23. Backet in the front of the chauffer, tapering downwards, and opening below in a narrow ſlit. The hair bags, in which the grain is to be preſſed after it has been warmed in the chauffer, are filled by placing them in this backet. The grain is lifted out of the chauffer with a ladle, and put into theſe bags; and a good quantity of oil runs from it through the ſlit at the bottom into a veſſel ſet to receive it.

24. The ſpatula attached to the lower end of the ſpindle, and turning round among the grain in the chauffer-pan, and thus preventing it from ſticking to the bottom or ſides, and getting too much heat.

Fig. N, Plan of part of the works.

1, 1. Furnaces for warming the grain.

2, 2. The backets for holding the ſacks while they are a-filling.

3, 3. The pan in which the bruiſed grain is heated by the chauffer.

4, 4. A trough for receiving the chips, into which the preſſed oil-cakes are cut, to be afterwards put into the pan and warmed.

5. The preſs-box for the ſecond preſſing.

6. The preſs-box for the firſt preſſing.

7. The ſix mortars.

8. The ſloping boards, to hinder the ſcattering of the oil ſeed.

9. The

9. The nether milftone, but out of its place.

10. Its centre a little higher than the reft.

11. A rib of wood going round the edge of the nether milftone, and even with its furface, but rifing a very little outwards, and furrounded with a border or hoop about an inch high, to prevent the feed from being fcattered on the ground.

Fig. Q. A fection lengthwife of the great block, with the mortars and prefs-boxes.

1. The fix peftles.

2. The fix mortars, each of which has an iron plate at its bottom.

3. The *driving* ftamper, which falls on the wedge of the firft preffing.

4. Ditto, for the fecond ditto.

5. The *difcharger*, which ftrikes on the inverted wedge in order to free the prefs.

6. Ditto, for the fecond preffing.

7. Wedge for freeing the prefs.

8. Wedge for preffing.

9. Wooden *cheeks*, two inches thick, which are placed between the middle wedge and the *fliding wedges* on each fide.

10. Prefs-irons, between which are placed the hair-bags containing the bruifed grain.

11. Iron plate, called the *fountain*, at the bottom, pierced with holes, correfponding with a hole in the block, for allowing the oil to run off from the preffed grain.

12. Veffel for receiving ditto.

13. A long iron plate at the bottom of the prefs box, under the drawing and difcharging wedges.

Fig. R. Another view of the prefs-irons.

1. The fide-irons laid flat.

2. The fame feen edgewife.

3. The pierced iron plate, upon which the two irons, n° 1. ftand upright, with the hair-bag between them.

4. One of the hair-bags. It may be obferved that the feams of thefe bags are made on the flat fides, and not on the edges, where they would be in danger of burfting.

5. A long hair-cloth, in which the bag is wrapped before it is fet into the prefs. The bag, being filled with bruifed grain, is placed with its bottom at *a*, and the top at *b*; the part *c a* is lapped over it, reaching to *b*, and then the other end *d* is lapped over that, and reaches to *a*, and the loop at its end ferves as a handle by which to lift it, and place it properly between the prefs-irons.

Fig. S. The principal pieces of the prefs.

1. The wooden cheeks.

2. The difcharging wedge.

3. The driving wedge.

4 and 5. The fliding blocks, which tranfmit the preffure produced by the driving wedge.

The foregoing enumeration and views of the different parts of a Dutch oil mill, are fufficient, we imagine, to enable an intelligent mill-wright, to whom the machine is altogether new, to underftand its manner of working, and its adaptation to the various parts of the procefs for extracting the oil from feeds or kernels. It would require a very minute defcription indeed to explain it to a perfon altogether unacquainted with mill-work.

The firft part of the procefs is bruifing the feed under the runner ftones (A). That this may be more expeditioufly done, one of the runners is fet about ⅔ds of its own thicknefs nearer the fhaft than the other. Thus they have different treads; and the grain, which is a little heaped towards the centre, is thus bruifed by both. The inner rake gathers it up under the outer ftone into a ridge, of which the fection is reprefented in Plate XL. fig. O. The ftone paffes over it, and flattens it. It is gathered up again into a ridge, of the form of fig. P. under the inner ftone, by the outer rake, which confifts of two parts. The outer part preffes clofe on the wooden border which furrounds the nether ftone, and fhoves the feed obliquely inwards, while the inner part of this rake gathers up what had fpread toward the centre. The other rake has a joint near the middle of its length, by which the outer half of it can be raifed from the nether ftone, while the inner half continues preffing on it, and thus fcrapes off the moift pafte. When the feed is fufficiently bruifed, the miller lets down the outer end of the rake. This immediately gathers the whole pafte, and fhoves it obliquely outwards to the wooden rim, where it is at laft brought to a part that is left unboarded, and it falls through into troughs placed to receive it. Thefe troughs have holes in the bottom, through which the oil drips all the time of the operation. This part of the oil is directed into a particular ciftern, being confidered as the pureft of the whole, having been obtained, without preffure, by the mere breaking of the hull of the feed.

In fome mills this operation is expedited, and a much greater quantity of this beft oil is obtained, by having the bed of mafonry which fupports the legger formed into a little furnace, and gently heated. But the utmoft care is neceffary to prevent the heat from becoming confiderable. This, enabling the oil to diffolve more of the fermentable fubftance of the feed, expofes the oil to the rifk of growing foon very rancid; and, in general, it is thought a hazardous practice, and the oil does not bring fo high a price.

When the pafte comes from under the ftones, it is put into the hair bags, and fubjected to the firft preffing. The oil thus obtained is alfo efteemed as of the firft quality, fcarcely inferior to the former, and is kept apart. (The great oil ciftern being divided into feveral portions by partitions.)

The oil cakes of this preffing are taken out of the bags, broken to pieces, and put into the mortars for the firft *ftamping*. Here the pafte is again broken down, and the parenchyma of the feed reduced to a fine meal. Thus free egrefs is allowed to the oil from every veficle in which it was contained. But it is now rendered much more clammy, by the forcible mixture of the mucilage,

(A) We are told that, in a mill at Reichenhoffen in Alface, a confiderable improvement has been made by paffing the feed between two fmall iron rollers, before it is put under the milftones. A great deal of work is faid to be faved by this preliminary operation, and finer oil produced, which we think very probable. The ftamping and preffing go on as in other mills.

cilage, and even of the finer parts of the meal. When sufficiently pounded, the workman ftops the peftle of a mortar, when at the top of its lift, and carries the contents of the mortar to the firft chauffer pan, where it is heated to about the temperature of melting bees wax (this, we are told, is the teft), and all the while ftirred about by the fpatula. From thence it is again put into hair bags, in the manner already defcribed; and the oil which drips from it during this operation is confidered as the beft of the fecond quality, and in fome mills is kept apart. The pafte is now fubjected to the fecond preffing, and the oil is that of the fecond quality.

All this operation of pounding and heating is performed by one workman, who has conftant employment by taking the four mortars in fucceffion. The putting into the bags and conducting of the preffing gives equal employment to another workman.

In the mills of Piccardy, Alface, and moft of Flanders, the operation ends here; and the produce from the chauffer is increafed, by putting a fpoonful or two of water into the pan among the pafte.

But the Dutch take more pains. They add no water to the pafte of this their *firft ftamping*. They fay that this greatly lowers the quality of the oil. The cakes which refult from this preffing, and are there fold as food for cattle, are ftill fat and foftifh. The Dutch break them down, and fubject them to the peftles for the *fecond ftamping*. Thefe reduce them to an impalpable pafte, ftiff like clay. It is lifted out, and put into the *fecond* chauffer pan; a few fpoonfuls of water are added, and the whole kept for fome time as hot as boiling water, and carefully ftirred all the while. From thence it is lifted into the hair bags of the laft prefs, fubjected to the prefs; and a quantity of oil, of the loweft quality, is obtained, fufficient for giving a fatisfactory profit to the miller. The cake is now perfectly dry, and hard, like a piece of board, and is fold to the farmers. Nay, there are fmall mills in Holland, which have no other employment than extracting the oil from the cakes which they purchafe from the French and Brabanters; a clear indication of the fuperiority of the Dutch practice.

The nicety with which that induftrious people conduct all their bufinefs is remarkable in this manufacture.

In their oil ciftern, the parenchymous part, which unavoidably gets through, in fome degree, in every operation, gradually fubfides, and the liquor, in any divifion of the ciftern, comes to confift of ftrata of different degrees of purity. The pumps which lift it out of each divifion are in pairs; one takes it up from the very bottom, and the other only from half depth. The laft only is barrelled up for the market, and the other goes into a deep and narrow ciftern, where the dreg again fubfides, and more pure oil of that quality is obtained. By fuch careful and judicious practices, the Dutch not only fupply themfelves with this important article, but annually fend confiderable quantities into the very provinces of France and Flanders where they bought the feed from which it was extracted. When we reflect on the high price of labour in Holland, on the want of timber for machinery, on the expence of building in that country, and on the enormous expence of wind mill machinery, both in the firft erection and the fubfequent wear and tear, it muft be evident, that oil mills erected in England on water falls, and after the Dutch manner, cannot fail of being a great national advantage. The chatellanie or feigneurie of Lille alone makes annually between 30,000 and 40,000 barrels, each containing about 26 gallons.

What is here delivered is only a fketch. Every perfon acquainted with machinery will underftand the general movements and operations. But the intelligent mechanic well knows, that operations of this kind have many minute circumftances which cannot be defcribed, and which, neverthelefs, may have a great influence on the whole. The rakes in the bruifing-mill have an office to perform which refembles that of the hand, directed by a careful eye and unceafing attention. Words cannot communicate a clear notion of this; and a mill, conftructed from the beft drawings, by the moft fkilful workman, may gather the feed fo ill, that the half of it fhall not be bruifed after many rounds of the machinery. This produces a fcanty return of the fineft oil; and the mill gets a bad character. The proprietor lofes his money, is difcouraged, and gives up the work.—There is no fecurity but by procuring a Dutch millwright, and paying him with the liberality of Britons. Such unhoped-for talks have been performed of late years by machinery; and mechanical knowledge and *invention* is now fo generally diffufed, that it is highly probable that we fhould foon excel our teachers in this branch. But this very diffufion of knowledge, by encouraging fpeculation among the artifts, makes it a ftill greater rifk to erect a Dutch oil mill without having a Dutchman, acquainted with its moft improved prefent form, to conduct the work. We do our duty in giving this counfel.

OKU-JESSO. See SEGALIEN in this *Suppl.*

OMPHALOPTER, or OMPHALOPTIC, in optics, a glafs that is convex on both fides, popularly called a *convex lens*.

ONISCUS. See *Encycl.*—Two new fpecies of this genus of infects were difcovered by *La Martiniere*, the naturalift who accompanied Peroufe on his laft voyage of difcovery. For the information of fuch of our readers as are entomologifts, we fhall give the author's defcription of thefe fpecies. Of the firft, which he fays only *nearly* anfwers to the *generic* character of onifcus, E (fig. 1.) is a view of the upper part of its body, and at F of the lower. Its body is cruftaceous, and of an opaque white, with two round ruft-coloured fpots on the anterior part of its corflet; two others, much larger, in the form of a crefcent, are on the *clytræ*; its fhield is alfo of the fame colour. The under part of the thorax is furnifhed with four pair of legs: the firft and third of which are terminated with fharp claws; the fecond, from its form, ferves it to fwim with; the fourth is very fmall, confifting of two membranaceous threads. Some fcales, alfo membranaceous and very channelled, may alfo perform the office of legs: of thefe the two lower are the largeft. Its belly is filled with vermicular inteftines of the fize of a hair; its mouth is placed between the firft and fecond pair of legs, and is of the form of a fmall trunk placed between two lips, joined only at the upper extremity. Plate XXXI.

Fig. 2. reprefents an infect of the genus *onifcus*, *Linn.* Its body is nearly of the form, confiftence, and colour, of the *onifcus afellus*, except that it is not divided.

vided by segments as this last is. It has a double tail, three times as long as the body; from the insertion of which, at the hinder part of the body, spring two legs, used chiefly by the animal in swimming upon its back. The insect, viewed on the lower part H, presents six pair of legs; the two first of which terminate in very sharp and thick points; it makes use of the third to swim with, and to balance its body, together with that pair which is inserted at the base of the tail; the fourth pair, and the largest of all, is armed with two very sharp points, which the animal forces into the body of any fish on which it seizes; the two last pair are nothing more than very finely divided membranes. Between the two first is situated its trunk, smooth, and about half a line long; at the base of the third pair are two points, of a horny consistence, very hard, and firmly fixed. The two horns also below the large pair of legs are, in like manner, very firmly united to its body. Martiniere imagines it to be by means of these darts that it pierces the body of the fish on which it is found, and that then, changing it situation, it finds means to introduce its trunk into the holes thus formed, When put into a glass it sinks to the bottom, and rises again to the surface with the greatest ease, advancing with the edge of its body, and describing curves. Its two long tails are very easily pulled off, without the animal appearing to suffer any pain.

OPAQUE, not translucent, nor transparent, or not admitting a free passage to the rays of light.

OPARO or OPARRO, the name given by Captain Vancouver to a small island which he discovered in latitude 27° 36′ south, and in longitude 215° 49′ east from Greenwich. It was estimated at about 6½ miles in length, and no other land was in sight. Its principal character is a cluster of high craggy mountains, forming, in several places, most romantic pinicles, with perpendicular cliffs nearly from their summits to the sea: the vacancies between the mountains would more properly be termed chasms than valleys. The tops of six of the highest hills bore the appearance of fortified places, resembling redoubts; having a sort of block-house, in the shape of an English glass-house, in the centre of each, with rows of pallisadoes a considerable way down the sides of the hills, nearly at equal distances. These overhanging, seemed intended for advanced works, and apparently capable of defending the citadel by a few against a numerous host of assailants. On all of them people were noticed as if on duty, constantly moving about. What we considered (says the author) as block-houses, from their great similarity in appearance to that sort of building, were sufficiently large to lodge a considerable number of persons, and were the only habitations we saw. Yet, from the number of canoes that in so short a time assembled round the English ship, it is natural to conclude, that the inhabitants are very frequently afloat; and to infer, that the shores, and not those fortified hills which appeared to be in the centre of the island, would be preferred for their general residence.

Whether the fortified places here described were intended for defences of the islanders against each other, or against attacks from some more powerful neighbours, could only be conjectured; but the latter idea seems the most probable. From the language of the people, and their resemblance to the Friendly islanders, Captain Vancouver considers them all as having sprung from the same original stock. The people of Oparo, however, are distinguished by two circumstances, certainly in their favour. Not one of them was tattowed; and though they appeared not to have ever seen a European before, they all seemed perfectly well acquainted with the uses to which they could apply iron, and preferred articles of it to looking glasses, beads, and other trinkets, with which savages are usually delighted. Though there appeared to be anchoring ground near the north-west end of the island, circumstances rendered it inconvenient for Captain Vancouver to land on it; so that we are yet in a great measure strangers to the dispositions of the people, though they appeared to be hospitable.

OPEN FLANK, in fortification, is that part of the flank which is covered by the orillon or shoulder.

OPENING *of the Trenches*, is the first breaking of ground by the besiegers, in order to carry on their approaches towards a place.

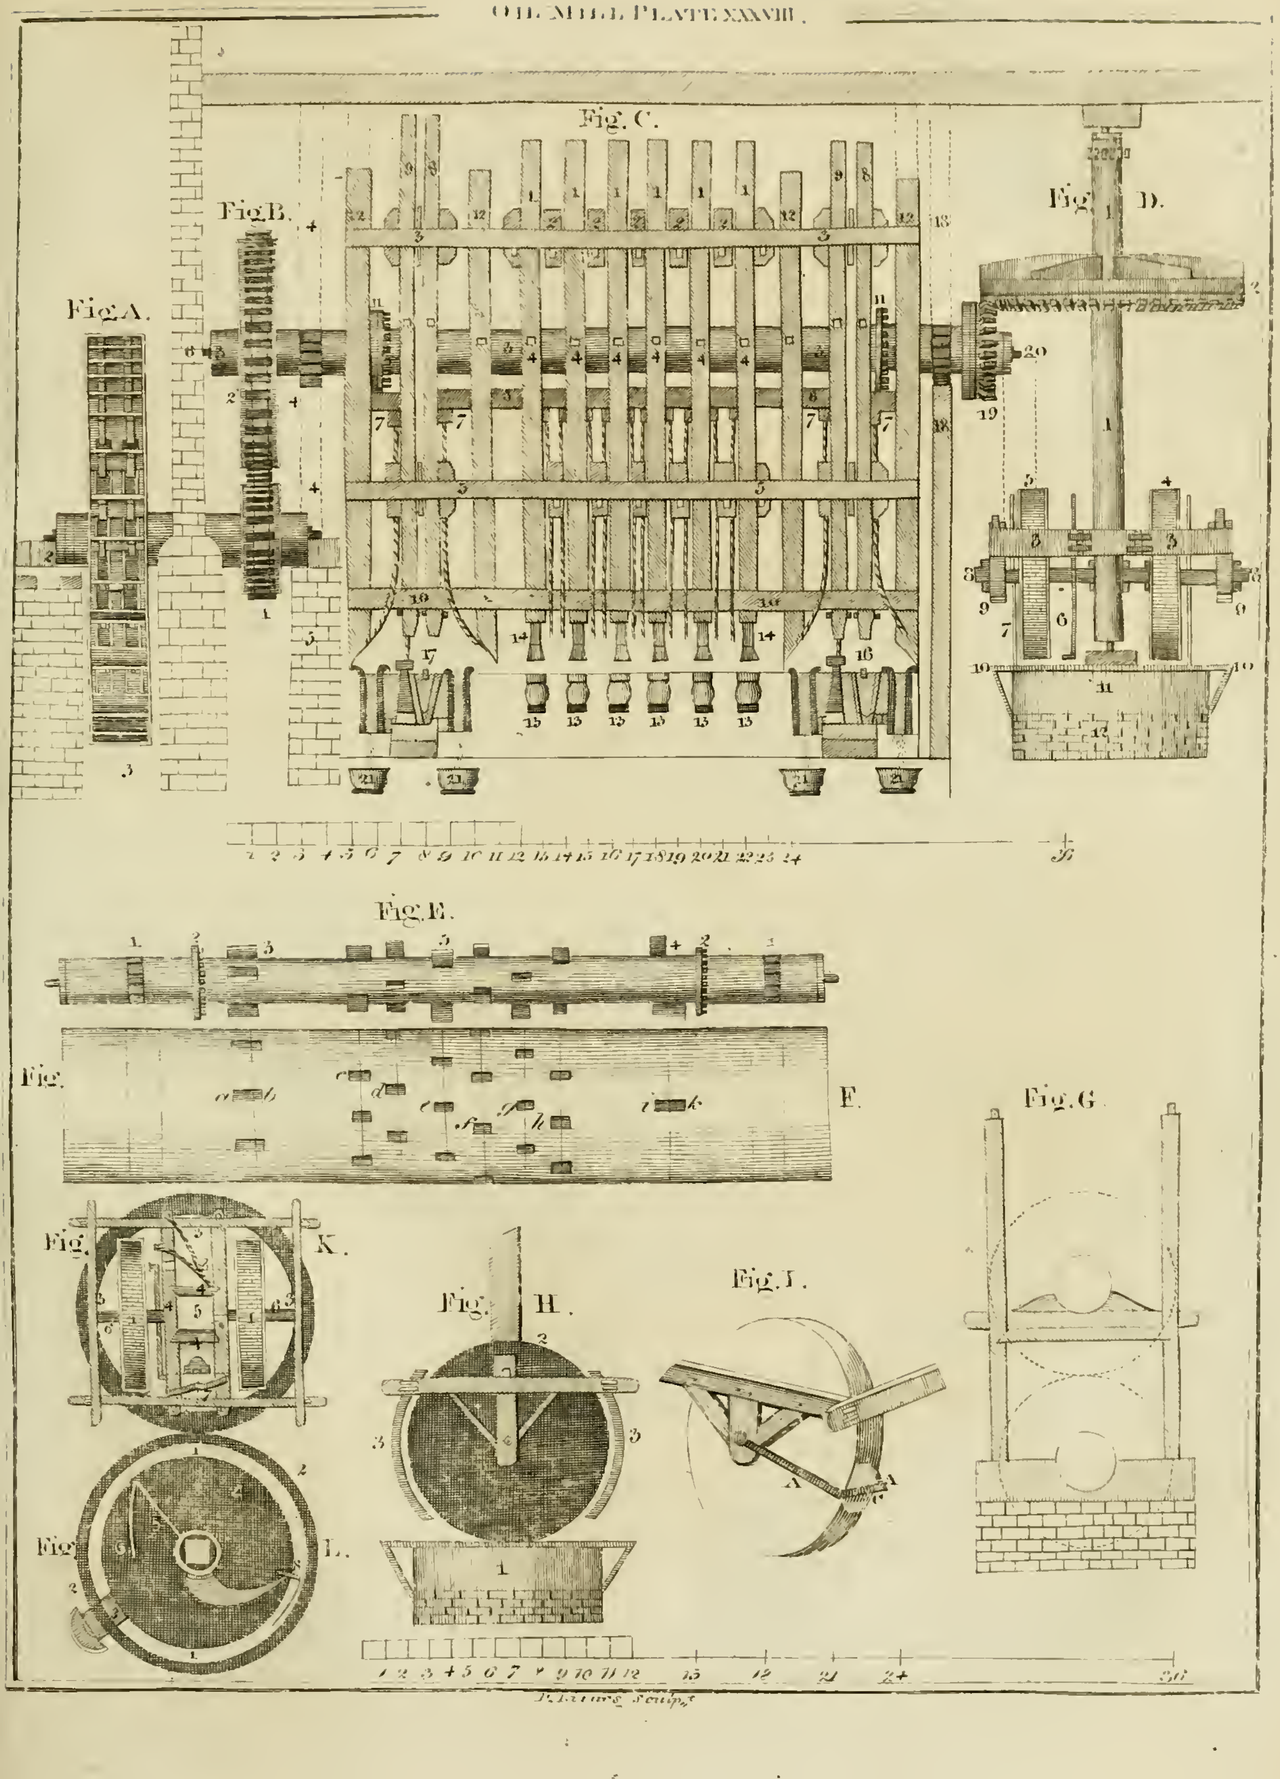
OPERA GLASS, is a diagonal perspective, of which the following concise and perspicuous description is taken from Dr Hutton's Mathematical Dictionary.—ABCD (Plate XLI.) represents a tube about four inches long; in each side of which there is a hole EF and GH, exactly against the middle of a plane mirror IK, which reflects the rays falling upon it to the convex glass LM; through which they are refracted to the concave eye-glass NO, whence they emerge parallel to the eye at the hole *r s*, in the end of the tube. Let P *a* Q be an object to be viewed, from which proceed the rays P *c*, *a b*, and Q *d*: these rays, being reflected by the plane mirror IK, will shew the object in the direction *c p*, *b a*, *d q*, in the image *p q*, equal to the object PQ, and as far behind the mirror as the object is before it: the mirror being placed so as to make an angle of 45 degrees with the sides of the tube. And as, in viewing near objects, it is not necessary to magnify them, the focal distances of both the glasses may be nearly equal; or, if that of LM be three inches, and that of NO one inch, the distance between them will be but two inches, and the object will be magnified three times, being sufficient for the purposes to which this glass is applied.

