foon tried to pafs through the line of foldiers, who oppofed but a feeble refiftance to their attempts. Europeans who have made a voyage round the world, efpecially Frenchmen, have no arms to ward off fimilar attacks. Accordingly the fair favages found little difficulty in breaking the ranks; the men then approached; and the confufion was growing general; when Indians, who feemed to be chiefs, made their appearance with fticks in their hands, and reftored order, every one returning to his poft, and the traffic beginning anew, to the great fatisfaction of both buyers and fellers.

While all this was paffing with the greateft tranquillity, and the cafks were filling with water, Peroufe thought he might venture to the diftance of 200 yards to vifit a charming village, fituated in the midft of a wood, or rather of an orchard, all the trees of which were loaded with fruit. The houfes were placed upon the circumference of a circle, of about 150 toifes in diameter, the interior forming a vaft open fpace, covered with the moft beautiful verdure, and fhaded by trees, which kept the air delightfully cool. Women, children, and old men, accompanied him, and invited him into their houfes. They fpread the fineft and frefheft mats upon a floor formed of little chofen pebbles, and raifed about two feet above the ground, in order to guard againft humidity. He went into the handfomeft of thefe huts, which probably belonged to a chief; and great was his furprife to fee a large cabin of latice-work, as well executed as any of thofe in the environs of Paris. The beft architect could not have given a more elegant curve to the extremities of the ellipfis that terminated the building; while a row of pillars, at five feet diftance from each other, formed a complete colonnade round the whole. The pillars were made of trunks of trees very neatly wrought, and between them were fine mats laid over one another with great art, like the fcales of a fifh, and drawing up and down with cords, like our Venetian blinds. The reft of the houfe was covered with leaves of the cocoa palm.

This charming country combines the advantages of a foil fruitful without culture, and of a climate which renders clothing unneceffary. The trees that produce the bread fruit, the cocoa nut, the banana, the guava, and the orange, hold out to thefe fortunate people as abundance of wholefome food; while the fowls, hogs, and dogs, which live upon the furplus of thefe fruits, afford them an agreeable variety of viands. What cold imagination could feparate the idea of happinefs from

fo

Mason. fo enchanting a place! But Maouna is not the abode of innocence. No arms were indeed perceived; but the bodies of the Indians, covered over with fcars, proved that they were often at war, or elfe quarrelling among themfelves; while their features announced a ferocity that was not perceptible in the countenances of the women. Nature had, no doubt, ftamped this character on their faces, by way of fhewing, that the half-favage, living in a ftate of anarchy, is a more mifchievous being than the moft ferocious of the brute creation.

Of their ferocity and their treachery, Peroufe had too foon the moft complete evidence. M. de Langle, the fecond in command, went afhore for frefh water, accompanied by fixty Frenchmen, officers, failors, and foldiers. They were received with an air of good humour by crowds of people waiting on the beach with immenfe quantities of fruit and hogs; but this calm was of fhort duration. The Indians picked a quarrel with them, pelted them with ftones, thrown with great dexterity and with equal force; and it was with difficulty that, of the fixty-one, forty-nine reached the fhips, many of whom were feverely wounded. Among the killed were De Langle, and Lamanon the naturalift (fee LAMANON in this *Suppl.*) Peroufe defcribes the men of Maouna as of gigantic ftature, and of great mufcular ftrength. See *NAVIGATORS Iflands* in this *Suppl.*

MASON (the Rev. William) was a man of fuch eminence both as a poet and as a fcholar, that a more particular account of his life and of his ftudies fhould be publifhed than our fcanty materials enable us to give. He was born at Hull, where his father poffeffed the vicarage of St Trinity; but where he received his fchool education we have not been able to learn. At the proper time he was admitted into St John's College, Cambridge; where he took the degrees of B.A. and M.A. and in 1747, he obtained a fellowfhip in Pembroke Hall. It was there that he contracted an intimate friendfhip with Gray the poet, and with Mr Hurd, now Bifhop of Worcefter. When the former of thefe gentlemen died, Mr Mafon took upon himfelf the office of editor of his works and guardian of his fame; and upon the promotion of the latter to the fee of Litchfield and Coventry, he expreffed his fatisfaction in fome beautiful verfes, which we read at the time, but do not recollect where.

In 1754 he entered into holy orders, and was patronifed by the then Earl of Holdernefs, who obtained for him the appointment of chaplain to the king, and prefented him with the valuable rectory of Afton in Yorkfhire. He was fome time afterwards made precentor of York Cathedral, when he publifhed a fmall volume of church mufic, which has alternately met with oppofition and applaufe. In our opinion fome of his anthems are unrivalled.

It was natural for the precentor of a cathedral church, who was likewife a poet, to turn his attention to facred mufic; and Mafon had been a poet from his early years. His *Elfrida* and *Caractacus*, two tragedies on the Grecian model, were both publifhed before the year 1757. Thefe two dramas, in the opinion of Dr Hurd, do honour to modern poetry, and are, according to him, a fufficient proof of the propriety of reviving the chorus on the Britifh ftage. In this fentiment few critics, we believe, will agree with his Lordfhip; but the tragedies have certainly great merit, and tranfcend perhaps every poem of the fame caft in our own or any other modern tongue. In the firft, the language is elegant and fweet; in the latter, it is daring and fublime. The author himfelf always confidered the former as the moft perfect; and Johnfon, whofe critical judgment will not be rafhly queftioned, feems to have been of the fame opinion. Johnfon's partiality to Oxford, as is well known, made him embrace every opportunity of turning into ridicule Cambridge men and Cambridge poems; but while he boafted of having fpent hours in burlefquing Caractacus for the amufement of his Oxford friends, he confeffed that Elfrida was too beautiful to be hurt by ridicule. The voice of the public, however, feems to give the preference to the latter, and to confider it as ftanding, like Dryden's celebrated ode, without a rival. In both are fentiments and expreffions which would do honour to the genius of Shakefpeare; and Caractacus, in the Greek verfion of Mr Glafs, would not have difgraced an Athenian theatre.

Befides his two tragedies, Mr Mafon publifhed many other poems. His Englifh Garden is univerfally read and admired, being unqueftionably the fineft poem of the kind that has appeared fince the days of Thomfon; though fome have affected to confider it as treating the fubject rather with profeffional fkill than with poetical genius. That there are in it a few profaic expreffions we fhall not controvert; for fuch feem infeparable from didactic poetry; but, taken as a whole, where fhall we find its equal? His elegies, particularly that on the death of his wife, and that on the demife of Lady Coventry, have been generally read and extolled, though not more than they deferve, as fuperior in claffic elegance to any thing of the kind in the Englifh tongue, and expreffing a manlinefs and tendernefs of the pathetic, rarely found in the moft polifhed elegies of Roman writers. The fplendor of genius, and accuracy of judgement, confpicuous in his dramas, are equally difplayed in his character as a lyric writer. His quarry was bold and impetuous, and he never fwept the ground with an ignominious flight. In his Sappho and Phaon he has happily imitated the ftyle of Dryden and Metaftafio; and at his death he was employed on a poem in which he propofed to meafure his ftrength with Dryden.

We have reafon to believe that this ingenious man was not only a poet and a mufical performer, but the inventor of the fafhionable inftrument the Piano Forte. We cannot indeed at prefent bring evidence of this fact; but we have inftituted fuch inquiries as, we hope, fhall enable us to afcertain the truth under the article *PIANO Forte*.

Poetry and mufic, and the duties of his office, might be fuppofed to have employed all his time; but, unfortunately, he caught the alarm which in 1769 was fpread over the nation by the expulfion of Mr Wilkes from the Houfe of Commons, and immediately enrolled himfelf among the fupporters of the *Bill of Rights*. The decifion of the Houfe, which pronounced Mr Lutteral duly elected in oppofition to Mr Wilkes, he confidered as a grofs violation of the rights of the people; and though he furely did not approve of the conduct of the exiled member, he joined with other freeholders in Yorkfhire in a petition to the king that he would diffolve the parliament.

Being now leagued with the oppofition, he joined in fome violent clamours for a parliamentary reform. In the

Mafon. the year 1779, when the city of London, and fome other commercial towns, agreed to prefent their petitions to parliament for a more economical expenditure of the public money, and a more equal reprefentation of the people, Mr Mafon came forward, and took an active part in promoting thefe defigns, as one who was convinced of their importance and neceffity. When the county of York affembled, on the 30th of December 1779, and refolved unanimoufly, "that a committee of correfpondence fhould be appointed, for the effectually promoting the object of the petition then agreed to, and alfo to prepare a plan of *affociation* to fupport that laudable reform, and fuch other meafures as may conduce to reftore the *freedom of parliament*," he was chofen upon the committee, and was confulted with, or affifted in drawing up thofe various high-fpirited refolutions and addreffes to the public, for which the Yorkfhire committee was fo celebrated; and which was afterwards generally adopted by the other affociated bodies of reformers. This part of his conduct is furely entitled to no praife. Thinking as we do of the parliamentary reformers, we cannot but regret that a man of Mr Mafon's talents and virtues fhould have embarked in their dangerous purfuits; and though we perceived lefs hazard in thofe purfuits than we do, we fhould ftill confider them as unfuitable to the character of a clergyman. Our author, however, was of a different opinion. In reply to a cenfure paffed by a dignified clergyman on the political conduct of himfelf and fome of his reverend brethren, he publifhed, without his name indeed, a fpirited defence of their proceedings and defigns in fome of the country papers. The York committee, too, at its next meeting, refolved, "that a Proteftant, by entering into holy orders, does not abandon his civil rights;" they alfo refolved, "that the thanks of the committee be given to thofe reverend gentlemen who, thus preferring the public good to their own private emoluments, have ftood forth the firm friends to the true interefts of their country."

Mr Mafon, however, fhowed, by his fubfequent conduct, that however earneftly he might wifh for what he doubtlefs confidered as an expedient reform in the commons-houfe of Parliament, he was firmly attached to the Britifh conftitution. He was indeed a whig; but he was a whig of the old fchool. In the beginning of 1794, when the reformers had betrayed the principles of French democrates, he deferted them, and ranged himfelf under the banners of the fervants of the crown; and for this conduct, which was certainly confiftent, he has been plentifully traduced by our Jacobin journalifts as an alarmift, who not only deferted his old friends, but afcribed to them a certain degree of guilt and political depravity.

The death of this great and good man, which happened in April 1797, was occafioned neither by age nor by inveterate difeafe. As he was ftepping into his chariot, his foot flipped, and his fhin grazed againft the ftep. This accident had taken place feveral days before he paid the proper attention to it; and on April the 3d a mortification enfued, which, in the fpace of forty-eight hours, put a period to his life.

That he was a fcholar and a poet of high eminence is univerfally acknowledged; and we are affured, that his pofthumous works, when publifhed, will not detract from his living fame. In private life, though he affected perhaps too much the faftidious manners of Mr Gray, whofe genius he eftimated with a degree of enthufiafm amounting almoft to idolatry, his character was diftinguifhed by philanthropy and the moft fervid friendfhips; and he may be confidered as a man who merits to be ranked with the ableft fupporters of Britifh liberty and Britifh morals.

Mafonry. FREE MASONRY, is a fubject which, after the copious detail given in the *Encyclopædia* of its lodges, and wardens, and grand mafters, we fhould not have refumed in this place, but to warn our countrymen againft the pernicious fuperftructures which have been raifed by the French and Germans on the fimple fyftem of Britifh mafonry.

Much falfehood is current refpecting the origin and antiquity of the mafonic affociations. That the Dionyfiacs of Afia Minor were a fociety of architects and engineers, who had the exclufive privilege of building temples, ftadia, and theatres, under the myfterious tutelage of Bacchus, feems to be unqueftionable. "We are alfo certain, that there was a fimilar trading affociation during the dark ages in Chriftian Europe, which monopolized the building of great churches and caftles, and enjoyed many privileges under the patronage of the various fovereigns. Circumftances (fays Dr Robifon), which it would be tedious to enumerate and difcufs, continued this affociation longer in Britain than on the continent;" but there is no good evidence, that, anterior to the year 1648, any man fought admiffion into it, who was not either a builder by profeffion, or at leaft fkilled in the fcience of architecture. At that period, indeed, Mr Afhmole, the famous antiquary (fee ASHMOLE, *Encycl.*), was admitted into a lodge at Warrington, together with his father-in-law Colonel Mainwaring: and thefe are the firft diftinct and unequivocal inftances that we have in Britain of men unconnected with the operative mafons being received into their myfterious fraternity. The fecrecy, however, of the lodges, made them fit places for the meetings of the royalifts; and accordingly many royalifts became free mafons. "Nay, the ritual of the mafter's degree feems to have been formed, or perhaps twifted from its original inftitution, fo as to give an opportunity of founding the political principles of the candidate, and of the whole brethren prefent. For it bears fo eafy an adaptation to the death of the king, to the overturning of the venerable conftitution of the Englifh government of three orders by a mean democracy, and its re-eftablifhment by the efforts of the loyalifts, that this would ftart into every perfon's mind during the ceremonial, and could hardly fail to fhew, by the countenances and behaviour of the brethren, how they were affected."

This fuppofition receives much countenance from the well known fact, that "Charles II. was made a mafon, and frequented the lodges. It is not unlikely, that befides the amufement of a vacant hour, which was always agreeable to him, he had pleafure in meeting with his loyal friends, and in the occupations of the lodge, which recalled to his mind their attachment and fervices. His brother and fucceffor James II. was of a more ferious and manly caft of mind, and had little pleafure in the frivolous ceremonies of mafonry. He did not frequent the lodges. But, by this time, they were the refort of many perfons who were not of the profeffion, or members of the trading corporation. This circum-

Masonry. ſtance, in all probability, produced the denominations of *free* and *accepted* maſons. A perſon who has the privilege of working at any incorporated trade, is ſaid to be a *freeman* of that trade. Others were *accepted* as brethren, and admitted to a kind of honorary freedom; as is the caſe in many other trades and incorporations, without having, (as far as we can learn for certain) a legal title to earn a livelihood by the exerciſe of it."

It was not till ſome years after this period that the lodges made open profeſſion of the cultivation of general benevolence, and that the grand aim of the fraternity was to enforce the exerciſe of all the ſocial virtues. The eſtabliſhment of a fund for the relief of unfortunate brethren did not take place till the very end of the laſt century; and we may preſume, that it was brought about by the warm recommendations of ſome benevolent members, who would naturally enforce it by addreſſes to their aſſembled brethren. Hence the probable origin of thoſe philanthropic diſcourſes, which are occaſionally delivered in the lodges by one of the brethren as an official taſk.

The boaſted philanthropy of maſons ſerves, however, another purpoſe. The inquiſitive are always prying and teazing, eager to diſcover the ſecrets of their neighbours; and hence the brethren are induced to ſay, that univerſal beneficence is the great aim of the order, for it is the only point on which they are at liberty to ſpeak. They forget, that univerſal beneficence and philanthropy are inconſiſtent with the excluſive and monopolizing ſpirit of an aſſociation, which not only confines its benevolence to its own members (like any other charitable aſſociation), but hoards up in its boſom ineſtimable ſecrets, whoſe natural tendency, they ſay, is to form the heart to this generous and kind conduct, and inſpire us with love to all mankind. The profane world cannot ſee the beneficence of concealing from public view a principle or a motive which ſo powerfully induces a maſon to be good and kind. The brother ſays, that publicity would rob it of its force; and we muſt take him at his word: and our curioſity is ſo much the more excited, to learn what are the ſecrets which have ſo ſingular a quality, for they muſt be totally unlike the principles of ſcience, which produce their effects only when made public.

From this account of maſonry, it would appear to have been at firſt a loyal aſſociation, and as ſuch it was carried over from England to the continent; for all the maſons abroad profeſs to have received their myſteries from Great Britain. It was firſt tranſported into France by the zealous adherents of King James, who, together with their unfortunate maſter, took refuge in that country; and it was cultivated by the French in a manner ſuited to the taſte and habits of that highly poliſhed and frivolous people. To the three ſimple Britiſh degrees of *apprentice*, *fellow-craft*, and *maſter*, they gradually added degrees innumerable, all decorated with ſtars and ribbons; and into their lodges they introduced the impieties and ſeditious doctrines of Voltaire and the other philoſophiſts. Indeed, if the account which the Abbè Barruel gives of maſonry be juſt, it muſt be admitted, that even the ſecrets of the moſt ancient lodges, though in one ſenſe harmleſs and juſt, are ſo expreſſed, that they may be eaſily twiſted to very dangerous purpoſes. This author was advanced by a few friends to the degree of maſter, without being obliged to take the oath of ſecrecy; and being furniſhed with the ſigns, he got admiſſion into a lodge, where he heard the ſecret regularly communicated, with all the ordinary forms to an apprentice. "It would be uſeleſs, (ſays he), to deſcribe the ceremonials and trials on ſuch occaſions; for in the firſt degrees, they are nothing more than the play of children. The grand object was the communication of the famous ſecret, when the candidate was ordered to approach nearer to the venerable. At that moment, the brethren, who had been armed with ſwords for the occaſion, drawing up in two lines, held their ſwords, elevated, leaning the points towards each other, and formed what in maſonry is called the *arch of ſteel*. The candidate paſſed under this arch to a ſort of altar elevated on two ſteps, at the furtheſt end of the lodge. The maſter, ſeated in an arm chair, or a ſort of throne, behind this altar, pronounced a long diſcourſe on the inviolability of the ſecret which was to be imparted, and on the danger of breaking the oath which the candidate was going to take. He pointed to the naked ſwords, which were always ready to pierce the breaſt of the traitor; and declared to him that it was impoſſible to eſcape their vengeance. The candidate then ſwore, "that rather than betray the ſecret, he conſented to have his head cut off, his heart and entrails torn out, and his aſhes caſt before the winds." Having taken the oath, the maſter ſaid the following words to him: "My dear brother, the ſecret of maſonry conſiſts in theſe words, EQUALITY AND LIBERTY; *all men are equal and free; all men are brethren*.". The maſter did not utter another ſyllable, and every body embraced the new *brother equal and free*. The lodge broke up, and we gayly adjourned to a maſonic repaſt." Maſonry.

In the Britiſh lodges, the author admits, that no other interpretation is given to this famous ſecret, than that, as all men are children of one common parent, and creatures of the ſame God, they are in duty bound to love and help each other as brethren; but he contends, that in France it was differently interpreted; and he ſupports his opinion by the following arguments:

On the 12th of Auguſt 1792, Louis XVI. was carried a priſoner to the tower of the *temple*, ſo called becauſe it formerly belonged to the knights templars. On that day, the rebel aſſembly decreed, that to the date of *liberty* the date of *equality* ſhould be added in future in all public acts; and the decree itſelf was dated the fourth year of *liberty*, the firſt year and firſt day of *equality*. It was on that day, for the firſt time, that the ſecret of free-maſonry mas made public; that ſecret ſo dear to them, and which they preſerved with all the ſolemnity of the moſt inviolable oath. At the reading of this famous decree, they exclaimed, "We have at length ſucceeded, and France is no other than an immenſe lodge. The whole French people are free maſons, and the whole univerſe will ſoon follow their example."

"I witneſſed (ſays our author) this enthuſiaſm; I heard the converſation to which it gave riſe; I ſaw maſons, till then the moſt reſerved, who freely and openly declared, 'Yes, at length the grand object of free-maſonry is accompliſhed, EQUALITY and LIBERTY; *all men are equal and brothers; all men are free*. That was the whole ſubſtance of our doctrine, the object of our wiſhes, *the whole of our grand ſecret!*'"

This is a very ſerious charge againſt the original ſecret

Masonry. cret of masonry, as it was understood in France; and though the author does not bring it directly against the same secret as understood in Britain, he yet seems to say, that in *all* lodges, the following question is put to the candidate before he is entrusted with any secret:—"Brother, are you disposed to execute all the orders of the grand-master, though you were to receive contrary orders from a king, an emperor, or any other sovereign whatever?" And as the brother is obliged to promise this unlimited obedience, it is easy to conceive how much a traiterous conspiracy may be promoted by means of mason lodges. The allegorical story which is told at the conferring of the degree of master, is capable of various and even contrary interpretations; for though in this country it was originally rendered subservient to the purposes of the royalists, in the occult lodges on the continent it has been made the vehicle of treason and impiety.

When the degree of master-mason is to be conferred, the lodge is hung round with black. In the middle is a coffin covered with a pall, the brethren standing round it in attitudes denoting sorrow and revenge. When the new adept is admitted, the master relates to him the following history or fable:

"Adoniram presided over the pavement of the workmen who were building the temple of Solomon's orders. They were three thousand workmen. That each one might receive his due, Adoniram divided them into three classes, apprentices, fellow crafts, and masters. He entrusted each class with a word, signs, and a gripe, by which they might be recognised. Each class was to preserve the greatest secrecy as to these signs and words. Three of the fellow-crafts, wishing to know the word, and by that means obtain the salary of master, hid themselves in the temple, and each posted himself at a different gate. At the usual time when Adoniram came to shut the gates of the temple, the first of the three met him, and demanded the *word of the masters*; Adoniram refused to give it, and received a violent blow with a stick on his head. He flies to another gate, is met, challenged, and treated in a similar manner by the second: flying to the third door, he is killed by the fellow-craft posted there, on his refusing to betray the word. His assassins buried him under a heap of rubbish, and marked the spot with a branch of acacia.

"Adoniram's absence gave great uneasiness to Solomon and the masters. He is sought for every where: at length one of the masters discovers the corpse, and, taking it by the finger, the finger parted from the hand; he took it by the wrist, and it parted from the arm; when the master, in astonishment, cried out, *Mac Benac*; which the craft interprets by "*the flesh parts from the bones*."

"Lest Adoniram should have revealed the *word*, the masters convened and agreed to change it, and to substitute the words *Mac Benac*; sacred words, that free-masons dare not pronounce out of the lodges, and there each only pronounces one syllable, leaving his neighbour to pronounce the other."

The history finished, the adept is informed, that the object of the degree he has just received is to recover the word lost by the death of Adoniram, and to revenge this martyr of the masonic secrecy. The generality of masons, looking upon this history as no more than a fable, and the ceremonies as puerile, give themselves very little trouble to search farther into these mysteries.

These sports, however, assume a more serious aspect when we arrive at the degree of elect (*Elu*). This degree is subdivided into two parts; the first has the revenging of Adoniram for its object, the other to recover the *word*, or rather the sacred doctrine which it expressed, and which has been lost.

In this degree of elect, all the brethren appear dressed in black, wearing a breast-piece on the left side, on which is embroidered a death's head, a bone, and a poignard, encircled by the motto of *Conquer or Die*. The same motto is embroidered on a ribband which they wear in saltier. Every thing breathes death and revenge. The candidate is led into the lodge blindfolded, with bloody gloves on his hands. An adept with a poignard in his hand threatens to run him through the heart for the crime with which he is accused. After various frights, he obtains his life, on condition that he will revenge the father of masonry in the death of his assassin. He is shewn to a dark cavern. He is to penetrate into it; and they call to him, Strike all that shall oppose you; enter, defend yourself, and avenge our master; at that price you shall receive the degree of elect. A poignard in his right hand, a lamp in his left, he proceeds; a phantom opposes his passage; he hears the same voice repeat, Strike, avenge Hiram, there is his assassin. He strikes, and the blood flows.—Strike off his head, the voice repeats; and the head of the corpse is lying at his feet. He seizes it by the hair (A), and triumphantly carries it back as a proof of his victory; shews it to each of the brethren, and is judged worthy of the new degree.

Our author says, that he has questioned divers masons whether this apprenticeship to ferocity and murder had never given them the idea, that the head to be cut off was that of kings; but they all affirmed that such an idea had never occurred to them till the French revolution had convinced them of the fact. At this indeed we are not surprised. The assassin of Hiram is no where said to have been a king; and why should the young elect have supposed, that when stabbing that assassin, he was training to be a regicide? The ceremony, however, is certainly ferocious in the highest degree, and obviously calculated to reconcile the masons of the occult lodges to the practice of assassination at the command of their superiors; and when it is remembered, that they are bound to pay obedience to those unseen superiors even against their lawful sovereigns, the atrocities of the revolution would naturally make them interpret this shocking ceremony as it is interpreted by the Abbé.

It was the same with respect to the religious part of this degree, where the adept is at once pontiff and sacrificer with the rest of the brethren. Vested in the ornaments of the priesthood, they offer bread and wine, according to the order of Melchisedec. The secret object of this ceremony is to re-establish religious equality, and to exhibit all men equally priests and pontiffs, to recal the brethren to natural religion, and to persuade them that the religion of Moses and of Christ had violated religious equality and liberty by the distinction of

(A) The reader may easily conceive that this corpse is no more than a mannikin containing bladders full of blood.

of priests and laity. It was the revolution again which opened the eyes of many of the adepts, who then owned that they had been dupes to this impiety, as they had been to the regicide essay in the former part.

Our author treats the fraternity of the occult lodges through the higher degrees of Scotch masonry, those of the Rosicrucians, and that of the knights Kadosch; and sums up his account in the following terms:

"In the two first degrees, that is to say, in those of *apprentice* and *fellow-craft*, the sect begins by throwing out its equality and liberty. After that, it occupies the attention of its novices with puerile games of fraternity or masonic repasts; but it already trains its adepts to the profoundest secrecy by the most frightful oaths.

"In that of *master*, it relates the allegorical history of Adoniram, who is to be avenged; and of the *word*, which is to be recovered.

"In the degree of *elect*, it trains the adepts to vengeance, without pointing out the person on whom it is to fall. It carries them back to the time of the patriarchs, when, according to them, men knew no religion but that of nature, and when every body was equally priest and pontiff. But it had not as yet declared that all religion revealed since the time of the patriarchs was to be thrown aside.

"This last mystery is only developed in the Scotch degrees. There the brethren are declared free: The word so long sought for is, Deism; it is the worship of Jehovah, such as was known to the philosophers of nature. The true mason becomes the pontiff of Jehovah; and such is the grand mystery by which he is extricated from that darkness in which the prophane are involved.

"In the degree *Rosæ Crucis*, he who wrested the *word*, who destroyed the worship of Jehovah, is Christ himself, the author of Christianity; and it is on the Gospel and on the Son of Man that the adept is to avenge the brethren, the pontiffs of Jehovah.

"At length, on his reception as Kadosch, he learns that the assassin of Adoniram is the king, who is to be killed to avenge the Grand Master Molay, and the order of the masons successors of the knights templars. The religion which is to be destroyed to recover the *word*, or the true doctrine, is the religion of Christ, founded on revelation. This word in its full extent is *equality* and *liberty*, to be established by the total overthrow of the altar and the throne.

"Such are the incipient degrees, the process, and the whole system of masonry; it is thus that the sect, by its gradual explanation of its twofold principle of *equality* and *liberty*, of its allegory of the founder of masonry to be avenged, of the word to be recovered, leading the adepts from secret to secret, at length initiates them into the whole Jacobinical code of revolution."

If this account of masonry be not greatly exaggerated, what are we to think of those men among ourselves, who, since the publication of the Abbè Barruel's book and Dr Robison's, have displayed a zeal for the propagation of their mysteries, by which they seemed not to be formerly actuated, and to which the importance of the business that, by their own account, is transacted in the lodges, cannot be thought to bear an adequate proportion? It is not enough to say that British masonry is harmless, and that the *equality* and *liberty* taught in our lodges are the equality and liberty taught in the bible. Without directly questioning this assertion, we only beg leave to put our countrymen in remembrance, that French and German masonry, as it was derived from Britain, must have been originally as harmless as our own; and to call their attention to the monstrous superstructures of impiety and rebellion which in these countries have been raised upon our foundation. Have there been no symptoms of sedition and irreligion among us, since the commencement of the French revolution, that we should be so confident that the equality and liberty of our lodges will never degenerate into the equality and liberty of the French Jacobins? This cannot be said; for it has been proved, that there are several occult lodges in Britain; and what security have we, or what security can we receive, that their number shall not increase? The legislature indeed has lately laid some salutary restraints on the meetings of masons; but such is the nature of these meetings, that nothing can effectually secure us against the introduction of the higher mysteries, but the voluntary shutting up for a time of all lodges. This has been done by the honest masons in Germany; and why may it not be done by the masons in Britain? The fund for the relief of poor brethren may surely be managed without secrecy; the signs and gripe may be communicated without the *word*, or exacting a promise of implicit obedience; and the relinquishing of the joys of a social hour would be no great sacrifice to the peace of the country.

But is British masonry really so harmless as the younger masons wish us to believe? The writer of these reflections was never initiated in its mysteries, and therefore cannot, from his own knowledge, say what is their tendency; but he has no hesitation to affirm, because he believes himself able to demonstrate, that it is grossly immoral to promise implicit obedience to unknown superiors, or to swear that one will keep inviolate a secret, to the nature of which he is an absolute stranger. He hopes, indeed, and is inclined to believe, that, in the decent lodges of Britain, the candidate is assured, before he is required to take the oath, that the secret to be communicated, and the obedience which he is to pay, militate in no respect against the civil government or the religion of his country: but still if the secret contain information of value, it is, in his opinion, sinful to keep it a secret; and he cannot conceive upon what principle a native of Britain can promise unlimited obedience to any human being. The mysteries of masonry must relate to something which is either important and laudable; frivolous, though innocent; or dangerous and immoral. To confine to a sect any information which is laudable and important, is surely not to act the part of genuine philanthropists; to administer the most tremendous oaths in the midst of frivolous amusements, is to violate one of the most sacred precepts of our holy religion; and, as no man will pretend to vindicate dangerous and immoral mysteries, masonry appears, in every point in which it can be placed, an association which no good Christian will think himself at liberty to encourage.

MASUAH (See MASSUAH, *Encycl.*) is in latitude 15° 35′ 5″ north, and in longitude 39° 36′ 30″ east of Greenwich. On the 22d of September 1769 Mr Bruce found the variation of the needle at Masuah to be 12° 48′ west.

MATMAI, or MATSUMAI, is the largest of the Kurile islands; and if it be not independent, is tributary to to Japan. The capital town of the same name, Matmai, is situated on the sea-shore, on the south-west side. It was built and is inhabited by the Japanese. It is a fortified place, furnished with artillery, and defended by a numerous garrison. The island of Matmai is the place of exile for persons of distinction at Japan: it is separated from that empire by only a narrow channel, but which is considered as dangerous, because the capes, which project on both sides, render the navigation difficult. The people are said to be sensible to friendship, hospitable, generous, and humane.

MAYORGA (Martin de). See *Don Martin*, &c. in this *Suppl.*

MAYOW (John), whose discoveries in chemistry have astonished the scientific part of the public, descended, says Wood, from a genteel family living at *Bree* in the county of *Cornwall*. His father was probably a younger son, bred to business; for our author was born in Fleet-street, London, in the parish of St Dunstan's in the West. At what school he received the rudiments of his education, a circumstance which the biographers of men eminent in the republic of letters should never omit, we have not been able to learn; but on the 27th of September 1661, when he had just completed his 16th year, he was admitted a scholar of Wadham college, Oxford. Some time afterwards, on the recommendation of Henry Coventry, Esq; one of the secretaries of state, he was chosen a probationer fellow of All-souls college. As Wood informs us that he had here a *Legist's place*, an expression by which we understand a law-fellowship, it is not wonderful that he took his degrees in the civil law, though physic and the physical sciences were the favourite objects of his study. He was indeed an eminent physician, practising both in London and in Bath, but in the latter city chiefly in the summer months, till the year 1679, when he died, some time during the month of September, in the house of an apothecary in York-street, Covent-Garden, and was buried in the church of that parish. He had been married, says Wood, a little before his death, not altogether to his content; and indeed he must have been very discontented, if he chose to die in the house of a friend rather than in his own. He published, "Tractatus quinque medico physici, 1. De salnitro; 2. De respiratione; 3. De respiratione fœtus in utero et ovo; 4. De motu musculari et spiritibus animalibus; 5. De Rachitide." These were published together in 8vo at Oxford, in 1764; but there is an addition of two of them, "De respiratione," and "De Rachitide," published together at Leyden in 1671.

The fame of this author has been lately revived and extended by Dr Beddoes, who published, in 1790, "Chemical Experiments and Opinions, extracted from a work published in the last century," 8vo; in which he gives to Mayow the highest credit as a chemist, and ascribes to him some of the greatest modern discoveries respecting air, giving many extracts from the three first of his treatises. His chief discovery was, that oxygen gas, to which he gave the name of *fire air*, exists in the nitrous acid, and in the atmosphere; which he proved by such decisive experiments, as to render it impossible to explain how Boyle and Hales could avoid availing themselves, in their researches into air, of so capital a discovery. Mayow also relates his manner of passing aeriform fluids under water, from vessel to vessel, which is generally believed to be a new art. He did not collect dephlogisticated air in vessels, and transfer it from one jar to another, but he proved its existence by finding substances that would burn in vacuo, and in water when mixed with nitre; and after animals had breathed and died with vessels filled with atmospheric air, or after fire had been extinguished in them, there was a residuum which was the part of the air unfit for respiration, and for supporting fire; and he further shewed, that nitrous acid cannot be formed, but by exposing the substances that generate it to the atmosphere. Mayow was undoubtedly no common man, especially since, if the above dates are right, he was only 34 at the time of his death. But he was not so unknown as Dr Beddoes supposed; for since the repetition of the same discovery by Priestley and Scheele, reference has frequently been made by the chemists to Mayow as the original inventor; thus allowing to him a species of merit, to which he has perhaps but a doubtful claim, and which, if that claim be well founded, must certainly be shared between him and Dr Hooke. See HOOKE in this *Supplement*.

MEAN, in general. See *Encycl.*

Arithmetical MEAN, is half the sum of the extremes. So 4 is an arithmetical mean between 2 and 6, or between 3 and 5, or between 1 and 7; also an arithmetical mean between a and b is $\frac{a+b}{2}$, or $\frac{1}{2}a + \frac{1}{2}b$.

Geometrical MEAN, commonly called a mean proportional, is the square root of the product of the two extremes; so that, to find a mean proportional between two given extremes, multiply these together, and extract the square root of the product. Thus, a mean proportional between 1 and 9, is $\sqrt{1 \times 9} = \sqrt{9} = 3$; a mean between 2 and $4\frac{1}{2}$ is $\sqrt{2 \times 4\frac{1}{2}} = \sqrt{9} = 3$ also; the mean between 4 and 6 is $\sqrt{4 \times 6} = \sqrt{24}$; and the mean between a and b is $\sqrt{ab}$.

Harmonical MEAN. See *Harmonical PROPORTION*, Encycl.

MEAN and Extreme Proportion, or *Extreme and Mean Proportion*, is when a line or any quantity is so divided that the less part is to the greater, as the greater is to the whole.

MEAN Anomaly of a Planet, is an angle which is always proportional to the time of the planet's motion from the aphelion or perihelion, or proportional to the area described by the radius vector; that is, as the whole periodic time in one revolution of the planet, is to the time past the aphelion or perihilion, so is 360° to the mean anomaly. See ANOMALY, *Encycl.*

MEAN Conjunction or *Opposition*, is when the mean place of the sun is in conjunction, or opposition, with the mean place of the moon in the ecliptic.

MEAN Distance of a Planet from the Sun, is an arithmetical mean between the planet's greatest and least distances.

MEAN Motion, is that by which a planet is supposed to move equably in its orbit; and it is always proportional to the time.

MEAN Time or *Equal Time*, is that which is measured by an equable motion, as a clock; as distinguished from apparent time, arising from the unequal motion of the earth or sun.

UNIVERSAL or PERPETUAL MEASURE, is a kind of of meaſure unalterable by time or place, to which the meaſures of different ages and nations might be reduced, and by which they may be compared and eſtimated. Such a meaſure would be very uſeful if it could be attained; ſince, being uſed at all times, and in all places, a great deal of confuſion and error would be avoided.

It has been attempted, at different times and in different countries, more eſpecially by the French, who, ſince the commencement of their revolutionary government, have laboured hard to obtrude their innovations in arts and ſcience, as well as in politics, upon all nations. Propoſals, however, have been made by ſoberer men for a ſtandard both of weights and of meaſures for all nations; and ſome of the moſt rational of theſe ſhall be noticed under the word Weights in this *Supplement*.

MECHANICS.—Our readers will recollect that in the article Physics, *Encycl.* we propoſed to diſtinguiſh by the term *Mechanical Philoſophy* that part of natural ſcience which treats of the local motions of bodies and the cauſes of thoſe phenomena. And, although all the changes which we obſerve in material nature are accompanied by local motion, and, when completely explained, are the effects (perhaps very remote) of thoſe powers of matter which we call *moving forces*, and of thoſe alone, yet in many caſes, this local motion is not obſerved, and we only perceive certain ultimate reſults of thoſe changes of place. This is the caſe (for example) in the ſolution of a grain of ſilver in a phial of aquafortis. In the beginning of the experiment, the particles of ſilver are contained in a ſmall ſpace at the bottom of the phial; but they are finally raiſed from the bottom, and uniformly diſſeminated over the whole fluid. If we fix our attention ſteadily on one particle, and trace it in its whole progreſs, we contemplate nothing but a particle of matter acted on by moving forces, and yielding to their action. Could we ſtate, for every ſituation of the particle, the direction and intenſity of the moving force by which it is impelled, we could conſtruct a figure, or a formula, which would tell us the preciſe direction and velocity with which it changes its place, and we could delineate its path, and tell the time when it will arrive at that part of the veſſel where it finally reſts in perfect equilibrium. Newton having done all this in the caſe of bodies acted on by the moving force called gravity, has given us a complete ſyſtem of mechanical aſtronomy. The philoſopher who ſhall be as fortunate in aſcertaining the paths and motions of the particles of ſilver, till the end of this experiment, will eſtabliſh a ſyſtem of the mechanical ſolution of ſilver in aquafortis; and the theorems and formulæ which characteriſe this particular moving force, or this modification of force, ſtating the laws of variation by a change of diſtance, will be the complete theory of this chemical fact. It is this modification of moving force which is uſually, (but moſt vaguely) called the *chemical affinity*, or the *elective attraction of ſilver and aquafortis*.

But alas! we are, as yet, far from having attained this perfection of chemical knowledge. All that we have yet diſcovered is, that the putting the bit of ſilver into the ſpirit of ſalt will not give occaſion to the exertion of this moving force: and we expreſs this obſervation, by calling that unknown force (unknown, becauſe we are ignorant of the law of its action) an *affinity*, an *elective* attraction. And we have obſerved many ſuch elections, and have been able to claſs them, and to tell on what occaſions they will or will not be exerted; and this ſcrap of the complete theory becomes a moſt valuable acquiſition, and the claſſification of thoſe ſcraps a moſt curious, and extenſive, and important ſcience. The chemical philoſopher has alſo the pleaſure of ſeeing gradual approaches made by ingenious men to the complete mechanical explanation of theſe unſeen motions and their cauſes, of which he has arranged the ultimate reſults.

The ordinary chemiſt, however, and even many moſt acute and penetrating enquirers, do not think of all theſe motions. Familiarly converſant with the reſults, they conſider them as principles, and as topics to reaſon from. They think a chemical phenomenon ſufficiently explained, when they have pointed out the affinity under which it is arranged. Thus they aſcribe the propagation of heat to the expanſive nature of fire, and imagine that they conceive clearly how the effect is produced. But if a mathematical philoſopher ſhould ſay, "What is this which you call an expanſive fluid? Explain to me diſtinctly, in what manner this property which you call expanſiveneſs operates in producing the propagation of heat."—We imagine that the chemiſt would find himſelf put to a ſtand. He will then, perhaps for the firſt time, try to form a diſtinct conception of an expanſive fluid, and its manner of operation. He will naturally think of air, and will reflect on the manner in which air actually expands or occupies more room; and he will thus contemplate local motion and mechanical preſſure. He will find, too late, that this gives him no aſſiſtance; becauſe the phenomena which he has been accuſtomed to explain by the expanſiveneſs of fluids have no reſemblance whatever to what we ſee reſult from the actual expanſion of air. Experience has made him acquainted with many effects which the air produces its expanſion; but they are of a totally different kind from thoſe which he thought that he had ſufficiently explained by the expanſiveneſs of fire. The only reſemblance he obſerves is, that the air and the heat, which were formerly perceived only in a ſmall ſpace, now appear in a much larger ſpace. The mathematician now deſires him to tell in what manner he conceives this expanſiveneſs, or this actual expanſion of air or gas. The chemiſt is then obliged to conſider the air or gas, as conſiſting of atoms or particles, which muſt be kept in their preſent ſituation by an external force, the moſt familiar of all to his imagination, namely, preſſure; and all preſſures are equally fit. Preſſure is a moving force, and can only be oppoſed to ſuch another moving force; therefore expanſiveneſs ſuppoſes, that the particles are under the influence of ſomething which would ſeparate them from each other, if it were not oppoſed by ſomething *perfectly of the ſame kind*. It cannot be oppoſed by greenneſs, nor by loudneſs, nor by fear, but only by what is competent to the production of motion; and it may be oppoſed by any *ſuch* natural power; therefore by gravity, or by magnetiſm, or electricity, or corpuſcular attraction, or by an elective attraction. The chemiſt, being thus led to the contemplation of the phenomenon in its moſt ſimple ſtate, can now judge with ſome diſtinctneſs, what is the nature of thoſe powers with which expanſiveneſs can be

Mechanics. be brought to co-operate or combine. And only now will be able to fpeculate on the means for explaining the propagation of heat; and he will perceive that the general laws of motion, and of the action of moving forces (doctrines which we comprehend under the title of DYNAMICS, *Suppl.*), muft be reforted to for a *complete* explanation of all chemical phenomena. The fame may be faid of the phenomena perceived in the growth of vegetables and animals. All of them lead us ultimately to the contemplation of an atom, which is characterifed by being fufceptible of local motion, and requires for this purpofe the agency of what we call a moving force.

We would diftinguifh this particular OBJECT of our CONTEMPLATION (confifting of two conftituent parts, the atom and the force, related, in fact, to each other by conftant conjunction) by the term MECHANISM. We conceive it to be the charactereftic of what we call MATTER; and we would confider it as the moft fimple MECHANICAL PHENOMENON. We are difpofed to think, that this moving force is as fimple and uniform as the atom to which it is related; and we would afcribe the inconceivable diverfity of the moving forces which we fee around us to combinations of this univerfal force exerted by many atoms at once; and therefore modified by this combination, in the very fame manner as we frequently fee thofe feemingly different moving forces combine their influence on a fenfible mafs of tangible matter, giving it a fenfible local motion. Having formed fuch notions, we would fay that we do not conceive either the atom or the force as being matter, but the two thus related. And we would then fay, that whatever object of contemplation does not ultimately lead us to this complex notion is IMMATERIAL; meaning by the epithet nothing more than the negation of this particular character of the object. It is equivalent to faying, that the phenomenon does not lead the mind to the confideration of an atom actuated by a moving force; that is, moved, or prevented from moving, by an oppofite preffure or force.

Such is the extenfion which the difcoveries of laft century have enabled us to give to the ufe of the term mechanifm, mechanical action, mechanical caufe, &c.

The Greeks, from whom we have borrowed the term, gave it a much more limited meaning; confining it to thofe motions which are produced by the intervention of machines. Even many of the naturalifts of the prefent day limit the term to thofe motions which are the *immediate* confequences of impulfe, and which are cafes of fenfible motion. Thus the chemift fays, that printers ink is a mechanical fluid, but that ink for writing is a chemical fluid. We make no objection to the diftinction, becaufe chemiftry is really a vaft body of real and important fcience, although we have, as yet, been able to clafs only very complicated phenomena, and are far from the knowledge of its elements. This diftinction made by the chemifts is very clear, and very proper to be kept in view; but we fhould be at a lofs for a term to exprefs the analogy which is perceivable between thefe fenfible motions and the hidden motions which obtain even in the chemical phenomena, unlefs we give mechanifm a ftill greater extenfion than the effects of percuffion or impulfion.

Mechanics, in the ancient fenfe of the word, confiders only the energy of *organa*, machines. The authors who have treated the fubject fyftematically, have obferved, Mechanics. that all machines derive their efficacy from a few fimple forms and difpofitions, which may be given to that piece of matter called the *tool* ὄργανον, or *machine*, which is interpofed between the workman or natural agent, and the tafk to be performed, which is always fomething to be moved, in oppofition to refifting preffures. To thofe fimple forms they have given the name of MECHANICAL POWERS, fimple powers, fimple machines.

The machine is interpofed for various reafons.

1. In order to enable a natural power, having a certain determinate intenfity, which cannot be increafed, to balance or overcome another natural power, acting with a greater intenfity. For this purpofe a piece of folid matter is interpofed, connected in fuch a manner with firm fupports, that the preffure exerted on the impelled point by the power occafions the excitement of a preffure at the working point, which is equal or fuperior to the refiftance, arifing from the work, to the motion of that point. Thus, if a rod three feet long be fupported at one foot from the end to which the refiftance of two pounds is applied, and if a preffure of one pound be applied to the other end of the rod, perpendicular to its length, the cohefive forces which connect the particles of the rod will all be excited, in certain proportions, according to their fituation, and the fupported point will be made to prefs on its fupport as much as three pounds would prefs on it; and a preffure in the oppofite direction will be excited at the working point, equal to the preffure of two pounds. The refiftance will therefore be balanced, and it will be overcome by increafing the natural power acting on the long divifion of the rod. This is called a LEVER. Toothed wheels and pinions are a perpetual fucceffion of levers in one machine or mechanical power.

2. The natural power may act with a certain velocity which cannot be changed, and the work requires to be performed with a greater velocity. A machine is interpofed, moveable round a fixed fupport, and the diftances of the impelled and working points are taken in the proportion of the two velocities. Then are we certain, that when the power acts with its natural velocity, the working point is moving with the velocity we defire.

3. The power may act only in one unchangeable direction, and the refiftance muft be overcome in another direction. As when a quantity of coals muft be brought from the bottom of a pit, and we have no power at command but the weight of a quantity of water. We let the water pull down one end of a lever, either immediately or by a rope, and we hang the coals on the other end, while the middle point is firmly fupported. This lever may be made perpetual, by lapping the ropes round a cylinder which turns round an axis firmly fupported. This is a FIXED PULLEY. We can fet unequal powers in oppofition, by lapping each rope round a different cylinder, having the fame axis. This is a WINDLASS or GIN. All thefe forms derive their energy from the lever virtually contained in them.

Any of thefe three purpofes may be gained by the interpofition of a folid body in another way. Inftead of being fupported in one point, round which it is moveable, it may be fupported by a folid path, along which it is impelled, and by its fhape it thrufts the refifting body

Mechanics. body out of its way. This is the cafe with the WEDGE when it is employed to force up a fwagging joift, or prefs things ftrongly together. If this wedge be lapped or formed round an axis, it becomes a SCREW or a SPIRAL WIPER. This is alfo the operation of the balance wheel of a horizontal or cylinder watch. The oblique face of the tooth is a wedge, which thrufts the edge of the cylinder out of its way. The pallet of a clock or watch is alfo a wedge, acted on in the oppofite direction.

Thefe are the different forms in which a folid body is interpofed as a mechanic power. All are reducible to the lever and the wedge.

But there are other mechanic powers befides thofe now mentioned. The carmen have a way of lowering a cafk of liquor into a cellar, by paffing a rope under it, making the end faft to fome ftake clofe to the ground, and bringing the other end of the rope round the cafk, and thus letting it flip down in the bight of the rope. In this procefs they feel but half of its weight, the other half being fupported by the end of the rope that is faftened to the ftake. This is called a PARBUCKLE by the feamen. A hanging pulley is quite the fame with this more artlefs method. The weight hangs by the axis of the pulley, and each half of the hanging rope carries half of the weight, and the perfon who pulls one of them upwards acts only againft half of the weight, the other being carried by the hook to which the ftanding rope is faftened. This mechanical power does not (as is commonly imagined) derive its efficacy from the pulley's turning round an axis. If it were made faft, or if the tackle rope merely paffed through a loop of the rope which carries the weight, it would ftill require only half of the weight acting on the running rope to balance it. The ufe of the motion round an axis is merely to avoid a very great friction. When the two hanging parts of the rope are not parallel, but inclined in any angle, the force neceffary for balancing the weight is to the weight as the fide is to the diagonal of the parallelogram formed by the directions of the three ropes. Varignon calls this the FUNICULAR MACHINE or power. Our failors call it the SWIGG.

We may employ the *quaqua verfum* preffure of fluidity with great effect as a mechanic power. Thus, in the hydroftatic bellows defcribed by Gravefande, § 1451, and by Defaguilliers, the weight of a few ounces of water is made to raife feveral hundred pounds. In like manner, Dr Wallis of Oxford, by blowing with a pipe into a bladder, raifed 64 pounds lying on it. Otto Guericke of Magdeburgh made a child balance, and even overcome, the pull exerted by the emperor's fix coach horfes, by merely fucking the air from below a pifton. Mr Bramah, ironmonger in Piccadilly, London, has lately obtained a patent for a machine acting on this principle as a prefs *. A pifton of one-fourth of an inch in diameter, forces water into a cylinder of 12 inches diameter, and by this intervention raifes the pifton of the cylinder. A boy, acting with the fourth part of his ftrength on the fmall pifton by means of a lever, raifes 42 tons, or 94,080 libs, preffing on the great pifton. It is very furprifing, that this application of the *quaqua verfum* preffure of fluids has been overlooked for more than a century, although the principle has been inculcated and lectured on by every itinerant teacher, and illuftrated by the above mentioned experiments of Gravefande and Wallis; nay, it has been exprefsly taught as a mechanic power of great efficacy by the Profeffor of Natural Philofophy at Edinburgh every feffion of the college for thefe twenty years paft, but he never thought of putting it in practice. It forms a moft compendious machine of prodigious power, and is fufceptible of the greateft ftrength. If the fame multiplication of power be attempted by toothed wheels, pinions, and racks, it is fcarcely poffible to give ftrength enough to the teeth of the racks, and the machine becomes very cumberfome and of great expence. But Mr Bramah's machine may be made abundantly ftrong in very fmall compafs. It only requires very accurate execution. We give it all praife; but Mr Bramah is miftaken when he publifhes it as the invention or difcovery of a new mechanic power: for it has been familiar to every ftudent of mechanics and hydroftatics ever fince Boyle's firft publication of his hydroftatic paradoxes.

* See MACHINERY in this *Suppl.*

Medical, Medici.

MEDICAL JURISPRUDENCE. See *MEDICINA Forenfis* in this *Suppl.*

MEDICI, is the name of an illuftrious family in Florence, which contributed more than perhaps any other family whatever to the revival of letters in Europe. To trace this family from its origin, or even to give biographical fketches of all the great men whom it produced, would occupy by far too great a part of our work; for, during fome centuries, almoft every individual of the houfe of Medici was diftinguifhed among his contemporaries. That houfe, after having rendered itfelf memorable in the annals of Florence, for oppofing the encroachments of the nobles on the liberties of the people, had loft much of its influence under the ariftocratic government of the Albizi, when it was raifed to a rank fuperior to what it had ever held, by

Giovanni de MEDICI, who was born in the year 1360. This man determined to reftore his family to fplendour; but, confcious of his critical fituation, furrounded as he was by powerful rivals and enemies, he affected rather a fecure privacy than a dangerous popularity. Even when raifed to the office of gonfalonier, or generaliffimo of the republic, he carefully avoided any defire of partaking in the magiftracy, and feemed to be entirely engroffed by merchandize, which he extended from the Eaft throughout Europe. This conduct, as on one hand it threw his enemies off their guard, on the other, enabled him to acquire an immenfe fortune, of which he made a proper difpofition amongft all ranks of people.

Many, even of the ruling party, either gained by his liberality, or pleafed with his amiable and retired conduct, propofed to the feigniory to admit him into the magiftracy; and though the propofal met with great oppofition, it was carried in the affirmative.

It was by rafhly declaring for the plebeians againft the nobles that an anceftor of Giovanni's had loft to his family their rank in the ftate. Giovanni, refolving not to fplit on the fame rock, continued to affect privacy and retirement, accepting any office in the ftate with the utmoft appearance of reluctance, and never attending at the Palazzo, unlefs particularly fent for by the feigniory. Rifing by thefe means in the efteem of the people, his enemies became, of courfe, unpopular; and having obtained a decided fuperiority over his opponents, he now ventured to procure, that thofe taxes which the nobles had exacted with the utmoft feverity and partiality from the people alone, fhould be levied

upon

Medici. upon the two firſt orders, in common with the plebeians; and that a law ſhould be ordained, by which perſonal property might be taxed.

The nobles ſeeing, with the deepeſt concern, their conſeqence ſo ſenſibly wounded, and their power ſo much diminiſhed, held ſeveral conſultations in private how they might effect his ruin; but their want of unanimity prevented any thing deciſive from being carried into execution. The people, alarmed for the ſafety of their leader and patron, offered him the ſovereignty, which his relations and friends urged him to accept; but this his prudence forbad him to take, as with the title of lord he would have gained that alſo of tyrant. Thus, by his ſingular prudence he died poſſeſſed of all the power of the ſtate, with the affectation of being the moſt diſintereſted citizen in the commonwealth. His death happened in the year 1428.

Giovanni was graceful in his perſon, and his affability to all eſtabliſhed his character for moderation. His extenſive knowledge and pleaſantry made his company eagerly ſought. As all his actions were placid and ſerene, he was not in want of that trumpet of ſedition, popular declamation, which he never attempted. Much to his honour, his elevation was not procured even by the baniſhment of a ſingle individual; a circumſtance until then unknown in Florence, where every new adminiſtration was marked with the ruin of families, and by ſcaffolds ſtained with blood.

"The maxims (ſays Mr Roſcoe) which, uniformly purſued, raiſed the houſe of Medici to the ſplendour which it afterwards enjoyed, are to be found in the charge given by this venerable old man, on his deathbed, to his two ſons Coſmo and Lorenzo. 'I feel (ſaid he) that I have lived the time preſcribed me. I die content, leaving you, my ſons, in affluence and in health, and in ſuch a ſtation, that, whilſt you follow my example, you may live in your native place honoured and reſpected. Nothing affords me more pleaſure than the reflection, that my conduct has given offence to no one; but that, on the contrary, I have endeavoured to ſerve all perſons to the beſt of my abilities. I adviſe you to do the ſame. With reſpect to the honours of the ſtate, if you would live with ſecurity, accept only ſuch as are beſtowed on you by the laws, and the favour of your fellow-citizens; for it is the exerciſe of that power which is obtained by violence, and not of that which is voluntarily given, that occaſions hatred and contention."

Medici (Coſmo de), the eldeſt ſon of the preceding, was born in 1389. During the life-time of his father, he had engaged himſelf deeply, not only in the extenſive commerce by which the family had acquired its wealth, but in the weightier matters of government. When Giovanni died he was in the prime of life; and though his complexion was ſwarthy, he had an agreeable perſon, was well made, of a proper ſtature, and in converſation united a happy intermixture of gravity with occaſional ſallies of pleaſantry and repartee. His conduct was uniformly marked by urbanity and kindneſs to the ſuperior ranks of his fellow-citizens, and by a conſtant attention to the intereſts and the wants of the lower claſs, whom he relieved with unbounded generoſity. By theſe means he acquired numerous and zealous partizans of every denomination; but he rather conſidered them as pledges for the continuance of the power which he poſſeſſed, than as inſtruments to be employed in extending it to the ruin and ſubjugation of the ſtate. An interchange of reciprocal good offices was the only tie by which the Florentines and the Medici were bound; and perhaps the long continuance of this connection may be attributed to the very circumſtance of its being in the power of either of the parties at any time to have diſſolved it. Medici.

But the prudence and moderation of Coſmo could not repreſs the ambitious deſigns of thoſe rival families, who wiſhed to poſſeſs or to ſhare his authority. In the year 1433, Rinaldo de Albizi, at the head of a powerful party, carried the appointment of the magiſtracy. At that time Coſmo had withdrawn to his ſeat in the country, to avoid the diſturbances which he ſaw likely to enſue; but at the requeſt of his friends he returned to Florence, where he was led to expect ſuch a union of parties, as might at leaſt preſerve the peace of the city. No ſooner did he make his appearance in the palace, where his preſence had been requeſted, on pretence of his being intended to ſhare in the adminiſtration of the republic, than he was ſeized upon by his adverſaries, and committed to priſon.

The conſpirators were divided in their opinions as to the diſpoſal of their priſoner. Moſt of them inclined to follow the advice of Peruzzi, who recommended taking him off by poiſon. Coſmo, confined in the Alberzettino, a room in one of the turrets of the Palazzo, could hear this dreadful conſultation, which was determining, not in what manner he ſhould be tried, but in what manner he ſhould be put to death; and finding that he was to die by an infuſion of poiſon ſecretly adminiſtered to him, a ſmall portion of bread was the only food which he thought proper to take.

Coſmo lived in this manner four days; and, ſhut up from all his kindred and friends, he ſoon expected to be numbered with the dead; but here, as it ſometimes happens, he found relief where leaſt expected, from the man who had been engaged to take him off. Malavolta, the keeper of the priſon, either from compunction, diſſatisfaction, or the youth and misfortunes of the illuſtrious ſufferer, relented; and inſtead of purſuing any criminal intentions againſt the life of Coſmo, after upbraiding him with entertaining ſo unworthy an opinion of him, declared that his fears were entirely groundleſs. To convince him of this, he ſat down, and partook of every thing the priſoner choſe to eat of. The expreſſions of gratitude, together with his moſt engaging manners, and great promiſes, entirely won Malavolta, who, to ingratiate himſelf ſtill farther in the good opinion of Coſmo, invited Fargaccio, the moſt celebrated wit in Florence, to dine with him the next day, from the idea that his ſprightly mirth would contribute to lighten his misfortunes.

In the mean time, his brother Lorenzo, and his couſin Averardo, having raiſed a conſiderable body of men in Romagna and other neighbouring diſtricts, and being joined by the commander of the troops of the republic, approached towards Florence to his relief. The apprehenſion, however, that the life of Coſmo might be endangered, if they ſhould proceed to open violence, induced them to abandon their enterpriſe. At length Rinaldo and his adherents obtained a decree of the magiſtracy, by which Coſmo was baniſhed to Padua for ten years, his brother to Venice for five years; and ſeveral

Medici. veral of their relations and adherents ſhared the ſame fate.

Coſmo received this determination of his judges with a compoſure that gained him the compaſſion and the admiration of many of his moſt inveterate enemies. He would gladly have left the city purſuant to his ſentence; but he was detained by his enemies till their authority ſhould be eſtabliſhed: and it was not till he thought of bribing the gonfalonier, and another creature of Rinaldo's, that he was privately taken from his confinement, and conducted out of Florence.

Padua, to which he was confined by his ſentence, was in the dominions of Venice; but before he could reach that place, he received a deputation from the ſenate, the purport of which was to condole with him for his misfortunes, and to promiſe him their protection and aſſiſtance in whatever he ſhould deſire. He experienced the treatment of a prince rather than that of an exile. Nor were that wiſe people without good reaſons for ſuch a conduct. Venice had long regarded Florence as her rival in commerce, and hoped, by conferring upon Coſmo the moſt flattering diſtinctions, to prevail upon him to reſide there in future; prudently ſuppoſing that the manufactories of Florence, and the great commerce the Medici had carried on throughout Italy, and extended far beyond it to the wealthieſt kingdoms in Europe, would become their own by enrolling him amongſt their ſubjects.

The readineſs with which Coſmo had given way to the temporary clamour raiſed againſt him, and the reluctance which he had ſhewn to renew thoſe rencounters which had ſo often deluged the ſtreets of Florence with blood, gained him new friends, even during his exile. The utmoſt exertions of his antagoniſts could not long prevent the choice of ſuch magiſtrates as were known to be attached to the cauſe of the Medici; and no ſooner did they enter on their office than Coſmo and his brother were recalled, and Rinaldo with his adherents were compelled to quit the city. This event took place about a year after the baniſhment of Coſmo.

The ſubſequent conduct of this great man (for great all allow him to have been) has been painted in different colours by different writers. Mr Noble, after Machieval, compares his cruelties to his fallen foes with thoſe of Sylla and Octavius to the partizans of Marius and Brutus; whilſt Roſcoe repreſents his conduct as in a high degree amiable and generous. It appears to us evident, from his own words, that he had exerciſed ſome cruelties on his exiled enemies; for when one of them wrote to him, that "the hen was hatching," he replied, "She will have but a bad time of it, ſo far from her neſt." When ſome other exiles acquainted him that "they were not aſleep," he anſwered, "he could eaſily believe that, for he thought he had ſpoiled their ſleeping." At another time, ſome of the citizens remonſtrated with him upon the odiouſneſs of his conduct in baniſhing ſo many perſons; telling him "the republic would be extremely weakened, and God offended, by the expulſion of ſo many good and pious men as he was ſending into baniſhment." His anſwer was, "it would be better for the republic to be weakened than utterly ruined; that two or three yards of fine cloth made many a one look like a good man: but that ſtates were not to be governed or maintained by counting a ſtring of beads, and mumbling over a few *Pater noſters*."

From this time the life of Coſmo de Medici was an almoſt uninterrupted ſeries of proſperity. His misfortunes had taught him, that the affectation of grandeur is more dangerous in a free ſtate than uſurpation. He adopted, therefore, the dreſs, behaviour, and manners, of a private citizen. His clothes were of the ſame faſhion and materials as the reſt of the Florentines. In the ſtreets he walked alone and unguarded. His table was ſupplied from what his eſtate of Mugello produced, nor had he one ſervant more than was abſolutely neceſſary; thus endeavouring to unite the character of a prince with that of a merchant, and a private perſon in a republic.

Whilſt he rejected all offices in the magiſtracy, no buſineſs was tranſacted without its being firſt ſettled at Mugello: nor did he contract any alliances but with the ſons and daughters of the citizens of Florence; yet all foreign princes and courts paid his children the reſpect due only to thoſe of ſovereigns; and the family of Coſmo received educations equal to thoſe of the greateſt potentates.

A proper judgment may be formed of his immenſe traffic, and the prodigious advantages accruing from it: For though a private citizen of Florence only, yet he poſſeſſed at one time more money than what was in all the treaſuries of the different ſovereigns in Europe. When Alfonſo king of Naples leagued with the Venetians againſt Florence, Coſmo called in ſuch immenſe debts from thoſe places, as deprived them of reſources for carrying on the war. During the conteſt between the houſes of York and Lancaſter, he furniſhed Edward IV. with a ſum of money ſo great, that it might almoſt be conſidered as the means of ſupporting that monarch on the throne.

In his public and private charities, in the number and grandeur of the edifices he erected, not only in Florence, but in the moſt diſtant parts of the world, and in the foundations which he endowed, he ſeemed to more than vie with majeſty. He ſupplied moſt of the exigencies of the ſtate from his private purſe; and there were few citizens that had not experienced his liberality, and many without the leaſt application, particularly the nobles.

But in nothing did his munificence produce ſo much good to the world, or acquire ſuch honour to himſelf, as when it was exerted for the promotion of ſcience, and the encouragement of learned men; and upon nothing did Coſmo delight ſo much to exert it. The ſtudy of the Greek language had been introduced into Italy towards the latter part of the preceding century; but it had again fallen into neglect. After a ſhort interval, an attempt was made to revive it, by the intervention of Emanuel Chryſoloras, a noble Greek, who taught that language at Florence, and other cities of Italy, about the beginning of the 15th century. His diſciples, who were numerous and reſpectable, kept the flame alive till it received new aid from other learned Greeks, who were driven from Conſtantinople by the dread of the Turks, or by the total overthrow of the Eaſtern Empire. To theſe illuſtrious foreigners, as well as to the learned Italians, who ſhortly became their ſucceſsful rivals, even in the knowledge of their national hiſtory and language, Coſmo afforded the moſt liberal ſupport and protection. The very titles of the works of ancient authors, which were brought to light by his munificence,

nificence, would extend this article beyond its proper limits. Such, indeed, was the eftimation in which thefe works were then held in Italy, that a manufcript of the hiftory of Livy, fent by Cofmo de Medici to Alfonfo king of Naples, with whom he was at variance, conciliated the breach between them.

As the natural difpofition of Cofmo led him to take an active part in collecting the remains of the ancient Greek and Roman writers, fo he was enabled by his wealth, and by his extenfive mercantile intercourfe with different parts of Europe and of Afia, to gratify a paffion of this kind beyond any other individual. To this end he laid injunctions on all his friends and correfpondents, as well as on the miffionaries and preachers who travelled into the remoteft countries, to fearch for and procure ancient manufcripts, in every language, and on every fubject. The fituation of the Eaftern Empire, then falling into ruins, afforded him an opportunity of obtaining many ineftimable works in the Hebrew, Greek, Chaldaic, Arabic, and other eaftern languages. From thefe beginnings arofe the celebrated library of the Medici; which, after various viciffitudes of fortune, and frequent and confiderable additions, has been preferved to the prefent times under the name of the *Bibliotheca Mediceo Laurentiana.*

Nor was Cofmo a mere collector of books, he was himfelf, even in old age, a laborious ftudent. Having been ftruck with the fublime fpeculations of Plato, which he had heard detailed in lectures by a Greek monk, who had come from Conftantinople to the council of Florence, he determined to found an academy for the cultivation of that philofophy. For this purpofe he felected Marfilio Ficino, the fon of his favourite phyfician, and deftined him, though very young, to be the fupport of his future eftablifhment. The education of Ficino was entirely directed to the Platonic philofophy; nor were the expectations which Cofmo had formed of him difappointed. The Florentine academy was fome years afterwards eftablifhed with great credit, and was the firft inftitution in Europe for the purfuit of fcience, detached from the fcholaftic method then univerfally adopted. It is true, the fanciful doctrines of Plato are as remote from the purpofes of life as the fubtleties of Ariftotle; but, by dividing the attention of the learned between them, the dogmas of the Stagyrite were deprived of that fervile refpect which had fo long been paid to them, and men learned by degrees to think for themfelves.

The foftering hand of Cofmo was held out to art as well as to fcience; and architecture, fculpture, and painting, all flourifhed under his powerful protection. The countenance fhewn by him to thefe arts was not fuch as their profeffors generally receive from the great. It was not conceded as a bounty, nor received as a favour, but appeared in the friendfhip and equality that fubfifted between the artift and his patron; and the fums of money, which Cofmo expended on pictures, ftatues, and public buildings, appear almoft incredible.

Cofmo now approached the period of his mortal exiftence; but the faculties of his mind remained unimpaired. About twenty days before he died, he fent for Ficino, and enjoined him to tranflate from the Greek the treatife of Xenocrates on death. Calling into his chamber his wife and his fon Piero, he entered into a narrative of all his public tranfactions; in which he gave a full account of his extenfive mercantile connections, and adverted to the ftate of his domeftic concerns. To Piero he recommended a ftrict attention to the education of his fons; and requefted, that his funeral might be conducted with as much privacy as poffible. He died on the firft of Auguft 1464, at the age of 75 years, deeply lamented by a great majority of the citizens of Florence. Their efteem and gratitude had indeed been fully fhewn fome time before, when, by a public decree, he was honoured with the title of *Pater Patriæ*, an appellation which was infcribed on his tomb; and which, as it was founded, fays Rofcoe, on real merit, has ever fince been attached to the name of Cofmo de Medici.

Medici (Lorenzo de), juftly ftyled the *magnificent*, was the grandfon of Cofmo, and about 16 years of age when his grandfather died. His father Piero de Medici, though poffeffed of more than ordinary talents, as well as of a very confiderable fhare of worth, was, from various circumftances, little qualified to maintain the influence which his family had gained in the republic of Florence. From very early life he had been tortured by the gout; and almoft uninterrupted pain had made him peevifh. Such a difpofition was not calculated to retain the affections of the giddy Florentines, or to perfuade republicans that they were free, while they fubmitted to the government of a fingle individual. All this Cofmo had forefeen, and had done what wifdom could do to preferve to his family that afcendency in the republic which he had himfelf acquired. He exhorted Piero to beftow the utmoft care on the education of his fons, of whofe capacity he expreffed a high opinion; he recommended to him Diotifalvo Neroni, a man whom he had himfelf raifed from obfcurity to an eminent rank, as a counfellor, in whofe wifdom and fidelity he might place the utmoft confidence: and to bind the inhabitants of Florence to the houfe of Medici by the ftrongeft of all ties, he had diftributed among them, under the denomination of loans, immenfe fums, which he knew they would not foon be able to repay.

Piero paid the utmoft deference to the dying injunctions of his father. He had himfelf an ardent love of letters; and under the eye of the venerable Cofmo, he had given his two fons, Lorenzo and Juliano, the beft poffible domeftic education. In the Greek language, in ethics, and in the principles of the Ariftotelian philofophy, Lorenzo, the eldeft, had the advantage of the precepts of the learned Argyropylus (A), and in thofe of the Platonic fect he was feduloufly inftructed by Marfilio Ficino (fee Ficinus, *Encycl.*); but for his moft valuable accomplifhments he was not indebted to any preceptor. To complete his education, however, it was judged expedient that he fhould vifit fome of the principal courts of Italy; and very foon after the death of his grandfather, he repaired to Rome, Bologna, Ferrara, Venice, and Milan, where he gained the efteem of all whofe efteem was of value.

(A) This man had fled from Conftantinople, when it was taken by the Turks, to Florence, where he was protected by Cofmo de Medici.

Medici.

Thus attentive was Piero to the advice of his father with respect to the education of his eldest son; nor was he less attentive to it in the choice of his principal counsellor. He intrusted the whole of his affairs into the hands of Neroni, and gave him Cosmo's accounts to peruse and settle. That ambition, which perhaps had lain lurking in this man's mind, was now called forth, and he basely formed the scheme of ruining the son of his patron, by building upon his misfortunes his own future grandeur. For this purpose, he lamented the absolute necessity there was for an immediate call upon those who were indebted to Piero as Cosmo's representative; telling him that a delay might subject him to the greatest inconveniences. Piero consented, though with reluctance, to his supposed friend's advice. The result was such as Neroni expected. Those who were friends of the father became enemies of the son; and had not Piero discovered the snare, and desisted from such rigorous proceedings, he might have found, when too late, that in supporting the character of the merchant, he had forgotten that of the statesman; for all the citizens of Florence were his debtors.

Soon after this, an attempt was made to assassinate Piero, by a powerful party which had always been inimical to the house of Medici; but it was defeated by Lorenzo, who displayed on that occasion a sagacity and promptitude of mind which would have done honour to the oldest statesman. A few of the conspirators were declared enemies to the state, and condemned to banishment; but by far the greater part of them were pardoned on the solicitation of Lorenzo, who declared, that "he only knows how to conquer, who knows how to forgive."

In the year 1469 Piero de Medici died; and Lorenzo succeeded to his authority as if it had been a part of his patrimony, being requested by the principal inhabitants of Florence, that he would take upon himself the administration of the republic in the same manner that his grandfather and father had done.

In the month of December 1470, a league was solemnly concluded between the pope, the king of Naples, the duke of Milan, and the Florentines, against Mahomet II. who had vowed not to lay down his arms till he had abolished the religion of Christ, and extirpated all his followers. The pope, however, (Paul II.), died on the 26th of July 1471; and Sixtus IV. succeeding to the chair of St Peter, Lorenzo was deputed from Florence to congratulate him on his elevation. Two more opposite characters can hardly be conceived than those of Sixtus and Lorenzo. The former was cruel, treacherous, and sordid; the latter was merciful, candid, and generous. Yet such instances of mutual good will took place between them on this occasion, that Lorenzo, who, under the direction of his agents, had a bank established at Rome, was formally invested with the office of treasurer of the Holy See.

Pisa had been under the dominion of Florence from the year 1406, and it had acquired some celebrity on account of its academy, which had existed almost two centuries. That academy, however, had fallen into decay; and, in the year 1472, the Florentines resolved to restore it to its pristine splendour. Five citizens, of whom Lorenzo de Medici was one, were appointed to superintend the execution of their purpose; but Lorenzo, who was the projector of the plan, undertook the chief management of it; and, in addition to 6000 florins annually granted by the state, expended, in effecting his purpose, a large sum of money from his private fortune. In doing this, he only imitated the example of his father and grandfather; for in the course of 37 years, reckoning from the return of Cosmo from banishment, this illustrious family had expended on works of charity or public utility upwards of 660,000 florins. "Some persons (said Lorenzo) would perhaps be better pleased to have a part of it in their purse; but I conceive that it has been of great advantage to the public, and well laid out, and am therefore perfectly satisfied."

In the year 1474, Lorenzo incurred the displeasure of the pope for opposing some of his encroachments on the petty princes of Italy; and the revenge planned by Sixtus was of such a nature as would have disgraced, we do not say a Christian bishop, but the rudest savage. He began by depriving Lorenzo of the office of treasurer of the Roman See, which he gave to the Pazzi, a Florentine family, who, as well as the Medici, had a public bank at Rome. By this step he secured the interest of the Pazzi, who, it is probable, were to govern Florence under the pope, when Lorenzo and Juliano de Medici should be cut off, and their friends and adherents driven from the republic. The principal agent engaged in the undertaking was Fransesco Salviati archbishop of Pisa, to which rank he had lately been promoted by Sixtus, in opposition to the wishes of the Medici. The other conspirators were Giacopo Salviati, brother to the archbishop; Giacopo Poggio, one of the sons of the celebrated Poggio Bracciolini (see POGGIUS, *Encycl.*); Barnardo Bandini, a daring libertine, rendered desperate by the consequence of his excesses; Giovanni Battisti Montesicco, who had distinguished himself as general of the pope's armies; Antonio Maffei, a priest of Volterra; and Stephano de Bagnona, one of the apostolic scribes; with several others of inferior note. The cardinal Riario, then at Pisa, was likewise an instrument in the conspiracy; but he can hardly be considered as an agent, for he was kept ignorant of what was going on, and enjoined only to obey whatever directions he might receive from the archbishop of Pisa.

The assassination of the illustrious youths was fixed for Sunday, April 26. 1478; the place the cathedral of Florence, at the moment the host was to be elevated; and their murder was to be the signal for seizing and expelling from the walls of the city all their relations and friends. What a transaction this for one who presumed to style himself the vicar of Christ, the common father of Christendom, to patronize!

The fatal day arrived, and Lorenzo was already in the church; but Juliano remained at home, occasioned by a slight indisposition. The conspirators, determining not to lose one of their victims, went to invite, to intreat him, to go. They embraced (B), and led him, by a tender violence, to the cathedral. The signal was given

(B) The assassins embraced Juliano, to discover whether he wore any secret armour, that they might know whre to strike with the surest aim.

Medici. given by the elevation of the consecrated wafer; and whilst the people fell upon their knees to adore, the assassins rose, and, as was concerted, two of them, Francisco Pazzi and Barnardo Bandini, fell upon Juliano. The latter directed his poignard so truly, that it entered into the bosom of the unoffending youth, and he fell mortally wounded at his feet.

In a moment, as must be supposed, all was confusion. Lorenzo, alarmed, put himself in a posture of defence, when in an instant, Antonio of Volterra, and Stephano a priest, the dependant of the archbishop, who, upon Giovanni Battisti's declining the infamous task, undertook his destruction, rushed upon him as their destined prey. The contest continued some time. Lorenzo had received a wound in his neck, and seemed to contend for his life in vain; but a servant, whom he had lately relieved from prison, inspired by gratitude, heroically threw himself between his beloved lord and his assassins, receiving in his body those weapons that were aimed at the breast of Lorenzo. This fidelity saved him; for by one vigorous effort he broke from Antonio and Stephano, and with a few friends rushed into the sacristy, shutting the doors behind them, which were of brass. Apprehensions being entertained, that the weapon which had wounded him was poisoned, a young man sucked the wound, endangering his own life to save that of Lorenzo.

The rage of the people to see one of their favourites expiring, and the other covered with blood, was inexpressible. The cardinal Riario found it difficult to save his life at that altar which he had stained by so horrid a deed, and to which he then fled for protection.

Whilst this infamous scene was acting in the cathedral, others of the conspirators were attempting to seize the Palazzo; but with no better success. The archbishop Salviatti, who had undertaken to head them, gave the magistrates suspicion by those violent emotions which agitated his whole frame. The nine senators who composed the magistracy, including the gonfalonier, who had been appointed by, and were, in other words, the privy council of the Medici, immediately attacked those who intended to have surprised them; and Salviatti and his followers had no sooner gained the second floor, than they found themselves prisoners.

Jacobo Pazzi soon appeared in the street, proclaiming, with exultation, the murder of Juliano; and inviting the Florentines to free themselves from the Medicean slavery; but perceiving that he was not joined by the people, the magistrates sent off 100 horse to the rescue of Lorenzo. This was the more to be commended, because they continued to be assaulted by the conspirators, who finding their situation desperate, forced themselves to the ground floor, determining, if possible, to seize the Palazzo. The magistrates, with their attendants, acted with such resolution and valour, that as often as they gained an entrance they drove them back, killing some of the assailants upon the spot, others they threw out of the windows upon the pavement; and to strike an awe into those that were without, they had the boldness and virtue to hang the archbishop from one of the windows, dressed as he was in his pontifical robes, with Poggio, another of the chief conspirators. Florence resounded in every part with the exclamation — Medici, Medici! down with their enemies!

Lorenzo was liberated from that part of the cathedral to which he had fled, and conveyed home in triumph, where his wounds were attended to, and where he found himself surrounded by his most valuable friends, to whom he was endeared by the shocking occurrences of the day. His partizans, however, did not spend their time only in lamentations for the death of one of the brothers, and exultations for the preservation of the other; they united in pursuing the conspirators, sparing none that fell into their hands. Jacobo Pazzi was taken flying with his forces into Romania, and immediately hung. An officer of the pope's, who commanded a brigade under Count Hirronimo, had alone the favour of decapitation. Bandini fled privately to Pisa, thence to Naples, and, lastly, to Constantinople; but Mahomet, to oblige Lorenzo, seized, and sent him back; and he was hung out of the same window from which the archbishop had suffered. An embassy was sent from Florence to thank the sultan in the name of the republic. Medici.

Throughout the whole of this just but dreadful retribution, Lorenzo had exerted all his influence to restrain the indignation of the populace. He entreated that they would resign to the magistrates the task of ascertaining and of punishing the guilty, lest the innocent should be incautiously involved in destruction; and his appearance and admonitions had an instantaneous effect. By his moderation, and even kindness to the relatives of the conspirators, he sought to obliterate the remembrance of past disturbances; and by his interference, even the survivors of the Pazzi were restored to their honours, of which they had been deprived by a decree of the state.

The generosity and moderation of Lorenzo had no effect on the temper of Sixtus, who solemnly excommunicated him, the gonfalonier, the magistrates, and their immediate successors; and in the bull which he issued on this occasion, he styles Lorenzo de Medici "the child of iniquity and the nursling of perdition!" Not content with this ebullition of resentment, he suspended the bishops and clergy of the Florentine territories from the exercise of their spiritual functions; thus laying the whole republic under an interdict. This had been a formidable weapon in the hands of his predecessors, who had, by means of it, overawed the most powerful monarchs; but the general character of Sixtus was so infamous, and his present injustice so manifest, that by the exertions of the bishop of Arezzo, a convocation was held in the cathedral church of Florence, in which Sixtus was accused of *fornication* and *adultery*, with other infamous vices; declared to be the principal instigator of the conspiracy against the Medici; and the sentence of excommunication which he had fulminated against Lorenzo and the Florentine magistrates was called in direct terms, the "execrable malediction of a damned judge (*maledictam maledictionem damnatissimi judicis*)!"

How such language could be reconciled to the notions which then prevailed of the sanctity of the pope, and the plenitude of his power, it is needless to inquire; but the reader will not be surprised that the prelates, who made use of it, paid no regard to the interdict of Sixtus. The pontiff, however, did not relax from his purpose. Whilst he brandished with one hand the spiritual weapon, which the Florentines treated with such contempt, in the other he grasped a temporal sword, which he now openly, as he had before secretly, aimed at the breast of Lorenzo. At his instigation the king of Naples

 dispatched

Medici. dispatched an envoy to Florence, to require the citizens to banish Lorenzo from the Tuscan territories, if they would not incur the vengeance both of him and of the pope. These threats produced not the intended effect; for the Florentines avowed their firm resolution to suffer every extremity, rather than betray the man whom they considered as guardian of the republic. War therefore was commenced and the republic was on the point of being ruined, when Lorenzo taking advantage of a truce, threw himself, with a resolution not to be equalled, into the hands of the king of Naples. He judged, perhaps, that any stipulations for his personal safety would be useless with a prince who had sported with honour, justice, mercy, and the most solemn treaties. But, whilst all viewed him as a victim who had devoted himself to save his country, he, by persuasive eloquence, obtained of this crafty perfidious monarch a separate peace, and returned to Florence crowned with a success that no one thought possible, and where he was received as its tutelar deity. The pope, however, continued inflexible, till a descent of the Turks upon Italy restored him to his senses, and made him willing to receive the submission of Florence, and reconcile its inhabitants to the church.

Soon after the termination of the hostilities between Sixtus and the republic of Florence, Lorenzo began to unfold plans for securiug the peace of Italy, which confer the highest honour on his political life. To counterpoise all the jarring interests of the petty states of which that country was composed, to restrain the powerful, succour the weak, and to unite the whole in one firm body which might be able, on the one hand, successfully to oppose the formidable power of the Turks, and, on the other, to repel the incursions of the French and Germans, were the important ends which this great man proposed to accomplish. But before he engaged in these momentous undertakings, he had further personal dangers to encounter. By the instigation of Cardinal Riario, and some Florentine exiles, one Battista Frascobaldi, with only two assistants, undertook to assassinate him in the church of the Carmeli, on the festival of the ascension 1481; but the plot was discovered, the conspirators executed, and Lorenzo henceforth seldom went abroad without being surrounded by a number of tried friends.

Lorenzo was now at liberty to prosecute his benevolent purposes; and after contributing to the expulsion of the Turks from Italy, he set himself in good earnest to support the weak states against the encroachments of the more powerful. This necessarily embroiled the republic at one time with the pope, at another with the king of Naples; now with the Venetians, and then with the Duke of Milan: but when some exclaimed against him as being too precipitate in involving the republic in dangerous and expensive wars, he explained to them the necessity of maintaining the balance of power, if they would preserve the independence of their own state; and so completely had he made himself master of this subject, that he convinced the most incredulous of the propriety of his measures, which, in 1488, introduced general tranquillity into Italy.

At this period, the city of Florence was at its highest degree of prosperity. The vigilance of Lorenzo had secured it from all apprehensions of external attack; and his acknowledged disinterestedness and moderation had almost extinguished that spirit of internal dissension for which it had been so long remarkable. The Florentines gloried in their illustrious citizen, and were gratified by numbering in their body a man who wielded in his hands the fate of nations, and attracted the respect and admiration of all Europe. Medici.

Yet amidst public affairs so intricate and so momentous, such was the capacity of this man's mind, and such his versatility of genius, that, for the greater part of his life, he carried on a commerce as extensive as that of his grandfather, whilst he afforded still greater encouragement to learning and learned men. Cosmo had greatly promoted the study of the ancient languages and ancient philosophy. Lorenzo did the same thing: but he did much more; he encouraged the cultivation of his own tongue, which had been neglected since the age of Petrarca; and by setting a great example himself, he produced a race of Italian poets, which have hardly been surpassed in any age or nation. To enumerate even the names of the elegant scholars whom he patronised, would extend this article far beyond its limits. In the academy of Pisa, of which mention has been already made, the studies were chiefly confined to the Latin language, and to those sciences of which it was the principal vehicle. At Florence the Greek tongue was taught under the sanction of a public institution, either by native Greeks or learned Italians, whose services were procured by the diligence of Lorenzo de Medici, and repaid by his bounty. He placed Michael Angelo at the head of an academy, which he erected for painting and sculpture, furnishing it with the best models of antiquity. He built and endowed a public library, and sent Lascaris, of imperial descent, to Constantinople more than once, to procure Greek manuscripts. For father Moriano, the orator, a monastery was built; and Florence owed many of her finest edifices to him. Politiano and Ficino were among his most intimate friends; and it is not perhaps too much to say, that he did more for letters and science and art than any other individual that ever existed. His own acquirements in learning were great; and his poetry, of which the reader will find many specimens in the elegant work of Roscoe, was exquisite.

Is it surprising, when we examine Lorenzo's character, that all Italy, all Christendom, even the Mahometans, gave him the most flattering marks of approbation, and strove who should oblige him most, by presenting him with whatever was rare and valuable? His palace was constantly filled with men famous in every elegant, every useful science, and the neighbouring princes flocked to it as the temple of wisdom. The celebrated prince of Mirandola, on his account, chose Florence for his residence, and died there.

To a most engaging person was added each grace, and every accomplishment. He was the favourite of the ladies, the envy of the men, and the admiration of both. The statesman of his time; unrivalled in chivalry; one of the most eminent orators that the world has produced. His poetic merit, with his judgment in, and patronage of that art, procured him the title of "Father of the Muses." In liberality to his fellow citizens, as well as in every other respect, except as a general, he exceeded even Cæsar himself; and had not peace been his dear delight, his talents would have made him a consummate commander. Yet with all these superior

perior accomplifhments, he did not think it beneath him to indulge in amufements which perfons, lefs wife, would have thought an impeachment of their underftanding, and he would often feek pleafure in his nurfery, fpending hours there in all the frivolous pranks of childifh diverfion. In fine, "the gravity of his life, if compared with its levity, muft make him appear as a compofition of two different perfons, incompatible, and, as it were, impoffible to be joined with the other."

Lorenzo, like moft other great men, had wifhed to fpend his laft years in the tranquillity of retirement. He therefore at an early period wound up his mercantile concerns, and divided his time between the cares of the republic at Florence, and the cultivation of his eftates in the country. He wifhed even to diveft himfelf of all public concerns, and get his fecond fon Giovanni admitted into holy orders at the age of feven years, that he might be fit for ecclefiaftical preferment before he fhould be deprived of the protection of his father. The young ecclefiaftic, who afterwards made fuch a figure as Leo X. was accordingly appointed by Louis XI. of France, abbot of Fonte Dolac, before he was eight years of age; and by Innocent VIII. a cardinal, when he was little more than thirteen. This added much to the influence of the family, not only in the Tufcan ftates, but through all Italy; and Lorenzo having introduced his eldeft fon into public life, and accomplifhed a marriage between him and the daughter of a noble family at Rome, thought he might commit the affairs of the republic in a great meafure to Piero, and indulge his own tafte in the converfation of his learned friends. This dream of felicity however was not realized. Early in the year 1492, he was attacked by a difeafe, under which he had long laboured, with fuch violence, that on the 8th of April he died in the midft of his weeping friends, after having taken of them, one by one, an affectionate farewel, and given to his fon Piero much falutary counfel, which he thought not fit to follow.

The character of this great and good man is developed in the detail which we have given of his conduct through life: But it may not be improper to add, that fuch was the love and veneration of the citizens to him, that the phyfician, who had attended him on his deathbed, afraid to return to Florence, left the houfe in a ftate of diftraction, and plunged himfelf into a well. Throughout the reft of Italy the death of Lorenzo was regarded as a public calamity of the moft alarming kind. Of the arch which fupported the political fabric of that country he had long been confidered as the centre, and his lofs feemed to threaten the whole with immediate deftruction. When Ferdinand king of Naples was informed of the event, he exclaimed, "This man has lived long enough for his own glory, but too fhort a time for Italy."

MEDICINA FORENSIS, is a phrafe ufed in Germany to denote thofe parts of anatomical and phyfiological knowledge, which enable phyficians and furgeons to decide certain caufes as judges in courts of juftice. In that country it has long been law and cuftom (if we miftake not, by the Caraline code of Charles V.) to refer cafes of *poifoning*, *child-murder*, *rape*, *pregnancy*, *impotency*, *ideotifm*, &c. to the medical faculty, which, in the univerfities and fome other great towns, is conftituted into a kind of court for the trial of fuch queftions. In this country there are no fuch courts; but in criminal trials medical gentlemen are often called upon to defcribe the fymptoms of *poifoning*, *child-murder*, *rape*, &c. and therefore it becomes them to obtain an accurate knowledge of thefe fymptoms, and to ftore their memories with a number of minute facts, to which they may have occafion to appeal when giving their evidence.

The importance of this fubject induced the profeffor of the inftitutes of phyfic in the univerfity of Edinburgh to refolve lately to read an annual courfe of lectures on MEDICAL JURISPRUDENCE. This, we doubt not, will prove a valuable courfe; for though it is hardly conceivable that, under the head *medical jurifprudence*, any *knowledge* can be communicated which a well-educated phyfician would not neceffarily have acquired, without attending fuch a courfe; yet it is very obvious, that the recollection of the young phyfician may receive great aid from his liftening to the well arranged lectures of an accurate profeffor. From thefe lectures he may ftore his mind with a collection of aphorifms which fhall be always ready on the day of examination; or the lectures themfelves may be delivered in queftions and anfwers with all the formalities of a criminal court.

We have heard it obferved, that to attend a courfe of fuch lectures would be of the utmoft advantage to all who may be called upon to ferve as jurymen in criminal trials; but of the truth of this obfervation we are more than doubtful. Perfons who are only *half* inftructed are always conceited of their own attainments; and men not acquainted with anatomy and phyfiology cannot be *more* than half inftructed by the ableft courfe poffible to be given of medical jurifprudence. Such perfons indeed can hardly avoid miftaking the fenfe of the profeffor's language, however perfpicuous that language may be. Of this we had lately a very ftriking inftance. A gentleman, by no means illiterate, though a ftranger to anatomical and phyfiological fcience, was expatiating to the writer of this article upon the general importance of medical jurifprudence, a courfe of which, he faid, he had attended for the fole purpofe of qualifying himfelf for difcharging the important duties of a juryman. Upon being afked what he had learned? he replied, that he had been taught, among other things which we thought frivolous, to difcern, from the fymptoms of *hanging* whether the dead man had been hanged by *himfelf* or by *another*. We need not furely obferve, that no fuch leffon was ever taught in any univerfity, or by any medical lecturer; but it is worthy of confideration whether lectures on medical jurifprudence may not have the moft pernicious effects on the minds of men fo little qualified as this gentleman to profit by them. To the regularly educated phyfician and furgeon fuch lectures may prove ufeful; to the plain citizen, not fkilled in anatomy and phyfiology, they muft prove dangerous; as their only tendency is to make him defpife the evidence given before him by the regular phyfician or furgeon; to place implicit confidence in his own fuperficial knowledge; and thus to decide at random on the life or death of his fellow-creature:

> A little learning is a dangerous thing;
> Drink deep, or tafte not the Pierian fpring.

MEDINA, the capital of the kingdom of Woolli in Africa, is fituated in 13° 40′ N. Lat. and 12° 40′ W. Long. It is a place of confiderable extent, and may contain from 800 to 1000 houfes. It is fortified in the common

Medusa, Megameter.

common African manner, by a surrounding high wall built of clay, and an outward fence of pointed stakes and prickly bushes; but the walls are neglected, and the outward fence has suffered considerably from the active hands of busy housewives, who pluck up the stakes for firewood. Mr Park passed through it on his route eastward, and was treated with much kindness both by the king and the people. The good old sovereign warned him of the dangers he was about to encounter, and endeavoured to persuade him to relinquish all thoughts of his journey eastward; but when he could not prevail, he gave him a guide, who conducted him in safety to Koojar, the frontier town of the kingdom towards Bondou, from which it is separated by an intervening wilderness of two days journey. Here our author was presented, by way of refreshment, with a liquor which tasted so much like the strong beer of his native country (and very good beer too), as to induce him to inquire into its composition; and he learned, with some degree of surprise, that it was actually made from corn which had been previously malted, much in the same manner as barley is malted in Great Britain: a root yielding a grateful bitter was used in lieu of hops, the name of which he forgot; but the corn which yields the wort is the *holcus spicatus* of botanists.