When the object is very near, as XY, it is viewed through a hole *x y*, at the other end of the tube AB, without an eye-glass; the upper part of the mirror being polished for that purpose as well as the under. The tube unscrews near the object-glass LM, for taking out and cleansing the glasses and mirror. The position of the object will be erect through the concave eye-glass.

The peculiar artifice of this glass is to view a person at a small distance, so that no one shall know who is observed; for the instrument points to a different object from that which is viewed; and as there is a hole on each side, it is impossible to know on which hand the object is situated which you are viewing. It is chiefly used in play-houses; and hence its name: but we have seen it most indecently employed by those who should have set a better example, even in a cathedral church!

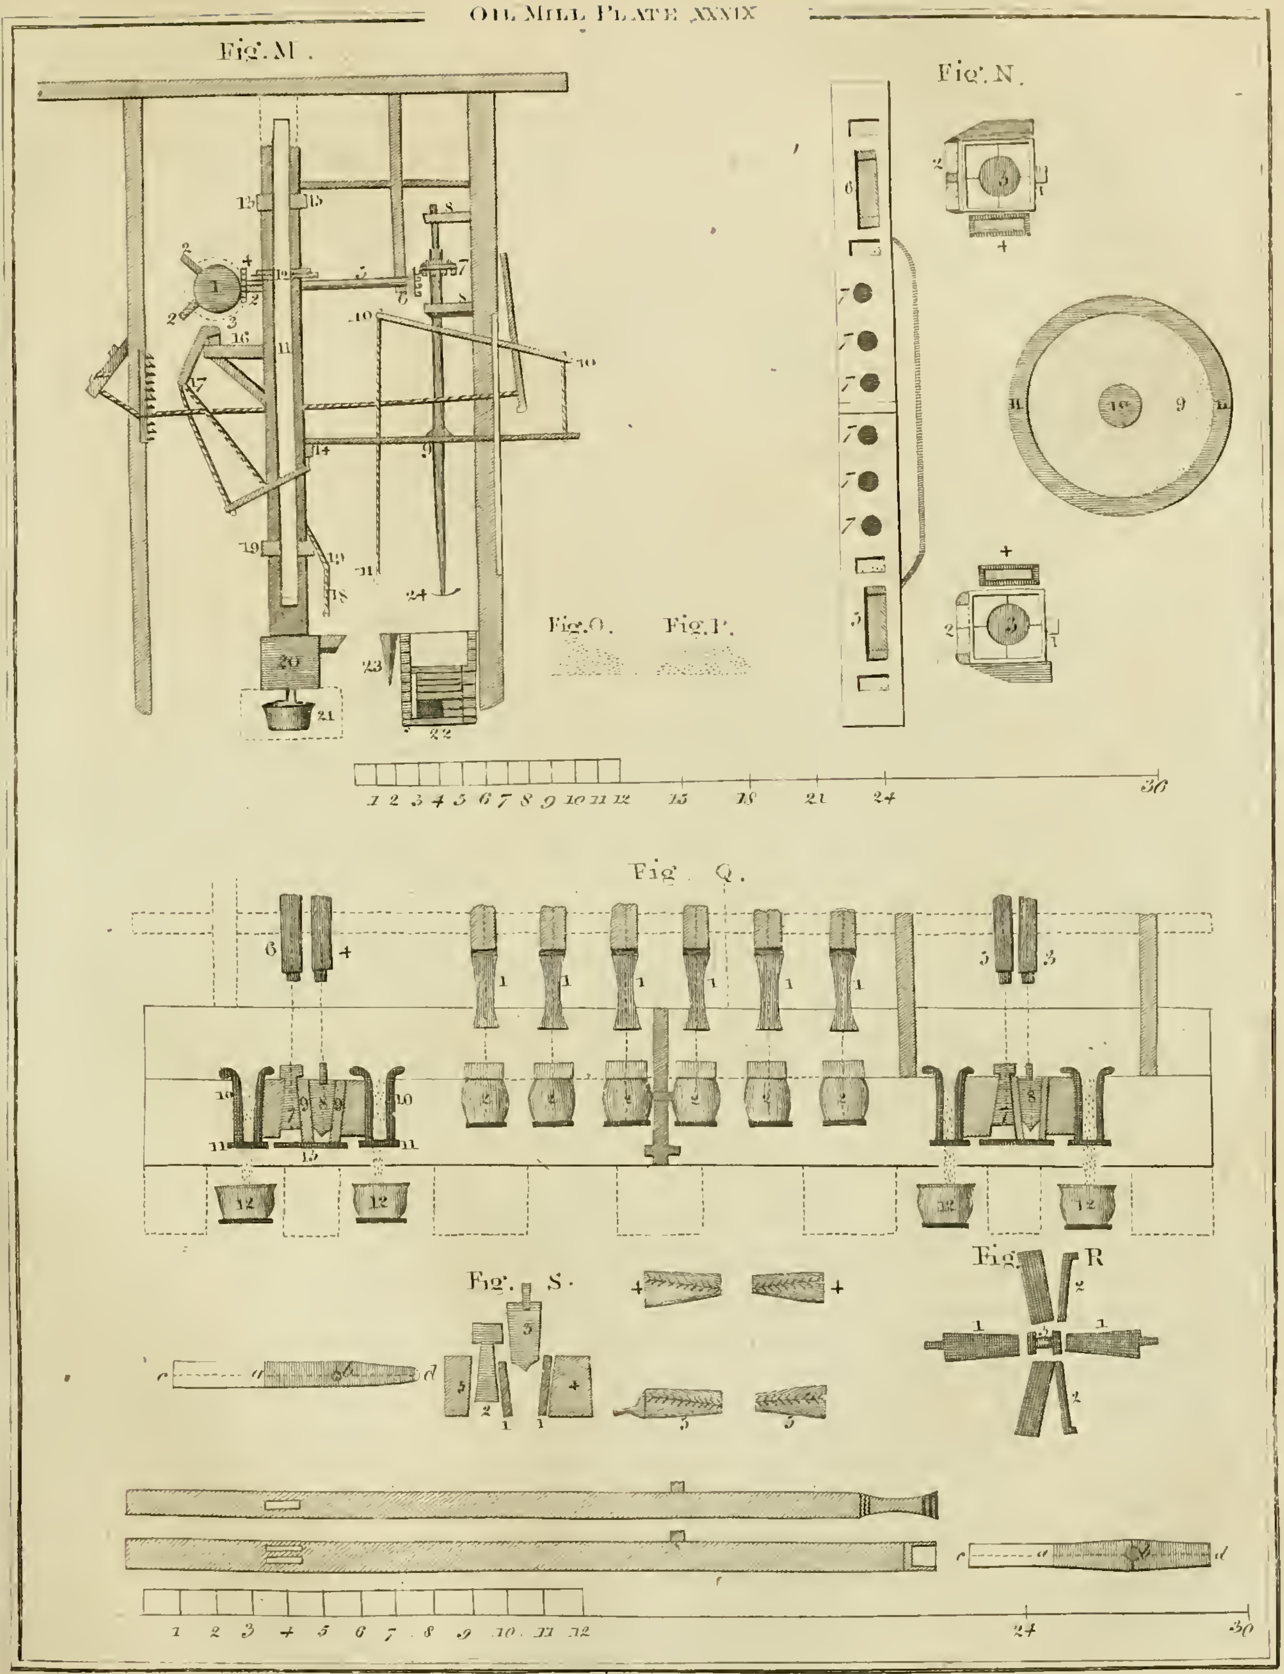
OPHRYS (See *Encycl.*), A new species of this plant has been lately described in the *Annual Hampshire Repository*, by a Fellow of the Linnean Society, in the following words:

" *Stem*—about 12 inches high, erect, stipulate, geniculate,



T. Evans Sculpt.

OIL MILL PLATE XXXIX



D. Lizars Sculpt.

culate, pubefcent at the upper genicles. *Spike*—ftrictly fpiral, flowers fpirally afcending, about 24, brightly white. Upper petal ovato-acuminate, pubefcent, lightly ciliate, ftraight. Two middle *petals* oblong-recurved. Two lower *petals* oblong-acuminate, lightly ciliate only on the lower fide near the bafe, projecting like elephant's tufks. *Nectary*, broad, recurved, ragged, bicipitate. *Leaves floral*—carinate acuminate, ciliate reaching and pointing to the middle of the flowers. *Leaves radical* —five or fix, about fix inches long, narrow, attenuate both ways, acuminate, the lower more haftate. *Leaves cauline*—lanceolate, alternate.

"Obfervation —This plant has much the habit, as well as autumnal florefcence, of Oriental fpiralis, and is fo perfectly fpiral alfo, that the fpecific name of the other fhould be altered, as being no longer exclufively fpiral; at the fame time that a fpecific name fhould be given to this: neither of which (fays the author) I fhall prefume to do, but fhall fuggeft it to the Linnean Society, of which I have the honour to be a Fellow."—This ophrys flowered, for the firft time, it is believed, in England, in Hampfhire, October 1796.

OPHIUCUS, a conftellation of the northern hemifphere; called alfo *Serpentarius*.

OPIUM (See *Encycl.*), is a medicine of fuch intrinfic value, and of fo high a price, that every method which promifes to increafe the quantity in the market muft be of importance. It was therefore, with much propriety, that *The Society for the Encouragement of Arts*, &c. fome time ago, voted 50 guineas to Mr John Ball of Williton, Somerfetfhire, for the difcovery of his method of preparing opium from poppies of the growth of England. The poppies, which he recommends as the moft productive, are the *double* or *femi-double*, of a dark colour; the feeds of which he advifes to be fown the latter end of February, and again about the fecond week in March, in beds three feet and a half wide (well prepared with good rotten dung, and often turned or ploughed, in order to mix it well, and have it fine), either in fmall drills, three in each bed, in the manner fallads are fown, and when about two inches high, to thin them one foot apart; or otherwife, to fow them in beds, in the broad-caft way, and thin them to the fame diftance. If they be kept free from weeds, they will grow well, and will produce from four to ten heads, fhewing large and different coloured flowers; and when their leaves die away, and drop off, the pods then being in a green ftate, is the proper time for extracting the opium, by making fuch longitudinal incifions as are, for this purpofe, made in the eaft (See OPIUM and PAPAVER, *Encycl.*). Immediately on the incifion being made, a milky fluid will iffue out; which is the opium, and which, being of a glutinous nature, will adhere to the bottom of the incifion; but fome poppies are fo productive, that it will drop from the pod on the leaves underneath The next day, if the weather fhould be fine, and a good deal of funfhine, the opium will be found a greyifh fubftance, and fome almoft turning black: it is then to be fcraped from the pods, and (if any there) from the leaves, with the edge of a knife, or other inftrument for that purpofe, into pans or pots; and in a day or two it will be of a proper confiftence to make into a mafs, and to be potted.

According to Mr Ball, fields cannot be fown with any thing more lucrative to the farmer than poppies, efpecially if thofe fields have a fouth expofure. "By a calculation (fays he) which I have made, fuppofing one poppy to grow in one fquare foot of earth, and to produce only one grain of opium, more than L.50 will be collected from one ftatute acre of land: but if we confider that one poppy produces from three or four to ten heads, that in each head from fix to ten incifions may be made, and that from many of them (I mean from one incifion) I have taken away two or three grains of opium—What muft then be the produce?"

Mr Ball produced to the Society letters from Dr Latham of Bedford-row, Dr Pearfon of Leicefter-fquare, and Mr Wilfon of Bedford-ftreet, declaring, that, in their opinion, his Englifh opium is equal in effect, and fuperior in purity, to the beft foreign opium.

OPTIC INEQUALITY, in aftronomy, is an apparent irregularity in the motions of far diftant bodies; fo called, becaufe it is not really in the moving bodies, but arifing from the fituation of the obferver's eye. For if the eye were in the centre, it would always fee the motions as they really are.

OPTIC *Pyramid*, in perfpective, is a pyramid formed by the vifible object which is the *bafe*, and the rays drawn from the perimeter of that object, which meet at the eye in a point, which is the *apex* of the pyramid. Hence, alfo, we may know what is meant by an *optic triangle*.

OPTIC *Rays*, particularly means thofe by which an optic pyramid, or optic triangle, is terminated.

ORAN, a confiderable city, occupied by the Spaniards, in the province of *Mafcara*, in the country of Algiers. It has ftrong and regular fortifications, and can eafily be fupplied from Spain with provifions and warlike ftores. It lies in 35′ of longitude weft from Greenwich, and in 35° 55′ north latitude. Since the year 1732, the Spaniards have held uninterrupted poffeffion of Oran. It has a parifh church, three monafteries, an hofpital: and the number of the inhabitants, according to the account given of it by the Spaniards, amount to 12,000. Towards the fea, the city rifes in the form of an amphitheatre, and is furrounded with forts and batteries. Clofe to the city lies a ftrong caftle, *Alcazava*, in which the Spanifh governor refides. On the higheft hill ftands Fort St Croix, whofe guns command the city and the adjacent country. From this fort they make fignals of the approach of fhips, and carefully watch the motions of the Moors, who often attempt predatory incurfions into the neighbouring diftricts. A confiderable number of Mahomedans take refuge in Oran; they dwell in a diftinct part of the city, receive pay from the court of Spain, and render fignal fervices againft the Moors. The greateft part of the inhabitants of Oran confifts of fuch as have been banifhed from Spain; and the fame may, in a great meafure, may be faid of the foldiers who compofe the garrifon. Five regiments are commonly ftationed here; but owing to continual defertion, their ftrength fcarcely equals that of four complete regiments. One of them wholly confifts of malefactors, who have been condemned to remain here for life; the reft are fuch as have been tranfported for one or more years. There is here likewife a military fchool. Around the city are pleafant gardens; but it is very dangerous to cultivate them, on account of the Moors and Arabs, who frequently lie in ambufh among them. The fame reafon prevents the cultivation of the fields in the vicinity; and the garrifon and inha-

inhabitants muft be fupplied with provifions immediately from Spain.

ORANGE-MEN, an appellation affumed by certain focieties in Ireland, of which the firft was formed in the county of Armagh, on the 21ft of November 1795, others in fome towns of Ulfter and Leinfter in the year 1797, another in the city of Dublin 1798; and fince that period, thefe focieties have fpread over the whole of our fifter kingdom. The object of thefe affociations is exhibited in the following authentic *Declaration of the Principles of Orange-men*, publifhed 1799.

" From the various attempts that have been made to poifon the public mind, and flander thofe who have had the fpirit to adhere to their king and conftitution, and to maintain the laws:—

" We, the Proteftants of Dublin, affuming the name of Orange-men, feel ourfelves called upon, not to vindicate our principles, for we know that our honour and loyalty bid defiance to the fhafts of malevolence and difaffection, but openly to avow thofe principles, and declare to the world the objects of our inftitution.

" We have long obferved, with indignation, the efforts that have been made to foment rebellion in this kingdom, by the feditious, who have formed themfelves into focieties, under the fpecious name of *United Irifhmen*.

" We have feen with pain the lower orders of our fellow-fubjects, forced or feduced from their allegiance, by the threats or machinations of *traitors*.

" And we have viewed with horror the fuccefsful exertions of *mifcreants*, to encourage a foreign enemy to invade this happy land, in hopes of rifing into confequence on the downfal of their country.

" We therefore thought it high time to rally round the conftitution, and there pledge ourfelves to each other, to maintain the laws, and fupport our good king againft all his enemies, whether *rebels* to their God or to their country; and by fo doing, fhew to the world that there is a body of men in this ifland, who are ready, in the hour of danger, to ftand forward in defence of that grand palladium of our liberties, the conftitution of Great Britain and Ireland, obtained and eftablifhed by the courage and loyalty of our anceftors under the Great King William.

" Fellow fubjects, we are accufed with being an *inftitution*, founded on principles too fhocking to repeat, and bound together by oaths, at which human nature may fhudder: but we caution you not to be led away by fuch malevolent falfehoods; for we folemnly affure you, in the prefence of the Almighty God, that the idea of injuring any one, on account of his religious opinion, never entered into our *hearts:* we regard every loyal fubject as our friend, be his religion what it may; we have no enmity but to the enemies of our country.

" We further declare, that we are ready, at all times, to fubmit ourfelves to the orders of thofe in authority under his Majefty, and that we will cheerfully undertake any duty which they fhall think proper to point out for us, in cafe either a foreign enemy fhall dare to invade our coafts, or that a domeftic foe fhall prefume to raife the ftandard of rebellion in the land. To thefe principles we are pledged—and in fupport of them we are ready to fpend the laft drop of our blood—(Signed) Thomas Verner, *Grand Mafter*; John Clau. Beresford, *Grand Secretary*; William James, J. De Joncourt, Edward Ball."

ORCHARD. As an appendix to this article in the *Encycl.* fome of our readers will be pleafed with the following means, employed by the Rev. Mr *Germerfhaufen*, for promoting the growth of young trees, and increafing the fize and flavour of the fruit in orchards.

Having planted feveral young plum trees in an orchard, he covered the ground, for fome years, around the trunks, as far as the roots extended, with flax-fhows (A); by which means thefe trees, though in a grafs-field, increafed in a wonderful manner, and far excelled others planted in cultivated ground. As far as the fhows reached, the grafs and weeds were choaked; and the foil under them was fo tender and foft, that no better mould could have beeen wifhed for by a florift.

When he obferved this, he covered the ground with the fame fubftance, as far as the roots extended, around an old plum-tree, which appeared to be in a languifhing ftate, and which ftood in a grafs-field. The confequences were, that it acquired a ftrong new bark; produced larger and better-tafted fruit; and that thofe young fhoots, which before grew up around the ftem, and which it was every year neceffary to deftroy, were prevented from fprouting forth, as the covering of flax-fhows impeded the free accefs of air at the bottom of the trunk.

In the year 1793, he tranfplanted, from feed-beds, into the nurfery, feveral fruit-trees; the ground around fome of which he covered, as above, with flax-fhows. Notwithftanding the great heat of the fummer, none of thofe trees where the earth was covered with fhows died or decayed; becaufe the fhows prevented the earth under them from being dried by the fun. Of thofe trees, around which the ground was not covered as before mentioned, the fourth part mifcarried; and thofe that continued alive were far weaker than the former.

The leaves which fall from trees in autumn may alfo be employed for covering the ground in like manner; but ftones, or logs of wood, muft be laid on them, to prevent their being difperfed by the wind. In grafsland, a fmall trench may be made around the roots of the tree, when planted, in order to receive the leaves. If flax-fhows are ufed, this is not neceffary; they lie on the furface of the ground fo faft as to refift the force of the moft violent ftorm. The leaves which our author found moft effectual in promoting the growth and fertility of fruit trees, are thofe of the walnut-tree. Whether it is, that, on account of their containing a greater abundance of faline particles, they communicate manure to the ground, which thereby becomes tender under them; or that they attract nitrous particles from the atmofphere; or that, by both thefe means, they tend to nourifh the tree both above and below.

Thofe who are defirous of raifing tender exotic trees from the feed, in order to accuftom them to our climate, may, when they tranfplant them, employ flax-fhows with

(A) Shows are the refufe of flax when it is fcutched or heckled.

with great advantage. This covering will prevent the frost from making its way to the roots; and rats and mice, on account of the sharp prickly points of the flax-shows, will not be able to shelter themselves under them.

ORCHILLA, a weed used in dyeing, which grows in the Canary islands, and is monopolized by the government. "It is a minute vegetable (says Sir George Staunton), of the lichen kind, growing chiefly upon rocks of a loose texture, and produces a beautiful violet blue colour."

ORDEAL. See this article in the *Encyclopædia*, at the end of which we have given, from Dr Henry's History of England, some strong reasons for suspecting that the ordeal, by fire at least, was a gross imposition on the credulity of an ignorant and superstitious age. This suspicion of imposture is raised to certainty by Professor Beckmann, who, in his History of Inventions, gives us the whole process by which the clergy conducted the trial, and brought proofs of innocence or of guilt at their pleasure. The person accused was put entirely under their management for three days before the trial, and for as many after it. They covered his hands (when he was to lift red-hot iron) both before and after the proof; sealed and unsealed the covering. The former was done, as they pretended, to prevent the hands from being prepared any how by art; the latter, that it might be accurately known whether or not they were burnt.