MEDUSA. In addition to the different species of this genus of vermes described in the *Encyclopædia*, that which is represented in two different attitudes, fig. 1. and 2. and which strongly resembles a bagpipe in shape, may be worthy of notice. It is merely a white transparent vesicle, furnished with several blue tentacles yellowish at their extremity; its long tail, which is also blue, appears to be composed of a number of small glandulous grains, flattened and united together by a gelatinous membrane. The upper part of the vesicle exhibits a kind of seam with alternate punctures of three different sizes; its elongated part, which may be considered as the head of the animal, is terminated by a single trunk, the exterior edge of which is fringed with 25 or 26 tentacles, much smaller than those which originate from the insertion of its long tail, and the number of which sometimes amounts to 30. By means of these last, the diameter of which it is capable of increasing at pleasure by forcing in a little of the air from its body, it fixed itself to the side of the vessel, in which it was placed, in such a manner as that the extremity of some of its tentacles occupied a surface of two or three lines from its body. The most moveable part of the vesicle is its elongation, or the head of the animal, as it is by means of this that it performs its different motions. The rounded substance, marked by the letter P, is situated in the centre of the larger tentacles, which are firmly fixed to the body of the animal near its tail; and is only an assemblage of a few minute gelatinous globules, from the middle of which arise other larger globules, with a small peduncle, about the middle of which is fixed a curved bluish coloured body, which is represented magnified in two positions at R. Martiniere, the naturalist, who accompanied Perouse in his voyage round the world, met with this animal in about the 20th degree of lat. and 179° of long. east from Paris.

Plate XXXVI.

MEGAMETER, a name sometimes given to the MICROMETER, which see, *Encycl.*

Mehall, Meninski.

MEHALL, in the language of Bengal, a place or district.

MENINSKI (Franciscus), a most celebrated German orientalist, was born in Lorraine, then subject to the emperor, in the year 1623; and for copiousness of learning, elegance of genius, and profound knowledge of languages, particularly those of the East, proved undoubtedly one of the principal ornaments of the age in which he lived. He studied at Rome under Giattino. When he was about 30, his love of letters induced him to accompany the Polish ambassador to Constantinople, where he studied the Turkish language under Bobovius and Ahmed, two very skilful teachers. So successful was he in this study, that when he had been there only two years, the place of first interpreter to the Polish embassy at the Porte was promised to him. When the place became vacant, he was accordingly appointed to it, and obtained so much credit by his conduct, that, after a time, he was sent for into Poland, and again sent out with full powers as ambassador to the Porte. For his able execution of this office, he was further honoured, by being naturalized in Poland; on which occasion he added the Polish termination of *ski* to his family name, which was Menin. Being desirous afterwards to extend his sphere of action, he went to the court of the emperor as interpreter of oriental languages in 1661. Here also, as in other instances, his talents and behaviour obtained the highest approbation; on which account he was not only sent as interpreter to several imperial ambassadors at the Porte, but was intrusted in many important and confidential services; and, in 1669, having paid a visit to the holy sepulchre at Jerusalem, was made one of the knights of that order. After his return to Vienna he was advanced to further honours; being made one of the counsellors of war to the emperor, and first interpreter of oriental languages. At Vienna he died at the age of 75, in the year 1698. His great work, 1. The "Thesaurus linguarum orientalium," was published at Vienna in 1680, in 4 vols folio; to which was added, in 1687, another volume, intitled, "Complementum Thesauri linguarum orientalium, seu onomasticum Latino-Turcico-Arabico-Persicum." The former volumes having become extremely scarce, partly on account of the destruction of a great part of the impression, in the siege of Vienna by the Turks in 1683, a design was formed some time ago in England of reprinting the work, by a society of learned men, among whom was Sir William Jones. But as this undertaking, probably on account of the vast expence which must have been incurred, did not proceed, the empress queen Maria Theresa, who had heard of the plan, took it upon herself, and with vast liberality furnished every thing necessary for its completion. In consequence of this, it was begun to be splendidly republished at Vienna in 1780, with this title: "Francisci a Mesgnien Meninski Lexicon Arabico-Persico-Turcicum, adjecta ad singulas voces et Phrases interpretatione Latina, ad usitatiores, etiam Italica." Of this edition only two vols folio are yet published, extending no farther than *zal*, the ninth letter of the Arabic alphabet, which is about a third of the whole. The delay of the rest is much to be lamented. In this addition, say the editors, the Lexicon of Meninski may be said to be increased, diminished, and amended. *Increased*, because many Arabic and Persian words

Meninſki, Merchetta. words are added, from Wankuli and Ferhengi, the beſt Arabic and Perſic lexicographers whom the Eaſt has produced; and from Herbelot are inſerted the names of kingdoms, cities, and rivers, as well as phraſes in common uſe among the Turks, &c. *Diminiſhed*, becauſe many uſeleſs ſynonyma are omitted, which rather puzzled than aſſiſted the ſtudent; as well as all the French, Poliſh, and German interpretations, the Latin being conſidered as ſufficient for all men of learning. *Amended*, with reſpect to innumerable typographical errors; which, however, from a work of this nature, no care can perhaps altogether exclude. The other works of Meninſki were occaſioned chiefly by a violent conteſt between him and a man named J. B. Podeſta, in which much acrimony was employed on both ſides. Theſe it is hardly worth while to enumerate, but they may all be ſeen in the account of his life from which this article is taken (A). It ſhould be obſerved, however, that in 1674, Podeſta publiſhed a book, intitled, "Prodromus novi linguarum orientalium collegii, juſſu Aug. &c. erigendi, in Univ. Viennenſi;" to which Meninſki oppoſed, 2. "Meninſkii Antidotum in Prodromum novi ling. orient. collegii, &c." 4to. But ſuch was the credit of his antagoniſt in the univerſity, that ſoon after there came out a decree in the name of the rector and conſiſtory, in which that antidote of Meninſki's is proſcribed and prohibited, for ſix ſpecific reaſons, as impious and infamous. Meninſki was defended againſt this formidable attack by a friend, in a ſmall tract, intitled, "Veritas defenſa, ſeu juſtitia cauſæ Dn. F. de M. M. [Meninſki] contra infame decretum Univerſitatis Viennenſis, Anno 1674, 23 Novembris, &c. ab Amico luci expoſita, Anno 1675," in which this friend expoſes, article by article, the falſehood of the decree, and exclaims ſtrongly againſt the arts of Podeſta. This tract is in the Britiſh Muſeum. Podeſta was oriental ſecretary to the emperor, and profeſſor of thoſe languages at Vienna; but is deſcribed in a very ſatirical manner by the defender of Meninſki. "Podeſta, natura Semi-Italus, ſtatura nanus, cæcutiens, balbus, imo bardus repertus, aliiſque vitiis ac ſtultitiis plenus, adeoque ad diſcendas linguas orientales inhabilis." A liſt of the works of Podeſta is, however, given by the late editors of Meninſki.

MERCHETTA, or *Marchetta Mulierum*, is commonly ſuppoſed to have been a right which, during the prevalence of the feudal ſyſtem, the lord had of paſſing the firſt night after marriage with his female villain. This opinion has been held by the greater part of our antiquarians; and we have adopted it in our hiſtory of Scotland publiſhed in the *Encyclopædia*. It appears, however, to be a miſtake. That there was a cuſtom called *merchetta mulierum*, which prevailed not only in England, Scotland, Wales, and the iſle of Guernſey, but alſo on the continent, is indeed a fact unqueſtionable; but Mr Aſtle has clearly proved, that, inſtead of being an adulterous connection, the *merchetta* was a compact between the lord and his vaſſal for the redemption of an *offence* committed by that vaſſal's *unmarried* daughter. He admits, however, that it denoted likewiſe a fine paid by a *ſokeman* or a *villain* to his lord for a licence to marry his daughter to a free man; and that if the vaſſal gave her away without obtaining ſuch a licence, he was liable to pay a heavier fine. He quotes two authorities in ſupport of his opinion from Bracton; one of which we ſhall tranſcribe, as being alone complete evidence.

Archæologia, vol. xii.

"Ric. Burre tenet unum meſuagium et debet telliagium ſectam curiæ, et *merchet*, hoc modo, *quod ſi maritare voluerit filiam ſuam cum quodam libero homine, extra villam, faciet pacem domini pro maritagio, et ſi eam maritaverit alicui cuſtumario villæ, nihil debuit pro maritagio.*"

"The probable reaſon of the cuſtom (ſays Mr Aſtle) appears to have been this. Perſons of low rank, reſiding on an eſtate, were either *aſcripti glebæ*, or were ſubjected to ſome ſpecies of ſervitude ſimilar to the *aſcripti glebæ*. They were bound to reſide on the eſtate, and to perform ſeveral ſervices to the lord. As women neceſſarily followed the reſidence of their huſbands, the conſequence was, that when a woman of low rank married a ſtranger, the lord was deprived of part of his live ſtock; he therefore required a fine to indemnify him for the loſs of his property," Further particulars on the *merchetta* are to be found in the Appendix to vol. 1ſt of *Sir David Dalrymple's Annals of Scotland.*

Meridian. MERIDIAN Line, an arch or part of the meridian of the place, terminated each way by the horizon. Or, a meridian line is the interſection of the plane of the meridian of the place with the plane of the horizon, often called a north and ſouth line, becauſe its direction is from north to ſouth.

In the article Astronomy (*Encycl.*), n° 376. and 377. we have given two methods of drawing a meridian line; but it may be proper to add, in this place, the following improvement of the former of theſe from Dr Hutton's Mathematical Dictionary. "As it is not eaſy (ſays the Doctor) to determine preciſely the extremity of the ſhadow, it will be beſt to make the ſtile flat at the top, and to drill a ſmall hole through it, noting the lucid point projected by it on the ſeveral concentric circles, inſtead of marking the extremity of the ſhadow itſelf on theſe circles."

We ſhall give another method of drawing a meridian line from the ſame valuable dictionary.

"Knowing the ſouth quarter pretty nearly, obſerve the altitude FE of ſome ſtars on the eaſt ſide of it, and not far from the meridian HZRN: then, keeping the quadrant firm on its axis, ſo as the plummet may ſtill cut the ſame degree, direct it to the weſtern ſide of the meridian, and wait till you find the ſtar has the ſame altitude as before, as *fe*. Laſtly, biſect the angle EC*e*, formed by the interſection of the two planes in which the quadrant has been placed at the time of the two obſervations, by the right line HR, which will be the meridian ſought.

Plate XXXVI.

Magnetical Meridian, is a great circle paſſing thro' or by the magnetical poles; to which meridians the magnetical needle conforms itſelf. See Magnetism, *Suppl.*

MESO-

(A) We have taken this article from the Biographical Dictionary; the editors of which took it from the life of Meninſki prefixed to the new edition of his great work.

MESO-LOGARITHM, a term used by Kepler to signify the logarithms of the cosines and cotangents.

MESURATA, a sea port of the kingdom of Tripoli, in Africa. A caravan proceeds from this place to Fezzan, and other interior parts toward the south of Africa. It is 260 miles north of Mourzook. E. Lon. 15. 5. N. Lat. 31. 3.

METALLIC TRACTORS. See PERKINISM in this *Suppl.*

METONIC CYCLE, called also the *Golden Number*, and *Lunar Cycle*, or *Cycle of the Moon*, that which was invented by Meton the Athenian; being a period of 19 years. See CYCLE, *Encycl.*

MHA RAJAH, the highest title of Hindoos.

MICROCOUSTICS, or MICROPHANES, instruments contrived to magnify small sounds, as microscopes do small objects.

MICROCOSMIC SALT. See CHEMISTRY-*Index*, *Suppl.*

MIDDLE LATITUDE, is half the sum of two given latitudes; or the arithmetical mean, or the middle between two parallels of latitude. Therefore,

If the latitudes be of the same name, either both north or both south, add the one number to the other, and divide the sum by 2; the quotient is the middle latitude, which is of the same name with the two given latitudes. But,

If the latitudes be of different names, the one north and the other south; subtract the less from the greater, and divide the remainder by 2, so shall the quotient be the middle latitude, of the same name with the greater of the two.

MIDSUMMER-DAY, is held on the 24th of June, the same day as the nativity of St John the Baptist is held.

MILK, or MILKYET, property in Bengal.

MILLS of various kinds are described in the article MECHANICS (*Encycl.*); and he who shall study that article, together with *Water-Works*, and MACHINERY, in this *Supplement*, will have a sufficient knowledge of the principles upon which mills must be constructed, so as that they may produce their proper effects. The subject is introduced into this place merely to put it into the power of our countrymen to adopt, if they shall think fit, the improvements which have been made in the machinery of flour mills in America.

The chief of these consist in a new application of the screw, and the introduction of what are called elevators, the idea of which was evidently borrowed from the chain-pump. The screw is made by sticking small thin pieces of board, about three inches long and two wide, into a cylinder, so as to form the spiral line. This screw is placed in a horizontal position, and by turning on its axis it forces wheat or flour from one end of a trough to the other. For instance, in the trough which receives the meal immediately coming from the stones, a screw of this kind is placed, by which the meal is forced on, to the distance of six or eight feet, perhaps, into a reservoir; from thence, without any manual labour, it is conveyed to the very top of the mill by the elevators, which consist of a number of small buckets of the size of tea cups, attached to a long band that goes round a wheel at the top, and another at the bottom of the mill. As the band revolves round the wheels, these buckets dip into the reservoir of wheat or flour below, and take their loads up to the top, where they empty themselves as they turn round the upper wheel. The elevators are inclosed in square wooden tubes, to prevent them from catching in any thing, and also to prevent dust. By means of these two simple contrivances, no manual labour is required from the moment the wheat is taken to the mill till it is converted into flour, and ready to be packed, during the various processes of screening, grinding, sifting, &c.

That this is a considerable improvement is obvious; and we are not without hopes that it may be adopted. The licentiousness of an English mob has indeed persecuted an Arkwright, expelled the inventor of the fly-shuttle from his native country, and by such conduct prevented the re-erection of the Albion mills, and the general establishment of saw-mills through the kingdom; but their sovereignty perhaps will not be roused by so easy and simple a contrivance as this to lessen the quantity of manual labour. For an account of the Dutch oil-mill, which was somehow omitted in its proper place in the *Encyclopædia*, see *OIL-Mill* in this *Supplement*.

MINERALOGY

1 Definition. IS a science, the object of which is the description and arrangement of *inorganic bodies* or *minerals*; or of *all* the bodies which belong to our globe, excepting *animal* and *vegetable* substances.

Since the publication of the article MINERALOGY, *Encycl.* scarcely a single day has passed without the discovery of some new mineralogical fact, or the detection of some old and unsuspected error. These improvements cannot be overlooked in the present *Supplement*. But they are so numerous in every part of the science, that we can hardly notice them without giving a pretty complete view of the present state of mineralogy. This will scarcely occupy more room, and must be much more useful as well as entertaining, than an undigested mass of annotations and remarks. We undertake this task the more readily, because in the article MINERALOGY in the *Encyclopædia*, the improvements of Mr Werner and his disciples, to which the science is indebted for a great part of its present accuracy, have been entirely overlooked.

The object of mineralogy is twofold. 1. To *describe* every mineral with so much accuracy and precision, that it may be easily distinguished from every other mineral. 2. To *arrange* them into a system in such a manner that every mineral may be easily referred to its proper place, and that a person may be able, merely by the help of the system, to discover the *name* of any mineral whatever. When these two objects are accomplished, mineralogy, 2 Object.

Deſcription of Minerals.

neralogy, ſtrictly ſo called, is completed. But were we to ſtop here, the utility of the ſcience, if it would be entitled to the name of ſcience, could hardly be conſidered as very great. We muſt therefore apply *chemiſtry* to diſcover the ingredients of which minerals are compoſed, and to detect, if poſſible, the laws which theſe ingredients have obſerved in their combination. Thus we ſhall really extend our knowledge of inorganic nature, and be enabled to apply that knowledge to the improvement of almoſt eve y art and manufacture.

3 Diviſion of the article.

Mineralogy naturally divides itſelf into three parts. The *firſt* treats of the method of deſcribing minerals; the *ſecond*, of the method of arranging them; and the *third* exhibits them in a ſyſtem deſcribed and arranged according to the rules laid down in the two firſt parts. Theſe three parts ſhall be the ſubjects of the following chapters; and we ſhall finiſh the article with a chapter on the chemical analyſis of minerals.

Chap. I. Of the Description of Minerals.

Nothing, at firſt ſight, appears eaſier than to deſcribe a mineral, and yet, in reality, it is attended with a great deal of difficulty. The mineralogical deſcriptions of the ancients are ſo looſe and inaccurate, that many of the minerals to which they allude cannot be aſcertained; and conſequently their obſervations, however valuable in themſelves, are often, as far as reſpects us, altogether loſt. It is obvious, that to diſtinguiſh a mineral from every other, we muſt either mention ſome peculiar property, or a collection of properties, which exiſt together in no other mineral. Theſe properties muſt be deſcribed in terms rigidly accurate, which convey preciſe ideas of the very properties intended, and of no other properties. The ſmalleſt deviation from this would lead to confuſion and uncertainty. Now it is impoſſible to deſcribe minerals in this manner, unleſs there be a peculiar term for each of their properties; and unleſs this term be completely underſtood. Mineralogy therefore muſt have a language of its own; that is to ſay, it muſt have a *term* to denote every mineralogical property, and each of theſe terms muſt be accurately defined. The language of mineralogy was invented by the celebrated Werner of Freyberg, and firſt made known to the world by the publication of his treatiſe on *The External Characters of Minerals*. Of this language we ſhall give a view in the following general deſcription of the properties of minerals (A).

4 Properties of minerals.

The properties of minerals may be divided into two claſſes. *1ſt*, Properties diſcoverable without deſtroying the texture of the mineral; *2d*, Properties reſulting from the action of other bodies on it. The firſt claſs has, by Werner and his diſciples, been called *external* properties, and by ſome French writers *phyſical*; the ſecond claſs has been called *chemical*.

The *external* properties may be arranged under the following heads:

External Characters.

1. Figure,	8. Ductility,	14. Sound,
2. Surface,	9. Fracture,	15. Smell,
3. Tranſparency,	10. Texture,	16. Taſte,
4. Colour,	11. Structure,	17. Gravity,
5. Scratch,	12. Fragments,	18. Magnetiſm,
6. Luſtre,	13. Feel,	19. Electricity.
7. Hardneſs,		

5 Figure.

I. By figure is meant the ſhape or form which a mineral is obſerved to have. The *figure* of minerals is either *regular*, *particular*, or *amorphous*. 1. Minerals which aſſume a regular figure are ſaid to be cryſtallized *. The *ſides* of a cryſtal are called *faces*; the ſharp line formed by the inclination of two faces is called an *edge*; and the corner, or angle, formed by the meeting of ſeveral edges in one point, is called a *ſolid angle*, or ſimply *an angle*. Thus a cube has ſix faces, twelve edges, and eight angles. 2. Some minerals, though not cryſtallized, affect a *particular* figure. Theſe particular figures are the following: *Globular*, like a globe; *oval*, like an oblong ſpheroid; *ovate*, like an egg; *cheeſe-ſhaped*, a very flattened ſphere; *almond-ſhaped*, like an almond; *lenticular*, like a double convex lenſe, compreſſed and gradually thinner towards the edges; *cuneiform*, like a wedge; *nodulous*, having depreſſions and protuberances like a potatoe; *botryoidal*, like grapes cloſely preſſed together; *dentiform*, longiſh and tortuous, and thicker at the bottom than the top; *wireform*, like a wire; *capillary*, like hair, finer than the preceding; *retiform*, threads interwoven like a net; *dentritic*, like a tree, having branches iſſuing from a common ſtem; *ſhrubform*, branches not ariſing from a common ſtem; *coraloidal*, branched like coral; *ſtalactical*, like iſicles; *clavated*, like a club, long, and thicker at one end than another; *faſciform*, long ſtraight cylindrical bodies, united like a bundle of rods; *tubular*, cylindrical and hollow. 3. When minerals have neither a regular nor particular ſhape, they are ſaid to be *amorphous*.

* See Chemistry, Part III. ch. iv. *Suppl.*

6 Surface.

II. By surface is meant the appearance of the external ſurface of minerals. The *ſurface* is either *uneven*, compoſed of ſmall unequal elevations and depreſſions; *ſcabrous*, having very ſmall *ſharp* and rough elevations, more eaſily felt than ſeen; *druſy*, covered with very minute cryſtals; *rough*, compoſed of very minute *blunt* elevations, eaſily diſtinguiſhable by the feel; *ſcaly*, compoſed of very minute thin ſcale-like leaves; *ſmooth*, free from all inequality or roughneſs; *ſpecular*, having a ſmooth poliſhed ſurface like a mirror; or *ſtreaked*, having elevated, ſtraight, and parallel lines. This laſt character is confined to the *ſurface* of cryſtals. The *ſtreaks* are either *tranſverſe*; *longitudinal*; *alternate*, in different directions on different faces; *plumoſe*, running from a middle rib; or *decuſſated*, croſſing each other.

7 Tranſparency.

III. By transparency is meant the proportion of light which minerals are capable of tranſmitting. They are *tranſparent* or *pellucid* when objects can be ſeen diſtinctly through them; *diaphanous*, when objects are ſeen

(A) The fulleſt account of Werner's external characters which we have ſeen in the Engliſh language, has been given by Dr Townſon in his *Philoſophy of Mineralogy*. We have availed ourſelves of this book, in order to exhibit ſome of the lateſt improvements of Werner and his diſciples. The reader may alſo conſult *Werner's Treatiſe*, publiſhed at Leipſic in 1774; or the *French tranſlation* publiſhed at Dijon in 1790. See alſo *Romé de Liſle. Des Caracters Exterieur des Mineraux.* And *Hauy Jour. d'Hiſt. Nat.* II. 56.

External Characters. ſeen through them indiſtinctly; *ſubdiaphanous*, when light paſſes but in ſo ſmall a quantity that objects cannot be ſeen through them (B); *opaque*, when no light is tranſmitted.

When opaque minerals become tranſparent in water, they are called *hydrophanous*. When objects are ſeen double through a tranſparent mineral, it is ſaid to *refract doubly*.

8 Colour. IV. The colours of minerals may be reduced to eight claſſes.

1. *Whites.*

Snow white. Pure white.

Reddiſh white. White with a light tint of red.

Yellowiſh white. White with a light tint of yellow.

Silver white. Yellowiſh white with a metallic luſtre.

Greyiſh white. White with a light tint of black.

Greeniſh white. White with a light tint of green.

Milk white. White with a light tint of blue.

Tin white. Milk white of a metallic luſtre.

2. *Greys.*

Bluiſh grey. Grey with a little blue.

Lead grey. Bluiſh grey with a metallic luſtre.

Pearl grey. Light grey with a ſlight mixture of violet blue.

Smoke grey. Dark grey with a little blue and brown.

Greeniſh grey. Light grey tinged with green.

Yellowiſh grey. A light grey tinged with yellow.

Steel grey. A dark grey with a light tint of yellow and a metallic luſtre.

Black grey. The darkeſt grey with a tint of yellow.

3. *Blacks.*

Greyiſh black. Black with a little white.

Browniſh black. Black with a tint of brown.

Black. Pure black.

Iron black. Pure black with a ſmall mixture of white and a metallic luſtre.

Bluiſh black. Black with a tint of blue.

4. *Blues.*

Indigo blue. A dark blackiſh blue.

Pruſſian blue. The pureſt blue.

Azure blue. A bright blue with ſcarce a tint of red.

Smalt blue. A light blue.

Violet blue. A mixture of azure blue and carmine.

Lavender blue Violet blue mixed with grey.

Sky blue. A light blue with a ſlight tint of green.

5 *Greens.*

Verdigris green. A bright green of a bluiſh caſt.

Seagreen. A very light green, a mixture of verdigris green and grey.

Beryl green. The preceding, but of a yellowiſh caſt.

Emerald green. Pure green.

Graſs green. Pure green with a tint of yellow.

Apple green. A light green formed of verdigris green and white.

Leek green. A very dark green with a caſt of brown.

Blackiſh green. The darkeſt green, a mixture of leek green and black.

Piſtachio green. Graſs green, yellow and a little brown

Olive green. A pale yellowiſh green with a tint of brown.

Aſparagus green. The lighteſt green, yellowiſh with a little brown and grey.

6. *Yellows.*

Sulphur yellow. A light greeniſh yellow.

Braſs yellow. The preceding, with a little leſs green and a metallic luſtre.

Lemon yellow. Pure yellow.

Gold yellow. The preceding with a metallic luſtre.

Honey yellow. A deep yellow with a little reddiſh brown.

Wax yellow. The preceding, but deeper.

Pyritaceous. A pale yellow with grey.

Straw yellow. A pale yellow, a mixture of ſulphur yellow and reddiſh grey.

Wine yellow. A pale yellow with a tint of red.

Ochre yellow. Darker than the preceding, a mixture of lemon yellow with a little brown.

Iſabella yellow. A pale browniſh yellow, a mixture of pale orange with reddiſh brown.

Orange yellow. A bright reddiſh yellow, formed of lemon yellow and red.

7. *Reds.*

Aurora red. A bright yellow red, a mixture of ſcarlet and lemon yellow.

Hyacinth red. A high red like the preceding, but with a ſhade of brown.

Brick red. Lighter than the preceding; a mixture of aurora red and a little brown.

Scarlet red. A bright and high red with ſcarce a tint of yellow.

Copper red. A light yellowiſh red with the metallic luſtre.

Blood red. A deep red, a mixture of crimſon and ſcarlet.

Carmine red. Pure red verging towards a caſt of blue.

Cochineal red. A deep red; a mixture of carmine with a little blue and a very little grey.

Crimſon red. A deep red with a tint of blue.

Fleſh red. A very pale red of the crimſon kind.

Roſe red. A pale red of the cochineal kind.

Peach bloſſom red. A very pale whitiſh red of the crimſon kind.

Mordoré. A dark dirty crimſon red; a mixture of crimſon and a little brown.

Browniſh red. A mixture of blood red and brown.

8. *Browns.*

Reddiſh brown. A deep brown inclining to red.

Clove brown. A deep brown with a tint of carmine.

Yellowiſh brown. A light brown verging towards ochre yellow.

Umber brown. A light brown, a mixture of yellowiſh brown and grey.

Hair brown. Intermediate between yellow brown and clove brown with a tint of grey.

Tombac brown. A light yellowiſh brown, of a metallic luſtre, formed of gold yellow and reddiſh brown.

Liver

(B) After Mr Kirwan, we have denoted theſe three degrees of tranſparency by the figures 4, 3, 2. When a mineral is ſubdiaphanous only at the edges, that is denoted by the figure 1. Opacity is ſometimes denoted by 0.

External Characters. Liver brown. A dark brown; blackiſh brown with a tint of green.

Blackiſh brown. The darkeſt brown.

Colours, in reſpect of intenſity, are either *dark*, *deep*, *light*, or *pale*. When a colour cannot be referred to any of the preceding, but is a mixture of two, this is expreſſed, by ſaying, that the prevailing one *verges* towards the other, if it has only a ſmall tint of it; *paſſes* into it, if it has a greater.

9 Streak. V. By the SCRATCH or STREAK, is meant the mark left when a mineral is ſcratched by any hard body, as the point of a knife. It is either *ſimilar*, of the ſame colour with the mineral; or *diſſimilar*, of a different colour.

10 Luſtre. VI. LUSTRE, is the gloſs, or brightneſs which appears on the external ſurface of a mineral, or on its internal ſurface when freſh broken. The firſt is called *external*, the ſecond *internal* luſtre. Luſtre is either *common*, that which moſt minerals poſſeſs; *ſilky*, like that of ſilk or mother-of-pearl; *waxy*, like that of wax; *greaſy*, like that of greaſe; or *metallic*, like that of metals.

As to the degree, the greateſt is called *ſplendent*, the next *ſhining*, the third *dulliſh*; and when only a few ſcattered particles ſhine, the luſtre is called *dull* (c).

11 Hardneſs. VII. We have uſed figures to denote the comparative HARDNESS of bodies; for an explanation of which, we refer to the article CHEMISTRY, Vol. I. p 226. of this *Supplement*.

12 Ductility and brittleneſs. VIII. With reſpect to DUCTILITY and BRITTLENESS, minerals are either *malleable*; *ſectile*, capable of being cut without breaking, but not malleable; *flexile*, capable of being bent, and when bent retaining their ſhape; or *elaſtic*, capable of being bent, but recovering their former ſhape. Minerals deſtitute of theſe properties are *brittle*. Brittle minerals, with reſpect to the eaſe with which they may be broken, are either *very tough*, *tough*, *fragile*, or *very fragile*.

13 Fracture. IX. By FRACTURE is meant the freſh ſurface which a mineral diſplays when broken. It is either *flat*, without any general elevation or depreſſion; or *conchoidal*, having wide extended roundiſh hollows and gentle riſings. When theſe are not *very* evident, the fracture is called *flat* conchoidal; when they are ſmall, it is called *ſmall* conchoidal; and when of great extent, *great* conchoidal.

The fracture may alſo be *even*, free from all aſperities; *uneven*, having many ſmall, ſharp, abrupt, irregular elevations and inequalities; and from the ſize of theſe, this fracture is denominated *coarſe*, *ſmall*, or *fine*; *ſplintery*, having ſmall, thin, half detached, ſharp edged ſplinters, according to the ſize of which this fracture is denominated *coarſe* or *fine*; or *rugged*, having many very minute ſharp hooks, more ſenſible to the hand than the eye.

14 Texture. X. By TEXTURE is meant the internal ſtructure or diſpoſition of the matter of which a mineral is compoſed, which may be diſcovered by breaking it. The texture is either *compact*, without any diſtinguiſhable parts, or the appearance of being compoſed of ſmaller parts; *earthy*, compoſed of very minute *almoſt* imperceptible rough parts; *granular*, compoſed of ſmall ſhapeleſs grains; *globuliform*, compoſed of ſmall ſpherical bodies; *fibrous*, compoſed of fibres which may be *long*, *ſhort*, *ſtraight*, *crooked*, *parallel*, *divergent*, *ſtellated*, *faſciculated*, or *decuſſated*; *radiated*, conſiſting of long narrow flattiſh lamellæ; or *lamellar* or *foliated*, conſiſting of ſmooth continued plates covering each other; theſe plates may be either *ſtraight*, *crooked*, or *undulating*. External Characters.

XI. The STRUCTURE or COMPOUND TEXTURE is the manner in which the parts that form the texture are diſpoſed. It is either *ſlaty*, in ſtraight layers like ſlate; *teſtaceous*, in incurvated layers; *concentric*, in concentric layers; or *columnar*, in columns. 15 Structure

The *texture* and *ſtructure* may at firſt view appear the ſame; but in reality they are very different. Thus common ſlate has often the *ſlaty ſtructure* and *earthy texture*. The texture of pitcoal is compact, but its ſtructure is often ſlaty.

XII. By FRAGMENTS is meant the ſhape of the pieces into which a mineral breaks when ſtruck with a hammer. They are either *cubic*; *rhomboidal*; *wedgeſhaped*; *ſplintery*, thin, long, and pointed; *tabular*, thin, and broad, and ſharp at the corners, as common ſlate; or *indeterminate*, without any particular reſemblance to any other body. The *edges* of indeterminate fragments are either *very ſharp*, *ſharp*, *ſharpiſh*, or *blunt*. 16 Fragments.

XIII. By the FEEL of minerals is meant the ſenſation which their ſurfaces communicate when handled. The feel of ſome minerals is *greaſy*, of others, *dry*, &c. 17 Feel.

XIV. Some minerals when ſtruck give a *clear* SOUND, as common ſlate; others a *dull* ſound. 18 Sound.

The SMELL, TASTE, SPECIFIC GRAVITY, and MAGNETISM of minerals, require no explanation.

With reſpect to ELECTRICITY, ſome minerals become electric when *heated*, others when *rubbed*, others cannot be rendered electric. The electricity of ſome minerals is *poſitive* or *vitreous*, of others *negative* or *reſinous*.

As for the CHEMICAL properties of minerals, they have been already explained in the article CHEMISTRY, which makes a part of this *Supplement*. And for the deſcription of the blow-pipe, and the manner of uſing it, we refer the reader to a treatiſe on that ſubject prefixed to the article MINERALOGY in the *Encyclopædia*.

CHAP. II. OF THE ARRANGEMENT OF MINERALS.

MINERALS may be arranged two ways, according to their external characters, and according to their chemical compoſition. The firſt of theſe methods has been called an *artificial* claſſification; the ſecond, a *natural* one. The firſt is indiſpenſably neceſſary for the ſtudent of nature; the ſecond is no leſs indiſpenſable for the proficient who means to turn his knowledge to account. Without the firſt, it is impoſſible to diſcover the *names* of minerals; and without the ſecond, we muſt remain ignorant of their uſe.

Almoſt every ſyſtem of mineralogy hitherto publiſhed, at leaſt ſince the appearance of Werner's *external characters*, has attempted to combine theſe two arrangements, and to obtain at one and the ſame time the advantages peculiar to each. But no attempt of this kind has hitherto ſucceeded. Whether this be owing to any thing impoſſible in the undertaking, or to the preſent

(c) Theſe four degrees have been denoted by Kirwan by the figures 4, 3, 2, 1, and no luſtre by 0. We have imitated him in the preſent article.

Artificial Syſtem.

preſent imperfect ſtate of mineralogy, as is more probable, we do not take upon us to determine. But ſurely the want of ſucceſs, which has hitherto attended all attempts to combine the two arrangements, ought to ſuggeſt the propriety of ſeparating them. By adhering ſtrictly to one language, the trouble of ſtudying two different ſyſtems would be entirely prevented. They would throw mutual light upon each other; the artificial ſyſtem would enable the ſtudent to diſcover the *names* of minerals; the natural would enable him to arrange them, and to ſtudy their properties and uſes.

The happy arrangement of Cronſtedt, together with the ſubſequent improvements of Bergman, Werner, Kirwan, Hauy, and other celebrated mineralogiſts, has brought the *natural* ſyſtem of mineralogy to a conſiderable degree of perfection. But an *artificial* ſyſtem is ſtill a deſideratum; for excepting Linnæus, whoſe ſucceſs was precluded by the ſtate of the ſcience, no one has hitherto attempted it. Though we are very far from thinking ourſelves ſufficiently qualified for undertaking ſuck a taſk, we ſhall neverthelefs venture, in the next chapter, to ſketch out the rudiments of an artificial ſyſtem. The attempt, at leaſt, will be laudable, even though we ſhould fail.

Chap. III. Artificial System.

19 Artificial claſſes.

Minerals may be divided into ſix claſſes:

1. Minerals that cannot be fuſed by the blow-pipe *per ſe*.
2. Minerals fuſible *per ſe* by the blow-pipe.
3. Minerals fuſible by the blow-pipe *per ſe* when expoſed to the blue flame, but not when expoſed to the yellow flame.
4. Minerals fuſible *per ſe* by the blow-pipe; and when in fuſion, partly evaporating in a viſible ſmoke.
5. Minerals which totally evaporate before the blow-pipe.
6. Minerals totally ſoluble in muriatic acid with effervеſcence, the ſolution colourleſs.

Under theſe heads we ſhall arrange the ſubjects of the mineral kingdom.

Class I. INFUSIBLE.

ORDER I. Specific gravity from 16 to 12.
Genus I. Colour whitiſh iron grey.
Species 1. Native platinum.

ORDER II. Sp. gr. 8.5844 to 7.006.
Genus I. Attracted by the magnet.
Sp. 1. Native iron.
Genus II. Not attracted by the magnet.
Sp. 1. Native copper.
Flexible and malleable. Colour uſually red.
Sp. 2. Wolfram.
Brittle. Colour uſually brown or black.

ORDER III. Sp. gr. from 6.4509 to 5.8.
Genus I. Forms a blue glaſs with microcoſmic ſalt, which becomes colourleſs in the yellow, but recovers its colour in the blue flame.
Sp. 1. Tungſtat of lime.
Genus II. Forms with microcoſmic ſalt a permanently coloured bead.
Sp. 1. Sulphuret of cobalt.

ORDER IV. Sp. gr. from 4.8 to 4.5.
Genus I. Tinges borax dark green.
Sp. 1. Common magnetic iron ſtone.
Genus II. Tinges borax reddiſh brown.
Sp. 1. Grey ore of manganeſe.

ORDER V. Sp. gr. from 4.4165 to 3.092. Infuſible with fixed alkalies.
Genus I. Hardneſs 20.
Sp. 1. Diamond.
Genus II. Hardneſs 15 to 17. Cauſes ſingle refraction.
Sp. 2. Teleſia.
Sp. 2. Corundum.
Genus III. Hardneſs 13. Single refraction.
Sp. 1. Ruby.
Cryſtallizes in octahedrons.
Genus IV. Hardneſs 12. Single refraction.
Sp. Chryſoberyl.
Genus V. Hardneſs 12. Cauſes double refraction. Becomes electric when heated.
Sp. 1. Topaz.
Genus VI. Hardneſs 10 to 16. Double refraction. Sp. gr. 4.2 to 4.165.
Sp. 1. Zircon.
Genus VII. Hardneſs 6 to 9. Feels greaſy.
Sp. 1. Cyanite.
Genus VIII. Hardneſs 9 to 10. Feel not greaſy. Double refraction. Sp. gr. 3.283 to 3.285.
Sp. 1. Chryſolite.
Genus IX. Hardneſs 12. Infuſible with borax. Colour of large maſſes black, of thin pieces deep green.
Sp. 1. Cylanite.
(*Phoſphat of lime.*)

ORDER VI. Sp. gr. from 2.9829 to 1.987. Infuſible with fixed alkalies.
Genus I. Hardneſs 12.
Sp. 1. Emerald.
Genus II. Hardneſs 10.
Sp. 1. Jade.
Genus III. Hardneſs 6 to 7. Somewhat tranſparent.
Sp. 1. Phoſphat of lime.
Before the blow-pipe becomes ſurrounded with a luminous green vapour.
Genus IV. Hardneſs 6. Opaque.
Sp. 1. Micarelle.
Genus V. Stains the fingers. Colour lead grey.
Sp. 1. Plumbago.
Spaniſh wax rubbed with plumbago does not become electric; or if it does, the electricity is negative. Streak lead grey even on earthen ware.

ORDER VII. Sp. gr. from 4.7385 to 4.569. Fuſible with fixed alkalies.
Genus I. Stains the fingers. Colour lead grey.
Sp. 1. Molybdena.
Spaniſh wax rubbed with molybdena becomes poſitively electric. Streak on earthen ware yellowiſh green.

ORDER VIII. Sp. gr. from 4.1668 to 2.479. Fuſible with fixed alkalies.
* Hardneſs from 10 to 12.

Genus

GENUS I. Ufually white. Cryftals dodecahedrons. Double refraction. Fracture imperfectly conchoidal or fplintery. Brittle.
Sp. 1. Quartz.
GENUS II. Ufually dark brown. Fracture perfectly conchoidal. Brittle. Eafily breaks into fplinters.
Sp. 1. Flint.
GENUS III. Not brittle. Fracture even or imperfectly conchoidal.
Sp. 1. Chalcedony.
Sp. 2. Jafper.
GENUS IV. Forms with potafs a violet glafs, with foda or borax a brown glafs, with microcofmic falt a honey yellow glafs. Colour green. Amorphous.
Sp. 1. Chryfoprafium.
GENUS V. Tinges foda red. The colour difappears before the blue flame, and returns before the yellow flame.
Sp. 1. Oxide of manganefe and barytes.
Sp. 2. Black ore of manganefe.
Sp. 3. Carbonat of manganefe.
(Brown ore of iron. Red ore of iron.)
** Hardnefs 9 to 3.
GENUS VI. Flexible and elaftic in every direction.
Sp. 1. Elaftic quartz.
GENUS VII. Emits white flakes before the blowpipe.
Sp. 1. Blende.
GENUS VIII. Becomes electric when heated.
Sp. 1. Calamine.
GENUS IX. Tinges borax green. Blackens before the blow-pipe.
Sp. 1. Mountain blue.
Colour blue.
Sp. 2. Green carbonat of copper.
Colour green.
GENUS X. Tinges borax green. Becomes attractable by the magnet by the action of the blowpipe.
Sp. 1. Brown iron ore.
Colour brown.
Sp. 2. Red iron ore.
Colour red.
GENUS XI. Tinges borax fmutty yellow. Becomes brownifh black before the blow-pipe.
Sp. 1. Carbonat of iron.
GENUS XII. Feels greafy.
Sp. 1. Steatites.
(Black ore of Manganefe. Carbonat of manganefe. Mica.)

ORDER IX. Sp. gr. from 2.39 to 1.7.
GENUS I. Luftre glaffy.
Sp. 1. Opal.
Sp. 2. Hyalite.
GENUS II. Luftre greafy.
Sp. 1. Pitchftone.
GENUS III. Luftre waxy or pearly.
Sp. 1. Staurolite.

CLASS II. FUSIBLE.

ORDER I. Sp. gr. from 19 to 10.
GENUS I. Colour yellow.
Sp. 1. Native gold.
GENUS II. Colour white.
Sp. 1. Native filver.
GENUS III. Colour yellowifh white.
Sp. 1. Alloy of filver and gold.

ORDER II. Sp. gr. from 7.786 to 4.5.
GENUS I. Flexible and malleable.
Sp. 1. Sulphuret of filver.
** Brittle.
GENUS II. Tinges borax white.
Sp. Tinftone.
GENUS III. Tinges borax green.
Sp. 1. Sulphuret of copper.
Colour bluifh grey.
Sp. 2. Chromat of lead.
Colour aurora red.
Sp. 3. Purple copper ore.
Colour purple.
GENUS IV. Tinges borax faint yellow. Becomes black when expofed to the vapour of fulphuret of ammonia.
Sp. 1. Galena.
Colour bluifh grey. Luftre metallic. Fragments cubic.
Sp. 2. Black lead ore.
Colour black. Luftre metallic.
Sp. 3. Lead ochre.
Colour yellow, grey, or red. Luftre o.
Sp. 4. Carbonat of lead.
Colour white. Luftre waxy.
Sp. 5. Phofphat of lead.
Ufually green. Luftre waxy. After fufion by the blow-pipe cryftallizes on cooling.
Sp. 6. Molybdat of lead.
Colour yellow. Streak white. Luftre waxy.

ORDER III. Sp. gr. from 4.35 to 3.
* Hardnefs 14 to 9.
GENUS I. Melts without frothing into a grey enamel.
Sp. 1. Garnet.
Colour red.
GENUS II. Melts into a brownifh enamel.
Sp. 1. Shorl.
Colour black. Opaque.
GENUS III. Froths and melts into a white enamel.
Sp. 1. Tourmaline.
Becomes electric by heat.
GENUS IV. Froths and melts into a greenifh black enamel.
Sp. 1. Bafaltine.
GENUS V. Froths and melts into a black enamel.
Sp. 1. Thallite.
Colour dark green.
Sp. 2. Thumerftone.
Colour clove brown.
** Hardnefs 5 to 8.
GENUS VI. Melts into a tranfparent glafs.
Sp. 1. Fluat of lime.
Powder phofphorefces when thrown on a hot iron.
GENUS VII. Melts into a black glafs.

Sp. 1.

Artificial Syftem.

Sp. 1. Hornblende.

GENUS VIII. Melts into a black bead with a fulphureous fmell, and depofits a blue oxide on the charcoal.

Sp. 1. Sulphuret of tin.

GENUS IX. Melts into a brown glafs. Tinges borax violet.

Sp. 1 Afbeftoid.

Colour green.

GENUS X. Melts into a brown (?) glafs. When fufed with potafs, and diffolved in water, the folution becomes of a fine orange yellow.

Sp. 1. Chromat of iron.

GENUS XI. Before the blow-pipe yields a bead of copper.

Sp. 1. Red oxide of copper.

(Sulphuret of copper.)

ORDER IV. Sp. gr. from 2.945 to 2.437.

GENUS I. Compofed of fcales.

Sp. 1. Talk.

Feels greafy. Spanifh wax rubbed by it becomes pofitively electric.

GENUS II. Compofed of thin plates, eafily feparable from each other.

Sp. 1. Mica.

Plates flexible and elaftic, may be torn but not broken. Spanifh wax rubbed by it becomes negatively electric.

Sp. 2. Stilbite.

Plates fomewhat flexible. Colour pearl white. Powder renders fyrup of violets green. Froths and melts into an opaque white enamel.

Sp. 3. Lepidolite.

Colour violet. Powder white with a tint of red. Froths and melts into a white femitranfparent enamel full of bubbles.

GENUS III. Texture foliated.

Sp. 1. Felfpar.

Fragments rhomboidal. Hardnefs 9 to 10.

Sp. 2. Leucite.

Always cryftallized. White. Powder renders fyrup of violets green. Hardnefs 8 to 10.

Sp. 3. Argentine felfpar.

Always cryftallized. Two faces dead white, two filvery white.

Sp. 4. Prehnite.

Colour green. Froths and melts into a brown enamel.

GENUS IV. Texture fibrous. Fibres eafily feparated.

Sp. 1. Afbeftus.

Feels fomewhat greafy.

GENUS V. Texture ftriated.

Sp. 1. Ædelite.

Abforbs water. Froths and melts into a frothy mafs.

GENUS VI. Texture earthy or compact.

Sp. 1. Lazulite.

Froths and melts into a yellowifh black mafs. If previoufly calcined, gelatinizes with acids.

Sp. 2. Borat of lime.

Tinges the flame greenifh, froths and melts into a yellowifh enamel garnifhed with fmall projecting points. If the blaft be continued, thefe dart off in fparks.

Artificial Syftem.

ORDER V. Sp. gr. from 2.348 to 0.68.

GENUS I. Hardnefs 10.

Sp. 1. Obfidian.

Colour blackifh, in thin pieces green.

GENUS II. Hardnefs 6 to 8.

Sp. 1. Zeolite.

Gelatinizes with acids. Becomes electric by heat.

GENUS III. Hardnefs 3 to 4.

Sp. 1. Amianthus.

Feels greafy. Texture fibrous.

Sp. 2. Mountain cork.

Elaftic like cork.

CLASS III. FUSIBLE BY THE BLUE FLAME, INFUSIBLE BY THE YELLOW.

GENUS I. Sp. gr. from 4.43 to 4.4.

Sp. 1. Sulphat of barytes

GENUS II. Sp. gr. from 3.96 to 3.51.

Sp. 1. Sulphat of ftrontites.

GENUS III. Sp. gr. from 2.311 to 2.167.

Sp. 1. Sulphat of lime.

CLASS IV. FUSIBLE, AND PARTLY EVAPORATING.

ORDER I. Sp. gr. from 10 to 5.

GENUS I. Colour white or grey. Luftre metallic.

* Sp. gr. 9 to 10.

Sp. 1. Native amalgam.

Tinges gold white. Creaks when cut.

Sp. 2. Alloy of filver and antimony.

Powder greyifh black.

** Sp. gr. from 6.467 to 5.309.

Sp. 3. Sulphuret of bifmuth.

Melts when held to the flame of a candle.

Sp. 4. Dull grey cobalt ore.

Streak bluifh grey. Hardnefs 10. When ftruck emits an arfenical fmell. Luftre fcarcely metallic.

GENUS II. Colour red, at leaft of the ftreak.

Sp. 1. Red filver ore.

Burns with a blue flame.

Sp. 2. Hepatic mercurial ore.

Does not flame, but gives out mercury before the blow-pipe.

GENUS III. Colour blue.

Sp. 1. Blue lead ore.

Burns with a blue flame and fulphureous fmell, and leaves a button of lead.

GENUS IV. Colour yellowifh green.

Sp. 1. Phofphat and arfeniat of lead combined.

When fufed by the blow-pipe, cryftallizes on cooling.

GENUS V. Colour ufually that of copper. Sp. gr.

Artificial System.

gr. 6.6084 to 6 6481.

Sp. 1. Sulphuret of nickel.

Exhales before the blow-pipe an arsenical smoke.

ORDER II. Sp. gr. from 4.6 to 3.44.

Genus I. Colour grey.

Sp. 1. Grey ore of antimony.

Burns with a blue flame, and leaves a white oxyd.

Sp. 2. Grey copper ore.

Crackles before the blow-pipe.

Genus II. Colour yellow.

Sp. 1. Pyrites.

Burns with a blue flame and sulphureous smell, and leaves a brownish bead.

Sp. 2. Yellow copper ore.

Melts into a black mass.

Class V. EVAPORATING.

ORDER I. Sp. gr. 13.6.

Genus I. Fluid.

Sp. 1. Native mercury.

ORDER II. Sp. gr. from 10 to 5.419.

Genus I. Colour red.

Sp. 1. Native cinnibar.

Genus II. Colour white or grey. Lustre metallic.

Sp. 1. Native bismuth.

Melts into a white bead, and then evaporates in a yellowish white smoke. Sp. gr. 9 to 9.5.

Sp. 2. Native antimony.

Melts and evaporates in a grey smoke. Sp. gr. 6.6 to 6.8.

Sp. 3. Native arsenic.

Evaporates without melting, and gives out a garlic smell.

ORDER III. Sp. gr. from 4.8 to 3.33.

Genus I. Colour red.

Sp. 1. Red antimonial ore.

Melts with a sulphureous smell. Sp. gr. 4.7.

Sp. 2. Realgar.

Melts with a garlic smell. Sp. gr. 3.384

Genus II. Colour yellow.

Sp. 1. Orpiment.

Class VI. SOLUBLE with EFFERVESCENCE in MURIATIC ACID.

Natural System.

Genus I. Sp. gr. from 4.338 to 4.3.

Sp. 1. Carbonat of barytes.

Genus II. Sp. gr. from 3.66 to 3.4.

Sp. 1. Carbonat of strontites.

Genus III. Sp. gr. from 2.3 to 1 or under.

Sp. 1. Carbonat of lime.

We have purposely avoided giving names to the classes, orders, and genera; because a more careful examination will doubtless suggest many improvements in the arrangement, and an artificial system ought to be brought to a great degree of perfection before its classes, orders, and genera be finally settled.

We have excluded from this arrangement all those bodies which in the following system are arranged under the class of combustibles; because there can scarcely be any difficulty in distinguishing them both from the other classes and from one another. For similar reasons we have excluded the class of salts.

Chap. IV. Natural System.

Avicenna, a writer of the 11th century, divided minerals into four classes; stones, salts, inflammable bodies, and metals (D). This division has been, in some measure, followed by all succeeding writers. Linnæus, indeed, the first of the moderns who published a system of mineralogy, being guided by the external characters alone, divided minerals into three classes, *petræ*, *mineræ*, *fossilia:* but Avicenna's classes appear among his orders. The same remark may be made with respect to the systems of Wallerius, Wolsterdorf, Cartheuser, and Justi, which appeared in succession after the first publication of Linnæus's *Systema Naturæ*, in 1736. At last in 1758, the system of Cronstedt appeared. He reinstated the classes of Avicenna in their place; and his system was adopted by Bergman, Kirwan, Werner, and the most celebrated mineralogists who have written since. We also shall adopt his classes, with a few slight exceptions; because we are not acquainted with any other division which is intitled to a preference.

10 Natural Classes.

We shall therefore divide this treatise into four classes. I. Stones. II. Salts. III. Combustibles. IV. Ores. The first class comprehends all the minerals which are composed chiefly or entirely of earths; the second, all the combination of acids and alkalies which occur in the mineral kingdom; the third, those minerals which are capable of combustion, and which consist chiefly of sulphur, carbon, and oil; the fourth, the mineral bodies which are composed chiefly of metals.

Class I. EARTHS and STONES.

We shall divide this class into three orders. The first order shall comprehend all chemical combinations of earths with each other; the second order, chemical combinations of earths with acids; and the third order, mechanical mixtures of earths or stones. All the minerals belonging to the first order exhibit the same homogeneous appearance to the eye as if they were simple bodies. We shall therefore, for want of a better name, call the first order *simple*; the second order we shall distinguish by the epithet of *saline*; and the third we shall call

(D) Corpora mineralia in quatuor species dividuntur, scilicet in lapides, et in liquifactiva, sulphurea, et sales. Et horum quædam sunt raræ substantiæ et debilis compositionis, et quædam fortis substantiæ, et quædam ductibilia, et quædam non. *Avicenna de congelatione et conglutinatione lapidum*, Cap. 3. *Theatrum Chemicum* t. iv. p. 997.

Earths and Stones

call *aggregates*; because most of the minerals belonging to it consist of various *simple stones*, cemented, as it were, together.

Order I. SIMPLE STONES.

21 Cronstedt's genera.

Cronstedt divided this order into nine genera, corresponding to nine earths; one of which he thought composed the stones arranged under each genus. The names of his genera, were *calcaræ*, *silicæ*, *granatinæ*, *argillaceæ*, *micacæ*, *fluores*, *asbestinæ*, *zeolithicæ*, *magnesiæ*. All his earths were afterwards found to be compounds, except the first, second, fourth, and ninth. Bergman, therefore, in his Sciagraphia, first published in 1782, reduced the number of genera to five; which was the number of primitive earths known when he wrote. Since that period three new earths have been discovered. Accordingly, in the latest systems of mineralogy, the genera belonging to this order amount to eight. Each genus is named from an earth; and they are arranged in the newest Wernerian system, which we have seen, as follows:

22 Improved

1. Jargon genus.	5. Magnesian genus.
2. Siliceous genus.	6. Calcareous genus.
3. Glucina genus.	7. Barytic genus.
4. Argillaceous genus.	8. Strontian genus.

Mr Kirwan, in his very valuable system of mineralogy, has adopted the same genera. Under each genus, those stones are placed, which are composed chiefly of the earth which gives a name to the genus, or which at least are supposed to possess the characters which distinguish that earth.

23 Still deficient.

A little consideration will be sufficient to discover that there is no natural foundation for these genera. Most stones are composed of two, three, or even four ingredients: and, in many cases, the proportion of two or more of these is nearly equal. Now, under what genus soever such minerals are arranged, the earth which gives it a name must form the smallest part of their composition. Accordingly, it has not been so much the chemical composition, as the external character, which has guided the mineralogist in the distribution of his species. The genera cannot be said properly to have any character at all, nor the species to be connected by any thing else than an arbitrary title. This defect, which must be apparent in the most valuable systems of mineralogy, seems to have arisen chiefly from an attempt to combine together an artificial and natural system. As we have separated these two from each other, it becomes necessary for us to attend more accurately to the natural distribution of genera than has hitherto been done. We have accordingly ventured to form new genera for this order, and we have formed them according to the following rules.

24 New genera.

The only substances which enter into the minerals belonging to this order, in such quantity as to deserve attention, are the following:

Alumina,	Glucina,
Silica,	Zirconia,
Magnesia,	Oxide of iron,
Lime,	Oxide of chromum,
Barytes,	Potass,

Simple Stones.

All those minerals which are composed of the *same* ingredients we arrange under the *same* genus. According to this plan, there must be as many genera as there are varieties of combinations of the above substances existing in nature. The varieties in the *proportion* of the ingredients constitute species. We have not imposed names upon our genera, but, in imitation of Bergman*, have denoted each by a symbol. This symbol is composed of the first letter of every substance which enters in any considerable quantity into the composition of the minerals arranged under the genus denoted by it. Thus, suppose the minerals of a genus to be composed of *alumina*, *silica*, and *oxide of iron*, we denote the genus by the symbol *asi*. The letters are arranged according to the proportion of the ingredients; that which enters in the greatest proportion being put first, and the others in their order. Thus the genus *asi* is composed of a considerable proportion of alumina, of a smaller proportion of silica, and contains least of all of iron. By this contrivance, the symbol of a genus contains, within the compass of a few letters, a pretty accurate description of its nature and character. Where the proportions of the ingredients vary in the same genus so much, that the letters which constitute its symbol change their place, we subdivide the genus into parts; and whenever the minerals belonging to any genus become too numerous, advantage may be taken of these subdivisions, and each of them may be formed into a separate genus. At present this seems unnecessary (E).

* *Opusc* iv. 231.

The following is a view of the different genera belonging to this order, denoted each by its symbol. Every genus is followed by the species included under it; and the whole are in the order which we mean to follow in describing them:

I. A.
Telesia,
Corundum,
Native alumina.

II. AMC.
Ruby.

III. AIM.
Ceylanite.

IV. S.
Quartz,
Elastic quartz,
Flint,
Opal,
Pitchstone,
Chrysoprasium.

V. 1. AS.
Topaz,
Sommite,
Shorlite.

2. SA.
Rubellite,
Hornslate,
Hornstone,
Chalcedony,
Jasper.
Tripoli.

VI. 1. ASI.
Micarell,
Shorl,
Granatite,

2. SAI.
Tourmaline,
Argentine felspar,
Mica,
Talc,
Basaltine,
Hornblende,
Obsidian,
Petrilite,
Felsite.

VII. SAP.
Felspar,
Lepidolite,
Leucite.

VIII. SAG.
Emerald.

IX. SAB.
Staurolite.

X. 1. ASL.
Chrysoberyl.

2. SAL.
Hyalite,
Ædelite.

3. SAWL

(E) We need hardly remark, that the last three genera of Werner belong to the second order of the first class of this treatise.

Earths and Stones.

3. SAWL.
Zeolite,
Stilbite,
Analcime.
4. SLA.
Lazulite.
XI. SALI.
Garnet,
Thumerstone,
Prehnite,
Thallite.
XII. 1. AMS.
Cyanite.
2. MSA.
Serpentine.
XIII. MSAI.
Potstone,
Chlorite.
XIV. SLAM.
Siliceous spar.
XV. SAMLI.
Argillite.
XVI. SM.
Kiffekill,
Steatites.
XVII. MSI.
Chrysolite,
Jade.
XVIII. SML.
Asbestus,
Asbestinite.
XIX. 1. SILM.
Pyroxen,
Asbestoid.
2. SMIL.
Actinolite.
XX. SL.
Shistose hornstone.
XXI. ZS.
Zircon.

25
I. A.
Telesia.

Genus I. A.

Species 1. Telesia (F).

Oriental ruby, *sapphire*, and *topaz* of mineralogists.—*Rubis d'orient* of De Lisle.

Three stones, distinguished from each other by their colour, have long been held in high estimation on account of their hardness and beauty. These stones were known among lapidaries by the names of *ruby*, *sapphire*, and *topaz*, and the epithet *oriental* was usually added, to distinguish them from other three, known by the same names and the same colours, but very inferior in hardness and beauty. Mineralogists were accustomed to consider these stones as three distinct species, till Romé de Lisle observed that they agreed in the form of their crystals, their hardness, and most of their other properties. These observations were sufficient to constitute them one species; and accordingly they were made one species by Romé de Lisle himself, by Kirwan, and several other modern mineralogical writers. But this species was destitute of a proper name, till Mr Hauy, whose labours, distinguished equally by their ingenuity and accuracy, have contributed not a little to the progress of mineralogy, denominated it *telesia*, from the Greek word τιλεσιος, which signifies *perfect*.

The telesia is found in the East Indies, especially in Pegu and the island of Ceylon; and it is most commonly crystallized. The crystals are of no great size: Their *primitive* form, according to Mr Hauy, is a regular six-sided prism, divisible in directions parallel both to its bases and its sides; and consequently giving for the form of its primitive nucleus, or of its *integrant molecule*, an equilateral three-sided prism *. The most usual variety is a dodecahedron, in which the telesia appears under the form of two very long slender six-sided pyramids, joined base to base †. The sides of these pyramids are isosceles triangles, having the angle at their vertex $22° 54'$, and each of those at the base $78° 48'$ (G). The inclination of a side of one pyramid to a contiguous side of the other pyramid is $139° 54$ ‡. In some specimens the summits of the pyramids are wanting, so that the crystal has the appearance of a six sided prism, somewhat thicker in the middle than towards the extremities §. The three alternate angles at each extremity of this prism are also sometimes wanting, and a small triangular face instead of them, which renders the bases of the supposed prism nine-sided. The inclination of each of these small triangles to the base is $122° 18$ ¶. For figures of these crystals we refer the reader to Romé de Lisle and Hauy ‖.

* *Ann de Chim.* xvii. 3. Plate XXVI. f. 1.

‡ *Ibid* and *Romé de Lisle*, ii. 315.

§ Fig. 2.

¶ *Hauy, ibid.*

‖ *Ibid.*

The texture of the telesia is foliated, and the joints are parallel to the base of the prism *. Its lustre varies from 3 to 4 (H). Transparency usually 3 or 4, sometimes only 2. It causes only a single refraction. Specific gravity from 4. to 4.288. Hardness from 15 to 17. It is either colourless or red, yellow or blue. These colours have induced lapidaries to divide the telesia into the three following varieties.

* *Hauy.*

Variety 1. Red telesia.

Oriental ruby.

Colour carmine red, sometimes verging towards violet. Sometimes various colours appear in the same stone, as red and white, red and blue, orange red. Hardness 17. Sp. gr. 4.288.

Variety 2. Yellow telesia.

Oriental topaz.

Colour golden yellow. Transp. 4. Hardness 15. Sp. gr. 4.0106.

Variety 3. Blue telesia.

Oriental sapphyr.

Colour Berlin blue, often so very faint that the stone appears almost colourless. Transp. 3, 4, 2. Hardness 17. Sp. gr. 3.991 to 4.083 †. That variety is not probably the same with the sapphyr of the ancients. Their sapphyr was distinguished by gold-coloured spots, none of which are to be seen in the sapphyr of the moderns ‡.

† *Greville, Nicholson's Jour.* iii. 11.

‡ *Hill's Theophrastus*, περι των λιθων, p. 100.

A specimen of this last variety, analysed by Mr Klaproth, was found to contain in 100 parts,

98.5	alumina,
1.0	oxyd of iron,
0.5	lime,
100.0 §	

§ *Beiträge*, i. 81.

The colouring matter of all these varieties is, according to Bergman's experiments, iron in different states of oxydation. He found that the topaz contained .06, the ruby .1, and the sapphyr .02 of that metal ‖. But when these experiments were made, the analysis of stones was not arrived at a sufficient degree of perfection to ensure accuracy. No conclusion, therefore, can be drawn from these experiments, even though we were certain that they were made upon the real varieties of telesia.

Earths and Stones. Simple Stones.

26 Corundum.

SPECIES 2. Corundum (1).

Corundum of Gmelin—*Admantine fpar* of Klaproth and Kirwan—*Corindon* of Hauy—*Corivindum* of Woodward.

This ftone, though it appears to have been known to Mr Woodward, may be faid to have been firft diftinguifhed from other minerals by Dr Black. In 1768, Mr Berry, a lapidary in Edinburgh, received a box of it from Dr Anderfon of Madras. Dr Black afcertained, that thefe fpecimens differed from all the ftones known to Europeans; and, in confequence of its hardnefs, it obtained the name of *adamantine fpar*. Notwithftanding this, it could fcarcely be faid to have been known to European mineralogifts till Mr Greville of London, who has doné fo much to promote the fcience of mineralogy, obtained fpecimens of it, in 1784, from India, and diftributed them among the moft eminent chemifts, in order to be analyfed. Mr Greville alfo learned, that its Indian name was Corundum. It is found in Indoftan, not far from the river Cavery, which is fouth from Madras, in a rocky matrix, of confiderable hardnefs, partaking of the nature of the ftone itfelf *. It occurs alfo in China; and a fubftance, not unlike the matrix of corundum, has been found in Teree, one of the weftern iflands in Scotland †.

The corundum is ufually cryftallized. Its primitive form, difcovered by Mr Hauy ‡ and the Count de Bournon §, is a rhomboidal parallelopiped, whofe fides are equal rhombs, with angles of 86° and 94°, according to Bournon, or whofe diagonals are to each other as $\sqrt{17}$ to $\sqrt{15}$, according to Hauy; which is very nearly the fame thing ¶. The moft common variety, for the primitive form has never yet been found, is the regular fix-fided prifm, the alternate angles of which are fometimes wanting ‖, and the triangular faces, which occupy their place, are inclined to the bafe at an angle of 122° 34′ *. Sometimes the corundum is cryftallized in the form of a fix-fided pyramid, the apex of which is generally wanting. For a defcription and figure of thefe, and all the other varieties of corundum hitherto obferved, we refer the reader to the differtation of the Count de Bournon on the fubject †.

* Garrow and Greville, Nicholfon's Jour. ii. 540.
† Greville, ibid.
‡ Jour. de Min. N° xxviii. 262.
§ Nicholfon's Jour. ii. 541.
¶ Fig. 3.
‖ Fig. 4.
* De Bournon.
† See alfo Hauy, Jour. de min. N° xxviii. 262.

The texture of the corundum is foliated, and the natural joints are parallel to the faces of the primitive rhomboidal parallelopiped. Luftre, when in the direction of the laminæ, 3; when broken acrofs, 0. Opake, except when in very thin pieces. Hardnefs 15. Sp. gr. from 37.10 to 4.180 ‡. Colour grey, often with various fhades of blue and green.

According to the analyfis of Klaproth, the corundum of India is compofed of

89.5	alumina,
5.5	filica,
1.25	oxide of iron,
96.25 §.	

‡ Klaproth. See alfo Mr Greville, Nicholfon's Jour. iii. 11.
§ Beiträge, i. 77.

A fpecimen from China of

84.0	alumina,
6.5	filica,
7.5	oxide of iron,
98.0 ‖.	

‖ Ibid. i. 73.

Notwithftanding the quantity of filica and of iron which thefe analyfes exhibit in the corundum, we have been induced to include it in the prefent genus on account of the ftrong refemblance between it and the third variety of telefia. The ftriking refemblance between the cryftals of telefia and corundum will appear evident, even from the fuperficial defcription which we have given; and the obfervations of De Bournon ¶ render this refemblance ftill more ftriking. It is not improbable, therefore, as Mr Greville and the Count de Bournon have fuggefted, that corundum may be only a variety of telefia, and that the feeming difference in their ingredients is owing to the impurity of thofe fpecimens of corundum which have hitherto been brought to Europe. Let not the difference which has been found in the primitive form of thefe ftones be confidered as an infuperable objection, till the fubject has been again examined with this precife object in view; for nothing is eafier than to commit an overfight in fuch difficult examinations.

¶ Nicholfon's Jour. iii. 9.

27 Native alumina.

SPECIES 3. Native alumina (K).

This fubftance has been found at Halles in Saxony in compact kidney-form maffes. Its confiftence is earthy. Luftre 0. Opaque. Hardnefs 4. Brittle. Sp. gr. moderate. Feels foft, but meagre. Adheres very flightly to the tongue. Stains very flightly. Colour pure white. Does not readily diffufe itfelf in water.

It confifts of pure alumina, mixed with a fmall quantity of carbonat of lime, and fometimes of fulphat of lime *.

* Schreber.

28 G. II. AMC. Ruby.

GENUS II. AMC.

SPECIES 1. Ruby (L).

Spinel and *balafs Ruby* of Kirwan—*Ruby* of Hauy—*Rubis fpinelle octoedre* of De Lifle—*Spinellus* of Gmelin.

This ftone, which comes from the ifland of Ceylon, is ufually cryftallized. The primitive form of its cryftals is a regular octohedron, compofed of two four-fided pyramids applied bafe to bafe, each of the fides of which is an equilateral triangle † (M). In fome cafes two oppofite fides of the pyramids are broader than the other two; and fometimes the edges of the octohedron are wanting, and narrow faces in their place. For figures and defcriptions of thefe, and other varieties of thefe cryftals, we refer the reader to *Romé de Lifle* and the *Abbé Eftner* ‡.

The texture of the ruby is foliated. Its luftre is 3. Tranfp. 3.4. It caufes a fingle refraction. Hardnefs 13. Sp. gr. 3.570 § to 3.625 ¶. Colour red; if deep, the ruby is ufually called *balafs*; if pale rofy, *fpinell*. The

30

Genus IV. s.

G. IV. s. Quartz.

species 1. Quartz §.

§ Kirwan's Min. i. 241.

This ſtone, which is very common in moſt mountainous countries, is ſometimes cryſtallized, and ſometimes amorphous. The primitive form of its cryſtals, according to Mr Hauy, is a rhomboidal parallelopiped; the angles of whoſe rhombs are 93° 22′, and 86° 38′; ſo that it does not differ much from a cube ‖. The moſt common variety is a dodecahedron *, compoſed of two ſix-ſided pyramids, applied baſe to baſe, whoſe ſides are iſoſceles triangles, having the angle at the vertex 40°, and each of the angles at the baſe 70°; the inclination of a ſide of one pyramid to the contiguous ſide of the other pyramid is 104°. There is often a ſix-ſided priſm interpoſed between the two pyramids, the ſides of which always correſpond with thoſe of the pyramids †. For a deſcription and figure of the other varieties of quartz cryſtals, and for a demonſtration of the law which they have followed in cryſtallizing, we refer the reader to *Romé de Liſle* ‡ and *Mr Hauy* §.

‖ Jour. de Min. N° xxviii. 255. * Fig. 6. † Fig. 7. ‡ Cryſtal. ii. 71. § Mem. Par. 1786, p. 78. See alſo Lametherie, Jour. de Phyſ. xlii. 470.

The texture of quartz is more or leſs foliated. Fracture, conchoidal or ſplintery. Its luſtre varies from 3 to 1, and its tranſparency from 4 to 1; and in ſome caſes it is opaque. It cauſes a double refraction. Hardneſs, from 10 to 11. Sp. gr. from 2.64 to 2.67, and in one variety 2.691. Its colour is exceedingly various; a circumſtance which has induced mineralogiſts to divide it into numerous varieties. Of theſe the following are the chief:

Simple Stones.

1. Pure colourleſs, perfectly tranſparent cryſtallized quartz, having much the appearance of artificial cryſtal: known by the name of *rock cryſtal*.

2. Quartz leſs tranſparent, and with a ſplintery fracture, has uſually been diſtinguiſhed by the name of *quartz*, and ſeparated from rock cryſtal. As there is no occaſion for this ſeparation, we have, in imitation of Mr Hauy, choſen the word quartz for the *ſpecific name*, comprehending under it all the varieties.

3. Blood red quartz; formerly called *compoſtella hyacinth*, and by Hauy *quartz hematoide*. It owes its colour to oxide of iron. The mineral known to mineralogiſts by the name of *ſinople*, and conſidered by them as a variety of *jaſper*, has been diſcovered by Dolomieu to be merely this variety of quartz in an amorphous ſtate *.

* Jour. de Min. N° xxviii. 255.

4. Yellow quartz; called falſe topaz.

5. Roſy red quartz; called Bohemian ruby.

For a fuller enumeration of theſe varieties, we refer the reader to *Smeiſſer's Mineralogy* †, *Kirwan's Mineralogy* ‡, and Gmelin's edition of the *Syſtema Naturæ* of Linnæus §. This laſt writer, however, has arranged ſeveral minerals under quartz which do not belong to it.

† i. 89. ‡ i. 244. § iii. 194.

Pure quartz is compoſed entirely of ſilica; but ſome of the varieties of this ſpecies are contaminated with metallic oxides, and with a ſmall quantity of other earths.

31 Elaſtic quartz.

species 2. Elaſtic Quartz (n).

This ſingular ſtone is moderately elaſtic, and flexible in every direction. Texture, earthy. Luſtre 0 or 1. Hardneſs, 9. Brittle. Sp. gr. 2.624. Colour, greyiſh white. Phoſphoreſces when ſcraped with a knife in the dark. The ſpecimen analyſed by Mr Klaproth contained

96.5	ſilica,
2.5	alumina,
5	oxide of iron.
99.5 ‖	

‖ Beiträge, ii. 116.

32 Flint.

species 3. Flint (o).

Pyromachus—Pierre a fuſil—Silex of Hauy.

This ſtone, which has become ſo neceſſary in modern war, is found in pieces of different ſizes, and uſually of a figure more or leſs globular, commonly among chalk, and often arranged in ſome kind of order. In Saxony it is ſaid to have been found cryſtallized in hexahedrons, compoſed of two low three-ſided pyramids applied baſe to baſe *.

* Gmelin's Syſtema Naturæ, iii. 318.

Its texture is compact. Its fracture, ſmooth conchoidal. Luſtre, external, 0, the ſtones being always covered by a white cruſt; internal, 1, inclining to greaſy. Tranſp. 2; when very thin, 3. Hardneſs, 10 or 11. Sp. gr. from 2.58 to 2.63. Colour varies from honey yellow to browniſh black. Very brittle, and ſplits into ſplinters in every direction. Two pieces of flint rubbed ſmartly together phoſphoreſce, and emit a peculiar odour. When heated it decrepitates, and becomes white and opaque. When expoſed long to the air

(n) *Kirwan's Min.* I. 316.—*Gerhard, Mem. Berlin,* 1783, 107.—*Klaproth's Beiträge,* 2 *Band.* 113. See alſo *Jour. de Phyſ.* XLI. 91.

(o) *Kirwan's Min.* I. 301.—*Dolomieu, Jour. de Min.* N° XXXIII. 693. and *Salivet, ibid.* 713. Theſe laſt gentlemen give the only accurate account of the method of making gun flints.

Earths and Stones.

air it often becomes covered with a white cruft. A fpecimen of flint, analyfed by Klaproth, contained

98.00 filica,
.50 lime,
.25 alumina,
0.25 oxide of iron,
1.00 water.

100.00 *

* Beiträge, i. 46.

Another fpecimen, analyfed by Dolomieu, was compofed of 97 filica,
1 alumina and oxide of iron,
2 water.

100 †

† Jour. de Min. N° xxxiii. 702.

The white cruft with which flint is enveloped, confifts of the fame ingredients, and alfo a little carbonat of lime. Dolomieu difcovered that water is effential to flint; for when it is feparated by heat the ftone lofes its properties ‡.

‡ Ibid.

The manufacture of gun flints is chiefly confined to two or three departments in France. The operation is exceedingly fimple: a good workman will make 1000 flints in a day. The whole art confifts in ftriking the ftone repeatedly with a kind of mallet, and bringing off at each ftroke a fplinter, fharp at one end and thicker at the other. Thefe fplinters are afterwards fhaped at pleafure, by laying the line at which it is wifhed they fhould break, upon a fharp iron inftrument, and then giving it repeatedly fmall blows with a mallet. During the whole operation the workman holds the ftone in his hand, or merely fupports it on his knee §.

§ Ibid.

33 Opal.

SPECIES 4. Opal (P).

This ftone is found in many parts of Europe. It is ufually amorphous. Its fracture is conchoidal, commonly fomewhat tranfparent. Hardnefs from 6 to 10. Sp. gr. from 1.7 to 2.66. The lownefs of its fpecific gravity, in fome cafes, is to be afcribed to accidental cavities which the ftone contains. Thefe are fometimes filled with drops of water. Some fpecimens of opal have the property of emitting various coloured rays, with a particular effulgency, when placed between the eye and the light. The opals which poffefs this property, are diftinguifhed by lapidaries by the epithet *oriental;* and often by mineralogifts by the epithet *nobilis.* This property rendered the ftone much efteemed by the ancients.

Variety 1. Opal edler—*Opalus nobilis.*

Luftre glaffy, 3. Tranfp. 3 to 2. Hardnefs, 6 to 8. Colour, ufually light bluifh white, fometimes yellow or green. When heated it becomes opaque, and fometimes is decompofed by the action of the atmofphere. Hence it feems to follow, that water enters effentially into its compofition. A fpecimen of this variety, analyfed by Klaproth, contained

90 filica,
10 water.

100 *

* Beiträge, ii. 153.

Variety 2. Semi-opal.

Fracture, imperfectly conchoidal. Luftre, glaffy, 2. Tranfp. 2 to 3. Hardnefs, 7 to 9. Its colours are very various, greys, yellows, reds, browns, greens of different kinds.

Simple Stones.

Specimens of this variety fometimes occur with rifts: thefe readily imbibe water, and therefore adhere to the tongue. Thefe fpecimens fometimes become tranfparent when foaked in water, by imbibing that fluid. They are then called *hydrophanes.*

Variety 3. Cat's eye *.

* Kirwan's Min. i. 301. Klaproth, Beiträge, i. 90.

This variety comes from Ceylon, and is feldom feen by European mineralogifts till it has been polifhed by the lapidary. Mr Klaproth has defcribed a fpecimen which he received in its natural ftate from Mr Greville of London. Its figure was nearly fquare, with fharp edges, a rough furface, and a good deal of brilliancy.

Its texture is imperfectly foliated. Luftre greafy, 2. Tranfp. 3 to 2. Hardnefs 10. Sp. gr. 2.56 to 2.66. Colour, grey; with a tinge of green, yellow, or white: or brown, with a tinge of yellow or red. In certain pofitions it reflects a fplendid white, as does the eye of a cat; hence the name of this ftone.

Two fpecimens, analyfed by Klaproth, the firft from Ceylon, the other from Malabar, were compofed of

95.00	94.50	filica,
1.75	2.00	alumina,
1.50	1.50	lime,
0.25	0.25	oxide of iron.
98.5†	98 25‡	

† Beiträge, i. 94. ‡ Ibid. p. 96.

34 Pitchftone.

SPECIES 5. Pitchftone §.
Menelites.

This ftone, which occurs in different parts of Germany, France, and other countries, has obtained its name from fome refemblance which it has been fuppofed to have to pitch. It is moft ufually in amorphous pieces of different fizes; and it has been found alfo cryftallized in fix-fided prifms, terminated by three-fided pyramids.

§ Kir. Min. i. 292.—Daubanton, Mem. Par. 1787, p. 86.

Its texture is conchoidal and uneven, and fometimes approaches the fplintery. Luftre greafy, from 3 to 1. Tranfp. 2 to 1, fometimes 0. Hardnefs 8 to 10. Exceedingly brittle; it yields even to the nail of the finger. Sp. gr. 2.049 to 2.39. Its colours are numerous, greyifh black, bluifh grey, green, red, yellow of different fhades. Sometimes feveral of thefe colours appear together in the fame ftone. A fpecimen of pitchftone from Mefnil-montant near Paris ‖, analyfed by Mr Klaproth, contained

‖ See Jour. de Phyf. xxxi. 219.

85.5 filiea,
11.0 air and water,
1.0 alumina,
.5 iron,
.5 lime and magnefia.

98.5 ¶

¶ Beiträge, ii. 169.

35 Chryfoprafium.

SPECIES 6. Chryfoprafium (Q).

This mineral, which is found in different parts of Germany, particularly near Kofemütz in Silefia, is always amorphous. Its fracture is either even or inclining to the fplintery. Scarcely any luftre. Tranfp. 2 to 3. Hardnefs 10 to 12. Sp. gr. 2.479. Colour, green. In a heat of 130° Wedgewood it whitens and becomes opaque.

G. V. I. AS. Topaz.

GENUS V. 1. AS.

SPECIES 1. Topaz (R).

Occidental ruby, topaz, and *ſapphyr.*

The name *topaz* has been reſtricted by Mr Hauy to the ſtones called by mineralogiſts occidental ruby, topaz, and ſapphyr; which, agreeing in their cryſtallization and moſt of their properties, were arranged under one ſpecies by Mr Romé de Liſle. The word *topaz*, derived from an iſland in the Red Sea (S), where the ancients uſed to find topazes, was applied by them to a mineral very different from ours. One variety of our topaz they denominated *chryſolite.*

The topaz is found in Saxony, Bohemia, Siberia, and Brazil, mixed with other minerals in granite rocks.

It is commonly cryſtallized. The primitive form of its cryſtals is a priſm whoſe ſides are rectangles, and baſes rhombs, having their greateſt angles 124° 22′, and the integral molecule has the ſame form †; and the height of the priſm is to a ſide of the rhomboidal baſes as 3 to 2 ‡. The different varieties of topaz cryſtals hitherto obſerved, amount to 6. Five of theſe are eight-ſided priſms, terminated by four-ſided pyramids, or wedge ſhaped ſummits, or by irregular figures of 7, 13, or 15 ſides §; the laſt variety is a twelve-ſided priſm, terminated by ſix-ſided pyramids wanting the apex. For an accurate deſcription and figure of theſe varieties we refer the reader to Mr Hauy ‖.

† Hauy, Jour. de Min. N° xxviii 287.
‡ Fig. 8.
§ Fig. 9.

The texture of the topaz is foliated. Its luſtre is from 2 to 4. Tranſp. from 2 to 4. It cauſes a double refraction. Hardneſs 12 to 14. Sp. gr. from 3.5311 to 3.564. The Siberian and Brazil topazes, when heated, become poſitively electrified on one ſide, and negatively on the other ¶. It is infuſible by the blow-pipe. The yellow topaz of Brazil becomes red when expoſed to a ſtrong heat in a crucible; that of Saxony becomes white by the ſame proceſs. This ſhews us that the colouring matter of theſe two ſtones is different.

‖ Jour. de Min. ibid.
¶ Hauy, ibid.

The colour of the topaz is various, which has induced mineralogiſts to divide it into the following varieties:

1. Red topaz, of a red colour inclining to yellow; called *Brazilian* or *occidental ruby.*

2. Yellow topaz, of a golden yellow colour, and ſometimes alſo nearly white; called *occidental* or *Brazil topaz.* The powder of this and the following variety cauſes ſyrup of violets to aſſume a green colour *.

3. *Saxon topaz.* It is of a pale wine yellow colour, and ſometimes greyiſh white.

* Vauquelin, Jour. de Min. N° xxix. 165.

Simple Stones.

4. *Aigue marine.* It is of a bluiſh or pale green colour.

5. *Occidental ſapphyr.* It is of a blue colour; and ſometimes white.

A ſpecimen of white Saxon topaz, analyſed by Vauquelin, contained 68 alumina,
31 ſilica.
99 *.

* Jour. de Min. N° xxiv. 3.

37

SPECIES 2. Sommite.

This ſtone was called ſommite by La Metherie, from the mountain Somma, where it was firſt found. It is Sommite.
uſually mixed with volcanic productions. It cryſtallizes in ſix-ſided priſms, ſometimes terminated by pyramids. Colour white. Somewhat tranſparent. Sp. gr. 3.2741. Infuſible by the blow-pipe. According to the analyſis of Vauquelin, it is compoſed of
49 alumina,
46 ſilica,
2 lime,
1 oxide of iron.
98 †

† Ibid. N° xxviii. 279.

38

SPECIES 3. Shorlite ‡.

This ſtone, which received its name from Mr Klaproth, is generally found, in irregular oblong maſſes or columns, inſerted in granite. Its texture is foliated. Fracture uneven. Luſtre 2. Tranſparency 2 to 1. Hardneſs 9 to 10. Sp. gr. 3.53. Colour greeniſh white, or ſulphur yellow. Not altered by heat. According to the analyſis of Klaproth, it is compoſed of
50 alumina,
50 ſilica.
100

‡ Kirwan's Min. i. 286.

39

G. V. 2. SA. Rubellite.

GENUS V. 2. SA.

SPECIES 4. Rubellite (T).

Red ſhorl of Siberia.

This ſtone is found in Siberia mixed with white quartz. It is cryſtallized in ſmall needles, which are grouped together and traverſe the quartz in various directions. Texture fibrous. Fracture even, inclining to the conchoidal. Tranſparency 2; at the edges 3. Hardneſs 10. Brittle. Sp. gr. 3.1. Colour crimſon, blood or peach red. By expoſure to a red heat it becomes ſnow white; but loſes none of its weight. It tinges ſoda blue, but does not melt with it.

According to the analyſis of Mr Bindheim, it is compoſed of 57 ſilica,
35 alumina,
5 oxides of iron and manganeſe.
97

40

Hornſlate.

SPECIES 5. Hornſlate (U).

Shiſtoſe porphyry.

This ſtone, which occurs in mountains, is generally amorphous; but ſometimes alſo in columns. Structure

41 Hornftone.

SPECIES 6. Hornftone (x).

Petrofilex—Chert.

This ftone, which makes a part of many mountains, is ufually amorphous; but, as Mr Kirwan informs us, it has been found cryftallized by Mr Beyer on Schneeberg. Its cryftals are fix-fided prifms, fometimes terminated by pyramids: hexahedrons, confifting of two three-fided pyramids applied bafe to bafe; and cubes, or fix-fided plates *. Its texture is foliated. Fracture fplintery, and fometimes conchoidal. Luftre 0. Tranfparency 1 to 2. The cryftals are fometimes opaque. Hardnefs 7 to 9. Sp. gr. 2.532 to 2.653. Colour ufually dark blue: but hornftone occurs alfo of the following colours; grey, red, blue, green, and brown of different fhades †,

* *Kirwan*, i. 303.

† *Schmeiffer's Min.* i. 103.

According to Kirwan, it is compofed of

72	filica,
22	alumina,
6	carbonat of lime.
100 ‡	

‡ *Ibid.* p. 305.

42 Chalcedony.

SPECIES 7. Chalcedony.

This ftone is found abundantly in many countries, particularly in Iceland and the Faro iflands. It is moft commonly amorphous, ftalactitical, or in rounded maffes; but it occurs alfo cryftallized in fix-fided prifms, terminated by pyramids, or more commonly in four or fix fided pyramids, whofe fides are convex. Surface rough. Fracture more or lefs conchoidal. Luftre 1. Somewhat tranfparent. Hardnefs 10 to 11. Sp. gr. 2.56 to 2.665. Not brittle.

According to Bergman, the chalcedony of Foroe is compofed of

84	filica,
16	alumina, mixed with iron.
100	

Variety 1. Common chalcedony.

Fracture even, inclining to conchoidal. Tranfparency 2 to 3; fometimes 1. Its colours are various; it is moft commonly greyifh, with a tint of yellow, green, blue, or pearl; often alfo white, green, red, yellow, brown, black, or dotted with red. When ftriped white and black, or brown, alternately, it is called *onyx*; when ftriped white and grey, it is called *chalcedonix*. Black or brown chalcedony, when held between the eye and a ftrong light, appears dark red.

Variety 2. Cornelian.

Fracture conchoidal. Tranfparency 3 to 1; often cloudy. Its colours are various fhapes of red, brown, and yellow. Several colours often appear in the fame mafs. To this variety belong many of the ftones known by the name of *Scotch pebbles*.

Simple Stones.

43 Jafper.

SPECIES 8. Jafper (y).

This ftone is an ingredient in the compofition of many mountains. It occurs ufually in large amorphous maffes, and fometimes alfo cryftallized in fix-fided irregular prifms. Its fracture is conchoidal. Luftre from 2 to 0, Either opaque, or its tranfparency is 1. Hardnefs 9 to 10. Sp. gr. from 2.5 to 2.82. Its colours are various. When heated, it does not decrepitate. It feems to be compofed of filica and alumina, and often alfo contains iron.

Variety 1. Common jafper.

Sp. gr. from 2.58 to 2.7. Its colours are different fhades of white, yellow, red, brown, and green; often variegated, fpotted, or veined, with feveral colours.

Variety 2. Egyptian pebble.

This variety is found chiefly in Egypt. It ufually has a fpheroidal or flat rounded figure, and is enveloped in a coarfe rough cruft. It is opaque. Hardnefs 10. Sp. gr. 2.564. It is chiefly diftinguifhed by the variety of colours, which always exift in the fame fpecimen, either in concentric ftripes or layers, or in dots or dentritical figures. Thefe colours are, different browns and yellows, milk white, and ifabella green; black alfo has been obferved in dots.

Variety 3. Striped jafper.

This variety is alfo diftinguifhed by concentric ftripes or layers of different colours: thefe colours are, yellow, brownifh red, and green. It is diftinguifhed from the laft variety by its occurring in large amorphous maffes, and by its fracture, which is nearly even.

44 Tripoli.

SPECIES 9. Tripoli.

This mineral is found fometimes in an earthy form, but more generally indurated. Its texture is earthy. Its fracture often fomewhat conchoidal Luftre 0. Generally opaque. Hardnefs 4 to 7. Sp. gr. 2.080 to 2.529. Abforbs water. Feel, harfh dry. Hardly adheres to the tongue. Takes no polifh from the nail. Does not ftain the fingers. Colour generally pale yellowifh grey, alfo different kinds of yellow, brown, and white.

It contains, according to Haaffe, 90 parts of filica, 7 alumina, and 3 of iron. A mineral belonging to this fpecies was analyfed by Klaproth, and found to contain

66.5	filica,
7.0	alumina,
2.5	oxide of iron,
1.5	magnefia,
1.25	lime,
19.	air and water.
97.75	

45 G. VI. 1. ASI. Micarell.

GENUS VI. 1. ASI.

SPECIES 1. Micarell *.

This name has been given by Mr Kirwan to a ftone which former mineralogifts confidered as a variety of mica. It is found in granite. Its texture is foliated, and

* *Kirwan's Min.* i. 212.

and it may be ſplit into thin plates. Luſtre metallic, 3. Opaque. Hardneſs 6. Sp. gr. 2.980. Colour browniſh black. At 153° Wedgewood, it melts into a black compact glaſs, the ſurface of which is reddiſh *.

* Kirw. ibid.

A ſpecimen analyſed by Klaproth contained

63.00 alumina,
29.50 ſilica,
6.75 iron.

99.25

46 Shorl. † Ibid. i. 265.

SPECIES 2. Shorl †.

No word has been uſed by mineralogiſts with leſs limitation than *ſhorl*. It was firſt introduced into mineralogy by Cronſtedt, to denote any ſtone of a columnar form, conſiderable hardneſs, and a ſpecific gravity from 3 to 3.4. This deſcription applied to a very great number of ſtones. And ſucceeding mineralogiſts, though they made the word more definite in its ſignification, left it ſtill ſo general, that under the deſignation of *ſhorl* almoſt 20 diſtinct ſpecies of minerals were included.

Mr Werner firſt defined the word *ſhorl* preciſely, and reſtricted it to one ſpecies of ſtones. We uſe the word in the ſenſe aſſigned by him.

Shorl is found abundantly in mountains, either maſſive or cryſtallized, in three or nine ſided priſms, often terminated by three ſided ſummits. The ſides of the cryſtals are longitudinally ſtreaked. Its texture is foliated. Its fracture conchoidal. Luſtre 2. Opaque. Hardneſs 10. Sp. gr. 2.92 to 3.212. Colour black. Streak grey. It does not become electric by heat. When heated to redneſs, its colour becomes browniſh red; and at 127° Wedgewood, it is converted into a browniſh compact enamel ‡. According to Wiegleb, it is compoſed of

‡ Ibid. i. 166.

41.25 alumina,
34.16 ſilica,
20.00 iron,
5,41 mangane ſe.

100.82 §

§ Crell's Beiträge, 1. Bandes. 4. Stück, p. 21.

SPECIES 5. Granatite.

Staurotide of Hauy—*Pierre de Croix* of De Liſle—*Staurolithe* of Lametherie.

47 Granatite.

We have adopted from Mr Vauquelin the term *granatite* to denote this ſtone, becauſe all the other names are ambiguous, having been applied to another mineral poſſeſſed of very different properties.

Granatite is found in Galicia in Spain, and Britanny in France. It is always cryſtallized in a very peculiar form; two ſix-ſided priſms interſect each other, either at right angles or obliquely ¶. Hence the name *croſsſtone*, by which it was known in France and Spain *. Mr Hauy has proved, in a very ingenious manner, that the primitive form of the granatite is a rectangular priſm, whoſe baſes are rhombs, with angles of $129\frac{1}{2}$° and $50\frac{1}{2}$°; and that the height of the priſm is to the greater diagonal of a rhomb as 1 to 6; and that its integrant molecules are triangular priſms, ſimilar to what would be obtained by cutting the primitive cryſtal in two, by a plane paſſing vertically through the ſhorter diagonal of the rhomboidal baſe. From this ſtructure he has demonſtrated the law of the formation of the cruciform varieties †. The colour of granatite is greyiſh or reddiſh brown.

¶ Fig. 10. * Romé de Liſle, ii. 435.

† Ann. de Chim. vi. 142.

According to the analyſis of Vauquelin, it is compoſed of

47.06 alumina,
30.59 ſilica,
15.30 oxide of iron,
3.00 lime.

95.95 ‡.

‡ Ibid. xxx. 106.

GENUS VI. 2. SAL.

48 G. VI. 2. SAL. Tourmaline.

SPECIES 4. Tourmaline (z).

This ſtone was firſt made known in Europe by ſpecimens brought from Ceylon; but it is now found frequently forming a part of the compoſition of mountains. It is either in amorphous pieces, or cryſtallized in three or nine ſide priſms, with four-ſided ſummits.