Some artificial preparation was therefore known, else no precautions would have been necessary. It is highly probable, that during the three first days the preventative was applied to those persons whom they wished to appear innocent; and that the three days after the trial were requisite to let the hands resume their natural state. The sacred sealing secured them from the examination of presumptuous unbelievers; for to determine whether the hands were burnt, the three last days were certainly not wanted. When the ordeal was abolished, and this art rendered useless, the clergy no longer kept it a secret. In the 13th century, an account of it was published by Albertus Magnus, a Dominican monk (A). If his receipt be genuine, it seems to have consisted rather in covering the hands with a kind of paste than in hardening them. The sap of the *althæa* (marshmallow), the slimy seeds of the flea-bane, which is still used for stiffening by the hat-makers and silk-weavers, together with the white of an egg, were employed to make the paste adhere. And by these means the hands were as safe as if they had been secured by gloves.

Hutton's Dictionary.

ORFFYREUS's WHEEL, in machanics, is a machine so called from its inventor, which he asserted to be a perpetual motion. This machine, according to the account given of it by Gravesande, in his *Oeuvres Philosophiques*, published by Allemand, Amst. 1774, consisted externally of a large circular wheel, or rather drum, 12 feet in diameter, and 14 inches deep; being very light, as it was formed of an assemblage of deals, having the intervals between them covered with waxed cloth, to conceal the interior parts of it. The two extremities of an iron axis, on which it turned, rested on two supports. On giving a slight impulse to the wheel, in either direction, its motion was gradually accelerated; so that, after two or three revolutions, it acquired so great a velocity as to make 25 or 26 turns in a minute. This rapid motion it actually preserved during the space of two months, in a chamber of the Landgrave of Hesse, the door of which was kept locked, and sealed with the Landgrave's own seal. At the end of that time it was stopped, to prevent the wear of the materials. The Professor, who had been an eye-witness to these circumstances, examined all the external parts of it, and was convinced that there could not be any communication between it and any neighbouring room. Orffyreus, however, was so incensed, or pretended to be so, that he broke the machine in pieces; and wrote on the wall, that it was the impertinent curiosity of Professor Gravesande which made him take this step. The Prince of Hesse, who had seen the interior parts of this wheel, but sworn to secrecy, being asked by Gravesande, whether, after it had been in motion for some time, there was any change observable in it, and whether it contained any pieces that indicated fraud or deception? answered both questions in the negative, and declared, that the machine was of a very simple construction.

ORICOU, a new species of the vulture, discovered by Vaillant at Orange river in South Africa. As he thinks it unquestionably the most beautiful of its genus, and tells us, as usual with him, a wonderful story about it, we have given a figure of this vulture in Plate XLI. Our traveller says, that it is more than three feet high, and eight or nine in breadth of wing. Its feathers, the general hue of which is a light brown, are of a particular kind on the breast, belly, and sides, where they are of unequal lengths, pointed, curved like the blade of a sabre, and bristle up distinct from each other. The feathers being thus separated, would disclose to view the skin on the breast, if it were not completely covered with a very thick and beautiful white down, which is easily seen between the ruffled plumage.

A celebrated naturalist has said, that "no bird has eye-lashes or eye-brows, or, at least, hair round the eyes like that in quadrupeds." This assertion, advanced as a general law of Nature, is a mistake. Not only the oricou has this peculiarity, but we know of many other species in which it exists; such as, in general, all the calaos, the secretary, and several other birds of prey. Beside these eye-lashes, the vulture in question has stiff black hairs on its throat. All the head and part of the neck are bare of feathers; and the naked skin, which is of a reddish colour, is dashed in certain places with blue, violet, and white. The ear, in its external circumference, is bounded by a prominent skin, which forms a sort

(A) In his work *De Mirabilibus Mundi*, at the end of his book *De Secretis Mulierum*, Amstelod. 1702, 12mo, p. 100. Experimentum mirabile quod facit hominem ire in ignem sine læsione, vel portare ignem vel ferrum ignitum sine læsione in manu. Recipe succum bismalvæ, et albumen ovi, et semen psylli et calcem, et pulveriza, et confice cum illo albumine ovi succum raphani; commisce; ex hac confectione illineas corpus tuum vel manum, et dimitte siccari, et postea iterum illineas, et post hoc poteris audacter sustinere ignem sine nocumento.

fort of rounded conch, that muft neceffarily heighten the faculty of hearing in this fpecies. This kind of conch is prolonged for fome inches, and defcends down the neck; which induced our author to give it the name of *oricou.*

Its ftrength, he fays, muft be very confiderable, if we may judge from its mufcles and finews; and he is perfuaded, that there is not a ftronger among the whole order of carnivorous birds, not excepting the famous condor, which fo many travellers have feen, but of which their defcriptions are fo different as to render its exiftence extremely doubtful. But there was no occafion for this reafoning, and thofe inferences, if what he relates as facts deferve any credit. The oricou which he defcribes, he firft perceived perched on the carcafe of a hippopotamos. eagerly devouring its flefh. He fhot at it, and wounded it flightly; upon which, "though it had already gorged itfelf with a confiderable quantity of flefh (for upon opening it, he found in its ftomach no lefs a quantity than *fix pounds and a half*), yet its hunger and voracity were fuch, that it ftruck its beak into the carcafe when attempting to take wing, as if defirous of carrying the whole of it away.

"On the other hand, the weight of the flefh it had devoured rendering it the more heavy, it could not eafily rife: fo that we had time (fays he) to reach it before it was on the wing, and we endeavoured to knock it on the head with the butt-ends of our mufkets. It defended itfelf a long time with great intrepidity. It bit or ftruck at our weapons with its beak, and its ftrength was ftill fo great, that every ftroke made a mark on the *barrel of the piece.*"

ORIENT, the eaft, or the eaftern point of the horizon.

Orient *Equinoctial,* is ufed for that point of the horizon where the fun rifes when he is in the equinoctial, or when he enters the figns Aries and Libra.

Orient *Aeftival,* is the point where the fun rifes in the middle of fummer, when the days are longeft.

Orient *Hybernal,* is the point where the fun rifes in the middle of winter, when the days are fhorteft.

OROTAVA, a town in the ifland of Teneriffe, at the bottom of thofe mountains out of which the Peek rifes, neatly built of ftone, on an irregular furface. The moft remarkable object near it is a dragon's blood tree, of which the trunk meafures, at the height of ten feet from the ground, 36 feet in girth. Concerning this tree there is a tradition current in the ifland, that it exifted, of no inconfiderable dimenfions, when the Spaniards made the conqueft of Teneriffe, about three centuries ago; and that it was then, what it ftill is, a landmark, to diftinguifh the boundaries of landed poffeffions near it.

Diftant about three miles on the fea-coaft is the puerto, or fea-port, of Orotava, where is carried on a confiderable degree of commerce, principally for the exportation of wine. It is chiefly, as at Madeira, in the hands of a few Britifh commercial houfes, which import, in return, the manufactures of Great Britain. Within a mile is a collection of living plants from Mexico, and other parts of the Spanifh dominions in America. From hence they are to be tranfplanted into Spain. It is an eftablifhment of fome expence; and, whatever may be its fuccefs, it fhews a laudable attention, on the part of that government, to the promotion of natural knowledge.

OROTCHYS and Bitchys, two tribes of Tartars, who were vifited by La Peroufe in 1787, and of whofe manners he gives fuch an account as renders it difficult to fay whether they have the beft claim to be called a favage or a civilized people. He fell in with a fmall village of them on the eaft coaft of Tartary, in a bay to which he gave the name of *Baie de Caftrie,* in Lat. 51° 29′ North, and Long. 139° 39′ Eaft from Paris.

Their village, their employment, their drefs, and their apparent ignorance of all religion, befpoke them favages. Their village was compofed of four cabins, built in a foid manner, of the trunks of fir-trees, and covered with bark. A wooden bench compaffed the apartment round about; and the hearth was placed in the middle, under an opening large enough to give vent to the fmoke.

This village was built upon a tongue of low marfhy land, which appeared to be uninhabitable during the winter; but on the oppofite fide of the gulph, on a more elevated fituation, and expofed to the fouth, there was, at the entrance of a wood, another village, confifting of eight cabins, much larger and better built than the firft. Above this, and at a very fmall diftance, were three yourts, or fubterraneous houfes, perfectly fimilar to thofe of the Kamtfchadales, defcribed in the third volume of Captain Cook's laft voyage; they were extenfive enough to contain the inhabitants of the eight cabins during the rigour of the cold feafon; befides, on fome of the fkirts of this village were feen feveral tombs, which were larger and better built than the houfes; each of them enclofed three, four, or five biers, of a neat workmanfhip, ornamented with Chinefe ftuffs, fome pieces of which were brocade. Bows, arrows, lines, and, in general, the moft valuable articles of thefe people, were fufpended in the interior of thefe monuments, the wooden door of which was clofed by a bar, fupported at its extremities by two props.

Their fole employment feemed to be the killing and curing of falmon, of which they eat raw, the fnout, the gills, the fmall-bones, and fometimes the entire fkin, which they ftript off with infinite dexterity. When the ftript falmon were carried to the huts, the women, in the moft difgufting manner, devoured the mucilaginous part of them, and feemed to think it the moft exquifite food. Every cabin was furrounded with a drying place for falmon, which remain upon poles, expofed to the heat of the fun, after having been during three or four days fmoked round the fire, which is in the middle of their cabin; the women, who are charged with this operation, take care, as foon as the fmoke has penetrated them, to carry them into the open air, where they acquire the hardnefs of wood.

The bones of the falmon fo cured were fcattered, and the blood fpread round the hearth; greedy dogs, though gentle and familiar enough, licked and devoured the remainder. The naftinefs and ftench of this people are difgufting. There is not perhaps anywhere a race of people more feebly conftituted, or whofe features are more different from thofe forms to which we attach the idea of beauty; their middle ftature is below four feet ten inches, their bodies are lank, their voices thin and feeble, like that of children; they have high cheek bones, ſmall blear eyes, placed diagonally; a large mouth, flat noſe, ſhort chin, almoſt beardleſs, and an olive-coloured ſkin, varniſhed with oil and ſmoke. They ſuffer their hair to grow, and tie it up nearly the ſame as we do; that of the women falls looſe about their ſhoulders, and the portrait which has juſt been drawn agrees equally well with their countenances as thoſe of the men, from whom it would be difficult to diſtinguiſh them, were it not for a ſlight difference in the dreſs, and a bare neck; they are not, however, ſubjected to any labour, which might, like the American Indians, change the elegance of their features, if nature had furniſhed them with this advantage. Their whole cares are limited to the cutting and ſewing their clothes, diſpoſing of their fiſh to be dried, and taking care of their children, to whom they give the breaſt till they are three or four years of age.

With reſpect to dreſs, the men and little boys are clothed with a waiſtcoat of nankeen, or the ſkin of a dog or a fiſh, cut in the ſhape of a waggoner's frock. If it reach below the knee, they wear no drawers; if it do not, they wear ſome in the Chineſe ſtyle, which fall as low as the calf of the leg. All of them have boots of ſeal's ſkin, but they keep them for the winter; and they at all times, and of every age, even at the breaſt, wear a leather girdle, to which are attached a knife in a ſheath, a ſteel to ſtrike a light with, a pipe, and a ſmall bag to contain tobacco. The dreſs of the women is ſomewhat different; they are wrapped up in a large nankeen robe, or ſalmon's ſkin, which they have the art of perfectly tanning, and rendering extremely ſupple. This dreſs reaches as low as the ankle-bone, and is ſometimes bordered with a fringe of ſmall copper ornaments, which make a noiſe ſimilar to that of ſmall bells. Thoſe ſalmon, the ſkins of which ſerve for clothing, are never caught in ſummer, and weigh thirty or forty pounds.

Though they had neither prieſts nor temples, they ſeemed to be believers in ſorcery, and took the motion of the Frenchmens hands, when writing, for ſigns of magic. Thus far they appeared ſavages.

Their ſacred regard of property, their attention to their women, and the delicacy of their politeneſs to ſtrangers, would, on the other hand, do honour to the moſt civilized nation. While Perouſe and his people were in the bay, one of the families took its departure on a voyage of ſome length, and did not return during their ſtay. When he went away, the maſter of the family put ſome planks before the door of his houſe, to prevent the dogs from entering it, and in this ſtate left it full of their effects. "We were ſoon (ſays our author) ſo perfectly convinced of the inviolable fidelity of theſe people, and their almoſt religious reſpect for property, that we left our ſacks full of ſtuffs, beads, iron tools, and, in general, every thing we uſed as articles of barter, in the middle of their cabins, and under no other ſeal of ſecurity than their own probity, without a ſingle inſtance of their abuſing our extreme confidence; and on our departure from this bay, we firmly entertained the opinion, that they did not even ſuſpect the exiſtence of ſuch a crime as theft."

Their attention to their women, ſo uncommon among ſavages, was diſplayed in their exempting them from hard labour; in their never concluding a bargain with the Frenchmen without previouſly conſulting their wives; and in their reſerving the pendent ſilver ear-rings and copper trinkets, which they purchaſed, for their wives and daughters. Of the delicacy of their manners to ſtrangers, we ſhall give the following intereſting inſtance in the words of Perouſe's tranſlator:

Obſerving with what repugnance they received preſents, and how often they refuſed them with obſtinacy, "I imagined (ſays Perouſe) I could perceive, that they were perhaps deſirous of more delicacy in the manner of offering them; and to try if this ſuſpicion were well founded, I ſat down in one of their houſes, and after having drawn towards me two little children, of three or four years old, and made them ſome trifling careſſes, I gave them a piece of roſe-coloured nankeen, which I had brought in my pocket. The moſt lively ſatisfaction was viſibly teſtified in the countenances of the whole family, and I am certain they would have refuſed this preſent, had it been directly offered to themſelves. The huſband went out of his cabin, and ſoon afterwards returning with his moſt beautiful dog, he entreated me to accept of it. I refuſed it, at the ſame time endeavouring to make him underſtand, that it was more uſeful to him than to me: but he inſiſted; and perceiving that it was without ſucceſs, he cauſed the two children, who had received the nankeen, to approach, and placing their little hands on the back of the dog, he gave me to underſtand, that I ought not to refuſe his children.

"The delicacy of ſuch manners cannot exiſt but among a very poliſhed people. It ſeems to me, that the civilization of a nation, which has neither flocks nor huſbandry, cannot go beyond it. It is neceſſary to obſerve, that dogs are their moſt valuable property; they yoke them to ſmall and very light ſledges, extremely well made, and exactly ſimilar to thoſe of the Kamtſchadales. Theſe dogs, of the ſpecies of wolf dogs, and very ſtrong, though of a middle ſize, are extremely docile, and very gentle, and ſeem to have imbibed the character of their maſters."

ORTHODROMICS, in navigation, is great-circle ſailing, or the art of ſailing in the arch of a great circle, which is the ſhorteſt courſe: For the arch of a great circle is *orthodromia*, or the ſhorteſt diſtance between two points or places.

ORYCTEROPUS, the name given by M. Geoffroy, profeſſor of zoology in the French muſeum of natural hiſtory, to the animal called by other zoologiſts *Myrmecophaga Capenſis*. (See MYRMECOPHAGA, *Encycl.*) He conſiders it as a diſtinct genus, and ſeems indeed to have proved, by a compariſon of the organs of the orycteropus with thoſe of the *tatous daſipus* of Linnæus, and of the *myrmecophagi*, that this genus is intermediate, by its forms and habits, between thoſe two families. It approaches to the *tatous* in its organs of maſtication, and the form of the toes and nails, and in having a ſhort and ſingle cæcum, whilſt that of the myrmecophagi is double, as in birds, by the reuniting of the bones of the os pubis, which are not articulated together in the myrmecophagi. The orycteropus, however, bears a relation to the laſt, ſince it has, like them, a very ſmall mouth, whence its tongue, covered with hair, may be protruded to a conſiderable length. Finally, the habits of the orycteropus reſemble thoſe of the animals to which it approaches the moſt; it does not climb trees, but lives under the earth like the tatous;

Oryćtero-pus || Ouadelim.

tous; it feeds like them on roots, but also it hunts after anthills, like the myrmecophagi. Its snout terminates in a blunt callous; a character which is peculiar to it. It may be distinguished in the works of naturalists by the following description:

Oryćteropus. Molar teeth (six) with flat vertices; the body covered with hair.

The oryćteropus, as appears from the preceding, connects the tatous with the myrmecophagi and with the *pangolin manis* of Linnæus. The large fossile species found in Paraguay, for which Citizen Cuvier has established a new genus, under the name of *megaterium*, is intermediate between the sloth and the myrmecophagus; and, lastly, the astonishing animal of New Holland, covered with bristles like the porcupine, supported by very short legs, and of very singular conformation, and with a head round at the occiput, terminating in a snout, without teeth, very slender, long, and cylindrical, and described by Mr George Shaw under the name of myrmecophaga aculeata, appears to have very striking relations to the pangolin and the oryćteropus; from hence it follows, that in consequence of these important acquisitions, we ought for the future to count, in the number of our natural orders, that of the *edentated*, or *edented*, consisting of the following genera: *Dasipus*, *oryćteropus myrmecophaga*, and *aculeata*, *manis*, *myrmecophaga*, *megaterium* et *bradypus*.

OSCILLATION, in mechanics, vibration, or the reciprocal ascent and descent of a pendulum.

Axis of Oscillation, is a line parallel to the horizon, supposed to pass through the centre or fixed point about which the pendulum oscillates, and perpendicular to the plane in which the oscillation is made.

Centre of Oscillation, in a suspended body, is a certain point in it, such that the oscillations of the body will be made in the same time as if that point alone were suspended at that distance from the point of suspension. Or it is the point into which, if the whole weight of the body be collected, the several oscillations will be performed in the same time as before: the oscillations being made only by the force of gravity of the oscillating body.

OSCULATION, in geometry, denotes the contact between any curve and its osculatory circle; that is, the circle of the same curvature with the given curve, at the point of contact or of osculation. See Involution in this *Suppl.*

Osculation also means the point of concourse of two branches of a curve which touch each other. For example, if the equation of a curve be $y = \sqrt{x} + \sqrt[4]{x^3}$, it is easy to see that the curve has two branches touching one another at the point where $x = 0$, because the roots have each the signs + and —.

OUADELIM and Labdesseba, two tribes of Arabs inhabiting the *Sahara* or Great Desart of Africa, of whom almost nothing was known to Europeans till the publication of Brisson's narrative of his shipwreck and captivity among the latter tribe. He describes the Ouadelim and Labdesseba as the most formidable of all the interior tribes of Arabs, and as often extending their ravages to the very gates of Morocco. "Their hordes (he says) are frequently intermingled with those of the Rousege, Rathidium, Chelus, Tucanois, and Ouadeli tribes, as they have no distinct boundaries, and change their habitations as the desart affords pasturage and water. They are tall, handsome, stout, and vigorous men. Their hair is bristled, and their nails, which they often use in battle, as long as claws; large hanging ears and a long beard give them a stern ferocious air. The Ouadelim in particular are fierce, arrogant, and warlike, but soon dispirited by obstinate resistance, especially when they have not a decided superiority in numbers. In their hordes they lodge by families, in tents which are covered with a thick cloth of camels hair, which the women spin and weave upon a loom so small, that they work sitting on the ground. The furniture of their tents consist of two large sacks of leather, in which they keep old clothes, and pieces of old iron, three or four goat skins for holding milk and water, two large stones for grinding their barley, a smaller one for driving the pins of their tents, an ozier matting which serves for a bed, a thick carpet for a covering, a small kettle, and some wooden dishes, with pack-saddles for their camels. The person who, besides these articles, possesses a few horses, camels, sheep, and goats, is reckoned wealthy, as there are many Arabs who only possess sheep and goats. Except sore eyes and the cholic, they are subject to few endemic diseases. The first disorder is caused by the reflection of light from the burning sands of the desart, the other proceeds from the verdigrease which contaminates all their victuals. Their kettles are not tinned, and never washed, so that they are quite crusted over with verdigrease, the virulence of which is probably diminished by the quantity of milk they use. When they reside long in one place, they sometimes plough the spots which are moistened by the rain, and sprinkle them with seed in a careless manner. Plentiful crops are often thus produced; but instead of waiting till the grain attains maturity, they cut it down, and dry it over hot cinders. Treachery and perfidy are the innate vices of the Arabs; assassinations are frequent; no man trusts the promise of another; no man makes a written agreement, as the poignard cancels all bonds and obligations. The men often relate their exploits to each other; the embellishing of a story is succeeded by a charge of falsehood, and the poignard solves every difficulty. The ancient rites of hospitality, however, are practised among these tribes in their utmost extent. The Arab, who in the field is a rapacious plunderer, becomes liberal and generous as soon as he enters his tent. War is only a species of rapine, and the victory is decided at the first shock. The Arab is devoid of sanguinary courage; he attacks only to plunder, and never thinks that booty is to be put in competition with his life. When the battle is ended, each party makes graves for the slain, and enclose the tombs with mounds of stones. The ages of the warriors are denoted by the space of ground which the grave occupies, and the funeral procession is closed by the howls of the females.

"The women never assume the name of their husbands, and never eat with them at meals. They are faithful to their husbands, and cannot be divorced except by the decree of the seniors of the horde. The Arabs display their opulence by the ornaments of their women, whose ears, arms, and legs, are generally adorned with rings of gold and silver. An Arab beauty must have long teeth shooting out of her mouth, a body extremely thick, and limbs of the longest size. At the birth of a son, every woman, to testify her joy, blackens

Ouadelim. ens her face for 40 days. At the birth of a daughter, ſhe only daubs the half of her face during the ſpace of 20 days. A mother treats her ſon with the ſame reſpect as her huſband, almoſt as ſoon as he is able to walk; ſhe prepares his food, ſerves him, and eats when he has finiſhed his repaſt. In the education of their young men, the moſt important acquiſitions are, dexterity in the uſe of the poignard, ſkill in embowelling their enemies with their long nails, and a plauſible air in uttering a falſehood. More rude and ferocious than the tribes whoſe territories lie upon the ſhore of the ſea, the Labdeſſeba and Ouadelim Arabs are alſo more confined and illiberal in their ideas, not only believing that they are the firſt nation in the world, but fancying that the ſun riſes only for them. Briſſon relates, that ſome of them expreſſed this idea in unequivocal terms. 'Behold (ſaid they) that luminary, which is unknown in thy country. During the night, thou art not enlightened, as we are, by that heavenly body, which regulates our days and our faſts. His children (the ſtars) point out to us the hours of prayer. You have neither trees nor camels, ſheep, goats, nor dogs. Are your women ſimilar to ours?' 'How long didſt thou remain in the womb of thy mother (ſaid another)?' 'As long (replied Briſſon) as thou in that of thine.' 'Indeed (ſaid a third, counting the fingers and toes of the Frenchman) he is made like us; he differs only in his colour and language.' 'Do you ſow barley in your houſes?' ſaid the Arabs, alluding to the ſhips of the Europeans. 'No (ſaid Briſſon), we ſow our fields almoſt in the ſame ſeaſon as you.' 'How! (cried ſeveral) do you inhabit the earth? we believed that you were born and lived upon the ſea.' Theſe Arabs, according to the Turkiſh proverb, believe that all the world is like their father's houſe: unacquainted with the manners of other nations, and unaccuſtomed to reflect upon the cauſes of national character, every variation from their own cuſtoms appears not only ridiculous, but monſtrous; every difference of opinion not only abſurd, but criminal. This ignorance of the Arabs, conjoined with their local and religious prejudices, enables us to account for the inſulting treatment which Briſſon and his companions received, without having recourſe to inherent depravity of nature." That treatment was indeed ſhocking.

Briſſon had ſurrendered himſelf, on his ſhipwreck, to Sidi Mahomet, a *Talbe* or prieſt of the tribe of Labdeſſeba. During the abſence of the prieſt, the Labdeſſeba, who guarded the captives, were attacked and maltreated by a party of the Ouadelims, and during the buſtle which enſued, Briſſon had almoſt loſt his life. Inſtead of compaſſionating his forlorn ſituation, the women threw ſand into his eyes, as they ſaid, to dry his eye-lids. The Arabs, into whoſe hands he had fallen, had only come down to the ſea-coaſt to gather wild grain, three days before the ſhipwreck; and to preſerve their booty, they immediately retreated to the interior part of the deſart. A guide preceded the horde, to place at intervals ſmall pyramids of ſtone, to direct their courſe, at a diſtance from every hoſtile tribe. After paſſing ſome very high mountains, wholly covered with ſmall greyiſh pebbles as ſharp as flints, they deſcended into a ſandy plain overſpread with thorns and thiſtles. When Briſſon was unable to walk, on account of the bleeding of his feet, he was mounted on a camel; the briſtly hair and hard trot of which ſoon excoriated him ſo much, that the blood run copiouſly down its flanks. By throwing heated ſtones into a wooden veſſel, filled with barley meal, diluted with water procured on the ſea-ſhore, preſerved in a goat's ſkin, and mixed with pitch to prevent putrefaction, the Arabs prepared a kind of ſoup, which they kneaded with their hands, and ate unchewed. They roaſted a goat in heated ſand, ate its fat raw, and, after having devoured the fleſh, gnawed the bones, and ſcraped them with their nails, threw them to Briſſon and his companions, deſiring them to eat quickly, and load the camels, that the journey might not be impeded. Proceeding eaſtward, they croſſed a vaſt plain, covered with ſmall ſtones white as ſnow, round and flat as a lental, where not a ſingle plant was produced. The earth beneath their feet reſounded dull and hollow, and the ſmall ſtones pricked them like ſparks of fire. The reflection of the rays of the ſun from the ſand was ſcorching; the atmoſphere was loaded with a red vapour, and the country appeared as if filled with flaming volcanoes. Neither birds nor inſects could be ſeen in the air. The profound ſilence was frightful. If a gentle breeze ever aroſe, it produced extreme languor, chopping of the lips, burning heat of the ſkin, with ſmall ſmarting pimples. This plain was even ſhunned by wild beaſts. After traverſing this plain, they entered another, where the wind had thrown up in furrows the ſand, which was of a reddiſh colour. On the tops of the furrows grew a few ſweet-ſcented plants, which were devoured by the camels. On quitting this ſandy plain, they entered a valley ſurrounded by mountains, where the ſoil was white and ſlimy, and where they found water of a noxious ſmell, covered with green moſs, and ſoon after diſcovered a horde of the friendly tribe Rouſſye.

After another journey of ſixteen days, they arrived at the tents of the Labdeſſeba horde, to which Sidi Mahomet belonged. The tents pitched among thick buſhy trees, and the numerous flocks feeding along the ſides of the hills, preſented at a diſtance an aſpect of happineſs and paſtoral ſimplicity. On approaching near, the trees of beautiful green foliage proved to be only old gummy ſtumps, almoſt void of branches, ſo encircled with thorns that their ſhade was inacceſſible. The women approached, with loud cries and the moſt fawning ſervility, to welcome their tyrants, to throw ſtones at the Chriſtians, and ſpit in their faces, while the children imitated the example of their mothers. Briſſon, who endeavoured to ingratiate himſelf with his maſter's favourite, not only failed in this, but incurred her implacable reſentment, through his irritability, which to the Arab women ſeemed extremely to reſemble petulance. During his reſidence with Sidi Mahomet, the hardſhips he endured were almoſt incredible. With the exceſſive heat, the milk of the ſheep, goats, and camels, diminiſhed, and then the dogs fared better than the Chriſtians, who were forced to ſubſiſt on wild herbs and raw ſnails. When the rains fell, and the leaſt preſſure made the water to ſpring up through the ſandy ſoil, the Chriſtians ſlept behind a buſh, unſheltered, on the bare ground. Briſſon and his maſter ſometimes reaſoned about religion; when the latter always anſwered the harangues of the former by declaring, that he preferred a bowl of churned milk to ſuch abſurdities.

absurdities. Several of his companions perished, and were left by the Arabs to be devoured by the ravens, while in the struggles of death. One of them was supposed to be murdered by his master for milking his camels clandestinely. An application made by Brisson to the consul at Mogador, by a letter entrusted to a Jewish merchant, was frustrated through the negligence of the vice-consul; and the Labdesseba Arabs thought the journey too dangerous to be encountered for the ransom of their slaves. He was, however, at last relieved, through the humanity of his master's brother-in-law, who carried him to Morocco, where his ransom was paid by the Emperor, and whence he returned to France. For a fuller account of these two savage tribes, see *Saugnier's and Brisson's Narratives*; or a very pleasing *Historical and Philosophical Sketch of the Discoveries, &c. of the Europeans in Northern and Western Africa*, published 1799 by *Symington* Edinburgh, and *Vernor* and *Hood* London.

OXYGLYCUS CERASUS, the name given by the Editor of Dalzel's History of Dahomy to a very singular fruit produced in that country, as well as in some other parts of Africa. It resembles a small olive in every respect but the colour; being of a dusky reddish hue, changing at the end next the stalk to a faint yellow. The pulp is firm, and almost insipid; the stone is hard like that of the olive. After having chewed one or more of such berries, and spit out or swallowed the pulp at pleasure, a glass of vinegar will taste, to the person trying the experiment, like sweet wine; a lime will seem to have the flavour of a very ripe China orange; and the same change is produced on other acids, the ordinary effects of which upon the palate is destroyed in a very unaccountable manner, without effervescence or any sensible motion. Indeed, the effect is very different from neutralization, arising from the mixture of acid and alkali; such combination producing a neutral saline liquor, whilst this miraculous berry seems to convert acids to sweets. Food or drink, not containing any acid, suffer no change by the previous use of this fruit; its effect upon acids continues, even after a meal, though in a much smaller degree. The natives use it to render palatable a kind of gruel called *guddoe*, which is made of bread after it becomes too stale for any other purpose. They describe it as the fruit of a large tree.

Plants six or seven inches high were raised from this fruit by Mr Dalzel, who tried to carry them from Angola to the botanic garden at St Vincent's; but they died on the passage. He preserved the berries in spirits, in syrup, and in a dry form; but they lost their singular quality in all those preparations. The plant is an evergreen, and the leaves in this infant state are like those of the olive.

OXY-MURIATIC ACID (See CHEMISTRY-*Index* in this *Suppl.*), is the principal agent in the new process of bleaching (see BLEACHING, *Suppl*); but, till very lately, at least, if not even at present, the bleachers were in the practice of adding some alkali to the acid, notwithstanding the strong objections which M. Bertholet made to that addition, and notwithstanding the proofs urged by Mr Rupp, that it increases the expence of bleaching about 40 *per cent.* The chief reason for persisting in a practice to which such objections were urged was, that the addition of the alkali deprives the liquor of its suffocating effects without destroying its bleaching powers. Mr Rupp, however, has contrived the following apparatus, in which may be safely used the pure oxy-muriatic acid simply dissolved in water, which is at once its cheapest and best vehicle.

Figure 1. (Plate XLI.) is a section of the apparatus. It consists of an oblong deal cistern ABCD, made water-tight. A rib EE of ash or beech wood is firmly fixed to the middle of the bottom CD, being mortised into the ends of the cistern. This rib is provided with holes at FF, in which two perpendicular axes are to turn. The lid AB has a rim GG, which sinks and fits into the cistern. Two tubes HH are fixed into the lid, their centres being perpendicularly over the centres of the sockets FF when the lid is upon the cistern. At I, is a tube by which the liquor is introduced into the apparatus. As it is necessary that the space within the rim GG be air-tight, its joints to the lid, and the joints of the tubes, must be very close; and, if necessary, secured with pitch. Two perpendicular axes KL, made of ash or beech wood pass through the tubes HH, and rest in the sockets FF. A piece of strong canvas M is sewed very tight round the axis K, one end of it projecting from the axis. The other axis is provided with a similar piece of canvas. N are pieces of cloth rolled upon the axis L. Two plain pulleys OO are fixed to the axis, in order to prevent the cloth from slipping down. The shafts are turned by a moveable handle P. Q is a moveable pulley, round which passes the cord R. This cord, which is fastened on the opposite of the lid (see fig. 2.), and passes over the small pulley S, produces friction by means of the weight T. By the spigot and fausset V, the liquor is let off when exhausted.

The dimensions of this apparatus are calculated for the purpose of bleaching twelve or fifteen pieces of $\frac{7}{8}$ calicoes, or any other stuffs of equal breadth and substance. When the goods are ready for bleaching, the axis L is placed on a frame in an horizontal position, and one of the pieces N being fastened to the canvas M by means of wooden skewers, in the manner represented in fig. 1. it is rolled upon the axis by turning it with the handle P. This operation must be performed by two persons; the one turning the axis and the other directing the piece, which must be rolled on very tight and very even. When the first piece is on the axis, the next piece is fastened to the end of it by skewers, and wound on in the same manner as the first. The same method is pursued till all the pieces are wound upon the axis. The end of the last piece is then fastened to the canvas of the axis K. Both axes are afterwards placed into the cistern, with their ends in the sockets FF, and the lid is put on the cistern by passing the axis through the tubes HH. The handle P is put upon the empty axis, and the pulley Q upon the axis on which the cloth is rolled, and the cord R, with the weight T, is put round it and over the pulley S. The use of the friction, produced by this weight, is to make the cloth wind tight upon the other axis. But as the effect of the weight will increase as one cylinder increases and the other lessens, Mr Rupp recommends that three or four weights be suspended on the cord, which may be taken off gradually as the person who works the machine may find it convenient. As the weights hang in open hooks, which are fastened to the

Oxy-Muriatic Acid.

the cord, it will be little or no trouble to put them on and to remove them.

Things being thus difpofed, the bleaching liquor is to be transferred from the veffels in which it has been prepared into the apparatus, by a moveable tube paffing through the tube I, and defcending to the bottom of the ciftern. This tube being connected with the veffels, by means of leaden or wooden pipes provided with cocks, hardly any vapours will efcape in the transfer. When the apparatus is filled up to the line *a*, the moveable tube is to be withdrawn, and the tube I clofed. As the liquor rifes above the edge of the rim G, and above the tubes HH, it is evident that no evaporation can take place, except where the rim does not apply clofely to the fides of the box; which will, however, form a very trifling furface if the carpenter's work be decently done. The cloth is now to be wound from the axis L upon the axis K, by turning this; and when this is accomplifhed, the handle P and pulley Q are to be changed, and the cloth is to be wound back upon the axis L. This operation is, of courfe, to be repeated as often as neceffary. It is plain, that by this procefs of winding the cloth from one axis upon the other, every part of it is expofed, in the moft complete manner, to the action of the liquor in which it is immerfed. It will be neceffary to turn, at firft, very brifkly, not only becaufe the liquor is then the ftrongeft, but alfo becaufe it requires a number of revolutions, when the axis is bare, to move a certain length of cloth in a given time, though this may be performed by a fingle revolution when the axis is filled. Experience muft teach how long the goods are to be worked; nor can any rule be given refpecting the quantity and ftrength of the liquor, in order to bleach a certain number of pieces. An intelligent workman will foon attain a fufficient knowledge of thefe points. It is hardly neceffary to obferve, that, if the liquor fhould retain any ftrength after a fet of pieces are bleached with it, it may again be employed for another fet.

With a few alterations, this apparatus might be made applicable to the bleaching of yarn. If, for inftance, the pulley O were removed from the end of the axis K, and fixed immediately under the tube H;—if it were perforated in all directions, and tapes or ftrings paffed thro' the holes, fkains of yarn might be tied to thefe tapes underneath the pulley, fo as to hang down towards the bottom of the box. The apparatus being afterwards filled with bleaching liquor, and the axis turned, the motion would caufe every thread to be acted upon by the liquor. Several axes might thus be turned in the fame box, and being connected with each other by pulleys, they might all be worked by one perfon at the fame time; and as all would turn the fame way and with the fame fpeed, the fkains could not poffibly entangle each other.

P.

Painting.

ENCAUSTIC PAINTING is an art of very high antiquity, which, after being loft for many ages, was reftored, as is commonly believed, by the celebrated Count Caylus, whofe method was greatly improved, firft by Mr Jofiah Colebrooke, and afterwards by Mifs Greenland, who brought the rudiments of her knowledge from Italy (fee ENCAUSTIC, *Encycl.*) In that country encauftic painting had employed the attention of various artifts and men of learning, fuch as Requeno, Lorgna, and Aftori, &c.; but the beft account of it that has fallen under our notice, is in that valuable mifcellany called the *Philofophical Magazine*, taken from a work of Giov. Fabbroni, publifhed at Rome in the year 1797.

According to this author, "the knowledge and ufe of encauftic painting is certainly older than the time of the Greeks and the Romans, to whom the learned Requeno feems to affign the exclufive poffeffion of this art; becaufe the Egyptians, who, with the Etrufcans, were the parents of the greater part of the inventions known among mankind, and from whom the Greeks learned fo much, were acquainted with and employed encauftic painting in the ancient ages of their greatnefs and fplendour, as is proved by the valuable fragments of the bandages and coverings of fome mummies which he had examined. No oil-painting (he fays), of only two or three hundred years old, exhibits a white paint which has kept fo well as that feen on thefe fragments; and this circumftance fufficiently proves the fuperiority of the encauftic method over the common oil painting, which, notwithftanding the general opinion, cannot, he thinks, have been unknown to the ancients.

"It is impoffible (fays he) that in Egypt and Phœnicia, where fo much ufe was made of flax, the oil procured in abundance from that plant fhould have been unknown. Thofe who have kept oil, or who have fpilt any of it, whether nut or lintfeed oil, muft have remarked that it poffeffes the property of foon drying by the effects of the atmofphere; and therefore it may be eafily believed that mankind muft foon have conceived the idea of employing it, particularly for fhips, which, as Herodotus fays, were painted with red ochre in the earlieft periods, and adorned with figures and ornaments. The ufe of oil afforded painting a much fimpler and eafier method than that of wax; it muft therefore have been firft adopted, and the tranfition from oil to wax muft be confidered as a ftep towards bringing the art to perfection; becaufe encauftic painting is not expofed to the irremediable inconveniences that arife in oil painting, the value of which we extolled through ignorance, and praifed as a new invention.

"Oil in general, and in particular drying oil which the painters ufe, has naturally a ftrong inclination to combine itfelf with the vital air or oxygen of the atmofphere, and by imbibing oxygen it becomes dry, and affumes the character of refin; but the colour then becomes darker, as is the cafe with tranfparent turpentine, which gradually becomes a black pitch.

"Accord-

"According to the new and more accurate method of decompofing bodies, oil confifts principally of hydrogen and carbon. By coming into contact with the atmofphere, and abforbing its oxygen and light, it undergoes a flow and imperceptible combuftion, which is not effentially different from the fpeedy and violent one which it would undergo in the common mode of burning. It firft paffes, by imbibing oxygen, into the ftate of a more or lefs dark refin; lofes gradually its effential hydrogen, which makes a new combination, and afterwards the oxygen itfelf which has attracted the carbon; and at length leaves behind a thin layer of actual carbon, which in the end becomes black in the courfe of time, and confiderably obfcures the oil-painting. By a continuance of the before-mentioned flow combuftion, the carbon itfelf, as it were, burns alfo: if it be ftrongly acted upon by the light, it attracts the oxygen of the atmofphere, and again brings forward the carbonic acid or fixed air, which gradually flies off. By this, which I may call the fecond degree of combuftion, the painting muft become dufty and friable, like crayon *painting*.

"Hence it appears (fays our author) that one can hope only for a tranfient or deceitful effect from the refrefhing of oil paintings with oil; becaufe the harmony of the tones, which the painter eftablifhes as fuited for the moment, does not proceed with equal fteps, and cannot preferve itfelf in the like meafure for the courfe of a few years, as each tint, as they fay, ought to increafe, or, to fpeak more properly, to burn in proportion to its antiquity. It thence follows, that mere wafhing may be prejudicial to an old painting; and that the method of refrefhing paintings, as it is called, by daubing over the furface, from time to time, with new drying oil, is highly prejudicial and ill calculated for the intended purpofe, fince the oil when it becomes dry contracts in its whole furface, carries with it the paint under it, and occafions cracks in the painting. New oil of this kind gives occafion to mineral paints to be reftored; but covers the picture with a new coat of refin, and then of carbon, which arifes from the gradual combuftion, and always caufes more blacknefs, and the decay of the painting which one wifhes to preferve.

"Wax, on the other hand, undergoes a change which is very different from that of drying oil. The wax, inftead of becoming black by the contact of the atmofphere, increafes in whitenefs, and, according to its natural quality, is not decompofed in the air, and it does not ftrongly attract the oxygen of the calces or metallic afhes which are commonly ufed in painting. Moreover, the fo-called earths, which are in themfelves white, and are never variable either by the prefence or abfence of oxygen, cannot be employed in oil-painting, becaufe that fluid makes them almoft tranfparent, and caufes them to remain as it were without body, and not to produce the wifhed-for effect. That beautiful white, which may be obferved on the before-mentioned Egyptian encauftic, is nothing elfe than a fimple earth, and, according to our author's chemical experiments, a chalk which is alfo unalterable."

That the ancients were once acquainted with the ufe of oil-painting, and neglected it on account of the great fuperiority of the encauftic method, our author thinks farther evident from the different accounts which we have of the ancient paintings. "Thus Petronius praifes the frefh appearance which the valuable works of Zeuxis and Apelles had, even in his time; but Cicero, on the other hand, fpeaks of the paintings of the ancients having fuffered from blacknefs. The former fpeaks of wax-painting, and the latter certainly alludes to paintings in oil. It is well known that paintings with wet chalks or water colours do not become black by age, and that this is the cafe alfo with encauftic. Of this any one may be convinced, not only by the expreffions of the above quoted authors, but by one's own eyes on furveying the Egyptian fragment alluded to. Galland proves, on various grounds, that a painting was made with oil fo early as the reign of Marcus Aurelius; and if no fpecimens of that period have reached us, this is perhaps to be afcribed to the frail and perifhable nature of this fpecies of painting."

Sign. Fabbroni, after fome farther obfervations, calculated to prove that metallic oxides or calces could not have been employed as pigments on fuch mummies as ftill retain their colours frefh, proceeds thus: "Thofe who are acquainted with the accuracy and certainty of the method not long fince introduced into chemical operations, will be convinced, that in 24 grains of the encauftic painting, which I ventured to detach from the above-mentioned Egyptian fragment, in order to fubject it to examination, the mixture of an hundredth part of a foreign fubftance would have been difcovered with the greateft certainty; that the refin of Requeno muft undoubtedly have been perceptible to me, and that the alkali of Bachelier and Lorgna could not have efcaped the counteracting medium. But in this Egyptian encauftic I found nothing except very pure wax, though I varied my analyfis in every known method. I muft therefore conclude, that modern learned writers, at leaft in refpect to this Egyptian mode of painting, were as far from the truth as the accounts of ancient authors appear to me precife and fatisfactory; and that the encauftum with which formerly the fore part of fhips and the walls of houfes and temples were painted, was fomething different from foap or refinous crayons.

"I am well aware that it will be afked, In what manner can wax at prefent be rendered fufficiently liquid for the ftrokes of the pencil, if it be not converted into powder or foap? This queftion, in my opinion, can be fully anfwered from the words of an ancient author, and, in the next place, by experience.

"Vitruvius in particular, book vii. chap. ix. expreffes himfelf in the following clear manner:

'Thofe (fays he) who wifh to retain cinnabar on walls, cover it, when it has been well laid on and dried, with punic wax diluted in a little oil (let this be well remarked; and after they have fpread out the wax with a hair brufh, they heat the wall by means of a brazier filled with burning coals (hence it is called encauftic painting), and then make it fmooth and level by rubbing it with wax tapers and clean cloths, as is done when marble ftatues are covered with wax. The effect of this wax cruft is, that the colour is not deftroyed by the light of the fun or the moon (A).'