Its texture is foliated: Its fracture conchoidal. Internal luſtre 2 to 3. Tranſparency 3 to 4; ſometimes only 2 (A). Cauſes only ſingle refraction §. Hardneſs 9 to 11. Sp. gr. 3.05 to 3.155. Colour brown, often ſo dark that the ſtone appears black; the brown has alſo ſometimes a tint of green, blue, red, or yellow.

§ Hauy, Jour. de Min. N° xxviii. 265.

When heated to 200° Fahrenheit, it becomes electric; one of the ſummits of the cryſtal negatively, the other poſitively ¶. It reddens when heated; and is fuſible *per ſe* with intumeſcence into a white or grey enamel.

¶ Æpinus.

A ſpecimen of the tourmaline of Ceylon, analyſed by Vauquelin, was compoſed of

40 ſilica,
39 alumina,
12 oxide of iron,
4 lime,
2.5 oxide of mangane ſe,

97.5 *.

* Ann. de Chim. xxx. 105.

SPECIES 5. Argentine felſpar †.

49 Argentine felſpar. † Kirwan, i. 327.

This ſtone was diſcovered by Mr Dodun in the black mountains of Languedoc. It is either amorphous, or cryſtallized in rhomboidal tables, or ſix or eight ſided priſms. Its texture is foliated. Fragments rectangular. Laminæ inflexible. Internal luſtre 4. Tranſparency 2. Colour white; two oppoſite faces of the cryſtals are ſilver white, two others dead white. Hardneſs of the ſilvery laminæ 6, of the reſt 9. Brittle. Sp. gr. 2.5. When the flame of the blow-pipe is directed againſt the edges of the cryſtal (ſtuck upon glaſs), it eaſily melts into a clear compact glaſs; but when the flame is directed againſt the faces, they preſerve their luſtre, and the edges alone ſlowly melt.

According to the analyſis of Dodun, it is compoſed of

46 ſilica,
36 alumina,
16 oxide of iron,

98

When this ſtone is expoſed to the atmoſphere, it is apt

(z) *Kirw.* I. 271.—*Berg.* II. 118. and V. 402.—*Gerhard. Mem. Berlin*, 1777. p. 14.—*Hauy Mem. Par.* 1784, 270.—*Wilſon Phil. Tranſ.* XLI. 308.—*Æpinus. Recueil ſur la Tourmaline.* See alſo *La Porterie. Le Sapphir, l'Oeil de Chat, et la Tourmaline de Ceylon demaſqués.*

(A) And when black only 1.

Earths and Stones.

apt to decay: Its furface becomes iridefcent, and at laft changes to ochre yellow: Its fpecific gravity is 2.3 or 2.212; and when breathed upon, it gives out an earthy fmell.

50 Mica.

SPECIES 6. MICA *.

* Kirw. i. 210—Gmelin, Nov. Com. Petrop. xii. 549.

This ftone forms an effential part of many mountains, and has been long known under the names of *glacies mariæ* and *Mufcovy glafs*. It confifts of a great number of thin laminæ adhering to each other, fometimes of a very large fize. Specimens have been found in Siberia nearly 2½ yards fquare (B).

It is fometimes cryftallized: Its primitive form is a rectangular prifm, whofe bafes are rhombs, with angles of 120° and 60° †: Its integrant molecule has the fame form. Sometimes it occurs in rectangular prifms, whofe bafes alfo are rectangles, and fometimes alfo in a fhort fix-fided prifms ‡; but is much more frequently in plates or fcales of no determinate figure or fize §.

† Fig. 11.

‡ Fig. 12.

§ Hauy, Jour. de Min. N° xxviii. 296.

Its texture is foliated. Its fragments flat. The lamellæ flexible, and fomewhat elaftic. Luftre metallic, from 3 to 4. Tranfparency of the laminæ 3 or 4, fometimes only 2 (C). Hardnefs 6. Very tough. Often abforbs water. Sp. gr. from 2.6546 to 2.9342. Feels fmooth, but not greafy. Powder feels greafy. Colour, when pureft, filver white or grey; but it occurs alfo yellow, greenifh, reddifh, brown, and black. Mica is fufible by the blow-pipe into a white, grey, green, or black, enamel; and this laft is attracted by the magnet (D). Spanifh wax rubbed by it becomes negatively electric ¶.

¶ Ibid.

A fpecimen of mica, analyfed by Vauquelin, contained

50.00	filica,
35.00	alumina,
7.00	oxide of iron.
1.35	magnefia,
1.33	lime,
94.68 *.	

* Ibid. 301.

Mica has long been employed as a fubftitute for glafs. A great quantity of it is faid to be ufed in the Ruffian marine for panes to the cabin windows of fhips; it is preferred, becaufe it is not fo liable as glafs to be broken by the agitation of the fhip.

51 Talc.

SPECIES 7. Talc †.

* Kirw. i. 150—Pott. Mem. Berl. 1746, p. 65.

This ftone has a very ftrong refemblance to mica, and was long confidered as a mere variety of that mineral. It occurs fometimes in fmall loofe fcales, and fometimes in an indurated form; but it has not hitherto been found cryftallized.

Its texture is foliated. The lamellæ are flexible, but not elaftic. Its luftre is from 2 to 4. Tranfparency from 2 to 4. Hardnefs 4 to 6. Sp. gr. when indurated, from 2.7 to 2.8. Feels greafy. Colour moft commonly whitifh or greenifh. Spanifh wax rubbed with it becomes *pofitively* electric ‡.

† Hauy, Jour. de Min. N° xxviii. 291.

Variety 1. Scaly talc.

Talcite of Kirwan.

This variety occurs under the form of fmall fcales, fcarcely cohering. Luftre 3 to 4. Very light. Adheres to the fingers. When rubbed upon the fkin, it gives it a glofs. Colour white, with a fhade of red or green; fometimes leek green.

Simple Stones.

Variety 2. Common talc.

Venetian talc.

This variety often occurs in oblong nodules. Luftre, nearly metallic, 4. Tranfparency 2 to 3; when very thin 4. Hardnefs 4 to 5. Colour white, with a fhade of green or red; or apple green, verging towards filver white. By tranfmitted light green.

Variety 3. Shiftofe talc.

Its ftructure is flaty. Fracture hackly and long fplintery. Eafily crumbles when rubbed in the fracture. External luftre 2 to 3; internal, 1: but fometimes, in certain pofitions, 3. Colour grey, with a fhade of white, green or blue. Becomes white and fcaly when expofed to the air.

A fpecimen of *common talc*, analyfed by Mr Chenevix, contained

48.0	filica,
37.0	alumina,
6.0	oxide of iron,
1.5	magnefia,
1.5	lime,
5.0	water,
99.0 §.	

§ Ann. de Chim. xxviii. 200.

SPECIES 8. Bafaltine ¶.

52 Bafaltine.

Bafaltic hornblende of Werner—*Actinote* of Hauy—*Zillertite* of Lametherie—*Shorl prifmatique hexagone* of Sauffure.

¶ Kirw. i. 219.

This ftone is found commonly in bafaltic rocks; hence its name, which we have borrowed from Mr Kirwan. It is cryftallized, either in rhomboidal prifms, or fix or eight fided prifms, terminated by three-fided pyramids. Its texture is foliated. Its fracture uneven. Luftre 3. Tranfparency, when in very thin plates, 1. Hardnefs from 9 to 10. Sp. gr. 3.333. Colour black, dark green, or yellowifh green. Streak white. Tranfmits a reddifh yellow light. Before the blow-pipe, it melts into a greyifh coloured enamel, with a tint of yellow *. A fpecimen, feemingly of this ftone, analyfed by Bergman, contained

*Le Lievre, Jour. de Min. N° xxviii. 269.

58	filica,
27	alumina,
9	iron,
4	lime,
1	magnefia,
99 †.	

† Berg. iii. 207.

SPECIES 9. Hornblende ‡.

Amphibole of Hauy (E).

53 Hornblende.

This ftone enters into the compofition of various mountains. Its texture is very confpicuoufly foliated. Fracture conchoidal. Fragments often rhomboidal. Luftre 2. Opaque. Hardnefs 5 to 9. Tough. Sp. gr. 2.922 to 3.41. Colour black, blackifh green, olive green,

‡ Kirw. i. 213.

(B) *Hift. General de Voyages*, T. XVIII. 272, quoted by Hauy *Jour. de Min.* N° XXVIII. 299.

(C) Black mica is often nearly opaque.

(D) *Hauy, ibid.* p. 795. Bergman, however, found pure mica infufible *per fe*; and this has been the cafe with all the fpecimens of Mufcovy glafs which we have tried.

(E) We fufpect, that under this name Mr Hauy comprehends *fhorl* alfo.

Earths and Stones.

green, or leek green. Streak greenifh. It neither becomes electric by friction nor heat*. Before the blow-pipe it melts into a black glafs. A fpecimen of black hornblende, analyfed by Mr Hermann, was compofed of

* Hauy, Jour. de Min. No xxviii. 267.

37 filica,
27 alumina,
25 iron,
5 lime,
3 magnefia.

97 †

† Beob. der Berlin, 5. Band. 317

54 Refplendent hornblende.

SPECIES 10. Refplendent Hornblende.

There are two minerals which Werner confiders as varieties of hornblende, and Mr. Kirwan as conftituting a diftinct fpecies These till future analyfes decide the point, we fhall place here under the name of refplendent hornblende, the name given them by Mr Kirwan ; and we fhall defcribe them feparately.

Variety 1. Labradore hornblende.

Texture, curved foliated. Luftre, in fome pofitions, o ; in others metallic, and from 3 to 4. Opaque. Hardnefs 8 to 9. Sp. gr. from 3.35 to 3.434. Colour, in moft pofitions, greyifh black ; in others, it reflects a ftrong iron grey, fometimes mixed with copper red.

Variety 2. Shiller fpar ‡.

‡ Kirw. i. 221.

Texture foliated. Luftre metallic, 4. Tranfparency, in thin pieces, 1. Hardnefs 8 to 9. Sp. gr. 2.882. Colour green, often with a fhade of yellow ; alfo golden yellow. In fome pofitions it reflects white, grey, or yellow. At 141 Wedgewood, hardened into a porcelain mafs. A fpecimen, analyfed by Gmelin, was compofed of

43.7 filica,
17 9 alumina,
23.7 iron,
11.2 magnefia.

——
96.5 §

§ Bergbaukunde, 1 Band. p. 92.

It has been found in the Hartz, ftuck in a ferpentine rock.

55. Obfidian.

SPECIES 11. Obfidian *.

* Kirw. i. 264.

Iceland agate.

This ftone is found either in detached maffes, or forming a part of the rocks which compofe many mountains. It is ufually invefted with a grey or opaque cruft. Its fracture is conchoidal. Its internal luftre 3. Tranfparency 1. Hardnefs 10. Sp. gr. 2.348. Colour black or greyifh black; when in very thin pieces, green. It melts into an opaque grey mafs. According to Bergman, it is compofed of

69 filica,
22 alumina,
9 iron.

——
100 †

† Berg. iii. 204.

56 Petrilite.

SPECIES 12. Petrilite ‡.

‡ Kirw. i. 325.

Cubic felfpar.

This ftone is found in the mafs of mountains. It is amorphous. Texture foliated. Fracture fplintery. Fragments cubic, or inclining to that form ; their faces unpolifhed. Luftre 2. Tranfparency partly 2, partly 1. Hardnefs 9. Sp. gr. 3.081. Colour reddifh brown. Does not melt at 160° Wedgewood.

57 Felfite

SPECIES 13. Felfite §.

§ Kirw. i. 326.

Compact felfpar.

This ftone alfo forms a part of many mountains, and is amorphous. Texture fomewhat foliated. Fracture uneven, approaching to the fplintery. Luftre 1. Tranfparency fcarce 1. Hardnefs 9. Colour azure blue, and fometimes brown and green Streak white. Before the blow-pipe, whitens and becomes rifty ; but is infufible *per fe*.

Simple Stones.

58 G. VII. SAP. Felfpar.

GENUS VII. SAP.

SPECIES 1. Felfpar *.

* Kirw. i. 310. and Jour de Phyf. paffim.

This ftone forms the principal part of many of the higheft mountains. It is commonly cryftallized. Its primitive form, according to De Lifle, is a rectangular prifm, whofe bafes are rhombs, with angles of 65° and 115†°. Sometimes the edges of the prifm are wanting, and faces in their place ; and fometimes this is the cafe alfo with the acute angles of the rhomb. For a defcription and figure of thefe, and other varieties, we refer the reader to *Romé de Lifle*‡, *Mr Hauy* §, and *Mr Pini* *.

† Fig. 13. and 14.

‡ Cryftall. ii. 401.

§ Mem. Par. 1784, p 273.

* Sur de Nouvelle Cbryftallifation, &c. 8.

Its texture is foliated. Its crofs fracture uneven. Fragments rhomboidal, and commonly fmooth and polifhed on four fides. Luftre of the polifhed faces often 3. Tranfparency from 3 to 1. Hardnefs 9 to 10. Sp. gr. from 2.437 to 2.7. Gives a peculiar odour when rubbed. It is made electric with great difficulty by friction. Fufible *per fe* into a more or lefs tranfparent glafs. When cryftallized, it decrepitates before the blow-pipe.

Variety 1. Pure Felfpar.

Moon ftone—Adularia.

This is the pureft felfpar hitherto found. It occurs in Ceylon and Switzerland ; and was firft mentioned by Mr Sage. Luftre nearly 3. Tranfparency 2 to 3. Hardnefs 10. Sp. gr. 2.559. Colour white ; fometimes with a fhade of yellow, green, or red. Its furface is fometimes iridefcent.

Variety 2. Common Felfpar.

Luftre of the crofs fracture o ; of the fracture, in the direction of the laminæ, from 3 to 1. Tranfparency 2 to 1. Colour moft commonly flefh red ; but often bluifh grey, yellowifh white, milk white, brownifh yellow ; and fometimes blue, olive green, and even black.

Variety 3. Labradore felfpar.

This variety was difcovered on the coaft of Labradore by Mr Wolfe ; and fince that time it has been found in Europe. Luftre 2 to 3. Tranfparency from 1 to 3. Sp. gr. from 2.67 to 2 6925. Colour grey. In certain pofitions, fpots of it reflect a blue, purple, red, or green colour.

Variety 4. Continuous felfpar.

This variety moft probably belongs to a different fpecies ; but as it has not hitherto been analyfed, we did not think ourfelves at liberty to alter its place.

It is found in large maffes. Texture earthy. Fracture uneven, fometimes fplintery Luftre o. Tranfparency 1. Hardnefs 10. Sp gr. 2.609. Colour reddifh grey, reddifh yellow, flefh red.

A fpecimen of green felfpar from Siberia, analyfed by Vauquelin, contained

62.83 filica,
17.02 alumina,
16.00 potafs,
3.00 lime,
1.00 oxide of iron.

——
99.85†

* *Klaproth*
† *Hauy*
‡ *Le Lievre, Jour de Min.* N° li. 219.
§ *Ibid.*
* *Klaproth, Ann. de Chim.* xxii. 37.

This ftone was firft called lilalite from its colour, that of the *lily*. Klaproth, who difcovered its component parts, gave it the name of *lepidolite* (G).

It is compofed of
53 filica,
20 alumina,
18 potafs,
5 fluat of lime,
3 oxide of manganefe,
1 oxide of iron.

100 †

† *Vauquelin, Ann. de Chim.* xxx. 105.

60 Leucite.

SPECIES 3. Leucite ‡

Vefuvian of Kirwan—*White Garnet* of Vefuvius.

This ftone is ufually found in volcanic productions, and is very abundant in the neighbourhood of Vefuvius. It is always cryftallized. The primitive form of its cryftals is either a cube or a rhomboidal dodecahedron, and its integrant molecules are tetrahedrons; but the varieties hitherto obferved are all polyhedrons: The moft common has a fpheroidal figure, and is bounded by 24 equal and fimilar trapeziods §; fometimes the faces are 12, 18, 36, 54, and triangular, pentagonal, &c. For a defcription and figure of feveral of thefe, we refer the reader to Mr Hauy *. The cryftals vary from the fize of a pin-head to that of an inch.

‡ *Kirw.* i. 285.
§ Fig. 15.
* *Jour. de Min.* N° xxvii. 185.

The texture of the leucite is foliated. Its fracture fomewhat conchoidal. Luftre 3; when in a ftate of decompofition 0. Tranfparency 3 to 2; when decompofing 0. Hardnefs 8 to 10; when decompofing 5 to 6. Sp. gr. 2.4648. Colour white, or greyifh white (H). Its powder caufes fyrup of violets to affume a green colour †. It is compofed, as Klaproth has fhewn, of
54 filica,
23 alumina,
22 potafs,

99 (I)

† *Vauquelin, Jour. de Min.* N° xxxix. 165.

It was by analyfing this ftone that Klaproth difcovered the prefence of potafs in the mineral kingdom; which is not the leaft important of the numerous difcoveries of that accurate and illuftrious chemift.

Leucite is found fometimes in rocks which have never been expofed to volcanic fire; and Mr. Dolomieu has rendered it probable, from the fubftances in which it is found, that the leucite of volcanoes has not been formed by volcanic fire, but that it exifted previoufly in the rocks upon which the volcanoes have acted, and that it was thrown out unaltered in fragments of thefe rocks ‡.

‡ *Jour. de Min.* N° xxxix. 177.

GENUS VIII. SAG.

61 G.VIII.SAG Emerald.

SPECIES 1. Emerald (K).

This ftone has hitherto been only found cryftallized. The primitive form of its cryftals is a regular fix-fided prifm; and the form of its integrant molecules is a triangular prifm, whofe fides are fquares, and bafes equilateral triangles §. The moft common variety of its cryftals is the regular fix-fided prifm, fometimes with the edges of the prifm or of the bafes, or the folid angles, or both wanting *, and fmall faces in their place †. The fides of the prifm are generally channelled.

§ *Hauy, Jour. de Min.* N° xix. 72
* Fig. 16.
† *Romé de Lifle*, ii. 245. and *Hauy, ibid.*

Its texture is foliated. Its fracture conchoidal. Luftre ufually from 3 to 4. Tranfparency from 2 to 4. Caufes a double refraction. Hardnefs 12. Sp. gr. 2.65 to 2.775. Colour green. Becomes electric by friction, but not by heat. Its powder does not phofphorefce when thrown on a hot iron ‡. At 150° Wedgewood it melts into an opaque coloured mafs. According to Dolomieu, it is fufible *per fe* by the blow-pipe *.

‡ *Dolomieu. Jour. de Min.* N° xviii. 19.
* *Ibid.*

This mineral was formerly fubdivided into two diftinct fpecies, the *emerald*, and *beryl* or *aqua marina*. Hauy demonftrated, that the emerald and beryl correfponded exactly in their ftructure and properties, and Vauquelin found that they were compofed of the fame ingredients; henceforth, therefore, they muft be confidered as varieties of the fame fpecies.

The variety formerly called *emerald* varies in colour from the pale to the perfect green. When heated to 120° Wedgewood, it becomes *blue*, but recovers its colour when cold. A fpecimen, analyfed by Vauquelin, was compofed of
64.60 filica,
14.00 alumina,
13.00 glucina,
3.50 oxide of chromum,
2.56 lime,
2.00 moifture or other volatile ingredient.

99.66 †

† *Ann. de Chim.* xxvi. 264.

The *beryl* is of a greyifh green colour, and fometimes blue, yellow, and even white: fometimes different colours appear in the fame ftone ‡ It is found in Ceylon, different parts of India, Brazil, and efpecially in Siberia and Tartary, where its cryftals are fometimes a foot long §.

62 G. IX. SAB Staurolite.

Genus IX. sab.

Species 1. Staurolite †.

† Kirw. i. 282.

Andreolite of Lametherie and Hauy—*Hyacinthe blanche cruciforme*, var. 9 of Romé de Lisle.

This stone has been found at Andreasberg in the Hartz. It is crystallized, and the form of its crystals has induced mineralogists to give it the name of *cross-stone*. Its crystals ‡ are two four-sided flattened prisms, terminated by four sided pyramids, intersecting each other at right angles: the plane of intersection passing longitudinally through the prisms (L).

‡ Fig. 17.

Its texture is foliated. Its lustre waxy, 2. Transparency from 1 to 3. Hardness 9. Brittle. Sp. gr. 2.355 to 2.361. Colour milk white. When heated slowly, it loses 0.15 or 0.16 parts of its weight, and falls into powder. It effervesces with borax and microcosmic salt, and is reduced to a greenish opaque mass. With soda it melts into a frothy white enamel. When its powder is thrown on a hot coal, it emits a greenish yellow light §.

§ Hauy, Jour. de Min. N° xxviii. 280.

A specimen analysed by Westrum was composed of

44	silica,
20	alumina,
20	barytes,
16	water.
100	

Klaproth found the same ingredients, and nearly in the same proportions *.

* Beiträge, ii. 80.

A variety of staurolite has been found only once, which has the following peculiarities.

Its lustre is pearly, 2. Sp. gr. 2.361. Colour brownish grey. With soda it melts into a purplish and yellowish frothy enamel. It is composed, according to Westrum, of

47.5	silica,
12.0	alumina,
20.0	barytes,
16.0	water,
4.5	oxides of iron and manganese.
100.0	

63 G. X. ASL. Chrysoberyl.

Genus X. 1. asl.

Species 1. Chrysoberyl †.

† Kirw. i. 261.

Oriental chrysolite of jewellers—*Cymophane* of Hauy.

Hitherto this stone has been found only in Brazil, the island of Ceylon, and as some affirm near Nortschink in Siberia. Werner first made it a distinct species, and gave it the name which we have adopted. It is usually found in round masses about the size of a pea, but it is sometimes also crystallized. The primitive form of its crystals is a four-sided rectangular prism, whose height is to its breadth as $\sqrt{3}$ to 1, and to its thickness as $\sqrt{2}$ to 1 *. The only variety hitherto observed is an eight-sided prism, terminated by six-sided summits †. Two of the faces of the prism are hexagons, two are rectangles, and four trapeziums; two faces of the summits are rectangles, and the other four trapeziums. Sometimes two of the edges of the prism are wanting, and small faces in their place ‡.

Simple Stones.

* Fig. 18.
† Fig. 19.
‡ Hauy, Jour. de Min. N° xxi. 5.

Its texture is foliated. Laminæ parallel to the faces of the prism. Lustre 3 to 4. Transparency 3 to 4. Causes single refraction. Hardness 12. Sp. gr. from 3.698 § to 3.7961 *. Colour yellowish green, surface sparkling. It is infusible by the blow-pipe *per se*, and with soda.

§ Werner.
* Hauy.

A specimen of chrysoberyl, analysed by Klaproth, was composed of

71.5	alumina,
18.0	silica,
6.0	lime,
1.5	oxide of iron.
97.0 †

4	water.
100 †	

† Ibid.

(L) See *Gillot*, *Jour. de Phys.* 1793, p. 1 and 2.

(M) Hence probably the name *hyalite*, which was imposed by Werner from ὕαλις, and λιθος, *a stone*.

Earths and Stones.

GENUS X. 3. SAWL.

SPECIES 4. Zeolite (N).

66 G. X. 3. SAWL. Zeolite.

This ſtone was firſt deſcribed by Cronſtedt in the Stockholm Tranſactions for 1756. It is found ſometimes amorphous and ſometimes cryſtallized. The primitive form of its cryſtals is a rectangular priſm, whoſe baſes are ſquares. The moſt common variety is a long four-ſided priſm, terminated by low four-ſided pyramids*.

* Hauy, Jour. de Min. N° xiv. 86.

Its texture is ſtriated or fibrous. Its luſtre is ſilky, from 3 to 1. Tranſparency from 2 to 4; ſometimes 1. Hardneſs 6 to 8; ſometimes only 4. Abſorbs water. Sp gr. 2.07 to 2.3. Colour white, often with a ſhade of red or yellow; ſometimes brick red, green, blue. When heated, it becomes electric like the tourmaline †. Before the blow-pipe it froths (O), emits a phoſphoreſcent light, and melts into a white ſemitranſparent enamel, too ſoft to cut glaſs, and ſoluble in acids. In acids it diſſolves ſlowly and partially without efferveſcence; and at laſt, unleſs the quantity of liquid be too great, it is converted into a jelly.

† Hauy, ibid N° xxviii. 276.

A ſpecimen of zeolite (P), analyſed by Vauquelin, contained

53.00	ſilica,
27.00	alumina,
9.46	lime,
10.00	water.
99.46 ‡.	

‡ Ibid. N° xliv. 576.

SPECIES 5. Stilbite.

67 Stilbite.

This ſtone was firſt formed into a diſtinct ſpecies by Mr Hauy. Formerly it was conſidered as a variety of zeolite.

The primitive form of its cryſtals is a rectangular priſm, whoſe baſes are rectangles. It cryſtallizes ſometimes in dodecahedrons, conſiſting of a four ſided priſm with hexagonal faces, terminated by four-ſided ſummits, whoſe faces are oblique parallelograms; ſometimes in ſix-ſided priſms, two of whoſe ſolid angles are wanting, and a ſmall triangular face in their place *.

* Hauy, Jour. de Min. N° xiv. 86.

Its texture is foliated. The laminæ are eaſily ſeparated from each other; and are ſomewhat flexible. Luſtre pearly, 2 or 3 (Q). Hardneſs inferior to that of zeolite, which ſcratches ſtilbite. Brittle. Sp. gr. 2.500†. Colour pearl white. Powder bright white, ſometimes with a ſhade of red. This powder, when expoſed to the air, cakes and adheres as if it had abſorbed water. It cauſes ſyrup of violets to aſſume a green colour. When ſtilbite is heated in a porcelain crucible, it ſwells up and aſſumes the colour and ſemitranſparency of baked porcelain. By this proceſs it loſes 0.185 of its weight. Before the blow-pipe it froths like borax, and then melts into an opaque white-coloured enamel ‡.

† Hauy, ibid. N° xxviii. 276.

‡ Vauquelin, ibid. N° xxxix. 161.

According to the analyſis of Vauquelin, it is compoſed of

Simple Stones.

52.0	ſilica,
17.5	alumina,
9.0	lime,
18.5	water.
97.0 *	

* Ibid. 164.

SPECIES 6. Analcime.

68 Analcime.

This ſtone, which was diſcovered by Mr Dolomieu, is found cryſtallized in the cavities of lava. It was firſt made a diſtinct ſpecies by Mr Hauy. Mineralogiſts had formerly confounded it with zeolite.

The primitive form of its cryſtals is a cube. It is ſometimes found cryſtallized in cubes, whoſe ſolid angles are wanting, and three ſmall triangular faces in place of each; ſometimes in polyhedrons with 24 faces. It is uſually ſomewhat tranſparent. Hardneſs about 8; ſcratches glaſs ſlightly. Sp. gr. above 2. When rubbed, it acquires only a ſmall degree of electricity, and with difficulty (R). Before the blow-pipe it melts without frothing, into a white ſemitranſparent glaſs†.

† Hauy, Jour. de Min. N° xiv. 86. and xxviii. 278.

GENUS X. 4. SLA.

SPECIES 7. Lazulite ‡.

69 G.X. 4. SLA. Lazulite.

This ſtone, which is found chiefly in the northern parts of Aſia, has been long known to mineralogiſts by the name of *lapis lazuli*. This term has been contracted into *lazulite* by Mr Hauy; an alteration which was certainly proper, and which therefore we have adopted.

‡ Kirw. i. 283.

Lazulite is always amorphous. Its texture is earthy. Its fracture uneven. Luſtre 0. Opaque, or nearly ſo. Hardneſs 8 to 9. Sp. gr. 2.76 to 2.945 *. Colour blue (S); often ſpotted white from ſpecks of quartz, and yellow from particles of pyrites.

* Briſſon.

It retains its colour at 100° Wedgewood; in a higher heat it intumeſces, and melts into a yellowiſh black maſs. With acids it efferveſces a little, and if previouſly calcined, forms with them a jelly.

Margraff publiſhed an analyſis of lazulite in the Berlin Memoirs for 1758. His analyſis has ſince been confirmed by Klaproth, who found a ſpecimen of it to contain

46.0	ſilica,
14.5	alumina,
28.0	carbonat of lime,
6.5	ſulphat of lime,
3.0	oxide of iron,
2.0	water.
100.0 †	

† Beiträge, i. 196.

GENUS XI. SALI.

SPECIES 1. Garnet (T).

70 G.XI. SALI. Garnet.

This ſtone is found abundantly in many mountains. It is uſually cryſtallized. The primitive form of its cryſtals

(N) *Kirw.* I. 278.—*Guettard*, IV. 637.—*Bucquet*, *Mem. Sav. Etrang.* IX. 576.—*Pelletier*, *Jour. de Phyſ.* XX. 420.

(O) Hence the name *zeolite*, given to this mineral by Cronſtedt; from *ζεω, to ferment, λιθος, a ſtone.*

(P) Dr Black was accuſtomed to mention, in the courſe of his lectures, that Dr Hutton had diſcovered *ſoda* in zeolite. This diſcovery has not hitherto been verified by any other chemical mineralogiſt.

(Q) Hence the name given to this mineral by Hauy, *ſtilbite*, from *στιλβω, to ſhine.*

(R) Hence the name *analcime* given it by Hauy, from *αναλκις, weak.*

(S) Hence the name *lazulite*, from an Arabian word *azul*, which ſignifies *blue*.

Earths and Stones.

crystals is a dodecahedron whose sides are rhombs, with angles of 78° 31′ 44″, and 120° 28′ 16″. The inclination of the rhombs to each other is 120°. This dodecahedron may be considered as a four-sided prism, terminated by four-sided pyramids *. It is divisible into four parallelopipeds, whose sides are rhombs; and each of these may be divided into four tetrahedrons, whose sides are isosceles triangles, equal and similar to either of the halves into which the rhomboidal faces of the dodecahedron are divided by their shorter diagonal. The integrant molecules of garnet are similar tetrahedrons †. Sometimes the edges of the dodecahedrons are wanting, and small faces in their place; and sometimes garnet is crystallized in polyhedrons, having 24 trapezoidal faces. For a description and figure of these, and other varieties of garnet, we refer to *Romé de Lisle* and *Hauy* ‡.

* Fig. 20. * *De Lisle*, ii 322. and *Hauy, Ann. de Chim.* xvii. 305.

† *Hauy, ibid.* 306.

‡ *Ibid.*

The texture of garnet, as Bergman first shewed, is foliated §. Its fracture commonly conchoidal. Internal lustre from 4 to 2. Transparency from 2 to 4; sometimes only 1 or 0. Causes single refraction ‖. Hardness from 10 to 14. Sp. gr. 3.75 to 4.188. Colour usually red. Often attracted by the magnet. Fusible *per se* by the blow-pipe.

§ *Opusc.* ii. 9.

‖ *Hauy, Jour de Min* N° xxviii. 260.

Variety 1. Oriental garnet (u).

Internal lustre 3 to 4. Transparency 4. Hardness 13 to 14. Sp. gr. 4 to 4.188. Colour deep red, inclining to violet (x).

Variety 2. Common garnet.

Fracture uneven, inclining to the conchoidal. Internal lustre 2 to 3. Transparency from 3 to 0. Hardness 10 to 11; sometimes only 9. Sp. gr. 3.75 to 4. Colour commonly deep red, inclining to violet; sometimes verging towards black or olive; sometimes leek green, brown, yellow.

Variety 3. Amorphous garnet.

Structure slaty. Lustre 2. Transparency 2 to 1. Hardness 11 to 12. Sp. gr. 3.89. Colour brownish or blackish red. Found in Sweden, Switzerland, and the East Indies.

GENUS XII. 2. MSA.

SPECIES 2. Serpentine (B).

75
G. XII. 2.
MSA.
Serpentine.

This ſtone is found in amorphous maſſes. Its fracture is ſplintery. Luſtre 0. Opaque. Hardneſs 6 to 7. Sp. gr. 2.2645 to 2.709. Feels rather ſoft, almoſt greaſy. Generally emits an earthy ſmell when breathed upon. Its colours are various ſhades of green, yellow, red, grey, brown, blue: commonly one or two colours form the ground, and one or more appear in ſpots or veins (c).

Before the blow-pipe it hardens and does not melt.

A ſpecimen of ſerpentine, analyſed by Mr Chenivix, contained

34.5	magneſia,
28.0	ſilica,
23.0	alumina,
4.5	oxide of iron,
0.5	lime,
10.5	water.
101.0 §	

§ Ann. de Chim. xxviii. 199.

GENUS

(z) Hence the name *thallite* given it by Lametherie, from θαλλος, *a green leaf.*

(A) Hence the name *cyanite*, impoſed by Werner.

(B) *Kirw.* I. 156.—*Margraf, Mem. Berlin*, 1759, p. 3.—*Bayen, Jour. de Phyſ.* XIII. 46.—*Mayer, Crell's Annals*, 1789, II. 416.

(c) Hence the name *ſerpentine*, given to the ſtone from a ſuppoſed reſemblance in colours to the ſkin of a ſerpent.

Earths and Stones.

Simple Stones.

GENUS XIII. MSAI.

76 G. XIII. MSAI. Potſtone. *Kirw.* i. 55.

SPECIES 1. Potſtone *.

This ſtone is found in neſts and beds, and is always amorphous. Its ſtructure is often ſlaty. Texture undulatingly foliated. Luſtre from 1 to 3. Tranſparency from 1 to 0; ſometimes 2. Hardneſs 4 to 6. Brittle. Sp. gr. from 2.8531 to 3.023. Feels greaſy. Sometimes abſorbs water. Colour grey with a ſhade of green, and ſometimes of red or yellow; ſometimes leek green; ſometimes ſpecked with red.

Potſtone is not much affected by fire; and has therefore been made into utenſils for boiling water; hence its name.

According to Wiegleb, the potſtone of Como contains

38	magneſia,
38	ſilica,
7	alumina,
5	iron,
1	carbonat of lime,
1	fluoric acid.
90	

77 Chlorite. *Kirw.* i. 47.

SPECIES 2. Chlorite †.

This mineral enters as an ingredient into different mountains. It is ſometimes amorphous, and ſometimes cryſtallized in oblong, four-ſided, acuminated cryſtals.

Its texture is foliated. Its luſtre from 0 to 2. Opaque. Hardneſs from 4 to 6; ſometimes in looſe ſcales. Colour green.

Variety 1. Farinaceous chlorite.

Compoſed of ſcales ſcarcely cohering, either heaped together, or inveſting other ſtones. Feels greaſy. Gives an earthy ſmell when breathed on. Difficult to pulveriſe. Colour graſs green; ſometimes greeniſh brown; ſometimes dark green, inclining to black. Streak white. When the powder of chlorite is expoſed to the blow-pipe it becomes brown. Before the blow-pipe, farinaceous chlorite froths and melts into a dark brown glaſs; with borax it forms a greeniſh brown glaſs ‡.

‡ *Vauquelin, Jour. de Min.* Nº xxix. 167.

Variety 2. Indurated chlorite.

This variety is cryſtallized. Luſtre 1. Hardneſs 6. Feel meagre. Colour dark green, almoſt black. Streak mountain green.

Variety 3. Slaty chlorite.

Structure ſlaty. Fragments flatted. Internal luſtre 1 to 2. Hardneſs 5. Colour greeniſh grey, or dark green inclining to black. Streak mountain green.

A ſpecimen of the firſt variety, analyſed by Vauquelin, contained

43.3	oxide of iron,
26.0	ſilica,
15.5	alumina,
8.0	magneſia,
2.0	muriat of potaſs,
4.0	water.
98.8 §	

§ *Ann. de Chim.* xxx. 306.

A ſpecimen of the ſame variety yielded Mr Hœpner

12.92	oxide of iron,
37.50	ſilica,
4.17	alumina,
43.75	magneſia,
1.66	lime.
100.0 *	

* *Sauſſure's Voyages*, ii. 133.

A ſpecimen of the ſecond variety, analyſed by the ſame chemiſt, contained

10.15	oxide of iron,
41.15	ſilica,
6.13	alumina,
39.47	magneſia,
1.50	lime,
1.50	air and water.
99.90 †	

† *Crell's Annals*, 1790, p. 56.

On the ſuppoſition that theſe analyſes are accurate, the enormous difference between them is a demonſtration that chlorite is not a chemical combination, but a mechanical mixture.

GENUS XIV. SLAM.

78 G. XIV. SLAM. Siliceous-ſpar.

SPECIES 1. Siliceous ſpar (D).

This ſtone has been found in Tranſylvania. It is cryſtallized in 4 or 6 ſided priſms, channelled tranſverſely, and generally heaped together. Its texture is fibrous. Its luſtre ſilky, 2. Its colours white, yellow, green, light blue. According to Bindheim, it contains

61.1	ſilica,
21.7	lime,
6.6	alumina,
5.0	magneſia,
1.3	oxide of iron,
3.3	water.
99.0 *	

* *Berg.* vi. 104.

GENUS XV. SAMLI.

79 G. XV. SAMLI. Argillite. † *Kirw.* i. 234.

SPECIES 1. Argillite †.

Argillaceous ſhiſtus—Common ſlate.

This ſtone conſtitutes a part of many mountains. Its ſtructure is ſlaty. Its texture foliated. Fracture ſplintery. Fragments often tabular. Luſtre, moſt commonly ſilky, 2; ſometimes 0. Tranſparency from 0 to 1. Hardneſs from 5 to 8. Sp. gr. from 2.67 to 2.88. Does not adhere to the tongue. Gives a clear ſound when ſtruck. Often imbibes water. Streak white or grey. Colour moſt commonly grey, with a ſhade of blue, green, or black; ſometimes purpliſh, yellowiſh mountain green, brown, bluiſh black: ſometimes ſtriped or ſpotted with a darker colour than the ground.

It is compoſed, according to Kirwan, of ſilica, alumina, magneſia, lime, oxide of iron. In ſome varieties the

(D) Is this the *tremolite* of Lowitz from the lake Baikal in Siberia? If ſo, the name of the genus ought to be SLM; for he found it contain no alumina. According to his analyſis, it was compoſed of

52	ſilica,
20	lime,
12	carbonat of lime,
12	magneſia,
96	

The

Earths and Stones.

the lime is wanting. Several varieties contain a conſiderable quantity of carbonaceous matter.

G. XVI. SLACMI. Smaragdite.

GENUS XVI. SLACMI.

SPECIES 1. Smaragdite.

This ſtone was called *ſmaragdite* by Mr Sauſſure, from ſome reſemblance which it has to the emerald. Its texture is foliated. The laminæ are inflexible. Fracture even. Hardneſs 7. Colour in ſome caſes fine green, in others it has the grey colour and metallic luſtre of mica: it aſſumes all the ſhades of colour between theſe two extremes *.

According to the analyſis of Vauquelin, it is compoſed of

50.0	ſilica,
13.0	lime,
11.0	alumina,
7.5	oxide of chromum,
6.0	magneſia,
5.5	oxide of iron,
1.5	oxide of copper.

81 G. XVII. SM. Kiffekil.

GENUS XVII. SM.

SPECIES 1. Kiffekil ‡.

Myrſen—Seafroth.

This mineral is dug up near Konie in Natolia, and is employed in forming the bowls of Turkiſh tobacco pipes. The ſale of it ſupports a large monaſtery of derviſes eſtabliſhed near the place where it is dug. It is found in a large fiſſure ſix feet wide, in grey calcareous earth. The workmen aſſert, that it grows again in the fiſſure §, and puffs itſelf up like froth (E). This mineral, when freſh dug, is of the conſiſtence of wax; it feels ſoft and greaſy; its colour is yellow; its ſp. gr. 1.600 *: when thrown on the fire it ſweats, emits a fetid vapour, becomes hard, and perfectly white.

According to the analyſis of Klaproth, it is compoſed of

50.50	ſilica,
17.25	magneſia,
25.00	water,
5.00	carbonic acid,
.50	lime.
98.25 †

† *Beiträge,* ii. 172.

82 Steatites.

SPECIES 2. Steatites (F).

Though this mineral was noticed by the ancients, little attention was paid to it by mineralogiſts, till Mr Pott publiſhed his experiments on it in the Berlin Memoirs for 1747.

It is uſually amorphous, but ſometimes it is cryſtallized in ſix-ſided priſms. Its texture is commonly earthy, but ſometimes foliated. Luſtre from 0 to 2. Tranſpareney from 0 to 2. Hardneſs 4 to 7. Sp. gr. from 2.61 to 2.794 ‡. Feels greaſy. Seldom adheres to the tongue. Colour uſually white or grey; often with a tint of other colours; the foliated commonly green. Does not melt *per ſe* before the blow-pipe.

‡ *Briſſon.*

Simple Stones.

Variety 1. Semi-indurated ſteatites.

Texture earthy. Fracture ſometimes coarſe ſplintery. Luſtre 0. Tranſparency 0, or ſcarce 1. Hardneſs 4 to 5. Abſorbs water. Takes a poliſh from the nail. Colour white, with a ſhade of grey, yellow, or green; ſometimes pure white; ſometimes it contains dendritical figures; and ſometimes red veins.

Variety 2. Indurated ſteatites.

Fracture fine ſplintery, often mixed with imperfectly conchoidal. External luſtre 2 to 1, internal 0. Tranſparency 2. Often has the feel of ſoap. Abſorbs water. Colour yellowiſh or greeniſh grey; often veined or ſpotted with deep yellow or red.

Variety 3. Foliated or ſtriated ſteatites.

The texture of this variaty is uſually foliated; ſometimes ſtriated. Fragments cubiform. Luſtre 3. Tranſparency 2 to 1. Hardneſs 6 to 7. Colour leek green, paſſing into mountain green or ſulphur yellow. Streak pale greeniſh grey. When heated to redneſs, it becomes grey; and at 147° Wedgewood, it forms a grey porous porcelain maſs*.

A ſpecimen of ſteatites, analyſed by Klaproth, contained

59.5	ſilica,
30.5	magneſia,
2.5	iron,
5.5	water.

Earths and Stones. Hardnefs 9 to 10. Brittle. Sp. gr. from 3.265 to 3.45. Colour green. It is infufible at 150°, but lofes its tranfparency, and becomes blackifh grey *. With borax it melts without effervefcence into a tranfparent glafs of a light green colour. Infufible with microcofmic falt † and fixed alkali ‡.

* Kir. Min. i. 263.

† Vauquelin, Ann. de Chim. xxi. 97.

Variety 1. Common chryfolite.

Found in Ceylon, and South America, and in Bohemia, amidft fand and gravel §. Luftre 3 to 4. Tranfparency 4 to 3. Colour yellowifh green, fometimes verging to olive green, fometimes to pale yellow.

‡ Kirw. ibid. § Coquebert, Jour. de Min. N° xxii. 20.

Variety 2. Olive chryfolite—*Olivine* *.

* Kirwan's Min. i. 263—Le Lievre, Jour. de Phyf. xxx. 397.

Found commonly among traps and bafalts; fometimes in fmall grains, fometimes in pretty large pieces; but it has not been obferved in cryftals. Luftre 2 to 3. Tranfparency 3 to 2. Colour olive green.

The firft variety, according to the analyfis of Klaproth, is compofed of 41.5 magnefia,
38.5 filica,
19.0 oxide of iron.

99.0 †

† Klaprotb's Beiträge, i. 103.

According to that of Vauquelin, it is compofed of
51.5 magnefia,
38.0 filica,
9.5 oxide of iron.

99.0 ‡

‡ Ann de Chim. ibid.

The fecond variety, according to the analyfis of Klaproth, is compofed of 37.58 magnefia,
50.00 filica,
11.75 oxide of iron,
.21 lime.

99.54 §

§ Beiträge, i. 112.

Species 2. Jade (H).

84 Jade.

This ftone was formerly called *lapis naphriticus*, and was much celebrated for its medical virtues. It is found in Egypt, China, America, and in the Siberian and Hungarian mountains. It is fometimes adhering to rocks, and fometimes in detached round pieces.

Its furface is fmooth. Its fracture fplintery. External luftre 0, or fcarce 1; internal waxy, 1. Tranfparency from 2 to 1. Hardnefs 10. Not brittle. Sp. gr. from 2.95 to 2.9829; or, according to Sauffure, to 3 389. Feels greafy. Looks as if it had imbibed oil. Colour dark leek green, or verging towards blue; in fome prominences inclining to greenifh or bluifh white. When heated it becomes more tranfparent and brittle, but is infufible *per fe*. According to Hoepfner, it is compofed of
47 filica,
38 carbonat of magnefia,
9 iron,
4 alumina,
2 carbonat of lime.

100

This is the ftone in which the inhabitants of New Zealand make into hatchets and other cutting inftruments.

Genus XIX. sml.

species 1. Afbeftus (I).

85 G. XIX. sml. Afbeftus.

This mineral was well known to the ancients. They even made a kind of cloth from one of the varieties, which was famous among them for its incombuftibility. It is found abundantly in moft mountainous countries, and no where more abundantly than in Scotland.

It is commonly amorphous. Its texture is fibrous. Its fragments often long fplintery. Luftre from 0 to 2; fometims 3, and then it is metallic. Tranfparency from 0 to 2. Hardnefs from 3 to 7. Sp. gr. from 2.7 to 0.6806. Abforbs water. Colour ufually white or green. Fufible *per fe* by the blow-pipe.

Variety 1. Common afbeftus.

Luftre 2 to 1. Tranfparency 1. Hardnefs 6 to 7. Sp. gr. 2.577 to 2.7. Feels fomewhat greafy. Colour leek green; fometimes olive or mountain green; fometimes greenifh or yellowifh grey. Streak grey. Powder grey.

Variety 2. Flexible afbeftus.

Amiantus.

Compofed of a bundle of threads flightly cohering. Fibres flexible. Luftre 1 to 2, fometimes 3. Tranfparency 1 to 2, fometimes 0. Hardnefs 3 to 4. Sp. gr. before it abforbs water, from 0.9088 to 2.3134; after abforbing water, from 1.5662 to 2.3803 *. Feels greafy. Colour greyifh or greenifh white; fometimes yellowifh or filvery white, olive or mountain green, pale flefh red, and mountain yellow.

* Briffon.

Variety 3. Elaftic afbeftus.

Mountain cork.

This variety has a ftrong refemblance to common cork. Its fibres are interwoven. Luftre commonly 0. Opaque. Hardnefs 4. Sp. gr. before abforbing water, from 0.6806 to 0.9933; after abforbing water, from 1.2492 to 1.3492. Feels meagre. Yields to the fingers like cork, and is fomewhat elaftic. Colour white; fometimes with a fhade of red or yellow; fometimes yellow or brown.

A fpecimen of the firft variety from Dalecarlia, analyfed by Bergman, contained
63.9 filica,
16.0 carbonat of lime,
12.8 carbonat of magnefia,
6.0 oxide of iron,
1.1 alumina.

92 G. XXI. SL. Shiſtoſe hornſtone.

GENUS XXI. SL.

SPECIES 1. Shiſtoſe hornſtone *.

* *Kirwan,* i. 305.

The ſtructure of this ſtone is ſlaty. Luſtre from 0 to 1. Commonly opaque. Hardneſs 9 to 10. Sp. gr. from 2.596 to 2.641. Colour dark bluiſh or blackiſh grey. Infuſible *per ſe*.

Variety 1. Siliceous ſhiſtus.

Commonly interſected by reddiſh veins of iron ſtone. Fracture ſplintery. Luſtre 0. Tranſparency from 0 to 1.

Variety 2. Baſanite or Lydian ſtone.

Commonly interſected by veins of quartz. Fracture even; ſometimes inclining to conchoidal. Luſtre ſcarce 1. Hardneſs 10. Sp. gr. 2.596. Powder black. Colour greyiſh black.

This, or a ſtone ſimilar to it, was uſed by the ancients as a touchſtone. They drew the metal to be examined along the ſtone, and judged of its purity by the

---

(K) *Kirw. Min.* I. 165. Is this the *tremolite* of Werner? It certainly is not the *tremolite* of the French mineralogiſts.

(L) Hence the name *pyroxen* given it by Hauy; from πυρ *fire*, and ξενος, *a ſtranger*. It means, as he himſelf explains it, *a ſtranger in the regions of fire*. By this he means to indicate, that pyroxen, though preſent in lava, is not a volcanic production.

(M) In this and the following ſpecies we have followed Mr. Kirwan's new arrangement exactly, without even venturing to give the ſynonimes of other authors. The deſcriptions which have been given are ſo many and incomplete, and the minerals themſelves are ſtill ſo imperfectly known, and have got ſo many names, that no part of mineralogy is in a ſtate of greater confuſion.

Earths and Stones.

the colour of the metallic streak. On this account they called it *βασανος, the trier*. They called it also *Lydian stone*, because, as Theophrastus informs us, it was found most abundantly in the river Tmolus in Lydia *. A specimen of the first variety, analysed by Wiegleb, contained

75.0	silica,
10.0	lime,
4.6	magnesia,
3.5	iron,
5.2	carbon.
98.3	

* Hill's Theophrastus, περι λιθων, p. 190.

This species is rather a mechanical mixture than a chemical combination.

93 G. XXII. zs. Zircon.

Genus XXII. zs.

SPECIES I. Zircon †.

Jargon—Hyacinth.

† Kirwan, i. 257. and 333.

This stone is brought from Ceylon, and found also in France, Spain, and other parts of Europe. It is commonly crystallized. The primitive form of its crystals is an octahedron ‡, composed of two four-sided pyramids applied base to base, whose sides are isosceles triangles (N). The inclination of the sides of the same pyramid to each other is 124° 12′; the inclination of the sides of one pyramid to those of another 82° 50′. The solid angle at the apex is 73° 44′ §. The varieties of the crystalline forms of zircon amount to seven. In some cases there is a four-sided prism interposed between the pyramids of the primitive form; sometimes all the angles of this prism are wanting, and two small triangular faces in place of each; sometimes the crystals are dodecahedrons, composed of a flat four-sided prism with hexagonal faces, terminated by four-sided summits with rhomboidal faces ‖; sometimes the edges of this prism, sometimes the edges where the prism and summit join, and sometimes both together, are wanting, and we find small faces in their place. For an accurate description and figure of these varieties, we refer to *Mr Hauy* ¶.

‡ Fig. 25.

§ Hauy, Jour. de Min. N° xxvi. 91.

‖ Fig. 26.

¶ Ibid.

The texture of the zircon is foliated. Internal lustre 3. Transparency from 4 to 2. Causes a very great double refraction. Hardness from 10 to 16. Sp. gr. from 4.2 to 4.165 *. Colour commonly reddish or yellowish; sometimes it is limpid.

* Ibid.

Before the blow-pipe it loses its colour, but not its transparency. With borax it melts into a transparent glass. Infusible with fixed alkali and microcosmic salt.

1. The variety formerly called *hyacinth* is of a yellowish red colour, mixed with brown. Its surface is smooth. Its lustre 3. Its transparency 3 to 4.

2 The variety formerly called *jargon of Ceylon*, is either grey, greenish, yellowish brown, reddish brown, or violet. It has little external lustre. Is sometimes nearly opaque.

The first variety, according to the analysis of Vauquelin, is composed of

64.5	zirconia,
32.0	silica,
2.0	oxide of iron.
98.5 †	

† Ibid. p. 106.

A specimen analysed by Klaproth contained

70.0	zirconia,
25.0	silica,
0.5	oxide of iron.
95.5 *	

* Beiträge, i. 231.

The second variety, according to Klaproth, who discovered the component parts of both these stones, contains

60.0	zirconia,
31.5	silica,
0.5	nickel and iron.
100.0 ‡	

‡ Ibid. i. 219.

Saline Stones.

Order II. SALINE STONES.

94 Genera.

Under this order we comprehend all the minerals which consist of an earthy basis combined with an acid. They naturally divide themselves into five genera. We shall describe them in the following order.

I. CALCAREOUS SALTS.
- Carbonat of lime,
- Sulphat of lime,
- Phosphat of lime,
- Fluat of lime,
- Borat of lime.

II. BARYTIC SALTS.
- Carbonat of barytes,
- Sulphat of barytes.

III. STRONTITIC SALTS.
- Carbonat of strontites,
- Sulphat of strontites.

IV. MAGNESIAN SALTS.
- Sulphat of magnesia.

V. ALUMINOUS SALTS.
- Alum.

95 G. I. Calcareous salts.

Genus I. CALCAREOUS SALTS.

This genus comprehends all the combinations of lime and acids which form a part of the mineral kingdom.

96 Carbonat of lime.

SPECIES I. Carbonat of lime.

No other mineral can be compared with carbonat of lime in the abundance with which it is scattered over the earth. Many mountains consist of it entirely, and hardly a country is to be found on the face of the globe where, under the names of limestone, chalk, marble, spar, it does not constitute a greater or smaller part of the mineral riches.

It is often amorphous, often stalactitical, and often crystallized. The primitive form of its crystals is a parallelopiped, whose sides are rhombs, with angles of 77° 30′ and 102° 30′ ‡. Its integrant molecules have the same form. The varieties of its crystals amount to more than 40; for a description and figure of which we refer to *Romé de Lisle* * and *Hauy* (O).

‡ Fig. 28.

* Crystal. i. 497.

When crystallized, its texture is foliated; when amorphous, its structure is sometimes foliated, sometimes striated, sometimes granular, and sometimes earthy. Its lustre

(N) Let ABC (fig. 27.) be one of the sides. Draw the perpendicular BD; then AB = 5, BD = 4, AD = 3.

(O) *Essai d'une Theorie*, &c. p. 75.—*Jour. de Phys.* 1793, August, p. 114.—*Jour. d'Hist. Nat.* 1792, February, p. 148.—*Ann. de Chim.* XVII. 249. &c.—*Jour. de Min.* N° XXVIII. 304.

luftre varies from o to 3. Tranfparency from o to 4. It caufes double refraction; and it is the only mineral which caufes double refraction through two parallel faces of the cryftal. Hardnefs from 3 to 9. Sp. gr. from 2.315 to 2.78. Colour, when pure, white. Effervefces violently with muriatic acid, and diffolves completely, or leaves but a fmall refiduum. The folution is colourlefs.

This fpecies occurs in a great variety of forms; and therefore has been fubdivided into numerous varieties. All thefe may be conveniently arranged under two general divifions.

I. Soft carbonat of lime.

Variety 1. Agaric mineral.

Mountain milk, or *mountain meal* of the Germans.

This variety is found in the clefts of rocks, or the bottom of lakes. It is nearly in the ftate of powder; of a white colour, fometimes with a fhade of yellow; and fo light that it almoft floats on water.

Variety 2. Chalk.

The colour of chalk is white, fometimes with a fhade of yellow. Luftre o. Opaque. Hardnefs 3 to 4. Sp. gr. from 2.315 to 2657. Texture earthy. Adheres flightly to the tongue. Feels dry. Stains the fingers, and marks. Falls to powder in water. It generally contains about $\frac{2}{100}$ of alumina, and $\frac{3}{100}$ of water; the reft is carbonat of lime.

Variety 3. Arenaceous limeftone.

Colour yellowifh white. Luftre 1. Tranfparency 1. So brittle that fmall pieces crumble to powder between the fingers. Sp. gr. 2.742. Phofphorefces in the dark when fcraped with a knife, but not when heated. It confifts almoft entirely of pure carbonat of lime.

Variety 4. Teftaceous tufa.

The colour of this variety is yellowifh or greyifh white. It is exceedingly porous and brittle; and is either compofed of broken fhells, or refembles mortar containing fhells; or it confifts of fiftulous concretions varioufly ramified, and refembling mofs.

II. Indurated carbonat of lime.

Variety 1. Compact limeftone.

The texture of this variety is compact. It has little luftre; and is moft commonly opaque. Hardnefs 5 to 8. Sp. gr. 1.3864 to 2.72. Colour grey, with various fhades of other colours. It moft commonly contains about $\frac{1}{10}$th of alumina, oxide of iron, &c.; the reft is carbonat of lime. This variety is ufually burnt as lime.

Variety 2. Granularly foliated limeftone.

Structure fometimes flaty. Texture foliated and granular. Luftre 2 to 1. Tranfparency 2 to 1. Hardnefs 7 to 8 Sp. gr. 2.71 to 2.8376. Colour white, of various fhades from other colours.

Variety 3. Sparry limeftone.

Structure fparry. Texture foliated. Fragments rhomboidal. Luftre 2 to 3. Tranfparency from 2 to 4; fometimes 1. Hardnefs 5 to 6. Sp. gr. from 2.693 to 2.718. Colour white; often with various fhades of other colours. To this variety belong all the cryftals of carbonat of lime.

Variety 4. Striated limeftone.

Texture ftriated or fibrous. Luftre 1 to o. Tranfparency 2 to 1. Hardnefs 5 to 7. Sp. gr. commonly from 2.6 to 2.77. Colours various.

Variety 5. Swine ftone.

Texture often earthy. Fracture often fplintery. Luftre 1 to o. Tranfparency o to 1. Hardnefs 6 to 7. Sp. gr. 2.701 to 2.7121. Colour dark grey, of various fhades. When fcraped or pounded it emits an urinous or garlic fmell.

Variety 6. Oviform.

This variety confifts of a number of fmall round bodies, clofely compacted together. Luftre o. Tranfparency o or 1. Hardnefs 6 to 7.

SPECIES 2. Sulphat of lime. 97 Sulphat of lime.

Gypfum — Selenite.

This mineral is found abundantly in Germany, France, England, Italy, &c.

It is found fometimes in amorphous maffes, fometimes in powder, and fometimes cryftallized. The primitive form of its cryftals, according to Romé de Lifle, is a decahedron *, which may be conceived as two four-fided pyramids applied bafe to bafe, and which, inftead of terminating in pointed fummits, are truncated near their bafes; fo that the fides of the pyramids are trapeziums, and they terminate each in a rhomb. Thefe rhombs are the largeft faces of the cryftal. The angles of the rhombs are 52° and 158°. The inclination of two oppofite faces of one pyramid to the two fimilar faces of the other pyramid is 145°, that of the other faces 110 †. Sometimes fome of the faces are elongated; fometimes it cryftallizes in fix-fided prifms, terminated by three or four-fided fummits, or by an indeterminate number of curvilinear faces. For a defcription and figure of thefe varieties, we refer to *Romé de Lifle* ‡.

* Fig. 29.

† *Cryftal.* i. 144.

‡ *Ibid.*

The texture of fulphat of lime is moft commonly foliated. Luftre from o to 4. Tranfparency from o to 4. It caufes double refraction. Its hardnefs does not exceed 4. Its fp. gr. from 1.872 to 2.311. Colour commonly white or grey.

Before the blow-pipe, it melts into a white enamel, provided the blue flame be made to play upon the edges of its laminæ. When the flame is directed againft its faces, the mineral falls into powder §.

It does not effervefce with muriatic acid, except it be impure; and it does not diffolve in it.

§ *Le Lievre, Jour. de Min.* N° xxviii. 315.

The following varieties of this mineral are deferving of attention.

Variety 1. Broad foliated fulphat.

Texture broad foliated. Luftre glaffy, from 4 to 2. Tranfparency from 4 to 3. Hardnefs 4. Sp. gr. 2.311. Colour grey, often with a fhade of yellow.

Variety 2. Grano-foliated fulphat.

Texture foliated, and at the fame time granular; fo that it eafily crumbles into powder. Luftre 2 to 3. Tranfparency 2 to 3. Hardnefs 4 to 3. Sp. gr. from 2.274 to 2.310. Feels foft. Colour white or grey, often with a tinge of yellow, blue, or green; fometimes flefh red, brown, or olive green.

Variety 3. Fibrous fulphat.

Texture fibrous. Fragments long fplintery. Luftre 2 to 3. Tranfparency 2 to 1; fometimes 3. Hardnefs 4. Brittle. Sp. gr. 2.300. Colour white, often with a fhade of grey, yellow, or red; fometimes flefh red, and fometimes honey yellow; fometimes feveral of thefe colours meet in ftripes.

Variety 4. Compact fulphur.

Texture compact. Luftre 1 or o. Tranfparency 2 to 1, Earths and Stones. 1, sometimes 0. Hardness 4. Sp. gr. from 1.872 to 2.288. Feels dry, but not harsh. Colour white, with a shade of grey, yellow, blue, or green; sometimes yellow; sometimes red; sometimes spotted, striped, or veined.

Variety 5. Farinaceous sulphat.

Of the consistence of meal. Lustre 0. Opaque. Scarcely sinks in water. Is not gritty between the teeth. Feels dry and meagre. Colour white. When heated below redness, it becomes of a dazzling white.

98 Phosphat of lime.

SPECIES 3. Phosphat of lime.

Apatite—Phosphorite—Chrysolite—of the French.

This substance is found in Spain, where it forms whole mountains, and in different parts of Germany. It is sometimes amorphous, and sometimes crystallized. The primitive form of its crystals is a regular six-sided prism *. Its integrant molecule is a regular triangular prism, whose height is to a side of its base as 1 to $\sqrt{2}$ †. Sometimes the edges of the primitive hexagonal prism are wanting, and small faces in their place; sometimes there are small faces instead of the edges which terminate the prism; sometimes these two varieties are united; sometimes the terminating edges and the angles of the prism are replaced by small faces ‡; and sometimes the prism is terminated by four sided pyramids §.

* Fig. 30.

† *Hauy, Jour. de Min.* N° xxviii. p. 310.

‡ Fig. 31.

§ *Hauy, ibid.*

Its texture is foliated. Its fracture uneven, tending to conchoidal. External lustre from 2 to 3, internal 3 to 2. Transparency from 4 to 2. Causes single refraction. Hardness 6 to 7. Brittle. Sp. gr. from 2.8249 to 3.218. Colour commonly green or grey; sometimes brown, red, blue, and even purple.

It is infusible by the blow-pipe. When its powder is thrown upon burning coals, it emits a yellowish green phosphorescent light. It is soluble in muriatic acid without effervescence or decomposition, and the solution often bomes gelatinous.

99 Fluat of lime.

SPECIES 4. Fluat of lime.

Fluor.

This mineral is found abundantly in different countries, particularly in Derbyshire. It is both amorphous and crystallized.

The primitive form of its crystals is the regular octohedron; that of its integrant molecules the regular tetrahedron ‖. The varieties of its crystals hitherto observed amount to 7. These are the primitive octohedron; the cube: the rhomboidal dodecahedron; the cubo octohedron ¶, which has both the faces of the cube and of the octohedron; the octohedron wanting the edges; the cube wanting the edges, and either one face *, or two faces in place of each. For a description and figure of these we refer to *Mr Hauy* †.

‖ *Hauy, ibid.* p. 325.

¶ Fig. 32.

* Fig. 33.

† *Ibid.*

The texture of fluat of lime is foliated. Lustre from 2 to 3, sometimes 0. Transparency from 2 to 4, sometimes 1. Causes single refraction. Hardness 8. Very brittle. Sp. gr. from 3.0943 to 3.1911. Colours numerous, red, violet, green, red, yellow, blackish purple. Its powder thrown upon hot coals emits a bluish or greenish light. Two pieces of it rubbed in the dark phosphoresce. It decrepitates when heated. Before the blow-pipe it melts into a transparent glass. §

§ *Ibid.*

It admits of a polish, and is often formed into vases and other ornaments.

100 Borat of lime.

SPECIES 5. Borat of lime.

Boracite.

This mineral has been found at Kalkberg near Luneburg, seated in a bed of sulphat of lime. It is crystallized. The primitive form of its crystals is the cube *. In general, all the edges and angles of the cube are truncated; sometimes, however, only the alternate angles are truncated †. The size of the crystals does not exceed half an inch.

Saline Stones.

* *Hauy, Jour. de Min.* N° xxvii. p. 325.

† *Hauy*, and *Westrum.*

The texture of this mineral is compact. Its fracture is flat conchoidal. External lustre 3; internal, greasy, 2. Transparency from 2 to 3. Hardness 9 to 10. Sp. gr. 2.566. Colour greyish white, sometimes passing into greenish white or purplish.

When heated it becomes electric; and the angles of the cube are alternately positive and negative ‡.

‡ *Hauy, ibid.* and *Ann. de Chim.* ix. 59.

Before the blow-pipe it froths, emits a greenish light, and is converted into a yellowish enamel, garnished with small points, which, if the heat be continued, dart out in sparks §.

§ *Le Lievre, Jour. de Min. ibid.*

According to Westrum, who discovered its component parts, it contains

68	boracic acid,
13.5	magnesia,
11	lime,
1	alumina,
2	silica,
1	iron.
96 ¶	

¶ *Ann. de Chim.* ii. 116.

101 Nitrat of lime.

SPECIES 6. Nitrat of lime.

Found abundantly mixed with native nitre. For a description see the article CHEMISTRY in this *Supplement*, n° 672.

102 G. II. Barytic salts.

GENUS II. BARYTIC SALTS.

This genus comprehends the combinations of barytes with acids.

103 Carbonat of barytes.

SPECIES 1. Carbonat of barytes.

Witherite.

This mineral was discovered by Dr Withering; hence Werner has given it the name of *witherite*. It is found both amorphous and crystallized. The crystals are octohedrons or dodecahedrons, consisting of four or six sided pyramids applied base to base; sometimes the six-sided pyramids are separated by a prism; sometimes several of these prisms are joined together in the form of a star.

Its texture is fibrous. Its fracture conchoidal. Its fragments long splintery. Lustre 2. Transparency 2 to 3. Hardness 5 to 6. Brittle. Sp. gr. 4.3 to 4.338. Colour greenish white. When heated it becomes opaque. Its powder phosphoresces when thrown on burning coals *.

* *Hauy,*

It is soluble with effervescence in muriatic acid. The solution is colourless.

According to Pelletier it contains

62	barytes,
22	carbonic acid,
16	water.
100 †	

† *Jour. de Min.* N° xxi. p. 46.

104 Sulphat of barytes.

SPECIES 2. Sulphat of barytes.

Borosclenite.

This mineral is found abundantly in many countries, particularly in Britain. It is sometimes in powder, often in amorphous masses, and often crystallized. The primitive form of its crystals is a rectangular prism, whose

Earths and Stones.

whofe bafes are rhombs, with angles of 101° 30′ and 78° 30′ *. The varieties of its cryftals are very numerous. For a defcription and figure of them we refer to *Romé de Lifle* † and *Hauy* ‡. The moft common varieties are the octohedron with cuneiform fummits, the fix or four fided prifm, the hexangular table with bevelled edges. Sometimes thefe cryftals are needle form.

* *Hauy, Effai d'une Theorie*, &c. p. 119.
† *Cryftal*. i. 588.
‡ *Ibid*. and *Ann. de Chim*. xii. 3.

Its texture is commonly foliated. Luftre from 0 to 2. Tranfparency from 2 to 0; in fome cafes 3 or 4. Hardnefs from 5 to 6. Sp. gr. from 4.4 to 4.44. Colour commonly white, with a fhade of yellow, red, blue, or brown.

When heated it decrepitates. It is fufible *per fe* by the blue flame of the blow-pipe, and is converted into fulphurat of barytes. Soluble in no acid except the fulphuric; and precipitated from it by water.

Variety 1. Foliated fulphat.

Luftre 3 to 3. Tranfparency from 4 to 2, fometimes 1. Colours white, reddifh, bluifh, yellowifh, blackifh, greenifh. Mr Werner fubdivides this variety into three, according to the nature of the texture. Thefe three fubdivifions are *granularly foliated*, *ftraight foliated*, *curve foliated*.

Variety 2. Fibrous fulphat.

Texture fibrous; fibres converging to a common centre. Luftre filky or waxy, 2. Tranfparency 2 to 1. Hardnefs 5. Colours yellowifh, bluifh, reddifh.

Variety 3. Compact fulphat.

Texture compact. Luftre 0 to 1. Tranfparency 1 to 0. Feels meagre. Almoft conftantly impure. Colours light yellow, red, or blue.

Variety 4. Earthy fulphat.

In the form of coarfe dufty particles, flightly cohering. Colour reddifh or yellowifh white.

Genus III. Strontitic Salts.

105 G. III. Strontitic falts.

This genus comprehends all the combinations of ftrontites and acids which form a part of the mineral kingdom.

Species 1. Carbonat of ftrontites

106 Carbonat of ftrontites.

This mineral was firft difcovered in the lead mine of Srontion in Argylefhire; and fince that time it is faid to have been difcovered, though not in great abundance, in other countries. It is found amorphous, and alfo cryftallized in needles, which, according to Hauy, are regular fix-fided prifms.

Its texture is fibrous; the fibres converge. Fracture uneven. Luftre 2. Tranfparency 2. Hardnefs 5. Sp. gr. from 3.4 to 3.66. Colour light green. Does not decrepitate when heated. Before the blow-pipe becomes opaque and white, but does not melt. With borax it effervefces, and melts into a tranfparent colourlefs glafs. Effervefces with muriatic acid, and is totally diffolved. The folution tinges flame purple.

Species 2. Sulphat of ftrontites.

Celeftine.

107 Sulphat of ftrontites.

This mineral has been found in Pennfylvania, in Germany, in France, in Sicily, and Britain. It was firft difcovered near Briftol by Mr Clayfield. There it is found in fuch abundance, that it has been employed in mending the roads.

It occurs both amorphous and cryftallized. The cryftals are moft commonly bevelled tables, fometimes rhomboidal cubes. Its texture is foliated. More or lefs tranfparent. Hardnefs 5. Sp. gr. from 3.51 to 3.96. Colour moft commonly a fine fky blue; fometimes reddifh; fometimes white, or nearly colourlefs §.

Aggregates.

§ *Clayfield, Nicholfon's Jour*. iii. 36.

Klaproth found a fpecimen of this mineral from Pennfylvania compofed of 58 ftrontites,
42 fulphuric acid.

100 ‖.

‖ *Beitrage*, ii. 97.

According to the analyfis of Mr Clayfield, the fulphat ftrontites found near Briftol is compofed of
58.25 ftrontites,
41.75 fulphuric acid of 2.24, and a little iron ¶.

100.00

¶ *Ibid. Nicholfon's Journal*.

According to the analyfis of Vauquelin, the fulphat of ftrontites found at Bouvron in France, which was contaminated with .1 of carbonat of lime, is compofed of
54 ftrontites,
45 fulphuric acid.

99 *

* *Jour. de Min*. N° xxxvii. 6.

Genus IV. Magnesian Salts.

108 G. IV. Magnefian Salts.

This genus comprehends the combinations of magnefia and acids which occur in the mineral kingdom. Only two fpecies have hitherto been found; namely,

Species 1. Sulphat of magnefia.

109 Sulphat of magnefia.

It is found in Spain, Bohemia, Britain, &c.; and enters into the compofition of many mineral waters.

For a defcription of it, we refer to Chemistry, n° 633. in this *Suppl*.

Species 2. Nitrat of magnefia.

110 Nitrat of magnefia.

Found fometimes affociated with nitre. For a defcription fee Chemistry, n° 674,

Genus V. Aluminous Salts.

111 G. V. Aluminous falts.

This genus comprehends thofe combinations of alumina and acids which occur in the mineral kingdom.

Species 1. Alum.

112 Alum.

This falt is found in cryftals, in foft maffes, in flakes, and invifibly mixed with the foil. For a defcription, we refer to Chemistry, n° 636.

Order III. AGGREGATES.

This order comprehends all mechanical mixtures of earths and ftones found in the mineral kingdom. Thefe are exceedingly numerous: the mountains and hills, the mould on which vegetables grow, and indeed the greater part of the globe, may be confidered as compofed of them. A complete defcription of aggregates belongs rather to geology than mineralogy. It would be improper, therefore, to treat of them fully here. But they cannot be altogether omitted; becaufe aggregates are the firft fubftances which prefent themfelves to the view of the practical mineralogift, and becaufe, without being acquainted with the names and component parts of many of them, the moft valuable mineralogical works could not be underftood.

113 Divifion of aggregates.

Aggregates may be comprehended under four divifions: 1. Mixtures of earths; 2. Amorphous fragments of ftones agglutinated together; 3. Cryftallized ftones, either agglutinated together or with amorphous ftones; 4. Aggregates formed by fire. It will be exceedingly convenient

Earths and Stones. convenient to treat each of these separately. We shall therefore divide this order into four sections.

Sect. I. *Aggregates of Earths.*

The most common earthy aggregates may be comprehended under the following genera:

1. Clay,
2. Colorific earths,
3. Marl,
4. Mould.

114 Clay.

Genus I. Clay.

Clay is a mixture of alumina and silica in various proportions. The alumina is in a state of an impalpable powder; but the silica is almost always in small stones, large enough to be distinguished by the eye. Clay, therefore, exhibits the character of alumina, and not of silica, even when this last ingredient predominates. The particles of silica are already combined with each other; and they have so strong an affinity for each other that few bodies can separate them; whereas the alumina, not being combined, readily displays the characters which distinguish it from other bodies. Besides alumina and silica, clay often contains carbonat of lime, of magnesia, barytes, oxide of iron, &c. And as clay is merely a mechanical mixture, the proportion of its ingredients is exceedingly various.

Clay has been divided into the following species:

115 Porcelain clay.

Species 1. Porcelain clay.

Its texture is earthy. Its lustre 0. Opaque. Hardness 4. Sp. gr. from 2.23 to 2.4. Colour white, sometimes with a shade of yellow or red. Adheres slightly to the tongue. Feels soft. Falls to powder in water.

A specimen, analysed by Hassenfratz, contained

62	silica,
19	alumina,
12	magnesia,
7	sulphat of barytes.
100 *	

* Ann. de Chim. xiv. 144.

A specimen, analysed by Mr Wedgewood, contained

60	alumina,
20	silica,
12	air of water.
92	

116 Common clay.

Species 2. Common clay.

Its texture is earthy. Lustre 0. Opaque. Hardness 3 to 6. Sp. gr. 1.8 to 2.68. Adheres slightly to the tongue. Often feels greasy. Falls to powder in water. Colour, when pure, white; often tinged blue or yellow.

Variety 1. Potter's clay.

Hardness 3 to 4. Sp. gr. 1.8 to 2. Stains the fingers slightly. Acquires some polish by friction. Colour white; often with a tinge of yellow or blue; sometimes brownish, greenish, reddish. Totally diffusible in water; and, when duly moistened, very ductile.

Variety 2. Indurated clay.

Hardness 5 to 6. Does not diffuse itself in water, but falls to powder. Discovers but little ductility. Colours grey, yellowish, bluish, greenish, reddish, brownish.

Aggregates

Variety 3. Shistose clay.

Structure slaty. Sp. gr. from 2.6 to 2.68. Feels smooth. Streak white or grey. Colour commonly bluish, or yellowish grey; sometimes blackish, reddish, greenish. Found in strata, usually in coal mines.

This variety is sometimes impregnated with bitumen. It is then called bituminous *shale*.

117 Lithomarga.

Species 3. Lithomarga.

Texture earthy. Fracture conchoidal. Lustre from 0 to 2. Opaque. Hardness 3 to 7. Sp. gr. when pretty hard, 2.815. Surface smooth, and feels soapy, Adheres strongly to the tongue. Falls to pieces, and then to powder, in water; but does not diffuse itself through that liquid. Fusible *per se* into a frothy mass.

Variety 1. Friable lithomarga.

Formed of scaly particles slightly cohering. Lustre 1 to 0. Hardness 3 to 4. Exceedingly light. Feels very smooth, and assumes a polish from the nail. Colour white; sometimes tinged yellow or red.

Variety 2. Indurated lithomarga.

Hardness 4 to 7. The softer sorts adhere very strongly to the tongue when newly broken; the harder very moderately. Colours grey, yellow, red, brown, blue.

A specimen of lithomarga from Osmund, analysed by Bergman, contained

60.0	silica,
11.0	alumina,
5.7	carbonat of lime,
4.7	oxide of iron,
0.5	carbonat of magnesia,
18.0	water and air.
99.9 *	

* Opusc. iv.

118 Bole.

Species 4. Bole.

Texture earthy. Fracture conchoidal. Lustre 0. Transparency scarce 1. Hardness 4. Sp. gr. from 1.4 to 2. Acquires a polish by friction. Scarcely adheres to the tongue. Feels greasy. Colour yellow or brown; sometimes red; sometimes spotted.

The lemnian earth which belongs to this species, according to the analysis of Bergman, contains

47,0	silica,
19,0	alumina,
6.0	carbonat of magnesia.
5.4	carbonat of lime,
5.4	oxide of iron,
17.0	water and air.
99.8 †	

† Ibid. p. 157.

119 Fullers earth.

Species 5. Fullers earth.

Texture earthy. Structure sometimes slaty. Fracture imperfectly conchoidal. Lustre 0. Opaque. Hardness 4. Receives a polish from friction. Does not adhere to the tongue. Feels greasy. Colour usually light green.

A specimen from Hampshire, analysed by Bergman, contained

51.8	silica,
25.0	alumina,
3.3	carbonat of lime,
3.7	oxide of iron,
0.7	carbonat of magnesia.
15.5	moisture.
100.0 ‡	

‡ Ibid. 159.

This

This earth is uſed by fullers to take the greaſe out of their cloth before they apply ſoap. It is eſſential to fullers earth that the particles of ſilica be very fine, otherwiſe they would cut the cloth. Any clay, poſſeſſed of this laſt property, may be conſidered as *fullers earth;* for it is the alumina alone which acts upon the cloth, on account of its ſtrong affinity for greaſy ſubſtances.

120 G. II. Colorific earths.

Genus II. Colorific Earths.

The minerals belonging to this genus conſiſt of clay, mixed with ſo large a quantity of ſome colouring ingredient as to render them uſeful as paints. The colouring matter is commonly oxide of iron, and ſometimes charcoal.

121 Red chalk.

Species 1. Red chalk.
Reddle.

Texture earthy. Fracture conchoidal. Luſtre 0. Opaque. Hardneſs 4. Sp. gr. inconſiderable. Colour dark red.

Feels rough. Stains the fingers. Adheres to the tongue. Falls to powder in water. Does not become ductile. When heated it becomes black, and at 159° Wedgewood melts into a greeniſh yellow frothy enamel.

Compoſed of clay and oxide of iron.

122 Yellow chalk.

Species 2. Yellow chalk.

Texture earthy. Fracture conchoidal. Hardneſs 3. Sp. gr. inconſiderable. Colour ochre yellow.

Feels ſmooth or greaſy. Stains the fingers. Adheres to the tongue. Falls to pieces in water. When heated becomes red; and at 156° Wedgewood melts into a brown porous porcelain.

According to Sage, it contains

50 alumina,
40 oxide of iron,
10 water, with ſome ſulphuric acid.
———
100 *

123 Black chalk.

Species 3. Black chalk.

Structure ſlaty. Texture earthy. Fragments ſplintery. Luſtre 0. Opaque. Hardneſs 5. Sp. gr. 2.144 to 2.277. Colour black. Streak black.

Feels ſmooth. Adheres ſlightly to the tongue. Does not moulder in water. When heated to redneſs it becomes reddiſh grey.

According to Wiegleb, it is compoſed of

64.50 ſilica,
11.25 alumina,
11.00 charcoal,
2.75 oxide of iron,
7.50 water.
———
97.00 †

124 Green earth.

Species 4. Green earth.

Texture earthy. Luſtre 0. Opaque. Hardneſs 6 to 7. Sp. gr. 2.637. Colour green.

Commonly feels ſmooth. Does not ſtain the fingers. Often falls to powder in water. When heated it becomes reddiſh brown; and at 147° Wedgewood melts into a compact glaſs.

Compoſed of clay, oxides of iron, and nickel.

125 G. III. Marl.

Genus III. Marl.

A mixture of carbonat of lime and clay, in which the carbonat conſiderably exceeds the other ingredient, is called *marl.*

Its texture is earthy. Luſtre 0. Opaque. Hardneſs from 4 to 8; ſometimes in powder. Sp. gr. from 1.6 to 2.877. Colour uſually grey, often tinged with other colours. Effervesces with acids.

Some marls crumble into powder when expoſed to the air; others retain their hardneſs for many years.

Marls may be divided into two ſpecies: 1. Thoſe which contain more ſilica than alumina; 2. Thoſe which contain more alumina than ſilica. Mr Kirwan has called the firſt of theſe *ſiliceous*, the ſecond *argillaceous*, marls. Attention ſhould be paid to this diſtinction, when marls are uſed as a manure.

Genus IV. Mould.

126 G. IV. Mould.

By *mould* is meant the ſoil on which vegetables grow. It contains the following ingredients: ſilica, alumina, lime, magneſia (ſometimes), iron, carbon derived from decayed vegetable and animal ſubſtances, carbonic acid, and water. And the good or bad qualities of *ſoils* depends upon a proper mixture of theſe ingredients. The ſilica is ſeldom in the ſtate of an impalpable powder, but in grains of a greater or ſmaller ſize: Its chief uſe ſeems to be to keep the ſoil open and pervious to moiſture. If we paſs over the carbon, the iron, and the carbonic acid, the goodneſs of a ſoil depends upon its being able to retain the quantity of moiſture which is proper for the nouriſhment of vegetables, and no more. Now the retentive power of a ſoil increaſes with the proportion of its alumina, lime, or magneſia, and diminiſhes as the proportion of its ſilica increaſes. Hence it follows, that in a dry country, a fertile ſoil ſhould contain leſs ſilica, and more of the other earths, than in a wet country.

Giobert found a fertile ſoil near Turin, where it rains annually 30 inches, to contain

From 77 to 79 ſilica,
9 — 14 alumina,
5 — 12 lime.

Near Paris, where it rains about 20 inches annually, Mr Tillet found a fertile ſoil to contain

Coarſe ſand 25
Fine ſand 21
— 46.0 ſilica,
16.5 alumina,
37.5 lime.
———
100.0 *

The varieties of mould are too numerous to admit an accurate deſcription: we ſhall content ourſelves, therefore, with mentioning the moſt remarkable.

127 Sand.

Species 1. Sand.

This conſiſts of ſmall grains of ſiliceous ſtones not cohering together, nor ſoftened by water. When the grains are of a large ſize, the ſoil is called *gravel.*

128 Clay.

Species 2. Clay.

This conſiſts of common clay mixed with decayed vegetable and animal ſubſtances.

129 Loam.

Species 3. Loam.

Any ſoil which does not cohere ſo ſtrongly as clay, but more ſtrongly than chalk, is called *loam.* There are many varieties of it. The following are the moſt common.

* *Mem. Par.* 1779, 313.

† *Ann. de Chim.* xxx. 13.

* *Kirwan on Manures.*

Variety

Earths and Stones.

Variety 1. Clayey loam; called alfo *ftrong*, *ftiff*, *cold*, and *heavy*, loam.

It confifts of a mixture of clay and coarfe fand.

Variety 2. Chalky loam.

A mixture of clay, chalk, and coarfe fand; the chalk predominating.

Variety 3. Sandy loam.

A mixture of the fame ingredients; the fand amounting to .8 or .9 of the whole.

130 Till.

SPECIES 4. Till.

Till is a mixture of clay and oxide of iron. It is of a red colour, very hard and heavy.

SECT II. *Aggregates of Amorphous Stones.*

THE aggregates which belong to this fection confift of amorphous fragments of ftones cemented together. They may be reduced to the following genera:

1. Sandftone,
2. Puddingftone,
3. Amygdaloid,
4. Breccia.

131 G. I. Sandftone.

GENUS I. SANDSTONE.

Small grains of fand, confifting of quartz, flint, hornftone, filiceous fhiftus, or felfpar, and fometimes of mica, cemented together, are denominated fandftones. They feel rough and fandy; and, when not very hard, eafily crumble into fand. The cement or bafis by which the grains of fand are united to each other is of four kinds; namely, lime, alumina, filica, iron. Sandftones, therefore, may be divided into four fpecies.

132 Calcareous.

SPECIES 1. Calcareous fandftones.

Calcareous fandftones are merely carbonat of lime or marl, with a quantity of fand interpofed between its particles. Though the quantity of fand, in many cafes, far exceeds the lime, calcareous fandftones are fometimes found cryftallized; and, in fome cafes, the cryftals, as might be expected, have fome of the forms which diftinguifh carbonat of lime. Thus the calcareous fandftone of Fountainbleau is cryftallized in rhomboidal tables. It contains, according to the analyfis of Laffone

62.5	filiceous fand,
37.5	carbonat of lime.
100	

Calcareous fandftones have commonly an earthy texture. Their furface is rough. Their hardnefs from 6 to 7. Their fpecific gravity about 2.5 or 2.6. Their colour grey; fometimes yellowifh or brown. They are fometimes burned for lime.

133 Aluminous.

SPECIES 2. Aluminous fandftones.

The bafis of argillaceous fandftones is alumina, or rather clay. Their ftructure is often flaty. Their texture is compact, and either fine or coarfe grained, according to the fize of the fand of which they are chiefly compofed. Their hardnefs is from 6 to 8, or even 9. Their colour is ufually grey, yellow, or brown.

They are often formed into mill-ftones, filtering-ftones, and coarfe whet-ftones.

134 Siliceous.

SPECIES 3. Siliceous fandftones.

Siliceous fandftones confift of grains of fand cemented together by filica, or fome fubftance which confifts chiefly of filica or flint. They are much harder than any of the other fpecies.

Sometimes ftones occur, confifting of grains of lime cemented together with filica. Thefe ftones are alfo denominated filiceous fandftones. Aggregates

135 Ferruginous.

SPECIES 4. Ferruginous fandftones.

The iron which acts as a cement in ferruginous fandftones is not far from a metallic ftate. When iron is completely oxidated, it lofes the property of acting as a cement. This is the reafon that ferruginous fandftones, when expofed to the air, almoft always crumble into powder.

The colour of ferruginous fandftones is ufually dark red, yellow, or brown. The grains of fand which compofe them are often pretty large. Their hardnefs is commonly inconfiderable.

136 G. II. Pudding ftone.

GENUS II. PUDDING STONE.

Pebbles of quartz, flint, or other fimilar ftones of a round or eliptical form, from the fize of rape feed to that of an egg, cemented together by a filiceous cement, often mixed with iron, have been denominated *pudding ftones*.

Pudding ftones, of courfe, are not inferior in hardnefs to quartz, flint, chalcedony, &c. of which the pebbles may confift. The colour of the cement is ufually yellow, brown, or red. Its fracture is conchoidal.

The finer forts of pudding ftones are capable of a fine polifh; the coarfe are ufed for mill-ftones.

137 G. III. Amygdaloid.

GENUS III. AMYGDALOID.

Rounded or eliptical maffes of chalcedony, zeolite, limeftone, lithomarga, fteatites, green earth, garnets, hornblende, or opal, cemented together by a bafis of indurated clay, trap, mullen, walken or kragg, conftitute an *amygdaloid*.

Amygdaloids are opaque. They have no luftre. Their fracture is uneven or conchoidal. Hardnefs 6 to 9. Their colours are as various as the ingredients of which they are compofed.

138 G. IV. Breccia.

GENUS IV. BRECCIA.

Angular fragments of the fame *fpecies* of ftone, agglutinated together, conftitute a *breccia*. This *calcareous* breccia confifts of fragments of marble cemented together by means of lime.

SECT. III. *Aggregates of Cryftals.*

THE minerals belonging to this fection confift either of cryftals of different kinds cemented together, or of cryftals and amorphous ftones cemented together.

They may be reduced under the following genera.

1. Granite,
2. Sienite,
3. Granatine,
4. Granitell,
5. Granilite,
6. Trap,
7. Porphyry.

139 G. I. Granite.

GENUS I. GRANITE.

An aggregate of felfpath, quartz, and mica, whatever be the fize or the figure of the ingredients, is denominated *granite*. This aggregate may be divided into two fpecies, namely, *common* granite, and *fhiftofe* granite or gneifs.

140 Common.

SPECIES 1. Common granite.

Its ftructure is always granular. The felfpar is often amor-

Earths and Stones. amorphous, and conſtitutes moſt frequently the greateſt part of the aggregate.

Common granites differ much in their appearance, according to the ſize, proportion, colour, and figure of their component parts. They are commonly very hard: Their ſpecific gravity varies from 2.5388 to 2.9564.

141 Gneiſs.

SPECIES 2. Shiſtoſe granite or gneiſs.

The ſtructure of gneiſs is always ſlaty, and this conſtitutes its ſpecific character. In gneiſs, the proportion of quartz and felſpar is nearly equal: the proportion of mica is ſmalleſt. It is evidently ſubject to the ſame varieties with common granite.

142 G. II. Sienite.

GENUS II. Sienite.

Mr Werner has given the name of *ſienite* to aggregates compoſed of felſpar, hornblende, and quartz; or of felſpar, hornblende, quartz, and mica. Theſe aggregates were formerly confounded with quartz.

Sienite is found both of a granular and ſlaty ſtructure: it might, therefore, like granite, be divided into two ſpecies. In ſienite the quartz is commonly in by far the ſmalleſt proportion.

143 G. III. Granatine.

GENUS III. GRANATINE.

Mr Kirwan has applied the name *granatine* to the following aggregates.

Quartz, Felſpar, Shorl.	Quartz, Mica, Garnet.	Quartz, Hornblende, Jade.	Felſpar, Mica, Shor
Quartz, Felſpar, Jade.	Quartz, Shorl, Hornblende.	Quartz, Hornblende, Garnet.	Felſpar, Mica, Hornblende.
Quartz, Felſpar, Garnet.	Quartz, Shorl, Jade.	Quartz, Jade, Garnet.	Felſpar, Quartz, Serpentine.
Quartz, Mica, Shorl.	Quartz, Shorl, Garnet.	Quartz, Hornblende, Hornſtone,	Felſpar, Quartz, Steatites.
Quartz, Mica, Jade.			

One of theſe aggregates, namely, *quartz*, *mica*, *garnet*, was called by Cronſtedt *morka* or *murkſten*.

144 G. IV. Granitell.

GENUS IV. GRANITELL.

Mr Kirwan gives the name of *granitell* to all aggregates compoſed of any two of the following ingredients: quartz, felſpath, mica, ſhorl, hornblende, jade, garnet, ſteatites. The moſt remarkable of theſe are:

Quartz, Felſpar.	Quartz, Hornblende.	Quartz, Steatites.	Felſpar, Hornblende.
Quartz, Mica.	Quartz, Jade.	Felſpar, Mica.	Felſpar, Jade.
Quartz, Shorl.	Quartz, Garnet.	Felſpar, Shorl.	Felſpar, Garnet.

Aggregates

Mica, Shorl.	Mica, Jade.	Hornblende, Jade.	Jade, Garnet.
Mica, Hornblende,	Mica, Garnet.	Hornblende, Garnet.	Steatites, Shorl.

Some of theſe aggregates have received particular names. The aggregate of *quartz* and *mica*, when its ſtructure is ſlaty, is called by Werner *ſhiſtoſe mica*: by the Swedes, it is denominated *ſtellſten*, whatever be its ſtructure.

The aggregate of hornblende and mica is called *grunſtein*, from the dark green colour which it uſually has.

145 G. V. Granilite.

GENUS V. GRANILITE.

Under the name of *granilite*, Mr Kirwan comprehends all aggregates containing more than three ingredients. Of theſe the following are the moſt remarkable.

Quartz, Felſpar, Mica, Shorl.	Quartz, Mica, Shorl, Garnet.	Quartz, Sulph. of barytes, Mica, Shorl.
Quartz, Felſpar, Mica, Steatites.	Quartz, Felſpar, Mica, Garnet.	Quartz, Sulph. of barytes, Mica, Hornblende.

146 G. VI. Trap.

GENUS VI. TRAP (P).

Under this genus we claſs not only what has commonly been called *trap*, but alſo wacken, and mullen, and kragſtone of Kirwan.

147 Common.

SPECIES 1. Common trap.

This ſtone is very common in Scotland, and is known by the name of *whinſtone*. Whole hills are formed of it; and it occurs very frequently in large rounded detached fragments. Sometimes it aſſumes the form of immenſe columns, and is then called *baſalt*. The Giants Cauſeway in Ireland, the iſland of Staffa, and the ſouth ſide of Arthur's Seat in Scotland, are well known inſtances of this figure.

Its texture is earthy or compact. Its fracture uneven. Its luſtre commonly 0. Opaque. Hardneſs 8 to 9. Not brittle. Sp. gr. from 2.78 to 3.021 *. Colour black, with a ſhade of grey, blue, or purple; ſometimes blackiſh or reddiſh brown; in ſome caſes greeniſh grey. By expoſure to the atmoſphere, it often becomes inveſted with a browniſh rind. Before the blow-pipe, it melts *per ſe* into a more or leſs black glaſs.

* *Kirwan.*

Trap conſiſts of ſmall cryſtals of hornblende, felſpar, olivine, &c. uſually ſet in a ground compoſed apparently of clay and oxide of iron. A ſpecimen, in the form of baſaltes, from Staffa, analyſed by Dr Kennedy of Edinburgh, contained

48 ſilica,
16 alumina,
16 oxide of iron,
9 lime,
5 moiſture,
4 ſoda,
1 muriatic acid.

99 †

† *Edin. Tranſ.* v. 89.

A

(P) *Kirw.* I. 231 and 431.—*Faujas de St Fond. Eſſai ſur l'Hiſt. Nat. des Roches de Trap.*—*Phil. Tranſ.* paſſim. See alſo a very ingenious ſet of experiments on the fuſion of trap, by Sir James Hall in *Tranſ. Edin.* V. 43.

Earths and Stones.

A specimen from Salisbury rock, near Edinburgh, contained, according to the analysis of the same gentleman,

46.0	silica,
19.0	alumina,
17.0	oxide of iron,
8.0	lime,
4.0	moisture,
3.5	soda,
1.0	muriatic acid.
98.5 *	

* Edin. Trans. v. 90.

Dr Kennedy conducted these analyses with great ingenuity and judgment; and the discovery in which they terminated, that trap contains soda, is certainly of importance, and may lead to valuable consequences both in a geological and mineralogical view.

148 Wacken.

SPECIES 2. Wacken †.

† Kirwan, i. 223.

‡ Kirwan.

This stone often forms considerable parts of hills, and, like trap, is amorphous. Its texture is earthy. Its fracture usually even. Lustre 0. Opaque. Hardness 6 to 9. Sp gr. from 2.535 to 2.893 ‡. Colour grey, with a shade of green, black, red, brown. When exposed to the atmosphere, it withers and becomes more grey.

It melts into a grey porous slag.

149 Mullen.

SPECIES 3. Mullen *.

* Kirwan, i. 225.

This stone is also found in considerable masses, and sometimes has a tendency to a columnar form like basalt. Texture earthy. Fracture uneven, and fine splintery. Lustre 0, except from some shining particles of basaltine. Opaque. Hardness from 7 to 9. Sp. gr. from 2.6 to 2.738. Colour ash or bluish grey; sometimes mixed with ochre yellow, in consequence of the decomposition of the stone. At 130° Wedgewood it melts into a black compact glass.

When mullen is exposed to the air, its surface becomes covered with a greyish white rind sometimes slightly ochry.

150 Kragstone.

SPECIES 4. Kragstone *.

* Kirw. i. 226.

This stone, which, like the others, forms considerable parts of rocks, was formed into a distinct species by Mr Kirwan. It's texture is earthy. It is exceedingly porous, and the pores are often filled with the crystals of other minerals. Fracture uneven. Lustre 0. Opaque. Hardness 5 to 7. Sp. gr. 2.314. Feels rough and harsh. Colour reddish grey. Streak yellowish grey. At 138° Wedgewood it melts into a reddish brown porcelain mass.

151 G. VII. Porphyry.

GENUS VII. PORPHYRY.

Any stone which contains scattered crystals or grains of felspar, visible to the naked eye, is denominated a *porphyry*. Besides felspar, porphyries generally contain small crystals of quartz, hornblende, and mica. These crystals are usually of a different colour from the stone in which they are found, and they are stuck in it as in a cement. It is evident from this definition, that the number of porphyries must be great. Each species receives its name from the stone which forms its basis. To describe them would be unnecessary. We shall only give a catalogue of the principal species.

Aggregate.

1. Hornstone porphyry.	8. Wacken porphyry.
2. Pitchstone porphyry.	9. Mullen porphyry.
3. Hornslate porphyry.	10. Krag porphyry.
4. Felspar or petunse porphyry.	11. Argillitic porphyry.
5. Clay porphyry.	12. Potstone porphyry.
6. Hornblende porphyry.	13. Serpentine porphyry.
7. Trap porphyry.	14. Sandstone porphyry.

The aggregates belonging to this section compose most of the mountains of the globe. In giving an account of them, we have adhered implicitly to the arrangement most generally received by mineralogists. It must be acknowledged, that this arrangement is by no means complete, and that some of the genera are too vague to be of much use. The number of aggregates already discovered is too great for giving to each a particular name. Perhaps it would be better henceforth to adopt the method proposed by Mr Hauy, namely, to constitute the genera from that ingredient which enters most abundantly into the aggregate, and which forms as it were its basis, and to distinguish the species according to the nature and proportion of the other ingredients. According to this plan, the aggregates hitherto discovered have been divided by Hauy into the following genera:

1. Felspathic rock.	7. Hornblendean rock.
2. Quartzous rock.	8. Petro siliceous rock.
3. Micaceous rock.	9. Garnetic rock.
4. Chloritous rock.	10. Calcareous rock.
5. Serpentine rock.	11. Argillaceous rock.
6. Trappean rock.	12. Corneous rock.

SECT. IV. *Volcanic Aggregates.*

AGGREGATES formed by volcanoes may be reduced to the following genera.

1. Lava.
2. Tufa.
3. Pumice.
4. Ashes.

GENUS I. LAVA. 152 G. I. Lava.

All substances which have issued out of a volcano in a state of fusion are called *lavas*. They have been divided into three species.

SPECIES 1. Vitreous lava. 153 Vitreous.

Found in small pieces.

Texture glossy. Fracture conchoidal. Lustre 3. Transparency from 3 to 1. Hardness 9 to 10. Sp. gr. from 2 to 3. Colour blackish, greenish, or whitish. Commonly somewhat porous.

SPECIES 2. Cellular lava. 154 Cellular.

This species is full of cells. Surface rough and full of cavities. Texture earthy. Lustre 0. Opaque. Hardness 7 to 9. Sp. gr. varies, but does not exceed 2.8. Colour brown or greyish black. Commonly somewhat magnetic.

SPECIES 3. Compact lava. 155 Compact.

This species is the most common of all; it runs into the

Combuſtibles.

the ſecond by inſenſible degrees; and indeed is ſeldom found of any conſiderable ſize without ſome pores. It bears in general a very ſtrong reſemblance to trap.

A ſpecimen of the lava of Catania in Sicily, analyſed by Dr Kennedy, contained

51.0 ſilica,
19.0 alumina,
14.5 oxide of iron,
9.5 lime,
4.0 ſoda,
1.0 muriatic acid.
———
99.0 *

A ſpecimen of the lava of Sta. Venere in Sicily he found to contain

50.75 ſilica,
17.50 alumina,
14.25 oxide of iron,
10.00 lime,
4.00 ſoda,
1.00 muriatic acid.
———
97.5 †

Thus we ſee, that the reſemblance between trap and lava holds not only in their external appearance, but alſo in their component parts.

* Tranſ. Edin. v. 93.

† Ibid. 94.

Combuſtible.

156 G. II. Puzzolana.

Genus II. puzzolana.

Found in ſmall pieces. Surface rough. Texture earthy and porous. Fracture uneven. Luſtre 0. Opaque. Hardneſs 3. Very brittle. Sp. gr. from 2.57 to 2.8. Colour brown or dark grey. Magnetic. Eaſily melts into a black ſlag.

When mixed with lime into a mortar, it poſſeſſes the property of hardening even under water. This property it owes moſt probably, as Mr Kirwan ſuppoſes, to the iron which it contains. The iron decompoſes the water of the mortar, and by this means it becomes too hard to be acted upon by water in a very ſhort time.

157 G. III. Pumice.

Genus III. pumice.

This is a very light ſubſtance ejected from volcanoes. It is porous. Hardneſs 3. Brittle. Sp. gr. below 1. Colour grey or brown.

In ſome varieties the luſtre and tranſparency are 0: in others, the luſtre is glaſſy, 2. Tranſparency from 1 to 2.

158 G. IV. Volcanic aſhes.

Genus IV. volcanic ashes.

Theſe are analogous to the aſhes of common pit coal. Looſe and ſmooth, very light and fine. Slowly diffuſible in water, and when wet ſomewhat ductile.

Class II. SALTS.

UNDER this claſs we comprehend all the combinations of alkalies with acids which exiſt in the mineral kingdom. As they have been already deſcribed in the article Chemistry, Suppl. we ſhall here only give a liſt of their names.

159 Genera.

Genus I. potass.

Sp. 1. Sulphat of potaſs.
2. Nitrat of potaſs.

Genus II. soda.

Sp. 1. Carbonat of ſoda.
2. Sulphat of ſoda.
3. Muriat of ſoda.
4. Borax.

Genus III. ammonia.

Sp. 1. Sulphat of ammonia.
2. Muriat of ammonia.

Class III. COMBUSTIBLES.

160 Genera.

THE combuſtible ſubſtances belonging to the mineral kingdom, excluding the metals, may be comprehended under the following genera.

1. Sulphur.
2. Carbon.
3. Bitumen.
4. Coal.
5. Amber.

161 G. I. Sulphur.

Genus I. sulphur.

species 1. Native ſulphur.

This ſubſtance is found abundantly in many parts of the world, eſpecially near Volcanoes, as Hecla, Ætna, Veſuvius, the Lipari iſlands, &c. It is either in the ſtate of powder, or maſſive, or cryſtallized. The primitive form of its cryſtals is an octohedron, compoſed of two four-ſided pyramids, joined baſe to baſe ‡. The ſides of theſe pyramids are ſcalene triangles, and ſo inclined that the plane where the baſes of the pyramids join in a rhomb, whoſe long diagonal is to its ſhort as 5 to 4 §. Sometimes the apices of the pyramids, to uſe the language of De Liſle, are truncated; ſometimes they are ſeparated from each other by a priſm; ſometimes they are truncated near their baſes, and a low four-ſided pyramid riſes from the truncature: this pyramid is alſo ſometimes truncated near its apex ¶. Finally, one of the edges of the pyramids is ſometimes truncated. For figures of theſe varieties and for the laws of their formation, we refer to *Mr Lefroy* *.

Colour yellow, with a ſhade of green; ſometimes reddiſh (q). Luſtre greaſy, 2. Tranſparency varies from 0 to 4. Cauſes double refraction †. Texture compact. Hardneſs 4 to 5. Brittle.—For its other properties, we refer to Chemistry in this *Suppl.*

Sometimes ſulphur is mixed with different proportions of earths. Theſe combinations are hardly ſuſceptible of accurate deſcription.

Sulphur combines alſo with metals. Theſe combinations ſhall be deſcribed in the fourth claſs.

‡ Fig. 34.

¶ Fig. 35.

* *Jour. de Min.* No xxix. 337.

† *Hauy.*

162 G. II. Carbon.

Genus II. carbon.

This genus comprehends all minerals compoſed of pure carbon, or of carbon combined with a little earth.

163 Diamond.

species 1. Diamond.

This mineral, which was well known to the ancients, is

(q) It then contains arſenic.

Combuftibles. is found in different parts of Afia, particularly in the kingdoms of Golconda and Vifapour; it is found alfo in Brazil.

It is always cryftallized; but fometimes fo imperfectly, that at the firft fight it might pafs for amorphous. Its primitive form is a regular octogon †; but it more commonly affumes a fpheroidal form, and then has ufually 36 curvilinear triangular faces, fix of which are raifed upon each of the faces of the primitive octogon ‡. Its integrant molecule, according to Hauy, is a regular tetrahedron.—For a more particular account of the cryftals of this mineral, we refer the reader to *Mr Romé de Lifle* * and *Mr Hauy* †.

† Fig. 36. ‡ Fig. 37. * *Cryftal.* ii. 191. † *Jour. de Min.* N° xxix. 343. ‡ *Hauy, ibid.*

Texture foliated. Luftre 4. Tranfparency from 2 to 4. Caufes fingle refraction. Hardnefs 20. Sp. gr. 3.5185 to 3.5310 ‡. Colour various; fometimes limpid, fometimes red, orange, yellow, green, blue, and even blackifh.

When rubebd it becomes pofitively electric, even before it has been cut by the lapidary, which is not the cafe with any other gem ‖.

‖ *Id. ibid.*

It is compofed of pure carbon §.

§ *Morveau, Ann. de Chim.* xxxi. 72.

164 Mineral charcoal.

SPECIES 2. Mineral charcoal.

Kilkenny coal—Wales culm.

This mineral has been found in Hungary, Italy, France, Ireland, and Wales. It occurs in ftratified maffes, or in lumps nefted in clay.

Colour black. Luftre 4, metallic. Opaque. Texture foliated. Hardnefs 5 to 7. Sp. gr. 1.4 to 1.526, Often ftains the fingers. Infoluble in acids. Deflagrates with nitre. Does not born till wholly ignited, and then confumes flowly without emitting flame or fmoke.

It confifts almoft entirely of *charcoal*, which, as Morveau has proved, is an oxide of carbon *.

* *Ibid.*

165 Anthracite.

SPECIES 3. Anthracite (R).

Anthracolite.

This fubftance, as Dolomieu informs us, is found exclufively in the primitive mountains. It is always amorphous. Colour black or brownifh black. Luftre 3 to 4. Structure flaty. Fragments rhomboidal. Hardnefs 6 to 7. Sp. gr. greater than that of coal. Often ftains the fingers.

Burns precifely like the laft fpecies, and leaves .40 of white afhes. According to Dolomieu, it is compofed of about

64.0	charcoal,
32.5	filica,
3.5	iron,
100.0 †	

† *Jour. de Min.* N° xxix. 338.

It is probable that the charcoal in the two laft fubftances is in the fame ftate in which it exifts in plumbago, combined with oxygen, but not containing fo much as charcoal does ‡.

‡ *Morveau, ibid.*

166 G. III. Bitumen.

GENUS III. BITUMEN.

By bitumen we underftand, with mineralogifts in general, an oil, which is found in different parts of the earth, in various ftates of confiftence. Thefe different ftates form diftinct fpecies; in our arrangement of which we fhall be guided by the obfervations which Mr Hatchett has made in his valuable paper on bituminous fubftances *.

* *Nicholfon's Journal*, ii. 201, 248.

(R) This name was given by Hauy from ανθραξ, *a coal.*

167 Naphtha.

SPECIES 1. Naphtha.

This fubftance is found fometimes on the furface of the water of fprings, and fometimes iffuing from certain ftrata. It is found in great abundance in Perfia.

It is as fluid and tranfparent as water. Colour white or yellowifh white. Smell ftrong, but not difagreeable. Sp. gr. when white, .708 * or .729 †; when yellowifh, .8475 ‡. Feels greafy. Catches fire on the approach of flame, burns with a white flame, and leaves fcarce any refiduum.

* *Mufchenbroek.* † *Boulduc.* ‡ *Briffon.*

Infoluble in alcohol. Does not freeze at 0° Fahrenheit. When pure naphtha is expofed to the air, it becomes yellow and then brown; its confiftence is increafed, and it paffes into *petroleum* *.

* *Hatchett.*

168 Petroleum.

SPECIES 2. Petroleum.

This fubftance is alfo found in Perfia, and likewife in many countries in Europe, particularly Italy, France, Switzerland, Germany, Sweden, England, and Scotland.

Not fo fluid nor tranfparent as water. Colour yellow, either pale or with a fhade of red or green; reddifh brown and reddifh black. Smell that of naphtha, but lefs pleafant. Sp. gr. 8783 *. When burned it yields a foot, and leaves a fmall quantity of coally refiduum.

* *Briffon.*

By expofure to the air it becomes like tar, and is then called *mineral tar* †.

† *Hatchett, ibid.*

169 Mineral tar.

SPECIES 3. Mineral tar.

This fubftance is found in many parts of Afia, America, and Europe. It is vifcid, and of a black, brownifh black, or reddifh colour. Smell fometimes ftrong, but often faint. Sp. gr. 1.1. When burned, emits a difagreeable bituminous fmell. By expofure to the air it paffes into *mineral pitch* and *maltha* *.

* *Hatchett, ibid.*

170 Mineral pitch and maltha.

SPECIES 4. Mineral pitch and maltha.

This fubftance has a ftrong refemblance to common pitch. When the weather is warm it is foft, and has fome tenacity; it is then called *adhefive mineral pitch*: when the weather is cold, it is brittle; its hardnefs is 5; and its fracture has a glaffy luftre. In this ftate it is called *maltha*. Colour black, dark brown, or reddifh. Luftre 0. Opaque. Sp. gr. from 1.45 to 2.07. Does not ftain the fingers. On a white hot iron it flames with a ftrong fmell, and leaves a quantity of grey afhes. It it is to the prefence of the earths which compofe thefe afhes that the great fpecific gravity of this bitumen is to be afcribed. By farther induration, it paffes into *afphalt.*

171 Afphalt.

SPECIES 5. Afphalt.

This fubftance is found abundantly in many parts of Europe, Afia, and America, efpecially in the ifland of Trinidad.

Colour black or brownifh black. Luftre greafy 2. Opaque. Fracture conchoidal, of a glaffy luftre. Hardnefs from 7 to 8. Very brittle. Sp. gr. 1.07 to 1.165 *. Feel fmooth, but not greafy. Does not ftain the fingers. Has little or no fmell, unlefs when rubbed or heated. When heated melts, fwells, and inflames; and when pure, burns without leaving any afhes.

* *Kirwan.*

172 Elaftic bitumen.

SPECIES 6. Elaftic bitumen.

Mineral caoutchouc.

This fubftance was found about the year 1786 in the lead

Combuſtibles. lead mine of Odin, near Caſtletown, Derbyſhire. It was firſt mentioned by Mr De Born.

Colour yellowiſh or reddiſh brown, ſometimes blackiſh brown. In its appearance it has a ſtrong reſemblance to caoutchouc or Indian rubber; hence its name. Conſiſtency various: ſometimes ſo ſoft as to adhere to the fingers; ſometimes nearly as hard as aſphalt. When ſoft it is elaſtic; when hard brittle. Sp. gr. 0.9053 to 1.0233 *.

* *Hatchett, ibid.*

Inſoluble in alcohol, ether, and oil of turpentine, but ſoluble in oil of olives. Not affected by nitric acid. When diſtilled, it yields a bituminous oil inſoluble in alcohol; the reſiduum is carbonaceous †.

† *Lametherie, Jour. de Phyſ.* xxxi. 312.

There is a variety of this ſubſtance found in a rivulet near the mine of Odin, which, when freſh cut, exactly reſembles fine cork in colour and texture; but in a few days after being expoſed to the air, becomes of a pale reddiſh brown. This ſubſtance contains within it a nucleus of elaſtic bitumen. It ſeems to be the elaſtic bitumen altered in its texture by the water ‡.

‡ *Hatchett, ibid.*

173 G. IV. Coal.

Genus IV. coal.

The ſubſtances belonging to this genus are compoſed of carbon, or rather charcoal, and bitumen.

174 Jet.

Species 1. Jet (s).

This ſubſtance is found in France, Spain, Germany, Britain, and other countries. It is found in detached kidneyform maſſes, of various ſizes, from an inch to ſeven or eight feet in length.

Colour full black. Luſtre 3 to 4; internal glaſſy. Opaque. Hardneſs 7 to 8. Not near ſo brittle as aſphalt. Texture ſtriated. Fracture conchoidal. Sp. gr. 1.259 *. It has no odour except when heated, and then it reſembles the odour of aſphaltum. Melts in a ſtrong heat, burns with a greeniſh flame, and leaves an earthy reſiduum †. Becomes ſomewhat electric by friction ‡. When diſtilled yields a peculiar acid §.

* *Briſſon.* † *Hatchett.* ‡ *Kirwan.* § *Vauquelin.*

This mineral is formed into buttons, beads, and other trinkets. The manufacture has been almoſt confined to France ‖.

‖ *Jour. de Min.* N° iv. 41.

175 Cannel coal.

Species 2. Cannel coal.

This mineral is found in Lancaſhire, and in different parts of Scotland, where it is known by the name of *parrot coal.*

Colour black. Luſtre common, 2. Opaque. Structure ſometimes ſlaty. Texture compact. Fracture conchoidal. Hardneſs 5 to 8. Brittle. Sp. gr. 1.232 to 1.426. Does not ſtain the fingers.

Kindles eaſily, and burns with a bright white flame like a candle (T), which laſts but a ſhort time. It does not cake. It leaves a ſtony or ſooty reſiduum.

A ſpecimen of Lancaſhire cannel coal, analyſed by Mr Kirwan, contained 75.20 charcoal,
21.68 maltha,
3.10 alumina and ſilica.

99.98 ¶

¶ *Mineral.* ii. 523.

A ſpecimen of the ſlaty kind from Airſhire, called *ſplent coal*, was compoſed of
47.62 charcoal,
32.52 maltha,
20.00 earths.

100.14 *

* *Ibid.* 524

Cannel coal is ſuſceptible of poliſh, and, like jet, is often wrought into trinkets.

176 Common coal.

Species 3. Common coal.

This very uſeful combuſtible is never found in the primitive mountains, but only in the ſecondary mountains, or in plains formed of the ſame materials with them. It is always in ſtrata, and generally alternates with clay, ſandſtone, or limeſtone.

Colour black, more or leſs perfect. Luſtre uſually greaſy or metallic, 2 to 4. Opaque. Structure generally ſlaty. Texture often foliated. Fracture various. Hardneſs 4 to 6. Sp. gr. 1.25 to 1.37. Uſually ſtains the fingers. Takes fire more ſlowly, and burns longer, than the laſt ſpecies. Cakes more or leſs during combuſtion.

Of this ſpecies there are many varieties, diſtinguiſhed in Britain by the names of caking coal, rock coal, &c. Theſe are too well known to require any deſcription.

Mr Kirwan analyſed a variety of different kinds of coal: The reſult of his experiments may be ſeen by the following table.

Whitehaven coal.	Wigan.	Swanſey.	Leitrem.	
57.0	61.73	73.53	71.43	charcoal.
41.3	36.7	23.14	23.37	maltha & aſph.
1.7	1.57	3.33	5.20	earths †.
100.0	100.00	100.00	100.00	

† *Mineral,* ii. 525.

177 Spurious coal.

Species 4. Spurious coal.

This mineral is generally found amidſt ſtrata of genuine coal. It is alſo called *parrot-coal* in Scotland.

Colour greyiſh black. Luſtre 0 to 1. Structure uſually ſlaty. Texture earthy. Hardneſs 7 to 8. Sp. gr. 1.5 to 1.6. Generally explodes, and burſts when heated.

Compoſed of charcoal, maltha, and aſphalt, and above .20 of ſtony matter.

178 G. V. Amber.

Genus V. amber.

Species 1. Common amber.

This ſubſtance, called *electrum* by the ancients, is found in different countries; but moſt abundantly in Pruſſia, either on the ſea-ſhore, or under-ground at the depth of about 100 feet, repoſing on *wood-coal* ‡. It is in lumps of different ſizes.

‡ *Kirw. Min.* ii. 66.

Colour yellow. Luſtre 3 to 2. Tranſparency 2 to 4. Fracture conchoidal. Hardneſs 5 to 6. Sp. gr. 1.078 to 1.085. Becomes electric by friction.

If a piece of amber be fixed upon the point of a knife, and then kindled, it burns to the end without melting ¶.

¶ *Hauy.*

By diſtillation it yields ſuccinic acid.

Class

(s) It was called *gagathes* by the ancients, from the river Gages in Licia, near which it was found; *jayet* in French, *azabache* in Spaniſh, *gagath* in German.

(T) Hence it has been called *cannel coal.* *Candle*, in the Lancaſhire and Scotch dialect, is pronounced *cannel.*

Class IV. METALLIC ORES.

THIS clafs comprehends all the mineral bodies, compofed either entirely of metals, or of which metals conftitute the moft confiderable and important part. It is from the minerals belonging to this clafs that all metals are extracted; for this reafon they have obtained the name of *ores*.

179 Orders. The metals hitherto difcovered amount to 21; we fhall therefore divide this clafs into 21 orders, allotting a diftinct order for the ores of every particular metal.

Metals exift in ores in one or other of the four following ftates: 1. In a metallic ftate, and either folitary or combined with each other. 2. Combined with fulphur. 3. In the ftate of oxides. 4. Combined with acids. Each order therefore may be divided into the four following genera.

180 Genera.

1. Alloys,	3. Oxides,
2. Sulphurets,	4. Salts.

It muft be obferved, however, that every metal has not hitherto been found in all thefe four ftates, and that fome of them are hardly fufceptible of them all. Some of the orders therefore want one or more genera, as may be feen from the following table.

Order I. *Gold ores.*
1. Alloys.

Order II. *Silver ores.*
1. Alloys.
2. Sulphurets.
3. Oxides.
4. Salts.

Order III. *Platinum ores.*
1. Alloys.

Order IV. *Ores of mercury.*
1. Alloys.
2. Sulphurets.
3. Oxides.
4. Salts.

Order V. *Copper ores.*
1. Alloys.
2. Sulphurets.
3. Oxides.
4. Salts.

Order VI. *Iron ores.*
1. Alloys.
2. Sulphurets.
3. Carburets.
4. Silicated iron.
5. Oxides.
6. Salts.

Order VII. *Tin ores.*
1. Sulphurets.
2. Oxides.

Order VIII. *Lead ores.*
1. Sulphurets.
2. Oxides.
3. Salts.

Order IX. *Zinc ores.*
1. Sulphurets.
2. Oxides.
3. Salts.

Order X. *Antimonial ores.*
1. Alloys.
2. Sulphurets.
3. Oxides.
4. Salts.

Order XI. *Bifmuth ores.*
1. Alloys.
2. Sulphurets.
3. Oxides.

Order XII. *Arfenic ores.*
1. Alloys.
2. Sulphurets.
3. Oxides.

Order XIII. *Cobalt ores.*
1. Alloys.
2. Sulphurets.
3. Oxides.
4. Salts.

Order XIV. *Nickel ores.*
1. Sulphurets.
2. Oxides.
3. Salts.

Order XV. *Manganefe ores.*
1. Oxides.
2. Salts.

Order XVI. *Tungsten ores.*
1. Oxides.
2. Salts.

Order XVII. *Ores of molybdenum.*
1. Sulphurets.

Order XVIII. *Ores of uranium.*
1. Oxides.
2. Salts.

Order XIX. *Ores of titanium.*
1. Oxides.

Order XX. *Ores of tellurium.*
1. Alloys.

Order XXI. *Ores of chromum.*
1. Oxides.

Order I. GOLD ORES.

No metal perhaps, if we except iron, is more widely fcattered through the mineral kingdom than gold *. Hitherto it has been found only in a metallic ftate; moft commonly in grains, ramifications, leaves, or rhomboidal, octahedral, or pyramidal cryftals. It is generally mixed with quartz, though there are inftances of its having occurred in calcareous rocks. It is not uncommon alfo to find it differminated through the ores of other metals; efpecially iron, mercury, copper, and zinc. The greateft quantity of gold is found in the warmer regions of the earth. It abounds in the fands of many African rivers, and is very common in South America and India. Europe, however, is not deftitute of this metal. Spain was famous in ancient times for its gold mines, and feveral of the rivers in France contain it in their fands †. But the principal gold mines in Europe are thofe of Hungary, and next to them thofe of Salzburg. Gold alfo has been difcovered in Sweden and Norway, and more lately in the county of Wicklow in Ireland ‡. 181 Where found.

* Bergman.

† Reaumur, Mem. Par. 1718, p. 68.

‡ Lloyd, Phil Tranf. 1796, p. 36. Mills, ibid. p 38 —Nicholfon's Journ. ii. 224.

Genus I. Alloys of gold.

Species 1. Native gold.

Native gold is never completely pure; it is alloyed with fome filver or copper, and fometimes with iron. In the native gold found in Ireland, indeed, the quantity of alloy appears to have been exceedingly fmall. 182 G.I. Native gold.

Its colour is yellow. Luftre metallic. Fracture hackly. Hardnefs 5. Sp. gr. from 12 to 19.

Order II. SILVER ORES.

Silver is found moft commonly in quartz, limeftone, hornftone; or combined with the ores of other metals, moft commonly with copper, antimony, zinc, cobalt, and lead. This laft metal indeed is feldom totally deftitute of filver. 183 Where found.

Genus I. Alloys of filver.

Species 1. Native filver *.

Native filver, fo called becaufe the filver is nearly in a ftate of purity, forms the principal part of fome of the richeft filver mines in the world. It is fometimes in fmall lumps; fometimes cryftallized in cubes, hexahedrons, octahedrons, or dodecahedrons; fometimes in leaves, or threads, often fo connected with each other as to refemble branches of trees, and therefore called *dendrites*. The filver in the famous mines of Potofi has this laft form. When newly extracted, it is not unlike fmall branches of fir †. 184 G.I. Native filver.

The colour of native filver is white; often tarnifhed. Luftre metallic. Fracture hackly. Hardnefs 6. Malleable. Sp. gr. from 1 to 10.338.

The filver in this fpecies is almoft conftantly alloyed with from .03 to .05 of fome other metal, frequently gold or arfenic.

* Kirw. ii. 108.—Catling. Act. Liter. Svecia, 1738, p. 20.

† Bergman's Phyf. Geogr. Jour. de Min. No xvi p. 26.

Silver.

185 Alloy of silver and gold.

SPECIES 2. Alloy of silver and gold.

Auriferous native silver.

This alloy is not uncommon in silver mines. Its colour is yellowish white. Its lustre metallic. Hardness 5. Malleable. Sp. gr. above 10.6. Dr. Fordyce found a specimen from Norway composed of

72 silver,
28 gold.

100 *

* *Phil. Transf.* 1776, p. 532.

SPECIES 3. Alloy of silver and antimony †.

Antimoniated silver ore.

186 Alloy of silver and antimony. This alloy, which is found in the silver mines of Spain and Germany, is sometimes in grains or lumps, and sometimes crystallized in six-sided prisms, whose sides are longitudinally channelled ‡.

Its colour is white. Its lustre metallic. Hardness 10. Brittle. Sp. gr. from 9.4406 § to 10.* Texture foliated. Fracture conchoidal. Before the blow-pipe the antimony evaporates in a grey smoke, and leaves a brownish slag, which tinges borax green. If borax be used at first, a silver bead may be obtained.

This alloy was long supposed to contain arsenic. Bergman examined it, and found only silver and antimony † His analysis has been confirmed by the experiments of Vauquelin and Selb ‡. According to Selb, it is composed of 89 silver,

11 antimony.

100

A specimen analysed by Klaproth, contained

84 silver,
16 antimony.

100

Another specimen contained

76 silver,
24 antimony.

100 ‡

§ *Hauy, Jour. de Min.* N° xxx. p. 473.
* *Kirwan, ibid.*
† *Opusc.* ii. 415.
‡ *Jour. de Min. ibid*
‡ *Beiträge*, ii. 301.

GENUS II. SULPHURETS OF SILVER.

187 G. II. Sulphurets. Common sulphuret of silver.

SPECIES 1. Common sulphuret of silver *.

Vitreous silver ore.

This ore occurs in the silver mines of Germany and Hungary. It is sometimes in masses, sometimes in threads, and sometimes crystallized. Its crystals are either cubes or regular octohedrons, whose angles and edges are often variously truncated. For a description of the varieties produced by these truncatures, we refer the reader to *Romé de Lisle* †.

Its colour is dark bluish grey, inclining to black; often tarnished. Internal lustre metallic. Texture foliated. Fracture uneven. Hardness 4 to 5. May be cut with a knife like lead. Flexible and malleable. Sp. gr. 6.909 ‡ to 7.215 ‖ In a gentle heat the sulphur evaporates. Melts when heated to redness.

A specimen of this ore, analysed by Klaproth, contained

85 silver,
15 sulphur.

100 *

* *Kirwan*, ii. 115.
† *Crystal.* iii. 441.
‡ *Brisson.*
‖ *Gellert.*
* *Beiträge*, i. 162.

Metallic ores.

SPECIES 2. Antimoniated silver ore *.

Sulphuret of silver with antimony and iron.

188 Antimoniated silver ore. This ore, which occurs in Saxony and Hungary, seems to be sulphuret of silver contaminated with antimony and iron, and ought therefore, in all probability, to be considered merely as a variety of the last species. It is sometimes in masses, but more frequently crystallized in six-sided prisms, tables, or rhomboids; generally indistinct and accumulated together.

Its colour is iron grey; often tarnished. Its lustre metallic. Fracture uneven. Hardness 4 to 5. Brittle. Sp. gr. 7.208 †. Before the blow-pipe the sulphur and antimony exhale, leaving a bead, which may be freed from iron by fusion with nitre and borax.

A specimen of this ore, analysed by Klaproth, contained

66.5 silver,
12.0 sulphur,
10.0 antimony,
5.0 iron,
1.0 silica,
0.5 arsenic and copper.

95.0 ‡

* *Kirwan* ii. 118.
† *Gellert.*
‡ *Beiträge*, i. 166.

SPECIES 3. Sulphuret of silver and copper ‖

Cupriferous sulphurated silver ore.

189 Sulphuret of silver and copper. This ore, which is found in the Korbolokinsk mountains in Siberia, was first described by Mr Renovantz. It is in amorphous masses, varying in size from that of the thumb to that of the fist.

Its colour is bluish grey like lead. Lustre metallic. Hardness 5 to 6. Brittle. Its powder, when rubbed on the skin, gives it a black colour and a leaden gloss. Before the blow-pipe the sulphuret of silver melts readily; that of copper with difficulty. This ore is composed of about

42 silver,
21 copper,
35 sulphur.

98

‖ *Kirwan*, ii. 121.

GENUS III. OXIDES OF SILVER.

190 G. III. Oxides. Calciform silver ore.

SPECIES 1. Calciform silver ore *.

This ore was first described by Mr Widenman. It is sometimes in masses, sometimes disseminated through other minerals.

Its colour is greyish black. Its streak bright. Its lustre metallic. Its fracture uneven. Hardness 4 to 5. Brittle. Sp. gr. considerable. Effervesces with acids. Melts easily before the blow pipe. Froths with borax.

According to Selb, it contains 72.5 silver,

15.5 copper,
12.0 carbonic acid.

100.0

* *Kirwan*, ii. 112.

SPECIES 2. Red silver ore (u).

191 Red silver ore. This ore is very common in several German silver mines. It occurs in masses, disseminated and crystallized. The primitive form of its crystals is a dodecahedron ‡, whose sides are equal rhombs, and which may be con-

‡ Fig. 38.

(u) *Kirw.* II. 122.—*Scopoli de Minera Argenti, Rubra.*—*Sage, Jour. de Phys.* XXXIV. 331. *and* XLI. 370; and *Nouv. Jour. de Phys.* II. 284.—*Westrum, Jour. de Phys.* XLIII. 291.—*Klaproth, Beiträge*, I. 141.

Silver. considered as a six-sided rhomboidal prism, terminated by three-sided summits*. Sometimes the prism is lengthened, and sometimes its edges, or those of the terminating summits, or both, are wanting. For a description and figure of these varieties, we refer to *De Lisle* † and *Hauy* ‡.

* *Romé de Lisle*, iii. 447.
† *Ibid.*
‡ *Jour. d'Hist. Naturelle*, N° 18. p. 216.

Its colour is commonly red. Streak red. External lustre metallic, internal common. Transparency from 3 to 1; sometimes opaque. Fracture flat conchoidal. Hardness 5 to 7. Brittle. Sp. gr. from 5.44 || to 5.592 *. Becomes electric by friction, but only when insulated †. Soluble in nitric acid without effervescence ‡. Before the blow-pipe melts, blackens, burns with a blue flame, gives out a white smoke with a slight garlic smell, and leaves a silver bead ||.

|| *Kirwan.*
* *Vauquelin, Jour. de Min* N° xvii. p. 2.
† *Hauy, ibid.* N° xxx. p. 476.
‡ *Hauy, ibid.* N° xxxi. p. 518.
|| *Vauquelin, ibid.*

Variety 1. Light red.

Colour intermediate between blood and cochineal red; sometimes variegated. Streak orange red. Powder black.

Variety 2. Dark red.

Colour commonly between dark cochineal red and lead grey; sometimes nearly black, and without any shade of red. Streak dark crimson red.

This ore was long supposed to contain arsenic. Klaproth first ascertained its real composition *; and his analysis has been confirmed by Vauquelin, who found a specimen composed of 56.6748 silver,
16.1300 antimony,
15.0666 sulphur,
12.1286 oxygen.
———
100.

* *Ann. de Chim.* xviii 81.

Klaproth proved, that the silver and antimony are in the state of oxides; and Vauquelin, that the sulphur is combined partly with the oxide of silver and partly with the oxide of antimony. Klaproth obtained a little sulphuric acid; but this acid, as Vauquelin, with his usual ingenuity, demonstrated, was formed during the analysis.

This ore sometimes contains a minute portion of arsenic, but never more than .02 †.

† *Vauquelin, ibid.* p. 8.

192
G. IV. Salts. Muriat of silver.

Genus IV. salts of silver.

species 1. Muriat of silver (x).

Corneous silver ore.

This ore occurs at Johanngeorgenstadt in Saxony, in South America, &c. It is often amorphous, sometimes nearly in powder, and sometimes crystallized in cubes or parallelopipeds.

Its colours are various: when exposed to the light it becomes brown. Internal lustre greasy, 2; external, 2 to 1. Acquires a gloss when scraped with a knife. Transparency 2 to 1. Texture foliated. Hardness 4 to 5. Sp. gr. 4.745 ‡ to 4.804 ||. Before the blow-pipe it instantly melts, and gradually evaporates, but may be reduced by adding an alkali.

‡ *Briss n.*
|| *Gellert.*

Metallic ores.

That this ore contains muriatic acid, has been long known. Mr Woulfe first shewed that it contained also sulphuric acid *: and this discovery has been confirmed by Klaproth, according to whose analysis this ore is composed of 67.75 oxide of silver,
6.00 oxide of iron,
21.00 muriatic acid,
.25 sulphuric acid,
1.75 alumina.
———
96.75 †

* *Phil. Transf.* 1770.

The alumina can only be considered as mixed with the ore. Sometimes its quantity amounts to .67 of the whole ‡.

† *Beiträge*, i. 134.
‡ *Ibid.* p. 137.

Order III. ORES OF PLATINUM (y).

Hitherto no mine of platinum has been discovered. It is found in small scales or grains on the sands of the river Pinto, and near Carthagena in South America. It is always in a metallic state, and always combined with iron. 193 Mines.

Genus I. alloys of platinum.

species 1. Native platinum.

194
G. I. Alloys. Native platinum.

Its colour is whitish iron grey. Magnetic. Sp. gr. from 12 to 16. Soluble in nitro-muriatic and oxy-muriatic acids.

Order IV. ORES OF MERCURY.

Mercury is employed in medicine; it serves to separate silver and gold from their ores; the silvering of looking-glasses, gilding, &c. are performed by means of it; and its sulphuret forms a beautiful paint.

195 Mines.

Mercury abounds in Europe, particularly in Spain, Germany, and Hungary: it is found also in China (z), the Phillipines ||, and in Peru, and perhaps Chili (a) in South America. The most productive mines of mercury are those of Idria *; of Almaden, near Cordova in Spain, which were wrought by the Romans (b); of the Palatinate †; and of Guanca Velica in Peru (c).

|| *Carreri's Voyage.*
* *Scopoli,*
† *Jour. de Min.* N° xxxvi. p. 915.

Mercury has never been found in Britain, nor has any mine worth working been discovered in France. It occurs most commonly in argillaceous shistus, limestones, and sandstones.

Jour. de Min. N° vi. and vii.

Genus I. alloys of mercury.

species 1. Native mercury.

196.
G. I. Alloys. Native mercury.

Native mercury is found in most mercurial mines: it is in small globules, scattered through different kinds of stones, clays, and ores.

Fluid. Colour white. Sp. gr. about 13.6.

Ores of Mercury.

SPECIES 2. Amalgam of silver *.

Native amalgam.

197 Amalgam of silver. This mineral has been found in the silver mine of Sahlberg †, in the province of Dalecarlia, in Sweden; in the mines of Deux Ponts ‡, in the Palatinate; and in other places. It is in thin plates, or grains, or crystallized in cubes, parallelopipeds, or pyramids.

Its colour is silvery white or grey. Lustre metallic. Creaks when cut. Sp. gr. above 10. Tinges gold white. Before the blow-pipe the mercury evaporates and leaves the silver.

A specimen of this amalgam, analysed by Klaproth, contained

64	mercury,
36	silver.
100 §	

Sometimes it contains a mixture of alumina, and sometimes the proportion of mercury is so great that the amalgam is nearly as soft as paste.

* Kirwan, ii. 223.
† Cronstedt's Min.
‡ Heyer, Crell's Annals, 1790.
§ Beiträge, i. 183.

198 G. II. Sulphurets Common sulphuret.

GENUS II. SULPHURETS OF MERCURY.

SPECIES 1. Common sulphuret ||.

Native cinnabar.

This ore, which is found in almost all mercurial mines, is sometimes in veins, sometimes disseminated, sometimes in grains, and sometimes crystallized. The form of its crystals is a tetrahedron or three-sided pyramid, most commonly wanting the summit; sometimes two of these pyramids are joined base to base; and sometimes there is a three sided prism interposed between them ¶.

Its colour is red. Its streak red and metallic. Lustre when crystallized 2 to 3; when amorphous, often c. Transparency, when crystallized, from 1 to 3; when amorphous, often 0. Texture generally foliated. Hardness from 3 to 8. Sp. gr. from 5.419 to 10.1285.

Before the blow-pipe evaporates with a blue flame and sulphureous smell. Insoluble in nitric acid *.

Variety 1. Dark red.

Colour cochineal red. Hardness 6 to 7. Sp. gr. when pure, 10.1285 †; sometimes only 7.2, or even 6.188 ‡.

Variety 2. Bright red.

Colour commonly scarlet. Sp. gr. 6.9022 § to 5.419 ||.

|| Kirwan, ii. 228.

* Hauy, Jour. de Min. N° xxxi. p. 518.
† Brisson.
‡ Muschenbroek.
§ Brisson.
|| Gellert.

199 G. III. Oxides. Hepatic mercurial ore.

GENUS III. OXIDES OF MERCURY.

SPECIES 1. Hepatic mercurial ore ¶.

This ore, which is the most common in the mines of Idria, is always amorphous, and is often mixed with native mercury and cinnabar.

Its colour is somewhat red. Its streak dark red and brighter. Lustre commonly metallic. Hardness from 6 to 8. Sp. gr. from 9.2301 * to 7.186 †. When heated the mercury evaporates.

Though this ore has never been accurately analysed, chemists have concluded that the mercury which it contains is in the state of a red oxide, because it is insoluble in nitric and soluble in muriatic acid ‡. When purest, it contains about .77 of mercury §. It contains also some sulphur and iron.

Werner has divided this species into two varieties, the *compact* and the *slaty*. The second is often nothing more than bituminous shale impregnated with oxide of mercury ||.

¶ Kirwan, ii. 224.
* Brisson.
† Kirwan.
‡ Sage, Jour. de Phys. xxiv. 61.
§ Scopoli, Jour. de Min. N° xxxvi. p. 919.
|| Kirwan, ii. 226.

GENUS IV. MERCURIAL SALTS.

SPECIES 1. Muriat of mercury *.

Corneous mercury.

Metallic Ores.

200 Mercurial Salts. Muriat of mercury. This ore, which occurs in the Palatinate, is sometimes in scales, sometimes in grains, and sometimes crystallized. Its crystals are either small four or six sided prisms whose sides are rhombs †, or cubes, or four-sided pyramids wanting their angles. They are always very small and generally confused.

Its colours are various; but it is most frequently white. Its lustre, when white, is pearly. Sometimes opaque, and sometimes semitransparent. Evaporates before the blow-pipe.

Mr Woulfe discovered that this ore generally contains some sulphuric acid ‡. Specimens have been found in which the quantity of sulphuric acid exceeds that of the muriatic §.

* Kirwan, ii. 226.
† Romé de Lisle, iii. 161.
‡ Phil. Trans. lxvi. 618.
§ Suckow.

ORDER V. COPPER ORES.

MANY of the most useful utensils are formed of copper: it enters largely into the composition of brass, bronze, and bell metal; not to mention the dyes and paints of which it is the basis.

201 Mines. Copper mines abound in most countries. They are wrought in China, Japan, Sumatra; the north of Africa; in Chili and Mexico; and in most parts of Europe; especially Britain, Germany, Russia, Hungary.

Copper is found most commonly in rocks of hornblende, shistus, and quartz.

202 G. I. Alloys. Native copper.

GENUS I. ALLOYS OF COPPER.

SPECIES 1. Native copper ||.

Native copper occurs now and then in the greater number of copper mines: Sometimes it is in masses, sometimes in plates and threads, which assume a variety of forms; and sometimes, as in Siberia, it is crystallized in cubes, or other forms nearly resembling cubes §.

Colour commonly that of copper, but sometimes dark brown. Lustre metallic. Streak brighter. Fracture hackly. Flexible and malleable. Hardness 6 to 7. Sp. gr. from 7.6 * to 8.5844 †.

|| Kirwan, ii. 127.—Cartheuser.
§ Hauy, Jour. de Min. N° xxxi. 509.
* Kirwan, Min. ii. 128.
† Hauy, ibid. p. 509.

SPECIES 2. White copper ore ‡.

Alloy of copper, iron, and arsenic.

203 White copper ore. This ore, which is said to be uncommon, occurs in masses. Colour white. Lustre metallic. Fracture uneven. Hardness 8 to 9. Brittle. Sp. gr. considerable.

Before the blow-pipe gives out a white arsenical smoke, and melts into a greyish black slag §.

‡ Kir. Min. ii. 152.
§ Widenman.

204 G. II. Sulphurets. Copper. Common sulphuret of copper.

GENUS II. SULPHURETS OF COPPER.

SPECIES 1. Common sulphuret of copper ||.

Vitreous copper ore.

This ore, which is found in Cornwall, Hungary, and Siberia, occurs in masses, plates, threads, and crystallized in six-sided prisms, or four-sided pyramids, joined base to base.

Colour bluish grey. Streak brighter grey. Lustre metallic. Hardness 4 to 7. Sp. gr. 5.452 ¶ to 5.565 *; sometimes so low as 4.129 †. Detonates with nitre.

Before the blow-pipe it melts easily; and while the fusion exhibits a green pearl, which, on cooling, is covered with a brown crust. Tinges borax green.

Werner makes two varieties of this ore: the first he calls

|| Kirwan, ii. 144.
¶ Kirwan.
* Gellert.
† Kirwan.

Copper Ores.

calls *compact*, from its fracture; and the second, for the same reason, he calls *foliated*. This last is somewhat darker coloured than the first, but in other respects they agree.

205 Copper pyrites. * Kirwan, ii. 140.

SPECIES 2. Copper pyrites *.

Yellow copper ore.

This ore, which is probably nothing else than sulphuret of iron combined with copper, and which, therefore, would be more properly placed among iron ores, is found frequently in copper mines, and mixed with common pyrites or sulphuret of iron. It is sometimes amorphous, and sometimes crystallized. Its crystals are either three or four sided pyramids applied base to base, or six-sided plates.

Its colour is yellow; often tarnished. Its internal lustre metallic. Hardness 6 to 7; sometimes 9. Brittle. Sp. gr. 4.314 † to 4.08 ‡. Deflagrates; but does not detonate with nitre §.

† *Brisson.* ‡ *Kirwan,* § *Id. Min.* ii. 141.

Before the blow-pipe decrepitates, gives a greenish sulphureous smoke, and melts into a black mass, which tinges borax green. Does not effervesce with nitric acid.

206 Purple copper ore. || Kirwan, ii. 142.

SPECIES 3. Purple copper ore ||.

This ore is found in masses, or plates, or disseminated; sometimes, also, it is crystallized in octahedrons. Colour various, but most commonly purple; internally reddish. Streak reddish and bright. Lustre metallic. Hardness 6 to 7. Brittle. Sp. gr. 4.956 to 4.983 ¶.

¶ *Ibid.* ii. 143.

Effervesces with nitric acid, and tinges it green. Deflagrates with nitre. Before the blow-pipe melts readily, without smoke, vapour, or smell; but is not reduced. Tinges borax a bright green.

A specimen of this ore, analysed by Klaproth, contained

58 copper,
18 iron,
19 sulphur,
5 oxygen.
———
100 †

† *Beiträge,* ii. 286.

207 Grey copper ore. ‡ Kirwan, ii. 146.

SPECIES 4. Grey copper ore ‡.

This ore is found in Cornwall, Saxony, Hungary, &c. It is often amorphous, but often also crystallized. The primitive form of its crystals is the regular tetrahedron; but, in general, either the angles or the edges, or both, are truncated or bevelled §.

§ *Romé de Lisle,* iii. 345.

Colour steel grey; often tarnished, and then dark grey. Streak dark grey; sometimes reddish brown. Powder blackish; sometimes with a tint of red. Lustre metallic. Hardness 7 or 8. Very brittle. Sp. gr. 4.8648 ||. Deflagrates with nitre. Before the blow-pipe crackles, but at last melts, especially if assisted by borax. The bead gives a white smoke, without any particular smell; tinges borax yellow or brownish red, but does not unite with it.

|| *Hauy. Jour. de Min.* N° xxxi. 512.

A specimen of this ore from Cremnitz, analysed by Klaproth, contained

31 copper,
14 silver,
34 antimony,
3 iron,
11 sulphur.
—
93

Napion, in an ore from the valley of Lanzo, found copper, silver, and antimony, nearly in the same proportions, but more iron, and some arsenic *. Savoresi, as Baron Born informs us, besides the ingredients of Klaproth's analysis, found some gold and mercury in grey copper ore †: and Klaproth himself found lead in most of the other specimens which he examined.

Metallic Ores.

* *Mem. Turin,* v. 173. † *Catal.* ii. 498.

208 G. III. Oxides. Red oxide of copper. ‡ Kirwan, ii. 135.

GENUS III. OXIDES OF COPPER.

SPECIES 1. Red oxide of copper ‡.

Florid red copper ore—Red copper glass.

This ore is found in Cornwall, and many other countries. It occurs in masses, disseminated, in scales, and crystallized. The figure of its crystals is most commonly the octahedron §.

§ *Hauy, Jour. de Min.* N° xxxi. 517.

Colour commonly cochineal red. Streak brick red. Lustre semimetallic. Transparency, when amorphous, generally 0; when crystallized, 3 or 4. Hardness from 4 to 7. Soluble with effervescence in nitric acid. Before the blow-pipe melts easily, and is reduced.

This ore was supposed to be composed of carbonic acid and red oxide of copper; but a specimen, examined by Vauquelin, which consisted of pure crystals, contained no acid ||. It must therefore be considered as an oxide of copper.

|| *Ibid.*

Werner has made three varieties of this ore, which, from their texture, he has denominated *compact*, *foliated*, and *fibrous*. The first is seldom or never found crystallized, and is opaque; the second occurs amorphous, crystallized, and in scales; the third is carmine, ruby, or scarlet red; and occurs always in short capillary crystals, or delicate flakes.

This ore sometimes contains a mixture of red oxide of iron; it is then called *brick red copper ore*, *copper malm*, or *copper ochre*.

This ore is sometimes mixed with bitumen. Its colour is then brownish black, and it is called *pitch ore*.

209 Green oxide of copper. * Kirwan, ii. 149.

SPECIES 3. Green oxide of copper *.

Green sand of Peru.

This ore, which was brought from Peru by Dombey, is a grass green powder, mixed with grains of quartz. When thrown on burning coals, it communicates a green colour to the flame. It is soluble both in nitric and muriatic acids without effervescence. The solution is green. It was supposed to contain muriatic acid †; but Vauquelin has discovered that the appearance of this acid was owing to the presence of some common salt, which is accidently mixed with the sand ‡.

† *Berthollet, Mem. Par.* 1786, 462. ‡ *Jour. de Min.* N° xxxi. 519.

210 G. IV. Salts. Blue carbonat of copper.

GENUS IV. SALTS OF COPPER.

SPECIES 1. Blue carbonat of copper (D).

Mountain blue—Azure de cuivre—Blue calx of copper—Kupfer lazur.

This ore, which occurs in the copper mines of Siberia, Sweden, Germany, Hungary, Cornwal, &c. is either amorphous or crystallized. The crystals are small, and difficult to examine. According to Romé de Lisle, their primitive form is an octahedron, the sides of which are isosceles triangles, and two of them more inclined than the others §. Be that as it may, the crystals of blue carbonat of copper are often rhomboidal prisms, either regular, or terminated by dihedral summits ||.

§ *Crystal.* iii. 343. || *Ibid.* p. 345.

Its colour is azure or smalt blue. Streak blue. Hardness

(D) *Kirwn.* II. 129.—*Morveau, Mem. Dijon,* 1782. 1 *Semestre,* p. 100.

Copper Ores. nefs 4 to 6. Brittle. Sp. gr. 3.608 ‡. It effervefces with nitric acid, and gives it a blue colour. Before the blow-pipe it blackens, but does not melt. Tinges borax green with effervefcence.

‡ Briffon.

The cryftals, according to Pelletier, are compofed of

66 to 70 copper,
18 — 20 carbonic acid,
8 — 10 oxygen,
2 — 2 water.

Fontana firft difcovered that this ore contained carbonic acid gas.

Variety 1. Earthy blue carbonat.

Mountain blue.

This variety generally contains a mixture of lime. It is never cryftallized; and fometimes is almoft in the ftate of powder. Luftre 0. Texture earthy.

Variety 2. Striated blue carbonat of copper.

Luftre glaffy. Tranfparency, when cryftallized, 2; when amorphous, 1. Texture ftriated; fometimes approaching to the foliated.

211 Green carbonat of copper.

SPECIES 2. Green carbonat of copper (E).

Oxygenated carbonat of copper—Malachite.

This ore is generally amorphous, but fometimes it is cryftallized in four-fided prifms, terminated by four-fided pyramids.

Colour green. Luftre filky. Hardnefs 5 to 7. Brittle. Sp. gr. 3.571 * to 3.653 ‡. Effervefces with nitric acid, and gives a blue colour to ammonia. Before the blow-pipe it decrepitates and blackens, but does not melt. Tinges borax yellowifh green. It is compofed of carbonic acid and green oxide of iron.

* Briffon. ‡ Kirwan.

Variety 1. Fibrous malachite.

Texture fibrous. Opaque when amorphous; when cryftallized its tranfparency is 2. Colour generally grafs green.

Variety 2. Compact malachite.

Texture compact. Opaque. Colour varies from the dark emerald green to blackifh green.

A fpecimen of malachite from Siberia, analyfed by Klaproth, contained

58.0 copper,
18.0 carbonic acid,
12.5 oxygen,
11.5 water.
———
100 *

* Beiträge, ii. 290.

This fpecies is fometimes mixed with clay, chalk, and gypfum, in various proportions; it is then known by the name of

Common mountain green.

Its colour is verdigris green. Luftre 0. Tranfparency 0 to 1. Hardnefs 3 to 4. Brittle. Texture earthy. Effervefces feebly with acids. Before the blow-pipe it exhibits the fame phenomena with malachite.

212 Sulphat of copper.

SPECIES 3. Sulphat of copper.

For a defcription of this falt, fee CHEMISTRY, n° 648. in this *Supplement.*

213 Arfeniat of copper.

SPECIES 4. Arfeniat of copper ‡.

Olive copper ore.

This ore is found at Cararach in Cornwal. It is generally cryftallized in fix-fided compreffed prifms. Its colour is olive green. Streak fometimes ftraw coloured, fometimes olive green. Luftre glaffy. Tranfparency from 4 to 2. Fracture conchoidal. Hardnefs 4 to 7. Before the blow-pipe deflagrates with an arfenical fmoke, and melts into a grey coloured bead. This bead, fufed with borax, leaves a button of pure copper ||.

‡ Kirwan, ii. 151.

Metallic Ores.

Klaproth difcovered that it was compofed of oxide of copper and arfenic acid.

|| Klaproth's Obfervations on Cornwal, p. 29.

Sometimes this ore is combined with iron. It then cryftallizes in cubes. Thefe cubes are of a dark green colour; before the blow-pipe they frothe, give out an arfenical fmoke, and do not fo quickly form a grey bead as the arfeniat of copper *.

* Ibid. p. 29.

ORDER VI. IRON ORES.

214. Mines.

To defcribe the ufes of iron, would be to write the hiftory of every art and manufacture, fince there is not one which is not more or lefs dependent upon this ufeful metal. Nor is its abundance inferior to its utility. It exifts almoft everywhere, and feems, as it were, the bond which connects the mineral kingdom together.

215 G. I. Alloys. Native iron.

GENUS I. ALLOYS OF IRON.

SPECIES 1. Native iron (F).

Native iron has been found in Siberia and in Peru in immenfe maffes, which feemed as if they had been fufed. Thefe maffes evidently did not originate in the place where they were found. See *Fire-balls, Suppl.*

Colour bluifh white. Fracture hackly. Luftre metallic. Malleable. Magnetic. Hardnefs 8 to 9. Sp. gr. 7.8. Prouft has difcovered, that the native iron found in Peru is alloyed with nickel ¶.

¶ Nicholfon's Jour. iii. 374.

216. G. III. Sulphurets. Common fulphuret of iron.

GENUS II. SULPHURETS OF IRON.

SPECIES 1. Common fulphuret of iron *.

Pyrites.

This mineral occurs very frequently both in ores and mixed with other bodies, for inftance in flates. It is often amorphous, and often alfo cryftallized. The primitive form of its cryftals is either a regular cube or an octohedron. The varieties of its form hitherto defcribed amount to 30; for a defcription of which we refer the reader to *Romé de Lifle* †.

* Kirwan, ii. 76.—Henkel's Pyritologia.

† Cryftal. iii. 208.

Its colour is yellow. Its luftre metallic. Hardnefs 8 to 10. Brittle. Sp. gr. 3.44 to 4.6. Soluble in nitric acid with effervefcence. Scarce foluble in fulphuric acid. Before the blow-pipe burns with a blue flame and a fulphureous fmell, and leaves a brownifh bead, which tinges borax of a fmutty green.

Variety 1. Common pyrites.

Fracture uneven. Hardnefs 10. Decrepitates when heated. Emits a fulphureous fmell when rubbed. Not magnetic. It occurs often in coal mines and in flates.

Variety 2. Striated Pyrites.

Texture ftriated. Hardnefs 10. Not magnetic.

Variety 3. Capillary.

Colour often fteel grey. Found in needle-form cryftals. Uncommon. Not magnetic.

Variety 4. Magnetic pyrites.

Found in maffes. Texture compact. Hardnefs 8, 9. Slightly magnetic. Seems to contain lefs fulphur than the other varieties.

In pyrites the proportion of the fulphur to the iron is variable; and this explains the variety of its cryftalline forms.

GENUS

(E) *Kirw.* II. 131.—*Fontana, Jour. de Phyf.* XI. 509.—*Klaproth, Beiträge,* II. 287.
(F) *Pallas, Phil. Tranf.* LXVI. 523.—*Rubin de Celis, ibid.* LXVIII. 37.—See alfo *Schreiber, Jour. de Phyf.* XLI. 3.; and *Stelin, Phil. Tranf.* LXIV. 461.

Iron Ore. Metallic Ores.

GENUS III. CARBURET OF IRON.

SPECIES 1. Plumbago *.

Graphite of Werner.

217 G. III. Plumbago.

This mineral is found in England, Germany, France, Spain, America, &c. It occurs in kidney-form lumps of various sizes. Its colour is dark iron grey or brownish black; when cut, bluish grey. Lustre metallic, from 3 to 4. Opaque. Structure slaty. Texture fine grained. Hardness 4 to 5. Brittle. Sp. gr. from 1.987 to 2.089; after being soaked in water 2.15; after being heated 2.3, and when heated after that 2.41 †. Feels somewhat greasy. Stains the fingers, and marks strongly. The use of this mineral when manufactured into pencils is known to every person.

Its composition was discovered by Scheele. When pure it contains

90	carbon,
10	iron.
100	

But it is often exceedingly impure: A specimen, for instance, from the mine of Pluffier, in France, analysed by Vauquelin, contained

23	carbon,
2	iron,
38	silica,
37	alumina.
100 ‡	

218. G. IV. Emery.

GENUS IV. IRON COMBINED WITH SILICA.

SPECIES 1. Emery *.

This mineral is commonly disseminated through other fossils, but sometimes in the East Indies it occurs in large masses.

Its colour is bluish grey, greyish brown, or bluish black, often covered with a yellowish rind; internally it discovers red or purple spots. Lustre 1 or 0; in some parts 2, and metallic. Opaque. Hardness 14. Brittle. Sp. gr. 3.92 †. Before the blow-pipe it blackens and gives a smutty yellow tinge to borax.

According to Wiegleb it contains

95.6	silica,
4.3	iron.
99.9	

219 G. V. Oxides.

GENUS V. OXIDES OF IRON.

This genus is very extensive; for iron is much more frequently found in the state of an oxide than in any other.

220 Black oxide of iron.

SPECIES 1. Black oxide of iron ‡.

Common magnetic iron stone—Blackish octohedral iron ore.

This species of ore is very common in Sweden; it is found also in Switzerland, Norway, Russia, &c. It occurs in masses, plates, grains, and crystallized. The primitive form of its crystals is a regular octohedron †. Sometimes two opposite sides of the pyramids are trapeziums, which renders the apex of the pyramids cuneiform. Sometimes the crystals pass into rhomboidal parallelopipeds, and into dodecahedrons with rhomboidal faces §.

Its surface is brownish black; internally bluish grey. Powder black *. Streak blackish grey, brighter. Lustre metallic. Hardness 9 to 10. Brittle. Sp. gr. from 4.094 to 4.688 †. Attracted by the magnet, and generally possessed of more or less magnetic virtue ‡. To this species belongs the magnet. Before the blow-pipe it becomes browner, but does not melt. Tinges borax dark green.

When pure it consists entirely of oxide of iron; and this oxide appears to contain from .15 to .24 oxygen, and from .76 to .85 iron §. Undoubtedly it consists of a mixture of iron in two different states of oxidation. It is often also mixed and contaminated with foreign ingredients.

There are two varieties of this ore. The first is what we have just described; the second is in the form of sand, and has therefore been called

Magnetic sand *.

This substance is found in Italy, Virginia, St. Domingo, the East Indies, and in the sand of the river Don at Aberdeen in Scotland. It is black, very hard, magnetic. Sp. gr. about 4.6 Not altered by the blowpipe *per se*; melts into a black glass with potass, and into a green glass with microcosmic salt, both opaque †. It probably contains some silica, as Kirwan has supposed ‡.

221 Specular iron ore.

SPECIES 2. Specular iron ore ¶.

Fer oligiste.

This ore is found abundantly in the isle of Elba near Tuscany. It is either in masses or crystallized. The primitive form of its crystals, and of its integrant molecules, is the cube *. The varieties hitherto observed amount to 7. These are the rhomboidal parallelopiped; the cube, with three triangular faces instead of two of its angles diagonally opposite; two six-sided pyramids, applied base to base, wanting the summits ‡, and sometimes the angles at the bases, and sometimes the alternate edges of the pyramid; a polyhedron of 24 sides, resembling a cube with three triangular faces for two angles diagonally opposite, and two triangles for the rest of its angles. For a description and figure of these varieties, we refer to *Romé de Lisle* † and *Hauy* ‡.

Colour steel grey; often tarnished, and beautifully iridescent, reflecting yellow, blue, red. Streak red. Powder dark red. Lustre metallic. Hardness 9 to 10. Not brittle. Sp. gr. 5.0116 † to 5.218 ‡. Slightly magnetic. Little altered by the blow-pipe. Tinges borax an obscure yellow.

This ore, according to Mr Mushet, is composed of

66.1	iron,
21.2	oxygen,
10.7	water and carbonic acid,
2.0	lime.
100.0 †	

The quantity of oxygen here stated is probably too small, owing to the unavoidable inaccuracy which results from the *dry way* of analysis which Mr Mushet followed.

Micaceous iron ore

Is generally considered as a variety of this species. Kirwan, however, supposes it to contain carbon, and to be a distinct species.

It is found in Saxony, and in the isle of Elba, &c. generally in amorphous masses, composed of thin six-sided laminæ. Colour iron grey. Streak bluish grey. Lustre metallic. Opaque. Feels greesy. Hardness 5 to 7. Brittle, Sp. gr. from 4.5 to 5.07. Slightly magnetic.

‡ Ibid. 660.
† Hauy,
‡ Brisson.
† Philos. Mag. iii. 354.

Iron Ores. magnetic. Infufible by the blow-pipe. Tinges borax greenifh brown.

212 Laminated fpecular iron ore.

SPECIES 3. Laminated fpecular iron ore.

Fer pyrocoti of Hauy.

This ore, which is found at Montd'or in Auvergn, was ufually arranged under the laft fpecies; but has been feparated from it, we think properly, by Mr Hauy, becaufe the form of its cryftals is incompatible with the fuppofition that their primitive nucleus is a cube, as we have feen is the cafe with common fpecular iron ore. Its cryftals are thin octagonal plates, bounded by fix linear trapeziums, alternately inclined different ways *.

Colour fteel grey. Powder reddifh black. Luftre metallic; furface polifhed. Fracture glaffy. Very brittle †. Hauy fuppofes that this ore has been produced by fire, and accordingly has given it a name which denotes its origin.

* De Lifle, iii. 188.

† Hauy, Jour. de Min. N° xxxi. 33.

223 Brown iron ore.

SPECIES 4. Brown iron ore ‡.

This fpecies of ore is found abundantly in Britain, particularly in Cumberland and Lancafhire; and it is alfo very common in other counties. It confifts of the brown oxide of iron, more or lefs contaminated with other ingredients.

‡ Kirw. ii. 163.

Its colour is brown. Its ftreak reddifh brown. Sp. gr. from 3.4771 to 3.951. Before the blow-pipe blackens, but does not melt. Tinges borax greenifh yellow.

Variety 1. Brown hæmatites.

The name hæmatites (bloodftone) was probably applied by the ancients only to thofe ores which are of a red colour, and have fome refemblance to clotted blood; but by the moderns it is applied to all the ores of iron which give a reddifh coloured powder, provided they be of a fibrous texture.

Brown hæmatites occurs in maffes of various fhapes, and it is faid alfo to have been found cryftallized in five or fix fided acute angled pyramids. Colour of the furface brown or black, fometimes iridefcent; internally nut brown. Powder red. Texture fibrous. Hardnefs 8 to 10. Brittle. Sp. gr. 3.789 § to 3.951 ‖. Not magnetic.

§ Gellert.

‖ Kirwan.

This variety has not been analyfed, but it feems to confift of brown oxide of iron, oxide of manganefe, and alumina ¶.

¶ Kirwan's Min. ii. 164.

Variety 2. Compact brown iron ftone.

This variety occurs in maffes of very various and often fantaftical fhapes.

Colour brown. Internal luftre metallic. Texture compact. Hardnefs 6 to 9. Brittle. Sp. gr. 3.4771 * to 3.551 †.

* Briffon.

† Kirwan.

Variety 3. Brown fcaly iron ore.

This variety is generally incumbent on other minerals. Colour brown. Luftre metallic. Stains the fingers, marks ftrongly. Feels unctuous. Texture foliated. Hardnefs 3 to 5. Brittle. So light as often to float on water.

Variety 4. Brown iron ochre.

This variety occurs both maffive and diffeminated. Colour from nut brown to orange. Luftre 0. Strongly ftains the fingers. Texture earthy. Hardnefs 3 to 4. When flightly heated reddens.

224 Red iron ore.

SPECIES 5. Red iron ore ‡.

‡ Kirw. ii. 168.

Colour red. Streak blood red. Sp. gr. from 3.423 to 5.005. Before the blow-pipe blackens, but does not melt. Tinges borax yellowifh olive green. When digefted in ammonia, it becomes black and often magnetic.

Variety 1. Red hæmatites.

Found in maffes, and all the variety of forms of ftalactites. Colour between brownifh red and fteel grey. Powder red. Internal luftre metallic. Texture fibrous. Hardnefs 9 to 10. Brittle. Sp. gr. 4.74 * to 5.005 †.

When pure it confifts of red oxide of iron, but it often contains manganefe and alumina ‡.

* Gellert.

† Kirwan.

‡ Kirwan's Min. ii. 169.

Variety 2. Compact red iron ore.

Found maffive and ftalactitic; fometimes in cryftals of various forms, but they feem to be only fecondary; fometimes in columns like bafalt.

Colour between brown red and fteel grey. Stains the fingers. Luftre 1 to 0; often femimetallic. Texture compact. Hardnefs 7 to 9. Brittle. Sp. gr. 3.423 to 3.76 §. Sometimes invefted with a rofy red ochre.

§ Kirwan.

Variety 3. Red ochre.

Found fometimes in powder, fometimes indurated. Colour blood red. Stains the fingers. Luftre 0. Texture earthy. Hardnefs 3 to 5. Brittle.

Variety 4. Red fcaly iron ore.

This variety is generally found incumbent upon other iron ores. Colour between cherry red and fteel grey. Stains the fingers. Luftre filky, inclining to metallic. Texture foliated. Feels unctuous. Hardnefs 3 to 4. Brittle. Heavy.

225 Argillaceous iron ore.

SPECIES 6. Argillaceous iron ore ‖.

Oxid of iron combined or mixed with clay.

This ore is exceedingly common; and though it contains lefs iron than the fpecies already defcribed, it is, in this country at leaft, preferred to them, becaufe the method of extracting pure iron from it is eafier, or rather becaufe it is better underftood.

‖ Kirw. ii. 173.

Colour moft commonly dark brown. Streak red or yellowifh brown. Sp. gr. from 2.673 to 3.471 *. Before the blow-pipe blackens, and tinges borax olive green and blackifh. It is compofed of oxide of iron, alumina, lime, filica in various proportions. It generally yields from 30 to 40 *per cent.* of iron.

* Kirwan.

Variety 1. Common argillaceous iron ore.

The minerals arranged under this variety differ confiderably from each other in their external characters. They are found in maffes of various fhapes, and often form large ftrata.

Colour various fhades of grey, brown, yellow, and red. Streak reddifh yellow or dark red. Luftre 0. Hardnefs from 3 to 8. Smell earthy when breathed upon.

Variety 2. Columnar or fcapiform iron ore.

This variety is found in columns, adhering to each other, but eafily feparable: They are commonly incurvated, and their furface is rough. Colour brownifh red. Streak dark red. Slightly ftains the fingers. Luftre 0. Adheres ftrongly to the tongue. Sound hollow. Feel dry. Texture earthy.

Variety 3. Acinofe iron ore.

This variety is found in maffes, and is commonly lenticular. Colour generally brownifh red. Luftre metallic, nearly. Texture granular. Hardnefs 5 to 9. Brittle.

Variety

Iron Ores.

Variety 4. Nodular, or kidney-form iron ore.

Ætites or *Eagleſtone*.

This variety, which was mentioned by the ancients, is generally found under the form of a rounded knob, more or leſs reſembling a kidney, though ſometimes it is quadrangular; and it contains within it a kernel, which is ſometimes looſe, and ſometimes adheres to the outſide rind. Colour of the ſtone yellowiſh brown; of the kernel ochre yellow. Surface generally fouled with earth. Luſtre of the rind metallic; of the kernel 0. Hardneſs from 4 to 7. Brittle.

Variety 5. Piſiform or granular iron ore.

This variety occurs in rounded maſſes, from the ſize of a pea to that of a nut. Surface rough. Colour commonly dark brown. Streak yellowiſh brown. Hardneſs 5 to 6. Brittle.

The oolitic ore found at Creuſot, near mount Cenis, belongs to this variety. It is compoſed of

50	lime,
30	iron,
20	alumina.
100	

226 Lowland iron ore.

SPECIES 7. Lowland iron ore *.

This ſpecies of ore is ſuppoſed to conſiſt of oxide of iron, mixed with clay and phoſphuret or phoſphat of iron. It is called lowland ore, becauſe it is found only in low grounds; whereas the laſt ſpecies is more commonly in high grounds; and is therefore cally *highland ore*.

* Kirw. ii. 179.

This ore occurs in amorphous maſſes, and alſo in grains or powder. Its colour is brown. Streak yellowiſh brown. Luſtre 0, or common. Texture earthy. Hardneſs 3 to 5.

Variety 1. Meadow lowland ore.

Colour blackiſh or yellowiſh brown: Both colours often meet in the ſame ſpecimen. Found in lumps of various ſizes, often perforated. Fracture compact. Moderately heavy.

Frequently yields from 32 to 38 *per cent.* of iron.

Variety 2. Swampy iron ore.

This variety is generally found under water. It is in lumps, which are commonly perforated or corroded, and mixed with ſand. Colour dark yellowiſh brown, or dark nut brown. Hardneſs 3 to 4. Brittle. Sp. gr. 2.944. It often contains .36 of iron.

Variety 3. Moraſſy iron ore.

This variety is found either in a looſe form or in perforated lumps. Colour light yellowiſh brown. Stains the fingers. Hardneſs 3. Friable.

227 G. VI. Salts. Sparry iron ore.

GENUS VI. SALTS OF IRON.

SPECIES 1. Sparry iron ore (G).

This ore is common in Germany, France, and Spain. It is found ſometimes in amorphous maſſes, and ſometimes cryſtallized.

Its colour is white; but it becomes tarniſhed by expoſure to the air, and then aſſumes various colours. Streak grey or white. External luſtre often metallic; internal common or glaſſy. Tranſparency 1 or 2; ſometimes 0. Texture foliated. Fragments rhomboidal. Hardneſs 5 to 7. Brittle. Sp. gr. 3.6 to 3.810. Not magnetic. Soluble in acids with very little efferveſcence. Before the blow-pipe decrepitates, becomes browniſh black, and magnetic; but is ſcarcely fuſible. Tinges borax ſmutty yellow, with ſome efferveſcence.

This ore, as Bergman aſcertained, conſiſts of iron, mangaueſe, lime, and carbonic acid.

One ſpecimen, according to his analyſis, contained

38	iron,
24	mangaueſe,
38	carbonat of lime.
100	

Another contained

22	iron,
28	manganeſe,
50	carbonat of lime.
100	

Whether the iron be combined with the carbonic acid is ſtill a diſputed point. The cryſtals of this ore are rhomboidal parallelopipeds; which is preciſely the form of carbonat of lime. This amounts nearly to a demonſtration, that the carbonic acid is combined with the lime; and that, as Cronſtedt and Hauy have ſuppoſed, this ore is merely carbonat of lime, contaminated with a quantity of the oxids of iron and manganeſe.

228 Arſeniat of iron.

SPECIES 2. Arſeniat of iron.

Mr Prouſt has diſcovered this ore in Spain. Its colour is greeniſh white. Its texture granular. Inſoluble in water and nitric acid. When melted on charcoal, the arſenical acid eſcapes with efferveſcence *.

* Ann. de Chim. i. 195.

229 Sulphat of iron.

SPECIES 3. Sulphat of iron.

For a deſcription of this ſalt, ſee CHEMISTRY, n° 631. in this *Suppl.*

ORDER VII. TIN ORES (H).

TIN is employed to cover plates of iron and copper, and to ſilver the backs of looking glaſſes: It enters into the compoſition of pewter; and forms a very important article in dyeing.

230 Mines.

Tin ores are by no means ſo common as the ores of the metals which we have already deſcribed. They are found only in the *primitive mountains* (I). Hence Werner ſuppoſes them to be the moſt ancient of all metallic ores. They occur moſt frequently in granite, ſometimes in porphyry, but never in limeſtone.

Almoſt

(G) *Kirw.* II. 190.—*Bergman*, II. 184.—*Bayen. Jour. de Phyſ.* VII. 213.— *Razowmowſki, Mem. Lauſanne*, 1783, p. 149.

(H) *Geoffroy, Mem. Par.* 1738, p. 103. —*Morveau, Ann. de Chim.* XXIV. 127.

(I) Geologiſts have divided mountains into three claſſes; *primitive, ſecondary*, and *tertiary*. The *primitive* occupy the centre of all extenſive chains; they are the higheſt, the moſt rugged, and exhibit the moſt pointed tops. They are conſidered as the moſt ancient mountains of the globe.

The *ſecondary* mountains occupy the outſide of extenſive ranges. They are uſually compoſed of ſtrata, more or leſs inclined, and commonly reſt againſt the ſides of the primitive mountains.—The *tertiary* mountains are much ſmaller than the others, and are often ſolitary. We uſe the terms *primitive, ſecondary*, &c. merely as proper

Tin Ores.

Almoft the only tin mines known to Europeans are thofe of Cornwal, Devonfhire, Saxony, Bohemia, Silefia, Hungary, Gallicia; thofe of the ifland of Banca and the peninfula of Malacca in India; and thofe of Chili and Mexico and America.

231 G. I. Sulphurets. Sulphuret of tin and copper

GENUS I. SULPHURETS OF TIN.

SPECIES 1. Sulphuret of tin and copper *.

Tin pyrites.

Hitherto this ore has only been found in Cornwal. There is a vein of it in that county, in the parifh of St Agnes, nine feet wide, and twenty yards beneath the furface †.

Its colour is yellowifh grey, paffing into the fteel grey. Not unlike grey copper ore. Luftre metallic. Hardnefs 5 to 6. Very brittle. Sp. gr. 4.35 ‡. Before the blow-pipe it melts eafily, with a fulphureous fmell, into a black bead, and depofits a bluifh oxide on the charcoal.

The compofition of this ore, as Klaproth informs us, was firft difcovered by Mr Rafpe. According to Klaproth's analyfis, it is compofed of

34	tin,
36	copper,
25	fulphur,
3	iron,
2	earth.
100 §	

* Kirw. ii. 200.

† Klaproth's Cornwal, p. 21.

‡ Klaproth.

§ Id. 58.

232 G. II. Oxides. Brown oxide of tin

GENUS II. OXIDES OF TIN.

SPECIES 1. Brown oxide of tin *.

Tinftone—Woodtin.

This ore, which may be confidered as almoft the only ore of tin, occurs in maffes, in rounded pieces, and cryftallized. Thefe cryftals are very irregular. Hauy fuppofes, that their primitive form is a cube †; but Romé de Lifle, with more probability, makes it an octohedron ‡; and in this opinion Mr Day agrees with him ||. The octohedron is compofed of two four-fided pyramids, applied bafe to bafe. The fides of the pyramids are ifofceles triangles, the angle at the vertex of which is 70°, and each of the other angles 55°. The fides of the two pyramids are inclined to each other at an angle of 90° §. The primitive form, however, never occurs, but cryftals of tinftone are fometimes found, in which the two pyramids are feparated by a prifm. For a complete defcription of the varieties of the cryftals of tinftone, we refer the reader to *Romé de Lifle* and *Mr Day* *.

* Kirw. ii. 197.

† Jour. de Min. No xxxii. 576.

‡ Cryftallog. iii. 413.

|| Philof. Mag. iv. 152.

§ Romé de Lifle, ibid.

Metalic Ores.

Its colour is commonly brown. Streak grey. Hardnefs 9 to 10. Sp. gr. 6.9 to 7.0. Brittle.

Variety 1. Common tinftone.

Colour dark brown; fometimes yellowifh grey, and fometimes nearly white. Streak light grey. Somewhat tranfparent when cryftallized. Hardnefs 10. Sp gr. 6.9 to 6.97. Before the blow-pipe it decrepitates, and on charcoal is partly reduced. Tinges borax white.

According to Klaproth, it is compofed of

77.50	tin,
21.50	oxygen,
.25	iron,
.75	filica.
100.00 †	

* Philof. Mag. ibid.

† Beiträge, ii. 256.

Variety 2. Woodtin.

This variety has hitherto been found only in Cornwal. It occurs always in fragments, which are generally rounded. Colour brown; fometimes inclining to yellow. Streak yellowifh grey. Opaque. Texture fibrous. Hardnefs 9. Sp. gr. 7.0. Before the blow-pipe becomes brownifh red; decrepitates when red hot, but is not reduced.

Klaproth obtained from it .63 of tin; and, in all probability, it is an oxide of tin nearly pure.

ORDER VIII. ORES OF LEAD.

The ufeful purpofes to which lead in its metallic ftate is applied, are too well known to require defcription. Its oxides are employed in painting, in dyeing, and fometimes alfo in medicine.

Ores of lead occur in great abundance in almoft every part of the world. They are generally in veins; fometimes in filiceous rocks, fometimes in calcareous rocks.

GENUS I. SULPHURETS OF LEAD. 233 G. I. Sulphurets. Galena, or pure fulphuret of lead.

SPECIES 1. Galena, or pure fulphuret of lead ‡.

This ore, which is very common, is found both in maffes and cryftallized. The primitive form of its cryftals is a cube. The moft common varieties are the cube, fometimes with its angles wanting, and the octohedron, compofed of two four-fided pyramids applied bafe to bafe: The fummits of thefe pyramids are fometimes cuneiform, and fometimes their folid angles are wanting ||.

Its colour is commonly bluifh grey, like lead. Streak bluifh grey and metallic. Luftre metallic. Sometimes ftains

‡ Kirw. ii. 216.

|| Romé de Lifle, iii. 364.

---

proper names, without affirming or denying the truth or falfehood of the theory on which thefe names are founded. That the reader may have a more accurate idea of the compofition of thefe different claffes of mountains, we have fubjoined a lift of the fubftances which, according to Werner, enter into the compofition of each.

I. PRIMARY MOUNTAINS.

1. Granite,	4. Argillaceous fhiftus,	7. Shiftofe porphyry,	10. Serpentine,
2. Gneifs,	5. Syenite,	8. Quartz,	11. Topaz rock.
3. Micaceous fhiftus,	6. Porphyry,	9. Primitive limeftone,	

II. SECONDARY MOUNTAINS.

1. Argillaceous fhiftus,	3. Secondary limeftone,	5. Grunftein,
2. Rubble ftone,	4. Shiftofe hornblende,	6. Amygdaloid.

III. TERTIARY MOUNTAINS.

1. Trap,	4. Sandftone,	7. Chalk,	10. Ferruginous clay,
2. Argillaceous fhiftus,	5. Breccia,	8. Sulphat of lime,	11. Potters earth.
3. Stratified limeftone,	6. Coal,	9. Rock falt,	

Ores of Lead. ſtains the fingers. Texture foliated. Fragments cubical. Hardneſs 5 to 7; ſometimes even 9. Brittle. Sp. gr. 6.884 to 7.786 §. Effervefces with nitric and muriatic acids. Before the blow-pipe decrepitates, and melts with a ſulphureous ſmell; part ſinks into the charcoal.

§ Watſon.

It is compoſed of from .45 to .83 lead, and from .086 to .16 of ſulphur. It generally contains ſome ſilver, and ſometimes alſo antimony and zinc.

Variety 1. Common galena.

This variety correſponds nearly with the above deſcription. Sp. gr. 7.051 to 7.786. Sometimes ſtains the fingers.

Compact galena.

Found only in amorphous maſſes. Texture compact, inclining to foliated. Hardneſs 6 to 8. Sp. gr. 6.886 to 7.444. Luſtre common. Streak lead grey, brighter and metallic. Often feels greaſy, and ſtains the fingers.

234 Sulphuret of lead, with ſilver and antimony.

SPECIES 2. Sulphuret of lead, with ſilver and antimony*.

Plumbiferous antimoniated ſilver ore.

Found in amorphous maſſes. Colour grey. Hardneſs 5 to 6. Brittle. Sp. gr. from 5.2 to 8.

* Kirw. ii. 119.

Variety 1. Light grey ſilver ore.

Colour light bluiſh grey. Streak light bluiſh grey, and brighter. Luſtre metallic. Texture compact. Before the blow-pipe partly evaporates, and leaves a ſilver bead on the charcoal, ſurrounded by yellow duſt.

According to Klaproth, it contains

48.06	lead,
20.40	ſilver,
7.88	antimony,
12.35	ſulphur,
2.25	iron,
7.00	alumina,
.25	ſilica.
98.09 †	

† Beitrāge, i. 172.

Variety 2. Dark grey ſilver ore.

Colour iron grey, verging on black. Powder black, and ſtains the fingers. Luſtre 0, Texture earthy.

According to Klaproth, it contains

41.00	lead,
21.50	antimony,
29.25	ſilver,
22.00	ſulphur,
1.75	iron,
1.00	alumina,
.75	ſilica.
97.25 ‡	

‡ Ibid. 175.

235 Blue lead ore.

SPECIES 3. Blue lead ore *.

This ore, which is found in Siberia, Germany, and Hungary, and is very rare, occurs ſometimes in maſſes, and ſometimes cryſtallized in ſix-ſided priſms.

* Kirw. ii. 220.

Colour between indigo blue and lead grey; ſometimes inclining to black. Internal luſtre metallic. Streak brighter. Texture compact. Hardneſs 6. Sp. gr. 5.461 †. Before the blow-pipe melts with a low blue flame and a ſulphureous ſmell, and is eaſily reduced.

† Gellert.

236 Black lead ore.

SPECIES 4. Black lead ore ‡.

This ore, which is found in Germany and Brittanny,

‡ Kirw. 221.

and which is ſuppoſed to be common galena decayed, is ſometimes in ſtalactites of various forms, and ſometimes cryſtallized in ſix-ſided priſms, which are generally truncated and confuſed. Metallic Ores.

Colour black, often with ſome ſtreaks of red. Streak light bluiſh grey. Internal luſtre metallic. Hardneſs 5 to 6. Brittle. Sp. gr. from 5.744 ‖ to 5.77*. Before the blow-pipe decrepitates, melts eaſily, and is reduced.

‖ Briſſon. * Gellert.

According to the experiments of Laumont, this ore is a ſulphuret of lead (or rather ſulphuret of oxide of lead), mixed with ſome phoſphat of lead.

237 Sulphuret of lead, biſmuth, and ſilver.

SPECIES 5. Sulphuret of lead, biſmuth, and ſilver.

This ore, which occurs in the valley of Schapbach in Saxony, was firſt taken notice of by Selb, and afterwards deſcribed by Weidenmann and Emerling.

Its colour is light bluiſh grey. Its luſtre metallic Its fracture uneven. Hardneſs 5. Melts eaſily before the blow-pipe, emitting ſome ſmoke, and leaves a ſilver bead.

A ſpecimen, analyſed by Mr Klaproth, contained

33.0	lead,
27.0	biſmuth,
15.0	ſilver,
16.3	ſulphur,
4.3	iron,
0.9	copper.
96.5 †	

† Beitrāge, ii. 297.

238 G. II. Oxides. Lead ochre.

Genus II. Oxides of Lead.

SPECIES 1. Lead ochre ‡.

This ore, which is a mixture of the oxide of lead with various earths, is found maſſive, and various degrees of hardneſs.

‡ Kirw. ii. 205.

Its colour is either yellow, grey, or red. Luſtre 0. Tranſparency 0 to 1. Hardneſs 6 to 8; ſometimes in powder. Sp. gr. from 4.165 to 5.545 §. Texture compact. Effervefces with nitric and muriatic acids. Eaſily reduced by the blow-pipe, leaving a black ſlag, unleſs the lead be mixed with too great a proportion of earth.

§ Kirwan.

239 G. III. Salts. Carbonat of lead.

Genus III. Salts of Lead.

SPECIES 1. Carbonat of lead ‡.

White lead ſpar.

This ore of lead, which is very common, is ſometimes in maſſes, and ſometimes cryſtallized. But the cryſtallization is in general ſo confuſed, that the primitive form of the cryſtals has not yet been aſcertained (K).

‡ Kirw. ii. 203.

Its colour is white. External luſtre, waxy or ſilky, from 3 to 1; internal 1 to 2. Generally ſomewhat tranſparent. Hardneſs 5 to 6. Brittle. Sp. gr. from 5.349 ‖ to 6.92 §. Effervefces with nitric and muriatic acids when they are heated. Soluble in fat oils. Blackened by ſulphuret of ammonia*. Decrepitates when heated. Before the blow-pipe, in a ſilver ſpoon, it becomes red by the yellow cone of the flame, while the blue cone renders it yellow †. On charcoal it is immediately reduced.

‖ Kirwan. § Gellert. * Pelletier, Ann. de Chim. ix. 56. † Ribbentropp, Ann. de Chim. xxv. 189.

It contains from .60 to .85 of lead, and from .18 to .24 of carbonic acid. It is generally contaminated with carbonat of lime and oxide of iron.

(K) See *Hauy*, *Jour. de Min.* N° XXXI. 502. and *Romé de Liſle*, III. 380.

Ores of Lead.

SPECIES 2. Phofphat of lead *.

240 Phofphat of lead. * Kirw. ii. 207.

This ore, which is found in Siberia, Scotland, England, Germany, Carinthia, Brittany, &c. is fometimes amorphous, and fometimes cryftallized. The primitive form of its cryftals, according to Romé de Lifle, is a dodecahedron, confifting of a fix-fided rectangular prifm, terminated by fix-fided pyramids, the fides of which are ifofceles triangles (L). Sometimes the pyramids are truncated, and even altogether wanting. The cryftals of this ore are often acicular.

Its colour is commonly green; fometimes yellowifh or brownifh, or greyifh white. Streak commonly greenifh white. Powder yellowifh. External luftre, waxy, 2 to 3. Somewhat tranfparent, except when its colour is greyifh white. Hardnefs 5 to 6. Brittle. Sp. gr. from 5.86* to 6.27†. Infoluble in water and fulphuric acid, and nearly infoluble in nitric acid; foluble in hot muriatic acid, with a flight effervefcence ‡. Before the blow-pipe it eafily melts on charcoal, and cryftallizes on cooling: with foda the lead is in fome meafure reduced.

* Briffon. † Klaproth. ‡ Fourcroy, Ann. de Chim. ii. 207.

The compofition of this ore was firft difcovered by Gahn.

According to Fourcroy's analyfis, a fpecimen from Erlenbach in Alface confifts of

96	phofphat of lead,
2	phofphat of iron,
2	water.
100	

Or it contains

79	oxide of lead,
1	oxide of iron,
18	phofphoric acid,
2	water.
100 ¶	

¶ Ibid.

SPECIES 3. Arfeniat of lead §.

241 Arfeniat of lead. § Kirw. ii. 209.

This ore, which has hitherto been found only in Andalufia in Spain, and always in quartz or feldfpar, is in fmall maffes. Colour meadow green, often paffing into wax yellow. Luftre waxy, 2. Tranfparency 2. Before the blow-pipe it melts, and retains its colour, and does not cryftallize on cooling. When heated to whitenefs, the arfenic acid efcapes, and the lead is reduced*.

* Prouft, Jour. de Phyf. xxx. 394.

SPECIES 4. Phofphat and arfeniat of lead.

Aefenio phofphat of lead †.

242 Phofphat and arfeniat of lead. † Kirw. ii. 210.

This ore, which has been found in Auvergne in France, is either in maffes, or cryftallized in fmall fix-fided prifms, with curvilineal faces.

Colour yellowifh green, or fhews alternate layers of pale and light green. Powder yellowifh. The cryftals are fomewhat tranfparent; but when maffive, this ore is opaque. Hardnefs 5 to 7. Brittle. Sp. gr. 6.8465 ‡. Soluble in hot muriatic acid, but not in nitric. When heated it decrepitates. Before the blow-pipe melts eafily, effervefces, emits a white fmoke, with an arfenical fmell. Some particles of lead are reduced, a brown fluid remains, which cryftallizes on cooling like phofphat of lead.

‡ Briffon.

Metallic Ores.

According to Fourcroy, from whom the whole of this defcription has been taken, it is compofed of

65	arfeniat of lead,
27	phofphat of lead,
5	phofphat of iron,
3	water.
100*	

* Ann. de Chim. ii. 23.

SPECIES 5. Molybdat of lead (M).