"It

(A) The reader will find the original of this paffage, with a tranflation fomewhat different, in the article ENCAUSTIC, *Encycl.*

"It here appears, that the Romans, who copied the Grecian procefs, which the latter borrowed from the Egyptians, mixed the wax with an oil to make it pliable under the brufh; but no maftic, alkali, or honey, as has been ingenioufly imagined, and which fome have thought might be employed with fuccefs. The difficulty now will be confined to point out in what manner this oil was employed. It does not appear that they ufed thofe fat oils which are commonly called drying oils; becaufe they could have employed thefe as we do, without the addition of wax, which, in fuch a cafe, would have been entirely fuperfluous. Fat oils which do not dry would not have been proper for that purpofe, as they would have kept the wax continually in the ftate of a foft pomade or falve. Befides, my experiments (continues the author) would without doubt have fhewn me the exiftence of any oily matter.

"With regard to effential or volatile oils, a knowledge of them is not allowed to the ancients, as the invention of diftilling is not older than the eighth or ninth century, and therefore falls in with the period of Geber or Avicenna." Yet it is certain, that, in order to ufe wax in their encauftic painting, they muft have combined it with an ethereal volatile oil, of which no traces fhould afterwards remain; becaufe this was neceffary for the folidity of the work, and becaufe no oil was found in the fragment that was examined. But naphtha is fuch an oil, much lighter (fays our author) than ether of vitriol itfelf. It is exceedingly volatile, and evaporates without leaving a trace of it behind. On this account it is ufed when fignatures and manufcripts are to be copied; becaufe the paper, which is moiftened by it, and fo rendered tranfparent, quickly becomes white and opaque as before by the complete evaporation of the naphtha. That the Affyrians, Chaldeans, and Perfians, were well acquainted with the properties of naphtha is known to every fcholar; and hence our author thinks it highly probable that it was ufed by thofe nations to render wax fit for painting. "It appears to me (fays he) that the Greeks, as was the cafe with many other things, learned encauftic from the Egyptians, who probably derived it from the Affyrians or Chaldeans; and if fo, we have difcovered the real mixture ufed for ancient encauftic painting."

To put the matter, however, beyond a doubt, Sign. Fabbroni prepared, for an eminent Saxon painter, a folution of Venetian wax in highly purified naphtha, defiring him to mix up with it the colours neceffary for a painting. The artift complied; and both he and our author were aftonifhed, as well as all their friends, at the high tone which the colours affumed, and the agreeable luftre which the painting afterwards acquired when it had been rubbed over with a foft cloth. A fimilar folution of wax was made for another artift, in which the fpirit of turpentine was ufed inftead of naphtha with equal fuccefs. Our author therefore concludes, we think with reafon, that if he has not difcovered the real compofition employed by the ancients in their encauftic paintings, he has at leaft approached much nearer to that difcovery than any of his predeceffors who have employed their learned labours in the fame field of inveftigation.

PAINTINGS, or PICTURES, are often done upon objects from which, when they are valuable, it would be defirable to transfer them. Thus, a connoiffeur in painting might naturally wifh to transfer an old and valuable picture from the ceiling or walls of his room to ftretched canvas: and fuch a man would confider himfelf as deeply indebted to the artift who fhould perform fo arduous a tafk. This tafk has actually been performed by Mr *Robert Salmon* of Woburn, Bedfordfhire, who was honoured by the *Society for the Encouragement of Arts, &c.* with the greater filver pallet, for communicating the method by which he accomplifhed it.

"The firft thing (fays Mr Salmon) to be attended to with refpect to paintings, either on plaftered walls or ceilings, or on boards, is, that the place in which they are be fecure from wet or damp. If the paintings are on old walls in large buildings, or other places where this cannot be attained by art, then the fummer feafon fhould be taken for the purpofe, as the picture will rarely efcape damage, if wet or damp gets at it while under the procefs. At the fame time, care fhould be taken that the room, or other place, be not overheated; as that would produce equally bad effects.

"Thefe precautions being taken, the next thing is to examine the furface of the painting. If there are any holes in the fame, they muft be carefully filled up with a pafte or putty, made of glue and whiting: this, if the holes are large, fhould be twice or thrice done, fo as entirely to fill them up, and leave the furface even and fmooth; but if there are any bruifed places, with paint ftill remaining on the furface of the bruifed parts, then this ftopping muft not be applied, but the fecuring-canvas, hereafter defcribed, muft be preffed down into thefe places. In the places that are ftopped, there will of courfe appear blemifhes when the picture is transferred; but the procefs is rendered much more certain and fure by being fo done. Attention muft next be paid to lay down any blifters, or places where the paint is leaving the ground: this is done by introducing, between the paint and the ground, fome very ftrong pafte of flour and water; and the furface of the bliftered paint being damped with a wet fponge or brufh, it may be preffed with the hand home to the ground, to which it will then adhere.

"All the unfound places being thus fecured, care muft be taken to clear the furface of any greafe or dirt, as alfo of any particles of the pafte that may happen to be left on it. The next thing is, to determine the fize of the painting meant to be taken off: If it is on a plain furface, a board of the fize of the picture muft be procured, not lefs than an inch in thicknefs, and framed together with well feafoned wood, in fmall pannels, fmooth and flufh on one fide. This done, a piece of fine open canvas muft be provided, fuch as the fineft fort ufed for hanging paper on; which canvas is to be fomewhat larger than the picture, and fo fewed together, and the feam fo preffed, that it be perfectly fmooth and even. This is what Mr Salmon calls the fecuring canvas; which, being fo prepared, is to be ftuck on the furface of the picture with a pafte made of ftrong beer, boiled till it is half reduced, and then mixed with a fufficient quantity of flour to give it a very ftrong confiftence. To large pictures on walls or ceilings, the canvas muft for fome time be preffed, and rubbed with the hand as fmooth as poffible, working it from the middle to the outfide, fo as to make it tolerably tight; obferving, as it dries, to prefs it, with the hand or cloth, into any hollow or bruifed places, fo that

that it may adhere to every part of the painting: this done, it is left to dry; which it will generally do in a day or two When dry, a fecond canvas, of a ftronger and clofer fort, and of the fame fize as the other, is in like manner to be attached on the top of the firft. This laft will want very little attention, as it will readily adhere to the firft; and, being dry, attention muft be paid to take off any fmall knots or unevennefs that may be upon the furface of it; which done, the whole fhould be again covered with a thin pafte of fize and whiting; which is to be pumiced over when dry, fo as to make the whole perfectly fmooth and even.

"The painting being thus fecured, the board, already prepared to the fize of the picture, is to be put with the fmooth fide againft the furface thereof, fo as exactly to cover as much as is intended to be transferred. The edges of the canvas, which, as is before directed, is to be larger than the painting, are then to be pulled tight over, and clofely nailed to the edge of the board. If the painting is large, and either on a ceiling or wall, the board muft, by proper fupports, be firmly fixed againft it, fo that it can readily be lowered down when the plafter and painting are detached.

"The canvas and board being fixed, the painting is to be freed from the wall or ceiling, together with a certain portion of the plaftering: this, with proper care and attention, may be readily done. If on a ceiling, the firft thing is to make fome holes through the plaftering, round the outfide of the board and painting; and, with a fmall faw, to faw the plaftering from one hole to another, till the whole is difunited from the other parts of the ceiling: this done, the workman muft get at the upper fide of the ceiling, where he muft free the plaftering from the laths, by breaking off the keys thereof, and with a chifel cut out the laths; whereby the plaftering, together with the picture, will be left refting on the board and fupports.

"If the painting is on a brick or ftone wall, the wall muft be cut away at top, and down the fides of the painting; and then, by means of chifels or faws in wooden handles, of different lengths, the wall muft be cut away quite behind the painting; leaving the fame, together with the plaftering, refting on the board. This operation may fometimes be done with a faw: or, if the wall be not thick, nor the other fide of much confequence, the bricks or ftones may be taken out from that fide, leaving the plaftering and painting as before. This laft method (fays the author) I have not practifed: the other, of cutting away fome part of the wall, I have, and fee no difficulty, or very great labour, in the operation; but that, of courfe, muft be various, according to the texture of the wall and mortar.

"If the paintings are on curved furfaces, fuch as the coves of ceilings, then the only difference of operation is, that fome ribs of wood muft be cut out, and boarded fmooth to the curve of the furface of the painting, and then fixed up thereto, in place of the before defcribed bearing-board; the painting is then to be freed, and left with the plaftering, refting on the bearers.

"For paintings on wainfcot or boards, the fame fecuring and procefs is to be exactly followed; only that, as the wainfcot or board can always be cut to the fize wanted, and laid horizontal, the fecuring-canvas is to be ftretched thereon, and turned over the edges of the fame till it is dry; after which, the edges are again to be turned up, and nailed to the board, in the fame manner as with refpect to paintings from walls.

"Having, as before defcribed, in any of the aforementioned cafes, freed the paintings from their original places, you have got them fecured to two thickneffes of canvas, with their furfaces on the board prepared for that purpofe; this being the cafe, they can readily be removed to any room or fhop, to be finifhed as follows: Having carried the painting into the fhop or room, which fhould be moderately warm and dry, but by no means overheated, lay the board on a bench or treffels, fo that the back of the picture be uppermoft: the plaftering or wood, as may happen, is then to be cleared away, leaving nothing but the body of paint, which will be firmly attached to the fecuring-canvas. To perform this, a large rafp, a narrow plane, and chifels, will be requifite. This operation, though difficult to be defcribed, would foon be learned by any one who fhould make the attempt; nor is it very tedious; and being performed, the picture is ready to be attached to its new canvas, as follows.

"The painting being cleared, and lying on the board, the back thereof is to be painted three or four times over fucceffively, with any good ftrong-bodied paint; leaving one coat to dry before another comes on: a day or two between each will generally be found fufficient. Each of thefe coats, and particularly the firft, fhould be laid on with great care, taking but a fmall quantity in the brufh at a time, and laying it very thin. This precaution is neceffary, to prevent any of the oil or paint from paffing through any fmall cracks or holes in the furface of the picture; as fuch oil or paint would run into the pafte, and fo attach the fecuring-canvas to the picture, as to prevent its being afterwards got off. If any fuch holes or cracks are obferved, they fhould be ftopped up with the glue and whiting pafte, and the painting then repeated, till a complete coat is formed on the back of the picture. It is then ready for attaching to its canvas. which is done by fpreading all over the picture a pafte made of copal varnifh, mixed with ftiff white lead, and a fmall quantity of any other old fat paint; all which being fpread equally over with a pallet-knife, fuch a canvas as the firft fecuring-canvas is laid thereon, and ftrained and nailed round the edges of the board; in which ftate it is left till it becomes tolerably dry: then a fecond canvas, of a ftronger fort, muft be in like manner attached on the firft, and left till it is perfectly dry and hard. This generally takes about two months; and the longer the painting is left, the more fecurely it will be attached to its canvas, and lefs liable to crack or fly therefrom. When fufficiently dry, all the four canvaffes are to be unnailed from the board, and the edges turned up the reverfe way, and nailed to a proper ftretching-frame. This is done by unnailing from the board a part on each fide at a time, and immediately nailing it to the ftretching-frame, fo as never to leave the canvas to crack or partially ftretch, which would damage the picture In this manner, by degrees, the cloths are entirely detached from the board, and firmly fixed on the ftretching-frame. The fuperfluous canvas, left larger than the frame, may then be cut off, and the wedges put in the frame, and moderately tightened up. There remains then only to clear the furface of the painting from the fecuring-canvas: which is done by repeatedly wafhing the furface with

with a fponge and moderately warm water. In doing this, no violence or force muft be ufed; and, by frequent and gentle wafhings, the pafte will all be worked out with the fponge. The edges of the outer canvas are then to be cut round, and ftripped off: the other, next the furface of the picture, is to be ferved in like manner; which done, nothing remains but to take the pafte clean off, and repair any defects: the picture will then be as ftrong as if painted on the canvas.

"For taking pictures off walls, without taking the walls down, or cutting away more thereof than the plaftering, the following procefs is propofed:

"The furface of the picture is to be firft fecured, in the manner before defcribed; but inftead of the plain board, a bearer fhould be prepared with a convex furface, compofed of ribs, boarded over, fo as to form part of a cylinder, of not lefs than five feet radius, and as long as the height of the picture. This bearer being prepared, in order to apply it, a floor or platform fhould be erected, and placed horizontally, with its furface level, and its edge immediately in contact with the bottom of the picture meant to be transferred. The ufe of this platform is for the above-defcribed bearer to reft and move upon; which bearer fhould be fet on its end, with one edge in contact with the wall, at one fide of the picture; confequently the other edge will be at fome diftance from the wall, according to the fize of the picture and convexity of the bearer. Being thus placed, the fuperfluous edge of the fecuring-canvas fhould be turned over, and nailed to that edge of the bearer that is next the wall: This done, the operation of cutting away the plaftering fhould be begun; which may be done with the corner and end of a fhort faw; fawing between the brick-work and plaftering, and leaving the thicknefs, or part of the thicknefs, of the plaftering on the painting faftened to the bearer. When this edge of the picture is freed, the whole height, for nine or ten inches under the edge of the bearer that is fartheft from the wall, muft then be gently forced nearer; confequently the other edge, together with the painting and plafter that is freed, will leave the wall, and give an opportunity of introducing the faw behind, and cutting away the fame to a certain diftance farther under; and, by repeating this, the whole of the picture will at length be freed, and left on the bearer. Each time the bearer is removed, and, as it were, rolled on the vertical furface of the wall, care muft be taken to turn and nail the fecuring-canvas on the top and bottom edges of the bearer, fo as to fecure the freed plaftering and picture from moving about; and, laftly, before the bearer and plaftering be moved, to nail the other edge of the picture in the fame way, which will fecure the whole to the bearer. This done, the picture and bearer are at liberty to be moved to a proper place, in order to be freed from the remaining plafter. The edges may then be unnailed; the painting and canvas flipped from this bearer on to a plain board; and the new canvas may be then put on; which is to remain till dry, as in other cafes.

"It may appear, that the bending of the canvas and plaftering to the convex bearer will crack the plafter, and damage the painting; but, from experience (fays Mr Salmon) I have obferved, that, to a curve of fuch or even lefs radius, plaftering will bend, without any vifible crack, even on the exterior part thereof; and that part next the bearer, not having occafion, in bending, to extend its parts, will confequently be much lefs liable to be difturbed by fuch bending."

In clearing the wood from the paintings, our author never made ufe of aquafortis, or any other liquid; the ufe of which he conceives would be very tedious, and attended with danger, left it fhould get through the paint, and wet or damp the pafte by which the fecuring canvas is fixed. In working off the wood, he generally made ufe of fuch planes as by the joiners are called the *levelled rabbit-plane*, and *fmall rounds*. By the corners of the former, and proper handling of the latter, the wood is cleared off without force or violence: even the fmalleft particles may, in general, be got off; although in fome paintings, and in particular parts of others, he has met with places on which he thought it beft to leave fome particles, or fine fplinters, of wood, but nothing more. Rafps, and fometimes a fine chifel, are ufeful, to clear off fuch parts as may be in hollow places, or where particles of wood are left, as above. The time required will be various, according to the manner in which the painting was originally done; fome being painted on boards previoufly prepared with a water colour; others immediately painted with oil on the wood. This laft fort is by much the moft difficult; the other is more eafy, as the previous preparation prevents the wood from imbibing the oil, and confequently admits it to be more eafily feparated.

PALILICUM, the fame as Aldebaran, a fixed ftar of the firft magnitude, in the eye of the bull, or fign Taurus.

PALLIFICATION, or Piling, in architecture, denotes the piling of the ground-work, or the ftrengthening it with piles, or timber driven into the ground; which is practifed when buildings are erected upon a moift or marfhy foil.

PALM, an ancient long meafure, taken from the extent of the hand. See Palmus, *Encycl.*

PALMÆ, palms. See *Encyclopædia*. The fubject is introduced here to notice a kind of palm, the product of North America, of which we have the following account by Dr Barton.

"There grows upon the river Mobile a fpecies of palm, which is but little known to naturalifts, but which promifes to be an important article of food to man. It has no ftalk or ftem above ground. The leaves fpread regularly all round, and when fully expanded are flabelliform. In the centre of thefe leaves is produced the receptacle of the fruit, which is of the form and fize of a common fugar-loaf. This receptacle confifts of a vaft number of drupes, or berries, of the fize and fhape of common plums: each is covered with a fibrous, farinaceous, pulpy coating, of confiderable thicknefs. This fubftance is faid to refemble manna in texture, colour, and tafte; or, perhaps, it ftill more refembles moift brown fugar, with particles of loaf-fugar mixed with it. It is a moft delicious and nourifhing food, and is diligently fought after in the places where it grows. Upon firft tafting it, it is fomewhat bitter and pungent.

PANORAMA, a word derived from παν and ὁραμα; and therefore employed of late to denote a painting, whether in oil or water colours, which reprefents an entire view of any country, city, or other natural objects, as they appear to a perfon ftanding in any fituation, and turning quite round. To produce this effect, the

Panorama, Paper.

the painter or drawer muſt fix his ſtation, and delineate correctly and connectedly every object which preſents itſelf to his view as he turns round, concluding his drawing by a connection with where he began. He muſt obſerve the lights and ſhadows, how they fall, and perfect his piece to the beſt of his abilities. There muſt be a circular building or framing erected, on which this drawing or painting may be performed; or the ſame may be done on canvas, or other materials, and fixed or ſuſpended on the ſame building or framing, to anſwer the purpoſe complete. It muſt be lighted entirely from the top, either by a glazed dome, or otherwiſe as the artiſt may think proper. There muſt be an incloſure within the ſaid circular building or framing, which ſhall prevent an obſerver going too near the drawing or painting, ſo as it may, from all parts it can be viewed, have its proper effect. This incloſure may repreſent a room, or platform, or any other ſituation, and may be of any form thought moſt convenient; but the circular form is particularly recommended. Of whatever extent this inſide incloſure may be, there muſt be over it (ſupported from the bottom, or ſuſpended from the top) a ſhade or roof; which, in all directions, ſhould project ſo far beyond this incloſure, as to prevent an obſerver from ſeeing above the drawing or painting when looking up; and there muſt be without this incloſure another interception, to repreſent a wall, paling, or other interception, as the natural objects repreſented, or fancy, may direct, ſo as effectually to prevent the obſerver from ſeeing below the bottom of the drawing or painting; by means of which interception, nothing can be ſeen on the outer circle but the drawing or painting intended to repreſent nature. The entrance to the inner incloſure muſt be from below, a proper building or framing being erected for that purpoſe, ſo that no door or other interruption may diſturb the circle on which the view is to be repreſented. And there ſhould be, below the painting or drawing, proper ventilators fixed, ſo as to render a current circulation of air through the whole: and the inner incloſure may be elevated, at the will of an artiſt, ſo as to make obſervers, on whatever ſituation he may wiſh they ſhould imagine themſelves, feel as if really on the very ſpot.

PAPER is an article of ſuch importance, and at preſent * of ſo enormous a price, that no improvement in its manufacture ſhould paſs unnoticed in a work of this nature. The diſcovery made in France by M. Bertholet of the efficacy of oxy-muriatic acid in expediting the proceſs of Bleaching (ſee that article in this *Suppl.*), has contributed eſſentially to facilitate the manufactures, not only of cotton and linen cloths, but alſo of paper, of which it has even increaſed the materials. Formerly writing paper could be made of *unprinted* linen alone; but by means of the proceſs of M. Bertholet even printed linen may be made into the fineſt and whiteſt paper. In the year 1795 a patent was granted to Mr Elias Carpenter of Bermondſay, Surrey, for a method of bleaching paper of ſuch materials in the *water-leaf* or *ſheet*, and ſizing it without drying.

* 1800.

In the preparation of the pulp, the coarſer rags are to be macerated for two or three days in a cauſtic alkaline ley, and wrought into ſheets of paper in the uſual way; a ſtrong wooden box or trough is then to be procured, of a ſize proportioned to that of the paper, lined on the inſide with white paint, and furniſhed with ſeveral ſtages of croſs bars of glaſs: the bottom of the box is to be covered with a ſtratum about one inch deep of cauſtic ley, and the paper laid by quarter reams, or leſs, acroſs the glaſs bar. A hole muſt be made in the box to admit the beak of an earthen-ware retort, into which muſt be put manganeſe and ſea ſalt, in powder, ſulphuric acid, and an equal quantity of water impregnated with the ſteams of burning ſulphur (ſulphureous acid). The cover of the box is to be made air-tight by luting or ſlips of paper dipped in paſte. The apparatus being thus prepared, the belly of the retort is to be plunged in water, kept boiling, and in a ſhort time the oxy-muriatic gas will be driven into the box, will penetrate the paper, and render it of a dazzling whiteneſs, while the alkaline ley at the bottom will, by gradually abſorbing it, prevent its becoming ſo concentrated as to deſtroy or injure the texture of the paper. From three to four pounds of ſulphuric acid will ſuffice for one hundred weight of paper, and the operation will be completed in about eight hours. The ſheets as they are taken out of the box are to be ſized with the following mixture:

To 1 cwt. of clippings of ſkin add 14 lb. of alum, 7 of calcined vitriol, and 1lb. of gum arabic, with a ſufficient quantity of water to ſize 50 reams of fools-cap.

The ſame method will ſerve equally well to clean engravings or printing; for though the oxy-muriac acid diſcharges all ſtains, dirt, &c. yet it is incapable of acting on printers ink.