243 Molybdat of lead.

This ore, which is found in Carinthia and at Leadhills in Scotland, was firft mentioned in 1781 by Mr Jacquin (N). It occurs either in maffes, or cryftallized in cubic, or rhomboidal, or octohedral plates.

Its colour is yellow. Streak white. Luftre waxy. Generally fomewhat tranfparent. Texture foliated. Fracture conchoidal. Hardnefs 5 to 6. Sp. gr. 5.486†; when purified from its gangue by nitric acid, 5.706‡. Soluble in fixed alkalies and in nitric acid. Communicates a blue colour to hot fulphuric acid. Soluble in muriatic acid, and decompofed by it. Before the blowpipe decrepitates, melts into a yellowifh grey mafs, and globules of lead are reduced ‖.

† Macquart. ‡ Hatchett. ‖ Macquart.

Klaproth firft proved that this ore was molybdat of lead.

A very pure fpecimen, analyfed by him, contained

64.42	oxide of lead,
34.25	molybdic acid,
98.67 ¶	

¶ Beiträge, ii. 275.

According to the analyfis of Mr Hatchett, it is compofed of

58.40	oxide of lead,
38.00	molybdic acid,
2.10	oxide of iron,
.28	filica.
98.78*	

* Phil. Tranf. lxxxvi. 323.

Macquart found a fpecimen to contain

58.74	lead,
4.76	oxygen,
28.00	molybdic acid,
4.50	carbonat of lime,
4.00	filica.
100.00†	

Its gangue is carbonat of lime.

† Jour. de Min. N° xvii. 32.

SPECIES 6. Sulphat of lead *.

244 Sulphat of lead.

This ore, which is found in Anglefey and in Andalufia, is generally cryftallized. The cryftals are regular octahedrons †, and very minute.

Colour white. Luftre 4. Tranfparency 4. Before the blow-pipe it is immediately reduced.

The compofition of this ore was firft afcertained by Dr Withering.

* Kirw. Min. ii. 211. † Hauy, Jour. de Min. N° xxxi. 508.

Order IX. ORES OF ZINC.

Hitherto zinc has not been applied to a great variety of ufes. It enters into the compofition of brafs; it is ufed in medicine; and Morveau has fhewn that its oxide

(L) *Cryftal.* III. 391. See alfo *Hauy's* remarks on the fame fubject in the *Jour. de Min.* N° XXXI. 506.

Ores of Zinc.

oxide might be employed with advantage as a white paint.

Ores of zinc are very abundant; they generally accompany lead ores, particularly galena. Calamine, or oxide of zinc, has never been discovered in the primitive mountains.

245 G I. Sulphurets. Common sulphuret of zinc.

GENUS I. SULPHURETS OF ZINC.

SPECIES I. Common sulphuret of zinc *.

Blende.

This ore very commonly accompanies sulphuret of lead. It occurs both in amorphous masses and crystallized. The primitive form of its crystals is a rhomboidal dodecahedron, consisting of a six-sided prism, terminated by three-sided pyramids. All the faces of the crystals are equal rhombs. This dodecahedron may be mechanically divided into four equal rhomboidal parallelopipeds, and each of these into six tetrahedrons, whose faces are equal isosceles triangles. The figure of its integrant particles is the tetrahedron, similar to these †.

The principal varieties of its crystals are the tetrahedron; the octohedron; the octohedron with its edges wanting ‡; a 24-sided crystal, 12 of whose faces are trapezoids, and 12 elongated triangles §; and, lastly, a 28-sided figure, which is the last variety, augmented by four equilateral triangles ‖.

Colour yellow, brown, or black. Streak reddish, brownish, or grey. Lustre commonly metallic. Generally somewhat transparent. Texture foliated. Hardness 6 to 8. Sp. gr. 3.93 * to 4.1665 †. Before the blow-pipe decrepitates, and gives out white flowers of zinc, but does not melt. Borax does not affect it. When breathed upon, loses its lustre, and recovers it very slowly ‡.

Variety 1. Yellow blende.

Colour commonly sulphur yellow, often passing into olive green or brownish red. Powder pale yellow. Streak yellowish or reddish grey, not metallic. Lustre metallic. Transparency 2 to 4. Often phosphoresces when scraped or rubbed §.

According to Bergman, it is composed of

64	zinc,
20	sulphur,
5	iron,
4	fluor acid,
1	silica,
6	water.
100 ‖	

Variety 2. Brown blende.

Colour different shades of brown. Surface often tarnished. Powder brownish grey. Streak reddish or yellowish grey, not metallic. Lustre commonly metallic. Transparency 0 to 2.

A specimen of this variety, analysed by Bergman, contained

44	zinc,
17	sulphur,
24	silica,
5	iron,
5	alumina,
5	water.
100 ¶	

Variety 3. Black blende.

Colour black, or brownish black; surface often tarnished blue; tips of the crystals often blood red. Powder brownish black. Streak reddish, brownish, or grey. Lustre common or metallic. Transparency 0 to 1; the red parts 2. Hardness 8.

A specimen of this variety, analysed by Bergman, contained

52	zinc,
26	sulphur,
4	copper,
8	iron,
6	silica,
4	water.

Metallic Ores.

246 G. II. Oxides. White oxide of zinc.

GENUS II. OXIDES OF ZINC.

SPECIES I. White oxide of zinc †.

Calamine.

This ore is either found loose, or in masses, or crystallized. The primitive form of its crystals appears, from the mechanical division of one of them by Mr Hauy, to be an octohedron composed of two four-sided pyramids, whose sides are equilateral triangles ‡. But the crystals are minute, and their figure not very distinct. They are either four or six-sided tables with bevelled edges, six-sided prisms, or three-sided pyramids.

Colour commonly white, grey, or yellow. Lustre often 0, sometimes 2 or 1. Opaque. The crystals are somewhat transparent. Hardness from 4 to 9, sometimes in powder. Sp. gr. from 2.585 to 3.674 §. When heated, becomes electric, without friction, like the tourmaline ‖. Not blackened by sulphuret of ammonia. Soluble in sulphuric acid. Before the blow-pipe decrepitates, and does not melt.

This ore consists of oxide of zinc more or less contaminated with iron, silica, lime, and other foreign ingredients. In one specimen Bergman found the following ingredients:

84	oxide of zinc,
3	oxide of iron,
12	silica,
1	alumina.
100 ¶	

In another specimen, which gelatinized with acids like zeolite, Klaproth found

66	oxide of zinc,
33	silica,
99	

In another specimen, analyzed by Pelletier, the contents were

52	silica,
36	oxide of zinc,
12	water.
100 *	

Mr Kirwan has divided this species into three varieties.

Variety 1. Friable calamine.

In masses which easily crumble between the fingers. Lustre 0. Opaque. Texture earthy. When its colour is white, it is pure oxide of zinc; when yellow, it is mixed with oxide of iron. The white often becomes yellow when placed in a red heat, but resumes its colour on cooling. Common in China, where it is called *wohan* or *ore of Tutenago*.

† Kirw. ii. 233.—Berg. ii. 321.

§ Kirwan.
‖ Hauy, Jour. de Min. ibid.
¶ Bergman, ii. 323.
* Jour. de Phys. xx. 428.

Ores of Antimony.

Variety 2. Compact calamine.

Colour different fhades of grey; fometimes yellow or brownifh red. Luftre 0. Opaque. Texture compact.

Variety 3. Striated calamine.

This variety alone is found cryftallized; but, like the others, it is alfo often amorphous. Colour white, and alfo various fhades of grey, yellow, and red. Somewhat tranfparent. Texture ftriated. Luftre 2 to 1.

247 G. III. Salts. Sulphat of zinc.

GENUS III. SALTS OF ZINC.

SPECIES 1. Sulphat of zinc.

For a defcription of this falt, we refer to CHEMISTRY, n° 643. *Suppl.*

ORDER X. ORES OF ANTIMONY.

Antimony is much ufed to give hardnefs to thofe metals which otherwife would be too foft for certain purpofes: printers types, for inftance, are compofed of lead and antimony. It is ufed alfo in medicine.

Ores of antimony are found abundantly in Germany, Hungary, France, Spain, Britain, Sweden, Norway, &c. They often accompany galena and hæmatites. They are found both in the fecondary and primitive ftratified mountains. Their gangue (o) is often quartz and fulphat of barytes.

248 G. I. Alloys Native antimony.

GENUS I. ALLOYS OF ANTIMONY.

SPECIES 1. Native antimony *.

This mineral, which was firft difcovered by Dr Swab, has been found in Sweden and in France, both in maffes and kidney fhaped lumps. Colour white, between that of tin and filver. Luftre metallic. Texture foliated. Hardnefs 6. Sp. gr. above 6. Deflagrates with nitre. Before the blow-pipe melts and evaporates, depofiting a white oxide of antimony.

It confifts of antimony, alloyed with 3 or 4 *per cent.* of arfenic.

* *Kirw.* ii. 245.

249 G. II. Sulphurets. Grey ore of antimony.

GENUS II. SULPHURETS OF ANTIMONY.

SPECIES 1. Grey ore of antimony *.

This ore, which is the moft common, and indeed almoft the only ore of antimony, occurs both maffive, diffeminated, and cryftallized. Its cryftals are four-fided prifms, fomewhat flattened, whofe fides are nearly rectangles, terminated by fhort four-fided pyramids, whofe fides are trapeziums †. Sometimes two of the edges are wanting, which renders the prifm fix-fided ‡.

Colour grey. Luftre metallic. Streak grey, metallic, and brighter. Powder black or greyifh black. Hardnefs 6 to 7. Sp. gr. from 4.1327 to 4.516 §. Often ftains the fingers. Before the blow-pipe melts eafily, burns with a blue flame, and depofits a white oxide on the charcoal. When placed in an open veffel, over a flow fire, the fulphur evaporates, and leaves a grey oxide of antimony. This oxide, if fufed with tartar, is reduced.

This ore, when taken out of the mine, almoft always contains a large proportion of quartz or other ftony matter. When pure, it is compofed of about

74	antimony,
26	fulphur.
100	

* *Kirw.* ii. 247.
† *Romé de Lifle*, iii. 49.
‡ *Ibid.*—See alfo *Hauy*, *Jour. de Min.* N° xxxii. 606.
§ *Briffon.*

Metallic Ores.

Werner has divided this fpecies into three varieties.

Variety 1. Compact fulphuret.

Colour bluifh grey, furface often tarnifhed, and then it is blue or purplifh. Luftre 1 to 2. Texture compact. Fracture fine grained, uneven. Powder black, dull, and earthy. Slightly ftains the fingers.

Variety 2. Foliated fulphuret.

Colour light fteel grey. Luftre 3 to 4. Texture foliated. Powder as that of the laft variety.

Variety 3. Striated fulphuret.

Colour dark fteel grey, and light bluifh grey, furface often tarnifhed, and then it is dark blue or purplifh. Luftre 3 to 2. Texture ftriated. Powder greyifh black. This variety alone has been hitherto found cryftallized.

250 Plumofe antimonial ore.

SPECIES 2. Plumofe antimonial ore †.

Sulphurets of antimony and arfenic.

This fpecies, which is fometimes found mixed with the cryftals of fulphurated antimony, is in the form of brittle, capillary, or lanuginous cryftals, often fo fmall that they cannot be diftinctly feen without a microfcope.

Colour fteel or bluifh grey, often tarnifhed, and then brown or greyifh black. Luftre 1, femimetallic. Before the blow-pipe emits a fmoke, which depofits a whitifh and yellowifh powder on the charcoal: it then melts into a black flag.

It is fuppofed to confift of fulphur, antimony, arfenic, and fome filver.

† *Kirw.* ii. 250.

251 Red antimonial ore.

SPECIES 3. Red antimonial ore †.

Hydrofulphuret of antimony.

This fpecies is generally found in cavities of fulphurated antimonial ore. It is cryftallized in delicate needles, often diverging from a common centre.

Colour red. Luftre 2, filky. Sp. gr. 4.7. Before the blow-pipe melts eafily, and evaporates with a fulphureous fmell.

This ore has not been analyfed. Mineralogifts have fuppofed it to be a natural kermes. If fo, we may conclude, from the experiments of Berthollet *, that it is a hydrofulphuret of antimony, and confequently compofed of oxide of antimony, fulphur, and fulphurated hydrogen gas.

† *Kirw.* ii. 250.
* *Ann. de Chim.* xxv. 259.

252 G. III. Oxides of antimony.

GENUS III. OXIDES OF ANTIMONY.

There is a fubftance found incumbent on fulphuret of antimony, of a yellow colour, and an earthy appearance, which has been fuppofed an oxide of antimony, and denominated antimonial ochre. But hitherto it has not been analyfed.

GENUS

(o) The word *gang* is ufed by German mineralogifts to denote a metallic vein. Now, it is not often that thefe veins confift entirely of *ore*; in general, they contain ftony matter befides. For inftance, in the copper mine at Airthry, near Stirling, the copper ore is merely a narrow ftripe in the middle of the vein, and the reft of it is filled up with fulphat of barytes. We ufe the word *gangue* (as the French do), to denote, not the *metallic* vein, but the *ftony* matter which accompanies the ore in the vein. The gangue of the copper ore at Airthry is fulphat of barytes.

Ores of Biſmuth. Metallic Ores.

253 G. IV. Salts. Muriat of antimony. * Kirw. ii. 251.

GENUS IV. SALTS OF ANTIMONY.

SPECIES 1. Muriat of antimony *.

This ore, which has been found in Bohemia, is ſometimes in quadrangular tables; ſometimes in acicular cryſtals grouped like zeolites; and ſometimes in priſms.

Colour pale yellowiſh or greyiſh white. Luſtre 3 to 1, nearly metallic. Tranſparency 2. Texture foliated. Melts eaſily by the flame of a candle, and emits a white vapour †. Before the blow-pipe decrepitates; when powdered, and juſt ready to melt, it evaporates, and leaves a white powder around. Between two pieces of coal it is reducible to a metallic ſtate.

† Hauy, Jour. de Min. N° xxxii. 609.

ORDER XI. ORES OF BISMUTH *.

* Pott, Obſerv. Chym. 134—Geoffroy, Mem. Par. 1753, p. 296.

BISMUTH is employed in the manufacture of pewter, of printers types, in ſoldering; and perhaps alſo its property of rendering other metals more fuſible, might make it uſeful in anatomical injections. The quantity conſumed in commerce is not great.

It has been found only in the primitive mountains, and is by no means common. When unaccompanied by any other metal, it does not form veins, but kidney-form maſſes. It often accompanies cobalt. Its gangue is commonly quartz. Its ores are not very abundant. They have been found chiefly in Sweden, Norway, Tranſylvania, Germany, France, and England.

254 G. I. Alloys. Native biſmuth. * Kirw. ii. 264.

GENUS I. ALLOYS OF BISMUTH.

SPECIES 1. Native biſmuth *.

This mineral, which is found at Schneeberg, Johangeorgenſtadt, &c. in Germany, has commonly the form of ſmall plates lying above one another. Sometimes it is cryſtallized in four-ſided tables, or indiſtinct cubes.

Colour white with a ſhade of red; ſurface often tarniſhed red, yellow, or purple. Luſtre metallic, 3 to 2. Opaque. Texture foliated or ſtriated. Hardneſs 6. Sp. gr. 9.022 † to 9.57 ‡. Exceedingly fuſible. Before the blow-pipe gives a ſilvery white bead, and at laſt evaporates in a yellowiſh white ſmoke, which is depoſited on the charcoal.

† Briſſon. ‡ Kirwan.

It is generally accompanied by cobalt, and ſometimes contains arſenic.

255 G. II. Sulphurets. Common ſulphuret of biſmuth. * Kirw. ii. 266.—Sage, Mem. Par. 1782, 307.

GENUS II. SULPHURETS OF BISMUTH.

SPECIES 1. Common ſulphuret of biſmuth *.

This ore, which is found in Sweden, Saxony, and Bohemia, occurs ſometimes in amorphous maſſes, and ſometimes in needleform cryſtals.

Colour commonly bluiſh grey, ſometimes white; ſurface often tarniſhed yellow, red, and purple. Powder black and ſhining. Luſtre metallic, 2 to 3. Streak obſcurely metallic. Texture foliated. Hardneſs 5. Brittle. Sp. gr. 6.131 † to 6.4672 ‡. When held to the flame of a candle, it melts with a blue flame and ſulphureous ſmell. Before the blow-pipe emits a reddiſh yellow ſmoke, which adheres to the charcoal. This powder becomes white when it cools, and reſumes its former colour when the flame is directed upon it *.

† Kirwan. ‡ Briſſon.

* Gillot, Jour. de Min. N° xxxii. 585.

This ore, according to Sage, contains 60 biſmuth. And, according to La Perouſe, it holds 36 ſulphur.

99

A ſpecimen, analyſed by Klaproth, contained

95 biſmuth,
5 ſulphur.

100 †

It is commonly accompanied by quartz, aſbeſtos, or ſparry iron ore.

† Beitrâge, i. 256.

256 G. III. Oxides. Yellow oxide of biſmuth. ‡ Kirw. ii. 263.

GENUS III. OXIDES OF BISMUTH.

SPECIES 1. Yellow oxide of biſmuth ‡.

Biſmuth ochre.

This ore generally accompanies the two ſpecies already deſcribed. It is found in two ſtates; either of an earthy conſiſtence, or cryſtallized in cubes or quadrangular plates.

Colour uſually greeniſh yellow, ſometimes grey. Soluble in nitrous acid without effervefcence, and may in a great meaſure be precipitated by the effuſion of water.

ORDER XII. ORES OF ARSENIC.

ARSENIC is uſed as an alloy for ſeveral other metals, eſpecially copper. It is ſometimes employed to facilitate the fuſion of glaſs, or to render it opaque, in order to form an enamel. Preparations of arſenic are employed as paints; and, like moſt other violent poiſons, it has been introduced into medicine.

This metal is ſcattered in great abundance over the mineral kingdom, accompanying almoſt every other metal, and forming alſo ſometimes peculiar veins of its own. Of courſe it occurs in almoſt every ſpecies of mountain, and is accompanied by a variety of gangues.

257 G. I. Alloys. Native arſenic. † Kirw. ii. 255.

GENUS I. ALLOYS OF ARSENIC.

SPECIES 1. Native arſenic †.

This mineral is found in different parts of Germany. It occurs generally in maſſes of various ſhapes, kidney-form, botryoidal, &c.

Colour that of ſteel. Its ſurface quickly becomes tarniſhed by expoſure to the air. Luſtre metallic (when freſh), 2 to 3. Streak bluiſh grey, metallic, and bright. Powder dull and black. Texture compact. Hardneſs 7 to 8. Brittle. Sp. gr. 5.67 † to 5.7249 ‡. Gives an arſenical ſmell when ſtruck. Before the blow-pipe emits a white ſmoke, diffuſes a garlic ſmell, burns with a blue flame, gradually evaporates, depoſiting a white powder.

† Kirwan. ‡ Briſſon.

It is always alloyed with ſome iron §, and often contains ſilver, and ſometimes gold.

§ De Born. Catal. of M. Raab. ii. 194.

258 G. II. Sulphurets. Orpiment.

GENUS II. SULPHURETS OF ARSENIC.

SPECIES 1. Orpiment (P).

Auripigmentum.

This ore, which is found in Hungary, Wallachia, Georgia, and Turkey in Aſia, is either maſſive or cryſtallized. The cryſtals are confuſed, and their figure cannot be eaſily determined; ſome of them appear octohedrons, and others minute four-ſided priſms.

Its colour is yellow. Streak orange yellow. Luſtre waxy, 2 to 3. Tranſparency from 0 to 2. Texture foliated. Hardneſs 4 to 8 Sp. gr. from 3.048 * to 3.521 †. Effervefces with hot nitric acid. Burns with a

Compoſed of 20 ſulphur,
80 arſenic.

100

260 G. III. Oxides. White oxide of arſenic.
* Kirw. ii. 258—Berg. ii. 285.

GENUS III. OXIDES OF ARSENIC.

SPECIES 1. White oxide of arſenic *.

Native calx of arſenic.

This ore is found in various parts of Germany, Hungary, &c. either in powder, or maſſive, or cryſtallized in priſmatic needles.

Colour white or grey, often with a tint of red, yellow, green, or black. Luſtre common, 1 to 2. Tranſparency 1 to 0; when cryſtallized, 2. Texture earthy. Hardneſs 6. Brittle. Sp. gr. 3.7 †. Soluble in hot diluted nitric acid without effervefcence. Soluble at 60° Fahrenheit in 80 times its weight of water. Before the blow-pipe ſublimes, but does not inflame. Tinges borax yellow.

† Kirwan.

ORDER XIII. COBALT ORES.

COBALT is employed to tinge glaſs of a blue colour, and is uſeful in painting upon porcelain.

Cobalt ores are found almoſt excluſively in the ſtratified mountains, except one ſpecies, ſulphuret of cobalt, which affects the primitive mountains. They are not very abundant; and for that reaſon cobalt is more valuable than many of the other metals which have been already treated of. They are commonly accompanied by nickel, biſmuth, or iron. They are moſt abundant in Germany, Sweden, Norway, and Hungary; they have been found alſo in Britain and France, but not in any great quantity.

261 G. I. Alloys. Cobalt alloyed with arſenic.
† Kirw. ii. 270.

GENUS I. ALLOYS OF COBALT.

SPECIES 1. Cobalt alloyed with arſenic †.

Dull grey cobalt ore.

This ore, which occurs in different parts of Germany, is either amorphous or cryſtallized. The forms of its cryſtals are the cube; ſometimes the cube with its angles, or edges, or both wanting; and the octahedron ‡.

‡ Romé de Liſle, iii. 123.

Metallic Ores.

Its colour, when freſh broken, is whitiſh or bluiſh grey, ſometimes with a ſhade of red; when expoſed to the air it ſoon becomes tarniſhed. Streak bluiſh grey and metallic. Luſtre ſcarcely metallic, 0 to 1. Texture compact. Hardneſs 10. Difficultly frangible. Sp. gr. when amorphous, 5.309 to 5.571 §; when cryſtallized 7.7207 †. When ſtruck it gives out an arſenical ſmell. Before the blow-pipe it gives out an arſenical vapour, becomes magnetic, and melts eaſily, unleſs it contains a great quantity of iron. Tinges borax dark blue, and a ſmall metallic bead is obtained.

§ Kirw. ii. 270.
† Hauy, Jour. de Min. N° xxxii. 588.

A ſpecimen of this ore from Cornwall, examined by Mr Klaproth, contained 20 cobalt,
24 iron,
33 arſenic.

77

with ſome biſmuth and ſtony matter *.

* Klaproth's Cornwall, p. 61.

Another ſpecimen from Tunaberg, according to the analyſis of the ſame chemiſt, contained
55.5 arſenic,
44.0 cobalt,
.5 ſulphur.

† Beiträge, ii. 307.

262 G. II. Sulphurets. White cobalt ore.
‡ Kirw. ii. 273.—Sage, Jour. de Phy. xxxix. 53.

GENUS II. SULPHURETS OF COBALT.

SPECIES 1. White cobalt ore ‡.

Sulphuret of cobalt, arſenic, and iron.

The deſcriptions which different mineralogiſts have given of this ore are ſo various, that it is impoſſible not to ſuppoſe that diſtinct ſubſtances have been confounded together.

It occurs either in maſſes, or cryſtallized in cubes, dodecahedrons, octohedrons, and icoſahedrons.

Colour tin white, ſometimes tarniſhed reddiſh or yellowiſh. Powder ſteel grey. Luſtre partly metallic, and from 2 to 4; partly 0 or 1. Texture foliated. Hardneſs 8 to 9. Sp. gr. from 6.284 † to 6,4509 ‡. Before the blow-pipe generally gives out an arſenical vapour, and does not melt.

† Kirwan.
‡ Hauy.

The analyſes that have been given of this ore are very various. Sometimes it has been found to contain no arſenic nor iron, and ſometimes to contain both. A ſpecimen from Tunaberg in Sweden, which ought to belong to this ſpecies, was analyſed by Taſſaert, and found to conſiſt of 49 arſenic,
36.6 cobalt,
5.6 iron,
6.5 ſulphur.

97.7 †

† Ann. de Chim. xxviii. 100.

Klaproth found a ſpecimen of the ſame ore to contain 55.5 arſenic,
44.0 cobalt,
0.5 ſulphur.

SPECIES 3. Yellow cobalt ore †.

Colour yellow. Dull and earthy. Hardneſs 4 to 5. Texture earthy. Streak brighter, unctuous. Gives a weak blue tinge.

266 G. IV. Salts. rſeniat of balt. Id. 278.

GENUS IV. SALTS OF COBALT.

SPECIES 1. Arſeniat of cobalt ‡.

Red cobalt ore.

This ſpecies, like moſt other ores of cobalt, has neither been accurately deſcribed nor analyſed.

It is found in maſſes of various ſhapes, and cryſtallized in quadrangular tables or acicular priſms.

Colour red. Luſtre from 2 to 3, ſometimes 0. Tranſparency 0 to 2. Hardneſs 5 to 7. Brittle. Before the blow-pipe becomes blackiſh grey. Diffuſes a weak arſenical ſmell. Tinges borax blue.

ORDER XIV. ORES OF NICKEL.

HITHERTO nickel has been found in too ſmall quantities to be applied to any uſe; of courſe there are, properly ſpeaking, no mines of nickel. It occurs only (as far as is yet known) in the ſecondary mountains, and it commonly accompanies cobalt. It has been found in different parts of Germany, in Sweden, Siberia, Spain, France, and Britain.

267 G. I. Sulphurets. Sulphuret of nickel with arſenic and iron. Ibid. 286.

GENUS I. SULPHURETS OF NICKEL.

SPECIES 1. Sulphuret of nickel with arſenic and iron.

*Kupfer nickel**.

This, which is the moſt common ore of nickel, occurs either maſſive or diſſeminated, but never cryſtallized.

Colour often that of copper, ſometimes yellowiſh white or grey. Recent fracture often ſilver white. Luſtre metallic, 2 to 3. Texture compact. Hardneſs 8. Sp. gr. 6.6086 to 6.6481 ‡. Soluble in nitric and nitro-muriatic acids. Solution green. Before the blowpipe exhales an arſenical ſmoke, and melts into a bead which darkens by expoſure to the air.

Briſſon.

It is compoſed of various proportions of nickel, arſenic, iron, cobalt, ſulphur; often contains biſmuth, and ſometimes ſilver and copper.

268 G. II. Oxides. Nickel ochre. Kirwan, 284.

GENUS II. OXIDES OF NICKEL.

SPECIES 1. Nickel ochre *.

This mineral occurs either in the form of a powder, or indurated, and then is either amorphous, or cryſtallized in acicular form cryſtals. The powder is generally found on the ſurface of other nickel ores.

Colour different ſhades of green. Luſtre 1 to 0. Texture earthy. Sp. gr. conſiderable. Slowly diſſolves in acids: ſolution green. Before the blow-pipe does not melt; but gives a yellowiſh or reddiſh brown tinge to borax.

This ore often contains ſulphat of nickel, which is ſoluble in water. The ſolution, when evaporated, gives oblong rhomboidal cryſtals, from which alkalies precipitate a greyiſh green oxide. This oxide is ſoluble by acids and by ammonia. The acid ſolution is green; the alkaline blue.

Metallic Ores

269 G. III. Salts. Arſeniat of nickel. † Kirwan, ii. 285.

GENUS III. SALTS OF NICKEL.

SPECIES 1. Arſeniat of nickel †.

This ore, which was lately diſcovered at Regendorff by Mr Gmelin, is found in ſhapeleſs maſſes, and is often mixed with plates of ſulphat of barytes.

Colour pale grey, here and there mixed with pale green. Streak white. Luſtre 0. Texture compact. Hardneſs 7. Difficultly frangible. Sp. gr. conſiderable. Adheres ſlightly to the tongue, and gives an earthy ſmell when breathed on. Soluble in hot nitric and muriatic acids: ſolution green.

Contains ſome cobalt and alumina.

ORDER XV. ORES OF MANGANESE (q).

HITHERTO mangaueſe, in its metallic ſtate, has ſcarcely been put to any uſe; but under the form of an oxide it has become of great importance. The oxide of manganeſe has the property of rendering colourleſs a variety of bodies which injure the tranſparency of glaſs; and it has been long uſed in glaſs manufactories for this purpoſe under the name of *glaſs ſoap*. By means of the ſame oxide, oxy-muriatic acid is prepared, which has rendered manganeſe of great importance in bleaching. Not to mention the utility of manganeſe to the chemiſt, the property which it has of facilitating the oxidation of other metals, and of rendering iron more fuſible—will probably make it, in no very remote period, of very conſiderable importance in numerous manufactories.

Ores of manganeſe occur often in ſtrata, both in the primitive and ſecondary mountains; ſcarcely ever, however, we believe, in thoſe mountains which are conſidered as the moſt ancient of all. They are very common, having been found abundantly in Germany, France, Spain, Britain, Sweden, Norway, Siberia, and other countries.

270 G. I. Oxides.

GENUS I. OXIDES OF MANGANESE.

Hitherto manganeſe has only been found in the ſtate of oxide. La Perouſe, indeed, ſuſpected that he had found it in a metallic ſtate: but probably there was ſome miſtake or other in his obſervations.

271 Oxide of manganeſe combined with barytes.

SPECIES 1. Oxide of manganeſe combined with barytes.

This ſpecies, which exiſts in great abundance in Romaneche near the river Soane in France, is found maſſive, forming a ſtratum in ſome places more than 12 feet thick.

Colour greyiſh black or browniſh black, of great intenſity. Luſtre, external, 0; internal, metallic, 1. Soon tarniſhes by expoſure to the air, and then becomes intenſely black. Texture granular. Fracture uneven; ſometimes conchoidal. Often porous. Hardneſs 11. Difficultly frangible. Sp. gr. from 3 950 to 4.10. Abſorbs water. When taken out of water after a minute's immerſion it has a ſtrong argillaceous ſmell. Conducts electricity nearly as well as if it were in a metallic ſtate. Infuſible by the blow-pipe. Tinges ſoda red; the colour diſappears before the blue cone of flame, and is reproduced by the action of the yellow flame.

SPECIES 2. Grey ore of manganefe *.

272 Grey ore of manganefe. * Kirwan, ii. 291.

This ore occurs both maffive and diffeminated: it is alfo fometimes cryftallized in flender four-fided prifms or needles.

Colour ufually dufky fteel grey; fometimes whitifh grey, or reddifh grey. Streak and powder black. External luftre 3 to 2; internal metallic, 2 to 1. Texture ftriated or foliated. Hardnefs 4 to 5. Brittle. Sp. gr. from 4.073 † to 4.8165 ‡. Before the blow-pipe darkens. Tinges borax reddifh brown.

† Vauquelin. ‡ Briffon.

A fpecimen of oxide of manganefe from the mountains of Vofges, which probably belonged to this fpecies, and which was analyfed by Vauquelin, was compofed of

82	oxide of manganefe,
7	carbonat of lime,
6	filica,
5	water.
100 §	

§ Jour. de Min. N° xvii. 13.

Sometimes it contains a little barytes and iron.

SPECIES 3. Black or brown ore of manganefe *.

273 Black or brown ore of manganefe. * Kirwan, ii. 292.—Wedgewood, Phil. Tranf. lxxiii. 284.

This ore is found fometimes in the ftate of powder, and fometimes indurated in amorphous maffes of various figures. Colour either black, fometimes with a fhade of blue or brown; or reddifh brown. Streak of the harder forts metallic; of the others, black. Luftre 0 to 1; internal (when it is indurated), metallic. Texture compact. Hardnefs 5 to 7. Sp. gr. 3.7076 to 3.9039; that of the powdery fometimes only 2. Before the blow-pipe it exhibits the fame phenomena as the laft fpecies.

A fpecimen of this ore, analyfed by Weftrum, contained

45.00	manganefe,
14.00	oxide of iron,
11.00	filica,
7.25	alumina,
2.00	lime,
1.50	oxide of copper,
18.00	air and water.
98.75	

GENUS II. SALTS OF MANGANESE.

274 G. II. Salts. Carbonat of manganefe. † Kirwan, ii. 297.

SPECIES 1. Carbonat of manganefe †.

White ore of manganefe.

This fpecies occurs in Sweden, Norway, and Tranffylvania. It is either in the form of loofe fcales, or maffive, or cryftallized in needles.

Colour white, or reddifh white. Texture either radiated or fcaly. Luftre of the fcaly 2. Tranfparency 1 to 2. Hardnefs of the maffive 6 to 9. Sp. gr. 2.794. Effervefces with mineral acids. Heated to rednefs, blackens. Tinges borax violet.

Metallic Ores.

SPECIES 2. Red ore of manganefe †.

Carbonat of manganefe and iron.

275 Red ore of manganefe. † Kirwan, ii. 297.—Napion, Mem. Turin, iv. 303.

This fpecies has been found in Piedmont and in the Pyrenees. It is fometimes in powder, fometimes maffive, fometimes cryftallized in rhomboidal prifms or needles.

Colour pale rofy red, mixed with white. Powder nearly white. Luftre 0. Tranfparency 1. Hardnefs 8. Sp. gr. 3.233. Effervefces with nitric and muriatic acids. When heated to rednefs becomes reddifh brown. Tinges borax red.

A fpecimen, analyfed by Ruprecht, contained

55.0	filica,
25.0	oxide of manganefe,
7.0	oxide of iron,
1.5	alumina.
98.5 §	

§ Jour de Phyf. xxxi. 22.

ORDER XVI. ORES OF TUNGSTEN.

As no eafy method has hitherto been difcovered of reducing tungften to a metallic ftate, we need not be furprifed that it has been applied to no ufe. Ores of tungften are by no means common. They have hitherto been found only in the primitive mountains. Their gangue is commonly quartz. They very often accompany tin ores.

GENUS I. OXIDES OF TUNGSTEN.

276 G. I. Oxides Wolfram.

SPECIES 1. Wolfram (R).

Oxides of tungften, iron, and *manganefe—Tungftat of iron* and *manganefe.*

This fpecies is found in different parts of Germany, in Sweden, Britain, France and Spain; and is almoft conftantly accompanied by ores of tin. It occurs both maffive and cryftallized. The primitive form of its cryftals, according to the obfervations of Mr Hauy, is a rectangular parallelopiped ‡, whofe length is 8.66, whofe breadth is 5, and thicknefs 4.33 *. It is not common, however, to find cryftals of this perfect form; in many cafes, the angles, and fometimes the edges, of the cryftal are wanting †; owing, as Mr Hauy has fhewn, to the fuperpofition of plates, whofe edges or angles decreafe according to a certain law ‡.

‡ Fig. 42. * Jour. de Min. N° xix. 8. † Fig. 43. ‡ Jour. de Min. N° xix. 8.

Colour brown or brownifh black. Streak reddifh brown. Powder ftains paper with the fame colour. Luftre external, 2; internal, 2 to 3; nearly metallic. Texture foliated. Eafily feparated into plates by percuffion. Hardnefs 6 to 8. Sp. gr. from 7.006 * to 7.333 †. Moderately electric by communication. Not magnetic. Infufible by the blow-pipe. Forms with borax a greenifh globule, and with microcofmic falt a tranfparent globule of a deep red ¶.

* Kirwan. † Hauy. ¶ Vauquelin, Jour. de Min. N° xix. 11.

The fpecimen of this ore, examined by Meffrs d'Elhuyart's, was compofed of

65	oxide of tungften,
22	oxide of manganefe,
13	oxide of iron.

§ *Vauquelin, Jour. de Min.* N° xix. 11.

GENUS II. SALTS OF TUNGSTEN.
SPECIES 1. Tungstat of lime (s).
Tungsten.

277 G. II. Salts. Tungstat of lime.

This ore, which is now exceedingly scarce, has hitherto been found only in Sweden and Germany. It is either massive or crystallized; and, according to Hauy, the primitive form of its crystals is the octahedron †.

† *Jour. de Min.* N° xxxiii. 657.

Colour yellowish white or grey. Lustre 3 to 2. Transparency 2 to 3. Texture foliated. Hardness 6 to 9. Sp. gr. 5.8 to 6.0665. Becomes yellow when digested with nitric or muriatic acids. Infusible by the blow-pipe. With borax forms a colourless glass, unless the borax exceed, and then it is brown. With microcosmic salt it forms a blue glass, which loses its colour by the yellow flame, but recovers it in the blue flame ‡.

‡ *Scheele* and *Bergman.*

It is composed of about 70 oxide of tungsten,
30 lime.
100

with a little silica and iron §.

§ *Scheele.*

278 Brown tungstat.

SPECIES 2. Brown Tungstat.

This ore is found in Cornwall, and is either massive or composed of small crystalline grains.

Colour grey, variegated with yellow and brown. Lustre 2, waxy. Hardness 6 to 7. Sp. gr. 5.57. Its powder becomes yellow when digested in aqua regia.

According to Klaproth, it is composed of

88.0 oxide of tungsten,
11.5 lime.

99.5

ORDER XVII. ORES OF MOLYBDENUM.

If ever molybdenum be found in abundance, it will probably be useful in dyeing and painting. At present it is very scarce, having only been found in Sweden, Germany, Carniola, and among the Alpes. Like tin and tungsten, it affects the primitive mountains.

279 G. I. Sulphuret. Common sulphuret.

GENUS I. SULPHURET OF MOLYBDENUM.
SPECIES 1. Common sulphuret (T).
Molybdena.

This ore, which is the only species of molybdenum ore at present known, is found commonly massive; sometimes, however, it is crystallized in hexahedral tables.

Colour light lead grey; sometimes with a shade of red. Streak bluish grey, metallic. Powder bluish. Lustre metallic, 3 to 2. Texture foliated. Lamellæ slightly flexible. Hardness 4. Sp. gr. 4.569 * to 4.7385 †. Feels greasy; stains the fingers. Marks bluish black. A piece of resin rubbed with this mineral becomes positively electric ‡. Insoluble in sulphuric and muriatic acids; but in a boiling heat colours them green. Effervesces with warm nitric acid, leaving a grey oxide undissolved. Before the blow-pipe, on a silver spoon, emits a white smoke, which condenses into a white powder, which becomes blue in the internal, and loses its colour in the external, flame. Scarcely affected by borax or microcosmic salt. Effervesces with soda, and gives it a reddish pearl colour.

* *Karsten.*
† *Brisson.*

Metallic Ores.

‡ *Hauy, Jour. de Min.* N° xix. 70.

Composed of about 60 molybdenum,
40 sulphur.

100 *

* *Klaproth.*

ORDER XVIII. ORES OF URANIUM.

Uranium has hitherto been found only in Germany, and has not been applied to any use. The only two mines where it has occurred are in the primitive mountains.

280 G. I. Oxides. Sulphuret of uranium.

GENUS I. OXIDES OF URANIUM.
SPECIES 1. Sulphuret of uranium †.
Pechblende.

† *Kirwan,* ii. 305.

This ore, which has been found at Johanngeorgenstadt in Saxony, and Joachimsthal in Bohemia, is either massive or stratified with other minerals.

Colour black or brownish black; sometimes with a shade of grey or blue. Streak darker. Powder opaque and black. Lustre semimetallic, from 3 to 1. Fracture conchoidal. Hardness 7 to 8. Very brittle. Sp. gr. from 6.3785 ‡ to 7.5, and even higher §. Imperfectly soluble in sulphuric and muriatic acids; perfectly in nitric acid and aqua regia. Solution wine yellow. Infusible with alkalies in a crucible: infusible by the blow-pipe *per se*. With borax and soda forms a grey opaque slag; with microcosmic salt, a green glass.

‡ *Morveau, Jour. de Min.* N° xxvii. 610.
§ *Klaproth, Beiträge,* ii. 197.

Composed of oxide of uranium and sulphur, and mixed with iron and silica, and sometimes lead.

A specimen of this ore from Joachimsthal, analysed lately by Klaproth, contained

86.5 uranium,
6.0 sulphuret of lead,
5.0 silica,
2.5 oxide of iron.

100.0 *

* *Beiträge,* ii. 221.

281 Yellow oxide of uranium.

SPECIES 2. Yellow oxide of uranium ‡.
Uranitic ochre.

‡ *Kirwan,* ii. 303.

This ore is generally found on the surface of the last species at Johanngeorgenstadt, and is either massive or in powder.

Colour yellow, red, or brown. Streak of the yellow sorts yellow; of the red, orange yellow. Lustre 0. Slightly stains the fingers. Feels meagre. Texture earthy. Hardness 3 to 4. Sp. gr. 3.2438 ‖. Infusible by the blow-pipe; but in a strong heat becomes brownish grey.

‖ *Hauy, Jour. de Min. ibid.*

Composed of oxide of uranium and oxide of iron.

(s) *Kirw.* II. 314.—*Scheele's Works* (French translation), II. 81.—*Bergman, ibid.* p. 94.—*Crell, Chem. Annalen.* 1784, 2 *Bard* 195.

Genus II. Salts of Uranium.

281 G. II. Salts Carbonat of uranium.

Species 1. Carbonat of uranium ¶.

This ſubſtance is alſo found at Johanngeorgenſtadt, and near Eibenſtock and Rheinbreidenbach §. It is ſometimes amorphous, but more commonly cryſtallized. Its cryſtals are ſquare plates, octahedrons, and ſix ſided priſms.

¶ Kirwan, ii. 304.
§ Gmelin.

Colour green; ſometimes nearly white; ſometimes, though rarely, yellow. Streak greeniſh white. Luſtre 3 to 2; internal, 2; ſometimes pearly; ſometimes nearly metallic. Tranſparency 2 to 3. Texture foliated. Hardneſs 5 to 6. Brittle. Soluble in nitric acid without effervеſcence. Infuſible by alkalies.

Compoſed of carbonat of uranium, with ſome oxide of copper. When its colour is yellow it contains no copper.

Order XIX. Ores of Titanium.

Titanium has been known for ſo ſhort a time, and its properties are yet ſo imperfectly aſcertained, that many of its uſes muſt remain to be diſcovered. Its oxide, as we learn from Mr Darcet, has been employed in painting on porcelain *. Hitherto it has been found only in the primitive mountains, the Crapacks †, the Alpes (u), and the Pyrenees ‡. It has been found alſo in Brittany ‖ and in Cornwal.

* Jour. de Min. N° xv. 27.
† Ibid. N° xii. 51.
‡ Jour. de Min. N° xxxii. 614.
‖ Ibid.

Genus I. Oxides of Titanium.

283 G. I. Oxides. Red oxide of titanium.

Species 1. Red oxide of Titanium.

Red ſhorl—Sagenite.

This ore has been found in Hungary, the Pyrenees, the Alpes, and in Brittany in France. It is generally cryſtallized. The primitive form of its cryſtals, according to the obſervations of Mr Hauy, is a rectangular priſm, whoſe baſe is a ſquare; and the form of its molecules is a triangular priſm, whoſe baſe is a right angled iſoſceles triangle, and the height is to any of the ſides of the baſe about the right angle as $\sqrt{12}$ to $\sqrt{5}$, or nearly as 3 : 2 ¶. Sometimes the cryſtals of titanium are ſix-ſided, and ſometimes four-ſided, priſms, and often they are implicated together ‡.

¶ Jour. de Min. N° xv. 28. and xxxii. 615.
‡ Fig. 44.

Colour red or browniſh red. Powder brick or orange red. Luſtre 3. Tranſparency commonly 0; ſometimes 1. Texture foliated. Hardneſs 9. Brittle. Sp. gr. from 4.18 * to 4.2469 †. Not affected by the mineral acids. When fuſed with carbonat of potaſs, and diluted with water, a white powder precipitates, heavier than the titanium employed. Before the blow-pipe it does not melt, but becomes opaque and brown. With microcoſmic ſalt it forms a globule of glaſs, which appears black; but its fragments are violet. With borax it forms a deep yellow glaſs, with a tint of brown. With ſoda it divides and mixes, but does not form a tranſparent glaſs.

* Klaproth.
† Vauquelin and Hecht.

When pure, it is compoſed entirely of oxide of titanium.

284 Menachanite.

Species 2. Menachanite (x).

Oxide of titanium combined with iron.

This ſubſtance has been found abundantly in the valley of Menachan in Cornwal; and hence was called menachanite by Mr Gregor, the diſcoverer of it. It is in ſmall grains, like gunpowder, of no determinate ſhape, and mixed with a fine grey ſand. Colour black. Eaſily pulverized. Powder attracted by the magnet. Sp. gr. 4.427. Does not detonate with nitre. With two parts of fixed alkali it melts into an olive coloured maſs, from which nitric acid precipitates a white powder. The mineral acids only extract from it a little iron. Diluted ſulphuric acid, mixed with the powder, in ſuch a proportion that the maſs is not too liquid, and then evaporated to dryneſs, produces a blue coloured maſs. Before the blow-pipe does not decrepitate nor melt. It tinges microcoſmic ſalt green; but the colour becomes brown on cooling: yet microcoſmic ſalt does not diſſolve it. Soluble in borax, and alters its colour in the ſame manner.

Metallic ores.

According to the analyſis of Mr Gregor, it is compoſed of

46	oxide of iron,
45	oxide of titanium.
91	with ſome ſilica and mangaueſe †.

† M. Gregor.

According to Mr Klaproth's analyſis, it is compoſed of

51.00	oxide of iron,
45.25	oxide of titanium,
3.50	ſilica,
.25	oxide of mangancſe.
100.00 ‡	

Jour. de Phyſ. xxxix. 72. 152.
‡ Beiträge, ii. 231.

A mineral, nearly of the ſame nature with the one juſt deſcribed, has been found in Bavaria. Its ſpecific gravity, however, is only 3.7. According to the analyſis of Vauquelin and Hecht, it is compoſed of

49	oxide of titanium,
35	iron,
2	manganeſe,
14	oxygen combined with the iron and manganeſe.
100 §	

§ Jour. de Min. N° xix. 57.

285 Calcareo-ſiliceous ore of titanium.

Species 3. Calcareo-ſiliceous ore of titanium.

Oxide of titanium combined with lime and ſilica—Titanite †.

This ore has hitherto been found only near Paſſau. It was diſcovered by Profeſſor Hunger. It is ſometimes maſſive, but more commonly cryſtallized in four-ſided priſms, not longer than one fourth of an inch.

† Kirwan, ii. 331.

Colour reddiſh, yellowiſh, or blackiſh brown; ſometimes whitiſh grey. Powder whitiſh grey. Luſtre waxy or nearly metallic, 2 to 3. Tranſparency from 0 to 2. Texture foliated. Hardneſs 9 or more. Brittle. Sp. gr. 3.510. Muriatic acid, by repeated digeſtion, diſſolves one-third of it. Ammonia precipitates from this ſolution a clammy yellowiſh ſubſtance. Infuſible by the blow pipe, and alſo in a clay crucible; but in charcoal is converted into a black opaque porous ſlag.

According to the analyſis of Klaproth, it is compoſed of

33	oxide of titanium,
35	ſilica,
33	lime.

Ores of Tellurium.

Order XX. ORES OF TELLURIUM.

Hitherto tellurium has only been found in Transylvania. It occurs in three different mines; that of Fatzbay, Offenbanya, and Nagyag, which are considered as gold mines. becaufe they contain lefs or more of that metal. Its gangue is commonly quartz.

286 G. I. Alloys. White gold ore of Fatzbay.

Genus I. alloys of tellurium.

species 1. White gold ore of Fatzbay.

Alloy of tellurium and iron, with fome gold.

This fpecies is generally maffive. Its colour is between tin white and lead grey. Luftre confiderable, metallic. Texture granular *.

According to Klaproth's analyfis, it is compofed of

72.0 iron,
25.5 tellurium,
2.5 gold.

100.0 †

287 Graphic gloden ore of Offenbanya.

species 2. Graphic golden ore of Offenbanya.

Tellurium alloyed with gold and filver.

This ore is compofed of flat prifmatic cryftals; the arrangement of which has fome refemblance to Turkifh letters. Hence the name of the ore.

Colour tin white, with a tinge of brafs yellow ‡. Luftre metallic, 3, Hardnefs 4 to 5. Brittle. Sp. gr. 5.723. Before the blow pipe decrepitates, and melts like lead. Burns with a lively brown flame and difagreeable fmell, and at laft vanifhes in a white fmoke, leaving only a whitifh earth ||.

According to Klaproth's analyfis it is compofed of

60 tellurium,
30 gold,
10 filver.

100 §

The yellow gold ore of Nagyag would belong to this fpecies were it not that it contains lead. Its compofition, according to Klaproth's anaylfis, is as follows:

45.0 tellurium,
27.0 gold,
19.5 lead,
8.5 filver,

100.0 and an atom of fulphur *.

288 Grey foliated gold ore of Nagyag.

species 3. Grey foliated gold ore of Nagyag.

This ore is found in plates, of different degrees of thicknefs, adhering to one another, but eafily feparable: thefe are fometimes hexahedral, and often accumulated fo as to leave cells between them.

Colour deep lead grey, paffing to iron black, fpotted. Luftre metallic, moderate. Texture foliated; leaves flightly flexible †. Hardnefs 6. Sp. gr. 8.919. Stains the fingers. Soluble in acids with effervefcence ‡.

According to Klaproth, it is compofed of

50.0 lead,
33.0 tellurium,
8.5 gold,
7.5 fulphur,
1.0 filver and copper.

100.0 §

Metallic Ores.

Order XXI. ORES OF CHROMUM.

Chromum has hitherto been found in too fmall quantities for its extenfive application to the arts. Whenever it becomes plentiful, its properties will render it of great importance both to the dyer and painter. Nature has ufed it to colour fome of her moft beautiful mineral productions: And can art copy after a better model? Hitherto it has been found only in two places, near Ekaterinbourg in Siberia, and in the department of the Var in France. In the firft of thefe places, and probably alfo in the fecond, its gangue is quartz.

289 G. I. Salts. Chromat of lead.

Genus I. salts of chromum.

species 1. Chromat of lead.

Red lead ore of Siberia.

This fingular mineral, which has now become fcarce, is found in the gold mines of Berefof near Ekaterimbourg in Siberia, cryftallized in four fided prifms, fometimes terminated by four-fided pyramids, fometimes not.

Colour red, with a fhade of yellow. Streak and powder a beautiful orange yellow. Luftre from 2 to 3. Tranfparency 2 to 3. Structure foliated. Texture compact. Fracture uneven. Hardnefs 5 to 4. Sp. gr. 6.0269 † to 5.75 ‡. Does not effervefce with acids. Before the blow pipe decrepitates; fome lead is reduced, and the mineral is converted to a black flag, which tinges borax green.

According to the analyfis of Vauquelin, it is compofed of

65.12 oxide of lead,
34.88 chromic acid.

100.00 ||.

species 2. Chromat of iron.

290 Chromat of iron.

This mineral, which has been found only near Gaffin in the department of Var in France, is in irregular meffas.

Colour brown, not unlike that of brown blende. Luftre metallic. Hardnefs moderate. Sp. gr. 4.0326. Melts with difficulty before the blow-pipe; to borax it communicates a dirty green. Infoluble in nitric acid. Melted with potafs, and diffolved in water, the folution affumes a beautiful orange yellow colour.

It is compofed of 63.6 chromic acid,
36.0 oxide of iron.

Chap. V. Of the Chemical Analysis of Minerals.

291 Analyfis of minerals.

The progrefs which the art of analyfing minerals has made within thefe laft twenty years is truly aftonifhing. To feparate five or fix fubftances intimately combined together, to exhibit each of them feparately, to afcertain the precife quantity of each, and even to detect the prefence and the weight of fubftances which do not approach $\frac{1}{100}$th part of the compound, would, at no very remote period, have been confidered as a hopelefs, if not an impoffible, tafk; yet this can now be done with the moft rigid accuracy.

292 Begun by Margraff.

The firft perfon who undertook the analyfis of minerals was Margraff of Berlin. His attempts were indeed rude; but their importance was foon perceived by other chemifts, particularly by Bergman and Scheele, whofe whoſe induſtry and addreſs brought the art of analyſing minerals to a conſiderable degree of perfection.

But their methods, though they had very conſiderable merit, and, conſidering the ſtate of the ſcience, are wonderful proofs of the genius of the inventors, were often tedious and uncertain, and could not in all caſes be applied with confidence. Theſe defects were perceived by Mr Klaproth of Berlin, who applied himſelf to the analyſis of minerals with a perſevering induſtry which nothing could fatigue, and an ingenuity and accuracy which nothing could perplex. He corrected what was wrong, and ſupplied what was wanting, in the analytical method; invented new proceſſes, diſcovered new inſtruments; and it is to his labours, more than to thoſe of any other chemiſt, that the degree of perfection, to which the analyſis of minerals has attained, is to be aſcribed.

293 Improved by Klaproth

Many improvements, however, were introduced by other chemiſts, eſpecially by Mr Vauquelin, whoſe analyſes in point of accuracy and ingenuity rival thoſe of Klaproth himſelf.

294 And other chemiſts.

We ſhall, in this chapter, give a ſhort deſcription of the moſt perfect method of analyſing minerals, as far as we are acquainted with it. We ſhall divide the chapter into four ſections. In the firſt, we ſhall give an account of the inſtruments uſed in analyſes; in the ſecond, we ſhall treat of the method of analyſing ſtones; in the third, of analyſing combuſtibles; and in the fourth, of the analyſes of ores.

Sect. I. *Of the Inſtruments of Analyſes.*

295 Method of obtaining chemical agents pure.

I. The chymical agents, by means of which the analyſis of minerals is accompliſhed, ought to be prepared with the greateſt care, becauſe upon their purity the exactneſs of the operation entirely depends. Theſe agents are the three alkalies, both pure and combined with carbonic acid; the ſulphuric, nitric, and muriatic acids; hydroſulphuret of potaſs and ſulphurated hydrogen gas diſſolved in water; pruſſic alkali, and a few neutral ſalts.

1. Potaſs and ſoda may be obtained pure, either by means of alcohol, or by the method deſcribed in the article Chemistry, n° 372. *Suppl.* Theſe alkalies are known to be pure when their ſolution in pure water occaſions no precipitate in lime and barytic water; when the precipitate which it produces in a ſolution of ſilver is completely diſſolved by nitric acid; and, laſtly, when ſaturated with carbonic acid it depoſits no ſilica.

2. Ammonia is procured by diſtilling one part of muriat of ammonia with two parts of quicklime, and receiving the gas in a diſh containing a quantity of pure water, equal in weight to the muriat employed. Its purity is known by the ſame teſts which aſcertain the purity of fixed alkalies.

3. The carbonats of potaſs and ſoda may be formed by diſſolving the potaſs and ſoda of commerce in pure water, ſaturating the ſolution with carbonic acid, and cryſtallizing them repeatedly. When pure, theſe cryſtals effloreſce in the air; and the precipitate which they occaſion in ſolutions of barytes and of ſilver is completely ſoluble in nitric acid. Carbonat of ammonia is obtained by diſtilling together one part of muriat of ammonia and two parts of carbonat of lime.

4. The ſulphuric acid of commerce often contains nitric acid, potaſs, lead &c. It may be purified by diſtillation in a low cucurbite. The firſt portion, when it comes over, muſt be ſet aſide; it contains the nitric acid. The other impurities remain behind in the cucurbite. Sulphuric acid, when pure, diſſolves indigo without altering its colour, does not attack mercury while cold, and cauſes no precipitate in pure alkaline ſolutions.

5. Nitric acid often contains both ſulphuric and muriatic acids. It is eaſily purified by throwing into it about three parts of litharge in fine powder for every 100 parts of the acid, allowing the mixture to remain for 24 hours, ſhaking it occaſionally, and then diſtilling it. The ſulphuric and muriatic acids combine with the lead, and remain behind in the retort. Pure nitric acid occaſions no precipitate in the ſolutions of barytes and ſilver.

6. The muriatic acid of commerce uſually contains ſulphuric acid, oxymuriatic acid, and oxide of iron. It may be purified by diſtillation with a little muriat of ſoda; taking care to ſet aſide the firſt portion which comes over. When pure it cauſes no precipitate in the ſolution of barytes, nor of pure alkalies, and does not attack mercury while cold.

7. Hydroſulphuret of potaſs is made by ſaturating a ſolution of pure potaſs with ſulphurated hydrogen gas; and water may be ſaturated with ſulphurated hydrogen gas in the ſame manner. See Chemistry, n° 857. *Suppl.*

8. The method of preparing pruſſic alkali, oxalic acid, and the other ſubſtances uſed in analyſes, has been already deſcribed in the article Chemistry, *Suppl.* it is unneceſſary therefore to repeat it here.

296 How to reduce the mineral to powder.

II. Before a mineral is ſubmitted to analyſis, it ought to be reduced to an impalpable powder. This is by no means an eaſy taſk when the ſtone is extremely hard. It ought to be raiſed to a bright red or white heat in a crucible, and then inſtantly thrown into cold water. This ſudden tranſition makes it crack and break into pieces. If theſe pieces are not ſmall enough, the operation may be repeated on each till they are reduced to the proper ſize. Theſe fragments are then to be beaten to ſmall pieces in a poliſhed ſteel mortar; the cavity of which ſhould be cylindrical, and the ſteel peſtle ſhould fit it exactly, in order to prevent any of the ſtone from eſcaping during the act of pounding. As ſoon as the ſtone is reduced to pretty ſmall pieces, it ought to be put into a mortar of rock cryſtal or flint, and reduced to a coarſe powder. This mortar ſhould be about four inches in diameter, and rather more than an inch in depth. The peſtle ſhould be formed of the ſame ſtone with the mortar, and care ſhould be taken to know exactly the ingredients of which this mortar is compoſed. Klaproth's mortar is of flint. We have given its analyſis in n° 32. of this article.

When the ſtone has been reduced to a coarſe powder, a certain quantity, whoſe weight is known exactly, 100 grains for inſtance, ought to be taken and reduced to as fine a powder as poſſible. This is beſt done by pounding ſmall quantities of it at once, not exceeding 10 grains. The powder is as fine as poſſible when it feels ſoft, adheres together, and as it were forms a cake under the peſtle. It ought then to be weighed exactly. It will almoſt always be found heavier after being pounded than it was before; owing to a certain quantity of the ſubſtance of the mortar which has been rubbed off during the grinding and mixed with the powder.

Analysis of Minerals. der. This additional weight must be carefully noted; and after the analysis, a portion of the ingredients of the mortar, corresponding to it, must be subtracted.

297 Chemical dishes. III. It is necessary to have a crucible of pure silver, or, what is far preferable, of platinum, capable of holding rather more than seven cubic inches of water, and provided with a cover of the same metal. There should also be ready a spatula of the same metal about four inches long.

The dishes in which the solutions, evaporations, &c. are performed, ought to be of glass or porcelain. Those of porcelain are cheaper, because they are not so apt to break. Those which Mr Vauquelin uses are of porcelain; they are sections of spheres, and are glazed both within and without, except that part of the bottom which is immediately exposed to the fire.

Sect. II. *Analysis of Stones* (y).

298 Ingredients of stones. The only substances which enter into the composition of the simple stones, as far at least as analysis has discovered, are the six earths, silica, alumina, zirconia, glucina, lime, and magnesia; and the oxides of iron, manganese, nickel, chromum, and copper (z). Seldom more than four or five of these substances are found combined together in the same stone: we shall suppose, however, in order to prevent unnecessary repetitions, that they are all contained in the mineral which we are going to analyse.

299 Method of decomposing stones. Let 100 or 200 grains of the stone to be analysed, previously reduced to a fine powder, be mixed with three times its weight of pure potass and a little water, and exposed in the silver or platinum crucible to a strong heat. The heat should at first be applied slowly, and the matter should be constantly stirred, to prevent the potass from swelling and throwing any part out of the crucible. When the whole water is evaporated, the mixture should be kept for half an hour or three quarters in a strong red heat.

If the matter in the crucible melts completely, and appears as liquid as water, we may be certain that the stone which we are analysing consists chiefly of silica; if it remains opaque, and of the consistence of paste, the other earths are most abundant; if it remains in the form of a powder, alumina is the prevalent earth. If the matter in the crucible be of a dark or brownish red colour, it contains oxide of iron; if it is grass green, manganese is present; if it is yellowish green, it contains chromum.

When the crucible has been taken from the fire and wiped on the outside, it is to be placed in a capsule of porcelain, and filled with water. This water is to be renewed from time to time till all the matter is detached from the crucible. The water dissolves a part of the combination of the alkali with the silica and alumina of the stone; and if a sufficient quantity were used, it would dissolve the whole of that combination.

Muriatic acid is now to be poured in till the whole of the matter is dissolved. At first a flaky precipitate appears, because the acid combines with the alkali which kept it in solution. Then an effervescence takes place, owing to the decomposition of some carbonat of potass formed during the fusion. At the same time the flaky precipitate is redissolved; as is also that part of the matter which, not having been dissolved in the water, had remained at the bottom of the dish in the form of a powder. This powder, if it consists only of silica and alumina, dissolves without effervescence; but if it contains lime, an effervescence takes place.

If this solution in muriatic acid be colourless, we may conclude that it contains no metallic oxide, or only a very small portion; if its colour be purplish red, it contains manganese; orange red indicates the presence of iron; and golden yellow the presence of chromum.

This solution is to be poured into a capsule of porcelain, covered with paper, and evaporated to dryness in a sand bath. When the evaporation is drawing towards its completion, the liquor assumes the form of jelly. It must then be stirred constantly with a glass or porcelain rod, in order to facilitate the disengagement of the acid and water, and to prevent one part of the matter from being too much, and another not sufficiently dried. Without this precaution, the silica and alumina would not be completely seperated from each other. 300

How the silica is separated. When the matter is reduced almost to a dry powder, a large quantity of pure water is to be poured on it; and, after exposure to a slight heat, the whole is to be poured on a filter. The powder which remains upon the filter is to be washed repeatedly, till the water with which it has been washed ceases to precipitate silver from its solutions. This powder is the whole of the *silica* which the stone that we are analysing contained. It must first be dried between folds of blotting paper, then heated red hot in a platinum or silver crucible, and weighed while it is yet warm. It ought to be a fine powder, of a white colour, not adhering to the fingers, and entirely soluble in acids. If it be coloured, it is contaminated with some metallic oxide; and shews, that the evaporation to dryness has been performed at too high a temperature. To separate this oxide, the silica must be boiled with an acid, and then washed and dried as before. The acid solution must be added to the water which passed through the filter, and which we shall denominate A.

The watery solution A is to be evaporated till its quantity does not exceed 30 cubic inches, or nearly an English pint. A solution of carbonat of potass is then to be poured into it till no more matter precipitates. It ought to be boiled a few moments to enable all the precipitate to fall to the bottom. When the whole of the precipitate has collected at the bottom, the supernatant liquid is to be decanted off; and water being substituted in its place, the precipitate and water are to be thrown upon a filter. When the water has run off, the filter with the precipitate upon it is to be placed between folds of blotting paper. When the precipitate has acquired some consistence, it is to be carefully collected by an ivory knife, mixed with a solution of pure potass, and boiled in a porcelain capsule. If any alumina

(y) Part of this section is to be considered as an abstract of a treatise of Vauquelin on the analysis of stones, published in the *Annales de Chimie*, Vol. XXX. p. 66.

(z) Barytes has also been discovered in one single stone, the *staurolite*; but its presence in stones is so uncommon, that it can scarcely be looked for. The method of detecting it shall be noticed afterwards.

Analyſis of Minerals. alumina or glucina be preſent, they will be diſſolved in the potaſs; while the other ſubſtances remain untouched in the form of a powder, which we ſhall call B.

301 And the alumina, Into the ſolution of potaſs as much acid muſt be poured as will not only ſaturate the potaſs, but alſo completely rediſſolve any precipitate which may have at firſt appeared. Carbonat of ammonia is now to be added in ſuch quantity that the liquid ſhall taſte of it. By this addition the whole of the alumina will be precipitated in white flakes, and the glucina will remain diſſolved, provided the quantity of carbonat of ammonia uſed be not too ſmall. The liquid is now to be filtered, and the alumina which will remain on the filter is to be waſhed, dried, heated red hot, and then weighed. To ſee if it be really alumina, diſſolve it in ſulphuric acid, and add a ſufficient quantity of ſulphat or acetite of potaſs; if it be alumina, the whole of it will be converted into cryſtals of alum.

302 Glucina, Let the liquid which has paſſed through the filter be boiled for ſome time, and the glucina, if it contains any, will be precipitated in a light powder, which may be dried and weighed. When pure, it is a fine, ſoft, very light, taſteleſs powder, which does not concrete when heated, as alumina does.

303 Lime, The reſiduum B may contain lime, magneſia, and one or more metallic oxides. Let it be diſſolved in weak ſulphuric acid, and the ſolution evaporated to dryneſs. Pour a ſmall quantity of water on it. The water will diſſolve the ſulphat of magneſia, and the metallic ſulphats; but the ſulphat of lime will remain undiſſolved. Let it be heated red hot in a crucible, and weighed. The lime amounts to 0.41 of the weight.

Let the ſolution containing the remaining ſulphats be diluted with a large quantity of water, let a ſmall exceſs of acid be added, and then let a ſaturated carbonat of potaſs be poured in. The oxides of chromum, iron, and nickel, will be precipitated, and the magneſia and oxide of manganeſe will remain diſſolved. The precipitate we ſhall call C.

304 Manganeſe, Into the ſolution let a ſolution of hydroſulphuret of potaſs be poured, and the mangancſe will be precipitated in the ſtate of a hydroſulphuret. Let it be calcined in contact with air, and weighed. The magneſia

305 Magneſia, may then be precipitated by pure potaſs, waſhed, expoſed to a red heat, and then weighed.

Let the reſiduum C be boiled repeatedly with nitric acid, then mixed with pure potaſs; and after being

306 Chromum, heated, let the liquid be decanted off. Let the precipitate, which conſiſts of the oxides of iron and nickel, be waſhed with pure water; and let this water be added to the ſolution of the nitric acid and potaſs. That ſolution contains the chromum converted into an acid. Add to this ſolution an exceſs of muriatic acid, and evaporate till the liquid aſſumes a green colour; then add a pure alkali: The chromum precipitates in the ſtate of an oxide, and may be dried, and weighed.

307 Iron, Let the precipitate, conſiſting of the oxides of iron and nickel, be diſſolved in muriatic acid; add an exceſs of ammonia: the oxide of iron precipitates. Let it be waſhed, dried, and weighed.

308 And nickel. Evaporate the ſolution, and the oxide of nickel will alſo precipitate; and its weight may be aſcertained in the ſame manner with the other ingredients.

The weights of all the ingredients obtained are now to be added together, and their ſum-total compared with the weight of the matter ſubmitted to analyſis. If the Analyſis of Minerals.
two are equal, or if they differ only by .03 or .04 parts, we may conclude that the analyſis has been properly performed: but if the loſs of weight be conſiderable, ſomething or other has been loſt. The analyſis muſt therefore be repeated with all poſſible care. If there is ſtill the ſame loſs of weight, we may conclude that the ſtone contains ſome ſubſtance, which has either evaporated by the heat, or is ſoluble in water.

309 A freſh portion of the ſtone muſt therefore be broken into ſmall pieces, and expoſed in a porcelain crucible to a ſtrong heat. If it contains water, or any other volatile ſubſtance, they will come over into the receiver; and their nature and weight may be aſcertained. Method of detecting volatile bodies.

If nothing comes over into the receiver, or if what comes over is not equal to the weight wanting, we may conclude that the ſtone contains ſome ingredient which is ſoluble in water.

310 To diſcover whether it contains *potaſs*, let the ſtone, reduced to an impalpable powder, be boiled five or ſix times in ſucceſſion, with very ſtrong ſulphuric acid, applying a pretty ſtrong heat towards the end of the operation, in order to expel the exceſs of acid; but taking care that it be not ſtrong enough to decompoſe the ſalts which have been formed. Method of aſcertaining whether ſtones contain potaſs

Water is now to be poured on, and the reſiduum, which does not diſſolve, is to be waſhed with water till it becomes taſteleſs. The watery ſolution is to be filtered, and evaporated to dryneſs, in order to drive off any exceſs of acid which may be preſent. The ſalts are to be again diſſolved in water; and the ſolution, after being boiled for a few moments, is to be filtered and evaporated to a conſiſtence proper for cryſtallizing. If the ſtone contains a ſufficient quantity of alumina, and if potaſs be preſent, cryſtals of alum will be formed; and the quantity of potaſs may be diſcovered by weighing them, it being nearly $\frac{1}{10}$th of their weight. If the ſtone does not contain alumina, or not in ſufficient quantity, a ſolution of pure alumina in ſulphuric acid muſt be added. Sometimes the alum, even when potaſs is preſent, does not appear for ſeveral days, or even weeks; and ſometimes, when a great quantity of alumina is preſent, if the ſolution has been too much concentrated by evaporation, the ſulphat of alumina prevents the alum from cryſtallizing at all. Care, therefore, muſt be taken to prevent this laſt ſource of error. The alum obtained may be diſſolved in water, and barytic water poured into it as long as any precipitate forms. The liquor is to be filtered, and evaporated to dryneſs. The reſiduum will conſiſt of potaſs and a little carbonat of potaſs. The potaſs may be diſſolved in a little water. This ſolution, evaporated to dryneſs, gives us the potaſs pure; which may be examined and weighed.

311 If no cryſtals of alum can be obtained, we muſt look Or ſoda.
for ſome other ſubſtance than potaſs. The ſtone, for inſtance, may contain ſoda. The preſence of this alkali may be diſcovered by decompoſing the ſolution in ſulphuric acid, already deſcribed, by means of ammonia. The liquid which remains is to be evaporated to dryneſs, and the reſiduum is to be calcined in a crucible. By this method, the ſulphat of ammonia will be volatilized, and the ſoda will remain. It may be rediſſolved in water, cryſtallized, and examined.

If ſulphuric acid does not attack the ſtone, as is often the caſe, it muſt be decompoſed by fuſion with ſoda, Analysis of Minerals. da, in the same manner as formerly directed with potass. The matter, after fusion, is to be diluted with water, and then saturated with sulphuric acid. The solution is to be evaporated to dryness, the residuum again dissolved in water, and evaporated. Sulphat of soda will crystallize first; and by a second evaporation, if the stone contains potass and alumina, crystals of alum will be deposited.

The presence of potass may be discovered, by mixing with a somewhat concentrated solution of muriat of platinum, the salt obtained, either by decomposing the stone immediately by an acid, or by saturating with an acid the matter obtained by fusing the stone with soda. If any potass be present, a very red precipitate will be formed. This precipitate is a triple salt, composed of potass, muriatic acid, and oxide of platinum. Ammonia, indeed, produces the same precipitate; but ammonia has not hitherto been discovered in stones.

312 Analysis of saline stones, In this manner may simple stones and aggregates be analysed. As to saline stones, their analysis must vary according to the acid which they contain. But almost all of them may be decomposed by one or other of two methods; of each of which we shall give an example.

I. Analysis of Carbonat of Strontites.

313 Of Carbonats, Klaproth analysed this mineral by dissolving 100 parts of it in diluted muriatic acid: during the solution, 30 parts of carbonic acid escaped. The solution crystallized in needles, and when dissolved in alcohol, burnt with a purple flame. Therefore it contained strontites. He dissolved a grain of sulphat of potass in six ounces of water, and let fall into it three drops of the muriatic solution. No precipitate appeared till next day. Therefore the solution contained no barytes; for if it had, a precipitate would have appeared immediately.

He then decomposed the muriatic acid solution, by mixing it with carbonat of potass. Carbonat of strontites precipitated. By the application of a strong heat, the carbonic acid was driven off. The whole of the earth which remained was dissolved in water. It crystallized; and when dried, weighed $69\frac{1}{2}$ *.

* *Klaproth's Beiträge*, i. 260.

II. Analysis of Sulphat of Strontites.

Mr Vauquelin analysed an impure specimen of this mineral as follows:

314 Sulphats, On 200 parts of the mineral, diluted nitric acid was poured. A violent effervescence took place, and part of the mineral was dissolved. The undissolved portion, after being heated red hot, weighed 167. Therefore 33 parts were dissolved.

The nitric solution was evaporated to dryness: A reddish substance remained, which indicated the presence of oxide of iron. This substance was redissolved in water, and some ammonia mixed with it; a reddish precipitate appeared, which, when dried, weighed 1, and was oxide of iron. The remainder of the solution was precipitated by carbonat of potass. The precipitate weighed, when dried, 20, and possessed the properties of carbonat of lime. Therefore 200 parts of this mineral contain 20 of carbonat of lime, 1 of oxide of iron, and the remainder of the 33 parts he concluded to be water.

The 167 parts, which were insoluble in nitric acid, were mixed with 500 parts of carbonat of potass, and 7000 parts of water, and boiled for a considerable time. The solution was then filtered, and the residuum washed and dried. The liquid scarcely effervesced with acids; but with barytes it produced a copious precipitate, totally indissoluble in muriatic acid. Therefore it contained sulphuric acid.

The undissolved residuum, when dried, weighed 129 parts. It dissolved completely in muriatic acid. The solution crystallized in needles; when dissolved in alcohol, it burnt with a purple flame; and, in short, had all the properties of muriat of strontites. Therefore these 129 parts were carbonat of strontites. Now, 100 parts of this carbonat contain 30 of carbonic acid; therefore 129 contain 38.7. Therefore the mineral must contain in 200 parts 90.3 of strontites.

Now, the insoluble residuum of 167 parts was pure sulphat of strontites; and we have seen that it contained 90.3 of strontites. Therefore the sulphuric acid must amount to 76.7 parts *.

* *Jour. de Min* N° xxxvii. p. 1.

Nearly in the same manner as in the first of these examples may the analysis of carbonat of lime and barytes be performed; and nearly in the same manner with the second, we may analyse the sulphats of lime and barytes.

Phosphats, 315 Phosphat of lime may be dissolved in muriatic acid, and the lime precipitated by sulphuric acid, and its quantity ascertained by decomposing the sulphat of lime obtained. The liquid solution may be evaporated to the consistence of honey, mixed with charcoal powder, and distilled in a strong heat. By this means phosphorus will be obtained. The impurities with which the phosphat may be contaminated will partly remain undissolved, and be partly dissolved, in muriatic acid. They may be detected and ascertained by the rules laid down in the second section of this chapter.

Fluats, 316 The fluat of lime may be mixed with sulphuric acid and distilled. The fluoric acid will come over in the form of gas, and its weight may be ascertained. What remains in the retort, which will consist chiefly of sulphat of lime, may be analysed by the rules already laid down.

And borats. 317 The borat of lime may be dissolved in nitric or sulphuric acid. The solution may be evaporated to dryness, and the boracic acid separated from the residuum by means of alcohol, which will dissolve it without acting on any of the other ingredients. The remainder of the dry mass may be analysed by the rules laid down in Sect. II. of this Chapter.

Sect. III. *Of the Analysis of Combustibles.*

The only combustibles of whose analysis it will be necessary to speak are coals and sulphur; for the method of analysing the diamond and oil has already been given in the article Chemistry, *Suppl.*

Earths of coal how examined. 318 Coal is composed of carbon, bitumen, and some portion of earth. The earths may be detected by burning completely a portion of the coal to be analysed. The ashes which remain after incineration consist of the earthy part. Their nature may be ascertained by the rules laid down in Sect. II. of this Chapter.

For the method of ascertaining the proportion of carbon and bitumen in coal, we are indebted to Mr Kirwan.

Method of detecting the relative proportions of charcoal and bitumen. 319 When nitre is heated red hot, and charcoal is thrown on it, a violent detonation takes place; and if the quantity of charcoal be sufficient, the nitre is completely decomposed. Now, it requires a certain quantity of pure carbon

Analyfis of Minerals.

carbon to decompofe a given weight of nitre. From the experiments of Lavoifier, it follows that, when the detonation is performed in clofe veffels under water, 13.21 parts of charcoal are capable of decompofing 100 parts of nitre *. But when the detonation is performed in an open crucible, a fmaller proportion of charcoal is neceffary, becaufe part of the nitre is decompofed by the action of the furrounding air. Scheele found that under thefe circumftances 10 parts of plumbago were fufficient to decompofe 96 parts of nitre, and Mr Kirwan found that nearly the fame quantity of charcoal was fufficient for producing the fame effect.

* *Mem. Sçav. Etrang.* xi. 610.

Macquer long ago obferved, that no volatile oily matter will detonate with nitre, unlefs it be previoufly reduced to a charcoal; and that then its effect upon nitre is precifely proportional to the charcoal which it contains †. Mr Kirwan, upon trying the experiment with *vegetable pitch* and *maltha*, found that thefe fubftances did not detonate with nitre, but merely burn upon its furface with a white or yellow flame; and that after they were confumed, nearly the fame quantity of charcoal was neceffary to decompofe the nitre which would have been required if no bitumen had been ufed at all ‡. Now coals are chiefly compofed of charcoal and bitumen. It occurred therefore to Mr Kirwan, that the quantity of charcoal which any coal contains may be afcertained by detonating it with nitre: For fince the bitumen of the coal has no effect in decompofing nitre, it is evident that the detonation and decompofition muft be owing to the charcoal of the coal; and that therefore the quantity of coal neceffary to decompofe a given portion of nitre will indicate the quantity of carbon which it contains: and the proportion of charcoal and earth which any coal contains being afcertained, its bituminous part may be eafily had from calculation.

† *Macquer's Dictionary*, 2d edit. p. 481.

‡ *Mineralogy*, ii. 522.

The crucible which he ufed in his experiments was large: it was placed in a wind furnace at a diftance from the flue, and the heat in every experiment was as equal as poffible. The moment the nitre was red hot, the coal, previoufly reduced to fmall pieces of the fize of a pin head, was projected in portions of one or two grains at a time, till the nitre would no longer detonate; and every experiment was repeated feveral times to enfure accuracy.

He found that 480 grains of nitre required 50 grains of Kilkenny coal to decompofe it by this method. Therefore 10 grains would have decompofed 96 of nitre; precifely the quantity of charcoal which would have produced the fame effect. Therefore Kilkenny coal is compofed almoft entirely of charcoal.

Cannel coal, when incinerated, left a refiduum of 3.12 in the 100 parts of earthy afhes. 66.5 grains of it were required to decompofe 480 grains of nitre; but 50 parts of charcoal would have been fufficient: therefore 66.5 grains of cannel coal contain 50 grains of charcoal, and 2.08 of earth; the remaining 14.42 grains muft be bitumen. In this manner may the compofition of any other coal be afcertained.

320 Method of analyfing fulphur.

As for fulphur, in order to afcertain any accidental impurities with which it may be contaminated, it ought to be boiled in thirty times its weight of water, afterwards in diluted muriatic acid, and laftly in diluted nitro muriatic acid. Thefe fubftances will deprive it of all its impurities without acting on the fulphur itfelf, at leaft if the proper cautions be attended to. The fulphur may then be dried and weighed. The deficiency in weight will mark the quantity of the fubftances which contaminate the fulphur. The folutions may be evaporated and examined, according to the rules laid down in the fecond and fourth fections of this chapter.

Sect. IV. *Of the Analyfis of Ores.*

321 No general method of analyfing ores.

The method of analyfing ores muft vary confiderably, according to the metals which they are fufpected to contain. A general method, therefore, of analyfing would be of no ufe, even if it could be given, becaufe it would be too complicated ever to be practifed. We fhall content ourfelves with exhibiting a fufficient number of the analyfis of ores, to take in moft of the cafes which can occur. He who wifhes for more information on the fubject, may confult the treatife of Bergman on the *Analyfes of Ores*; Mr Kirwan's treatife on the fame fubject; and, above all, he ought to ftudy the numerous analyfes of ores which have been publifhed by Mr Klaproth.

I. Analyfis of Red Silver Ore.

322 Method of analyfing red filver ore.

Mr Vauquelin analyfed this ore as follows:

He reduced 100 parts of it to fine powder, poured over it 500 parts of nitric acid previoufly diluted with water, and applied a gentle heat to the mixture. The colour of the powder, which before the mixture with nitric acid was a deep purple, became gradually lighter, till at laft it was pure white. During this change no nitrous gas was extricated; hence he concluded, that the metals in the ore were in the ftate of oxides.

When the nitric acid, even though boiled gently, did not appear to be capable of diffolving any more of the powder, it was decanted off, and the refiduum, after being carefully wafhed, weighed 42.06.

Upon thefe 42.06 parts concentrated muriatic acid was poured; and by the application of heat, a confiderable portion was diffolved. The refiduum was repeatedly wafhed with muriatic acid, and then dried. Its weight was 14.6666. One portion of thefe 14.6666 parts, when thrown upon burning coals, burnt with a blue flame and fulphureous fmell. Another portion fublimed in a clofe veffel without leaving any refiduum. In fhort, they had all the properties of fulphur. Therefore 100 parts of red filver ore contain 14.6666 of fulphur.

The muriatic acid folution was now diluted with a great quantity of water; it became milky, and depofited a white flaky powder, which when wafhed and dried weighed 21.25. This powder, when heated with tartar in a crucible, was converted into a bluifh white brittle metal, of a foliated texture, and poffeffing all the other properties of antimony. Red filver ore, therefore contains 21.25 of oxide of antimony.

The folution in nitric acid remained now to be examined. When muriatic acid was poured into it, a copious white precipitate appeared, which, when wafhed and dried, weighed 72.66. It had all the properties of muriat of filver. According to Mr Kirwan's tables, 72.66 of muriat of filver contain 60.57 of oxide of filver. Therefore red filver ore, according to this analyfis, is compofed of

60.57	oxide of filver,
21.25	oxide of antimony,
14.66	fulphur.
96.48	

The

Analyſis of Minerals.

The loſs, which amounts to 3.52 parts, is to be aſcribed to unavoidable errors which attend ſuch experiments.

II. Antimoniated Silver Ore.

323 Analyſis of antimoniated ſilver ore.

Klaproth analyſed this ore as follows:

On 100 parts of the ore, reduced to a fine powder, he poured diluted nitric acid, raiſed the mixture to a boiling heat, and after pouring off the acid, added new quantities repeatedly, till it would diſſolve nothing more. The reſiduum was of a greyiſh yellow colour, and weighed, when dry, 26.

Theſe 26 parts he digeſted in a mixture of nitric and muriatic acid; part was diſſolved, and part ſtill remained in the form of a powder. This reſiduum, when waſhed and dried, weighed 13 parts. It had the properties of ſulphur; and when burnt, left a reſiduum of one part, which had the properties of ſilica. Antimoniated ſilver ore, therefore, contains, in the 100 parts, 12 parts of ſulphur and 1 of ſilica.

When the nitro-muriatic ſolution was diluted with about 20 times its weight of water, a white precipitate appeared; which, when heated to redneſs, became yellow. Its weight was 13. No part evaporated at a red heat: therefore it contained no arſenic. On burning coals, eſpecially when ſoda was added, part was reduced to a metal, having the properties of antimony; and in a pretty high heat, the whole evaporated in a grey ſmoke. Theſe 13 parts were therefore oxide of antimony: They contain about 10 parts of metallic antimony; and as the ſtate of oxide was produced by the action of the nitric acid, we may conclude that antimoniated ſilver ore contains 10 parts of antimony.

The nitric acid ſolution remained ſtill to be examined. It was of a green colour. When a ſolution of common ſalt was poured in, a white precipitate was obtained, which poſſeſſed the properties of muriat of ſilver. When dried, it weighed 87.75 parts; and when reduced, 65.81 parts of pure ſilver were obtained from it. Antimoniated ſilver ore, therefore, contains 65.81 of ſilver.

Into the nitric acid ſolution, thus deprived of the ſilver, he dropped a little of the ſolution of ſulphat of ſoda; but no precipitate appeared. Therefore it contained no lead.

He ſuperſaturated it with pure ammonia, on which a grey precipitate appeared. When dried, it weighed 5 parts. This, on burning coals, gave out an arſenical ſmell. It was rediſſolved in nitric acid; ſulphurated alkali occaſioned a ſmutty brown precipitate; and pruſſic alkali a pruſſian blue, which, after torrefaction, was magnetic. Hence he concluded, that theſe five parts were a combination of iron and arſenic acid.

The nitric ſolution, which had been ſuperſaturated with ammonia, was blue; he therefore ſuſpected that it contained copper. To diſcover this, he ſaturated it with ſulphuric acid, and put into it a poliſhed plate of iron. The quantity of copper was ſo ſmall, that none could be collected on the iron.

III. Grey Copper Ore.

324 Analyſis of grey copper ore.

Klaproth analyſed this ore as follows:

Three hundred grains of it, not completely freed from its matrix, were reduced to a fine powder; four times their weight of nitric acid was poured on them, and the whole was digeſted. The acid was then poured off, and an equal quantity again digeſted on the reſiduum. The two acid ſolutions were mixed together. The reſiduum was of a yellowiſh grey colour, and weighed 188 grains.

On this reſiduum ſix times its weight of muriatic acid was boiled. The reſiduum was waſhed, firſt with muriatic acid, and afterwards with alcohol, and the waſhings added to the muriatic acid ſolution. The reſiduum, when dried, weighed 105.5 grains. Part of it burned with a blue flame; and was therefore ſulphur. The reſiduum amounted to 80.25 grains, and had the properties of ſilica. When melted with black flux, about ¾ths of a grain of ſilver were obtained from it. Thus 300 parts of grey copper ore contain 25.25 gr. of ſulphur, and 79.5 of ſilica.

The muriatic acid ſolution, which was of a light yellow colour, was concentrated by diſtillation, a few cryſtalls of muriat of ſilver appeared in it, which contained about ¼th grain of ſilver. The ſolution, thus concentrated, was diluted with a great quantity of water; a white precipitate was depoſited, which, when dried, weighed 97.25 grains. It poſſeſſed the properties of oxide of antimony, and contained 75 grains of antimony. Therefore 300 grains of grey copper ore contain 70 of antimony.

The nitric acid ſolution was of a clear green colour. A ſolution of common ſalt occaſioned a white precipitate, which was muriat of ſilver, and from which 31.5 grains of ſilver were obtained.

A little ſulphat of potaſs, and afterwards ſulphuric acid, were added, to ſee whether the ſolution contained lead; but no precipitate appeared.

The ſolution was then ſuperſaturated with ammonia; a looſe fleaky browniſh red precipitate appeared, which, when heated to redneſs, became browniſh black, and weighed 9¼th grains. This precipitate was diſſolved in muriatic acid; half a grain of matter remained undiſſolved, which was ſilica. The muriatic acid ſolution, when pruſſic alkali was added, afforded a blue precipitate; and ſoda afterwards precipitated 1.5 grains of alumina. Therefore 300 grains of grey copper ore contain 7.25 grains of iron, and 1.5 of alumina.

Into the nitric ſolution ſuperſaturated with ammonia, and which was of an azure blue colour, a poliſhed plate of iron was put: By this method 69 grains of copper were obtained.

IV. Sulphuret of Tin.

325 Analyſis of ſulphuret of tin.

Klaproth analyſed this ore as follows*:

On 120 grains of the ore reduced to powder, ſix times their weight of nitro-muriatic acid, compoſed of 2 parts of muriatic, and 1 of nitric acid, were poured. There remained undiſſolved 43 grains, which had the appearance of ſulphur; but containing green ſpots, was ſuſpected not to be pure. After a gentle combuſtion, 13 grains remained; 8 of which were diſſolved in nitro-muriatic acid, and added to the firſt ſolution. The remaining 5 were ſeparated by the filtre, and heated along with wax. By this method about a grain of matter was obtained, which was attracted by the magnet; and which therefore was iron. The reſiduum weighed 3 grains, and was a mixture of alumina and ſilica. Thus 120 grains of ſulphuret of tin contain 30 grains of ſulphur, 1 of iron, and 3 of alumina and ſilica.

* Obſervations on the Foſſils of Cornwall, p. 48.

The

Analysis of Minerals.

The nitro muriatic solution was completely precipitated by potass. The precipitate was of a greyish green colour. It was washed and dried, and again dissolved in diluted muriatic acid. Into the solution a cylinder of pure tin was put, which weighed exactly 217 grains. The solution became gradually colourless, and a quantity of copper precipitated on the cylinder of tin, which weighed 44 grains. To see whether it was pure, a quantity of nitric acid was digested on it; the whole was dissolved, except one grain of tin. Therefore 120 grains of sulphuret of tin contains 43 grains of copper.

The cylinder of tin now weighed only 128 grains; so that 89 grains had been dissolved. Into the solution a cylinder of zinc was put; upon which a quantity of tin precipitated. When washed and dried, it weighed 130 grains. The tin he melted with tallow and powdered charcoal; and when cold, he washed off the charcoal. Among the tin globules were found some black flocculi of iron, which weighed one grain. Deducting this grain, and the 89 grains of the tin cylinder which had been dissolved, we see that the 120 grains of sulphuret of tin contained 40 grains of tin besides the grain which had been detected in the copper.

V. Plumbiferous Antimoniated Silver Ore.

326 Analysis of plumbiferous antimoniated silver ore.

Klaproth analysed this ore as follows:

He digested 400 grains of it, reduced to a fine powder, first in five times its weight of nitric acid, and then in twice its weight of the same acid. He then diluted this last portion of acid with eight times its weight of water, and continued the digestion. The undissolved residuum, when washed and dried, weighed 326 grains.

On this residuum he boiled muriatic acid repeatedly. The solution, on cooling, deposited acicular crystals. These he carefully separated, and put by. The undissolved residuum weighed 51 grains. It had the properties of sulphur. When burned, it left one grain of silica.

The muriatic acid solution was concentrated to half its former bulk by distillation: this made it deposite more acicular crystals. He continued the distillation as long as any crystals continued to appear. He then collected the whole of these crystals together. They had the properties of muriat of lead. When mixed with twice their weight of black flux, and heated in a crucible lined with charcoal, they yielded $160\frac{1}{8}$ grains of lead.

Sulphuret of ammonia was now added to the muriatic acid solution; an orange-coloured precipitate appeared, which shewed that the solution contained antimony. It was precipitated by a copious effusion of water, and by soda. The oxide of antimony being reduced to a mass with Spanish soap, mixed with black flux, and heated in a lined crucible, yielded 28.5 grains of antimony.

Into the nitric acid solution, obtained by the first part of the process, a solution of muriat of soda was dropped; a white precipitate was deposited, and over it acicular crystals. These crystals he dissolved, by pouring boiling water on the precipitate. The water was added to the nitric acid solution. The white precipitate was muriat of silver: when heated with twice its weight of soda, it yielded 81.5 grains of silver.

He now concentrated the nitric acid solution by evaporation; and then adding a solution of sulphat of soda, a white precipitate was obtained, which had the properties of sulphat of lead, and weighed 43 grains. It contained 32 grains of pure lead.

He now poured ammonia into the solution; a pale brown precipitate was obtained, which weighed 40 grains, and which appeared to consist of oxide of iron and alumina. He redissolved it in nitric acid, precipitated the iron by prussic alkali, and the alumina by soda. The alumina, after being heated to redness, weighed 28 grains; consequently the oxide of iron was 12 grains, which is equivalent to 9 grains of iron.

VI. Molybdat of Lead.

Mr Hatchett analysed this ore as follows*:

On 250 grains of the ore, reduced to a fine powder, he poured an ounce of strong sulphuric acid, and digested the mixture in a strong heat for an hour. When the solution was cool, and had settled, he decanted it off, and washed the undissolved powder with pure water, till it came away tasteless. This operation was repeated twice more; so that three ounces of sulphuric acid were used. All these solutions were mixed together, and filtered.

327 Analysis of molybdat of lead.

* Phil. Trans. lxxxvi. 320.

Four ounces of a solution of carbonat of soda were poured upon the powder which remained undissolved, and which consisted of sulphat of lead. The mixture was boiled for an hour, and then poured off. The powder was then washed, and diluted nitric acid poured on it: The whole was dissolved, except a little white powder, which, when washed, and dried on a filter by the heat of boiling water, weighed seven-tenths of a grain. It possessed the properties of silica.

The nitric acid solution was saturated with pure soda; a white precipitate was obtained, which, when washed, and dried for an hour in a heat rather below redness, weighed 146 grains. It possessed the properties of oxide of lead.

To see whether this oxide of lead contained any iron, it was dissolved in diluted nitric acid, and the lead precipitated by sulphuric acid. The solution was then saturated with ammonia: a brown powder precipitated, which, when dried, weighed one grain, and had the properties of oxide of iron.

The sulphuric acid solution was of a pale blue colour: It was diluted with 16 times its weight of pure water, and then saturated with ammonia. It became of a deep blue colour, and appeared turbid. In 24 hours a pale yellow precipitate subsided, which, when collected on a filter, and dried by a boiling water heat, weighed 4.2 grains. Its colour was yellowish brown. Muriatic acid dissolved it, and prussiat of potass precipitated it from its solution in the state of prussian blue. It was therefore oxide of iron.

The sulphuric acid solution, saturated with ammonia, was gradually evaporated to a dry salt. This salt was a mixture of molybdat of ammonia and sulphat of ammonia. A strong heat was applied, and the distillation continued till the whole of the sulphat of ammonia was driven off; and to be certain that this was the case, the fire was raised till the retort became red hot. The residuum in the retort was a black blistered mass; three ounces of nitric acid, diluted with water, were poured upon it, and distilled off. The operation was again repeated.

Analysis of Minerals.

peated. By this method the oxide of molybdenum was converted into a yellow powder, which was yellow acid of molybdenum. It weighed 95 grains.

VII. Grey Ore of Manganese.

Mr Vauquelin analysed this ore as follows *.

* *Jour. de Min.* N° xvii. p. 12.

318 Analysis of grey ore of manganese.

When 200 grains of it were exposed to a strong heat in a retort, there came over 10 grains of water, and 18 cubic inches of oxygen gas, mixed with a little carbonic acid gas. The mineral now weighed only 176 grains. Therefore the weight of the gas was 14 grains.

On 200 grains of the same mineral muriatic acid was poured, and heat applied. 75 cubic inches of oxy-muriatic acid gas came over, which, though mixed with some carbonic acid gas, enflamed metals when reduced to powder. When no more gas came over, the residuum was boiled. The whole was dissolved except a white powder. which weighed 12 grains, and which possessed the properties of silica.

Carbonat of potass was poured into the solution; a white precipitate was obtained, which became black by exposure to the air, and weighed 288 grains Strong nitric acid was boiled on it repeatedly to dryness. It became of a deep black colour, and, when well washed with water and dried, weighed 164 grains. This powder was black oxide of manganese.

To see whether it contained iron, nitric acid, with a little sugar, was poured upon it, and digested on it. The acid dissolved it completely. Therefore no oxide of iron was present.

Into the water with which the black oxide of manganese had been washed, carbonat of potass was poured; a white powder precipitated, which, when dried, weighed 149 grains, and which possessed the properties of carbonat of lime.

VIII. Wolfram.

329 Analysis of wolfram.

Messrs Vauquelin and Hecht analysed this mineral as follows:

On 200 parts of Wolfram in powder, three times its weight of muriatic acid were poured, and the mixture boiled for a quarter of an hour: a yellow powder appeared, and the solution was of a brown colour. The acid was allowed to cool, and then carefully decanted off, and the residuum washed. The residuum was then digested for some hours with ammonia, which dissolved a part of it. The residuum was washed, and new muriatic acid again poured over it; then the residuum was digested with ammonia, as before: and the operation was continued till the whole wolfram was dissolved.

All the ammoniacal solutions being joined together, were evaporated to dryness, and the salt which remained was calcined: a yellow powder was obtained; it weighed 134 grains, and was yellow acid of tungsten.

Into the muriatic acid solutions, which were all mixed together, a sufficient quantity of sulphuric acid was poured to decompose all the salts. The solution was then evaporated to dryness; and the salts which were obtained by this evaporation were redissolved in water. A white powder remained, which weighed three grains, and which possessed the properties of silica.

The excess of acid of the solution was saturated with carbonat of potass; the liquor became brown, but nothing precipitated. When boiled, a red powder precipitated, and the brown colour disappeared. The addition of more carbonat of potass caused a farther precipitation of a yellowish powder. This precipitate consisted of the oxides of iron and manganese combined. Nitric acid was distilled off it repeatedly; it was then boiled in acetous acid. The acetous solution was precipitated by potass. Nitric acid was again distilled off it, and it was again boiled in acetous acid. This process was repeated till nitric acid produced no further change. The different powders which could not be dissolved in the acetous acid were collected, mixed with a little oil, and heated red hot. The powder became black, and was attracted by the magnet. It was therefore oxide of iron. It weighed 36 grains.

The acetous solution contained the oxide of manganese: It was precipitated by an alkali, and, when dried, weighed 12.5 grains.

IX. Oxide of Titanium and Iron.

330 Analysis of oxide of titanium and iron.

Vauquelin analysed this ore as follows:

A hundred parts of the ore, reduced to a fine powder, and mixed with 400 parts of potass, were melted in a silver crucible for an hour and a half. When cool, the mixture was diluted with water; a powder remained of a brick red colour, which when washed and dried weighed 124 parts.

The watery solution had a fine green colour; when an excess of muriatic acid was added, it became red. By evaporation the liquor lost its colour. When evaporated to dryness, a salt remained, which was totally dissolved by water. From this solution carbonat of potass precipitated two parts, which had the properties of oxide of manganese.

The 124 parts of residuum were boiled in a solution of pure potass for an hour. The solution was saturated with an acid, filtered, and carbonat of potass added, which precipitated three parts. These had the properties of oxide of titanium.

The remainder of the 124 parts of residuum, which still was undissolved, was boiled with diluted muriatic acid. The liquor became yellow, and deposited 46 parts of a white powder, with a tint of red. This powder was soluble in sulphuric and muriatic acids: from these solutions, it was precipitated of a brick red colour by the infusion of nut-galls; of a green colour by sulphuret of ammonia and prussiat of potass; and of a white colour by carbonat of potass and pure ammonia. A rod of tin made these solutions red; a rod of zinc made them violet. These 46 parts therefore are oxide of titanium.

The muriatic solution, from which these 46 parts were deposited, formed, with prussiat of potass, a prussian blue; and ammonia precipitated from it 50 parts, which had the properties of yellow oxide of iron.

Mirabeau. MIRABEAU (Honnoré Gabriel, Compte de), well known both by his writings and the active part which he took in bringing about the French revolution, was born in 1749 of a noble family. Throughout life he difplayed a fpirit averfe from every reftraint, and was one of thofe unhappy geniufes in whom the moft brilliant talents ferve only as a fcourge to themfelves and all around them. It is told by his democratical panegyrifts, as a wonderful proof of family tyranny under the old government, that not lefs than 67 *lettres de cachet* had been obtained by Mirabeau the father againft this fon and others of his relatives. This ftory, if true, proves, with at leaft equal force, what many anecdotes confirm, that, for his fhare of them, the fon was not lefs indebted to his own ungovernable difpofition than to the feverity of his parent. He was indeed a monfter of wickednefs. Debauchery, gaming, impiety, and every kind of fenfuality, were not enough for him. He was deftitute of decency in his vices; and to fupply his expences, fcrupled not to perform tricks which would difgrace a thief-catcher. His father and mother difagreeing, commenced a procefs of feparation; when Mirabeau, juft liberated from prifon for a grofs mifdemeanor, was in want of money. He went to his father, fided with him againft his mother, on whom he poured a torrent of invectives; and, for 100 guineas, wrote his father's memorial for the court. He then went to his mother; and by a fimilar conduct got the fame fum from her; and both memorials were prefented. That the father of fuch a man fhould frequently get him fhut up in prifon, can excite no furprife; for confinement only could withhold him from the perpetration of crimes.

The talents of Mirabeau led him frequently to employ his pen; and his publications form the chief epochas of his life. His firft publication was, 1. *Effai fur le Defpotifme*, "An Effay on Defpotifm," in 8vo. Next, in one of his confinements, he wrote, 2. a work in two vols 8vo, *On Lettres de Cachet*. 3. *Confiderations fur l'Ordre de Cincinnatus*, 8vo. A remonftrance againft the order of Cincinnatus, propofed at one time to be eftablifhed in America. The public opinion in America favoured this remonftrance, and it proved effectual. 4. His next work was in favour of the Dutch, when Jofeph II. demanded the opening of the Sheldt, in behalf of the Brabançons. It is entitled, *Doutes fur la Liberté de l'Efcaut*, 8vo. 5. *Lettre à l'Empereur Jofeph II. fur fon Réglement concernant l'Emigration*; a pamphlet of forty pages, in 8vo. 6. *De la Caiffe d'Efcompte*; a volume in 8vo, written againft that eftablifhment. 7. *De la Banque d'Efpagne*, 8vo; a remonftrance againft eftablifhing a French bank in Spain. A controverfy

Mirabeau. controversy arising upon this subject, he wrote again upon it. 8. Two pamphlets on the monopoly of the water company in Paris.

Soon after the publication of these works, he was sent in a public character to the court of Berlin; where he conducted the king's affairs just as he had formerly done those of his father and mother, fully ready to sacrifice all parties, and to sell himself to the highest bidder. With such a disposition, he could not long avoid the notice of the Prussian illuminees; and Nicolai Biester, Gedicke, and Leuchsenring, soon became his constant companions. At Brunswick he met with Mauvillon, the worthy disciple of Philo Knigg, and at that time a professor in the Caroline college. This was the man who initiated the profligate Marquis in the last mysteries of illuminism.

Mirabeau was still at Berlin when Frederick II. died. That monarch, as is well known, was a naturalist, who, holding this life for his all, encouraged the propagation of infidelity in his dominions, from which resulted the very worst consequences to the peace of society. Of this truth his successor Frederick William was duly sensible; and determined to support the church establishment in the most peremptory manner, consistent with the principles of religious toleration. He published, therefore, soon after his accession, an edict on religion, which is a model worthy of imitation in every country; but it was attacked with the greatest virulence in numberless publications. It was called an unjustifiable tyranny over the consciences of men; the dogmas supported by it were termed absurd superstitions; the king's private character and his religious opinions were ridiculed and scandalously abused. The most daring of these attacks was a collection of anonymous letters on the constitution of the Prussian states, universally believed to be the composition of Mirabeau, who certainly wrote a French translation, with a preface and notes more impudent than the work itself. The monarch is declared to be a tyrant; the people of the Prussian dominions are addressed as a parcel of tame wretches, crouching under oppression; and the inhabitants of Silesia, represented as still in a worse condition, are repeatedly called upon to rouse themselves, and assert their rights.

About this time he published, 9. An *Essai sur le Secte des Illuminés;* one of the strangest and most impudent books that ever appeared. In it he describes a sect existing in Germany, called the *Illuminated;* and says, that they are the most absurd and gross fanatics imaginable, waging war with every appearance of reason, and maintaining the most *ridiculous superstitions.* He gives some account of these, and of their rituals and ceremonies, as if he had seen them all; yet no such society as he describes ever existed: and Mirabeau employed his powers of deception, merely to screen from observation the real *illuminati,* by holding out to the rulers of states this *ignis fatuus* of his own brain. For a while the essay certainly contributed to blind the eyes of the German princes; and Nicolai, with others of the junto, adopting the whim, called Mirabeau's fanatics *Obscuranten,* and joined with him in placing on the list of *Obscuranten* several persons whom they wished to make ridiculous.

Long before his initiation in the mysteries of illuminism, Mirabeau had been acquainted with all the revolutionary powers of the masonic lodges; nor did he, when initiated, undervalue those which flowed, or might flow, from Weishaupt's inventive genius. On his return to France, he began to introduce the new mysteries among some of his masonic brethren. His first associate was the Abbe Talleyrand de Perigord, who had already begun to act the part of Judas in the first order of the church. But to have only introduced the mysteries was not sufficient for the Marquis; he would have teachers come from Germany, who were better versed than he was in the illuminizing arts. Well acquainted with the reasons that had induced the chiefs of the order to defer the conversion of France, he found means to convince them, that the time was now come for the accomplishment of their views; and at his request a deputation was sent by Spartacus to illuminize that great kingdom. See ILLUMINATI, n° 40, 41, *Suppl.*

When the assembly of Notables was convened at Paris, Mirabeau foretold that it would soon be followed by a meeting of the States; and at that period he published a volume against the stockjobbing, then carried to a great height, intitled, 10. *Denonciation de l'agiotage au Roi, et a l'Assemblée de Notables,* 8vo. A *lettre de cachet* was issued against him in consequence of this publication; but he eluded pursuit, and published a pamphlet as a sequel to the book. His next work was against M. Necker, 11. *Lettre á M. de Cretelle, sur l'Administration de M. Necker,* a pamphlet in 8vo. 12. A volume in 8vo, against the Stadtholdership: *Aux Bataves, sur le Stadthouderat.* 13. *Observations sur la maison de force appellé Bicetre,* an 8vo pamphlet. 14. Another tract, intitled, *Conseils à un jeune Prince qui sent la nécessité de refaire son education.* 15. He now proceeded to a larger and more arduous work than any he had yet published, on the Prussian monarchy under Frederick the Great: *De la Monarchie Prussienne sous Frederic le Grand,* 4 vols, 4to, or eight in 8vo. In this work he undertakes to define precisely how a monarchy should be constituted. When the orders were issued for convening the States-general, Mirabeau returned into Provence; and at the same time published, 16. *Histoire Secrette de la Cour de Berlin,* two volumes of letters on the Secret History of the Court of Berlin. This work was condemned by the parliament of Paris, for the unreserved manner in which it delivered the characters of many foreign princes. As the elections proceeded, he offered himself a candidate in his own order at Aix; but he was so abhorred by the noblesse, that they not only rejected him, but even drove him from their presence. This affront settled his measures, and he determined on their ruin. He went to the commons, disclaimed his being a gentleman, set up a little shop in the market-place of Aix, where he sold trifles; and now fully resolved what line he should pursue, he courted the commons, by joining in all their excesses against the noblesse, and was at last returned a member of the assembly.

In consequence of this, he went to Paris; where the part he took was active, and such as tended, in general, to accelerate all the violences of the revolution. He now published, periodically, 17. his *Lettres à ses Commettans,* Letters to his Constituents, which form, when collected, 5 vols 8vo. It is supposed, that the fatal measure of the junction of the three orders into one national

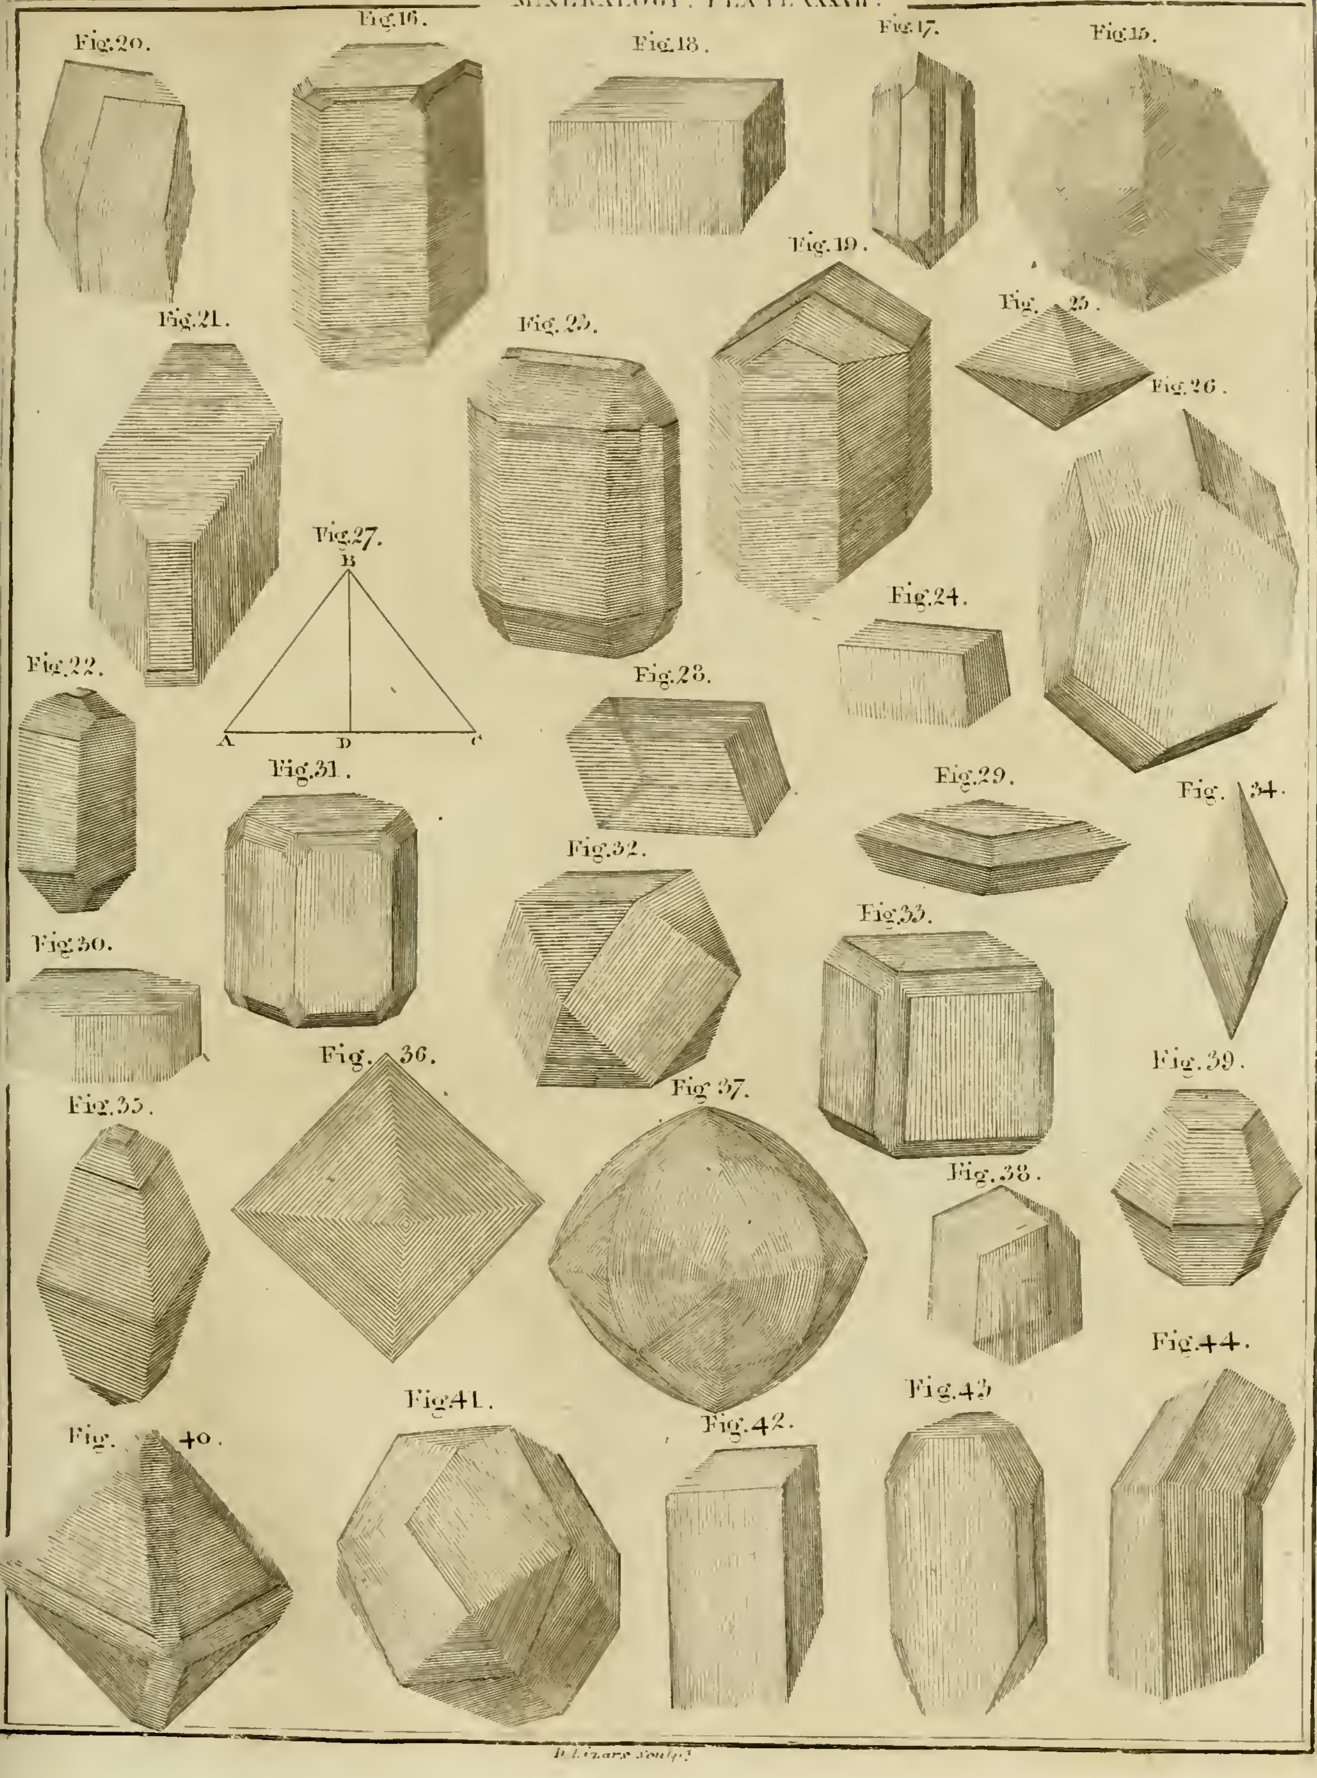
MINERALOGY. PLATE XXXVII.



D. Lizars Sculpt

tional aſſembly, was greatly promoted by theſe letters. The public events of theſe times, and the part taken in them by Mirabeau, are the ſubject of general hiſtory. He lived to ſee the conſtitution of 1789 eſtabliſhed, but not to ſee its conſequences—the deſtruction of the monarchy, the death of the king, and the ruin of all property! He was accuſed, as well as the duke of Orleans, of hiring the mob which attacked Verſailles on the 5th and 6th of October 1789; but with him was alſo acquitted by the tribunal of the Châtelet. The dominion of his eloquence in the National Aſſembly had long been abſolute, and, on the 29th of January 1791, he was elected preſident. At the latter end of March, in the ſame year, he was ſeized by a fever, and died on the 2d of April.

The talents of Mirabeau will not be doubted, though they were certainly rather brilliant than profound. To be noticed, and to lead, were the ſole objects of his ambition; and for the attainment of them, he took the ſide of the diſcontented, as the beſt field for his matchleſs eloquence. Yet there was no man more devoted to the principles of a court than this Marquis, provided he could have a ſhare in the adminiſtration; and a ſhare he would have obtained, if any thing moderate would have ſatisfied him: But he thought nothing worthy of him but a place of active truſt, and a high department; ſtations which all knew him not qualified to fill. Wanting knowledge of great things, he was learned only in the buſtling detail of intrigue, and would, at any time, have ſacrificed his deareſt friend, and the intereſts of his country, for an opportunity of exerciſing his brilliant eloquence, and indulging his propenſity to ſatire and lampoon. But the greateſt obſtacle to his advancement under the old government was the abject worthleſſneſs of his character. Drinking was the only vice in which he did not indulge; and from this he was reſtrained by his exhauſted conſtitution. To his brother, the Viſcount, who was frequently intoxicated, the Marquis one day ſaid, "How can you, brother, ſo expoſe yourſelf? "What (replied the Viſcount)! how inſatiable are you? Nature has given you every vice; and having left me only this one, you grudge it me!

MISTRAL, the name of a wind, which is mentioned in almoſt every account that we have of Provence, and which is remarkable for blowing almoſt the whole year from north-weſt or weſt-north-weſt, in a climate where the wind ſhould be variable. It is ſaid to contribute to the ſalubrity of the air, by diſperſing the exhalations of the marſhes and ſtagnant waters, ſo common in the ſouth of Languedoc and Provence; but at times it is alſo very injurious, or at leaſt very troubleſome. It is not, however, on either of theſe accounts that it is introduced into this Work, but for the ſake of the cauſes aſſigned by Sauſſure for its conſtancy, which may be applied to other winds that nearly reſemble it; and which he found might be reduced to three.

"The firſt and moſt effectual cauſe (he ſays) is the ſituation of the Gulf of Lyons, the banks of which are the principal theatre of its ravages. This Gulf, in fact, is ſituated at the bottom of a funnel, formed by the Alps and Pyrenees. All the winds blowing from any point between weſt and north, are forced by theſe mountains to unite in the Gulf. Thus, winds which would not have prevailed but at one extremity of the Gulf, or even much beyond it, are obliged to take this route, after having undergone the repercuſſion of theſe mountains; and the middle of the Gulf, inſtead of the calm which it might have enjoyed, is expoſed to the united efforts of two ſtreams of wind, deſcending in different directions. Hence ariſe thoſe whirlwinds which ſeem to characteriſe the miſtral, and appear to have induced the ancients to call it *Circius*, *à turbine ejus ac vertigine*. See *Aul. Gellius*. l. ii. cap. 22.

"The ſecond cauſe is, the general ſlope of the grounds, deſcending from all ſides towards the Gulf; which becoming all at once lower and more ſoutherly than the lands extending behind it, is, from theſe joint circumſtances, rendered the hotteſt point of all the adjacent country: and, as the air on the ſurface of the earth always tends from the colder to the warmer regions, the Gulf of Lyons is actually the centre towards which the air from all colder points between eaſt and weſt muſt preſs. This cauſe, then, alone would be productive of winds directed to the Gulf, even if the repercuſſion of the mountains did not exert its influence.

"Finally, it is well known, that in all gulfs the land-winds blow more forcibly than oppoſite to plains and promontories, whatever be the ſituation of thoſe gulfs. I apprehend, indeed, on ſtrict examination (ſays our author), that this cauſe is blended with the preceding; but as the fact is generally admitted, and in ſome caſes can be explained only by reaſons drawn from the effects of heat, it may not improperly, perhaps, be diſtinctly mentioned. It is, at leaſt, neceſſary to ſuppoſe, that ſeveral cauſes produce the miſtral, in order to underſtand why, notwithſtanding the variableneſs of the ſeaſons and temperatures, that wind is ſo ſingularly conſtant in Lower Languedoc and Lower Provence. A very remarkable inſtance of this conſtancy is recorded by the Abbé Papon, in his *Voyage de Provence*, tom. ii. p. 81. He aſſerts, that during the years 1769 and 1770, the miſtral continued for fourteen months ſucceſſively. But the three cauſes which I have ſtated, taken ſeparately, will explain its frequency, and, united, will account for its force."

MIXT ANGLE, or *Figure*, is one contained by both right and curved lines.

Mixt Number, is one that is partly an integer and partly a fraction; as $3\frac{1}{7}$.

Mixt Ratio, or *Proportion*, is when the ſum of the antecedent and conſequent is compared with the difference of the antecedent and conſequent;

$$\text{as if}\left\{\begin{array}{l} 4:3::12:9 \\ a:b::c:d \end{array}\right.$$

$$\text{then}\left\{\begin{array}{l} 7\ :\ 1\ ::\ 21\ :\ 3 \\ a+b:a-b::c+d:c-d. \end{array}\right.$$

MOCASSIMAH, in Bengal, revenue ſettled by a diviſion of the produce.

MOCHULKAH, bond or obligation.

MŒRIS, a lake in EGYPT, occaſionally mentioned in that article (*Encycl.*), and generally ſuppoſed the production of human art. Of this, however, Mr Brown ſays it bears no mark. "The ſhape, as far as was diſtinguiſhable, ſeems not inaccurately laid down in D'Anville's map, unleſs it be, that the end neareſt the Nile ſhould run more in a north-weſt and ſouth-eaſt direction. The length may probably be between 30 and 40 miles; the breadth, at the wideſt part he could gain, was 5000 toiſes, as taken with a ſextant; that is, nearly ly six miles. The utmost possible extent of circuit must of course be 30 leagues. On the north-east and south is a rocky ridge, in every appearance primeval. In short, nothing can present an appearance more unlike the works of men. Several fishermen, in miserable boats, are constantly employed on the lake. The water is brackish, like most bodies of water under the same circumstances. It is, in the language of the country, *Birket-el-kerun*, probably from its extremities bearing some resemblance to horns.

MOFUSSEL, a relative term, signifying the subordinate lands or districts, opposed to SUDDER, which is the head.

MOHACZ, MOHATZ, or *Mohoz*, a town in the Lower Hungary, upon the Danube, between the river Sarwizu to the north, and the Drave to the south; four German miles from either, six from Esseck to the north, and nine from Colocoa to the south. This otherwise small place is memorable for two great battles here fought; the first between Lewis king of Hungary and Solyman the Magnificent, in 1526: in which that unfortunate Prince Lewis (being about 20 years old), with 25,000 men, fought 300,000 Turks; when, being overpowered by numbers, 22,000 of the Christian army were slain upon the place; 5000 waggons, eighty great cannon, 600 small ones, with all their tents and baggage, were taken by the victors; and the King, in his flight over the brook Curass, fell into a quagmire, and was swallowed up. After which, Solyman took and slew 200,000 Hungarians, and got such a footing in that kingdom, that he could never be expelled. This fatal battle was fought October 29. The second, in some part, retrieves the loss and infamy of the former. The Duke of Loraine being sent by the Emperor, with express orders to pass the Drave and take Esseck, his highness, July 10, 1687, with great difficulty passed that river, then extremely swelled with rains; but finding the Prime Visier encamped at Esseck, with an army of 100,000 men, so strongly, that it was not possible to attack him in that post without the ruin of the Christian army, he retreated, and repassed it the 23d of the same month; where, upon the 29th, the Prime Visier passed that river at Esseck; and upon August 12th, there followed a bloody fight, in which the Turks lost 100 pieces of cannon, 12 mortars, all their ammunition, provision, tents, baggage, and treasure, and about 8000 men upon the place of battle, besides what were drowned in passing the river, which could never be known. After which victory, General Dunewalt, September 30th, found Esseck totally deserted by the Turks, and took possession of it.

MOHER, in Bengal, a gold coin, worth about 33 shillings.

MOHERIR, a writer of accounts.

MOINEAU, a flat bastion raised before a curtin when it is too long, and the bastions of the angles too remote to be able to defend one another. Sometimes the moineau is joined to the curtin, and sometimes it is divided from it by a moat. Here musquetry are placed to fire each way.

MOLE (See TALPA, *Encycl.*), is an animal exceedingly troublesome, both to gardeners and farmers; and there are persons who contrive to make a livelihood by the trade of *mole-catching*. These men, it is well known, are generally quacks and cheats; and the secrets which they sell for extirpating those destructive animals are of very little avail. Even poison seldom produces any considerable effect; because the mole, while it does not drink, lives only on roots and worms. Under the word MOLE (*Encycl.*), some directions will be found for clearing fields of this destructive animal; but the following are perhaps preferable, as they seem to have been the result of much experience:

Immediately at day-break, it will be necessary to make a tour round the garden or meadow, from which it is wished to extirpate the moles; for at that time they will be all found at work, as may be seen by the hills newly thrown up. If the person is then close to the hill, he must proceed as the gardeners do, and turn up with a stroke of the spade the hill together with the digger. The passage is then cut through before the animal is aware of the attack; and therefore it has not power to escape. If the mole-hill be fresh, even though the animal may not be throwing up earth, the person ought not to lose his time in waiting, but should immediately proceed to the operation above-mentioned.

If you find a fresh hill standing by itself, which seems to shew by its situation that it has no communication with any other, which is always the case when the mole has worked from the surface downwards in endeavouring to procure a more convenient habitation, after the hill has been turned up with the spade, a bucket of water should be poured over the mouth of the passage. By these means the animal, which is at no great distanc, will be obliged to come forth, and may be easily caught with the hand.

You may discover also whether a hill has any communication with another, if you apply your ear to it, and then cough or make a loud noise. If it has no communication with the neighbouring hills, you will hear the terrified animal make a noise by its motion. It will then be impossible for it to escape; and you may either pour water into the hole, or turn up the hill with a spade, until the mole is found; for, in general, it never goes deeper into the earth than from fifteen to eighteen inches.

When any of the beds in a garden have been newly watered, the mole, attracted by the coolness and moisture, readily repairs thither, and takes up its residence in them, making a passage at the depth of scarcely an inch below the surface. In that case it may easily be caught. When you see it at work, you need only tread behind the animal with your feet on the passage to prevent its retreat, and then turn up the hill with a spade; by which means you will be sure to catch it.

When you dig after it with a spade, the animal forces its way downwards into the earth in a perpendicular direction, in order that it may the better escape the threatened danger. In that case it will not be necessary to dig long, but to pour water over the place, which will soon make the animal return upwards.

People, in general, are not aware of the great mischief occasioned in fields and gardens by these animals. We are, however, informed by Buffon, that in the year 1740 he planted fifteen or sixteen acres of land with acorns, and that the greater part of them were in a little time carried away by the moles to their subterranean retreats. In many of these there were found half a bushel, and in others a bushel. Buffon, after this circumstance, caused a great number of iron traps to be constructed;

Moments, Mongearts. constructed; by which, in less than three weeks, he caught 1300. To this instance of the devastation occasioned by these animals, we may add the following: In the year 1742 they were so numerous in some parts of Holland, that one farmer alone caught between five and six thousand of them. The destruction occasioned by these animals is, however, no new phenomenon. We are informed by history, that the inhabitants of the island of Tenedos, the Trojans, and the Æolians, were infested by them in the earliest ages. For this reason a temple was erected to Apollo Smynthius, the destroyer of moles. See *Economische Hefte*, Vol. VII. Part 5. and Vol. IX. Part 4.; or *Phil. Magazine*, N° 5.

MOMENTS, in the new doctrine of infinites, denote the indefinitely small parts of quantity; or they are the same with what are otherwise called infinitesimals and differences, or increments and decrements; being the momentary increments or decrements of quantity considered as in a continual flux.

Moments are the generative principles of magnitude; they have no determined magnitude of their own, but are only inceptive of magnitude.

Hence, as it is the same thing if, instead of these moments, the velocities of their increases and decreases be made use of, or the finite quantities that are proportional to such velocities; the method of proceeding which considers the motions, changes or fluxions of quantities, is denominated by Sir Isaac Newton, the *method of fluxions*.

Leibnitz, and most foreigners, considering these infinitely small parts, or infinitesimals, as the differences of two quantities, and thence endeavouring to find the differences of quantities, *i. e.* some moments, or quantities indefinitely small, which taken an infinite number of times shall equal given quantities, call these moments differences; and the method of procedure, the differential calculus.

MONGEARTS, one of the tribes of wandering Arabs which inhabit the SAHARA, or Great Desert of Africa. Their time is wholly occupied by tending their cattle; and because they are little skilled in the use of arms, *Mongeart* is a term of contempt among the people by whom they are surrounded. The country, with its produce, will be described under the title SAHARA in this *Supplement*; it is the business of this article merely to exhibit the manners of the people.

They are all Mahometans, and offer up prayers three times a-day, sometimes oftener; but having no mosques, these prayers are never pronounced in public, except when the horde is visited by a priest, who seldom comes but upon account of the childrens education. Then all the Arabs assemble at the hour of prayer, place themselves in a line, turn to the east, and, wanting water in the desert, rub their face and hands with sand; while the priest recites aloud the general prayer. It is the same as that which is rehearsed by the public crier in the mosques in civilized countries.

The priests are employed in travelling about the country to instruct the children. There is nothing like force in their education. The little boys meet in the morning of their own accord, at the place of instruction, which is to them a place of recreation. They go there with a small board inscribed with the Arabic characters, and a few maxims of the Koran. The oldest, and the best informed, receive their lessons directly from the priests, and afterwards communicate them to their fellows. They are never corrected; because it would be a crime to beat a child, who, according to the received notions, has not sufficient reason to distinguish good from evil. This lenity extends even to the children of Christians, though in a state of slavery. They are treated in all respects like the children of Arabs; and the man who should be rash enough to strike one of them would endanger his life. Very different is their treatment of Negro children; who may indeed join in all the amusements of the young Arabs, and even attend the public schools; but if they be guilty of a fault, they are severely punished.

Mongearts. When the child of a Mongeart becomes tired of the places of public instruction, he quits them at pleasure, and, without feeling constraint, or hearing reproach, goes and employs himself in tending his father's flocks: and accordingly there are very few among them who can read. Those who persevere in the study of the Koran are made priests, after having past an examination before the learned elders, and enjoy the greatest public consideration. They have no need of cattle; for those of the nation being theirs, they find their subsistence everywhere.

It is generally at seven or eight years of age that children undergo the painful operation of circumcision. Their head is also shaved, nothing being left but four locks of hair; one of which is cut off in a meeting of the family, at each remarkable action performed by the child. If, at the age of 12 or 13, he kill a wild boar, or other beast of prey, that should fall upon his flock, he loses one of his locks. If, in the passage of a river, a camel be carried away by the stream, and he save it by swimming to its assistance, another is cut off. If he kill a lion, a tyger, or a warrior of an hostile nation, in a surprise or an attack, he is considered as a man, and his head is entirely shaved.

Different from the other Arabs their neighbours, and indeed from the Mahometans in general, the Mongearts trouble no man on account of his religion. The only one which they do not tolerate is the Jewish; and were a Jew to enter their territory, and have the misfortune to be taken, he would certainly be burnt alive.

According to M. Saugnier, the women are much more respected among the Mongearts than among the neighbouring nations; but the evidences which he gives of that respect are very extraordinary.

When a Mongeart is desirous of undertaking the care of a family, he pitches upon the girl that pleases him the most, and asks her of her father without further formality; nor can the latter refuse her, unless the man who pretends to her hand have done something contrary to the laws of the nation. The girl is conducted by her parents to the tent of her future husband, where there is always an abundant repast prepared for the ceremony. Presents are made to the father; but if the son-in-law be poor, his wife's family assist him, and furnish him with the means of increasing his flocks; if, on the contrary, he be rich, and the father poor, he supports the whole family in his own tent. The employment of the wife, thus married, is to prepare the food; to spin the goats and camels hair, of which the tents are made; to milk the cattle; to pick up the necessary supply of wood for the night; and when the hour of repast is come, to wait upon her husband. She then eats

Mongearts. by herself what has been left by him and his male slaves. She is, indeed, in no great danger of having a rival brought into the family; for though polygamy be allowed by his religion, the poverty of the Mongeart generally prevents him from taking a plurality of wives. She is, however, liable to be divorced at will when she does not bear boys; but if she have the good fortune to have one or more male children, her husband's regard for her is inconceivable. She has no longer a divorce to fear, has an absolute authority in the tent, and passes her whole time in conversation, sleep, or dancing, as she thinks fit. The captive negresses do all her work, and are no longer assisted in their labour by the Arab's wife, who treats them, on the contrary, with the greatest harshness and arrogance.

When a woman is not agreeable to her husband, or when he is disagreeable to her, they have it in their power to part. The formality in this case consists in the wife's retiring to her parents. If the husband be attached to her, he goes thither in quest of her; but if she persist in refusing to return, she is free, and at liberty to marry another. If, however, she have had a child, especially a boy, she has not the same privilege; in that case, if her retreat should last more than eight days, it might be punished with death.

When a man beats his wife, it is a sure sign that he is sincerely attached to her, and that he does not mean to part with her; if he content himself with reproaches, the wife thinks herself despised, and infallibly retires to her parents. Hence it is, that in the most trifling disputes the women are cruelly beaten: they prefer it to the complaints that the husband might make to their parents; this proof being the most certain one of a man's fondness for his wife. When a girl marries, she makes up her mind to such treatment, deeming it much more supportable than the humiliations she would otherwise experience from her family, in consequence of her husband's complaints.

The conjugal fidelity of the Mongeart women is incorruptible. Differing in their opinions from many other Mahometans, they believe themselves immortal like the men; but they do not flatter themselves with the possibility of happiness in the other world, unless they shall have been faithful to their husbands in this. Women, who have been false to their husband's bed, will be doomed, they think, to eternal slavery to the more virtuous part of their sex, without ever partaking, in the smallest degree, of their bliss.

Mongeart women often visit one another; and on those occasions, the honour consists in letting the female who comes to see her friend or relation do all the work of the tent. The visitor assumes the management of every thing, dresses the victuals, churns the butter, and keeps herself continually employed; while her friend entertains her with an account of the different affairs of the family or nation. The heartiness of the welcome is measured by the extent of the work submitted to the guest, who generally prepares double the usual quantity of food; so that the Arab is obliged to invite his neighbours to partake of the repast. The slaves are always pleased with these entertainments, a larger portion then coming to their lot. It is the business of the visitor to do the honours: nor will she suffer any body about her to remain dissatisfied.

The laws of hospitality are observed among the Mongearts as among all the wandering Arabs. Indeed they are carried to such a length, that were a man to enter the tent of him whom he had wounded, or even killed, he would there meet with a sacred and inviolable asylum, although surrounded by those who must naturally desire his ruin. The tent of the chief is always that to which strangers, upon their arrival in the horde, are directed. But the chief could not entertain, at his own expence, all the strangers that happen to pass; and therefore every tent in the horde is obliged to furnish him with two pounds of ground barley *per* week, to enable him to maintain the ancient hospitality.

The chiefs of hordes are always the eldest of their families. The difference of wealth is not considered: the chief often having several individuals at his house richer than himself, who nevertheless obey him in every particular. He is, properly speaking, their king; examines their difference with the old men, and judges without appeal. As to himself, he cannot be tried but by the chiefs of several hordes assembled. It is his business to determine the spots where the tents are to be pitched, the moment of departure, and the place where the caravan is to stop. If the pasturage do not suffice for the herds of all the horde, it divides, and the chief assigns the ground for the different encampments. They are very often composed of no more than seven or eight tents, according to the quality of the ground they meet with. The tent of the chief is always the largest and most lofty, and is placed in the centre of the divisions. When it is determined upon to quit an encampment, which never happens till the pasture is exhausted, the chief sets off to choose another spot. In these removals the women alone do all the work. Early in the morning they fold up the tent, and load every thing upon the camels backs; they then move slowly on, that the cattle may have time to feed upon the way.

Great respect is paid by the Mongearts to all old men, who enjoy the same prerogatives as the priests, and such Arabs as have visited the tomb of Mahomet at Mecca. Together with the chief they are the judges of the horde, and take cognizance of all offences, the pain of death being the only punishment which they cannot decree. An assembly of several chiefs is the only tribunal which can inflict capital punishment; but as the accused has generally a number of friends, it seldom happens that he is capitally convicted.

A war between two Mongeart tribes seldom happens, and is never bloody; but the different families destroy one another fast enough in their intestine broils. They are all thieves; and indeed theft is a crime only in the day-time, being authorised by law during the night, in order to compel them to take care of their cattle. Could they find redress when robbed by night, they would be less vigilant; and their herds and flocks would be more exposed to the wild beasts that over-run their country; but being obliged to be on their guard even against their nearest neighbours, they are always ready to repel both the lion and the tiger. Theft, even in the day-time, is so far from being punished, unless detected at the instant of commission, that when any thing is stolen unperceived, it becomes the lawful property of the thief. In vain would the rightful owner recognize it in his neighbour's tent; he cannot reclaim it; it ceases to be his from the moment he has been negligent in its care. Hence arises this peoples inclination for rapine; they

Mongearts. they do not think they commit a crime, and only follow, in this regard, a custom allowed by their laws.

When an Arab is going to market, or on his return from thence, if he do not take the greatest care to keep his journey a secret, he is often attacked. Neighbouring Arabs are desirous of profiting by his industry; and as there are no persons in the country appointed to apprehend robbers, the hope of booty spurs them on to the attack. That they may have nothing to fear, they lie in wait, when the night is coming on, for him whom they mean to pillage. Their intention is never to kill; they only endeavour to surprise, to disarm, and to make themselves masters of every thing that comes in their way. But it sometimes happens, that the man they intend to plunder, being acquainted with the customs of his country, keeps an attentive ear, stands on his guard, fires upon his assailants at the first motion he observes, and then fights desperately with his dagger. The report of the musket almost always brings out the neighbouring Arabs, who, in virtue of the laws of hospitality, take the defence of the weaker side. They run up well armed; and then woe to the aggressors, if they do not save themselves by a speedy flight.

The flocks and herds of the Mongearts are composed of nothing but sheep, goats, and camels; all animals patient of thirst. Horses are very scarce in these cantons, none but the possessors of numerous herds being able to keep them; because, for want of water, it is necessary to have milk in sufficient abundance to give it them to drink. Great care is taken to preserve the camel's urine, both to mix with milk, and to wash the different vessels in which they put their food. Detestable as is this mixture of milk and urine, they are often reduced to the use of it; hunger and thirst give a relish to every thing.

The only workmen useful to this nation are blacksmiths or goldsmiths, as they may be called indifferently. The Mongearts not being sufficiently laborious to apply themselves to such occupations, these workmen come from Bilidulgerid, and disperse themselves all over the different parts of the desert. Wherever there are tents they are sure to find work. They are fed for nothing, and receive besides the hire for their labour. They make trinkets for the women, such as ear-rings and bracelets, &c. mend the broken vessels, by rivetting them, and clean the arms. They are generally paid in skins, goats and camels hair, or ostrich feathers, according to their agreement. Those who have silver pay them a tenth part of its weight for any thing wrought out of that metal. On their return they sell what they have earned; four or five excursions at most enabling them to live afterwards at their ease in their own country.

The Mongearts always carry a leathern bag, suspended from their neck, in which they put their tinder, their pipe, and their tobacco. Their daggers are elegant; the hilt is always black, and inlaid with ivory; the blade is crooked, and sharp on either side; the sheath is of brass on one side, and of silver on the other, and of very tolerable workmanship. They wear sabres when they can get them, and prefer those of Spanish make. Their muskets are always highly ornamented; the stock is very small, and inlaid on every side with ivory, and the barrel embossed with brass or silver, according to the opulence of the owner. There is a spring to the lock, covering the priming, to prevent the piece from going off, contrary to the intention of him who carries it. The poor, who do not possess muskets, wear daggers, made like the Flemish knives, with leathern sheaths. They arm themselves also with a thick stick, to the end of which they fix a kind of iron wedge. This weapon is exceedingly dangerous at close quarters. Others carry *zagays*, or slender javelins. In a word, the principal riches of an Arab, and his highest gratifications, are a handsome musket and a good dagger. He prefers them to neatness of apparel; for as to dress, it is indifferent to him whether he be clothed in Guinea blues, woollen stuffs, or goats skins. Their arms being their principal ornament, they take particular care to put the muskets in leathern bags, by way of keeping them in good order, and preserving them from the rust. Mongearts.

All the riches of the Mongearts consist in their herds; and accordingly they take the greatest care to preserve them. If a beast be sick, every thing is done to cure it; no care is spared; it is even treated with more attention than a man: but when it evidently appears that there is no hope of saving its life, they kill and eat it. If it be a camel, the neighbours are called in to partake of the repast; if a goat, the inhabitants of the tent suffice for its consumption. An animal that dies without shedding blood is unclean. Its throat must be cut; the person who kills it turning to the east, and pronouncing beforehand the first words of the general prayer. An animal killed by a wild boar is unclean; nor is it eaten although its blood has been shed, because the wild boar is itself an unclean beast. That species is so numerous in the desart, that they do more mischief than all the other wild beasts together. The Arabs kill as many as they can, but never taste their flesh.

Whatever losses an Arab may meet with, he is never heard to complain; he rises superior to poverty, supports hunger, thirst, and fatigue, with patience, and his courage is proof against every event. God will have it so, says he: he employs, however, every means in his power to avert misfortune; and often exposes himself to the greatest dangers to procure matters of no real utility.

When a father of a family dies, all the effects in his tent are seized upon by the eldest son present at his decease. Gold, silver, trinkets, every thing disappears; and the absent children have only an equal share in the division of the cattle and the slaves. The girls are entirely excluded from all participitation, and take up their residence with their elder brother. If the deceased leave children in helpless infancy, the mother takes them with her to her sister's, if she have a sister married; if not, to her own maternal roof. The dead man's possessions, however, are not lost; the chief of the horde takes care of them, and delivers them in equal portions to the heirs, as soon as they are old enough to manage their own property. If an Arab die without male children, his wife returns to her relations, and his brother inherits his effects.

The Mongearts have a rooted abhorrence of the Spaniards, and never fail to massacre every man of that nation who is so unfortunate as to be shipwrecked on their coasts, while they reserve the women for sale at Morocco. The reason of this hatred is, that the inhabitants of the Canaries make frequent descents on the Mongeart coasts, and carry off men, women, cattle, and every

Monnier. every thing that they meet with; and these people, being ignorant of the fate of their countrymen, retaliate by death on all Spaniards that fall into their hands, whilst they treat the British and French as well as they can.

MONNIER (Peter Charles Le), was born at Paris on the 20th of November 1715. The profession of his father, or the rank which he held in society, we have not learned, and we are equally ignorant of the mode in which he educated his son. All that we know is, that young Monnier, from his earliest years, devoted himself to the study of astronomy; and that, when only sixteen years of age, he made his first observation, viz. of the opposition of Saturn. At the age of twenty he was nominated a member of the Royal Academy of Sciences at Paris. In the year 1735 he accompanied Maupertuis in the celebrated expedition to Lapland, to measure a degree of latitude. In 1748 he went to Scotland with Lord Macclesfield, to observe the annular eclipse of the sun, which was most visible in that country; and he was the first astronomer who had the pleasure to measure the diameter of the moon on the disk of the sun.

Louis XV. it is well known, was extremely fond of astronomy, and greatly honoured its professors: he loved and esteemed Le Monnier. I have seen the king himself (says Lalande) come out of his cabinet, and look around for Le Monnier; and when his younger brother was presented to him on his appointment to the office of first physician, his Majesty was pleased to wish him the merit and reputation of his brother the astronomer. All the remarkable celestial phenomena were always observed by the king, in company with Le Monnier. Thus he observed with him, at his chateau of St Hubert, the two celebrated transits of Venus thro' the disk of the sun in the years 1761 and 1769; as appears from the Memoirs of the Royal Parisian Academy of Sciences. It well deserves to be here recorded in what manner the king behaved during these important observations, and how little he disturbed his astronomers (the celebrated La Condamine being likewise permitted to observe the transit in his presence) in this occupation; the proper time for which, if permitted to pass by, could not be recalled. Le Monnier relates in his Dissertation, that "his Majesty perceiving that we judged the last contacts to be of the greatest importance, a profound silence at that moment reigned around us." At the transit of Venus in 1769, the king allowed the Marquis de Chabert, an intelligent and expert naval officer, who was just returned from a literary voyage to the Levant, to assist at the observation. In a court like that of Louis XV. so scrupulously observant of etiquette, these will be allowed to have been most distinguished marks of honour, and of royal favour and condescension.

In the year 1750, La Monnier was ordered to draw a meridian at the royal Chateau of Bellevue, where the king frequently made observations. The monarch on this occasion rewarded him with a present of 15,000 livres; but Le Monnier applied this sum of money likewise in a manner that redounded to the honour of his munificent sovereign and of his country, by procuring new and accurate instruments, with which he afterwards made his best and most remarkable observations. In 1742, the king gave him in Paris *Rue de la Poste*, a beautiful free dwelling, where, till the breaking out of the revolution, he resided, and pursued his astronomical labours, and where his instruments in part yet remain. Some of them the present French government has, at the instance of Lalande, purchased for the National Observatory. In 1751, the king presented him with a block of marble, eight feet in height, six feet in breadth, and fifteen inches in thickness, to be used for fixing his mural quadrant of five feet. This marble wall, together with the instruments appended to it, turns on a large brass ball and socket, by which the quadrant may be directed from south to north; thus serving to rectify the large mural quadrant of eight feet, which is immoveably made fast to a wall towards the south.

With these quadrants Le Monnier observed, for the long period of forty years, the moon with unwearied perseverance at all hours of the night. It is requisite, to be a diligent astronomer, to be able to conceive to what numberless inconveniences the philosopher is exposed during an uninterrupted series of lunar observations. As the moon during a revolution may pass through the meridian at all hours of the day or night; the astronomer who, day after day, prosecutes such observations, must be prepared at all, even the most inconvenient, hours, and sacrifice to them his sleep and all his enjoyments. How secluded from all the pleasures of social intercourse, and how fatiguing such a mode of life is, those astronomers, indeed, know not who then only set their pendulum clocks in motion, when some of the eclipses of the sun, moon, or of the satellites of Jupiter, are to be viewed. At this time, and in the present state of the science, these are just the most insignificant observations; and an able astronomer, well supplied with accurate instruments, may *every* day, if he take into his view the whole of his profession, make more important and more necessary observations.

Le Monnier was Lalande's preceptor, and worthy of such a scholar; and he promoted his studies by his advice, and by every other means in his power. Le Monnier's penetrating mind, indeed, presaged in young Lalande, then only sixteen years old, what in the sequel has been so splendidly confirmed. In his twentieth year, he became, on the recommendation of his preceptor, a member of the Royal Academy: and in 1752 he was proposed by him as the fittest person to be sent to Berlin, to make with La Caille's, who had been sent to the Cape of Good Hope, correspondent observations, for the purpose of determining the parallaxes of the moon, then but imperfectly known. Le Monnier lent his pupil for this expedition his mural quadrant of five feet. His zeal for astronomy knew no bounds. For this reason Lalande, in his *Notice des Travaux du C. Le Monnier*, says of himself: "*Je suis moi-meme le principal resultat de son zele pour l'astronomie.*"

La Monnier was naturally of a very irritable temper: as ardently as he loved his friends, as easily could he be offended; and his hatred was then implacable. Lalande, as he himself expresses it, had the misfortune to incur the displeasure of his beloved preceptor; and he never after could regain his favour. But Lalande's gratitude and respect for him always continued undiminished, and were on every occasion with unremitting constancy publicly declared: patiently he endured from him undeserved ill treatment; so much did he love and esteem

eſteem his inſtructor and maſter to the day of his death. "I have not ceaſed to exclaim (writes Lalande, as Diogenes exclaimed to his maſter Antiſthenes, "You cannot find a ſtick ſtrong enough to drive me away from you!"

What a noble trait in the character of Lalande, who in 1797 wrote likewiſe an eulogium on Le Monnier in the ſtyle of a grateful pupil, penetrated with ſentiments of profound veneration and eſteem for his beloved maſter; but Le Monnier would not read it. This is not the place to give a circumſtantial account of this intricate quarrel: we ſhall only further remark, that Lalande was the warm friend and admirer of the no leſs eminent aſtronomer La Caille, whom Le Monnier mortally hated. An intimate friendſhip likewiſe ſubſiſted between Le Monnier and D'Alembert; but Lalande had no friendly intercourſe with the latter.

Among the ſcholars of Le Monnier may likewiſe be reckoned Henwart, the celebrated geometrician and profeſſor of mathematics at Utrecht; who, in a letter to Von Zach, aſtronomer to the Duke of Saxe Gotha, dated the 26th of May 1797, ſays, "Le Monnier is a penetrating and philoſophical aſtronomer: I learned much from him in Paris; though I lodged with the late De l'Iſle, where I frequently made obſervations in company with Meſſier. Le Monnier was the friend of D'Alembert; and conſequently an oppoſer of Lalande."

This great man, who had, for ſome years, ceaſed to exiſt either for the ſcience of aſtronomy, or for the comfort of his friends, died at Lizeaux, in the province of Normandy, in 1799, aged 84 years. He left behind him ſome valuable manuſcripts, and a number of good obſervations; with reſpect to which he had always been very whimſical, and of which in his latter years he never would publiſh any thing. He had by him a ſeries of lunar obſervations, and a multitude of obſervations of the ſtars, for a catalogue of the ſtars, which he had announced ſo early as the year 1741; among which was twice to be found the new planet Uranus: (See *Lalande's Aſtronomic, Tables*, p. 188, (A). The more he was requeſted to communicate his obſervations, the more obſtinate he became; he even threatened to deſtroy them. At the breaking out of the revolution, Lalande was greatly alarmed for the ſafety of theſe papers; he wiſhed to preſerve them from deſtruction, and made an attempt to get them into his poſſeſſion; but all his endeavours were in vain. He was only able to learn, that Le Monnier had hidden them under the roof of his houſe. Le Monnier having been firſt ſeized with a fit of the apoplexy ſo early as the 10th of November 1791, Lalande apprehended, leſt, if no one except himſelf ſhould know where he had hidden his papers, the infirm old man might perhaps have himſelf forgot it. He hopes, however, that La Grange, who married his ſecond daughter, may have ſome information concerning them. Le Monnier left behind him no ſon.

MONOMIAL, in algebra, is a ſimple or ſingle nomial, conſiſting of only one term; as a or ax, or $a^2 b x^3$, &c.

MONOTRIGLYPH, a term in architecture, denoting the ſpace of one triglyph between two pilaſtres, or two columns.

MONSELEMINES, are a people which inhabit that part of Biledulgerid (ſee *Encycl.*) that borders on the territories of the Emperor of Morocco. They are a mixed race, being deſcended from the ancient Arabs and fugitive Moors; and they occupy a ſpace of land, of which the limits are indicated by lofty columns placed at intervals towards the deſart. Their territory extends from about 30 leagues beyond Cape Non, to the diſtance of 20 leagues from St Croix or Agader. Though of different qualities, it is, for the moſt part, very fertile, and produces the neceſſaries of life with little cultivation. The plains are watered by an infinite number of ſtreams, and abound with palm, date, fig, and almond trees. The gardens produce excellent grapes, which are dried by the Arabs, and converted into brandy by the Jews. Great quantities of oil, wax, and tobacco, appear in the public markets.

More induſtrious and more laborious than their neighbours, the Monſelemine nation cultivates the earth. The chiefs of families chooſe the ground moſt fit for cultivation. Its ſurface is turned ſlightly over with a kind of hoe, and then the ſeed is ſown upon it: the field is ſurrounded with buſhes, to mark the ſpot, and to preſerve it from the cattle of the wandering Arabs. When the crop is ripe, which is generally at the end of Auguſt, three months after the ſowing of the ſeed, it is cut about ſix inches from the ear, and formed into little bundles; during which time every one labours without intermiſſion from morning to night. The corn is brought before the tent, thraſhed, winnowed, and placed in the magazines. When the harveſt is over, they ſet fire to the long ſtubble, and abandon the field for two or three years. Their magazines are large holes in the earth, formed like the fruſtum of a cone, the inſides of which are hardened by burning wood in them, before the half-winnowed corn be depoſited. When filled with corn, they are covered with planks placed cloſe to each other; over which a layer of earth is laid level with the ſoil, to prevent it from being diſcovered by enemies. In theſe magazines every one ſhares in proportion to the number of men he employed in the common labour.

The inhabitants of the plains remain by the cultivated fields in ſeed time, and return at the time of harveſt. During the intervals they wander in all directions with their cattle, taking only neceſſaries along with them, and having recourſe to the magazines when they require

quire

(A) Such is the French and German account of his diſcovery of this planet; but our readers have been very inattentive, if they have not perceived, in various articles of this Work, complete proofs of the plagiariſm of our neighbours on the Continent, from the celebrated philoſophers and divines of England. As it is extremely probable that, half a century hence, a claim may be put in for Le Monnier's diſcovery of the Georgium Sidus (*Uranus*), ſimilar to that which in 1757 the Editor of Abbè St Real's works put in for that Abbé being the author of Leſlie's *Short Method with the Deiſts* (ſee Leslie in this *Suppl.*), we think it our duty to declare, that in 1800 there was no evidence whatever on which to found that claim, and that the diſcovery was then univerſally allowed to have been made by Herſchel.

quire a fupply. The more opulent people, and the artizans who are engaged in fedentary occupations, dwell in towns, which are all fituated upon the declivity of hills. Their houfes are built of ftone and earth, according to the Moorifh conftruction, low and covered with floping terraces; yet they are fo much injured by the heavy rains which prevail for three months of the year, as to be rendered uninhabitable in 15 or 20 years. Thofe who refide in towns are generally weavers, fhoemakers, goldfmiths, potters, &c. and have no cattle; but the more opulent perfons have flocks and herds of cows, horfes, camels, fheep, goats, befides poultry, which are kept by their flaves at a diftance from the towns. In the towns they take two meals a-day; one at ten o'clock, and the other at the fetting of the fun, though the inhabitants of the country only eat in the evening. In the towns they fleep in mats upon the floors of their apartments, and make ufe of linen; but the inhabitants of the country fleep upon terraces in the open air. The paftoral families of the country practife hofpitality like thofe of the defart, and make the traveller pay nothing for his entertainment. In the towns this practice is impoffible, as the concourfe of ftrangers, efpecially on market-days, would foon impoverifh the inhabitants. In this manner hofpitality is always extinguifhed among a trading and commercial people. It is only where the fuperfluity of commodities runs neceffarily to wafte, that it is ever practifed iu a great extent; but where every commodity can find a market, every kind of property acquires a definite value, and will be preferved with the fame care as money.

By M. Saugnier the government of the Monfelemines is faid to be republican; but he writes inconfiftently about it. In one place, he fays that they choofe their chiefs annually; in another, that in the time of war they choofe from the natives or fugitive Moors indifcriminately, chiefs, whofe authority lafts no longer than the campaign, during which it is abfolute; and he afterwards reprefents their government as a kind of theocracy, during war as well as peace. But we muft follow him in his detail, as it has been well arranged in a late anonymous publication, entitled, *An Hiftorical Sketch of Difcoveries in Africa.*

At the end of each campaign, he fays the chief gives an account of his actions to the affembled aged men, and is rewarded or punifhed according to his conduct; after which his fucceffor is appointed, and he ferves in the army he commanded as an undiftinguifhed individual. The country is populous, and would be ftill more fo, were it not for the continual wars which its inhabitants are obliged to fupport againft the Emperor of Morroco. The liberty they enjoy imparts energy and courage to their character, and renders their arms invincible to the Moors. They confider it as the moft invaluable poffeffion, and defend it to the laft extremity. The nature of the country, furrounded on every fide by fteep and arid mountains, contributes to fruftrate the efforts of their enemies. The Monfelemine, richer than the fubject of Morocco, is always well clothed and armed. He pays no tribute, enjoys the fruit of his labour and commerce, and, as no contributions are requifite for the charges of the ftate, whatever he acquires is his own. The fugitive Moors are never armed, except when they go to battle; but the natives go continually armed, whether they refide in the country, refort to the markets, attend the affemblies of the nation, or pay vifits.

As the Monfelemine territory is the retreat of the rich Moors, who wifh to fly from the tyranny of the Emperor of Morocco, they are too well acquainted with the Moorifh cuftoms to be furprifed by that prince. No fooner does a Moorifh army take the field, than the inhabitants of the country cantons mount their horfes, and occupy the paffes of the mountains; while the women and flaves, efcorted by a fufficient number of warriors, retire to the anterior parts of the country, or, if they be hard preffed, to the defart. Among the paftoral tribes there are many that addict themfelves entirely to arms, and ferve as cavalry in the time of war. During peace they efcort caravans, or exercife themfelves in military evolutions, and the management of their horfes. Being almoft always on horfeback, and wearing no boots, they have a callous lump on that part of the leg that comes in contact with the iron of the ftirrup. Their horfes, which they break in an admirable manner, are the beft in the world: as they are treated with great care by their mafters, they know them, and are obedient to their voice, and will admit no ftranger to mount them.

The Monfelemines derive their origin and name from Mofeilama, a contemporary of Mahomet; and, in their love of liberty, as well as in many of their cuftoms, refemble the Arabs of remoter times. They refpect the prophet like other Mahometans; but neither believe that he was infallible, nor that his defcendants are all infpired by God, nor that their will fhould be a law, nor that fuch faith is neceffary in order to be a good Mahometan. Their priefts are refpected, and in old age generally become the civil judges of the nation; but the influence of the high prieft is almoft defpotic. Though he has no troops, he may command the nation; and war and peace depend upon his will. Though he has no property, every thing is at his difpofal: he requires nothing from any one, and yet all are inclined to give. He adminifters juftice according to the opinion of his counfel, without pretending to be infpired by the prophet.

On Friday the Monfelemines affemble in their mofques to pray: this is likewife the day of their principal market, when their merchandize is expofed to fale in the public fquares, where the old men judge without appeal, when difputes arife. Different from their neighbours of Morocco and Sahara, the Monfelemines never attempt to make profelytes. Their Chriftian flaves are treated with humanity; but they owe this to the avarice of their mafters. Thefe deteft Chriftians, but they love money, and are afraid left ficknefs or death fhould deprive them of the ranfom of the flave, or of the advantage of his labour. Among the inhabitants of the defart, a Chriftian, that adopts the religion of Mahomet, is admitted as a citizen and member of the family, and is prefented with cattle to form an eftablifhment. The Monfelemines pay more attention to the value of their property than the fituation of the infidel. A Chriftian who enters a mofque at Morocco is put to death, or forced to affume the turban. The Monfelemines would turn him civilly out, and content themfelves with impofing the higheft poffible fine. Among the Moors, a Chriftian difcovered in an intrigue with a woman of that nation fuffers death, or fubmits to

con-

Monfelemines, Monterey. conversion ; but the Monselemines prefer money to religion. From them the Christian has nothing to fear : the woman alone is punished, being put into a fack and thrown into the sea. If a Christian slave among the neighbouring nations defends himself against his master, he is punished with death ; but money saves him among the Monselemines ; he would at most receive a slight correction.

The Jews are allowed the free exercise of their religion among the Monselemines, but are treated with the same indignity as among other Mahometan tribes. A Jew is not permitted to carry arms ; and if he should make use of them against an Arab, he would be punished with death, and probably involve his family in his fate. The Jews inhabits the towns only, where they follow trade and various arts, but are not allowed to cultivate the earth.

Polygamy is permitted, as in other Mahometan countries ; but the situation of the women is more respectable, and they are not so much secluded as among the Moors. They mingle more in society, walk at large, and visit their friends ; neither are their apartments so inviolable. Among the Monselemines, that degrading picture of humanity is never seen which sometimes occurs in Morocco, a woman drawing the plough with an ass, a mule, or some other beast of burden. More happier than the women of the Sahara, and treated with greater attention by their husbands, they are more humane in their dispositions. Like other Arab women, they stain the edges of their eyelids black with henna, and paint their faces red and yellow. Their children are brought up with great care, and are not obliged to exhibit proofs of their courage before they can be considered as men, as is the custom in the desart. Avarice is the principal defect in the character of the Monselemines. They hoard their money with the utmost care, bury it in the earth, and in many cases die without discovering their secret even to their children. Misers, says M. Saugnier, should go to that country, where they would learn means of economy ; which would shew them, that, in comparison with the Monselemines, they are themselves perfect prodigals.

The medicinal applications of the Monselemines, which differ not from those of the MONGEARTS and other inhabitants of the desart, are extremely simple, but appear sufficiently complex from the mummery of the priests, who are the depositories of their medical science. Flesh wounds are cauterised with a hot iron, and then covered with herbs dipped in turtles oil and tar. In headachs, a compress is applied with such violence that the blood starts from the forehead. In internal diseases, the general remedies are regimen, rest, and a few maxims of the Koran mysteriously applied to the affected parts.

MONTEREY BAY, in North California, was visited in 1786 by La Perouse, who places it in 36° 58′ 43″ N. Lat. and 124° 40′ W. Long. from Paris. It is formed by New-year point to the north, and by that of Cyprus to the south ; has an opening of eight leagues in this direction, and nearly six of depth to the eastward where the land is sandy and low. The sea breaks there as far as the foot of the sandy downs with which the coast is surrounded, with a roaring which may be heard more than a league off. The lands north and south of this bay are high, and covered with trees. Those ships which are desirous of touching there ought to follow the south coast, and after having doubled the Point of Pines, which stretches to the northward, get sight of the presidency, and may come to an anchor in ten fathoms within it, and a little within the land of this point, which shelters from the winds from the offing. The Spanish ships, which propose to make a long stay at Monterey, are accustomed to bring up within one or two cables lengths of the land, in six fathoms, and make fast to an anchor, which they bury in the sand of the beach ; they have then nothing to fear from the southerly winds, which are sometimes very strong ; but, as they blow from the coast, do not expose them to any danger. The two French frigates, which our author commanded, found bottom over the whole bay, and anchored four leagues from the land, in 60 fathoms, soft muddy ground ; but there is a very heavy sea, and it is only an anchorage fit for a few hours, in waiting for day, or the clearing up of the fog. At full and change of the moon it is high water at half past one o'clock : the tide rises seven feet ; and as this bay is very open, the current in it is nearly imperceptible. It abounds with whales ; a genus of fishes, of which our *scientific* voyagers knew so little, that they were surprised at their spouting water !

The coasts of Monterey Bey are almost continually enveloped in fogs, which cause great difficulty in the approach to them. But, for this circumstance, there would be few more easy to land upon ; there is not any rock concealed under water that extends a cable's length from the shore ; and if the fog be too thick, there is the resource of coming to an anchor, and there waiting for a clear, which will enable you to get a good sight of the Spanish settlement, situated in the angle formed by the south and east coast. The sea was covered with pelicans. These birds, it seems, never go farther than five or six leagues from the land ; and navigators, who shall hereafter meet with them during a fog, may rest assured that they are within that distance of it.

A lieutenant-colonel, whose residence is at Monterey, is governor of the Californias : the extent of his government is more than 800 leagues in circumference, but his real subjects consist only of 282 cavalry, whose duty it is to garrison five small forts, and to furnish detachments of four or five men to each of the 25 missions, or parishes, established in old and new California. So small are the means which are adequate to the restraining about 50,000 wandering Indians in this vast part of America, among whom, nearly 10,000 have embraced Christianity. These Indians are, in general, small and weak (A), and discover none of that love of liberty and independence which characterises the northern nations, of whose arts and industry they are also destitute. Their colour very nearly approaches that of the negroes whose hair is not woolly ; the hair of these people is strong, and of great length ; they cut it four or five inches from the roots. Several among them have a beard ; others, according to the missionary fathers, have never had any ; and this is a question which is even undecided.

(A) The chief surgeon of the expedition says they are *strong*, but stupid.

Monterey. decided in the country. The governor, who had travelled a great way into the interior of these lands, and who had passed 15 years of his life among the savages, assured our author, that those who had no beards had plucked them up with bivalve shells, that served them as pincers: the president of the missions, who had resided an equal length of time in California, maintained the contrary;—it was difficult, therefore, for travellers to decide between them." The difficulty, surely, was not great. By their own account, the governor had travelled much farther into the country than the missionary; and his report being confirmed by the evidence of their own senses, was intitled to unlimited credit.

These Indians are extremely skilful in drawing the bow; they killed, in the presence of the French, the smallest birds: it is true, they display an inexpressible patience in approaching them; they conceal themselves, and, as it were, glide along near to the game, seldom shooting till within 15 paces. Their industry in hunting the larger animals is still more admirable. Perouse saw an Indian, with a stag's head fixed upon his own, walk on all fours, as if he were brousing the grass; and he played this pantomime to such perfection, that all the French hunters would have fired at him at 30 paces, had they not been prevented. In this manner they approach herds of stags within a very small distance, and kill them with a flight of arrows.

Before the Spanish settlements, the Indians of California cultivated nothing but maize, and almost entirely lived by fishing and hunting. There is not any country in the world which more abounds in fish and game of every description; hares, rabbits, and stags are very common there; seals and otters are also found there in prodigious numbers; but to the northward, and during the winter, they kill a very great number of bears, foxes, wolves, and wild cats. The thickets and plains abound with small grey tufted partridges, which, like those in Europe, live in society, but in large companies of three or four hundred; they are fat, and extremely well flavoured. The trees serve as habitations to the most delightful birds; and the ornithologists of the voyage stuffed a great variety of sparrows, titmice, speckled wood-peckers, and tropic birds. Among the birds of prey are found the white-headed eagle, the great and small falcon, the goss-hawk, the sparrow-hawk, the black vulture, the large owl, and the raven. On the ponds and sea-shore are seen the wild duck, the grey and white pelican with yellow tufts, different species of gulls, cormorants, curlews, ring-plovers, small sea water hens, and herons; together with the bee-eater, which, according to most ornithologists, is peculiar to the old continent.

The country about Monterey Bay is inexpressibly fertile. The crops of maize, barley, corn, and pease, cannot be equalled but by those of Chili; our European cultivators can have no conception of a similar fertility; the medium produce of corn is from seventy to eighty for one; the extremes sixty and a hundred. Fruit trees are still very rare there, but the climate is extremely suitable to them: it differs a little from that of the southern French provinces. The forest trees are, the stone-pine, cyprus, evergreen oak, and occidental plane-tree. There is no underwood; and a verdant carpet, over which it is very agreeable to walk, covers the ground. There are also vast savannahs, abounding with all sorts of game. Monterey

Perouse writes with great respect of the wise and pious conduct of the Spanish missionaries at Monterey, who so faithfully fulfil the purpose of their institution. Totally unlike the monks at Conception in Chili (see that article in this *Suppl.*), they have left the lazy life of a cloister, to give themselves up to cares, fatigues, and solicitudes of every kind. They invited the officers of the frigates to dine with them at their monastery, contiguous to which stands the Indian village, consisting of about 50 cabins, which serve as dwelling-places to 740 persons of both sexes, comprising their children, which compose the mission of Saint Charles, or of Monterey. These cabins are the most miserable that are to be met with among any people; they are round, six feet in diameter, by four in height; some stakes, of the size of an arm, fixed in the earth, and which approach each other in an arch at the top, compose the timber work of it; eight or ten bundles of straw, very ill arranged over these stakes, defend the inhabitants, well or ill, from the rain and wind; and more than half of this cabin remains open when the weather is fine; their only precaution is to have each of them two or three bundles of straw at hand by way of reserve.

All the exhortations of the missionaries have never been able to procure a change of this general architecture of the two Californias. The Indians say, that they like plenty of air; that it is convenient to set fire to their houses when they are devoured in them by two great a quantity of fleas; and that they can build another in less than two hours. The independent Indians, who as hunters so frequently change their places of abode, have a stronger motive.

The monks gave the most complete information respecting the government of this species of religious community; for no other name can be given to the legislation they have established. They are superiors both in spiritual and temporal affairs: the products of the land are entirely entrusted to their administration. There are seven hours allotted to labour in the day, two hours to prayers, and four or five on Sundays and festivals, which are altogether dedicated to rest and divine worship. Corporal punishments are inflicted on the Indians of both sexes who neglect pious exercises; and several sins, the punishment of which in Europe is reserved only to Divine Justice, are punished with chains or the stocks.

The Indians, as well as the missionaries, rise with the sun, and go to prayers and mass, which last an hour; and during this time there is cooked in the middle of the square, in three large kettles, barley meal, the grain of which has been roasted previous to being ground; this species of boiled food, which the Indians call *atole*, and of which they are very fond, is seasoned neither with salt nor butter, and to us would prove a very insipid mess. Every cabin sends to take the portion for all its inhabitants in a vessel made of bark: there is not the least confusion or disorder; and when the coppers are empty, they distribute that which sticks to the bottom to the children who have best retained their lessons of catechism. This meal continues three quarters of an hour, after which they all return to their labours; some go to plough the earth with oxen, others to dig the garden; in a word, every one is employed in different

Monterey. rent domeftic occupations, and always under the fuperintendance of one or two of the religious.

The women are charged with little elfe but the care of their houfewifery, their children, and roafting and grinding the feveral grains: this laft operation is very long and laborious, becaufe they have no other means of doing it but by crufhing the grain in pieces with a cylinder upon a ftone. M. de Langle, being a witnefs of this operation, made the miffionaries a prefent of his mill; and a greater fervice could not have been rendered them, as by thefe means four women would in a day perform the work of a hundred, and time enough will remain to fpin the wool of their fheep, and to manufacture coarfe ftuffs.

At noon the dinner was announced by the bell; the Indians quitted their work, and fent to fetch their rations in the fame veffels as at breakfaft: but this fecond mefs was thicker than the firft; there was mixed in it corn and maize, and peafe and beans; the Indians name it *pouffole*. They return again to their labour from two o'clock till four or five; afterwards they attend evening prayers, which continue near an hour, and are followed by a new ration of *atole* like that at breakfaft. Thefe three diftributions are fufficient for the fubfiftence of the far greater number of Indians; and this very economical foup might perhaps be very profitably adopted in our years of fcarcity; fome feafoning would certainly be neceffary to be added to it, their whole knowledge of cookery confifting in being able to roaft the grain before it is reduced into meal. As the Indian women have no veffels of earth or metal for this operation, they perform it in large bafkets made of bark, over a little lighted charcoal: they turn thefe veffels with fo much rapidity and addrefs, that they effect the fwelling and burfting of the grain without burning the bafket, though it is made of very combuftible materials.

The corn is diftributed to them every morning; and the fmalleft difhonefty, when they give it out, is punifhed by whipping: but it is very feldom, indeed, they are expofed to it. Thefe punifhments are adjudged by Indian magiftrates, called *caciques;* there are in every miffion three of them, chofen by the people from amongft thofe whom the miffionaries have not excluded: but thefe caciques are like the governors of a plantation, paffive beings, blind executors of the will of their fuperiors; and their principal functions confift in ferving as beadles in the church, and their maintaining order and an air of contemplation. The women are never whipped in public, but in an enclofed and fomewhat diftant place, left perhaps their cries might infpire too lively a compaffion, which might ftimulate the men to revolt; thefe laft, on the contrary, are expofed to the view of all their fellow-citizens, that their punifhment may ferve as an example. In general they afk pardon; in which cafe the executioner leffens the force of his lafhes, but the number of them is never receded from.

The rewards are particular fmall diftributions of grain, of which they make little thin cakes, baked on burning coals: and on the great feftivals the ration is in beef; many of them eat it raw, efpecially the fat, which they efteem equal to the beft butter or cheefe. They fkin all animals with the greateft addrefs; and when they are fat, they make, like the ravens, a croaking of pleafure, devouring, at the fame time, the moft delicate parts with their eyes.

They are frequently permitted to hunt and fifh on their own account; and on their return they generally make the miffionaries fome prefent in game and fifh; but they always proportion the quantity to what is abfolutely neceffary for them, always taking care to increafe it if they hear of any new guefts who are on a vifit to their fuperiors. The women rear fowls about their cabins, the eggs of which they give their children. Thefe fowls are the property of the Indians, as well as their clothes, and other little articles of houfehold furniture, and thofe neceffary for the chace. There is no inftance of their having robbed each other, though their faftenings to the doors confift only of a fimple bundle of ftraw, which they place acrofs the entrance when all the inhabitants are abfent.

The men in the miffions have facrificed much more to Chriftianity than the women; becaufe they were accuftomed to polygamy, and were even in the cuftom of efpoufing all the fifters of a family. The women, on the other hand, have acquired the advantage of exclufively receiving the careffes of one man only. With this, however, it would appear that they are not fatisfied; for the religious have found it neceffary to conftitute themfelves the guardians of female virtue. At an hour after fupper, they have the care of fhutting up, under lock and key, all thofe whofe hufbands are abfent, as well as the young girls above nine years of age; and during the day they are entrufted to the fuperintendance of the matrons. So many precautions are ftill infufficient; for our voyagers faw men in the ftocks, and women in irons, for having deceived the vigilance of thefe female arguffes, who had not been fufficiently fharp-fighted.

The converted Indians have preferved all the ancient ufages which their new religion does not prohibit; the fame cabins, the fame games, the fame dreffes: that of the richeft confifts of an otter's fkin cloak, which covers their loins, and defcends below their groin; the moft lazy have only a fimple piece of linen cloth, with which they are furnifhed by the miffion, for the purpofe of hiding their nakednefs; and a fmall cloak of rabbit's fkin covers their fhoulders, which is faftened with a pack-thread under the chin; the head and the reft of the body is abfolutely naked; fome of them, however, have hats of ftraw, very neatly matted. The womens drefs is a cloak of deer fkin, ill tanned; thofe of the miffions have a cuftom of making a fmall boddice with fleeves, of them: it is their only apparel, with a fmall apron of rufhes, and a petticoat of ftag's fkin, which covers their loins, and defcends to the middle of the leg. The young girls, under nine years of age, have merely a fimple girdle; and the children of the other fex are quite naked.

The independent favages are very frequently at war; but the fear of the Spaniards makes them refpect their miffions; and this, perhaps, is not one of the leaft caufes of the augmentation of the Chriftian villages. Their arms are the bow, and arrow pointed with a flint very fkilfully worked: thefe bows are made of wood, and ftrung with the finews of an ox. Our author was affured, that they neither eat their prifoners, nor their enemies killed in battle; that, neverthelefs, when they had

had vanquifhed, and put to death on the field of battle, chiefs, or very courageous men, they have eaten fome pieces of them, lefs as a fign of hatred or revenge, than as a homage which they paid to their valour, and in the full perfuafion that this food would be likely to increafe their own courage. They fcalp the vanquifhed as in Canada, and pluck out their eyes; which they have the art of preferving free from corruption, and which they carefully keep as precious figns of their victory. Their cuftom is to burn their dead, and to depofit their afhes in morais.

MOORS, in common language, are the natives of Morocco, of whom an account is given under that title in the *Encyclopædia*; but there is another people, a mixed race, called alfo Moors, who lead a wandering and paftoral life in the habitable parts of the Great Defert, and in the countries adjacent to it. Of the origin of thefe Moorifh tribes, as diftinguifhed from the inhabitants of Barbary, nothing farther feems to be known than what is related by John Leo the African; whofe account may be abridged as follows:

Before the Arabian conqueft, about the middle of the feventh century, all the inhabitants of Africa, whether they were defcended from Numidians, Phœnicians, Carthaginians, Romans, Vandals, or Goths, were comprehended under the general name of *Mauri*, or Moors. All thefe nations were converted to the religion of Mahomet, during the Arabian empire, under the Kaliphs. About this time many of the Numidian tribes, who led a wandering life in the defert, and fupported themfelves upon the produce of their cattle, retired fouthward acrofs the Great Defert, to avoid the fury of the Arabians; and by one of thofe tribes, fays Leo (that of Zanhaga), were difcovered, and conquered, the Negro nations on the Niger. By the Niger, is here undoubtedly meant the river of Senegal, which in the Mandingo language is called *Bafing*, or the Black River.

To what extent thefe people are now fpread over the African continent, it is difficult to afcertain. There is reafon to believe, that their dominion ftretches from weft to eaft, in a narrow line or belt, from the mouth of the Senegal (on the northern fide of that river) to the confines of Abyffinia. Mr Park defcribes them as refembling, in complexion, the Mulattoes of the Weft Indies, and as having cruelty and low cunning pictured in their countenances. "From the ftaring wildnefs in their eyes (fays he), a ftranger would immediately fet them down as a nation of lunatics. The treachery and malevolence of their character are manifefted in their plundering excurfions againft the Negro villages. Oftentimes, without the fmalleft provocation, and fometimes under the faireft profeffions of friendfhip, they will fuddenly feize upon the Ngroes cattle, and even on the inhabitants themfelves. Ths Negroes very feldom retaliate. The enterprifing boldnefs of the Moors, their knowledge of the country, and, above all, the fuperior fleetnefs of their horfes, make them fuch formidable enemies, that the petty Negro ftates, which border upon the defert, are in continual alarm while the Moorifh tribes are in the vicinity, and are too much awed to think of refiftance.

"Like the roving Arabs, the Moors frequently remove from one place to another, according to the feafon of the year, or the convenience of pafturage. In the month of February, when the heat of the fun fcorches up every fort of vegetation in the defert, they ftrike their tents, and approach the Negro country to the fouth; where they refide until the rains commence, in the month of July. At this time, having purchafed corn, and other neceffaries from the negroes, in exchange for falt, they again depart to the northward, and continue in the defert until the rains are over, and that part of the country becomes burnt up and barren.

"This wandering and reftlefs way of life, while it inures them to hardfhips, ftrengthens, at the fame time, the bonds of their little fociety, and creates in them an averfion towards ftrangers, which is almoft infurmountable. Cut off from all intercourfe with civilized nations, and boafting an advantage over the Negroes, by poffeffing, though in a very limited degree, the knowledge of letters, they are at once the vaineft and proudeft, and perhaps the moft bigotted, ferocious, and intolerant, of all the nations on the earth; combining in their character the blind fuperftition of the Negro with the favage cruelty and treachery of the Arab." But for them Mr Park would have accomplifhed the utmoft object of his miffion, and have reached Tombuctoo, and even Houffa, with no other danger than what arifes neceffarily from the climate, from wild beafts, and from the poor accommodation afforded in the huts of the hofpitable Negroes. The wandering Moors, however, have all been taught to regard the Chriftian name with inconceivable abhorrence; and to confider it nearly as lawful to murder a European as it would be to kill a dog. It is, therefore, much lefs furprifing that our traveller did not proceed farther along the banks of the Nigre, than that he efcaped the fnares of fo relentlefs a people.

MORINDA, is a plant, of which a very meagre defcription has been given in the *Encyclopædia*, though it is of much importance in oriental commerce. It is cultivated to a great extent in the province of *Maleva*, in the Eaft Indias, where it furnifhes a valuable dye-ftuff; and is thus defcribed by William Hunter, Efq; in the fourth volume of the Afiatic refearches:

"It is a tree of a middling fize; the *root* branchy; the *trunk* columnar, erect, covered with a fcabrous bark. *Branches*, from the upper part of the trunk, fcattered; of the ftructure of the trunk. *Leaves* (feminal) oval, obtufe, entire (mature), oppofite, decuffated, ovate, pointed at both ends, fmooth, with very fhort petioles. *Stipules*, lanced, very fmall, withering. *Peduncles*, from the axils of the leaves, folitary, bearing an aggregate flower. *Calyx*, common receptable roundifh, collecting the feffile flowers into an irregular head. *Perianth*, moft entire, fcarce obfervable above. *Coral*, one petalled, funnel-form. *Tube*, cylindric: *Border*, five cleft; the *divifions* lanced. *Stamen: Filaments*, five, threadform, arifing from the tube, and adhering to it through two thirds of their length, a little fhorter than the tube. *Anthers*, linear, erect. *Piftil. Germ*, beneath, four-celled, containing the rudiments of four feeds. *Style*, thread form, longer than the ftamens. *Stigma*, two cleft, thickifh. *Pericarp*, common, irregular, divided on the furface into irregular angular fpaces; compofed of berries, pyramidal, compreffed on all fides by the adjacent ones, and concreted with them; lopped; containing towards the bafe a flefhy pulp. *Seeds*, in each berry four; towards the point oblong, externally convex, internally angular."

The

The fpecies here defcribed is the *morinda arborea pedunculis folitariis* of Linnæus. It grows beft in a black rich foil, free from ftones, in fituations moderately moift, not too high, yet fufficiently elevated to prevent the rain water from ftagnating, and where a fupply of water can be had for the dry months. As the colouring matter, for which alone it is valuable, refides chiefly in the bark of the root, the fmall twigs, which contain little wood, bear a higher price than the larger pieces. The natives employ it in dyeing a pale red, or clay colour; which Mr Hunter fays is more valuable for its durability than for its beauty. They likewife ufe it in dyeing a dark purple or chocolate colour; but for the procefs, in both cafes, we muft refer to the original memoir.

MORION, in botany, a name given by the ancients to a kind of nightfhade. See Solanum, *Encycl.*

Morion, in ancient mineralogy, a name given to one of the femipellucid gems, more commonly called *pramnion*. It is a ftone appearing externally of a fine deep black; but when held up againft a candle, or againft the fun-beams, it gives a very beautiful red in different degrees.

MOSHAIRA, or Moshahereh, penfion or allowance in Bengal.

MOSS, the name given in Scotland, and we believe alfo in fome parts of England, to what is more properly called a *morafs*, a *fen*, or a *bog*. On the formation of thefe moffes fome conjectures have been hazarded in the *Encyclopædia*, where the reader will likewife find a copious account of the method which has for many years been fuccefsfully employed to convert the Moss of Kincardine into an arable foil, or rather to remove the fubftance called *mofs* or *peat* from the rich foil which is found below it. A method, however, has been invented by Mr John Smith of Swindrig-muir, in the fhire of Ayr, for *actually* converting the fubftance called mofs into a vegetable mould, which has been found by experience to carry rich crops of corn, hay, potatoes, &c. Of this gentleman's practice we have the following account in a fmall pamphlet publifhed in Edinburgh, 1798, by Fairbairn and Dickfon.

" The firft thing to be done is to mark off, and cut out, proper main or mafter drains, in order to carry off the fuperfluous water, taking care to preferve the greateft poffible level; which drains are fo conftructed as to divide the field into inclofures from fix to ten Scotch acres. If the mofs hangs or declines, the inclofures may be of any dimenfion whatever. The dimenfions of thefe drains when firft made are eight feet wide, by four and a half feet deep, declining to two and a half feet at bottom, and coft at the rate of one fhilling per fall of eighteen and a half feet, running meafure. The ridges are then to be marked off regularly, fix or feven yards broad, formed with the fpade in the manner following:

" In the centre of each ridge, a fpace of about 20 inches is allowed to remain untouched, on each fide of which a furrow is opened, and turned upon the untouched fpace, fo as completely to cover it (like what is called the feering of a gathered ridge). Thus begun, the work is continued, by cutting with the fpade, in width about 12 inches, and turning it over to appearance as if done with a plough, until you come to the divifion furrow, which fhould be two feet wide, cut out and thrown upon the fides of the ridges. The depth of the divifion furrow is to be regulated by circumftances, according as the mofs is wet or dry, but fo as to anfwer the purpofe of as it were bleeding the mofs, and conducting the water to the main drains.

" It may be here obferved, that the fuccefs of the aftercrops depends very much upon a proper formation of the ridges. They muft not be made too high in the middle, for there they will be too dry like a peat, upon which the lime cannot act, and near the furrows they will be too wet, which is equally prejudicial; they fhould therefore be conftructed with a gentle declivity to the furrows, fo as the rain which falls may rather filtrate through the ridge to the furrows than run quickly off the furface.

" The next operation is to top drefs the ridges with lime, at the rate of from four to eight chalders per acre. Five Winchefter bufhels make a boll, and eight bolls a chalder of fhell lime, producing fixteen bolls powdered lime. The quicker the lime is put on after being flacked the better.

" The proper feafon to prepare the mofs for a firft crop is early the preceding fummer; in that cafe the lime, aided by the heat, the after rains, and the winter frofts, makes confiderable progrefs in the procefs of putrefaction, confequently forms a mould to receive the feed.

" Though oats have fometimes fucceeded as a firft crop, potatoes have been found greatly preferable. The method of planting them is fimple, and attended with little expence. The mofs, prepared by ridges, and limed as before defcribed, beds for the potatoes are, in the fpring, marked off, acrofs the ridges, five or fix feet broad, with intermediate fpaces of about two feet, as furrows or trenches. The beds are covered over with a thin ftratum of dung, about eighteen fingle-horfe carts to an acre, the cuttings of the potatoes are laid or placed upon the beds, about ten or twelve inches afunder, and the whole covered over with a thin ftratum of mofs from the intermediate trenches, which is followed by another covering from the trenches when the potatoe plants make their firft appearance; the covering in whole four or five inches. In this ftate they remain without any hoeing till the crop is taken up. The produce on Mr Smith's mofs has never been lefs than from forty to fifty bolls of excellent potatoes, eight Winchefter bufhels to the boll, and the bufhel a little heaped.

" When the potatoe crop is removed, the ridges are again formed as before defcribed, and the divifion furrow cleared out. In performing this part of the work, it will naturally occur, that a great part of the manured furface will be buried in filling up the trenches between the potatoe beds: but that is not the cafe; the workman makes two cuts with the fpade, at eighteen inches diftance, upon the fide of the trench; another, one foot from the edge of it, as deep as the trench; which, inftead of turning over, he preffes a foot forward into the trench, which is continued the length of it; and when he comes to the other fide he does the fame, making both meet, and fo proceeds; fo that no part of the manured furface is thrown down, and the ridge is left in the fame form as before the lazy-beds* were made.