This, however, is not the only improvement in the manufacture of paper derived from modern chemiſtry. In Crell's *Chemical Annals* for the year 1797, we have an account of ſome curious experiments made by M. L. Brugnatelli, with the view of rendering

Paper incombuſtible, and the writing on it, of courſe, indeſtructible by fire. Of all the ſubſtances which he tried, he found the liquor of flints the moſt proper to ſecure paper from deſtruction by fire. He dipped a ſheet of paper ſeveral times in the above liquor freſh made, or daubed it ſeveral times over the whole paper with a hair bruſh, and dried it in the ſun or in an ovan. Paper prepared in this manner loſt ſome of its ſoftneſs, became a little rougher than before, and acquired a lixivious cauſtic taſte. In other reſpects it was not different from common white paper. When this paper was laid upon glowing coals, it did not burn like common paper, but became red, and was converted to a coal, which however did not fall into aſhes like the coal of common paper, ſo that it might therefore be conſidered as petrified paper. This coal, however, is exceedingly friable; for when it is taken between the fingers, or preſſed together in any manner whatever, it drops to pieces. Still the diſcovery muſt be a valuable one, if there be any kind of ink of ſuch a nature as that the characters written with it continue viſible on this coal. Such an ink M. Brugnatelli made by combining diſſolved nitrite of zinc with common ink; and found, that the colour of this mixture, though it appeared ſomewhat pale on common paper, became ſo dark on prepared paper, that words written with it appeared more conſpicuous than words written with common ink. When the paper was burnt, or reduced to a coal, thoſe characters were ſo viſible, in a clear *white* colour on a *dark* ground, that they could be read with as much eaſe as characters written with the beſt ink on white

white paper. If the ingenious author fucceed in his attempts to difcover a method of rendering his prepared paper lefs friable when burnt, his difcovery will be one of the moft important of the prefent age.

PARABOLIC Conoid, is a folid generated by the rotation of a parabola about its axis. This folid is equal to half its circumfcribed cylinder; and therefore if the bafe be multiplied by the height, half the product will be the folid content.

Parabolic Pyramidoid, is a folid figure, thus named by Dr Wallis from its genefis or formation, which is thus: Let all the fquares of the ordinates of a parabola be conceived to be fo placed, that the axis fhall pafs perpendicularly through all their centres; then the aggregate of all thefe planes will form the parabolic pyramidoid. This figure is equal to half its circumfcribed parrallelopipedon. And therefore the folid content is found by multiplying the bafe by the altitude, and taking half the product; or the one of thefe by half the other.

Parabolic fpace, is the fpace or area included by the curve line and bafe or double ordinate of the parabola.

Parabolic Spindle, is a folid figure conceived to be formed by the rotation of a parabola about its bafe or double ordinate.

Parabolic Spiral, is a curve arifing from the fuppofition that the common or Apollonian parabola is bent or twifted till the axis come into the periphery of a circle, the ordinates ftill retaining their places and perpendicular pofitions with refpect to the circle, all thefe lines ftill remaining in the fame place. This figure is fometimes called the *Helecoid parabola*.

PARABOLOIDES, parabolas of the higher orders. The equation for all curves of this kind being $a^{m-n} x^n = y^m$, the proportion of the area of any one to the complement of it to the circumfcribing parallelogram, will be as m to n.

PARACENTRIC Motion, denotes the fpace by which a revolving planet approaches nearer to, or recedes farther from, the fun, or centre of attraction.

Paracentric Solicitation of Gravity, is the fame as the vis centripeta.

PARACHUTE, a kind of large and ftrong umbrella, contrived to break a perfon's fall from an air-balloon, fhould any accident happen to the balloon at a high elevation. This contrivance was firft thought of by Blanchard, who at different times, by means of the parachute, let fall from his balloon dogs and other animals. He ventured even to defcend in this manner himfelf; but, whether from the bad conftruction of his parachute, or from falling among trees, he had the misfortune to break one of his legs. Citizen Garnerin, as he choofes to be called, was more fuccefsful. On the 21ft of October 1797, he afcended from the garden de Mauffeux at half paft five in the evening; between the balloon and the car, in which he fat, was placed the parachute, half opened, and forming a kind of tent over the aerial traveller; and when the whole apparatus was at a confiderable height, he feparated the parachute and car from the balloon. The parachute unfolding itfelf, was, by his weight and that of the car, drawn of courfe towards the earth. Its fall was at firft flow and vertical; but foon afterwards it exhibited a kind of balancing or vibration, and a rotation gradually increafing, which might be compared with that of a leaf falling from a tree. The aëronaut, however, reached the ground unhurt.

This parachute was of cloth, and its diameter, when unfolded, about twenty-five feet. To ufe fuch inftruments with fuccefs, it is neceffary that the car be fufpended at a confiderable diftance from the parachute, fo as that the centre of gravity of the whole fhall be vertically below the centre of refiftance made by the air to the defcent of the parachute; for if the car be otherwife placed, it is evident that the parachute will incline to one fide, defcend obliquely, ofcillate, and the fmalleft irregularity in its figure will caufe it to turn round its vertical axis.

PARAGUATAN, a kind of wood which grows in Guiana, and promifes to be of great utility as a dye ftuff. We have feen no botanical defcription of the tree; but from the report made to the Council of Trade and Mines, by D. Dominique Garcia Fernandez, infpector of coinage, we learn that its bark, boiled in water, affords a coloured extract which refifts the agency of acids for a longer time than brazil or logwood; that the colour may be revived by means of alkalies, after it has been deftroyed by combination with acids; that vinegar, lemon juice, and tartar, render this colour more brilliant, while they entirely deftroy the colours of brazil and logwood; that the fecula of the bark of paraguatan fixes and attaches itfelf to wool, cotton, and filk; and that the colour is brighter on filk than on wool, and brighter on wool than on cotton. The fame fecula dried is afterwards foluble in alcohol, to which it communicates a tinge fimilar to that afforded by cochineal; but it muft be confeffed, that the colour obtained from paraguatan has not the force of that of cochineal, though it is fuperior to thofe of madder, brazil wood, and logwood. From thefe facts D. Fernandez confiders the paraguatan as one of the moft valuable productions which America furnifhes to Spain.

PARALLAX (fee *Encycl.*) is ufed, not only in aftronomy, but alfo in levelling, for the angle contained between the line of true level, and that of apparent level. And, in other branches of fcience, for the difference between the true and apparent places.

PARALLEL Ruler, is a mathematical inftrument, confifting of two equal rulers, either of wood or metal, connected together by two flender crofs bars or blades of equal length, moveable about the points of junction with the rulers. There are other forms of the inftrument; fome, for inftance, having the two blades croffing in the middle, and fixed only at one end of them, the other two ends fliding in grooves along the two rulers, &c.

The ufe of this inftrument is obvious. For the edge of one of the rulers being applied to any line, the other opened to any extent will be always parallel to the former; and confequently any parallels to this may be drawn by the edge of the ruler, opened to any extent.

PARALLELS, or Places of Arms, in a fiege, are deep trenches, 15 or 18 feet wide, joining the feveral attacks together; and ferving to place the guard of the trenches in, to be at hand to fupport the workmen when attacked. There are ufually three in an attack: the firft is about 600 yards from the covert-way, the fecond between 3 and 400, and the third near or on the

the glacis. It is ſaid they were firſt invented or uſed by Vauban.

PARALLELISM OF THE EARTH's AXIS, is that invariable ſituation of the axis, in the progreſs of the earth thro' the annual orbit, by which it always keeps parallel to itſelf; ſo that if a line be drawn parallel to its axis, while in any one poſition, the axis, in all other poſitions or parts of the orbit, will always be parallel to the ſame line.

PARAMETER, a certain conſtant right line in each of the three conic ſections; otherwiſe called alſo *latus rectum*.

PARAMARIBO, the capital of the Dutch ſettlement at Surinam, is ſituated on the right ſide of the beautiful river Surinam, at about 16 or 18 miles diſtance from its month. It is built upon a kind of gravelly rock, which is level with the reſt of the country, in the form of an oblong ſquare; its length is about a mile and a half, and its breadth about half as much. All the ſtreets, which are perfectly ſtraight, are lined with orange, ſhaddock, tamarind, and lemon trees, which appear in everlaſting bloom; while, at the ſame time, their branches are weighed down with the richeſt cluſters of odoriferous fruit. Neither ſtone nor brick is made uſe of here for pavement; the whole being one continued gravel, not inferior to the fineſt garden walks in England, and ſtrewed on the ſurface with ſea-ſhells. The houſes, which are moſtly of two and ſome of three ſtories high, are all built of fine timber, a very few excepted; moſt of the foundations are of brick, and they are roofed with thin ſplit boards, called *ſhingles*, inſtead of ſlates or tiles. Windows are very ſeldom ſeen in this country, glaſs being inconvenient on account of the heat; inſtead of which they uſe gauze frames: ſome have only the ſhutters, which are kept open from ſix o'clock in the morning until ſix at night. As for chimneys, there are none in the colony; no fires being lighted except in the kitchens, which are always built at ſome diſtance from the dwelling-houſe, where the victuals are dreſſed upon the floor, and the ſmoke let out by a hole made in the roof: theſe timber houſes are, however, very dear in Surinam, one of them having coſt above L. 15,000 ſterling. There is no ſpring water to be met with in Paramaribo; moſt houſes have wells dug in the rock, which afford but a brackiſh kind of beverage, only uſed for the negroes, cattle, &c. and the Europeans have reſervoirs or ciſterns, in which they preſerve rain water for their own conſumption; thoſe of nicer taſte let it firſt drop through a filtering-ſtone into large jars or earthen pots, made by the native Indians on purpoſe, which they barter at Paramaribo for other commodities. The inhabitants of this country, of every denomination, ſleep in hammocks, the negro ſlaves excepted, who moſtly lie on the ground: the hammocks uſed by thoſe in ſuperior ſtations are made of cotton, ornamented with rich fringe; theſe are alſo made by the Indians, and ſometimes worth above twenty guineas; neither bedding nor covering is neceſſary, except an awning to keep off the muſquitoes. Some people indeed lie on bedſteads; in that caſe they are ſurrounded, inſtead of curtains, with gauze pavilions, which admit the air freely, and at the ſame time keep off the ſmalleſt inſect. The houſes in general at Paramaribo are elegantly furniſhed with paintings, gilding, cryſtal chandeliers, china jars, &c.; the rooms are never papered or plaſtered, but beautifully wainſcotted with cedar, and Brazil, and mahogany wood.

The number of buildings in Paramaribo is computed at about 1400, of which the principal is the governor's palace, whence there is a private paſſage through the garden which communicates with Fort Zelandia. This houſe, and that of the commandant, which has lately been burnt, were the only brick buildings in the colony. The town-hall is an elegant new building, and covered with tiles; here the different courts are held, and underneath are the priſons for European delinquents, the military excepted, who are confined in the citadel of Fort Zelandia. The Proteſtant church, where divine worſhip is performed both in French and Low Dutch, has a ſmall ſpire with a clock; beſides which there is a Lutheran chapel, and two elegant Jewiſh ſynagogues, one German the other Portugueſe. Here is alſo a large hoſpital for the garriſon, and this manſion is never empty. The military ſtores are kept in the fortreſs, where the ſociety ſoldiers are alſo lodged in barracks, with proper apartments for ſome officers. The town of Paramaribo has a noble road for ſhipping, the river before the town being above a mile in breadth, and containing ſometimes above 100 veſſels of burden, moored within a piſtol-ſhot of the ſhore. Before Holland became a province of France, and thereby loſt her trade, there were ſeldom fewer than 80 ſhips at Paramaribo, loading coffee, ſugar, cocoa, cotton, and indigo, for the mother country, including alſo the Guinea men that brings ſlaves from Africa, and the North American and Leeward Iſland veſſels, which bring flour, beef, pork, ſpirits, herrings, and mackarel ſalted, ſpermaceti candles, horſes, and lumber; for which they receive chiefly molaſſes to be diſtilled into rum. This town is not fortified, but is bounded by the river on the ſouth-eaſt; by a large ſavannah on the weſt; by an impenetrable wood on the north-eaſt; and is protected by Fort Zelandia on the eaſt. This citadel is only ſeparated from the town by a large eſplanade, where the troops parade occaſionally. The fort is a regular pentagon, with one gate fronting Paramaribo, and two baſtions which command the river; it is very ſmall but ſtrong, being made of rock or hewn ſtones, ſurrounded by a broad foſſe well ſupplied with water, beſides ſome outworks. On the eaſt ſide fronting the river, is a battery of 21 pieces of cannon. On one of the baſtions is a bell, which is ſtruck with a hammer by the centinel, who is directed by an hour-glaſs. On the other is planted a large enſign-ſtaff, upon which a flag is hoiſted upon the approach of ſhips of war, or on public rejoicing days. The walls are ſix feet thick, with embraſures, but no parapet.

Paramaribo is a very lively place, the ſtreets being generally crowded with planters, ſailors, ſoldiers, Jews, Indians, and Negroes, while the river is covered with canoes, barges, &c. conſtantly paſſing and repaſſing like the wherries on the Thames, often accompanied with bands of muſic; the ſhipping alſo in the road adorned with their different flags, guns firing, &c. not to mention the many groupes of boys and girls playing in the water, altogether form a pleaſing appearance; and ſuch gaiety and variety of objects ſerve, in ſome meaſure, to compenſate for the many inconveniences of the climate. Their carriages and dreſs are truly magnificent; ſilk embroidery, Genoa velvets, diamonds, gold and ſilver lace, Paramaribo, Paris.

lace, being daily worn, and even the mafters of trading fhips appear with buttons and buckles of folid gold. They are equally expenfive at their tables, where every thing that can be called delicate is produced at any price, and ferved up in plate and china of the neweft fafhion, and moft exquifite workmanfhip. But nothing difplays the luxury of the inhabitants of Surinam more than the number of flaves by whom they are attended, often twenty or thirty in one family. White fervants are feldom to be met with in this colony.

The current money are ftamped cards of different value, from five fhillings to fifty pounds: gold and filver is fo fcarce, that the exchange premium for fpecie is often above 10 *per cent.* A bafe Dantzic coin called a *bit*, value fomething lefs than fixpence, is alfo current in Surinam. English and Portuguefe coin are fometimes met with, but moftly ufed as ornaments by the Mulatto, Samboe, Quaderoon, and Negro girls. The Negro flaves never receive any paper money; for as they cannot read, they do not underftand its value; befides, in their hands, it would be liable to many accidents, from fire or children, and particularly from the rats, when it becomes a little greafy.

This town is well fupplied with provifions, *viz.* butchers meat, fowls, fifh, and venifon. Vegetables in particular the country abounds with; befides the luxuries peculiar to this climate, they import whatever Europe, Africa, and Afia can afford. Provifions, however, are exceffively dear in general, efpecially thofe imported, which are moftly fold by the Jews and mafters of fhips. The firft enjoy extraordinary privileges in this colony; the latter erect temporary warehoufes for the purpofe of trade, during the time their fhips are loading with the productions of the climate. Wheat flour is fold from four-pence to one fhilling per pound; butter, two fhillings; butcher's meat never under one fhilling, and often at one fhilling and fixpence; ducks and fowls from three to four fhillings a couple. A fingle turkey has fometimes coft one guinea and a half; eggs are fold at the rate of five, and European potatoes twelve, for fixpence. Wine three fhillings a bottle. Jamaica rum a crown a gallon. Fifh and vegetables are cheap, and fruit almoft for nothing.

PARIS (Francis), a man more famous after his death than during his life, by the miracles which were faid to be performed at his tomb. He is generally known by the name of Abbé Paris; and his pretended miracles, with others of like manufacture, have furnifhed deiftical writers, and Mr Hume in particular, with a kind of argument againft the reality of the miracles of which we have an account in the Gofpel. It is merely that we may ftate his pretenfions fairly, that we have introduced him to the notice of our readers; for in every other refpect he is wholly unworthy of their regard. He was the fon of a counfellor in Parliament, and had the profpect, if he had chofen it, of fucceeding to his father's appointment; but he chofe rather to become an ecclefiaftic, and he became a very zealous one. He gave up all his poffeffions to his brother, refufed preferment intended for him by the cardinal de Noailles, devoted himfelf entirely to retirement, and made ftockings for his own fupport, and for the affiftance of the poor. He died perhaps in confequence of his rigorous mode of life, May 1. 1727, at the age of only 37. His brother raifed a monument to him in the fmall churchyard of St Medard, to which the poor and the pious foon began to flock; and after a time it was reported, that in confequence of their prayers at that tomb, fome fick perfons had received cures. As Paris had been a rigorous Janfenift, this was a fine opportunity for that fect to gain credit to their caufe; the miracles were therefore multiplied, and a variety of perfons affected the moft fingular convulfions.

Paris.

The minds of the people becoming inflamed by thefe extravagancies, the court found it neceffary to fhut up the churchyard, which was done on the 27th of January 1732. On this occafion, fome profane wit wrote upon the wall of the place,

> De par le Roy, defenfe a Dieu,
> De faire miracles en ce lieu.

The convulfions were continued, for a little while, in private houfes, but by degrees the matter fubfided, and the Abbé Paris was forgotten.

The diftinction between miracles, exhibited to ferve a party, and attefted only by thofe who are zealous in its fupport, and miracles performed in the fight of unbelievers, who, in fpite of their deep-rooted prejudices, were converted by them, is too ftriking to be overlooked by any, but thofe who are defirous of drawing a falfe and impious parallel; yet has Mr Hume dared to reprefent the miracles performed at the tomb of this faint as outvying in number, nature, and evidence, the miracles of Chrift and his apoftles—with what truth, the following obfervations will fhew:

1ft, It was often objected by the enemies of the faint, and the objection was never confuted by his friends, that the *proftrations* at his fepulchre, like animal magnetifm more lately, *produced* more difeafes than they *cured*. Such, furely, was not the nature of our Saviour's miracles.

2dly, Though the crowds of fick and infirm perfons who flocked to the tomb for relief were, by all accounts, innumerable; yet all the cures, of which the zealous hiftorian of the Miracles could procure vouchers, amounted only to NINE! Now, were thoufands, and ten thoufands of difeafed perfons to apply to fome circumforaneous quack, in full affurance of his extraordinary abilities and fkill in phyfic, could it furprife any perfon, if the diftempers of *eight* or *nine* of them fhould take a favourable turn while they were under a courfe of his ufelefs medicines?

3dly, We do not read that of thofe nine who were cured by the dead Abbé, the greater part were Jefuits and enemies to the Janfenifts; whereas the greater part of our Saviour's miracles were performed upon unconverted Jews, and one of them upon the fervant of the high prieft, who was thirfting for his blood.

4thly, The cures reported to have been performed at the grave of Paris were all fuch as might have been accomplifhed by natural means. Thus, a Spaniard who had loft one eye, and was diftreffed with an inflammation in the other, had the inflamed eye gradually cured, but not the loft eye reftored. Another perfon having pricked his eye with an awl, loft the fight of it in confequence of the aqueous humour dropping out; but his fight was reftored *whilft* he was paying his devotions to the Abbé—and fo it would have been while he was curfing the Abbé, had he continued his execrations for a fufficient length of time.

Paris, Parkhurst.

5*thly*, None of the cures said to have been performed were *instantaneous*. *All* the worshippers at the tomb persisted for *days*, several of them for *weeks*, and some for *months*, daily imploring the intercession of the Abbé *before* they received relief from their complaints.

6*thly*, Most of the devotees had been using *medicines* before they applied to the saint, and continued to use them *during the whole time* of their application; whilst it is confessed that the distempers of others had *abated* before they determined to solicit his help.

7*thly*, Some of the cures attested were *incomplete*, and only of a temporary duration. Thus, the Spaniard was relieved only from the most inconsiderable part of his complaint, and that too but for a very short period; for soon after his return home he relapsed into his former malady, as was fully attested by certificates and letters from Madrid. All this has been completely proved by the Archbishop of Sens; who in his *Pastoral Instruction*, published at the time the miracles were making a noise, has,

8*thly*, Clearly detected the deceit and little artifices by which those pretended miracles were so long supported. To that work we refer our readers; requesting them, after they have read it, to compare the evidence for the miracles of Paris with the evidence which in the article MIRACLE, *Encycl.* we have stated for the reality of the Gospel miracles, and to judge for themselves with the impartiality of philosophers.

Paris wrote a few very indifferent books of annotations on the Epistles to the Romans, to the Galatians, and the Hebrews; but few have ever read them, nor would they have rescued the author from oblivion, without the aid of his lying wonders.

PARKHURST (the Rev. John), was the second son of John Parkhurst, Esq; of Catesby in Northamptonshire. His mother was Ricarda Dormer, daughter of Judge Dormer. He was born in June 1728, was educated at the school of Rugby in Warwickshire, and was afterwards of Clare-hall, Cambridge; B. A. 1748, M. A. 1752; and many years fellow of his college.

Being a younger brother, he was intended for the church; but not long after his entering into holy orders his elder brother died. This event made him the heir of a very considerable estate; though, as his father was still living, it was some time before he came into the full possession of it; and when he did come into the possession of it, the acquisition of fortune produced no change on his manners or his pursuits. He continued to cultivate the studies becoming a clergyman; and from his family connections, as well as from his learning and piety, he certainly had a good right to look forward to preferment in his profession; but betaking himself to retirement, and to a life of close and intense study, he sought for no preferment; and, according to the author of the biographical sketch of him published in the Gentleman's Magazine, he lived not in an age when merit was urged forward. Yet, in the capacity of a curate, but without any salary, he long did the duty, with exemplary diligence and zeal, in his own chapel at Catesby, which, after the demolition of the church of the nunnery there, served as a parish-church, of which also he was the patron.

When, several years after, it fell to his lot to exercise the right of presentation, he was so unfashionable as to consider church-patronage as a trust rather than a property; and, accordingly, resisting the influence of interest, favour, and affection, presented to the vicarage of Epsom, in Surrey, the Rev. Jonathan Boucher, who still holds it. This gentleman was then known to him only by character; but having distinguished himself in America, during the revolution, for his loyalty, and by teaching the unsophisticated doctrines of the church of England to a set of rebellious schismatics at the peril of his life, Mr Parkhurst thought, and justly thought, that he could not present to the vacant living a man who had given better proofs of his having a due sense of the duties of his office.