" When the potatoe crop is taken off, and the ridges formed as before defcribed, they remain in that ftate till fpring, when oats are fown (a wet or dry feafon has from

* This is a vulgar Scottifh phrafe for beds of a particular kind of potatoe.

from experience been found a matter of indifference), and harrowed in with a fmall harrow drawn by two men. Four men with eafe harrow at leaft one acre one rood per day, two and two by turns with the harrow, and the other two in the interim with fpades, fmoothing the inequalities, breaking and dividing the mould, and clearing out the divifion furrows; which laft in all operations upon mofs are effentially neceffary. The early or hot feed oats are always preferred for feed. The late or cold feed runs too much to ftraw, falls down, and becomes floomy, confequently the grain is of mean quality, and unproductive in meal.

"The produce of the firft crop of oats after potatoes is feldom lefs than ten bolls per acre, the Linlithgow boll of fix Winchefter bufhels, and confiderably more has been known; as good grain in quality, and meals as well as any in the country. It has been fold when growing, what is called upon the foot, including the ftraw, from eight to ten pounds per acre. To prepare for a fecond crop of oats, the ridges muft be dug acrofs, and turned over in the manner before defcribed, and the divifion furrows cleared out as foon as convenient after the firft crop is removed.

"Such is the effect of lime in confolidating mofs, aided by the draining, that often after the fecond, and always after the third year, it can be ploughed by horfes within two bouts or ftitches of the divifion furrow; and alfo harrowed by horfes, and the crops taken off by carts.

"Five and often fix confecutive crops of oats are taken, without any other manure than what it received the firft year for potatoes, without any apparent figns of it being exhaufted. The produce of the firft two crops of oats has been mentioned to be ten bolls, and the third, fourth, fifth, and fixth, produce from fix to ten bolls per acre. The mofs is now turned into a feeming rich dark brown mould; and what renders it lefs productive of corn crops the fourth, fifth, and fixth years is, its naturally running into fweet and luxuriant graffes. The foft meadow grafs, the daify, fome plaintain, but principally the white clover, are the moft prevalent graffes; or more probably it may be afcribed to thefe crops being ploughed, in place of being dug with the fpade, as the former years were. Along with the fifth or fixth crop of oats, rye grafs is fown, which, with the natural graffes in general, produce an abundant crop of hay.

"If the mofs in the original ftate has been wet and fpongy, it will be found to have fubfided fome feet after the third or fourth year's operation has been performed; but care muft always be taken to deepen, clear out, and keep clear the main drains and the divifion furrows, to prevent a fuperabundance of moifture, which would infallibly be the cafe were they neglected in confequence of the fubfidence of the mofs. Indeed mofs of all forts will fubfide lefs or more, in proportion as it has been dry or wet in its original ftate; at the fame time, as ftated before, care muft be taken not to lay it too dry, but to keep in a proper degree of temperature between thefe two extremes."

By having recourfe to the pamphlet from which this extract has been made, the reader may fatisfy himfelf of the real advantages of this fpecies of agriculture. The author calculates, with much apparent fairnefs, the expence of improvement, and the value of each crop, and concludes that no wafte can be improved with equal advantage as mofs. It muft not, however, be concealed, that we have heard practical farmers, who feemed to be acquainted with the fubject, give it as their opiuion that this mode of cultivation anfwers only in moffes of no great depth; though our author affirms that it has with great fuccefs been practifed by Mr Smith in moffes of the depth of 14 feet.

MOTION IN FLUIDS. When in the publication of this *Supplement* we had arrived at the title FLUIDS, we were ftruck with the importance given, in fome of the journals, to *The Experimental Refearches of* Venturi *concerning the Principle of the lateral communication of Motion in Fluids, applied to the Explanation of various Hydraulic Phenomena.* Of thefe refearches we intended to lay an abridged account before our readers under the prefent title; but having examined the work with fome attention, we find in it hardly any thing of confequence which the mechanical philofopher may not learn from our articles *RESISTANCE of Fluids* and RIVER in the *Encyclopædia*. That our readers, however, may find fomething under a title to which we rafhly referred them, we fhall, in the words of Nicholfon's Journal of Natural Philofophy, &c. inform them what Venturi's work contains.

"This author, who is profeffor of experimental philofophy at Modena, has introduced an horizontal current of water into a veffel filled with the fame fluid at reft. This ftream entering the veffel with a certain velocity, paffes through a portion of the fluid, and is then received in an inclined channel, the bottom of which gradually rifes until it paffes over the border or rim of the veffel itfelf. The effect is found to be, not only that the ftream itfelf paffes out of the veffel through the channel, but carries along with it the fluid contained in the veffel; fo that after a fhort time no more of the fluid remains than was originally below the aperture at which the ftream enters. This fact is adopted as a principle or primitive phenomenon by the author, under the denomination of the lateral communication of motion in fluids, and to this he refers many important hydraulic facts. He does not undertake to give an explanation of this principle, but fhews that the mutual attraction of the particles of water is far from being a fufficient caufe to account for it.

The firft phenomenon which the author propofes to explain by this eftablifhed principle, is the emiffion of a fluid through different adjutages applied to the refervoir which contains it. It is known that the vein of fluid which iffues from an orifice or perforation through a thin plate, becomes contracted, fo as to exhibit a fection equal to about 0,64 of the orifice itfelf, fuppofed to be circular; and that the place of the greateft contraction is ufually at the diftance of one femi-diameter of the orifice itfelf. If a fmall adjutage be adapted to the orifice, having its internal cavity of the fame conoidal form as the fluid itfelf affects in that interval, the expenditure is the fame as by the fimple orifice. But if at the extremity of this adjutage a cylindric tube be affixed, of a greater diameter than that of the contracted vein, or a divergent conical tube, the expence of fluid increafes, and may exceed the double of that which paffes through the aperture in the thin plate, though the adjutage poffefs an horizontal or even afcending direction.

By

By the interpofition of a fmall adjutage, adapted to the form of the contracted vein, Venturi afcertained, in the firft place, that there is an increafe of velocity in the tubes he employed, though the velocity of emiffion itfelf be lefs than that of the ftream which iffues from a hole in a thin plate. He afterwards proves, by the fact, that the interior velocity and expenditure of fluid, which is increafed through tubes, even in the horizontal or afcending direction, is owing to the preffure of the atmofphere. If the fmalleft hole be made in the fide of the tube near the place of contraction of the vein, the increafed expenditure does not take place; and when a verticle tube is inferted in fuch a hole, the lower end of which tube is immerfed in water or mercury, it is found that afpiration takes place, and the water or mercury rifes; and this afpiration in conical tubes is lefs in proportion, as the place of infertion of the upright tube is more remote from the fection where the greateft contraction would have taken place. And, laftly, the difference between the expenditure of fluid, through an orifice made in a thin plate, and that which is obferved through an additional tube, does not take place in vacuo.

The influence of the weight of the atmofphere on the horizontal or afcending flux being thus eftablifhed, the author confiders it as a fecondary caufe, referable to, and explicable by, his principle of the lateral communication of motion in fluids. In conical divergent tubes, for example, the effect of this lateral communication is, that the central cylindrical jet, having for its bafis the fection of the contracted vein, carries with it the lateral fluid which would have remained ftagnant in the enlarged part of the cone. Hence a vacuum tends to be produced in this enlarged part which furrounds the central cylindric ftream; the preffure of the atmofphere becomes active to fupply the void, and is exerted on the furface of the refervoir, fo as to increafe the velocity of the fluid at the interior extremity of the tube.

The author proves, that the velocity or total expenditure of fluid through an aperture of given dimenfions, may be increafed by a proper adjutage in the proportion of 24 to 10; he applies this refult to the conftruction of the funnels of chimneys. He determines the lofs of emitted fluid, which may be fuftained by finuofity in pipes. He fhews by experiment, that a pipe which is enlarged in any part affords a much lefs quantity of fluid than if it were throughout of a diameter equal to that of its fmalleft fection. This, as he remarks, is a circumftance to which fufficient attention has not been paid in the conftruction of hydraulic machines. It is not enough to avoid elbows and contractions; for it fometimes happens that, by an intermediate enlargement, the whole of the advantage arifing from other judicious difpofitions of the parts of the machine is loft.

There are two cafes of the increafe of expenditure through defcending pipes. The firft is owing to the lateral communication of motion which takes place in defcending pipes, in the fame manner as in thofe which poffefs an horizontal fituation; the fecond arifes from the acceleration by gravity which takes place in the fluid while it falls through the defcending tube. This fecond kind of augmentation was known to the ancients, though they poffeffed no good theory nor decifive experiments refpecting it. The author endeavours to eftablifh a theory on the principle of virtual afcenfion combined with the preffure of the atmofphere. His deductions are confirmed by experiment, in which he has fucceeded fo far as to feparate the two caufes of augmentation, and affigned to each their refpective degree of influence.

Profeffor Venturi then proceeds to different objects of enquiry, to which his principle feemed applicable. He gives the theory of the water-blowing machine (fee *Water Blowing Machine* in this *Suppl.*), and he determines by calculation the quantity of air which one of thefe machines can afford in a given time. He obferves, that the natural falls of water in the mountains always produce a local wind; and he even thinks, that the falling ftreams in the internal parts of mountains are in fome inftances the caufe of the winds which iffue from caves. He proves, by the facts, that it is poffible, in certain inftances, to carry off, without any machinery, the waters from a fpot of ground, though it may be fituated on a lower level than that of the channel which is to receive the water.

The whirlpools, or circular eddies of water fo frequent in rivers, are, according to the theory of our author, the effect of motion communicated from the parts of the current which are moft rapid, to thofe lateral parts which are leaft fo. In the application of this principle, he points out the circumftances adapted to produce fuch eddies at the furface or at the bottom of rivers. He concludes, that every movement of this kind deftroys a part of the force of the current, and that in a channel through which water conftantly flows, the height of this fluid will be greater than it would have been if the dimenfions of the channel had been uniformly reduced to the meafure of its fmalleft fection.

There is another kind of whirling motion fomewhat different in its nature from thefe laft. It is produced in the water of a refervoir, when it is fuffered to flow through an horizontal orifice. The author deduces the theory of thefe vortices from the doctrine of central forces. The form of the hollow funnel, which in this cafe opens through the fluid of the refervoir, is a curve of the 64th fpecies of the lines of the third order, enumerated by Newton. Theory and experiment both unite here in proving, that it is not only poffible, but that there really exifts in nature a vortex, the concavity of which is convex towards the axis, and of which the revolutions of its different parts follow the ratio of the fquare of the diftance from the centre. Daniel Bernoulli was in the wrong, in his Hydrodynamics, to reproach Newton for having fuppofed a vortex to be moved according to this law.

In the laft place, the author confiders that lateral communication of motion which takes place in the air as well as in the water. This is the caufe of fuch local and partial winds as fometimes blow contrary to the direction of the general wind. It is by virtue of the fame principle, that the refonant vibration, excited laterally in the extremity of an organ-pipe, is communicated to the whole column of air contained in the pipe itfelf.

From the fame principle, the author deduces the augmentation of force which found receives in conical divergent tubes, compared with thofe of a cylindrical form. On this occafion, he points out the remarkable diffe-

differences which appear to take place between the resonant vibrations of air contained in a tube, and the sonorous pulsations propagated through the open atmosphere. See *Speaking Trumpet*, Encycl.

In an appendix, Venturi relates different experiments which he has made to determine the convergence and velocity of the fluid filaments which press forward to issue out of a reservoir by an orifice through a thin plate. He proves, by a very clear experiment, that the contraction of the vein is made at a greater distance from the orifice under strong than under weak pressures. He explains why, in a right-lined orifice, the sides of the contracted vein correspond with the angles of the orifice and the angles with the sides. He examines the expenditure through a tube, the extremity of which is thrust into the reservoir itself, according to the method of Borda in the Memoirs of the Academy of Sciences for the year 1766."

For a full account of the author's experiments, and his deductions from them, we refer the reader either to the original work, intitled, *Recherches expérimentales sur le Principe de la Communication latérale du Mouvement dans les Fluides, appliqué à l'Explication de différens Phénoménes hydrauliques. Par le Citoyen J. B. Venturi, Professeur de Physique expérimentale à Modène, Membre de la Société Italienne, &c. &c. A Paris chez Houel et Ducros, Rue du Bacq*, No. 940—*Théophile Barrois, Rue Haute feuille*, N. 22. *Ann.* VI. 1797—or to the 2d and 3d vols of the valuable Journal from which this abstract is taken.

MOURZOUK, the capital of Fezzan in Africa, is situated on a small river, and supplied with water from multitudes of springs and wells. Being formerly built of stone, it still retains the appellation of a Christian town; and the medley which it presents to the eye, of the vast ruins of ancient buildings, and the humble cottages of earth and sand that form the dwellings of its present Arab inhabitants, is singularly grotesque and strange. It is surrounded by a high wall, which not only affords the means of defence, but enables the government to collect, at its three gates, a tax on all goods (provisions excepted) that are brought for the supply of its people. A caravan sets out annually from Mesurata to this place; and hence the Fezzaners themselves dispatch every year a caravan to Cashna and another to Bornou. For the lătitude of Mourzouk, see Fezzan in this *Suppl.* Dr Brookes, in his Gazetteer, places it in 15° 5′ E. Long.

MOWAZZEF, in Bengal, fixed revenue.

MOZART, the celebrated German musician, was born at Salzburg in the year 1756. His father was also a musician of some eminence, but not to be compared with the son; of whom we have the following account in one of the monthly miscellanies, taken by Mr Bushby from some biographical sketches by two eminent German professors,

At the age of three years, young Mozart, attending to the lessons which his sister, then seven years old, was receiving at the herpsichord, he became captivated with harmony; and when she had left the instrument, he would instantly place himself at it, find the thirds, found them with the liveliest joy, and employ whole hours at the exercise. His father, urged by such early and striking indications of genius, immediately began to teach him some little airs; and soon perceived that his pupil improved even beyond the hopes he had formed of him. Half an hour was generally sufficient for his acquiring a minuet or a little song, which, when once learned, he would of himself perform with taste and expression.

At the age of six years he had made such a progress as to be able to compose short pieces for the harpsichord, which his father was obliged to commit to paper for him. From that time nothing made any impression upon him but harmony; and infantine amusements lost all their attractions unless music had a share in them. He advanced from day to day, not by ordinary and insensible degrees, but with a rapidity which hourly excited new surprise in his parents—the happy witnesses of his progress.

His father returning home one day with a stranger, found little Mozart with a pen in his hand. "What are you writing," said he? "A concerto for the harpsichord," replied the child. "Let us see it (rejoined the father); it is a marvellous concerto without doubt." He then took the paper, and saw nothing at first but a mass of notes mingled with blots of ink by the mal-address of the young composer, who, unskilled in the management of the pen, had dipped it too freely in the ink; and having blotted and smeared his paper, had endeavoured to make out his ideas with his fingers; but on a closer examination his father was lost in wonder; and his eyes delighted and flowing with tears, became rivetted to the notes. "See (exclaimed he to the stranger) how just and regular it all is! but it is impossible to play it; it is too difficult." "It is a concerto (said the child), and must be practised till one can play it. Hear how this part goes." He then sat down to perform it; but was not able to execute the passages with sufficient fluency to do justice to his own ideas. Extraordinary as his manual facility was universally allowed to be for his age, it did not keep pace with the progress of his knowledge and invention. Such an instance of intellectual advancement, in a child only six years of age, is so far out of the common road of nature, that we can only contemplate the fact with astonishment, and acknowledge, that the possible rapidity of mental maturation is not to be calculated.

In the year 1762, his father took him and his sister to Munich, where he performed a concerto before the elector, which excited the admiration of the whole court; nor was he less applauded at Vienna, where the emperor called him the *little sorcerer*.

His father gave him lessons only on the harpsichord; but he privately taught himself the violin; and his command of the instrument afforded the elder Mozart the utmost surprise, when he one day at a concert took a second violin, and acquitted himself with more than passable address. True genius sees no obstacles. It will not therefore excite our wonder, if his constant succees in whatever he attempted begot an unbounded confidence in his own powers; he had even the *laudable* hardihood to undertake to qualify himself for the *first* violin, and did not long remain short of the necessary proficiency.

He had an ear so correct, that he felt the most minute discordancy; and such a fondness for study, that it was frequently necessary to take him by force from the instrument. This love of application never diminished. He every day passed a considerable time at his harpsichord, and generally practised till a late hour at night.

Mozart night. Another characteriftical trait of real genius; always full of its object, and loft as it were in itfelf.

In the year 1763 he made, with his father and fifter, his firft grand mufical journey. He vifited Paris; and was heard by the French court in the chapel-royal at Verfailles, where his talent on the organ was admired even more than on the harpfichord. At Paris the mufical travellers gave two concerts, which procured them the higheft reputation, and the diftinction of public portraits. It was here that a fet of fonatas for the harpfichord, fome of his earlieft compofitions, were engraved and publifhed.

From Paris they went to London, where they alfo gave two concerts, confifting of fymphonies compofed by young Mozart, who even at that early age fang alfo with much expreffion, and practifed publicly with his fifter. Mozart played already at fight, and in a concert, at which the king was one of his auditors, a bafs being placed before him as a *ground*, immediately applied to it a moft beautiful melody. Thofe who are beft acquainted with the extent of fuch a tafk, will be the moft aftonifhed at fuch mature familiarity with the intricacies of the fcience, and fuch prompt and ready invention in fo juvenile a mind.

From London, where Mozart alfo publifhed fix fonatas for the harpfichord, the mufical family went to Holland, thence again to France, and in 1766 returned to Salzburg. There this extraordinary youth remained more than a year in perfect repofe; devoting the whole of his time to the ftudy of compofition, the principles of which he fcrutinized with the depth and penetration of confirmed manhood. Emmanuel Bach, Haffe, and Handel, were his chief guides and models; though he by no means neglected the old Italian mafters.

In 1768 he again vifited Vienna, where Jofeph II. engaged him to fet to mufic a comic opera, entitled, *La Finta Semplice*, which obtained the approbation of Haffe and Metatafio. At the houfe of the prince of Kaunitz, it often happened that the firft Italian air which came to hand would be given him, that in the prefence of the company he might add to it accompaniments for numerous inftruments; which he would write in the firft ftyle of excellence, and without the leaft premeditation. This is at once a proof with what acutenefs of obfervation he had liftened to the mufic of the beft mafters; how intimate he had already rendered himfelf with the characters, capacities, and effects of the different inftruments; and what fkill he had acquired in that abftrufe art of mixed combination which, while it calculates the conjoint effect of founds, as they regard the eftablifhed laws of harmony, accommodates the different parts to the fcales, tones, and powers of the refpective inftruments by which they are to be executed. It was at this time alfo that, although but twelve years of age, he compofed the mufic for the confecration of the church of orphans, at the performance of which he himfelf prefided.

In 1769 Mozart again returned to Salzburgh, where he became *maitre de concert*. Not having yet feen Italy, in December of the fame year he fet out for that feat of the fine arts. Thofe talents which had already excited the admiration of Germany, France, and England, now awakened in that land of mufical tafte the moft lively enthufiafm.

In 1771 he had no fooner given perfonal proofs of his genius, than *la fcrittura* for the following carnival was conferred upon him. He vifited Bologna, then as famous for harmonic excellence as Naples, where the celebrated theorift Martini was amazed to fee a German boy work and execute the theme of a fugue which he prefented to him, in the extraordinary ftyle in which Mozart acquitted himfelf. He next went to Florence. Florence even enhanced the eulogiums which Bologna had lavifhed upon him.

During the holy week he arrived at Rome, and affifted at the *Miferere* in the Sixtine chapel; which performance is juftly confidered as the *ne plus ultra* of vocal mufic. This circumftance claims particular notice, as inducing a proof of another faculty of his mind, only to be equalled by thofe wonderful powers which he had already demonftrated. He was prohibited from taking a copy of this *Miferere*, and therefore piqued himfelf on retaining it in his memory. Having heard it with attention, he went home, made out a manufcript from recollection, returned the next day to the chapel, heard the piece a fecond time, corrected the rough draught, and produced a tranfcript which furprifed all Rome. This *Miferere* formed a *fcorer* numerous in its parts, and extremely difficult of execution. His mind had embraced and retained the whole!

He foon after received from the Pope the order of the gilt fpur; and at Bologna was complimented, by an unanimous decifion, with the title of *Member and Mafter of the Phil-harmonic Academy*. As a proof, *pro forma*, of his qualifications for this academical honour, a fugue, for four voices, in the church ftyle, was required of him, and he was fhut up alone in his chamber. He completed it in half an hour, and received his diploma. This evinced that he poffeffed an imagination conftantly at his command, and that his mind was ftored with all the riches of his beloved fcience.

The opera which he compofed for Milan was called *Mithridates*. This piece procured him *la fcrittura* for the grand opera of the carnival of 1773, which was his *Lucio Sulla*. At length, after a tour of fifteen months, he returned to Salzburgh.

In 1771 Mozart vifited Paris; but not relifhing the mufic of that capital, he foon quitted it, and returned to his domeftic comforts. In 1781, at the requeft of the elector of Bavaria, he compofed the opera of *Idomeneo* for the carnival of that year. The general merit of this opera is fo great, that it might ferve for the bafis of a diftinguifhed reputation. At his twenty-fifth year he was invited to Vienna, where he continued fpreading, as from a centre, the tafte of his compofitions through all Germany, and the luftre of his name over the whole of Europe.

Of all the virtuofi of the piano forte who then crowded Vienna, Mozart was much the moft fkilful. His finger was extraordinarily rapid and tafteful, and the execution of his left hand exceeded every thing that had before been heard. His touch was replete with delicacy and expreffion; and the profound ftudy he had beftowed on his art, gave his performance a ftyle the moft brilliant and finifhed. His compofitions had a rapid circulation; and every new piece the connoiffeurs were ftruck with the originality of its caft, the novelty of the paffages, and the energy of the effect.

Jofeph II. folicitous for the perfection of the German opera, engaged Mozart to compofe a piece. He accordingly

Mozart. cordingly produced *L'enlevement du Serail;* performed for the firſt time in 1782. It excited the jealouſy of the Italian company, who therefore ventured to cabal againſt it. The emperor, addreſſing himſelf to the compoſer, ſaid, "It is *too fine* for our ears, my dear Mozart, and moſt *charmingly crowded* with notes." "Preciſely what it ought to be," replied the ſpirited muſician, who juſtly ſuſpected that this remark had been ſuggeſted to Joſeph by the envious Italians. "Though I cannot deſcribe, as an auricular evidence, (ſays the faithful author of the biography), the applauſes and the admiration which this opera produced at Vienna, yet I have witneſſed the enthuſiaſm it excited at Prague among all the connoiſſeurs, as well as among thoſe whoſe ears were leſs cultivated. It was ſaid, that all which had been heard before was not muſic: it drew the moſt overflowing audiences: every body was amazed at its new traits of harmony, and at paſſages ſo original, and till then ſo unheard from wind inſtruments."

The cautious reader will perhaps heſitate to admit, in its fulleſt extent, this account by the author of the biography; but even after an allowance for ſome exaggeration, the moſt phlegmatic will grant that much muſt have been atchieved by this great maſter, to afford a baſis for ſo glowing a picture of the merit and ſucceſs of *L'enlevement du Serail.* During the compoſition of this opera, he married Mademoiſelle Weber, a diſtinguiſhed virtuoſa; and the piece was ſuppoſed to owe to this felicitous circumſtance much of that endearing character, that tone of tenderneſs, and that expreſſion of the ſofter paſſions, which form its principal attractions.

"The Marriage of Figaro," which was in the higheſt repute at all the theatres, was in the year 1787 transformed into an Italian opera; and Mozart, at the inſtance of the emperor, ſet it to muſic. This piece was highly received everywhere, and kept poſſeſſion of the theatre at Prague during almoſt the whole of the winter in which it firſt appeared: numerous extracts were made from it, and the ſongs and dances of Figaro were vociferated in the ſtreets, the gardens, and the taverns. Mozart came that very winter to Prague, and performed in public on the piano forte. His auditors at all times liſtened to him with admiration; but whenever he played extempore, and indulged the ſpontaneous and uninterrupted ſallies of his fancy, which he ſometimes would for more than half an hour, every one was ſeized with the moſt enthuſiaſtic raptures, and acknowledged the unrivalled reſources of his imagination. About this time the manager of the theatre contracted with him for the compoſition of a new opera, which, when produced, was called *Il diſſoluto Punito,* or *Don Giovanni.* His reputation was now ſo exalted, that the Bohemians piqued themſelves on the circumſtance that this opera was compoſed for their entertainment.

But this fame, this great and univerſal applauſe, had not yet produced to the admired artiſt any ſolid advantages; he had obtained no place, no ſettled income; but ſubſiſted by his operas, and the inſtructions and occaſional concerts which he gave. The profits of theſe proved inſufficient for the ſtyle which he was obliged to ſupport; and his finances became much deranged. The critical ſituation in which he now found himſelf, made him reſolve to quit Vienna, and ſeek an aſylum in London; to which metropolis he had often been invited; but Joſeph nominating him *compoſiteur de la chambre,* though, with a very inadequate ſalary, he was induced to accept it; and Germany had the advantage of retaining him.

It is lamentable that premature genius too rarely enjoys a long career: The acceleration of nature in the mental powers ſeems to hurry the progreſs of the animal œconomy, and to anticipate the regular cloſe of temporal exiſtence.

In the year 1791, Mozart, juſt after he had received the appointment of *Maitre de chapelle* of the church of St Peter, and when he was only thirty five years of age, paid the laſt tribute; and left the world at once to admire the brilliancy, and lament the ſhortneſs of his earthly ſojournment.

Indefatigable, even to his death, he produced, during the laſt few months of his life, his three great maſter pieces *La Flutte Enchantée, La Clemence de Titus,* and a *Requiem,* his laſt production. *La Flutte Enchantée* was compoſed for one of the theatres at Vienna; and no dramatic *Olio* could ever boaſt a greater ſucceſs. Every air ſtruck the audience with a new and ſweet ſurpriſe; and the *tout enſemble* was calculated to afford the deepeſt and moſt varied impreſſions. This piece had, in fact, ſo great a number of ſucceſſive repreſentations, that for a long time it was unneceſſary to conſult the opera-bill; which only announced a permanent novelty. And the airs ſelected from it, and repeated throughout the empire, as well in the cottage as in the palace, and which the echoes have reſounded in the moſt diſtant provinces, favoured the idea that Mozart had actually the deſign to enchant all Germany with his *Flutte Enchantée.*

La Clemence de Titus was requeſted by the ſtates of Bohemia for the coronation of Leopold. The compoſer began it in his carriage during his route to Prague, and finiſhed it in eighteen days.

Some circumſtances attending the compoſition of the piece which we have already mentioned as the laſt effort of his genius, are too intereſting to be omitted. A ſhort time before his death, a ſtranger came to him with the requeſt that he would compoſe, as ſpeedily as poſſible, a *requiem* for a catholic prince, who, perceiving himſelf on the verge of the grave, wiſhed, by the execution of ſuch a piece, to ſooth his mind, and familiariſe it to the idea of his approaching diſſolution. Mozart undertook the work; and the ſtranger depoſited with him as a ſecurity 400 ducats, though the ſum demanded was only 200. The compoſer immediately began the work, and during its progreſs felt his mind unuſually raiſed and agitated. He became at length ſo infatuated with his *requiem,* that he employed not only the day, but ſome hours of the night in its compoſition. One day, while he was converſing with Madame Mozart on the ſubject, he declared to her that he could not but be perſuaded that it was for himſelf he was writing this piece. His wife, diſtreſſed at her inability to diſſipate ſo melancholy an impreſſion, prevailed on him to give her the *ſcore.* He afterwards appearing ſomewhat tranquillized, and more maſter of himſelf, ſhe returned the *ſcore* to him, and he ſoon relapſed into his former deſpondency. On the day of his death he aſked for the *requiem,* which was accordingly brought to his bed: "Was I not right (ſaid he), when I declared that it

was

Mozart. was for myfelf I was compofing this funeral piece?" And the tears trickled from his eyes. This production of a man, impreffed during its compofition with a prefentiment of his approaching death, is *unique* in its kind, and contains paffages which have frequently drawn tears from the performers.

Only one complaint efcaped him during his malady: "I muft quit life (faid he), precifely at the moment when I could enjoy it, free from care and inquietude; at the very time when, independent of fordid fpeculations, and at liberty to follow my own principles and inclinations, I fhould only have to write from the impulfes of my own heart: and I am torn from my family juft when in a fituation to ferve it." Mozart, at the time of his death, was confiderably involved in debt; but Vienna and Prague difputed the honour of providing for his widow and children.

The countenance of this great mafter did not indicate any thing uncommon. He was fmall of ftature; and, except his eyes, which were full of fire, there was nothing to announce fuperiority of talent. His air, unlefs when he was at the harpfichord, was that of an abfent man. But when he was performing, his whole phyfiognomy became changed: a profound ferioufnefs recalled and fixed his eyes; and his fentiments were expreffed in every movement of his mufcles. Never has a mufician more fuccefsfully embraced the whole extent of his art, and fhone with greater luftre in all its departments. His great operas, no lefs than his moft fimple fongs; his learned fymphonies as well as his airy dances—all carry the ftamp of the richeft imagination, the deepeft fenfibility, and the pureft tafte. All his works develope the originality of his genius; and imply a mind great and exalted; an imagination which ftrikes out for itfelf a new courfe. He therefore merits to be ranked with that fmall number of original geniufes, thofe *phænomena fplendida*, who form an epoch in their art, by carrying it to perfection, or giving it an unknown career.

It is in the employment of wind inftruments that Mozart difplays his greateft powers. His melody is always fimple, natural, and full of force; and expreffes with precifion the fentiments and individual fituations of his perfonages. He wrote with extraordinary facility. "*La Clemence de Titus*," the reader will recollect, coft him the ftudy of but eighteen days; and his *requiem*, which is equal in length to an opera, was produced in four weeks. It is alfo worthy of remark, that the overture to his *Don Giovanni* was not begun till the night before the piece was to be performed. At midnight, after having devoted the evening to amufement, he locked himfelf up in his ftudy, and compofed it in a few hours. His memory was wonderfully retentive, as we may judge from his copying by recollection the *miferere* at Rome. But a fact equally aftonifhing is, that, foon difcovering the eagernefs of people to procure his works, and fearful that they might be pirated, it was his conftant cuftom to tranfcribe from the *fcores* of his fonatas only a part for one hand, and at the public performance to fupply the other by memory.

He very early began to difplay that true dignity of an artift which renders him indifferent to the praifes of thofe who are unqualified to judge. The commendations of the ignorant great he never confidered as fame. His hearers, whether the wealthy or the titled, muft have acquired fome credit for their judgment before he could be ambitious of their applaufe. Indeed he entertained fo juft a fenfe of fcientific elevation and importance, that he would infift upon refpect. And the leaft noife or idle babble, while he was at the inftrument, excited a difpleafure which he was too indignant to conceal. Once, to the honour of his feelings, he fuddenly rofe from his feat, and left his inattentive auditory to experience the keen though filent reproach of infulted genius.

His mind was by no means unlettered; not was it embellifhed with one fcience alone. He was mafter of feveral languages, and had made confiderable progrefs in the mathematics. He was honeft, mild, generous, full of franknefs; and with his friends had an air at once amiable, gay, and free from the leaft tincture of pedantry.

Far from viewing with envy the fuccefs of others, a weaknefs too clofely interwoven in the general nature of man, he was always juft to the talents of his fellow profeffors; and valued and refpected merit wherever he found it; a clearer proof of which cannot be adduced than the following circumftance: At a concert, where a new piece compofed by the celebrated Jofeph Haydn was performed, a certain mufician, who never difcovered any thing worthy of praife except in his own productions, did not fail to criticife the mufic; exclaiming to Mozart, "There now! there again! why, that is not what *I* fhould have done:" "No; neither fhould I (replied Mozart); but do you know why? Becaufe neither you nor I fhould have been able to conceive it."

Mumbo. MUMBO-JUMBO, a ftrange bugbear employed by the Pagan Mandingoes (fee MANDING, *Suppl.*) for the purpofe of keeping their women in fubjection. Polygamy being allowed among thefe people, every man marries as many wives as he can conveniently maintain; and the confequence is, that family quarrels fometimes rife to fuch a height, that the hufband's authority is not fufficient to reftore peace among the ladies. On thefe occafions, the interpofition of *Mumbo-Jumbo* is called in; and it is always decifive. This ftrange minifter of juftice, who is either the hufband himfelf, or fome perfon inftructed by him, difguifed in a fort of mafquerade habit, made of the bark of trees, and armed with the rod of public authority, announces his coming by loud and difmal fcreams in the woods near the town. He begins the pantomime at the approach of night; and as foon as it is dark, he enters the town, and proceeds to the *Bentang* or market-place, at which all the inhabitants immediately affemble.

It may eafily be fuppofed that this exhibition is not much relifhed by the women; for as the perfon in difguife is entirely unknown to them, every married female fufpects that the vifit may poffibly be intended for herfelf; but they dare not refufe to appear when they are fummoned; and the ceremony commences with fongs and dances, which continue till midnight, about which time Mumbo fixes on the offender. This unfortunate victim being thereupon immediately feized, is ftripped naked, tied to a poft, and feverely fcourged with Mumbo's rod, amidft the fhouts and derifion of the whole affembly; and it is remakable, that the reft of the women are the loudeft in their exclamations on this occafion againft their unhappy fifter. Daylight puts an end to this indecent

indecent and unmanly revel. It is truly aftonifhing that the women fhould be deluded by fo clumfy an impofture, and that the men fhould fo faithfully keep their own fecret. That the women are deluded feems evident; for Mr Park affures us, that the drefs of Mumbo is fuffered to hang on a tree at the entrance of each town; which could hardly be the cafe, if the women were not perfuaded that it is the drefs of fome fupernatural being.

MUNSHY, a Perfian fecretary or writer.

MUNSUB, in the language of Bengal, a dignity or command conferred by the emperor.

MUNSUBDAR, a dignitary or commander.

MURRAY (William), afterwards Earl of Mansfield and Lord Chief Juftice of England, was the fourth fon of David Vifcount Stormont. He was born on the 2d day of March 1705 at Perth, in the kingdom of Scotland, of which kingdom his father was a peer. His refidence in Scotland, however, was of fhort duration; for he was carried up to London at the early age of three years. Hence his total exemption from the peculiarities of the dialect of his native country.

At the age of fourteen he was admitted as a king's fcholar of Weftminfter fchool; and during his refidence in that feminary, fays his contemporary Bifhop Newton, he gave early proofs of his uncommon abilities, not fo much in his poetry, as in his other exercifes; and particularly in his declamations, which were fure tokens and prognoftics of that eloquence which grew up to fuch a maturity and perfection at the bar, and in both houfes of parliament. At the election in May 1723, he ftood firft on the lift of thofe gentlemen who were fent to Oxford, and was entered of Chrift Church, June the 18th, in that year. In the year 1727 he had taken the degree of B. A. and on the death of King George the Firft, was amongft thofe of the univerfity who compofed verfes on that event.

In April 1724 he was admitted a ftudent of Lincoln's Inn, though he ftill continued to refide much in the univerfity; where, on the 26th of June 1730, he took the degree of M. A. and foon afterwards left Oxford, determined to make the tour of Europe before he fhould devote himfelf ferioufly to bufinefs. About this period he wrote two letters to a young nobleman on the ftudy of ancient and modern hiftory, which are publifhed by his biographer Mr Holliday, and fhew how amply his own mind was then ftored with general literature.

On his return to England he commenced his legal ftudies; but proceeded not in the way then ufually adopted, of labouring in the chambers of a fpecial pleader, or copying (to ufe the words of Blackftone) the trafh of an attorney's office. Being bleffed with the powers of oratory in their higheft perfection, and having foon an opportunity of difplaying them, he very early acquired the notice of the chancellor and the judges, as well as the confidence of the inferior practifers. How much he was regarded in the houfe of lords, Pope's well-known couplet will prove:

Grac'd as thou art with all the power of words,
So known, fo honour'd at the houfe of lords.

The graces of his elocution, however, produced their ufual effect with a certain clafs of people, who would not believe that fuch bright talents could affociate with the more folid attainments of the law, or that a man of genius and vivacity could be a profound lawyer. As Pope obferved at that time,

The Temple late two brother ferjeants faw,
Who deem'd each other oracles of law;
With equal talents thefe congenial fouls,
One lull'd the exchequer, and one ftunn'd the rolls;
Each had a gravity would make you fplit,
And fhook his head at Murray as a wit.

It is remarkable that this ridiculous prejudice accompanied Lord Mansfield to the end of his judicial life, in fpite of daily proofs exhibited in the court of King's Bench and in the Houfe of Lords, of very profound knowledge of the abftrufeft points of jurifprudence. Lord Chefterfield has given his fanction to this unfounded opinion. In a letter to his fon, dated Feb. 12. 1754, he fays, "The prefent Solicitor General Murray has lefs law than many lawyers, but he has more practice than any, merely upon account of his eloquence, of which he has a never-failing ftream."

In the outfet of Lord Mansfield's life, it will be the lefs furprifing, that a notion fhould have been entertained of his addicting himfelf to the purfuits of Belles Lettres too much, when the regard fhewn to him by Mr Pope, who defpotically ruled the regions of literature at that period, is confidered. That great Poet feemed to entertain a particular affection for our young lawyer, and was eager to fhew him marks of his regard. He addreffed to him his imitation of the 6th Epiftle of the Firft Book of Horace; and even condefcended to become his mafter in the art of elocution. "Mr Murray (fays his biographer) was one day furprifed by a gentleman of Lincoln's Inn, who could take the liberty of entering his rooms without the ceremonious introduction of a fervant, in the fingular act of practifing the graces of a fpeaker at a glafs, while Pope fat by in the character of a friendly preceptor. Mr Murray, on this occafion, paid that poet the handfome compliment of *Tu es mihi Mæcenas* (A)."

Whatever propenfities this fprightly lawyer might have towards polite literature, he did not permit them to divert his attention from his profeffion. He foon diftinguifhed himfelf in an extraordinary manner, as may be feen by thofe who are converfant with, or chufe to refer to the Books of Reports. In the year 1736, the murder of Captain Porteous by a mob in Edinburgh, after he had been reprieved, occafioned a cenfure to fall on that city, and a bill of pains and penalties was brought into parliament againft the Lord Provoft and the corporation; which, after various modifications, and a firm and unabated oppofition in every ftage of its progrefs, paffed into a law. In both Houfes Mr Murray was employed as an advocate, and fo much to the fatisfaction of his clients, that afterwards, in September 1743, he was prefented with the freedom of Edinburgh in a gold box, profeffedly, as it was declared,

(A) It is thus that eminence is attained even by genius, and Mr Murray was properly employed; though we do not clearly perceive the ufe of the glafs, when his mafter was watching all his geftures.

Murray. red, for his signal services by speeches to both Houses of Parliament in the conduct of that business.

On the 24th of November 1738, he had married Lady Elizabeth Finch, daughter of the Earl of Winchelsea, and in the month of November 1742, was appointed Solicitor General in the place of Sir John Strange who resigned (B). He likewise was chosen to represent the town of Boroughbridge in Parliament, for which place he was also returned in 1747 and 1754.

In the month of March 1746-7 he was appointed one of the managers for the impeachment of Lord Lovat by the House of Commons, and it fell to his lot to observe on the evidence previous to the Lords giving their judgment. This task he executed with so much candour, moderation, and gentleman-like propriety, that Lord Talbot, at the conclusion of his speech, paid him the following compliment: "The abilities of the learned manager who just now spoke, never appeared with greater splendour than at this very hour, when his candour and humanity has been joined to those great abilities which have already made him so conspicuous, that I hope one day to see him add lustre to the dignity of the first civil employment in this nation." Lord Lovat himself also bore testimony to the abilities of his adversary: "I thought myself (says his lordship) very much loaded by one Murray (c), who your lordships know was the bitterest evidence there was against me. I have since suffered by another Mr Murray, who, I must say with pleasure, is an honour to his country, and whose eloquence and learning is much beyond what is to be exprest by an ignorant man like me. I heard him with pleasure, though it was against me. I have the honour to be his relation, though perhaps he neither knows it nor values it. I wish that his being born in the North may not hinder him from the preferment that his merit and learning deserve."

During the time that Mr Murray continued in office, he supported, with great ability, the administration with which he was connected; and, of course, rendered himself obnoxious to those who were in opposition. Nothing, however, could be urged either against his public conduct or his private life; but he was involved in some trouble by an ill-devised tale, concurring with the known principles of the family of Stormont, to make him suspected of Jacobitism. Of this affair, a full and particular account is given by the late Lord Melcombe in the following words:

"Messrs Murray, Fawcett, and Stone, were much acquainted, if not school-fellows, in earlier life. Their fortune led them different ways; Fawcett's was to be a country lawyer and recorder of Newcastle. Johnson, now Bishop of Gloucester, was one of their associates. On the day the King's birth day was kept, they dined at the Dean of Durham's at Durham; this Fawcett, Lord Ravensworth, Major Davidson, and one or two more, who retired after dinner into another room. The conversation turning upon the late Bishop of Gloucester's preferments, it was asked who was to have his prebend of Durham? The Dean said, that the last news from London was, that Dr Johnson was to have it: Fawcett said, he was glad that Johnson got off so well, for he remembered him a Jacobite several years ago, and that he used to be with a relation of his who was very disaffected, one Vernon, a mercer, where the Pretender's health was frequently drunk. This passing among a few familiar acquaintance, was thought no more of at the time: it spread, however, so much in the North (how I never heard accounted for), and reached town in such manner, that Mr Pelham thought it necessary to desire Mr Vane, who was a friend to Fawcett, and who employed him in his business, to write to Fawcett, to know if he had said this of Johnson, and if he had, if it was true.

"This letter was written on the 9th of January; it came to Newcastle the Friday following. Fawcett was much surprised; but the post going out in a few hours after its arrival, he immediately acknowledged the letter by a long, but not very explicit, answer. This Friday happened to be the club-day of the neighbouring gentlemen at Newcastle. As soon as Lord Ravensworth, who was a patron and employer of Fawcett, came into the town, Fawcett acquainted him with the extraordinary letter he had received; he told him that he had already answered it; and being asked to shew the copy, said he kept none; but desired Lord Ravensworth to recollect if he held such a conversation at the Deanry of Durham the day appointed for the birth-day. Ravensworth recollected nothing at all of it: they went to the club together, and Ravensworth went the next moreing to see his mother in the neighbourhood, with whom he staid till Monday; but this thing of such consequence lying upon his thoughts, he returned by Newcastle. He and Fawcett had another conversation; and in endeavouring to refresh each other's memory about this dreadful delinquency of Johnson, Fawcett said he could not recollect positively at such a distance of time, whether Johnson drank these healths, or had been present at the drinking of them, but that Murray and Stone had done both several times. Ravensworth was excessively alarmed at this with relation to Stone, on account of his office about the prince; and thus the affair of Johnson was quite forgotten, and the episode became the principal part. There were many more conferences between Ravensworth and Faw- Murray.

(B) On this occasion a doggrel poem was published by one Morgan, a person then at the bar, entitled, "The Causidicade," in which all the principal lawyers were supposed to urge their respective claims to the post. At the conclusion it is said,

> Then Murray, prepar'd with a fine panegyric
> In praise of himself, would have spoke it like Garrick;
> But the President stopping him said, "As in truth
> "Your worth and your praise is in every one's mouth,
> "'Tis needless to urge what's notoriously known,
> "The office, by merit, is your's all must own;
> "The voice of the public approves of the thing,
> "Concurring with that of the Court and the King."

(c) One of the evidences against him.

Murray.

cett upon this subject, in which the latter always persisted that Stone and Murray were present at the drinking, and did drink those healths. It may be observed here, that when he was examined upon oath, he swore to the year 1731 or 1732, at latest. Fawcett comes up as usual about his law business, and is examined by Messrs Pelham and Vane, who never had heard of Murray or Stone being named: he is asked, and answers only with relation to Johnson, never mentioning either of the others; but the love of his country, his king, and posterity, burned so strongly in Ravensworth's bosom, that he could have no rest till he had discovered this enormity. Accordingly, when he came to town, he acquainted the ministry and almost all his great friends with it, and insisted upon the removal of Stone. The ministry would have slighted it as it deserved; but as he persisted, and had told so many of it, they could not help laying it before the king, who, though he himself slighted it, was advised to examine it; which examination produced the most injudicious proceeding in parliament *."

* Lord Melcombe's Diary, p. 220.

This is Lord Melcombe's account; and the same author informs us, that Mr Murray, when he heard of the committee being appointed to examine this idle affair, sent a message to the king, humbly to acquaint him, that if he should be called before such a tribunal on so scandalous and injurious an account, he would resign his office, and would refuse to answer. It came, however, before the House of Lords, 22d January 1753, on the motion of the Duke of Bedford.

The debate was long and heavy, says Lord Melcombe; the Duke of Bedford's performance moderate enough; he divided the House, but it was not told, for there went below the bar with him the Earl Harcourt, Lord Townshend, the Bishop of Worcester, and Lord Talbot only. The Bishop of Norwich and Lord Harcourt both spoke, not to much purpose; but neither of them in the least supported the Duke's question.

Upon the whole, Lord Melcombe concludes, "It was the worst judged, the worst executed, and the worst supported point that I ever saw of so much expectation."

The King, his late Majesty, viewed it in its true light; and is reported to have said, "Whatever they were when Westminster boys, they are now my very good friends." He was likewise, as we have been informed by a gentleman connected with the family of Stormont, so delighted with Mr Murray's speech in his own vindication, that he desired to have a copy of it, as a model of dignified and candid eloquence. Fawcett, the original author of the story, seems indeed to have been a very sneaking knave, totally unworthy of credit. Bishop Johnson, who was overlooked in the turmoil, excited by the supposed guilt of Murray and Stone (see Stone, in this *Suppl.*) went to Fawcett's chambers in the Temple, and desired an interview. Being told by the servant that his master was not at home, he renewed his visit very early next morning, and declared his resolution to wait till Mr Fawcett should rise, the laundress having inadvertently confessed that he was still in bed. Fawcett, upon this, left his thorny pillow with reluctance; for something sharper than thorns (says Mr Holliday) awaited him, which he could not now possibly avoid. The result of the interview produced expressions of deep contrition, together with a letter addressed to the Lord Bishop of Gloucester, acknowledging, in the most explicit terms, that his Lordship was innocent of the charge which he had been the instrument of bringing against him.

Murray.

On the advancement of Sir Dudley Ryder to the chief justiceship of the King's Bench in 1754, Mr Murray succeeded him as attorney general; and on his death, November 1756, again became his successor as chief justice, when he was created Baron of Mansfield, in the county of Nottingham, with remainder to the heirs male of his body lawfully begotten.

As soon as Lord Mansfield was established in the King's Bench, he began to make improvements in the practice of that court. On the 12th of November, four days after he had taken his seat, he made a very necessary regulation, observing, "Where we have no doubt, we ought not to put the parties to the delay and expence of a farther argument; nor leave other persons, who may be interested in the determination of a point so general, unnecessarily under the anxiety of suspence."

The anxiety of suspence, from this period, was no longer to be complained of in the court of King's Bench. The regularity, punctuality, and dispatch of the new chief justice, afforded such general satisfaction, that they, in process of time, drew into that court most of the causes which could be brought there for determination.

Sir James Burrows says, "I am informed, that at the sittings for London and Middlesex only, there are not so few as 800 causes set down in a year, and all disposed of. And though many of them, especially in London, are of considerable value, there are not more, upon an average, than between 20 and 30 ever heard of afterwards in the shape of special verdicts, special cases, motions for new trials, or in arrest of judgment. Of a bill of exceptions there has been no instance (I do not include judgments upon criminal prosecutions; they are necessary consequences of the convictions). My reports give but a very faint idea of the extent of the whole business which comes before the court: I only report what I think may be of use as a determination or illustration of some matter of law. I take no notice of the numerous questions of fact which are heard upon affidavits (the most tedious and irksome part of the whole business). I take no notice of a variety of contestations, which, after having been fully discussed, are decided without difficulty or doubt. I take no notice of many cases which turn upon a construction so peculiar and particular, as not to be likely to form a precedent for any other case. And yet, notwithstanding this immensity of business, it is notorious, that, in consequence of method, and a few rules which have been laid down to prevent delay (even where the parties themselves would willingly consent to it), nothing now hangs in court. Upon the last day of the very last term, if we exclude such motions of the term as by desire of the parties went over of course as peremptories, there was not a single matter of any kind that remained undetermined, excepting one case relating to the proprietary Lordship of Maryland, which was professedly postponed on account of the present situation of America. One might speak to the same effect concerning the last day of any former term for some years backward."

The same author also informs us that, excepting two cases, cafes, there had not been, from the 6th of November 1756 to the time of his then prefent publication, 26th May 1776, a final difference of opinion in the court in any cafe, or upon any point whatfoever. "It is remarkable, too (he adds), that, excepting thefe two cafes, no judgment given during the fame period has been reverfed, either in the exchequer chamber or in parliament; and even thefe reverfals were with great diverfity of opinion among the judges." Of the two cafes here mentioned, one was the famous queftion concerning literary property, which the majority of the judges of the court of King's Bench held to be permanent; and in fupport of which opinion, fuch arguments were urged by the chief juftice, as have not yet perhaps been completely anfwered.

The ill fuccefs of the war, which had lately been begun, occafioned a change in the adminiftration; and the conflicts of contending parties rendered it impracticable for the crown, at that juncture, to fettle a new miniftry. In order therefore to give paufe to the violence of both fides, Lord Mansfield was induced to accept the poft of chancellor of the exchequer on the 9th of April 1757; which he held until the 2d of July in the fame year. During this interval, he employed himfelf, with great fuccefs, to bring about a coalition; which being effected, produced a feries of events, which raifed the glory of Great Britain to the higheft point at which it has ever been feen. In the fame year he was offered, but refufed, the office of Lord High Chancellor; and in November 1758, he was elected a governor of the charter houfe, in the room of the Duke of Marlborough, then lately deceafed.

For feveral years after this period, the tenor of Lord Mansfield's life was marked only with a moft fedulous difcharge of the duties of his office. In 1760 Geo. II. died, and the new reign commenced with alterations in the adminiftration; which gave rife to a virulent fpirit of oppofition, conducted with a degree of violence and afperity never known at any former time. As a friend to the then adminiftration, Lord Mansfield was marked out for a more than ordinary fhare of malicious invective. It is in allufion to this, that Warburton, after tracing the rife and progrefs of the irreligion and licentioufnefs which then prevailed, and obferving that, amid fuch general corruption, the pure adminiftration of public juftice ftill afforded a cheerful confolation to thinking men, proceeds thus:

"But the evil genius of England would not fuffer us to enjoy it long; for, as if envious of this laft fupport of government, he hath now inftigated his blackeft agents to every extent of their malignity; who, after the moft villanous infults on all other orders and ranks in fociety, have at length proceeded to calumniate even the king's fupreme court of juftice, under its ableft and moft unblemifhed adminiftration. After this, who will not be tempted to defpair of his country, and fay with the good old man in the fcene,

——" *Ipfa fi cupiat falus*
" *Servare, prorfus non poteft, hanc Familiam* (D)?"

A change of adminiftration again took place in 1765, which introduced the Marquis of Rockingham and his friends to govern the country; and the meafures then adopted not agreeing with Lord Mansfield's fentiments, he, for the firft time, became an opponent of government. On the bill for repealing the ftamp act, he fpoke, and divided againft it; and is fuppofed to have had fome fhare in the compofition of the protefts on that occafion, though he did not fign them. In the fame year, he is faid to have animadverted, with no fmall degree of feverity, on the incautious expreffions of Lord Camden, on the affair of prohibiting the exportation of corn, that it was but a 40 days tyranny at the outfide. (E).

In 1767 the Diffenters caufe was determined, in which Lord Mansfield delivered a fpeech, which has fince been printed, and fhews his Lordfhip to have been a fteady friend to religious toleration, as well as to the rights of the eftablifhed church. The confcientious Diffenters themfelves lavifhed upon that fpeech the higheft praife; whilft others of them, in the fucceeding year, deluged the public prints with torrents of abufe on the Chief Juftice. In that year was the general election. Mr Wilkes returned from abroad, became a candidate for the city of London, and afterwards was chofen reprefentative for the county of Middlefex. Having been outlawed fome years before, he now applied for a reverfal of that proceeding. On the 8th of June, the confideration of it came before the court of King's Bench; when the judges delivered their opinions very fully, and were unanimous that the outlawry was illegal, and muft be reverfed. On this occafion Lord Mansfield took the opportunity of entering into a full ftatement of the cafe, and a juftification of his own conduct. The reader will find the cafe reported by Sir James Burrow; from whom we fhall extract the following, which appears to have been the moft important part of his Lordfhip's fpeech.

" It is fit to take fome notice of the various terrors hung out; the numerous crowds which have attended, and now attend, in and about the hall, out of all reach of hearing what paffes in court; and the tumults which in other places have fhamefully infulted all order and government. Audacious addreffes in print dictate to us, from thofe they call the people, the judgment to be given now, and afterwards upon the conviction. Reafons of policy are urged, from danger to the kingdom, by commotions and general confufion.

" Give me leave to take the opportunity of this great and refpectable audience, to let the whole world know all fuch attempts are vain. Unlefs we have been able to find an error which will bear us out to reverfe the outlawry, it muft be affirmed. The conftitution does not allow reafons of ftate to influence our judgment: God

(D) See the dedication of the 5th edition of the Divine Legation of Mofes, which deferves to be read at prefent with peculiar attention, as the work of a man of gigantic talents, deeply read in law as well as in theology.

(E) The fpeeches in the debate were never printed; but the fubftance of them all was confolidated in a pamphlet publifhed at the time, intitled, " A Speech againft the fufpending and difpenfing prerogative," 8vo. Since reprinted in Debrett's Debates, Vol. IV. p. 384.

God forbid it should! We must not regard political consequences, how formidable soever they may be; we are bound to say, *Fiat Justitia, ruat Cœlum.* The constitution trusts the king with reasons of state and policy: He may pardon offences; it is his to judge whether the law or the criminal should yield. We have no election. None of us encouraged or approved the commission of either of the crimes of which the defender is convicted: none of us had any hand in his being prosecuted. As to myself, I took no part (in another place) in the addresses for that prosecution. We did not advise or assist the defender to fly from justice; it was his own act, and he must take the consequences. None of us have been consulted, or had any thing to do with the present prosecution. It is not in our power to stop it; it was not in our power to bring it on. We cannot pardon. We are to say what we take the law to be. If we do not speak our real opinions, we prevaricate with God and our own consciences.

"I pass over many anonymous letters I have received: those in print are public; and some of them have been brought judicially before the court. Whoever the writers are, they take the wrong way. I will do my duty unawed. What am I to fear? That *mendax infamia* from the press, which daily coins false facts and false motives? The lies of calumny carry no terror to me. I trust that my temper of mind, and the colour and conduct of my life, have given me a suit of armour against these errors If, during this king's reign, I have ever supported his government, and assisted his measures, I have done it without any other reward than the consciousness of doing what I thought right. If I have ever opposed, I have done it upon the points themselves, without any collateral views.' I honour the king, and respect the people. But many things acquired by the favour of either are, in my account, objects not worth ambition. I wish popularity; but it is that popularity which follows, not that which is run after.— It is that popularity which, sooner or later, never fails to do justice to the pursuit of noble ends by noble means. I will not do that which my conscience tells me is wrong upon this occasion, to gain the huzzas of thousands, or the daily praise of all the papers which come from the press. I will not avoid doing what I think is right, though it should draw on me the whole artillery of libels, all that falsehood and malice can invent, or the credulity of a deluded populace can swallow. I can say with a great magistrate, upon an occasion, and under circumstances not unlike, '*Ego hoc animo semper fui, ut invidiam virtute partam, gloriam, non invidiam putarem.*'

"The threats go furthur than abuse: Personal violence is denounced. I do not believe it: it is not the genius of the worst men of this country in the worst of times. But I have set my mind at rest. The last end that can happen to any man never comes too soon, if he falls in support of the law and liberty of his country (for liberty is synonymous to law and government). Such a shock, too, must be productive of public good: It might awake the better part of the kingdom out of that lethargy which seems to have benumbed them; and bring the mad part back to their senses, as men intoxicated are sometimes stunned into sobriety.

"Once for all, let it be understood, that no endeavours of this kind will influence any man who at present sits here. If they had any effect, it would be contrary to their intent: Leaning against their impression might give a bias the other way. But I hope, and I know, that I have fortitude enough to resist even that weakness. No libels, no threats, nothing that has happened, nothing that can happen, will weigh a feather against allowing the defendant, upon this and every other question, not only the whole advantage he is intitled to from substantial law and justice, but every benefit from the most critical nicety of form, which any other defender could claim under the like objection. The only effect I feel is an anxiety to be able to explain the grounds upon which we proceed; so as to satisfy all mankind, that a flaw of form given way to in this case, could not have been got over in any other."

In January 1770, Lord Mansfield again was offered the Great Seal, which was given to Mr Charles York: and in Hilary Term 1771, he a third time declined the same offer, and the Seal was entrusted to Lord Bathurst.

The year 1770 was also memorable for various attacks made on his Lordship's judicial character, in both the Houses of Lords and Commons. In one of these, the propriety of a direction given to the jury in the case of the king and Woodfal was called in question; which occasioned his Lordship to produce to the House a copy of the unanimous opinion of the court of King's Bench in that cause; which, after being much canvassed and opposed, was suffered to stand its ground without being over-ruled.

On the 19th of October 1776, his Lordship was advanced to the dignity of an Earl of Great Britain, by the title of the Earl of Mansfield, and to his male issue; and for want of such issue, to Louisa Viscountess Stormont, and to her heirs-male by David Viscount Stormont her husband. The same title, in 1792, was limited to Lord Stormont himself; who afterwards succeeded to it.

We come now to a period of his Lordship's life, which furnishes an event disgraceful to the age and country in which the fact was committed. An union of folly, enthusiasm, and knavery, had excited alarms in the minds of some weak people, that encouragements were given to the favourers and professors of the Roman Catholic faith inconsistent with religion and true policy. The act of Parliament, which excited the clamour, had passed with little opposition, and had not received any extraordinary support from Lord Mansfield. The minds of the public were inflamed by artful misrepresentations; the rage of a popular mob was soon directed towards the most eminent persons. Accordingly, in the night between Tuesday the 6th and Wednesday the 7th of June 1780, his Lordship's house in Bloomsbury Square was attacked by a party of rioters, who, on the Friday and Tuesday preceding, had, to the amount of many thousands, surrounded the avenues of both Houses of Parliament, under pretence of attending Lord George Gordon when he presented the petition from the Protestant Association. On Tuesday evening the prison of Newgate had been thrown open, all the combustible part reduced to ashes, and the felons let loose upon the public. It was after this attempt to destroy the means of securing the victims of criminal justice that the rioters assaulted the residence of the chief magistrate of the first criminal court in the kingdom; nor were they dispersed till they had burnt all the furniture, pictures, books, manuscripts, deeds, and, in short, every thing which fire could consume in his Lordship's

Murray. ſhip's houſe; ſo that nothing remained but the walls, which were ſeen next morning almoſt red-hot from the violence of the flames, preſenting a melancholy and awful ruin to the eyes of the paſſengers. For a fuller account of thoſe dreadful riots, ſee BRITAIN, n° 644. *Encyclopædia.*

So unexpected was this daring outrage on order and government, that it burſt on Lord Mansfield without his being prepared in the ſlighteſt manner to reſiſt it. He eſcaped with his life only, and retired to a place of ſafety, where he remained until the 14th of June, the laſt day of term, when he again took his ſeat in the court of King's Bench. "The reverential ſilence (ſays Mr Douglas) which was obſerved when his Lordſhip reſumed his place on the Bench, was expreſſive of ſentiments of condolence and reſpect, more affecting than the moſt eloquent addreſs the occaſion could have ſuggeſted.

"The amount of that part of Lord Mansfield's loſs which might have been eſtimated, and was capable of a compenſation in money, is known to have been very great. This he had a right to recover againſt the *hundred.* Many others had taken that courſe; but his Lordſhip thought it more conſiſtent with the dignity of his character not to reſort to the indemnification provided by the legiſlature. His ſentiments, on the ſubject of a reparation from the ſtate, were communicated to the Board of Works in a letter, dated 18th July 1780, written in conſequence of an application which they had made to him (as one of the principal ſufferers), purſuant to directions from the treaſury, founded on a vote of the Houſe of Commons, requeſting him to ſtate the nature and amount of his loſs. In that letter, after ſome introductory expreſſions of civility to the ſurveyor general, to whom it was addreſſed, his Lordſhip ſays, 'Beſides what is irreparable, my pecuniary loſs is great. I apprehended no danger, and therefore took no precaution. But how great ſoever that loſs may be, I think it does not become me to claim or expect reparation from the ſtate. I have made up my mind to my misfortune, as I ought, with this conſolation, that it came from thoſe whoſe object manifeſtly was general confuſion and deſtruction at home, in addition to a dangerous and complicated war abroad. If I ſhould lay before you any account or computation of the pecuniary damage I have ſuſtained, it might ſeem a claim or expectation of being indemnified. Therefore you will have no further trouble upon this from, &c.—*Mansfield.*'"

From this time the luſtre of Lord Mansfield continued to ſhine with unclouded brightneſs until the end of his political life, unleſs his oppoſition to the meaſures of the preſent adminiſtration, at the early period of their appointment, ſhall be thought to detract, in ſome ſmall degree, from his merit. It is certain many of his admirers ſaw, with concern, a connection with the opponents of government at that juncture, ſcarce compatible with the dignity of the chief juſtice of Great Britain. At length infirmities preſſed upon him, and he became unable to attend his duty with the ſame punctuality and aſſiduity with which he had been accuſtomed. It has been ſuppoſed that he held his office after he was diſabled from executing the duties of it, from a wiſh to ſecure the ſucceſſion of it to a very particular friend. Be this as it may, the chief juſtice continued in his office until the month of June 1788, when he ſent in his reſignation.

1800.

From this period the bodily powers of his Lordſhip continued to decline; his mental faculties, however, remained without decay almoſt to the laſt. During this time he was particularly inquiſitive and anxious about the proceedings in France, and felt his ſenſibility, in common with every good man, wounded by the horrible inſtance of democratic infatuation in the murder of the innocent Louis XVI. He lived juſt long enough to expreſs his ſatisfaction at the check given to the French by the Prince of Cobourg in March 1793; on the 20th of which month, after continuing ſome days in a ſtate of inſenſibility, he departed this life, at the age of 88 years.

"In his political oratory (ſays a writer of the preſent times), he was not without a rival; no one had the honour of *ſurpaſſing* him; and let it be remembered, that his competitor was PITT.

"The rhetorician that addreſſed himſelf to Tully in theſe memorable words—*Demoſthenes tibi præripuit ne primus eſſes Orator, tu illi ne ſolus*—anticipated their application to Mansfield and Pitt. If the one poſſeſſed Demoſthenean fire and energy, the other was at leaſt a Cicero. Their oratory differed in ſpecies, but was equal in merit. There was, at leaſt, no ſuperiority on the ſide of Pitt. Mansfield's eloquence was not, indeed, of that daring, bold, declamatory kind, ſo irreſiſtibly powerful in the momentary huſtle of popular aſſemblies; but it was poſſeſſed of that pure and Attic ſpirit, and ſeductive power of perſuaſion, that delights, inſtructs, and eventually triumphs. It has been very beautifully and juſtly compared to a river, that meanders through verdant meads and flowery gardens, reflecting in its cryſtal boſom the varied objects that adorn its banks, and refreſhing the country through which it flows.

"To illuſtrate his oratory by example, would require voluminous tranſcripts from the records of Parliament; and it is unneceſſary, as we can appeal to living recollection.

"Having added weight and dignity to the offices of attorney and ſolicitor general, his reputation as a ſpeaker, a lawyer, and a politician, elevated him to the peerage, and the exalted poſt of chief juſtice of England. He aſcended to the dignities of ſtate by rapid ſtrides: they were not beſtowed by the caprice of party favour or affection. They were (as was ſaid of Pliny) liberal diſpenſations of power upon an object that knew how to add new luſtre to that power, by the rational exertion of his own.

"Here we can ſpeak of this great man within our own recollection; and however party prejudices may adopt their different favourites, and each contend in detracting from the merit of the other, it is, we believe, generally underſtood that precedence is allowed the Earl of Mansfield, as the firſt magiſtrate that ever ſo pre-eminently graced that important ſtation. The wiſdom of his deciſions, and unbiaſſed tenor of his public conduct, will be held in veneration by the ſages of the law, as long as the ſpirit of the conſtitution, and juſt notions of equity, continue to have exiſtence. No man has ever, in an equal degree, poſſeſſed that wonderful ſagacity in diſcovering chicanery and artifice, and ſeparating fallacy from truth, and ſophiſtry from argument, ſo as to hit the exact equity of the caſe. He ſuffered not juſtice to be ſtrangled in the nets of form.

"His memory was aſtoniſhing—he never took notes, or, Murray. or, if he did, feldom or ever confulted them." His references to expreffions which fell from him in the courfe of the debate, or his quotations from books, were fo faithful that they might have been faid to have been repeated *verbatim*. The purpofes to which he employed thefe amazing talents were ftill more extraordinary: if it was the weak part of his opponent's arguments that he referred to, he was fure to expofe its fallacy, weaknefs, or abfurdity, in the moft poignant fatire, or hold it up in the moft ridiculous point of view. If, on the contrary, it were a point on which his adverfaries laid their chief ftrefs, he ftated the words correctly; collected their obvious meaning, confidered the force of the feveral arguments that had or might have been raifed upon them, with a precifion that would induce an auditor almoft to fuppofe that he had previoufly confidered the whole, and that his fpeech was the refult of much previous ftudy.

"It may be faid of Mansfield as of Virgil, that if he had any faults, they might be confidered in the fame manner with thofe of fome eminent fixed ftar, which, if they exift at all, are above the reach of human obfervation. The luminous æther of his life was not obfcured by any fhade dark enough to be denominated a defect. On account of his defcent, local prejudices and propenfities were imputed to him, and his conduct, on that account, examined with a microfcopic eye; but the optic through which it is viewed poffeffed a party tinge, equally odious and deceptive.

"His political principles were ever confiftent; and to preferve confiftency in fuch ftations and in fuch times as occupied the life of Mansfield, conftitutes an ordeal ftrongly impreffive of virtue. It has been faid that he wanted fpirit. Is the uniform oppofition of popular opinion, and apparently the contempt of it, any proof of the affertion? His fpeech and conduct in the affair of Wilkes's outlawry, when popular prejudice ran in torrents, illuftrate each other. He defpifed (to borrow an expreffion of his own) that mufhroom popularity that is raifed without merit, and loft without a crime. He difdained being the flave of popular impulfe, or to acknowledge the fhouts of a mob for the trumpet of fame."

He had a mind too great to be afhamed of revering the ordinances of religion; and as, after the moft impartial inquiry, he was a firm believer of the truth and importance of Chriftianity, he frequented the church regularly, and received the holy facrament on the higher feftivals. Mr Holliday has publifhed a fermon, which he fays was dictated by Lord Mansfield to his friend bifhop Johnfon, and preached by that prelate before the Houfe of Lords. It is a very ferious and appropriate difcourfe; but judging upon internal evidence, we fhould not have fuppofed it the compofition of the eloquent and argumentative chief juftice of England. His Lordfhip's will, which was written with his own band, upon little more than half a fheet of paper, begins with the following elegant and pious paragraph, with which we fhall conclude this fketch of his character:

"When it fhall pleafe Almighty God to call me to that ftate, to which, of all I now enjoy, I can carry only the fatisfaction of my own confcience, and a full reliance upon his mercy through Jefus Chrift, I defire that my body may be interred as privately as may be; and out of refpect for the place of my early education, I fhould wifh it to be in Weftminfter Abbey." It was interred in Weftminfter Abbey, in the fame vault with the Countefs (who had died April 10, 1784, between the late Earl of Chatham and Lord Robert Manners.

Mufeum. MUSEUM, in the language of the prefent day, is a building in which are depofited fpecimens of every object that is in any degree curious, whether fuch objects be natural or artificial. What the word *mufeum* expreffed originally, has been told under that title in the *Encyclopædia*.

A complete mufeum contains collections of preferved beafts, birds, fifhes, reptiles, &c.; models of machines; rare manufcripts; and indeed fpecimens of every thing neceffary to illuftrate phyfical fcience, to improve art, to aid the antiquarian in his refearches, and to exhibit the manners and cuftoms of men in diftant ages and nations. As natural objects of uncommon fize or beauty, and other rare productions, were, in the earlieft periods, confecrated to the gods, the temples were, of courfe, the firft repofitories of fuch collections, or, in other words, the firft *Mufeums*. This, we think, has been completely proved by Profeffor Beckmann *. *Inventions vol. ii. p. 44.

"When Hanno (fays he) returned from his diftant voyages, he brought with him to Carthage two fkins of the hairy women whom he found on the Gorgades iflands, and depofited them as a memorial in the temple of Juno, where they continued till the deftruction of the city. The horns of a Scythian animal, in which the Stygian water that deftroyed every other veffel could be contained, were fent by Alexander as a curiofity to the temple of Delphi, where they were fufpended with an infcription, which has been preferved by Ælian. The monftrous horns of the wild bulls which had occafioned fo much devaftation in Macedonia, were, by order of King Philip, hung up in the temple of Hercules. The unnaturally formed fhoulder bones of Pelops were depofited in the temple of Elis. The horns of the fo called Indian ants were fhewn in the temple of Hercules at Erythræ; and the crocodile found in attempting to difcover the fources of the Nile was preferved in the temple of Ifis at Cæfarea. A large piece of the root of the cinnamon tree was kept in a golden veffel in one of the temples at Rome, where it was examined by Pliny. The fkin of that monfter which the Roman army in Africa attacked and deftroyed, and which probably was a crocodile, an animal common in that country, but never feen by the Romans before the Punic war, was, by Regulus, fent to Rome, and hung up in one of the temples, where it remained till the time of the Numantine war (A). In the temple of Juno, in the ifland of Melita, there were a pair of elephants teeth of extraordinary fize, which were carried away by Mafiniffa's admiral, and tranfmitted to that prince, who, though he fet a high value upon them, fent them again back, becaufe he heard they had been taken from a temple. The head of a bafilifk was exhibited in one of the temples of Diana; and the bones of that fea monfter, probably a whale, to which Andromeda was expofed, were preferved at Joppa, and afterwards brought to Rome.

(A) We think, with the tranflator of Beckmann's Hiftory, that this animal was not the crocodile, but the *Boa conftrictor*. See Boa and Serpent, *Encycl.*

Rome. In the time of Paufanias, the head of the celebrated Calydonian boar was fhewn in one of the temples of Greece ; but it was then deftitute of briftles, and had fuffered confiderably by the hand of time. The monftrous tufks of this animal were brought to Rome, after the defeat of Anthony, by the Emperor Auguftus, who caufed them to be fufpended in the temple of Bacchus. Appollonius tells us, that he faw in India fome of thofe nuts which in Greece were preferved in the temples as curiofities."

Though thefe curiofities were preferved in the temples for purpofes very different from thofe for which our collections are made, there can be no doubt but that they contributed to promote the knowledge of natural hiftory. If it be true, as Pliny and Strabo inform us, that Hippocrates availed himfelf of the accounts which were hung up in the temple of Æfculapius of different difeafes, and of the medicines and mode of treatment by which they were cured ; it will eafily be believed, that the natural hiftorians availed themfelves, in a fimilar manner, of the various rare objects which were preferved in the temples of the other gods. This, we fee, Pliny actually did.

Suetonius informs us, that Auguftus had, in his palace, a collection of natural curiofities; and it is well known that Alexander gave orders to all huntfmen, bird-catchers, fifhermen, and others, to fend to Ariftotle whatever rare animals they could procure. M. Beckmann feems to be of opinion, that the firft private mufeum was formed by Apuleius, who, next to Ariftotle and his fcholar Theophraftus, certainly examined natural objects with the greateft ardour and judgment ; who caufed animals of every kind, and particularly fifh, to be brought to him either dead or alive, in order to defcribe their external and internal parts, their number and fituation, and to determine their characterifing marks, and eftablifh their real names ; who undertook diftant journeys to become acquainted with the fecrets of nature ; and who, on the Getulian mountains, collected petrefactions, which he confidered as the effects of Deucalion's flood.

The principal caufe why collections of natural curiofities were fcarce in ancient times, muft have been the ignorance of naturalifts in regard to the proper means of preferving fuch bodies as foon fpoil or corrupt. Some methods were indeed known and practifed, but they were all defective and inferior to that by fpirit of wine, which prevents putrefaction, and which, by its perfect tranfparency, permits the objects which are covered by it to be at all times viewed and examined. Thefe methods were the fame as thofe employed to preferve provifions, or the bodies of great men deceafed. They were put into falt brine or honey, or were covered over with wax. Thus the hippopotamus, defcribed by Columna, was fent to him from Egypt preferved in falt. The body of Agefipolis King of Sparta, who died in Macedonia, was fent home in honey ; the celebrated purple dye of the ancients was preferved frefh for many years by the fame means ; and at this day, when the Orientals are defirous of tranfporting fifh to any diftance, they cover them over with wax.

In thofe centuries which are ufually called the middle ages, the Profeffor finds no traces of what can be called a mufeum, except in the treafuries of emperors, kings, and princes, where, befides articles of great value, curiofities of art, antiquities, and relics, one fometimes found fcarce and fingular foreign animals, which were dried and preferved. Such objects were to be feen in the old treafury at Vienna ; and in that of S. Denis was exhibited the claw of a griffin, fent by a king of Perfia to Charlemagne ; the teeth of the hippopotamus, and other things of the like kind. In thefe collections, the number of the rarities always increafed in proportion as a tafte for natural hiftory became more prevalent, and as the extenfion of commerce afforded better opportunities for procuring the productions of remote countries. Menageries were eftablifhed to add to the magnificence of courts, and the ftuffed fkins of rare animals were hung up as memorials of their having exifted. Public libraries alfo were made receptacles for fuch natural curiofities as were from time to time prefented to them ; and as in univerfities the faculty of medicine had a hall appropriated for the diffection of human bodies, curiofities from the animal kingdom were collected there alfo by degrees ; and it is probable that the profeffors of anatomy firft made attempts to preferve different parts of animals in fpirit of wine, as they were obliged to keep them by them for the ufe of their fcholars; and becaufe in old times dead bodies were not given up to them as at prefent, and were more difficult to be obtained. Private collections appear for the firft time in the 16th century ; and there is no doubt (fays our author) that they were formed by every learned man who at that period applied to the ftudy of natural hiftory.

MUSHROOM, a fungous, of which fome of the principal fpecies have been defcribed in the *Encyclopædia* under the generic name Agericus. There is, however, one fpecies not mentioned there—the *Boletus hirfutus* of Bulliard, which is certainly worthy of notice, fince one of the French Chemifts has lately extracted from it a bright, fhining, and very durable yellow dye. This pretty large mufhroom grows commonly on walnut and apple-trees. Its colouring-matter is contained in abundance, not only in the tubular part, but alfo in the parenchyma of the body of the mufhroom. In order to extract it, the mufhroom is pounded in a mortar, and the liquor thence obtained is boiled for a quarter of an hour in water. An ounce of liquor is fufficient to communicate colouring-matter to fix pounds of water. When the liquor has been ftrained, the ftuff to be dyed is put into it, and boiled for a quarter of an hour. All kinds of ftuff receive this colour and retain it ; but on linen and cotton it is lefs bright. This colour may be modified, in a very agreeable manner, by the effect of mordants.

The procefs fucceeded beft on filk. When this fubftance, after being dyed, is made to pafs through a bath of foft foap, it acquires a fhining golden-yellow colour, which has a perfect refemblance to the yellow of that filk employed to imitate embroidery in gold, and which has hitherto been brought from China and fold at a dear rate, as the method of dyeing it is unknown in Europe. The yellow colour extracted from this mufhroom may be employed alfo with advantage for painting in water colours as well as in oil.

MUTSUDDIES, in Bengal, writers, accountants, officers of government.

MUZCOORET, allowances to zemindars in land or money. See Zemindar, *Suppl.*

N.

Nabob ‖ Nancowry.

NABOB, or Nowab, a title of courtefy given in India to Mahomedans high in ftation, particularly provincial governors.

The Sun's NADIR, is the axis of the cone projected by the fhadow of the earth: fo called, becaufe that axis being prolonged, gives a point in the ecliptic diametrically oppofite to the fun.

NAIB, a deputy.

NAKED, in architecture, as the naked of a wall, &c. is the furface, or plane, from whence the projectures arife; or which ferves as a ground to the projectures.

NANCOWRY, or Soury, as it is fometimes called, is one of the Nicobar ifles, and fituated nearly in the centre of the clufter (See Nicobar, *Encycl.*). Its length may be about eight miles, and its breadth nearly equal. The ifland of Comerty, which is near it, is more extenfive, but does not perhaps contain more folid land, being excavated by a very large bay from the fea. The fpace between thefe two iflands forms a capacious and excellent harbour, the eaftern entrance of which is fheltered by another ifland, called Tricut, lying at the diftance of about a league. The inlet from the weft is narrow, but fufficiently deep to admit the largeft fhips when the wind is fair.

The Danes have long maintained a fmall fettlement at this place, which ftands on the northern-moft point of Nancowry, within the harbour. A ferjeant and three or four foldiers, a few black flaves, and two rufty old pieces of ordnance, compofe the whole of their eftablifhment. They have here two houfes; one of which, built entirely of wood, is their habitation; the other, formerly inhabited by their miffionaries, ferves now for a ftorehoufe.

Thefe iflands are in general woody, but contain likewife fome portions of clear land. From the fummits of their hills the profpects are often beautiful and romantic. The foil is rich, and probably capable of producing all the various fruits and vegetables common to hot climates. The natural productions of this kind, which moftly abound, are cocoa nuts, *papias*, plantains, limes, tamarinds, beetle-nuts, and the *melôri*, a fpecies of breadfruit; yams, and other roots are cultivated and thrive; but rice is here unknown. The *mangoftain* tree, whofe fruit is fo juftly extolled, grows wild; and pine-apples of a delicious flavour are found in the woods.

Of all the Nicobar ifles Nancowry and Comerty are faid to be the beft peopled; the population of both being fuppofed to amount to eight hundred. The natives of Nancowry and of the Nicobar iflands in general, live in villages on the fea-fhore, and never erect their habitations inland (a). Their houfes are of a circular form, and are covered with elliptical domes, thatched with grafs and the leaves of cocoa nut. They are raifed up-on piles to the height of fix or eight feet above the ground; the floor and fides are laid with planks, and the afcent is by a ladder. In thofe bays or inlets which are fheltered from the furf, they erect them fometimes fo near the margin of the water as to admit the tide to flow under, and wafh away the ordure from below.

Nancowry.

In front of their villages, and a little advanced in the water, they plant beacons of a great height, which they adorn with tufts made of grafs, or the bark of fome tree. Thefe objects are difcernible at a great diftance, and are intended probably for landmarks; their houfes, which are overfhadowed by thick groves of cocoa-nut trees, feldom being vifible from afar.

The Nicobareans, though indolent, are in general robuft and well-limbed. Their features are fomewhat like the Malays, and their colour is nearly fimilar. The women are much inferior in ftature to the men, but more active in all domeftic affairs. Contrary to the cuftom of other nations, the women fhave the hair of their heads, or keep it clofe cropt, which gives them an uncouth appearance, in the eyes of ftrangers at leaft.

The inhabitants of Nancowry perform, every year, a very extraordinary ceremony in honour of the dead. It is thus defcribed by Lieutenant Colebrooke:

" On the anniverfary of this feftival, if it can be fo called, their houfes are decorated with garlands of flowers, fruits, and branches of trees. The people of each village affemble, dreft in their beft attire, at the principal houfe in the place, where they fpend the day in a convivial manner; the men, fitting apart from the women, fmoke tobacco, and intoxicate themfelves; while the latter are nurfing their children, and employed in preparations for the mournful bufinefs of the night. At a certain hour of the afternoon, announced by ftriking the *Goung*, the women fet up the moft difmal howls and lamentations, which they continue without intermiffion till about fun-fet; when the whole party get up, and walk in proceffion to the burying-ground. Arrived at the place, they form a circle around one of the graves, when a ftake, planted exactly over the head of the corpfe, is pulled up. The woman who is neareft of kin to the deceafed, fteps out from the crowd, digs up the fkull, and draws it up with her hands. At fight of the bones, her ftrength feems to fail her; fhe fhrieks, fhe fobs; and tears of anguifh abundantly fall on the mouldering object of her pious care. She clears it from the earth, fcrapes off the feltering flefh, and laves it plentifully with the milk of frefh cocoa-nuts, fupplied by the byftanders; after which fhe rubs it over with an infufion of faffron, and wraps it carefully in a piece of new cloth. It is then depofited again in the earth, and covered up; the ftake is replanted, and hung with the various trappings and imple-

(a) The great Nicobar iflands is perhaps an exception, where, it is faid, a race of men exifts, who are totally different in their colour and manners. They are connfidered as the *Aborigines* of the country. They live in the interior parts among the mountains, and commit frequent depredations on the peaceable inhabitants of the coafts.

implements belonging to the deceafed. They proceed then to the other graves; and the whole night is fpent in repetitions of thefe difmal and difguftful rites.

"On the morning following, the ceremony is concluded by an offering of many fat fwine; when the facrifice made to the dead affords an ample feaft to the living: they befmear themfelves with the blood of the flaughtered hogs, and fome, more voracious than others, eat the flefh raw. They have various ways, however, of dreffing their meat, but always eat it without falt. A kind of pafte made of the *melori* ferves them for bread; and they finifh their repaft with copious potations of *taury*, an inebriating liquor."

The Nicobareans are hofpitable and honeft, and are remarkable for a ftrict obfervance of truth, and for punctuality in adhering to their engagements. Such crimes as theft, robbery, and murder, are unknown in thefe iflands; but they do not want fpirit to revenge their injuries, and will fight refolutely; and flay their enemies, if attacked or unjuftly dealt with. Their only vice, if this failing can be fo called, is inebriation; but in their cups they are generally jovial and good-humoured. It fometimes, however, happens at their feafts, that the men of different villages fall out; and the quarrel immediately becomes general. In thefe cafes they terminate their differences in a pitched battle; where the only weapons ufed are long fticks, of a hard and knotty wood. With thefe they drub one another moft heartily, till, no longer able to endure the conflict, they mutually put a ftop to the combat, and all get drunk again.

NANKAR, ancient allowance to zemindars in land or money.

NANKEEN, or NAN-KING, is a well-known cotton ftuff, which derives its name from the ancient capital of China (See NAN-KING, *Encycl.*). It is, however, according to Van Braam, manufactured at a great diftance from that city, in the diftrict of *Fong-kiang-fou*, fituated in the fouth-eaft of the province of *Kiang-nam* upon the fea-fhore. The colour of nankeen is natural, the down of which it is made being of the fame yellow tinge with the cloth. The colour, as well as fuperior quality of this cotton, feems to be derived from the foil; for it is faid that the feeds of the nankeen cotton degenerate in both particulars when tranfplanted to another province, however little different in its climate. The common opinion, that the colour of the ftuff is given by a dye, occafioned an order from Europe, fome years ago, to dye the pieces of nankeen of a deeper colour than they had at that period; and the reafon of their being then paler than formerly is as follows:

Shortly after the Americans began to trade with China, the demand increafed to nearly double the quantity it was poffible to furnifh. To fupply this deficiency, the manufacturers mixed common white cotton with the brown; this gave it a pale caft, which was immediately remarked; and for this lighter kind no purchafer could be found, till the other was exhaufted. As the confumption is grown lefs for thefe fome years paft, the mixture of cotton is no longer neceffary, and nankeen is become what it was before. By keeping them two or three years, it even appears that they have the property of growing darker. This kind of ftuff muft be acknowledged to be the ftrongeft yet known. Many perfons have found that clothes made of it will laft three or four years, although for ever in the wafh. This it is that makes them the favourite wear for breeches and waiftcoats both in Europe and America. The white nankeen is of the fame quality, and is made of white cotton as good as the brown, and which alfo grows in Kiang-nam.

NAPLES-YELLOW, called alfo *Neapolitan earth*, in Italian *Giallolino*, and in French *Jaune de Naples*, is a beautiful pigment, concerning which we have much information from the indefatigable Beckmann. "It has (fays he) the appearance of an earth, is of a pale orange-yellow colour, ponderous, granulated, exceedingly friable, does not effloresce, nor become moift when expofed to the air, but when applied to the tongue feems to adhere to it. When reduced to a fine powder, it remains for fome time fufpended in water, but foon depofits itfelf at the bottom in the form of a flime. When boiled with water, the water, at leaft fometimes, is obferved to have a fomewhat faline tafte. It does not effervefce with acids, but is in part diffolved by aqua regia (nitro-muriatic acid). In the fire it emits no fulphureous vapour, is difficult to be fufed, and by that operation undergoes no material change, only that its colour becomes fomewhat redder. When fufed with colourlefs glafs, it gives it a milk-white colour, a fure proof that it contains no iron; and, with inflammable fubftances, there is obtained from it a regulus which has the appearance of a mixture of lead and antimony.

"This article is brought from Naples for the moft part in the form of an earthy cruft about three or four lines in thicknefs, and it fometimes retains the form of the veffel in which it has hardened. It can be procured alfo as a fine powder, as the colourmen keep it fometimes ready pounded for ufe."

About the nature of the fubftance called Naples-yellow there has been much diverfity of opinion. Moft of thofe who have written about it, confider it as originating from fire, and as a volcanic production of Mount Vefuvius or Mount Ætna; others have pronounced it to be a natural ochre. Guettard thought it rather a kind of bole; but Pott approached neareft the truth, by afferting it to be an artificial preparation *. Fougeroux is entitled to the merit of having proved this, and of having fhewn the poffibility of preparing it. According to his experiments, Naples-yellow will be obtained if you boil for feven or eight hours, firft over a flow and then over a ftrong fire, a mixture finely pulverifed of twelve parts of pure white lead, one part of alum, one part of fal ammoniac, and three parts of diaphoretic antimony † (white oxide of antimony by nitre). But before Fougeroux, who may have obtained an account of the procefs during his travels through Italy, a more certain procefs was publifhed in the year 1758, by Giambattifta Pafferi, in his interefting work on the painting of earthen ware ‡. The articles to be employed, according to this author, are, "one pound of antimony, a pound and a half of lead, one ounce of *alume di feccia*, and the fame quantity of common falt." I am inclined (fays M. Beckmann) to think that this receipt was not unknown to Fougeroux, and that he confidered *alume di feccia* to be alum. Profeffor Leonhardi, a man of very found learning, has tranflated this expreffion by the word alum. I will, however, freely confefs, that I confider *alume di feccia* not to mean alum, but falt of tartar, or potafh. Pafferi

* *Lithogeognofie*, v. ii. p. 15.

† *Mem. of the Acad. of Sciences*, 1766.

‡ *In Nuova raccolta d'opufculi fcientifici*, t. iv.

Naples, Nardus.

feri says, that the proportions may be varied different ways; and he gives six other receipts, in which he does not mention *alume di feccia*, but only *feccia;* and this word certainly means *weinhefen* or winestone (tartar). Professor Leonhardi himself seems to confirm this opinion, by saying, that Vairo, professor of chemistry at Naples, has translated "the ashes of wine lees" *(cineres infectorii)* by the words *alume di feccia.*

After Fougeroux's paper was printed, De la Lande published a receipt which he had received from the well-known prince San Severo, and in which lead and antimony only are employed; but no mention is made either of alum, tartar, or any other salt. This receipt is as follows:

Take lead well calcined and sifted, with a third part of its weight of antimony pounded and sifted also. Mix these substances well together, and sift them again through a piece of silk. Then take large flat earthen dishes, not varnished, cover them with white paper, and spread out the powder upon them to the depth of about two inches. Place these dishes in a potter's furnace, but only at the top, that they may not be exposed to too violent a heat. The reverberation of the flame will be sufficient. The dishes may be taken out at the same time as the earthen-ware, and the substance will then be found hard, and of a yellow colour. It is then pounded on a piece of marble with water, and afterwards dried for use.

The enamel painters in Germany prepare a yellow glazing, not very different from the real Naples yellow, by a prescription, according to which, "one pound of antimony, six ounces of red lead, and two ounces of white sand, are to be fused together. The produce, which appears quite black, is to be pounded, and then fused again; and this process is to be repeated till the whole mass becomes thoroughly yellow. Half a pound of this mass is to be mixed with two ounces of red lead, and afterwards fused; and by this tedious process an orange-yellow pigment will be obtained."

All artists who speak of the use of Naples yellow, give cautions against applying iron to it, as the colour by these means becomes greenish, or at least dirty. For this reason, it must be pounded on a stone, and scraped together with an ivory spatula. It is employed chiefly in oil painting, because the colour is softer, brighter, and richer than that of ochre, yellow lead, or orpiment, and because it far exceeds these pigments in durability. It is employed in particular when the yellow ought to have the appearance of gold, and in this respect it may be prepared with gum water, and used as a water colour. A still greater advantage of it is, that it is proper for enamel painting, and on that account may be employed on porcelain or earthen ware (A). Professor Beckmann, however, recommends to artists to examine whether the oxide prepared from wolfram, by boiling in the muriatic acid, which has a beautiful yellow colour, might not be used in the same manner as Naples yellow.

NARDUS. Under this generic term we have, in the *Encyclopædia*, given, from the *Philosophical Transactions*, a description of the plant or grass which Dr Blane considers as the spikenard of the ancients. It is our duty, in this place, to inform our readers, that Sir William Jones, in the 2d and 4th volumes of the *Asiatic Researches*, seems to have completely proved that the spikenard of Dioscorides and Galen, or *Nardus Indica*, was a very different plan from the Andropogon of Dr Blane, and that it grows in a country far distant from *Mackran*. The proofs brought by the illustrious president of the Asiatic Society, in support of his own opinion, are too numerous and circumstantial to be introduced into such a work as this. We shall therefore only give one of them; which though, when separated from the rest, it loses much of its force, must be allowed, even singly, to have great weight.

Nardus, Nares.

The true Indian spikenard is confessedly called by the Arabs *Sumbulu'l Hind;* for so they translate the name of it in Dioscorides. Now (says Sir William) I put a fair and plain question severally to three or four Mussulman physicians: "What is the Indian name of the plant which the Arabs call *Sumbulu'l Hind?*" They all answered, but some with more readiness than others, *Játámansí*. After a pretty long interval, I shewed them the spikes (as they are called) of *Játámansí*, and asked, what was the Arabic name of that Indian drug? They all answered readily, *Sumbulu'l Hind*. The same evidence may be obtained in this country by any other European who seeks it; and if among twelve native physicians, versed in Arabian and Indian philology, a single man should, after due consideration, give different answers, I will cheerfully submit to the Roman judgment of *non liquet*. But the *Játámansí* * evidently belongs to the natural order which Linnæus calls *aggregate;* with the following *characters:* * Plate XXX.

Calyx, scarce any; *margin*, hardly discernible. *Corolla*, one petal; *tube* somewhat gibbous; *border* five cleft. *Stamina*, three *Anthers*. *Pistula*, *Germ* beneath; one *Style* erect. *Seed*, solitary, crowned with a pappus. *Root*, fibrous. *Leaves*, hearted, fourfold; *radical* leaves petioled.

It appears therefore (continues the learned author) to be the Protean plant Valerian, a sister of the Mountain and Celtick Nard, and of a species which I should describe in the Linnean style, *Valeriana Játámansí floribus triandris, foliis cordatis quaternis, radicalibus petiolatis.* The radical leaves, rising from the ground, and enfolding the young stem, are plucked up with a part of the root, and being dried in the sun or by an artificial heat, are sold as a drug, which, from its appearance, has been called spikenard. The Játámansí is a native of the most remote and hilly parts of India, such as NE'PA'L, Marang Butan, near which Ptolemy fixes the native soil of the *Nardus Indica*. It grows erect above the surface of the ground resembling an ear of green wheat; and when recent, it has a faint odour, which is greatly increased by the simple process of drying it.