Parkhurst

In the year 1754, Mr Parkhurst married Susanna Myster, daughter, and, we believe, heiress of John Myster, Esq; of Epsom. It was thus that he became patron of the living which he bestowed on Mr Boucher. This lady died in 1759, leaving him a daughter and two sons; both the sons are now dead. In the year 1761, he married again Millicent Northey, daughter of Thomas Northey, Esq; by whom he had one daughter, now married to the Rev. Joseph Thomas.

In the year 1753, he began his career of authorship, by publishing, in 8vo, "A friendly address to the Rev. Mr John Wesley, in relation to a principal Doctrine maintained by him and his Assistants." This work we have not seen; but though we have no doubt of its value, we may safely say that it was of very little importance, when compared with his next publication, which was "An Hebrew and English Lexicon, without Points; to which is added, a methodical Hebrew Grammar, without Points, adapted to the use of Learners, 1762," 4to. To attempt a vindication of all the etymological and philosophical disquisitions which are scattered through this dictionary, would be very fruitless; but it is not perhaps too much to say, that we have nothing of the kind equal to it in the English language. He continued, however, to correct and improve it; and in 1778 another edition of it came out much enlarged, and a third in 1792.

His philological studies were not confined to the Hebrew language; for he published a Greek and English Lexicon to the New Testament; to which is prefixed, a plain and easy Greek Grammar, 1769, 4to; a second edition, 1794: and at his death there was in the press a new edition of both these lexicons; in a large 8vo, with his last corrections; for he continued to revise, correct, add to, and improve, these works, till within a few weeks of his death. As, from their nature, there cannot be supposed to be any thing in dictionaries that is particularly attractive and alluring, this continued increasing demand for these two seems to be a sufficient proof of their merit.

He published, "The Divinity and Pre-existence of our Lord and Saviour Jesus Christ, demonstrated from Scripture; in Answer to the first Section of Dr Priestley's Introduction to the History of early Opinions concerning Jesus Christ; together with Strictures on some other Parts of the Work, and a Postscript relating to a late Publication of Mr Gilbert Wakefield, 1787," 8vo. This work was very generally regarded as completely performing all that its title-page promised; and accordingly the whole edition was soon sold off. The brief, evasive, and very unsatisfactory notice taken

 taken of this able pamphlet by Dr Prieftley, in "A Letter to Dr Horne," &c. fhewed only that he was unable to anfwer it.

Mr Parkhurft was a man of very extraordinary independency of mind and firmnefs of principle. In early life, along with many other men of diftinguifhed learning, it was alfo objected to him, that he was an Hutchinfonian; and on this account alone, in common with them, it has been faid that he was neglected and fhunned.

There is not, in the hiftory of the times, fays the biographer already quoted, a circumftance more difficult to be accounted for than the unmerited, but increafing, difcountenance fhewn to thofe perfons to whom Hutchinfonianifm was then objected. Methodifts, Papifts, and fectaries of any and of every name, all ftood a better chance of being noticed and efteemed than Hutchinfonians. Had it even been proved that the few peculiar tenets by which they were diftinguifhed from other Chriftians were erroneous, the oppofition they experienced might have been deemed *hard meafure*, becaufe even their opponents allowed their principles to be inoffenfive, and themfelves to be learned.

Is this a fair ftate of the cafe? We think not. The early Hutchinfonians had imbibed all the peculiar notions of their mafter, and maintained them with a degree of acrimony which would have difgraced any caufe. Being in general very little acquainted with the higher mathematics, as Mr Hutchinfon himfelf feems likewife to have been, they cenfured dogmatically works which, without that knowledge, they could not fully underftand; whilft they maintained, with equal dogmatifm, as matters of fact, hypothefes, which a moderate fhare of mathematical fcience would have fhewn them to be impoffible. Had they ftopt here, no harm would have been done; they might have enjoyed their favourite notions in peace: but unfortunately they accufed of Atheifm, Deifm, or Socinianifm, all who thought not exactly as *they* thought, both in natural philofophy and in theology. Becaufe Newton and Clarke had demonftrated that the motions of the planets cannot be the effect of the impulfion of any material fluid, Hutchinfon, with fome of his followers, affirmed, that thefe two illuftrious men had entered into a ferious defign to overturn the Chriftian religion, and eftablifh in England the worfhip of the Heathen Jupiter, or the Stoical *anima mundi*. Becaufe the bifhops Pearfon, Bull, and others, who had uniformly been confidered as the ableft defenders of the Catholic faith, thought not exactly as Hutchinfon thought of the filiation of the Son of God, they were condemned by the pupils of his fchool as *Arians*, or at leaft *Semi-arians*; and the writer of this fketch has heard a living Hutchinfonian pronounce the fame cenfure, and for the fame reafon, on the prefent illuftrious Bifhop of Rochefter, and the no lefs illuftrious Whitaker.

That men, who thus condemned all that before them had been deemed great and good in phyfical fcience and Chriftian theology, fhould meet with fome difcountenance while they continued of fuch a fpirit, needs not furely excite much wonder; but that the difcountenance is increafing, we believe not to be true. The Hutchinfonians, as foon as they became lefs violent againft thofe who differed from them, had their fhare of preferment, in proportion to their number, with others; and we doubt not they will continue to have it, while they allow that a man may be no heretic, though he believe not Mr Hutchinfon to have been infallible. The late excellent Bifhop Horne was an avowed Hutchinfonian, though not an outrageous one like Julius Bate; and we have been told, and have reafon to believe, that the Bifhop of St Afaph is likewife a moderate favourer of the fame fyftem. There may be others on the epifcopal bench; but perhaps two out of twenty-fix is the full proportions of Hutchinfonian divines of eminence in England. It is true that Mr Parkhurft was a man of great learning and great worth; but before we attribute his want of preferment in the church to his Hutchinfonianifm, it is incumbent upon us to fay why Mr Whitaker, who is no Hutchinfonian, is ftill nothing more than the rector of Ruan-Lanyhorne.

Mr Parkhurft, however, was not, if his biographer deferves credit, a thorough-paced Hutchinfonian; for though he continued to read Hutchinfon's writings as long as he read at all, he was ever ready to allow, that he was oftentimes a confufed and bad writer, and fometimes unbecomingly violent. To have been deterred from reading the works of an author, who, with all his faults, certainly throws out many ufeful hints, for fear of being thought a Hutchinfonian, would have betrayed a pufillanimity of which Mr Parkhurft was incapable. What he believed he was not afraid to profefs; and never profeffed to believe any thing which he did not very fincerely believe. An earneft lover of truth, he fought it where only it is to be found—in the Scriptures (A). The ftudy of thefe was at once the bufinefs and the pleafure of his life; from his earlieft to his lateft years he was an hard ftudent: and had the daily occupations of every 24 hours of his life been portioned out, as it is faid thofe of king Alfred were, into three equal parts, there is reafon to believe that a deficiency would rarely have been found in the eight hours allotted to ftudy. What the fruits have been of a life fo conducted, few theologians, it is prefumed, need to be informed, it being hardly within the fcope of a fuppofition, that any man will now fit down to the ftudy of the Scriptures without availing himfelf of the affiftance to be obtained from his learned labours. Thefe labours ceafed at Epfom in Surrey, where this great and good man died, on March the 21ft, 1797. Befides the works which we have mentioned, there is in the Gentleman's Magazine, for Auguft 1797, a curious letter of his on the confufion of Tongues at Babel.

Mr Parkhurft's character may be collected with tolerable accuracy even from this imperfect fketch of his life. His notions of church patronage do him honour; and as a farther inftance of the high fenfe he entertain-

 ed

(A) This is vague language, which is the fource of much ufelefs controverfy, and therefore ought to be avoided. If by *truth*, in this paffage, be meant *religious* truth, we admit the affertion in the only fenfe in which we think it can have been made. If the author means *all* truth, he writes nonfenfe; for the Scriptures treat not of *geometry* or *algebra*, where truth is certainly to be found; and *we think* that they have a higher object than even *mechanics* and *aftronomy*.

Parkhurst, Parkinson. ed of strict justice, and the steady resolution with which he practised it on all occasions, an incident which occurred between him and one of his tenants, within these ten years, may here be mentioned. This man falling behind hand in the payment of his rent, which was L. 500 *per annum*, it was represented to his landlord that it was owing to his being over-rented. This being believed to be the case, a new valuation was made; and it was then agreed that, for the future, the rent should not be more than L 450. Justly inferring, moreover, that if the farm was *then* too dear, it must necessarily have been *always* too dear, unasked, and of his own accord, he immediately struck off L. 50 from the commencement of the lease; and instantly refunded all that he had received more than L. 450 *per annum*.

Mr Parkhurst was in his person rather below the middle size, but remarkably upright, and firm in his gait. He was all his life of a sickly habit: and his leading so remarkably studious and sedentary a life (it having, for many years, been his constant practice to rise at five, and, in winter, to light his own fire) to the very verge of David's limits of the life of man, is a consolatory proof to men of similar habits, how much, under many disadvantages, may still be effected by strict temperance and a careful regimen. He also gave less of his time to the ordinary interruptions of life than is common. In an hospitable, friendly, and pleasant neighbourhood, he visited little; alleging, that such a course of life neither suited his temper, his health, nor his studies. Yet he was of sociable manners; and his conversation always instructive, often delightful: for his stores of knowledge were so large, that he too has often been called a walking library. He belonged to no clubs; he frequented no public places; and there are few men who, towards the close of life, may not, on a retrospect, reflect with shame and sorrow, how much of their precious time has thus been thrown away, or perhaps worse than thrown away.

Like many other men of infirm and sickly frames, Mr Parkhurst was also irritable, and quick, warm, and earnest, in his resentments, though never unforgiving. But whether it be or be not a matter of reproach to possess a mind so constituted, it certainly is much to any man's credit to counteract and subdue it by an attention to the injunctions of religion. This Mr Parkhurst effectually did: and few men have passed through a long life more at peace with his neighbours, more respected by men of learning, more beloved by his friends, or more honoured by his family.

Biog. Dict. PARKINSON (John). Of this ingenious English botanist, one of the first and most industrious cultivators of that science among us, the memorials that remain are very scanty. He was born in 1567, was bred an apothecary, and resided in London. He rose to such reputation in his profession as to be appointed apothecary to King James I.; and, on the publication of his Theatre of Plants, he obtained from the unfortunate successor of that prince the title of *Botanicus Regis primarius*. The time of his death cannot be exactly ascertained; but, as his Herbal was published in 1640, and it appears that he was living at that time, he must have attained his 73d year.

Parkinson's first publication was, his 1. *Paradisi in Sole Paradisus terrestris*, or, A Garden of all Sorts of Pleasant Flowers which our English Ayre will permit to be nursed up: with a Kitchen-garden of all manner of Herbes, Roots, and Fruits, for Meat or Sause, &c. &c. Collected by John Parkinson apothecary, of London, 1629, folio, 612 pages. In this work the plants are arranged without any exact order: nearly 1000 plants are separately described, of which 780 are figured on 129 tables, which appear to have been cut expressly for this work. Parkinson was, it is conceived, the first English author who separately described and figured the subjects of the flower-garden; and this book is therefore a valuable curiosity, as exhibiting a complete view of the extent of the English garden at the beginning of the 17th century. It may, perhaps, be necessary to inform the reader, that *Paradisus in Sole*, is meant to express the author's name, *Park in sun*.. 2. In 1640 he published his *Theatrum Botanicum;* or Theatre of Plants, or an Herbal of a large extent: containing therein, a more ample and exact History and declaration of the Physical Herbs and Plants than are in other Authors, &c. &c. London, folio, 1746 pages—This work had been the labour of the author's life; and he tells us that, owing to "the disastrous times," and other impediments, the printing of it was long retarded. Dr Pulteney is of opinion that, allowing for the defects common to the age, Parkinson will appear "more of an original author than Gerard or Johnson, independent of the advantages he might derive from being posterior to them. His theatre was carried on through a long series of years, and he profited by the works of some late authors, which Johnson, though they were equally in his power, had neglected to use. Parkinson's descriptions, in many instances, appear to be new. He is more particular in pointing out the places of growth. Johnson had described about 2850 plants, Parkinson has near 3800. These accumulations rendered the *Theatrum Botanicum* the most copious book on the subject in the English language; and it may be presumed that it gained equally the approbation of medical people, and of all those who were curious and inquisitive in this kind of knowledge."

Parkinson, Parsons. Biog. Dict. PARSONS (James), an excellent physician and polite scholar, was born at Barnstaple, in Devonshire, in March 1705. His father, who was the youngest of nine sons of Colonel Parsons, and nearly related to the baronet of that name, being appointed barrack-master at Bolton in Ireland, removed with his family into that kingdom soon after the birth of his then only son James, who received at Dublin the early part of his education, and, by the assistance of proper masters, laid a considerable foundation of classical and other useful learning, which enabled him to become tutor to Lord Kingston. Turning his attention to the study of medicine, he went afterwards to Paris, where (to use his own words) "he followed the most eminent professors in the several schools, as Astruc, Dubois, Lemery, and others; attended the anatomical lectures of the most famous [Hunaud and De Cat]; and chemicals at the King's Garden at St Come. He followed the physicians in both hospitals of the Hotel Dieu and La Charité, and the chemical lectures and demonstrations of Lemery and Bouldoc; and in botany Jussieu. Having finished these studies, his professors gave him honourable attestations of his having followed them with diligence

gence and induftry, which intitled him to take the degrees of doctor and profeffor of the art of medicine, in any univerfity in the dominions of France. Intending to return to England, he judged it unneceffary to take degrees in Paris, unlefs he had refolved to refide there; and as it was more expenfive, he therefore went to the univerfity of Rheims, in Champaign, where, by virtue of his atteftations, he was immediately admitted to three examinations, as if he had finifhed his ftudies in that academy; and there was honoured with his degrees June 11. 1736, In the July following he came to London, and was foon employed by Dr James Douglas to affift him in his anatomical works, where in fome time he began to practife. He was elected a member of the Royal Society in 1740; and, after due examination, was admitted a licentiate of the college of phyficians April 1. 1751; paying college fees and bond ftamps of different denominations to the amount of L. 41 : 2 : 8, fubject alfo to quarterage of L. 2 *per annum*. In 1755 he paid a farther fum of 7, which, with the quarterage money already paid, made up the fum of L. 16, in lieu of all future payments." On his arrival in London, by the recommendation of his Paris friends, he was introduced to the acquaintance of Dr Mead, Sir Hans Slone, and Dr James Douglas. This great anatomift made ufe of his affiftance, not only in his anatomical preparations, but alfo in his reprefentations of morbid and other appearances; a lift of feveral of which was in the hands of his friend Dr Maty, who had prepared an *eloge* on Dr Parfons, which was never ufed, but which, by the favour of Mrs Parfons, Mr Nichols has preferved at large. Though Dr Parfons cultivated the feveral branches of the profeffion of phyfic, he was principally employed in the obftetrical line. In 1738, by the intereft of his friend Dr Douglas, he was appointed phyfician to the public infirmary in St Giles's. In 1739 he married Mifs Elizabeth Reynolds, by whom he had two fons and a daughter, who all died young. Dr Parfons refided for many years in Red Lion Square, where he frequently enjoyed the company and converfation of Dr Stukely, Bifhop Littleton, Mr Henry Baker, Dr Knight, and many other of the moft diftinguifhed members of the Royal and Antiquarian Societies, and that of Arts, Manufactures, and Commerce; giving weekly an elegant dinner to a large but felect party. He enjoyed alfo the literary correfpondence of D'Argenville, Buffon, Le Cat, Beccaria, Amb. Betrand, Valltravers, Afcanios, Turberville Needham, Dr Garden, and others of the moft diftinguifhed rank in fcience. As a practitioner, he was judicious, careful, honeft, and remarkably humane to the poor; as a friend, obliging and communicative; chearful and decent in converfation, fevere and ftrict in his morals, and attentive to fill with propriety all the various duties of life. In 1769, finding his health impaired, he propofed to retire from bufinefs and from London; and with that view difpofed of a confiderable number of his books and foffils, and went to Briftol. But he returned foon after to his old houfe, and died in it after a week's illnefs, on the 4th of April, 1770. By his laft will, dated in October 1766, he gave his whole property to Mrs Parfons; and in cafe of her death before him, to Mifs Mary Reynolds her only fifter, "in recompence for her affectionate attention to him and to his wife, for a long courfe of years, in fickenefs and in health." It was his particular requeft, that he fhould not be buried till fome change fhould appear in his corpfe; a requeft which occafioned him to be kept unburied 17 days, and even then fcarce the flighteft alteration was perceivable. He was buried at Hendon, in a vault which he had caufed to be built on the ground purchafed on the death of his fon James, where his tomb had a very commendatory infcription.

It would carry us beyond our ufual limits to enter into an enumeration of the many curious articles at various times communicated to the public by Dr Parfons, which may be feen in the Anecdotes of Bowyer. We fhall therefore clofe this article with an extract from Dr Maty's eulogium: "The furprifing variety of branches which Dr Parfons embraced, and the feveral living as well as dead languages he had a knowledge of, qualified him abundantly for the place of affiftant fecretary for foreign correfpondences, which the council of the Royal Society beftowed upon him about the year 1750. He acquitted himfelf to the utmoft of his power of the functions of this place, till a few years before his death, when he refigned in favour of his friend, who now gratefully pays this laft tribute to his memory. Dr Parfons joined to his academical honours thofe which the Royal College of Phyficians of London beftowed upon him, by admitting him, after due examination, licentiate, on the firft day of April 1751. The diffufive fpirit of our friend was only equalled by his defire of information. To both thefe principles he owed the intimacies which he formed with fome of the greateft men of his time. The names of Folkes, Hales, Mead, Stukely, Needham, Baker, Colinfon, and Garden, may be mentioned on this occafion, and many more might be added. Weekly meetings were formed, where the earlieft intelligence was received and communicated of any difcovery both here and abroad; and new trials were made to bring to the teft of experience the reality or ufefulnefs of thefe difcoveries. Here it was that the microfcopical animals found in feveral infufions were firft produced; the propagation of feveral infects by fection afcertained; the conftancy of Nature amidft thefe wonderful changes eftablifhed. His Remains of Japhet, being Hiftorical Enquiries into the Affinity and Origin of the European Languages, are a moft laborious performance, tending to prove the antiquity of the firft inhabitants of thefe iflands as being originally defcended from Gomer and Magog, above 1000 years before Chrift, their primitive and ftill fubfifting language, and its affinity with fome others. It cannot be denied but that there is much ingenuity, as well as true learning, in this work, which helps conviction, and often fupplies the want of it. But we cannot help thinking that our friend's warm feelings now and then miflead his judgment, and that fome at leaft of his conjectures, refting upon partial traditions, and poetical fcraps of Irifh filids and Welfh bards, are lefs fatisfactory than his tables of affinity between the feveral northern languages, as deduced from one common ftock. Literature, however, is much obliged to him for having in this, as well as in many of his other works, opened a new field of obfervations and difcoveries. In enumerating our learned friend's differtations, we find ourfelves at a lofs whether we fhould follow the order of fubjects or of time; neither is it eafy to account

Parfons

account for their furprifing variety and quick fucceffion. The truth is, that his eagernefs after knowledge was fuch, as to embrace almoft with equal facility all its branches, and with equal zeal to afcertain the merit of inventions, and afcribe to their refpective, and fometimes unknown, authors, the glory of the difcovery. Many operations, which the ancients have tranfmitted to us, have been thought fabulous, merely from our ignorance of the art by which they were performed. Thus the burning of the fhips of the Romans at a confiderable diftance, during the fiege of Syracufe, by Archimedes, would perhaps ftill continue to be exploded, had not the celebrated M. Buffon in France fhewn the poffibility of it, by prefenting and defcribing a model of a fpeculum, or rather affemblage of mirrors, by which he could fet fire at the diftance of feveral hundred feet. In the contriving, indeed, though not in the executing of fuch an apparatus, he had in fome meafure been foreftalled by a writer now very little known or read. This Dr Parfons proved in a very fatisfactory manner; and he had the pleafure to find the French philofpher did not refufe to the Jefuit his fhare in the invention, and was not at all offended by the liberty he had taken. Another French difcovery, I mean a new kind of painting fathered upon the ancients, was reduced to its real value, in a paper which fhewed our author was poffeffed of a good tafte for the fine arts: and I am informed that his fkill in mufic was by no means inferior, and that his favourite amufement was the flute. Richly, it appears from thefe performances, did our author merit the honour of being a member of the Antiquarian Society, which long ago had affociated him to its labours. To another fociety, founded upon the great principles of humanity, patriotifm, and natural emulation, he undoubtedly was greatly ufeful (A). He affifted at moft of their general meetings and committees, and was for many years chairman to that of agriculture; always equally ready to point out and to promote ufeful improvements, and to oppofe the interefted views of fraud and ignorance, fo infeparable from very extenfive affociations. No fooner was *this* fociety (B) formed, than Dr Parfons became a member of it. Intimately convinced of the noblenefs of its views, though from his ftation in life little concerned in its fuccefs, he grudged neither attendance nor expence. Neither ambitious of taking the lead, nor fond of oppofition, he joined in any meafure he thought right; and fubmitted cheerfully to the fentiments of the majority, though againft his own private opinion. The juft ideas he had of the dignity of our profeffion, as well as of the common links which ought to unite all its members, notwithftanding the differences of country, religion, or places of education, made him bear impatiently the fhackles laid upon a great number of refpectable practitioners: he wifhed, fondly wifhed, to fee thefe broken; not with a view of empty honour and dangerous power, but as the only means of ferving mankind more effectually, checking the progrefs of defigning men and illiterate practitioners, and diffufing through the whole body a fpirit of emulation. Though by frequent difappointments he forefaw, as well as we, the little chance of a fpeedy redrefs, he nobly perfifted in the attempt; and had he lived to the final event, would undoubtedly, like Cato, ftill have preferred the conquered caufe to that fupported by the gods. After having tried to retire from bufinefs and from London, for the fake of his health, and having difpofed of moft of his books with that view, he found it inconfiftent with his happinefs to forfake all the advantages which a long refidence in the capital, and the many connections he had formed, had rendered habitual to him. He therefore returned to his old houfe, and died in it, after a fhort illnefs, April 4. 1770. The ftyle of our friend's compofition was fufficiently clear in defcription, tho' in argument not fo clofe as could have been wifhed. Full of his ideas, he did not always fo difpofe and connect them together, as to produce in the minds of his readers that conviction which was in his own. He too much defpifed thofe additional graces which command attention when joined to learning, obfervation, and found reafoning. Let us hope that his example and fpirit will animate all his colleagues: and that thofe practitioners who are in the fame circumftances will be induced to join their brethren, fure to find amongft them thofe great bleffings of life, freedom, equality, information, and friendfhip. As long as thefe great principles fhall fubfift in this fociety, and I truft they will outlaft the longeft liver, there is no doubt but the members will meet with the reward honeft men are ambitious of, the approbation of their confcience, the efteem of the virtuous, the remembrance of pofterity."