NARES (JAMES), doctor of music, an eminent composer and teacher in that science, under whom some of the first musicians of the present day received the whole or part of their education, was the son of Mr Nares, who was, for many years, steward to Montague and Biog. Dict. new edit.

(A) In the Memoirs of the Academy of Sciences for 1767, Fougeroux has proved that the giallolino prepared by him produced on porcelain a much more beautiful colour than the Naples yellow sold in the shops.

Nares.

and Willoughby, earls of Abingdon. He was born, as well as his brother, the late Mr Juſtice Nares, at Stanwell in Middleſex; the former in 1715, the latter in 1716. His muſical education he commenced under Mr Gates, then maſter of the royal choriſters; and completed it under the celebrated Dr Pepuſch. Thus prepared, he officiated, for ſome time, as deputy to Mr Pigott, organiſt of Windſor; but on the reſignation of Mr Saliſbury, organiſt of York, in 1734, was choſen to ſucceed him, being then only nineteen. It is related, on undoubted authority, that when the old muſician firſt ſaw his intended ſucceſſor, he ſaid, rather angrily, "What! is that child to ſucceed me?" which being mentioned to the organiſt-elect, he took an early opportunity, on a difficult ſervice being appointed, to play it throughout half a note below the pitch, which brought it into a key with ſeven ſharps; and went through it without the ſlighteſt error. Being aſked why he did ſo? he ſaid, that "he only wiſhed to ſhew Mr Saliſbury what a child could do." His knowledge in all branches of his profeſſion was equal to his practical ſkill in this inſtance; and, during his reſidence at York, where he was abundantly employed as a teacher, and where he married, Mr Nares, by his good conduct, as well as profeſſional merit, obtained many powerful friends. Among the foremoſt of theſe was Dr Fontayne, the reſpectable and venerable dean of York; who, when Dr Green died, towards the letter end of 1755, exerted his intereſt ſo ſuccesſfully, that he obtained for him the united places of organiſt and compoſer to his Majeſty. He removed therefore to London in the beginning of 1756; and, about the ſame time, was created doctor in muſic at Cambridge.

On the reſignation of Mr Gates, in 1757, Dr Nares obtained alſo the place of maſter of the choriſters; which having been, for a long time, without increaſe, notwithſtanding the increaſe of expences attending it, was, by royal favour, augmented about 1775, firſt with the ſalary of the violiſt; and, on the revival of that place for Mr Croſdill, in 1777, with that of lutaniſt, which was annexed to it for ever. It was in this ſituation that Dr Nares ſuperintended the education of many pupils, who have ſince become famous; particularly Dr Arnold, who, though with him only for a ſhort time, was highly diſtinguiſhed by him for talents and application. The anthems and ſervices which Dr Nares produced, as compoſer to the royal chapel, were very numerous; many of them have ſince been printed, and many which exiſt only in manuſcript ſtill continue to be performed in the choirs with much effect. Having been originally a muſician rather by accident than choice, with very ſtrong talents and propenſities alſo for literature, Dr Nares was particularly attentive to expreſs the ſenſe of the words he undertook to ſet; and was the firſt who attempted to compoſe the Te Deum for the choir ſervice, in ſuch a manner as to ſet off the ſentiments it contains to advantage. Before his time, it had been ſet rather to a regular ſtrain of chaunt than to any expreſſive melodies. The merits of Dr Nares were not overlooked by his royal patrons, whom he had occaſionally the honour to attend in private, though not a part of his regular duty. To manifeſt his reſpect and gratitude for them, he compoſed his dramatic ode, entitled The Royal Paſtoral; the words of which were written by Mr Bellamy, author of a book, entitled Ethic Amuſements.

In July 1780, Dr Nares was obliged, by declining health, to reſign the care of the choriſters, in which place he was ſucceeded by Dr Ayrton, his pupil and valued friend. In his ſixty-eighth year, a conſtitution, never robuſt, gave way, and he died on February 10. 1783. Teſtimony has been borne to the merits of Dr Nares by ſeveral writers, but more particularly by Mr Maſon, in his preface to a book of anthems, printed for the uſe of York Cathedral; and in his late Eſſays on Church Muſic, page 138. The late Lord Mornington, ſo well known for muſical talents, frequently conſulted him; and Sir John Hawkins derived advantage from his acquaintance, in the progreſs of his Hiſtory of Muſic. Throughout life, he was not leſs reſpected as a man than admired as a muſician; he had a vivacity that rendered his ſociety always pleaſing; and a generous contempt for every thing baſe, that manifeſted itſelf on all proper occaſions, and very juſtly commanded eſteem.

His printed works are theſe: 1. Eight ſets of Leſſons for the Harpſichord; dedicated to the Right Hon. Willoughby Earl of Abingdon. Printed in 1748; reprinted in 1757. 2. Five Leſſons for the Harpſichord, with a Sonata in ſcore for the Harpſichord or Organ; dedicated to the Right Honourable the Counteſs of Carliſle; publiſhed in 1758 or 1759. 3. A Set of Eaſy Leſſons for the Harpſichord, three in number; with a dedication to the public, ſigned J. N. 4. A Treatiſe on Singing, ſmall ſize. 5. Il Principio; or A regular Introduction to playing on the Harpſichord or Organ. This was the firſt ſet of progreſſive leſſons publiſhed on a regular plan. 6. The Royal Paſtoral, a Dramatic Ode; dedicated to his Royal Highneſs the Prince of Wales; printed in ſcore, with an overture and choruſes. 7. Catches, Canons, and Glees; dedicated to the late Lord Mornington. 8 Six Fugues, with Introductory Voluntaries for the Organ or Harpſichord. 9. A Conciſe and Eaſy Treatiſe on Singing, with a Set of Engliſh Duets for Beginners. A different work from the former ſmall treatiſe. 10. Twenty Anthems, in ſcore, for one, two, three, four, and five Voices. Compoſed for the Uſe of his Majeſty's Chapels Royal, 1778. 11. Six Eaſy Anthems, with a favourite Morning and Evening Service, left for publication at his death, and publiſhed in 1788, with a portrait and a conciſe account of the author. Of theſe compoſitions the following ſhort character is given by an eminent muſician, to whom they are all well-known: "The leſſons are compoſed in a maſterly and pleaſing ſtyle; free from thoſe tricks and unmeaning ſucceſſions of ſemitones, to which a good ear and ſound judgment never can be reconciled. The treatiſes on ſinging contain duets compoſed for the uſe of the children of the royal chapels, ſuperior to any thing yet publiſhed; and ſuch as every teacher ought to peruſe. His catches, canons, and glees, are natural and pleaſing; eſpecially the glee to all Lovers of Harmony, which gained the prize medal at the catch-club in 1770. The Royal Paſtoral is compoſed throughout in a very maſterly manner; particularly the choruſes, with which each part concludes. This ode, containing 108 pages, was written, and all the vocal and inſtrumental parts tranſcribed for performing, within twelve days. The

ſix

Navigators. fix fugues, with introductory voluntaries for the organ, contain the ftrongeft proofs of ingenuity and judgement; few, if any, have ever been written that can be preferred to them. In both fets of the anthems, the fame characteriftics appear; and the fervice of the latter very juftly acquired the title of *favourite*; nor can there be any doubt that the works of this author will be admired as long as a tafte for mufic fhall fubfift."

NAVIGATORS ISLANDS, an archipelago in the South Sea, difcovered by Bougainville, who gave to them that name, becaufe the natives do not pafs between the different villages, which are all built in creeks and bays, but in their canoes. The Navigators Iflands are ten in number; namely, *Opoun*, *Leoné*, *Fanfoué*, MAOUANA, *Oyolava*, *Calinaffé*, *Pola*, *Shika*, *Offamo*, and *Ouera*.

We have already given an account of the foil and productions of MAOUANA; and as the other iflands of this clufter are equally fertile, we need not go over the fame ground again. It may be proper, however, to obferve, that in fome of them the fugar-cane was found growing fpontaneoufly, though its juice contained lefs of the faccharine fubftance than the fugar cane of the Weft Indies, which our voyagers attributed to its growing in a richer foil and in the fhade. According to Peroufe, the Navigators Iflands are fituated about the 14th degree of fouth latitude, and between the 171ft and 175th degrees of longitude weft from Paris. In Oyolava the fmoke was feen hovering over a village as over a large European town; and the number of canoes which from that ifland furrounded the frigates was immenfe. Thefe are very ticklifh veffels, and would be abfolutely ufelefs to any body but fuch excellent fwimmers as the iflanders, who are no more furprifed or uneafy at their overfetting than we are at the fall of a hat. Taking up the canoe on their fhoulders, they empty it of water, and then get in again, with the certainty of having the fame operation to perform a fecond time in half an hour. Sometimes they join two canoes together by means of a crofs piece of wood, in which they make a ftep to receive the maft; and in this way they are lefs liable to be overfet, fometimes performing a long voyage without any fuch accident. It is needlefs to add, that thefe canoes are very fmall, generally containing only five or fix perfons, though fome few of them may contain as many as fourteen.

The natives of the Navigators Iflands are tall and well made. Their ufual height is five feet nine, ten, and eleven inches; but their ftature is lefs aftonifhing than the coloffal proportions of the different parts of their bodies. "Our curiofity (fays Peroufe), which often led us to meafure them, gave them an opportunity of making frequent comparifons of their bodily ftrength with ours. Thefe comparifons were not to our advantage; and we perhaps owe our misfortunes (fee MAOUANA in this *Suppl.*) to the idea of individual fuperiority refulting from repeated trials. Their countenances often appeared to exprefs a fentiment of difdain, which I hoped to deftroy, by ordering our arms to be ufed in their prefence: but my end could only have been gained by directing them againft human victims; for otherwife they took the noife for fport, and the trial for a diverfion.

"Among thefe Indians a very fmall number is below the height indicated above. I have, however, meafured feveral who were only five feet four inches, but Navigators thefe are the dwarfs of the country; and although their ftature refembles ours, their ftrong and nervous arms, their broad chefts, and their legs and thighs, are of a very different proportion.

"The men have the body painted or tatowed, fo that any one would fuppofe them clad, although they go almoft naked. They have only a girdle of feaweeds encircling their loins, which comes down to their knees, and gives them the appearance of the river gods of fabulous hiftory, whom it is cuftomary to depict with rufhes round their waift. Their hair is very long. They often twift it round their heads, and thus add to their native ferocity of countenance, which always expreffes either furprife or anger. The leaft difpute between them is followed by blows of fticks, clubs, or paddles; and often, without doubt, cofts the combatants their lives. They are almoft all covered with fcars, which can only be the confequence of their individual quarrels. The ftature of the women is proportioned to that of the men. They are tall, flender, and not without grace; but they lofe, while yet in their prime, thofe elegant forms, of which Nature has not broken the mould among this barbarous race, but of which fhe appears to leave them in poffeffion only for a moment, and with reluctance. Among a great number of women that I had an opportunity of feeing, I only obferved three really pretty. The grofs effrontery of the reft, the indecency of their motions, and the difgufting offers which they made of their favours, rendered them fit mothers and wives for the ferocious beings that furrounded us." Our author gives the following inftance of indecent manners, which is, perhaps, without a parallel.

The young and prettieft females foon attracted the attention of feveral Frenchmen, who, in fpite of the Commodore's prohibition, endeavoured to form a connection with them, and were fuccefsful. The looks of the Europeans expreffing defires which were foon divined, fome old women undertook the negociation. The altar was prepared in the handfomeft hut in the village, all the blinds were let down, and the inquifitive were excluded. The victim was then laid in the arms of an old man, who exhorted her, during the ceremony, to moderate the expreffion of her pain; while the matrons fang and howled: the ceremony being performed in their prefence. and under the aufpices of the old man, who ferved at once as prieft and altar. All the women and children in the village were round the houfe, gently lifting up the blinds, and feeking to enjoy the fight through the fmalleft crevices in the mats. Whatever former navigators may have faid, Peroufe was convinced that, in the Navigators Iflands at leaft, the young girls, before they are married, are miftreffes of their perfons, and that they are not difhonoured by their complaifance. It is even more than probable, that in marrying they are called to no account concerning their paft conduct; but he had no doubt that they are obliged to be more referved when provided with a hufband.

Thefe people cultivate certain arts with fuccefs. Under the article MAOUANA mention has been made of the elegant form which they give to their huts. It is not with fuch folly as is commonly fuppofed that they difdain our inftruments of iron; for they finifh their work very

Navigators.

very neatly with tools made of a very fine and compact species of basaltes in the form of an adze. For a few glass beads they sold to Perouse large three-legged dishes of a single piece of wood, and so well polished that they seemed to have been laid over with a coat of the finest varnish. It would take an European workman several days to produce one of these dishes, which, for want of proper instruments, must cost an Indian several months labour. They set, however, scarcely any value upon them, because they set little upon the time they employ. The fruit trees and nutritious roots that grow spontaneously around them, insure to them their subsistence, as well as that of their hogs, dogs, and fowls; and if they sometimes stoop to work, it is to procure enjoyments rather agreeable than useful. They manufacture very fine mats, and some paper stuffs. Our author remarked two or three of them, whom he took for chiefs, with a piece of cloth tied round their waist like a petticoat, instead of a girdle of weeds. It is composed of real thread, prepared no doubt from some filamentous plant like the nettle or flax; and is manufactured without a shuttle, the threads being absolutely laid over one another like those of their mats. This cloth, which has all the suppleness and solidity of ours, is very fit for the sails of their canoes; and appeared far superior to the paper stuff of the Society and Friendly Islands, which they manufacture also. Their canoes are well constructed, and furnish a good proof of the skill with which they work in wood. For a few glass beads they gave to the Frenchmen, among other things, a wooden vessel filled with cocoa nut oil, exactly of the shape of our earthen pots, and such as no European would undertake to fashion by any other means than a turning lathe. Their ropes are round, and twisted like watch chains of ribbon: their mats are very fine; but their stuffs are inferior to those of the Easter and Sandwich Islands.

Perouse derives the natives of those islands, whose colour, he says, nearly resembles that of the Algerines and other nations on the coast of Barbary, from the Malays; and as we do not vouch for the truth of his theory, though we admit it to be ingenious, we shall give the reasoning by which he supports it in his own words.

"We did not at first discover (says he) any identity between their language and that of the natives of the Society and Friendly Islands, of which we had vocabularies; but a more mature examination convinced us, that they speak a dialect of the same language. A fact which tends to prove it, and which confirms the opinion of the English concerning the origin of these people, is, that a young domestic, a native of the province of Tagayan in the north of Manilla, understood and explained to us the greater part of their words. It is well known that the Tagayan, the Talgal, and the generality of languages spoken in the Philippines, are derived from the Malay: a language more diffused than were those of the Greeks and Romans, and common to the numerous tribes that inhabit the islands of the great Pacific Ocean. It appears to me evident, that all these different nations are the progeny of Malay colonies, which, in some age extremely remote, conquered the islands they inhabit. I should not even wonder, if the Chinese and Egyptians, whose antiquity is so much vaunted, were mere moderns in comparison of the Malays. But however this may be, I am satisfied that the aborigines of the Philippine Islands, Formosa, New Guinea, New Britain, the New Hebrides, the Friendly Islands, &c. in the southern hemisphere, and those of the Marianna and Sandwich islands in the northern, were that race of woolly headed men still found in the interior of the islands of Luconia and Formosa. They were not to be subjugated in New Guinea, New Britain, and the New Hebrides; but being overcome in the more eastern islands, which were too small to afford them a retreat in the centre, they mixed with the conquering nation. Thence has resulted a race of very black men, whose colour is still several shades deeper than that of certain families of the country, probably because the latter have made it a point of honour to keep their blood unmixed. I was struck with these two very distinct races in the Islands of Navigators, and cannot attribute to them any other origin.

"The descendants of the Malays have acquired in those islands a degree of vigour and strength, a lofty stature, and a Herculean form, which they do not inherit from their forefathers, but which they owe, without doubt, to an abundance of food, to a mild climate, and to the influence of different physical causes which have been constantly acting during a long series of generations. The arts which they perhaps brought with them may have been lost for want of materials and instruments to practise them; but the identity of language, like Ariadne's clue, enables the observer to follow all the windings of this new labyrinth. The feudal government is also preserved here; that government which little tyrants may regret; which was the disgrace of Europe for several centuries; and of which the Gothic remains are still to be found in our laws, and are the medals that attest our ancient barbarism: that government, which is the most proper to keep up a ferocity of manners, because the smallest disputes occasion wars of village against village, and because wars of this nature are conducted without magnanimity, and without courage. Surprises and treachery are employed by turns; and in these unfortunate countries, instead of generous warriors, nothing is to be found but base assassins (A). The Malays are still the most perfidious nation

(A) This was written under the old government of France by a man who, like other declaimers in the cause of liberty, forgot the excellencies, and insisted only on the defects of the feudal institutions. Had Perouse, however, returned to Europe, and witnessed the *philosophic* government of his country, he would have perceived, that *liberty* and *equality*, and *the rights of man*, are as well calculated to generate base assassins, as the Gothic remains of that Government by which he supposed Europe to have been so long disgraced. He might even have lived to regret, that his lot was not cast among the bold and ferocious inhabitants of Maouna; for the treachery and cruelty of these people bears no proportion, even in his affecting narrative, to the systematic cruelty of those who decreed, that the end sanctifies the means, and that nothing, however atrocious in the estimation of antiquated moralists, is to be omitted, which contributes to elevate the mean above the noble.

tion of Asia; and their children have not degenerated, because the same causes have led to and produced the same effects. It may be objected, perhaps, that it must have been very difficult for the Malays to make their way from west to east, to arrive at these different islands; but the westerly winds blow as frequently as the easterly in the vicinity of the equator, along a zone of seven or eight degrees from north to south, where the wind is so variable, that it is hardly more difficult to navigate east than west. Besides, these different conquests may not have been effected at the same time: the people in question may, on the contrary, have spread themselves by little and little, and gradually have introduced that form of government which still exists in the peninsula of Malacca, at Java, Sumatra, and at Borneo, as well as in all the other countries subject to that barbarous nation."

NAZER, Nazr, Nezer, Nuzzer, Nuzzerana; a present from an inferior; fees of office.

NEBULOUS, or Cloudy, a term applied to certain fixed stars which shew a dim hazy light; being less than those of the sixth magnitude, and therefore scarcely visible to the naked eye, to which at best they only appear like little dusky specks or clouds. Through a moderate telescope, these nebulous stars plainly appear to be congeries or clusters of several little stars.

NECKAR Isle, a small barren island, or rather rock, discovered by Perouse in the Pacific Ocean. Though its sterility renders it of no importance in itself, its exact situation must be interesting to navigators, who are therefore obliged to the French Commodore for having ascertained its latitude to be 23° 34′ north, and its longitude to be 166° 52′ west from Paris. From the soundings the *Neckar* seemed to be only the top or nucleus of a much more considerable island, which, probably from being composed of a soft and dissoluble substance, the sea had gradually washed away. In proportion as the frigates left the shore, the depth, which at the distance of a mile was very little, gradually increased, till, at the distance of about ten miles, no bottom was found with a line of 150 fathoms; and over the whole of that shore the bottom consisted of coral and broken shells.

NEPAL, a kingdom of India, situated to the north-east of the city of Patna, at the distance of ten or twelve days journey. Within the distance of four days journey from Nepal the road is good in the plains of Hindostan, but in the mountains it is bad, narrow, and dangerous. At the foot of the hills the country is called *Teriani;* and there the air is very unwholesome from the middle of March to the middle of November; and people in their passage catch a disorder called in the language of that country *aul;* which is a putrid fever, and of which the generality of people, who are attacked with it, die in a few days; but on the plains there is no apprehension of it. Although the road be very narrow and inconvenient for three or four days at the passes of the hills, where it is necessary to cross and recross the river more than fifty times, yet, on reaching the interior mountain before you descend, you have an agreeable prospect of the extensive plain of Nepal, resembling an amphitheatre covered with populous towns and villages: the circumference of the plain is about 200 miles, a little irregular, and surrounded by hills on all sides, so that no person can enter or come out of it without passing the mountains.

There are three principal cities in the plain, each of which was the capital of an independent kingdom; the principal city of the three is situated to the northward of the plain, and is called *Cat'hmandu:* it contains about 18,000 houses; and this kingdom, from south to north, extends to the distance of twelve or thirteen days journey as far as the borders of Tibet, and is almost as extensive from east to west. The king of Cat'hmandu has always about 50,000 soldiers in his service. The second city to the south-west of Cat'hmandu is called *Lelit Pattan;* it contains near 24,000 houses. The third principal city to the east of Lelit Pattan is called *B'hatgan;* it contains about 12,000 families; and is the metropolis of a district which extends towards the east to the distance of five or six days journey; and borders upon another nation, also independent, called *Ciratas*, who profess no religion. Besides these three principal cities, there are many other large and less considerable towns or fortresses; one of which is *Timi*, and another *Cipoli*, each of which contains about 8000 houses, and is very populous. All those towns, both great and small, are well built; the houses are constructed of brick, and are three or four stories high; their apartments are not lofty; they have doors and windows of wood well worked and arranged with great regularity. The streets of all their towns are paved with brick or stone, with a regular declivity to carry off the water. In almost every street of the capital towns there are also good wells made of stone, from which the water passes through several stone canals for the public benefit. In every town there are large square varandas well built, for the accommodation of travellers and the public: these varandas are called *Pali;* and there are also many of them, as well as wells, in different parts of the country for public use. There are also, on the outside of the great towns, small square reservoirs of water, faced with brick, with a good road to walk upon, and a large flight of steps for the convenience of those who choose to bathe.

The religion of Nepal is of two kinds: the more ancient is professed by many people who call themselves *Baryesu;* they pluck out all the hair from their heads; their dress is of coarse red woollen cloth, and they wear a cap of the same; they are considered as people of the religious order, and their religion prohibits them from marrying, as it is with the Lamas of Tibet, from which country their religion was originally brought; but in Nepal they do not observe this rule, except at their discretion. They have large monasteries, in which every one has a separate apartment or place of abode. They observe also particular festivals, the principal of which is called *Yatra* in their language, and continues a month or longer according to the pleasure of the king. The ceremony consists in drawing an idol, which at Lelit Pattan is called *Baghero*, in a large and richly ornamented car, covered with gilt copper: round about the idol stand the king and the principal Baryesus; and in this manner the vehicle is almost every day drawn thro' some one of the streets of the city by the inhabitants, who run about beating and playing upon every kind of instrument their country affords, which make an inconceivable noise.

The

The other religion, the more common of the two, is that of the Brahmens, and is the fame as is followed in Hindoftan, with the difference that, in the latter country, the Hindus being mixed with the Mahommedans, their religion alfo abounds with many prejudices, and is not ftrictly obferved; whereas in Nepal, where there are no Muffelmans (except one Cafhmirian merchant), the Hindu religion is practifed in its greateft purity: every day of the month they clafs under its proper name, when certain facrifices are to be performed and certain prayers offered up in their temples: the places of worfhip are more in number in their towns than are to be found in the moft populous and moft flourifhing cities of Chriftendom; many of them are magnificent according to their ideas of architecture, and conftructed at a very confiderable expence; fome of them have four or five fquare cupolas, and in fome of the temples two or three of the extreme cupolas, as well as the doors and windows of them, are decorated with gilt copper.

In the city of Lelit Pattan the temple of Baghero is more valuable, on account of the gold, filver, and jewels it contains, than even the houfe of the king. Befides the large temples, there are alfo many fmall ones, which have ftairs, by which a fingle perfon may afcend, on the outfide all around them; and fome of thofe fmall temples have four fides, others fix, with fmall ftone or marble pillars polifhed very fmooth, with two or three pyramidal ftories, and all their ornaments well gilt, and neatly worked according to their ideas of tafte. On the outfide of fome of their temples there are great fquare pillars of fingle ftones from twenty to thirty feet high, upon which they place their idols fuperbly gilt. The greateft number of their temples have a good ftone ftaircafe in the middle of the four fquares, and at the end of each flight of ftairs there are lines cut out of ftone on both fides: around about their temples there are alfo bells, which the people ring on particular occafions; and when they are at prayers, many cupolas are alfo quite filled with little bells hanging by cords in the infide about the diftance of a foot from each other, which make a great noife on that quarter where the wind conveys the found. There are not only fuperb temples in their great cities, but alfo within their caftles.

To the eaftward of Cat'hmandu, at the diftance of about two or three miles, there is a place called *Tolu*, by which there flows a fmall river, the water of which is efteemed holy, according to their fuperftitious ideas, and thither they carry people of high rank, when they are thought to be at the point of death: at this place there is a temple, which is not inferior to the beft and richeft in any of the capital cities. They alfo have it on tradition, that at two or three places in Nepal valuable treafures are concealed under ground: one of thofe places they believe is Tolu; but no one is permitted to make ufe of them except the king, and that only in cafes of neceffity. Thofe treafures, they fay, have been accumulated in this manner: When any temple had become very rich from the offerings of the people, it was deftroyed, and deep vaults dug under ground one above another, in which the gold, filver, gilt copper, jewels, and every thing of value, were depofited. This was found to be actually the cafe when the miffionary, from whofe memoir this account of Nepal is taken, was at Cat'hmandu. One of the kings, or pretenders to the crown, who were then at war with each other, being in the utmoft diftrefs for want of money to pay his troops, ordered the vaults at Tolu to be opened; and found in the firft vault more money, befides filver and gold idols, than he had immediate occafion for.

To the weftward alfo of the great city of Lelit Pattan, at the diftance of only three miles, is a caftle called *Banga*, in which there is a magnificent temple. No one of the miffionaries ever entered into this caftle; becaufe the people who have the care of it, have fuch a fcrupulous veneration for the temple, that no perfon is permitted to enter it with his fhoes on; and the miffionaries, unwilling to fhew fuch refpect to their falfe deities, never entered it. The author of this memoir, however, who acted as phyfician to the commandant, was of courfe admitted within the caftle, and got a fight of the celebrated temple, which he declares that for magnificence he believes fuperior to every thing in Europe.

Befides the magnificence of the temples, which their cities and towns contain, there are many other rarities. At Cat'hmandu, on one fide of the royal garden, there is a large fountain, in which is one of their idols called *Narayan*. This idol is of blue ftone, crowned and fleeping on a mattrafs alfo of the fame kind of ftone, and the idol and the mattrafs appear as floating upon the water. This ftone machine is very large, being about 18 or 20 feet long, and broad in proportion, but well worked, and in good repair.

In a wall of the royal palace of Cat'hmandu, which is built upon the court before the palace, there is a great ftone of a fingle piece, which is about fifteen feet long, and four or five feet thick; on the top of this great ftone there are four fquare holes at equal diftances from each other; in the infide of the wall they pour water into the holes; and in the court fide, each hole having a clofed canal, every perfon may draw water to drink. At the foot of the ftone is a large ladder, by which people afcend to drink; but the curiofity of the ftone confifts in its being quite covered with characters of different languages cut upon it. Some lines contain the characters of the language of the country, others the characters of Tibet, others Perfian, others Greek, befides feveral others of different nations; and in the middle there is a line of Roman characters, which appears in this form, AVTOMNEW INTER LHIVERT; but none of the inhabitants have any knowledge how they came there, nor do they know whether or not any European had ever been in Nepal before the miffionaries, who arrived there only the beginning of the prefent century. They are manifeftly two French names of feafons, with an Englifh word between them.

There is alfo to the northward of the city of Cat'hmandu a hill called *Simbi*, upon which are fome tombs of the Lamas of Tibet, and other people of high rank of the fame nation. The monuments are conftructed after various forms: two or three of them are pyramidal, very high, and well ornamented; fo that they have a very good appearance, and may be feen at a confiderable diftance. Round thefe monuments are remarkable ftones covered with characters, which probably are the infcriptions of fome of the inhabitants of Tibet, whofe bones were interred there. The natives of Nepal not only look upon the hill as facred, but imagine it is protected by their idols; and from this erroneous fuppofition never think of ftationing troops there for the

Newton. defence of it, although it be a poſt of great importance, and only at a ſhort mile's diſtance from the city. During the hoſtilities, however, which prevailed when our author was in the country, this ſacred hill was fortified by one of the armies, who, in digging their ditches among the tombs, found conſiderable pieces of gold, with a quantity of which metal the corpſes of the grandees of Tibet are always interred.

The kingdom of Nepal our author believes to be very ancient, becauſe it has always preſerved its peculiar language and independence. It was completely ruined, however, about thirty or forty years ago by the diſſenſions of its nobles, who, on the death of their ſovereign, and, as it would ſeem, the extinction of the royal line, could not agree in their choice of a proper ſucceſſor. The conſequence was, that different ſovereigns were ſet up by the nobles of different diſtricts; and theſe waged war with each other, with a degree of treachery and ſavage atrocity that has hardly a parallel in the annals of the world. Even the Brahmens, whom we are accuſtomed to conſider as a mild and innocent people, were, in the civil wars of Nepal, guilty of the meaneſt and baſeſt villanies: they brought about treaties between the rival ſovereigns, and then encouraged him whom they favoured, to maſſacre the adherents of the other in cold blood.

NEWTON (John), an eminent Engliſh mathematician, was born at Oundle in Northamptonſhire, 1622. After a proper foundation at ſchool, he was ſent to Oxford, where he was entered a commoner of St Edmund's Hall in 1637. He took the degree of bachelor of arts in 1641; and the year following was created maſter, among ſeveral gentlemen that belonged to the king and court, then reſiding in the univerſity. At which time, his genius being inclined to aſtronomy and the mathematics, he applied himſelf diligently to thoſe ſciences, and made a great proficiency in them, which he found of ſervice during the times of the uſurpation. After the reſtoration of Charles II. he reaped the fruits of his loyalty; being created doctor of divinity at Oxford Sept. 1661, he was made one of the king's chaplains, and rector of Roſs in Herefordſhire, in the place of Mr John Toombes, ejected for nonconformity. He held this living till his death, which happened at Roſs on Chriſtmas-day 1678. Mr Wood gives him the character of a capricious and humourſome perſon: however that may be, his writings are ſufficient monuments of his genius and ſkill in the mathematics. Theſe are, 1. *Aſtronomia Britannica*, &c. in three parts, 1656, in 4to. 2. Help to Calculation; with Tables of Declination, Aſcenſion, &c. 1657, 4to. 3. *Trigonometria Britannica*, in two books, 1658, folio; one compoſed by our author, and the other tranſlated from the Latin of Henry Gellibrand. 4. *Chiliades centum Logarithmorum*, printed with, 5. Geometrical Trigonometry, 1659. 6. Mathematical Elements, three parts, 1660, 4to. 7. A perpetual Diary or Almanack, 1662. 8. Deſcription of the uſe of the Carpenter's Rule, 1667. 9. Ephemerides, ſhewing the Intereſt and rate of Money at 6 *per cent.* &c. 1667. 10. *Chiliades centum Logarithmorum, et Tabula Partium proportionalium*, 1667. 11. The Rule of Intereſt, or the caſe of Decimal Fractions, &c. Part II. 1668, 8vo. 12. School Paſtime for young Children, &c. 1669, 8vo. 13. Art of practical Gauging, &c. 1669. 14. Introduction to the Art of Rhetoric, 1671. 15. The Art of Natural Arithmetic, in whole Numbers, and Fractions Vulgar and Decimal, 1671, 8vo. 16. The Engliſh Academy, 1677, 8vo. 17. Coſmography. 18. Introduction to Aſtronomy. 19. Introduction to Geography, 1678, 8vo *.

Nicole. * Biog. Dict. new edit.

NICOLE (Francis), a very celebrated French mathematician, was born at Paris December 23. 1683. His early attachment to the mathematics induced M. Montmort to take the charge of his education; and he opened out to him the way to the higher geometry. He firſt became publicly remarkable by detecting the fallacy of a pretended quadrature of the circle. This quadrature a M. Mathulon ſo aſſuredly thought he had diſcovered, that he depoſited, in the hands of a public notary at Lyons, the ſum of 3000 livres, to be paid to any perſon who, in the judgment of the Academy of Sciences, ſhould demonſtrate the falſity of his ſolution. M. Nicole, piqued at this challenge, undertook the taſk, and expoſing the paralogiſm, the Academy's judgment was, that Nicole had plainly proved that the rectilineal figure which Mathulon had given as equal to the circle, was not only unequal to it, but that it was even greater than the polygon of 32 ſides circumſcribed about the circle. The prize of 3000 livres Nichole preſented to the public hoſpital of Lyons.

The Academy named Nicole, Eleve-Mechanician, March 12. 1707; Adjunct in 1716, Aſſociate in 1718, and Penſioner in 1724; which he continued till his death, which happened the 18th of January 1758, at 75 years of age.

His works were all inſerted in the different volumes of the Memoirs of the Academy of Sciences; and are as follow: 1. A General Method for determining the Nature of Curves formed by the Rolling of other Curves upon any Given Curve; in the volume for the year 1707. 2. A General Method for Rectifying all Roulets upon Right and Circular Baſes, 1708. 3. General Method of determining the Nature of thoſe Curves which cut an Infinity of other Curves given in Poſition, cutting them always in a Conſtant Angle, 1715. 4. Solution of a Problem propoſed by M. de Lagny, 1716. 5. Treatiſe of the Calculus of Finite Differences, 1717. 6. Second Part of the Calculus of Finite Differences, 1723. 7. Second Section of ditto, 1723. 8. Addition to the two foregoing papers, 1724. 9. New Propoſition in Elementary Geometry, 1725. 10. New Solution of a Problem propoſed to the Engliſh Mathematicians, by the late M. Leibnitz, 1725. 11. Method of Summing an Infinity of New Series, which are not ſummable by any other known method, 1727. 12. Treatiſe of the Lines of the Third Order, or the Curves of the Second Kind, 1729. 13. Examination and Reſolution of ſome Queſtions relating to Play, 1730. 14. Method of determining the Chances at Play. 15. Obſervations upon the Conic Sections, 1731. 16. Manner of generating in a Solid Body all the Lines of the Third Order, 1731. 17. Manner of determining the Nature of Roulets formed upon the Convex Surface of a Sphere; and of determining which are Geometric and which are Rectifiable, 1732. 18. Solution of a Problem in Geometry, 1732. 19. The Uſe of Series in reſolving many Problems in the Inverſe Method of Tangents, 1737. 20. Obſervations on the Irreducible Caſe in Cubic Equations, 1738. 21. Obſervations upon Cubic Equations, 1738. 22. On the Triſection of

Nieuwland. an Angle, 1740. 23. On the Irreducible Case in Cubic Equations, 1741. 24. Addition to ditto, 1743. 25. His Last Paper upon the same, 1744. 26. Determination, by Incommensurables and Decimals, the Values of the Sides and Areas of the Series in a Double Progression of Regular Polygons, inscribed in and circumscribed about a Circle, 1747 *.

Hutton's Dictionary.

NIEUWLAND (Peter), professor of mathematics and natural philosophy in the university of Leyden, was born at Diemermeer, a village near Amsterdam, on the 5th of November, 1764. His father, by trade a carpenter, having a great fondness for books, and being tolerably well versed in the mathematics, instructed his son himself till he attained to his eleventh year. Young Nieuwland appears to have displayed strong marks of genius at a very early period. When about the age of three, his mother put into his hand some prints, which had fifty verses at the botom of them by way of explanation. These verses she read aloud, without any intention that her son should learn them; and she was much surprised some time after to hear him repeat the whole from memory, with the utmost correctness, on being only shewn the prints.

Before he was seven years of age he had read more than fifty different books, and in such a manner that he could frequently repeat passages from them both in prose and in verse. When about the age of eight, Mr Aeneæ at Amsterdam, one of the greatest calculators of the age, asked him if he could tell the solid contents of a wooden statue of Mercury which stood upon a piece of clock-work. "Yes (replied young Nieuwland), provided you give me a bit of the same wood of which the statue was made; for I will cut a cubic inch out of it, and then compare it with the statue." Poems which (says his eulogist) display the utmost liveliness of imagination, and which he composed in his tenth year, while walking or amusing himself near his father's house, were received with admiration, and inserted in different poetical collections.

Such an uncommon genius must soon burst through those obstacles which confine it. Bernardus and Jeronimo de Bosch, two of the first and wealthiest men at Amsterdam, became young Nieuwlands benefactors, and contributed very much to call forth his latent talents. He was taken into the house of the former in his eleventh year, and he received daily instruction from the latter for the space of four years. While in this situation he made considerable progress in the Latin and Greek languages, and he studied philosophy and the mathematics under Wyttenbach. In the year 1783 he translated the two dissertations of his celebrated instructors, Wyttenbach and de Bosch, on the opinions which the ancients entertained of the state of the soul after death, which had gained the prize of the Teylerian theological society.

From the month of September 1784 to 1785, Nieuwland resided at Leyden as a student in the university, and afterwards applied with great diligence, at Amsterdam, to natural philosophy and every branch of the mathematics, under the direction of Professor Van Swinden. He had scarcely begun to turn his attention to chemistry, when he made himself master of the theory of the much lamented Lavoisier, and could apply it to every phenomenon. He could read a work through with uncommon quickness, and yet retain in his mind the principal part of its contents. Nieuwland.

Nieuwland's attention was directed to three principal pursuits, which are seldom united; poetry, the pure mathematics, and natural philosophy. In the latter part of his life he added to these also astronomy. Among the poems which he published, his Orion alone has rendered his name immortal in Holland. Of the small essays which he published in his youth, the two following are particularly deserving of notice: 1. A comparative View of the Value of the different Branches of Science; and, 2. The best Means to render general, not learning, but Soundness of Judgment and Good Taste.

One of his great objects was to bring the pure mathematics nearer to perfection, to clear up and connect their different parts, and in particular to apply them to natural philosophy and astronomy. Cornelius Douwes discovered an easy method of determining the latitude of a place at sea, not by the meridian altitude of the sun, but by two observations made at any other period of the day. This method, however, being still imperfect, Nieuwland turned his thoughts towards the improvement of it, and in the beginning of the year 1789 wrote a paper on the subject, which he transmitted to M. de Lalande at Paris, from whom it met with great approbation. In the year 1792, when Nieuwland resided two months at Gotha with Major Von Zach, these two learned men often conversed on this method of finding the latitude, and calculated the result of observations which they had made with a sextant and an artificial horizon. The above paper, enlarged by these observations, was inserted by Major Von Zach with Nieuwland's name in the first Supplement to Bode's Astronomical Almanack, Berlin, 1793.

This, however, was not the only service which Nieuwland endeavoured to render to astronomy. It had been observed by Newton, Euler, De la Place, and others, that the axes of the planets do not stand perpendicular, but inclined, to the plane of their orbits; and Du Sejour, in his analytical treatise on the apparent motion of the heavenly bodies, considers it as highly probable that this phenomenon depends on some *physical* cause; which, however, he does not venture to assign. Nieuwland proceeded farther, and laid down principles, from which he drew this conclusion, that the above phenomenon is intimately connected with the whole system of attraction. On these principles he made calculations, the result of which was exactly equal to the angle of the inclination of the earth's axis to the plane of its orbit. Nieuwland communicated his discovery with much modesty to the celebrated Professor Damen at Leyden, who proposed some objections to it which discouraged Nieuwland, and induced him to revise his calculations with more accuracy. Major Von Zach transmitted the paper which contained them to M. De la Place at Paris, and caused it to be printed also, for the opinion of the learned, in the Supplement to Professor Bode's Astronomical Almanack for the year 1793.

The writer of this article is not acquainted either with the principles which this young astronomer assumed, or with the calculations which he made from them; but if he holds gravitation to be essential to matter, and the inclination of the axes of the planets to be the necessary result of the law of gravitation, he is undoubtedly

doubtedly in an error. The axes of the planets are not all equally inclined, nor does the inclination vary in exact proportion to the ſquares of the diſtances.

Nieuwland's talents and diligence ſoon recommended him to the notice of his country. In his twenty-ſecond year, he was appointed a member of the commiſſion choſen by the College of Admiralty at Amſterdam for determining the longitude and improving marine charts. On this labour he was employed eight years, and undertook alſo to prepare a nautical almanack, and to calculate the neceſſary tables. The mathematical part was in general entruſted to Nieuwland; but he aſſiſted alſo his two colleagues van Swinden and van Keulen, in the departments aſſigned to them, with ſuch aſſiduity, that moſt of the work publiſhed on the longitude, together with the three additional parts, were the fruits of his labour. In the ſecond edition of the explanation of the nautical almanack, he had alſo the principal ſhare; and he was the author, in particular, of the explanation of the equation of time, the method of determining the going of a time-piece, and of calculating the declination of the moon.

Soon after Nieuwland engaged in this employment, it appeared as if his deſtination was about to be changed. In the year 1787, he was choſen by the States of Utrecht to ſucceed Profeſſor Hennert; but on account of certain circumſtances this appointment did not take place. He was, however, invited to Amſterdam by the magiſtrates of that city, to give lectures on mathematics, aſtronomy, and navigation. While in this ſituation, he wrote his uſeful and excellent treatiſe on navigation, the firſt part of which was publiſhed at Amſterdam in 1793, by George Hulſt van Keulen; and it is much to be wiſhed that M. van Swinden would complete this work from the papers bequeathed to him by his deceaſed friend the author.

In aſtronomical purſuits, Nieuwland applied not only to the theoretical, but alſo to the practical part; and in this ſtudy he was encouraged and aſſiſted by Major von Zach, with whom he reſided ſome time in the courſe of the year 1792, and who inſtructed him in the proper uſe of the ſextant. This affectionate friend publiſhed alſo all his obſervations and calculations in the before-mentioned Supplement to Bode's Aſtronomical Almanack.

In the year 1789, Nieuwland was choſen member of a learned ſociety whoſe object was chemical experiments; and ſo apt was his genius for acquiring knowledge, that in a little time he made himſelf completely maſter of the theory of chemiſtry. A proof of this is the treatiſe which he read on the 24th of May 1791, in the ſociety, diſtinguiſhed by the motto of *Felix Meritis*, and which has been printed in the firſt part of the New General Magazine (*Niew Algemeen Magazyn*). At the ſame time he was able to examine the important diſcoveries made by the ſociety, to aſſiſt in preparing an account of them for the preſs, and to publiſh them with ſufficient accuracy in the French language. Three parts of this work appeared under the title of *Recherches Phyſico-chymiques*. The firſt part appeared in 1792, and was afterwards reprinted in the *Journal de Phyſique*. The ſecond was publiſhed in 1793, and the fourth in 1794. Some letters of his on chemiſtry may be found alſo in a periodical work called *The Meſſenger* (*Letterbode*).

This ingenious and diligent man was of great ſervice alſo in the philoſophical department to the above ſociety, *Felix Meritis*, of which he had been choſen a titular member on the 15th of January 1788, and an honorary member on the 15th of March 1791. The papers for which it was indebted to him are as follows:—1. On the Neweſt Diſcoveries in Aſtronomy, and the Progreſs lately made in that Science, 1788. This is an extract from a Latin oration which he intended to deliver at Utrecht when he expected to ſucceed Profeſſor Hennert.—2. On the Figure of the Earth, 1798.—3. On the Courſe of Comets, and the Uncertainty of the Return of the Comet now Expected, 1790.—4. On the Nature of the Mathematics. The principal object of this paper was to illuſtrate the idea, that the mathematics may be conſidered as a beautiful and perfect language.—5. On the Periodical Decreaſe or Increaſe in the Light of Certain Fixed Stars, and Particularly of the Star Algol, 1790.—6. On the Solution of Spherical Trigonometry by Means of a New Inſtrument Invented by Le Guin, 1791. M. le Guin having tranſmitted to the College of Admiralty at Amſterdam an inſtrument which might be uſed with great advantage in trigonometrical operations, and by which, in calculating the longitude, one could deduce the real from the apparent diſtance, the admiralty charged Nieuwland to examine this inſtrument; and he found that it might be of excellent ſervice for the above purpoſe.—7. On the Relative Value or Importance of the Sciences, 1791.—8. On the Syſtem of Lavoiſier, 1792.—9. On the Selenotopographia of Schröder, 1793.—10. On what is Commonly Called Cultivation, Inſtruction, or Enlightening, 1793.

Nieuwland had applied cloſely to the mathematics, aſtronomy, and navigation, for ſix years; during which time he made conſiderable improvements in nautical charts, and filled up his vacant hours with the ſtudy of philoſophy and chemiſtry. In the month of July 1793 he was invited to the univerſity of Leyden, to be profeſſor of philoſophy, aſtronomy, and the higher mathematics, in the room of the celebrated Damen; and the admiralty of Amſterdam requeſted him to continue his nautical reſearches, which he did with great aſſiduity till the period of his death. The only variation which he now made in his ſtudies related to natural philoſophy, for with the mathematics he was already ſufficiently acquainted. He applied therefore to the experimental part, and ſpared no pains nor labour to become perfect in it; which would certainly have been the caſe, had he not been ſnatched from ſcience and his friends at the early age of thirty. He died of an inflammation in his throat, accompanied with a fever, on the 13th of November 1794.

In his external appearance, Nieuwland was not what might be called handſome, nor had he ever been at pains to acquire that eaſe of deportment which diſtinguiſhes thoſe who have frequented polite company. His behaviour and converſation were however agreeable, becauſe he could diſcourſe with facility on ſo many ſubjects, and never wiſhed to appear but under his real character. On the firſt view one might have diſcerned that he was a man of great modeſty and the ſtricteſt morality. His father was a Lutheran, and his mother anabaptiſt; but he himſelf was a member of what is called the reformed church, *i. e.* a Calviniſt, and always ſhewed ed the utmoft refpect for the Supreme Being both by his words and his actions.

NIGER, a large river in Africa, of which many erroneous accounts have been publifhed, and among them that which we have given in the *Encyclopædia Britannica*. By Herodotus, Pliny, Ptolemy, and other ancient authors, it is uniformly faid to flow from *weft* to *eaft*, dividing Africa as the Danube divides Europe; and from the report of the Africans, the firft of thefe authors calls it a large river abounding with crocodiles. In the twelfth century, however, Edrifi defcribes the Niger, which he calls the Nile of the negroes, as running from *eaft* to *weft*, and falling into the Atlantic Ocean; and his account was univerfally adopted by fubfequent writers, till its falfehood was difcovered by the African Affociation. From a number of concurring reports, Major Houghton was led to believe that the courfe of the Niger is from *weft* to *eaft*, according to the moft ancient account; and the truth of thefe reports has been eftablifhed beyond all controverfy by Mr Park, who faw the Niger himfelf, and actually accompanied it for many miles in its majeftic courfe as laid down by Herodotus.

This river rifes in or near the country of MANDING (which fee in this *Supplement*), between the parallels of 10 and 11 degrees of north latitude, and between the 5th and 9th degree of weft longitude, which comprehends a fpace the moft elevated of all this portion of Africa. This is evident from the oppofite courfes of the three great rivers which rife in it. Thefe are the Gambia, which runs to the weft north-weft; the Senegal, which runs to the north-weft; and the Joilba (A), or Niger, running to the eaft north-eaft. The head of the principal branch of the Senegal river is about 80 geographical miles to the weft of that of the Niger; and the head of the Gambia is again about 100 miles weft of the Senegal.

Mr Park traced the Niger to Silla, a confiderable town about 420 miles from its fource; and it was there larger than the Thames at Weftminfter. But 420 miles are but a very fmall part of the courfe of the Niger, which doubtlefs receives many tributary ftreams before it reach Caffiana, 700 miles farther eaftward, where there is every reafon to believe that it was viewed by the ancient Romans. Our traveller collected at Silla what information he could from the Moorifh and Negro traders concerning the further courfe of this majeftic ftream, as well as of the kingdoms through which it runs; and the following notices he believes to be authentic:

Two fhort days journey to the eaftward of Silla, is the town of Jenne, which is fituated on a fmall ifland in the river; and is faid to contain a greater number of inhabitants than Sego itfelf, or any other town in Bambarra. (See SEGO, *Suppl.*) At the diftance of two days more, the river fpreads into a confiderable lake, called *Dibbie* (or the dark lake); concerning the extent of which, all the information which our author could obtain was, that in croffing it, from weft to eaft, the canoes lofe fight of land one whole day. From this lake, the water iffues in many different ftreams, which terminate in two large branches, one whereof flows towards the north-eaft, and the other to the eaft; but thefe branches join at Kabra, which is one day's journey to the fouthward of Tumbuctoo, and is the port or fhipping-place of that city. The tract of land which the two ftreams encircle, is called Jinbala, and is inhabited by negroes; and the whole diftance, by land, from Jenne to Tumbuctoo, is twelve days journey.

From Kabra, at the diftance of eleven days journey, down the ftream, the river paffes to the fouthward of Houffa, which is two days journey diftant from the river. Of the further progrefs of this great river, and its final exit, all the natives with whom Mr Park converfed feemed to be entirely ignorant. Their commercial purfuits feldom induce them to travel further than the cities of Tombuctoo and Houffa; and as the fole object of thofe journeys is the acquirement of wealth, they pay but little attention to the courfe of rivers, or the geography of countries. It is, however, highly probable that the Nigre affords a fafe and eafy communication between very remote nations. All our author's informants agreed, that many of the negro merchants who arrive at Tumbuctoo and Houffa, from the eaftward, fpeak a different language from that of Bambara, or any other kingdom with which they are acquainted. But even thefe merchants, it would feem, are ignorant of the termination of the river; for fuch of them as can fpeak Arabic, defcribe the amazing length of its courfe in very general terms, faying only, that they believe *it runs to the world's end*.

Major Rennel, by comparing a great many accounts of the progrefs of this river beyond Houffa, with the idea which prevails in that city of its termination, has fhewn it to be in a very high degree probable, that the waters of the Niger have no direct communication with the fea, but that they are fpread out into a great lake in Wangara and Ghana, and evaporated by the heat of the fun. See WANGARA in this *Supplement*.

NILE, the name of a celebrated river, which, as it has been defcribed in the *Encyclopædia*, fhould not have been introduced into this place, did we not think ourfelves bound candidly to confefs that, in our opinion, its fources, at leaft thofe fources which were the objects of ancient curiofity, have never yet been feen by any European. This feems to be proved, beyond the poffibility of controverfy, by Major Rennel in the Appendix to Mr Park's Travels, and by Mr Browne in his account of the *Bahr-el-abiad*, and *Dar-Fur* or *Soudan*. See SOUDAN in this *Supplement*.

Mr Bruce himfelf acknowledges that the Nile, which waters Egypt, is the confluence of two ftreams, and that the weftern ftream, which he, with others, calls *Bahr-el abiad*, or the *white river*, is the largeft of the two. Were a man therefore to travel from Cairo up the banks of the Nile in queft of its fource, he would, doubtlefs, when he fhould arrive at the divifion of the river into two channels, continue his journey up the greater of thefe; for what could induce him to turn afide with the lefs? Not the *name*; for neither the lefs nor the greater has by itfelf the name which, in Egypt, is given to both when united. The former, which undoubtedly has its fource in Abyffinia, is there called the Abay or Abavi; and, in other countries through which

(A) This is the negro name of the river, and fignifies the *great water*.

which it runs, the Bahr el-Afrek; the latter is, from its source to its junction with the Abay, called the Bahr-el-abiad. Pliny believed that the Nile came from the west; and Ptolemy says expressly that its remote source is in the *mountains of the moon*. But this Nile must be the White River, which certainly rises to the westward of Abyssinia, and, according to Abulfeda, in the mountains of Komri or Kummeri; which, in Arabic, signifies *lunar*, being the adjective of Kummer, the moon.

In perfect conformity with this ancient account of the source of the Nile, Mr Ledyard was told at Cairo by certain persons from Dar-Fur, that this celebrated river has its co; fountains in their country, at the distance of 55 days journey to the westward of Senaar, which brings them to the Komri mountains of Abulfeda, who, as well as Ptolemy and Edrisi, places the head of the Nile in a quarter far removed from Abyssinia. Ptolemy has indeed mentioned both branches; and while he describes the eastern in such a way as that it cannot be taken for any other than the Abyssinian branch, or the Nile of Bruce and the Portuguese Jesuits, speaks of a larger branch flowing from a more distant source, situated to the south-west. But this can be no other than Bruce's white river, the *Bahr-el-abiad* of Ledyard and Browne. It is true, there is an apparent difference in the account given by these two last mentioned travellers of the country in which the Bahr-el-abiad rises; but it is a difference only apparent. Ledyard was told at Cairo that it rises in Dar-Fur; Mr Browne, who resided long in Dar-Fur, was there told, that the sources of the river are near to a place called *Donga*, the residence of the chief or king of an idolatrous nation to the southward of Dar-Fur. It is to be observed, however, that the slave-merchants who trade between Donga and Cairo are always attached to the Soudan or Dar-Fur caravan; and that therefore the persons who told Ledyard that the Nile rises in their country were probably from Donga, though he took them for Furians from the name of their caravan. Mr Browne informs us that the country about Donga is very mountainous, and that in the spot where the river rises there are said to be forty distinct hills, which are called *Kumri*. From them issues a great number of springs, that, uniting into one great channel, form the Bahr-el-abiad, which suffers the same periodical increase and diminution as the Nile in Egypt. The people of Donga are quite naked, black, and, as we have already observed, idolaters. Major Rennel places the mountains of the moon between 5° 40′ and 8° 10′ N. Lat. and between 24° 30′ and 30° 25′ E. Long. Their latitude and longitude, as laid down by Mr Browne, are somewhat, tho' very little, different; whilst Geesh, the source of Bruce's Nile, lies between the 10th and 11th degree of N. Lat. and in about the 37th degree of E. Long.

NIMIQUAS, a nation, or, more properly, two tribes in South Africa, called by Vaillant the *Less* and *Greater* Nimiquas.

The country of the Less Nimiquas extends in longitude from the mountains of Camis to the sea on the west, *i. e.* from 15° 25′ to 18° 25′ east from London, and in latude from 28° 12′ to 29° 36′ south. From the information which our author could collect, he thinks that the number of inhabitants throughout the whole of this tract does not exceed 6000 souls. Even this number is annually diminished by the frequent attacks of Boshmen, and the aridity of the soil. Of the BOSHMEN we have already given such an account as can leave no doubt of the destructive nature of their incursions; and the soil must be arid indeed, if it be true, as Vaillant assures us, that in the country of the Less Nimiquas rain never falls except when it thunders, and that thunder is so rare as frequently not to be heard for the space of a whole year.

For this want of rain our author accounts in a satisfactory manner: "The country (he says) having neither forests nor lofty mountains to arrest the clouds, those which come from the north pass freely over it, and proceed on to Camis, where they burst and fall, either in rain in the valleys, or in snow on the summits of these mountains, which are the loftiest throughout the south of Africa." The country is of course not fruitful, and its sterility obliges the inhabitants frequently to change their residence, so that they are the most wandering of all the Hottentot tribes. In this barren region the Dutch colonists suppose that gold mines may be found; but our author discovered among the hordes no traces of this metal, though he found many indications of rich copper mines.

The Less Nimiquas, though of a tolerable stature, are not so tall as their neighbours to the eastward; and indeed Vaillant affirms, that the people to the east in the southern part of Africa are much superior to those of the west both in moral and physical qualities, while the animals are far inferior. The Less Nimiquas are great believers in witchcraft; and our author gives a ridiculous account of an interview that he had with an old witch named *Kakoes*, who had a complete ascendency, not only over the whole horde, but also over the savage Boshmen. These robbers, he says, never attempted to plunder the territory where she took up her residence; and she has been known, when their thefts came to her knowledge, to proceed alone, and unguarded, to their retreats in the midst of the woods, to threaten them with her vengeance, and thus compel them to a restitution of the stolen property. All her influence, however, over her own tribe, could procure for our author and his attendants only six sheep.

The women of the horde received his Hottentots with great kindness; and petmitted them to discover very singular charms, of which it is needless here to insert a description. Among this people he saw abundance of bracelets, necklaces, and ear-rings of copper; and some of these ornaments were so well made and finely polished, that they must have been manufactured in Europe, and the fruits of an intercourse with the whites. But he saw several others, which, from their grotesque shape and rude workmanship, evidently shewed that they were fabricated by the savages themselves.

"These ornaments (says he) are worn by the Nimiquas in the same manner as by the other savages; yet I observed among them some whimsical peculiarities. I have seen persons with six ear-rings of the same shape in one ear, and none in the other: I have seen some with bracelets from the wrist to the elbow on one arm, while the other arm was bare: I have seen others with one side of the face painted in compartments of various colours, while on the other side both the colours and figures were different. In general, I observed great propensity to ornaments among the Less Nimiquas; for

Nimiquas. for their kroffes and all their garments were plentifully covered with glafs and copper beads, ftrung on threads, and faftened on every part of their drefs. They even wore them in their hair, which was plaftered with greafe in the moft difgufting manner. Many had their heads covered with a reddifh incruftation, compofed of greafe and a powder refembling brick-duft, with which their hair was fo pafted together, that you would have fworn it to be a cap of red mortar. Thofe who had it in their power to difplay this luxury of drefs, were as proud as are our *petits-maitres*, when they can fhake a head loaded with powder, perfume, and pomatum. The *nuyp-kros*, or fhort apron, of the women, was adorned with rows of glafs-beads hanging down to their feet; in other refpects they were dreffed like the other Hottentots."

The country of the *Greater Nimiquas* is placed by the author in nearly the fame longitude with that of the Lefs, and between 25° and 28° fouth latitude. It is barren like the other; but the people are much taller, being generally about five feet ten inches high. The men are dull and ftupid, but the women are lively and extremely amorous; and both men and women are comparatively handfome and of a flender make. Extravagantly addicted to fmoking tobacco, the youg girls bartered their favours for a fingle pipe; and as Vaillant was chief of the caravan, a white, and poffeffor of tobacco of much better quality, many advances were made to him. "I have no doubt (fays he) but I might have formed, for a few pipefuls only, an alliance with every family in the horde. I was even preffed fo clofely, as to be obliged to employ fome refiftance: but, at the fame time, I muft confefs, that my refufals were given in fuch a way as not to offend; and they who, in confequence of their advances, had been expofed to them, having foon found other arrangements to make, did not fhew me the lefs friendfhip. I muft here add, that the girls alone appeared to me thus free; while the married women on the contrary were modeft and referved. This is a characteriftic difference, which diftinguifhes the Greater Nimiquas from the Hottentot people in general; as likewife does the low cringing air they affume when they have any thing to afk."

It has been faid by Kolben, that the Nimiqua women, when they bear twins, deftroy one of the infants; but Vaillant affures us that this is a falfehood, as is likewife another tale which is current in the colony. It has been faid that the fathers, to fhow what affection they bear their children, feed their eldeft in a particular manner, as being of right the firft object of paternal care. For this purpofe they put him in a coop as it were; that is, they fhut him up in a trench made under their hut, where, being deprived of motion, he lofes little by perfpiration, while they feed and cram him in a manner with milk and greafe. By degrees the child fattens and gets as round as a barrel; and when he is come to fuch a ftate as not to be able to walk, but to bend under his own weight, the parents exhibit him to the admiration of the horde; who from that period conceive more or lefs efteem and confideration for the family, according as the monfter has acquired more or lefs rotundity.

Such was the account given to our author by a man who affirmed that he had been an eye-witnefs of this mode of cramming the heir-apparent; but whenever any queftions were afked on the fubject of the Nimiquas themfelves, the perfons addreffed were ready to laugh in our author's face. "Still (fays he), as it appeared ftrange to me, that a man fhould talk of what he had feen, when he had in reality feen nothing; as it was poffible that the fable might have fome foundation, without being true in all particulars—I was willing to convince myfelf what could have given rife to it; and every time I vifited a horde, I took care, under different pretences, to examine, one after another, all the huts of the kraal, and to afk which was the eldeft child of the family: but I nowhere faw any thing that indicated either this pretended coop, or this pretended cramming."

Nimiquas ‖ Nizolius.

The Nimiquas are great cowards; yet, like the furrounding nations, they have their affagays and poifoned arrows; and, like them, can handle thefe arms with dexterity. They poffefs alfo thofe war oxen, fo formidable in battle, and fo favourable to the cowardice or inactivity of the combatants. They have even a peculiar implement of war, which their neighbours have not. This is a large buckler, of the height of the perfon who bears it, behind which the Nimiqua can completely conceal himfelf. But, befide that his natural apathy prevents him from giving or taking offence, he is in reality pufillanimous and cowardly from the coldnefs of his difpofition. To utter only the name of *Houzouana* before him is fufficient to make him tremble. See HOUZOUANAS in this *Suppl.*

Notwithftanding his frigidity, the Nimiqua is not infenfible to pleafure. He even feeks with avidity thofe which, acquiring but little exertion, are capable of agitating him and procuring agreeable fenfations. Their mufical inftruments are the fame as thofe of the other Hottentots; but their dancing is very different, and refembles the temper of the nation. If the countenance have received from nature features that can exprefs our paffions, the body alfo has its attitudes and movements that paint our temper and feelings. The dance of the Nimiqua is frigid like himfelf, and fo devoid of grace and hilarity, that, were it not for the extreme gaiety of the women, it might be called the dance of the dead.

Thefe tortoifes, to whom dancing is a fatigue, fhew little eagernefs for any thing but wagers; games of calculation and chance, and all the fedentary amufements which require patience and reflection, of which they are more capable than they are of motion. When our author, with great propriety, prohibited gaming in his camp, the Nimiquas, who had ftaid long with him, took their departure.

NITTA, a fpecies of the MIMOSA, which flourifhes on the banks of the Senegal in Africa. It is valuable to the inhabitants for its fruit, the pods of which are long and narrow, containing a few black feeds enveloped in a fine mealy powder, of a bright yellow colour, which refembles the flour of fulphur, and has a fweet mucilaginous tafte. When eaten by itfelf it is clammy; but when mixed with milk or water, it conftitutes a very pleafant and nourifhing food, fupplying the place of corn to the negroes.—*Park's Travels.*

NIZOLIUS (Marius), a grammarian of Italy, who by his wit and erudition contributed much to the promotion of letters in the 16th century. He publifhed, in 1553, *Lib.* 4. *De veris Principiis et vera Ratione philofo-*

philosophandi, contra Pseudo philosophos. In this work he attacks, with much vivacity, the schoolmen, not only for the barbarism of their terms, but for many ridiculous opinions which they held. Leibnitz was so struck with its solidity and elegance, that, to expose the obstinacy of those who were zealously attached to Aristotle, he gave a new edition of it, with critical notes of his own, 1670, in 4to. Nizolius published also *Thesaurus Ciceronianus, sive Apparatus Linguæ Latinæ e Scriptis Tullii Ciceronis collectus*, in folio. This is a good Latin dictionary, composed of the words and expressions of Cicero; to which, it seems, Nizolius shewed as much bigotry as the schoolmen to their notions; and fell under the character of those pedants whom Erasmus has ridiculed in his *Ciceronianus*. We do not find the year either of his birth or death.

Biog. Dictionary.

NOCTURNAL ARCH, is the arch of a circle described by the sun, or a star, in the night.

NONAGESIMAL, or NONAGESIMAL *Degree*, called also the *Mid heaven*, is the highest point, or 90th degree of the ecliptic, reckoned from its intersection with the horizon at any time; and its altitude is equal to the angle that the ecliptic makes with the horizon at their intersection, or equal to the distance of the zenith from the pole of the ecliptic. It is much used in the calculation of solar eclipses.

NONAGON, a figure having nine sides and angles. In a regular nonagon, or that whose angles and sides are all equal, if each side be 1, its area will be 6.1818242 $= \frac{9}{4}$ of the tangent of 70°, to the radius 1.

NORMAL, is used sometimes for a perpendicular.

NUEL, or NEWEL, the upright post about which stairs turn, being that part of the staircase which sustains one end of the steps.

O.

OASIS (plur. OASES), a fertile spot in the midst of a sandy desart. In the SAHARA, or Great Desart of Africa, there are many *Oases* of exreme fertility.

OBLATE, flatted or shortened; as an oblate spheroid, having its axis shorter than its middle diameter; being formed by the rotation of an ellipse about the shorter axis.

OBLIQUE ASCENSION, is that point of the equinoctial which rises with the centre of the sun, or star, or any other point of the heavens, in an oblique sphere.

OBLIQUE *Circle*, in the stereographic projection, is any circle that is oblique to the plane of projection.

OBLIQUE *Descension*, that point of the equinoctial which sets with the centre of the sun, or star, or other point of the heavens, in an oblique sphere.

OBLIQUE *Force*, or *Percussion*, or *Power*, or *Stroke*, is that made in a direction oblique to a body or plane. It is demonstrated, that the effect of such oblique force, &c. upon the body, is to an equal perpendicular one, as the sine of the angle of incidence is to radius.

OBLONG SPHEROID, is that which is formed by an ellipse revolved about its longer or transverse axis; in contradiction from the *oblate spheroid*, or that which is flatted at its poles, being generated by the revolution of the ellipse about its conjugate or shorter axis.

OBSERVATORY, PORTABLE. See ASTRONOMY, n° 504, *Encycl.*

OCCIDENT EQUINOCTIAL, that point of the horizon where the sun sets, when he crosses the equinoctial, or enters the sign Aries or Libra.

OCCIDENT *Estival*, that point of the horizon where the sun sets at his entrance into the sign Cancer, or in our summer when the days are longest.

OCCIDENT *Hybernal*, that point of the horizon where the sun sets at midwinter, when entering the sign Capricorn.

OCTANT, the eighth part of a circle.

ODD, in arithmetic, is said of a number that is not even. The series of odd numbers is 1, 3, 5, 7, &c.

ODDLY-ODD. A number is said to be oddly-odd, when an odd number measures it by an odd number. So 15 is a number oddly-odd, because the odd number 3 measures it by the odd number 5.

ODOUR, that quality of certain bodies which excites the sensation of smell. In the *Annales de Chimie*, Vol. XXI. p. 254, we have a detailed account of certain experiments made by M. Benedict Prevost of Geneva, with a view to render the *emanations of odorant bodies perceptible to sight*. The account is by much too long for a work like ours; especially as we feel not ourselves inclined to attribute to the experiments all the importance which seems to have been allowed to them by the first class of the French National Institute. We shall therefore state only a few of them, which seem most to favour the author's hypothesis.

1. A concrete odorant substance, laid upon a wet glass or broad saucer covered with a thin stratum of water, immediately causes the water to recede, so as to form a space of several inches around it.

2. Fragments of concrete odorant matter, or small morsels of paper or cork, impregnated with an odorant liquor, and wiped, being placed on the surface of water, are immediately moved by a very swift rotation. Romieu had made this observation on camphor, and erroneously attributed the effect to electricity. The motion was perceptible even in pieces of camphor of seven or eight gros.

3. An odorant liquor being poured on the water, stops the motion till it is dissipated by evaporation. Fixed oil arrests the motion for a much longer time,

Odour.

and until the pellicle it forms on the water is taken off.

4. When the furface of the water is cleaned by a leaf of metal, of paper, or of glafs, plunged in and withdrawn fucceffively until the pellicle is removed, the gyratory motion is renewed. If a piece of red wax or of taper be dipped in water, and the drops fhaken off into a glafs of water containing odorant bodies in motion, the movement will be ftopped. The fame effect is not produced by metal.

5. A morfel of camphor, plunged to the depth of three or four lines in water without floating, excites a movement of trepidation in the furrounding water, which repels fmall bodies in its vicinity, and carries them again to the camphor by ftarts. The author concludes, that an elaftic fluid efcapes from the odorant body in the manner of the fire of a fufee or the difcharge of fire-arms.

6. When there is a certain proportion between the height of the water and that of the fmall fragment of camphor, the water is brifkly driven off, returns again to the camphor, and again retires, as if by an explofion, the recoil of which often caufes the camphor to make part of a revolution on its axis.

7. Camphor evaporates thirty or forty times more fpeedily when placed upon water, than when entirely furrounded with air.

8. Camphor, during the act of diffipation in the air, preferves its form and its opaque whitenefs; upon water it is rounded, and becomes tranfparent as if it had undergone a kind of fufion. It may be inferred, that this arifes from the acquired motion, which caufes it to prefent a greater furface to the air.

9. When fmall pieces of camphor are plunged in water, the camphor becomes rounded and tranfparent, does not acquire any motion, and its diffipation is lefs perceptible than in the air. The concurrence of air and water is therefore neceffary to difengage the fluid which is the caufe of the motion and total diffipation of odorant bodies.

10. The motion of odorant bodies upon water decays and ceafes fpontaneoufly at the end of a certain time; becaufe the water having then contracted a ftrong fmell, the volatilization takes place in all the points of its furface; and the fmall mafs being thus furrounded by the odorant fluid, which is no longer air, diffolves, as in the ordinary odorant fluids, without forming the gafeous jet which is the caufe of the motion. The author compares the volatilization of the aromatic fubftance to a combuftion excited by water.

M. Prevoft hopes, that thefe, and other experiments which he explains, will contribute to the theory of odours, which fo nearly refembles that of the gafes. He does not flatter himfelf with having exhaufted this fubject, but confiders his difcoveries as the means of rendering odour perceptible by water, not only to the fight, but even to the touch, as are likewife the vibrations of fonorous bodies. Men deprived of the fenfe of fmell, and even the blind, according to him, may in this manner diftinguifh odorant bodies from thofe which have no fmell. "Perhaps (fays he) this kind of odorofcope may, by improvement, become an odorimeter. The exceptions, fuch for example as that of the cerumen of the ears, which produces much effect on water without being perceptibly odorant, and that of the fingers when hot or moift, are merely apparent; for if our fenfes do not in thofe cafes difcover odour, thofe of animals more powerfully energetic, fuch as the dog, perceive and diftinguifh individuals by its peculiar character. The odorofcope may afford the information which is wanting refpecting thefe effluvia. Thus it is that the fat of game, the fmell of which is nearly to us imperceptible, is very much fo to dogs, and exhibits fenfible marks by the odorofcope."

Profeffor Venturi of Modena, who heard Prevoft's memoir read in the National Inftitute, had himfelf made fome experiments with camphor kept feparately in the air, in the water, and at the furface of the water; whence he deduces, that the moft active virtue for diffolving camphor refides at that part where both the air and the water touch the camphor at the fame time. Hence he explains why, in like circumftances, camphor evaporates more quickly in a moift than in a dry air; and why the Hollanders ufe water in their procefs for fubliming this fubftance.

It might be thought that the camphor was decompofed at the furface of the water; that the water might feize the acidifying part, which renders the camphor concrete; and that the volatile part is diffipated in the atmofphere. The author rejects this notion. He thinks that water with camphor floating on its furface becomes charged with no more than a very fmall portion: 1. Becaufe in thefe circumftances the water acquires the fame tafte and fmell of camphor as it obtains when a fmall quantity of this fubftance is kept plunged in the fame fluid. This water, by expofure to the air, lofes the qualities with which it had been charged, and becomes infipid, and without fmell. 2. Becaufe when the water is faturated with all it can take up, the diffipation of the camphor continues at its furface as before. 3. Becaufe the aerial emanations of camphor made at the furface of water do themfelves cryftallize into camphor.

Camphor at the furface of the water does nothing, therefore, but diffolve; and when diffolved at the ordinary temperature of the atmofphere, it is not at firft in the ftate of vapour as has been thought. It is fimply a liquid which extends itfelf over the furface of water itfelf; and by this means coming into contact with a great furface of air, it is afterwards abforbed and evaporated. This is proved by the following facts: 1 The folution of camphor at the furface of water is more rapid in proportion to the extent of the furface. In narrow veffels, the fection of the column would not be completed in ten days, even though the water might be extremely pure. 2. When the column of camphor has projecting parts, the liquid may be feen iffuing by preference from certain points of the column, covering the furface of the water, and driving fmall floating bodies before it, in the fame manner as floating bodies go and return in a bafon into which the water of a canal enters with rapidity. 3. If a fmall piece of camphor, already wetted at one end, be brought near the edge of water contained in a broad faucer, and be made to touch the faucer itfelf, it depofits a vifible liquor, which is oily; and by attaching itfelf to the faucer, deftroys the adhefion between the veffel and the border of the water, fo that the water retires on account of the affinity of aggregation, which not being oppofed by the attraction of the faucer, caufes the water to terminate in a round edge.

edge. If you remove the piece of camphor, the water will not return to its place until the oily fluid is evaporated. 4. In the same manner, when the column of camphor is half immersed in the water, the oily liquor which issues forth destroys the adhesion of the water to the column, and produces a small surrounding cavity. The solution stops, or is retarded for a moment, until the fluid, extending itself over the water, becomes evaporated: the water then returns to its place, and touches the same part of the camphor; the solution begins again, and in this manner the process is effected by alternations of contact and apparent repulsion.

Of these memoirs by Prevost and Venturi, the English reader will find accurate and full translations in the first volume of *Nicholson's Philosophical Journal*, together with some judicious observations on them by the editor, which we shall take the liberty to adopt. "The philosophical consideration of odorant bodies is somewhat obscured by the old method of generalizing, or referring the properties of bodies to some distinct principle or thing supposed capable of being separated from the body itself. Thus the odours of bodies have been supposed to depend on a substance imagined in a loose way to be common to them all and separable from them. Hence the terms, principle of smell, spiritus rector, and even in the modern nomenclature we find *aroma*. There does not in effect seem to be any more reason to infer the existence of a common principle of smell than of taste. The smell of ammoniac is the action of that gas upon the organ of sense; and this odorant invisible matter is exhibited to the sight when combined with an acid gas. But in the same manner as ammoniac emanates from water, and leaves most part of that fluid behind, so will the volatile parts of bodies be most eminently productive of this action; and very few, if any, natural bodies will be found which rise totally. The most striking circumstance in the effect is, that an act of such power should be attended with a loss by exhalation which is scarcely to be appreciated by weight, or in any other method during a short interval of time. But we know so little of nervous action, and of other phenomena of electricity, of galvanism (See Galvanism in this *Suppl.*), or even of heat, which strongly affect the senses, but elude admeasurement by gravitation, that the difficulty of weighing the effluvia of odorant bodies becomes less astonishing."

ŒCONOMISTS, a sect of philosophers in France, who have made a great noise in Europe, and are generally believed to have been unfriendly to religion. The founder of this sect was a *Dr Duquesnai*, who had so well insinuated himself into the favour of Louis XV. that the king used to call him his *thinker*. The sect was called *œconomists*, because the œconomy and order to be introduced into the finances, and other means of alleviating the distresses of the people, were perpetually in their mouths. The Abbé Barruel admits, that there may have been some few of them who directed their speculations to no other object; but he brings very sufficient proof that the great aim of the majority of the sect was to eradicate from the minds of the people all reverence for divine revelation.

"Duquesnai (says he) and his adepts had more especially undertaken to persuade their readers, that the country people, and mechanics in towns, were entirely destitute of that kind of instruction necessary for their professions; that men of this class, unable to acquire knowledge by reading, pined away in an ignorance equally fatal to themselves and to the state; that it was necessary to establish free schools, and particularly throughout the country, where children might be brought up to different trades, and instructed in the principles of agriculture. D'Alembert, and the Voltairean adepts, soon perceived the advantages they could reap from these establishments. In union with the œconomists, they presented various memorials to Louis XV. in which not only the temporal but even the spiritual advantages of such establishments for the people are strongly urged. The king, who really loved the people, embraced the project with warmth. He opened his mind on the subject to Mr Bertin, whom he honoured with his confidence, and had entrusted with his privy purse;" and it was with great difficulty that this minister could convince him of the dangerous designs of the sect.

"Determined (says he) to give the king positive proof that the œconomists imposed upon him, I sought to gain the confidence of those pedlars who travel through the country, and expose their goods to sale in the villages, and at the gates of country seats. I suspected those in particular who dealt in books to be nothing less than the agents of philosophism with the good country folks. In my excursions into the country I fixed my attention above all on the latter. When they offered me a book to buy, I questioned them what might be the books they had? Probably catechisms or prayer-books? Few others are read in the villages? At these words I have seen many smile. No, they answered, those are not our works; we make much more money of Voltaire, Diderot, and other philosophic writings. What! said I; the country people buy Voltaire and Diderot? Where do they find the money for such dear works? Their constant answer was, we have them at a much cheaper rate than prayer-books; we can sell them at ten sols (5d.) a volume, and have a pretty profit into the bargain. Questioning some of them still farther, many of them owned that those books cost them nothing; that they received whole bales of them without knowing whence they came, but being simply desired to sell them in their journeys at the lowest price.

"Louis XV. warned by the discovery made by his minister, was at length satisfied that the establishment of these schools, so much urged by the conspirators, would only be a new instrument of seduction in their hands. He abandoned the plan; but, perpetually harassed by the protecting sophisters, he did not strike at the root of the evil, and but feebly impeded its progress. The pedlars continued to promote the measures of the conspirators; yet this was but one of the inferior means employed to supply the want of their free schools, as a new discovery brought to light one far more fatal.

"About the middle of the month of September 1789, little more than a fortnight antecedent to the atrocious 5th and 6th of October, at a time when the conduct of the National Assembly, having thrown the people into all the horrors of a revolution, indicated that they would set no bounds to their pretensions, Mr Le Roy, lieutenant of the King's hunt, and an academician, being at dinner at the house of Mr D'Angevilliers, intendant of the buildings of his majesty, the conver-

Œconomists.

conversation turned on the disasters of the revolution, and on those that were too clearly to be foreseen. Dinner over, the nobleman above-mentioned, a friend of Le Roy, hurt at having seen him so great an admirer of the sophisters, reproached him with it in the following expressive words : *Well! this, then, is the work of Philosophy!* Thunderstruck at these words—Alas ! cried the academician, *to whom do you say so? I know it but too well, and I shall die of grief and remorse!* At the word *remorse*, the same nobleman questioned him whether he had so greatly contributed towards the revolution as to upbraid himself with it in that violent manner? ' Yes (answered he), I have contributed to it, and far more than I was aware of. I was secretary to the committee to which you are indebted for it ; but I call heaven to witness, that I never thought it would go to such lengths. You have seen me in the king's service, and you know that I love his person. I little thought of bringing his subjects to this pitch, *and I shall die of grief and remorse!*'

" Pressed to explain what he meant by this committee, this secret society, entirely new to the whole company, the academician resumed : ' This society was a sort of club that we philosophers had formed among us, and only admitted into it persons on whom we could perfectly rely. Our sittings were regularly held at the Baron D'Holbach's. Lest our object should be surmised, we called ourselves œconomists. We created Voltaire, though absent, our honorary and perpetual president. Our principal members were D'Alembert, Turgot, Condorcet, Diderot, La Harpe, and that Lamoignon, keeper of the seals, who on his dismission shot himself in his park.'

" The whole of this declaration was accompanied with tears and sighs ; when the adept, deeply penitent, continued : ' The following were our occupations; the most of those works which have appeared for this long time past, against religion, morals, and government, were ours, or those of authors devoted to us. They were all composed by the members or by the orders of the society. Before they were sent to the press, they were delivered in at our office. There we revised and corrected them ; added to, or curtailed them, according as circumstances required. When our philosophy was too glaring for the times, or for the object of the work, we brought it to a lower tint ; and when we thought that we might be more daring than the author, we spoke more openly. In a word, we made our writers say exactly what we pleased. Then the work was published under the title or name we had chosen, the better to hide the hand whence it came. Many, supposed to have been posthumous works, such as *Christianity Unmasked*, and divers others *attributed to Freret and Boulanger* after their deaths, were issued from our society.

' When we had approved of those works, we began by printing them on fine or ordinary paper, in sufficient number to pay our expences, and then an immense number on the commonest paper. These latter we sent to hawkers and booksellers free of cost, or nearly so, who were to circulate them among the people at the lowest rate. These were the means used to pervert the people, and bring them to the state you now see them in. I shall not see them long, *for I shall die of grief and remorse!*'

Oil.

This recital is too well authenticated to be called in question, and too plain to need a commentary. Let it be a warning against all secret societies, by whatever title of benevolence they may be designed by those who form them.

OIL-MILL, a mill for expressing the oils from fruits, or grains, &c. As these kingdoms do not produce the olive, it would be needless to describe the mills which are employed in the southern parts of Europe. We shall content ourselves, therefore, with a description of a Dutch oil-mill, employed for grinding and pressing lintseed, rape-seed, and other oleaginous grains. Farther, to accommodate our description still more to our local circumstances, we shall employ water as the first mover ; thus avoiding the enormous expence and complication of a windmill.

In Plate XXXVIII. fig. A,

1. Is the elevation of a wheel, over or undershot, as the situation may require.

2. The bell-metal socket, supported by masonry, for receiving the outer gudgeon of the water-wheel.

3. The water course.

Fig. B.

1. A spur wheel upon the same axis, having 52 teeth.

2. The trundle that is driven by N° 1. and has 78 staves.

3. The *wallower*, or axis for raising the pestles. It is furnished round its circumference with *wipers* for lifting the *pestles*, so that each may fall twice during one turn of the water wheel, that is, three *wipers* for each pestle.

4. A frame of timber, carrying a concave half cylinder of bell-metal, in which the wallower (cased in that part with iron plates) rests and turns round. It will be seen in profile, fig. G.

5. Masonry supporting the inner gudgeon of the water wheel and the above-mentioned frame.

6. Gudgeon of the wallower, which bears against a bell-metal step fixed in the wall. This double support of the wallower is found to be necessary in all mills which drive a number of heavy stampers.

Fig. C, Is the elevation of the pestle and press-frame, their furniture, the mortars, and the press-pestles.

1. The six pestles.

2. Cross pieces between the two rails of the frame, forming, with these rails, guides for the perpendicular motion of the pestles.

3. The two rails. The back one is not seen. They are checked and bolted into the standards N° 12.

4. The tails of the *lifts*, corresponding to the wipers upon the wallower.

5. Another rail in front, for carrying the *detents* which hold up the pestles when not acting. It is marked 14 in fig. M.

6. A beam a little way behind the pestles. To this are fixed the pulleys for the ropes which lift and stop the pestles. It is represented by 16 in fig. M.

7. The said pulleys with their ropes.

8. The *driver*, which strikes the wedge that presses the oil.

9. The *dischaarger*, a stamper which strikes upon the inverted wedge, and loosens the press.

 10.

10. The lower rail with its crofs pieces, forming the lower guides of the peftles.

11. A fmall cog-wheel upon the wallower, for turning the *fpatula*, which ftirs about the oil-feed in the *chauffer-pan*. It has 28 teeth, and is marked N° 6. in fig. M.

12. The four ftandards, mortifed below into the *block*, and above into the joifts and beams of the building.

13. The fix *mortars* hollowed out of the block itfelf, and in fhape pretty much like a kitchen pot.

14. The feet of the peftles, rounded into cylinders, and fhod with a great lump of iron.

15. A board behind the peftles, ftanding on its edge, but inclining a little backwards. There is fuch another in front, but not reprefented here. Thefe form a fort of trough, which prevents the feed from being fcattered about by the fall of the peftles, and loft.

16. The firft *prefs-box* (alfo hollowed out of the block), in which the grain is fqueezed, after it has come for the firft time from below the milftones.

17. The fecond *prefs-box*, at the other end of the block, for fqueezing the grain after it has paffed a fecond time under the peftles.

18. Frame of timber for fupporting the other end of the wallower, in the fame manner as at N° 4. fig. B.

19. Small cog-wheel on the end of the wallower for giving motion to the milftones. It has 28 teeth.

20. Gudgeon of the wallower, bearing on a bell metal focket fixed in the wall.

21. Veffels for receiving the oil from the prefs-boxes.

22. Joifts fupporting the block.

Fig. D. Elevation and mechanifm of the milftones.

1. *Upright fhaft*, carrying the great cog-wheel above, and the *runner milftones* below in their frame.

2. Cog-wheel of 76 cogs, driven by N° 19. of fig. C.

3. The frame of the *runners*. This will be more diftinctly underftood in N° 4. fig. H.

4. The innermoft runner, or the one neareft the fhaft.

5. Outermoft ditto, being farther from the fhaft.

6. The *inner rake*, which collects the grain under the outer runner.

7. The *outer rake*, which collects the grain under the inner runner. In this manner the grain is always turned over and over, and crufhed in every direction. The inner rake lays the grain in a flope, of which fig. O. is a fection; the runner flattens it, and the fecond rake lifts it again, as is marked in fig. P; fo that every fide of a grain is prefented to the milftone, and the reft of the *legger* or *nether milftone* is fo fwept by them, that not a fingle grain is left on any part of it. The outer rake is alfo furnifhed with a rag of cloth, which rubs againft the border or hoop that furrounds the nether milftone, fo as to drag out the few grains which might otherwife remain in the corner.

8. The ends of the iron axle which paffes through the upright fhaft, and through the two runners. Thus they have two motions: 1*mo*, A rotation round their own axis. 2*do*, That by which they are carried round upon the nether milftone on which they roll. The holes in thefe milftones are made a little widifh; and the holes in the ears of the frame, which carry the ends of the iron axis, are made oval up and down. This great freedom of motion is neceffary for the runner milftones, becaufe frequently more or lefs of the grain is below them at a time, and they muft therefore be at liberty to get over it without ftraining, and perhaps breaking, the fhaft.

9. The ears of the frame which lead the two extremities of the iron axis. They are mortifed into the under fide of the bars of the fquare frame that is carried round with the fhaft.

10. The border or hoop which furrounds the nether milftone.

11. and 12. The nether milftone and mafonry which fupports it.

Fig. E. Form of the wallower, fhewing the difpofition of the wipers along its furface.

1. Two parts of this fhaft, which are nicely rounded, and fortified with iron plates, and which reft upon the bell-metal concaves, which are reprefented in n° 4. of fig. C.

2. The little wheels at each end, for giving motion to the two fpatulæ, marked n° 11. fig. C.

3. The wipers for the fecond prefs.

4. The wipers for the firft prefs.

5. The wipers for the fix peftles.

Fig. F. Reprefents the furface of the wallower unfolded into a rectangular parallelogram, in order to fhew the diftribution of the wipers, and confequently the fucceffion of the ftrokes given by the different peftles. This diftribution has fomething peculiar. Each peftle has three wipers; and there are alfo three for the driver and difcharger of the fecond prefs. The driver and wiper of the firft prefs have but one and a half; one for the driver, and the half for the difcharger; fo that it ftrikes twice, and the driver only once, in a turn of the fhaft. This is the Dutch practice, which differs from that of Flanders. The fucceffion of the ftrokes may be conceived as follows: Reckon the ftampers, including thofe of the preffes, from the water-wheel toward the other end of the wallower, and calling them *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, *k*, and fuppofing that *a* makes the firft ftroke, they proceed in the following order for one turn of the wallower:

ab, *d*, *f*, *h*, *c*, *e*, *g*, *ab*, *d*, *f*, *h*, *c*, *e*, *g*, *ab*, *d*, *f*, *h*, *c*, *e*, *g*.

Here it may be obferved that *a* and *b* ftrike together. They would do fo if allowed; but one of them is held up by its detent till the workman fees proper to difengage it. Each peftle, and the driver and difcharger of the fecond prefs, makes three ftrokes for one turn of the wallower. But the driver *k* of the firft prefs makes only one ftroke in that time, namely, in the interval between the laft ftrokes of *e* and *g*. The difcharger *i* of this prefs makes two ftrokes; one of them in this fame interval, and the other along with the firft ftroke of *e*. The fecond preffing requires a much more violent preffure than the firft, becaufe the cake muft be left perfectly dry and hard.

Fig. G, Profile of the frame of timber which carries the wallower, and greatly contributes to render its motion fteady.

Fig. H. Is a view of one of the milftones.

1. The nether milftones, and the mafonry fupporting the whole.

2. The runner.

3. A

Oil.

3. A ſort of caſe which encloſes the two wings of the milſtone at a very ſmall diſtance from it, in order to prevent the grain which ſticks to it from being ſcattered. There is another method practiſed at ſome mills.

Fig. I. Repreſents that of Sardamm. AA are two iron rods, about half an inch ſquare, hanging on the axle, on each ſide of the milſtone. Theſe rods are joined by a croſs piece C, which almoſt touches the milſtone. A piece of leather is put between, which rubs upon the milſtone, and clears it of the grain which chances to ſtick to it. N° 4. and 6. repreſent the ears of this frame, by which the end of the iron axle is ſupported, and carried round by the upright ſhaft n° 5.

Fig. K. Plan of the runner milſtones, and the frame which carries them round.

1, 1. Are the two milſtones.

3, 3, 3, 3. The outſide pieces of the frame.

4, 4, 4, 4. The croſs bars of the frame which embrace the upright ſhaft 5, and give motion to the whole.

6, 6. The iron axis upon which the runners turn.

7. The outer rake.

8. The inner ditto.

Fig. L. Repreſents the nether milſtone ſeen from above.

1. The wooden gutter, which ſurrounds the nether milſtone.

2. The border or hoop, about ſix inches high, all round, to prevent any ſeed from being ſcattered.

3. An opening or trap-door in the gutter, which can be opened or ſhut at pleaſure. When open, it allows the bruiſed grain, collected in and ſhoved along the gutter by the rakes, to paſs through into troughs placed below to receive it.

4. Portion of the circle deſcribed by the outer runner.

5. Portion of the circle deſcribed by the inner one. By theſe we ſee that the two ſtones have different routes round the axis, and bruiſe more ſeed.

6. The outer rake.

7. The inner ditto.

8. The ſweep, making part of the inner rake, occaſionally let down for ſweeping off all the ſeed when it has been ſufficiently bruiſed. The preſſure and action of theſe rakes is adjuſted by means of wooden ſprings, which cannot be eaſily and diſtinctly repreſented by any figure. The oblique poſition of the rakes (the outer point going foremoſt) cauſes them to ſhove the grain inwards or toward the centre, and at the ſame time to turn it over, ſomewhat in the ſame manner as the mould-board of a plough ſhoves the earth to the right hand, and partly turns it over. Some mills have but one ſweeper; and indeed there is great variety in the form and conſtruction of this part of the machinery.

Fig. M. Profile of the peſtle frame.

1. Section of the horizontal ſhaft.

2. Three wipers for lifting the peſtles.

3. Little wheel of 28 teeth for giving motion to the ſpatula.

4. Another wheel, which is driven by it, having 20 teeth.

5. Horizontal axle of ditto.

6. Another wheel on the ſame axle, having 13 teeth.

7. A wheel upon the upper end of the ſpindle, having 12 teeth.

8. Two guides, in which the ſpindle turns freely, and ſo that it can be ſhifted higher and lower.

9. A lever, moveable round the piece n° 14. and having a hole in it at 9, through which the ſpindle paſſes, turning freely. The ſpindle has in this place a ſhoulder, which reſts on the border of the hole 9; ſo that by the motion of this lever the ſpindle may be diſengaged from the wheel-work at pleaſure. This motion is given to it by means of the lever 10, 10, moveable round its middle. The workman employed at the chauffer pulls at the rope 10, 11, and thus diſengages the ſpindle and ſpatula.

11. A peſtle ſeen ſidewiſe.

12. The *lift* of ditto.

13. The upper rails, marked n° 3. in fig. C.

14. The rail, marked n° 5. in fig. C. To this are fixed the detents, which ſerve to ſtop and hold up the peſtles.

15. A detent, which is moved by the rope at its outer end.

16. A bracket behind the peſtles, having a pulley, through which paſſes the rope going to the detent 15.

17. The ſaid pulley.

18. The rope at the workman's hand, paſſing through the pulley 17, and fixed to the end of the detent 15.

This detent naturally hangs perpendicular by its own weight. When the workman wants to ſtop a peſtle, he pulls at the rope 18, during the riſe of the peſtle. When this is at its greateſt height, the detent is horizontal, and prevents the peſtle from falling by means of a pin projecting from the ſide of the peſtle, which reſts upon the detent, the detent itſelf being held in that poſition by hitching the loop of the rope upon a pin at the workman's hand.

19. The two lower rails, marked n° 10. fig. C.

20. *Great* wooden, and ſometimes ſtone, *block*, in which the mortars are formed, marked n° 21. in fig. C.

21. Veſſel placed below the preſs boxes for receiving the oil.

22. Chauffer, or little furnace, for warming the bruiſed grain.