Parfons || Paffigraphy.

PARODICAL Degrees, in an equation, a term that has been fometimes ufed to denote the feveral regular terms in a quadratic, cubic, bequadratic, &c. equation, when the indices of the powers afcend or defcend orderly in an arithmetical progreffion. Thus, $x^3 + m x^2 + n x = p$ is a cubic equation where no term is wanting, but having all its parodic degrees; the indices of the terms regularly defcending thus, 3, 2, 1, 0.

PARTY Arches, in architecture, are arches built between feparate tenures, where the property is intermixed, and apartments over each other do not belong to the fame eftate.

Party Walls, are partitions of brick made between buildings in feparate occupations, for preventing the fpread of fire. Thefe are made thicker than the external walls; and their thicknefs in London is regulated by act of Parliament of the 14th of George III.

PASSIGRAPHY, the art of writing on any fubject fo as to be underftood by all nations (See *Univerfal Characters* in this *Supplement*). In France, where every thing is admired that is new, and every vagary of the imagination of a pretended philofopher thought practicable, a propofal has lately been made to introduce one univerfal language into the world, conftructed by a few metaphyficians on the laws of human thought. And to this language, in its written form, is to be given the name of *paffigraphy*. Such readers as think this idle

nd dream

(A) The Society for the Encouragement of Arts, Manufactures, and Commerce. He likewife was affociated to the Economical Society at Berne, Dec. 26. 1763.

(B) A Medical Society inftituted by Dr Fothergill, and other refpectable phyficians, licentiates, in vindication of their privileges; where, it fhould feem, this eulogy was intended to be pronounced.

dream worthy their attention (which is far from being the cafe with us), will find fome ingenious thoughts on the hiftory of a philofophical language, in the 2d volume of *Nicholfon's Journal of Natural Philofophy, &c.*

PATH OF THE VERTEX, a term frequently ufed by Mr Flamfteed in his Doctrine of the Sphere, denoting a circle, defcribed by any point of the earth's furface as the earth turns round its axis. This point is confidered as vertical to the earth's centre; and is the fame with what is called the vertex or zenith in the Ptolomaic projection.

PEARL FISH, is commonly confidered as an *afcidia* (fee MYTILUS, *Encycl.*); but this is denied by a late author, who feems to have paid great attention to the pearl-fifhery at Ceylon. It has never, he fays, been accurately defcribed. It does not refemble the *afcidia* of Linnæus; and as he thinks it may form a new genus, he gives the following account of it:

"The fifh is faftened to the upper and lower fhells by two white flat pieces of mufcular fubftance, which have been called ears, and extend about two inches from the thick part of the body, growing gradually thinner. The extremity of each ear lies loofe, and is furrounded by a double brown fringed line. Thefe lie almoft the third part of an inch from the outer part of the fhell, and are continually moved by the animal. Next to thefe, above and below, are fituated two other double fringed moveable fubftances, like the bronchiæ of a fifh. Thefe ears and fringes are joined to a cylindrical piece of flefh of the fize of a man's thumb, which is harder and of a more mufcular nature than the reft of the body. It lies about the centre of the fhells, and is firmly attached to the middle of each. This, in fact, is that part of the pearl-fifh which ferves to open and fhut the fhells. Where this column is faftened, we find on the flefh deep impreffions, and on the fhell various nodes of round or oblong forms, like imperfect pearls. Between this part and the hinge (*cardo*) lies the principal body of the animal, feparated from the reft, and fhaped like a bag. The mouth is near the hinge of the fhell, enveloped in a veil, and has a double flap or lip on each fide; from thence we obferve the throat (*œfophagus*) defcending like a thread to the ftomach. Clofe to the mouth there is a curved brownifh tongue, half an inch in length, with an obtufe point; on the concave fide of this defcends a furrow, which the animal opens and fhuts, and probably ufes to convey food to its mouth. Near its middle are two bluifh fpots, which feem to be the eyes. In a pretty deep hole, near the bafe of the tongue, lies the beard (*byffus*), faftened by two flefhy roots, and confifting of almoft 100 fibres, each an inch long, of a dark green colour, with a metallic luftre; they are undivided, parallel, and flattened. In general, the *byffus* is more than three quarters of an inch without the cleft (*rima*); but if the animal is difturbed, it contracts it confiderably. The top of each of thefe threads terminates in a circular gland or head, like the *ftigma* of many plants. With this *byffus* they faften themfelves to rocks, corals, and other folid bodies; by it the young pearl-fifh cling to the old ones, and with it the animal procures its food, by extending and contracting it at pleafure. Small fhell fifh, on which they partly live, are often found clinging to the former. The ftomach lies clofe to the root of the beard, and has, on its lower fide, a protracted obtufe point. Above the ftomach are two fmall red bodies, like lungs; and from the ftomach goes a long channel or gut, which takes a circuit round the mufcular column above-mentioned, and ends in the anus, which lies oppofite to the mouth, and is covered with a fmall thin leaf, like a flap. Though the natives pretend to diftinguifh the fexes by the appearance of the fhell, calling the flat ones males, and thofe which are thick, concave, and vaulted, females, our author, on a clofe infpection, could not perceive any vifible fexual difference."

The pearls are only in the fofter part of the animal, and never in the firm mufcular column above-mentioned. They are found, in general, near the earth, and on both fides of the mouth. From the appearance of the fhell a judgment may be formed, with greater or lefs probability, whether it contains pearls or not. Thofe which have a thick calcareous cruft upon them, to which *ferpulæ* (fea tubes) *Tubuli mariæ irregulariter intorti, Crifta-gali Chamar lazuras, Lepas tintinabulum, Madreporee, Millipore, Cellipore, Gorgontæ, Spongiæ*, and other Zoophytes, are faftened, have arrived at their full growth, and commonly contain the beft pearls; but thofe that appear fmooth, contain either none, or fmall ones only.

In the article (*Encycl.*) intitled, *Manner of Fifhing for PEARLS in the Eaft Indies*, we have moft unaccountably faid, that "the beft divers will keep under water near *half an hour*, and the reft not lefs than a quarter!" This is a very great miftake; for M. *Le Beck* affures us, that the time during which a diver is able to remain under water feldom exceeds two minutes; and that, even after that fhort period, he difcharges, on emerging from the fea, a quantity of water, and fometimes a little blood, from his mouth and nofe. We have mentioned the danger which the divers run of becoming a prey to monftrous fifhes. Thefe fifhes are fharks; of which fuch a dread is juftly entertained, that the moft expert divers will not, on any account, defcend, till the conjurer has performed his ceremonies of enchantment. Thefe confift in a number of prayers, learned by heart, that nobody, probably not even the conjurer himfelf, underftands, which he, ftanding on the fhore, continues muttering and grumbling from fun-rife until the boats return. During this period, he is obliged to abftain from food and fleep, otherwife his prayers would have no avail: he is, however, allowed to drink; which privilege he indulges in a high degree, and is frequently fo giddy, as to be rendered very unfit for devotion. Some of the conjurers accompany the divers in their boats; which pleafes them very much, as they have their protectors near at hand.

PEDOMETER (fee *Encycl.*), is the name given by Mr Lewin Thugwell to an inftrument, which is rather an improved PERAMBULATOR than the inftrument which we have noticed by the name of Pedometer. The chief improvement made by him on the PERAMBULATOR (fee that article, *Encycl.*) is in the fize of the wheel, of which the circumference meafures $16\frac{1}{2}$ feet, or one pole, adapted to Gunter's concife method of arithmetic, and divided into 25 equal parts, correfponding to the links of his chain for land-meafuring. There is likewife a contrivance in Mr Thugwell's pedometer, for compelling the attention of the traveller to the inftrument at the end of every mile. It is very ingenious, and abundantly fimple; but we hardly think it of fuffi-

cient

cient importance to fill the ſpace which a complete deſcription of it would occupy in this work. It is fully deſcribed in the *Letters and Papers of the Bath and Weſt of England Society, for the Encouragement of Agriculture;* and likewiſe in the 6th volume of the *Repertory of Arts and Manufactures*.

PEGUE, the ancient capital of the kingdom of the ſame name (ſee PEGU, *Encycl.*), appears to have been a quadrangle, each ſide meaſuring about a mile and a half. It was ſurrounded by a ditch and wall; which, before the latter tumbled down, and the former was filled up, muſt have furniſhed no contemptible defence. The breadth of the ditch appears to be about 60 yards; its depth, where not choked up, about ten or twelve feet; and there is ſtill in it water enough to impede an eaſtern ſiege. The wall has been at leaſt 25 feet high, and its breadth at the baſe not leſs than 40. It is compoſed of brick, badly cemented together with clay mortar, and has had on it ſmall equidiſtant baſtions, about 300 yards aſunder.

Nothing can exhibit a more ſtriking picture of deſolation than the inſide of this wall. We have elſewhere given an account of the almoſt inceſſant wars between the kings of Pegue and Birma or Barma. In the year 1757, the Birman ſovereign carried the city of Pegue by aſſault, razed every dwelling to the ground, and diſperſed, or led into captivity, all the inhabitants. The pagodas, which are very numerous, were the only buildings that eſcaped the fury of the conqueror; and of theſe the great pagoda of SHOEMADOO has alone been attended to, and repaired.

This extraordinary edifice is built on a double terrace, one raiſed upon another. The lower and greater terrace is about ten feet above the natural level of the ground. It is quadrangular. The upper and leſſer terrace is of a like ſhape, raiſed about 20 feet above the lower terrace, or 30 above the level of the country. Theſe terraces are aſcended by flights of ſtone ſteps, broken and neglected. On each ſide are dwellings of the *Rahaans* or prieſts, raiſed on timbers four or five feet from the ground. Their houſes conſiſt only of a ſingle hall. The wooden pillars that ſupport them are turned with neatneſs. The roof is of tile, and the ſides of ſheathing-boards. There are a number of bare benches in every houſe, on which the *Rahaans* ſleep. They appear to have no furniture.

Shoemadoo is a pyramid, compoſed of brick and plaſter, with fine ſhell mortar, without excavation or aperture of any ſort: octagonal at the baſe, and ſpiral at the top. Six feet from the ground there is a wide ledge, which ſurrounds the baſe of the building; on the plane of which are 57 ſmall ſpires, of equal ſize, and equidiſtant. One of them meaſured 27 feet in height, and 40 in circumference at the bottom. On a higher ledge there is another row, conſiſting of 53 ſpires, of ſimilar ſhape and meaſurement. A great variety of mouldings encircles the building; and ornaments, ſomewhat reſembling the *fleur de lys*, ſurround what may be called the baſe of the ſpire. Circular mouldings likewiſe gird this part to a conſiderable height; above which there are ornaments in ſtucco, not unlike the leaves of a Corinthian capital; and the whole is crowned by a *tee*, or umbrella of open iron-work, from which riſes an iron rod with a gilded pendant.

The extreme height of the building, from the level of the country, is 361 feet; and above the interior terrace, 331 feet. On the ſouth eaſt angle of the upper terrace there are two handſome ſaloons, or *keouns*, lately erected. The roof is compoſed of different ſtages, ſupported by pillars. Captain Symes, from whoſe memoir in the Aſiatic Reſearches this account is taken, judged the length of each ſaloon to be about 60 feet, and the breadth 30. The ceiling of one of them was already embelliſhed with gold leaf, and the pillars lacquered; the other, when he ſaw it, was not completed. They are made entirely of wood. The carving on the outſide is very curious. He ſaw ſeveral unfiniſhed figures, intended to be fixed on different parts of the building; ſome of them not ill ſhapen, and many exceedingly groteſque. Splendid images of Gaudma (the *Birman* object of adoration) were preparing, which he underſtood were deſigned to occupy the inſide of theſe *keouns*.

At each angle of the interior terrace is a pyramidical pagoda, 67 feet in height, reſembling, in miniature, the great pagoda. In front of the one in the ſouth-weſt corner are four gigantic repreſentations in maſonry of Palloo, or the *man deſtroyer*, half beaſt, half human, ſeated on their hams, each with a large club on the right ſhoulder.

Nearly in the centre of the eaſt face of the area are two human figures in ſtucco beneath a gilded umbrella. One ſtanding, repreſents a man with a book before him, and a pen in his hand. He is called *Thagiamee*, the recorder of mortal merits and mortal miſdeeds. The other, a female figure kneeling, is *Maha Sumdere*, the protectreſs of the univerſe, as long as the univerſe is doomed to laſt: but when the time of general diſſolution arrives, by her hand the world is to be overwhelmed, and deſtroyed everlaſtingly.

On the north ſide of the great pagoda are three large bells, of good workmanſhip, ſuſpended near the ground between pillars. Several deers horns are ſtrewed around. Thoſe who come to pay their devotions firſt take up one of the horns, and ſtrike the bell three times, giving an alternate ſtroke to the ground. This act is to announce to the ſpirit of Gaudma the approach of a ſuppliant. There are ſeveral low benches near the bottom of the pagoda, on which the perſon who comes to pray places his offering; which generally conſiſts of boiled rice, a plate of ſweetmeats, or cocoa-nut fried in oil. When it is given, the devotee cares not what becomes of it. The crows and dogs commonly eat it up in the preſence of the donor, who never attempts to prevent or moleſt the animals.

There are many ſmall pagodas on the areas of both terraces, which are neglected, and ſuffered to fall into decay. Numberleſs images of Gaudma lie indiſcriminately ſcattered. A pious Birman who purchaſes an idol, firſt procures the ceremony of conſecration to be performed by the *Rahaans*, then takes his purchaſe to whatever ſacred building is moſt convenient, and there places it either in the ſhelter of a *keoun*, or on the open ground before the temple: nor does he ever after ſeem to have any anxiety about its preſervation, but leaves the divinity to ſhift for itſelf.

From the upper ledge that ſurrounds the baſe of Shoemadoo, the proſpect of the country is extenſive and pictureſque; but it is a proſpect of Nature in her rudeſt ſtate. There are few inhabitants, and ſcarcely

any

Pegue. any cultivation. The hills of *Martaban* rife to the eaft-ward: and the *Sitang* river, winding along the plains, gives here and there an interrupted view of its waters. To the north-north weft, above 40 miles, are the *Galladzet* hills, whence the Pegue river takes its rife; hills remarkable only for the noifome effects of their atmofphere. In every other direction the eye looks over a boundlefs plain, chequered by a wild intermixture of wood and water.

The prefent king of the Birmans has entirely altered the fyftem of his predeceffors. He has turned his attention to the population and improvement, rather than the extenfion, of his dominions; and feems more defirous to conciliate his new fubjects by mildnefs, than to rule them through terror. He has abrogated feveral fevere penal laws impofed upon the *Taliens* or Peguers: juftice is now diftributed impartially; and the only diftinction at prefent between a Birman and Talien confifts in the exclufion of the latter from all public offices of truft and power.

No act of the Birman government is more likely to reconcile the Taliens to the Birman yoke than the reftoration of their ancient place of abode, and the prefervation and embellifhment of the pagoda of Shoemadoo. So fenfible was the king of this, as well as of the advantages that muft accrue to the ftate from an increafe of culture and population, that fome years ago he iffued orders to rebuild Pegue, encouraged new fettlers by liberal grants, and invited the fcattered families of former inhabitants to return and repeople their deferted city.

Pegue, in its renovated ftate, feems to be built on the plan of the former city. It is a fquare, each fide meafuring about half a mile. It is fenced round by a ftockade, from 10 to 12 feet high. There is one main ftreet running eaft and weft, which is interfected at right angles by two fmaller ftreets, not yet finifhed. At each extremity of the principal ftreet there is a gate in the ftockade, which is fhut early in the evening. After that hour, entrance during the night is confined to a wicket. Each of thefe gates is defended by a forry piece of ordnance, and a few mufqueteers, who never poft centinels, and are ufually afleep. There are alfo two other gates on the north and fouth fides of the ftockade.

The houfes of the inhabitants of Pegue are far from commodious, agreeably to European notions of accommodation; but they are at leaft as much fo as the houfes of other Indian towns. There are no brick buildings in Pegue, except fuch as belong to the king, or are dedicated to Guadma. The king has prohibited the ufe of brick or ftone in private buildings, from the apprehenfion, that if people got leave to build brick houfes, they might erect brick fortifications, dangerous to the fecurity of the ftate. The houfes, therefore, are all made of mats or fheathing-boards, fupported on bamboos or pofts. Being compofed of fuch combuftible materials, the inhabitants are under continual dread of fire, againft which they take every precaution. The roofs are lightly covered; and at each door ftands a long bamboo, with a hook at the end, to pull down the thatch: alfo another pole, with a grating of fplit bamboo at the extremity, about three feet fquare, to fupprefs flame by preffure. Almoft every houfe has earthen pots of water on the roof. And there is a particular clafs of people, whofe bufinefs it is to prevent and extinguifh fires.

Peifhcar || Pell.

PEISHCAR, in Bengal, principal in office.

PEISHCUSH, a fine, tribute, or prefent.

PELL (Dr John), an eminent Englifh mathematician, defcended from an ancient family in Lincolnfhire, was born at Southwick in Suffex, March 1. 1610, where his father was minifter. He received his grammar education at the free fchool at Stenning in that county. At the age of 13 he was fent to Trinity college in Cambridge, being then as good a fcholar as moft mafters of arts in that univerfity; but though he was eminently fkilled in the Greek and Hebrew languages, he never offered himfelf a candidate at the election of fcholars or fellows of his college. His perfon was handfome; and being of a ftrong conftitution, ufing little or no recreations, he profecuted his ftudies with the more application and intenfenefs.

In 1629 he drew up the "Defcription and Ufe of the Quadrant, written for the Ufe of a Friend," in two books; the original manufcript of which is ftill extant among his papers in the Royal Society. And the fame year he held a correfpondence with Mr Briggs on the fubject of logarithms.

In 1630, he wrote *Modus fupputandi Ephemerides Aftronomicas, &c. ad. an.* 1630 *accommodatus*; and, A Key to unlock the meaning of Johannes Trithemius, in his Difcourfe on Steganography: which Key he imparted to Mr Samuel Hartlib and Mr Jacob Homedæ. The fame year he took the degree of Mafter of Arts at Cambridge. And the year following he was incorporated in the Univerfity of Oxford. June the 7th, he wrote A Letter to Mr Edmond Wingate on Logarithms: and, Oct. 5. 1631, *Commentationes in Cofmographiam Alftedii.*

In 1632 he married Ithamaria, fecond daughter of Mr Henry Reginolles of London, by whom he had four fons and four daughters.—March 6. 1634, he finifhed his "Aftronomical Hiftory of Obfervations of Heavenly Motions and Appearances;" and April the 10th, his *Ecliptica Prognoftica*, or Foreknower of the Eclipfes, &c. In 1634 he tranflated "The Everlafting Tables of Heavenly Motions," grounded upon the Obfervations of all Times, and agreeing with them all, by Philip Lanfberg, of Ghent in Flanders. And June the 12th, the fame year, he committed to writing "The Manner of Deducing his Aftronomical Tables out of the Tables and Axioms of Philip Lanfberg."—March the 9th, 1625, he wrote, "A Letter of Remarks on Gellibrand's Mathematical Difcourfe on the Variation of the Magnetic Needle." And the 3d of June following, another on the fame fubject.

His eminence in mathematical knowledge was now fo great, that he was thought worthy of a Profeffor's chair in that fcience; and, upon the vacancy of one at Amfterdam in 1639, Sir William Bofwell, the Englifh Refident with the States General, ufed his intereft, that he might fucceed in that Profefforfhip. It was not filled up, however, till 1642, when Pell was chofen to it; and he read with great applaufe public lectures upon Diophantus. In 1644 he printed at Amfterdam, in two pages 4to, "A Refutation of Longomontanus's Difcourfe," *De Vera Circuli Menfura.*

Pell.

In 1646, on the invitation of the Prince of Orange, he removed to the new college at Breda, as Profeſſor of Mathematics, with a ſalary of 1000 guilders a year. His *Idea Matheſeos*, which he had addreſſed to Mr Hartlib, who in 1639 had ſent it to Des Cartes and Merſenne, was printed 1650 at London, in 12mo, in Engliſh, with the title of *An Idea of Mathematics*, at the end of Mr John Durie's Reformed Library-keeper. It is alſo printed by Mr Hook, in his Philoſophical Collections, N° 5. p. 127. ; and is eſteemed our author's principal work.

In 1652 Pell returned to England; and in 1654 he was ſent by the Protector Cromwell agent to the Proteſtant Cantons in Switzerland; where he continued till June 23. 1658, when he ſet out for England, where he arrived about the time of Cromwell's death. His negociations abroad gave afterwards a general ſatisfaction, as it appeared he had done no ſmall ſervice to the intereſt of King Charles II. and of the church of England; ſo that he was encouraged to enter into holy orders: and in the year 1661 he was inſtituted to the rectory of Fobbing in Eſſex, given him by the king. In December that year, he brought into the upper houſe of convocation the kalendar reformed by him, aſſiſted by Sancroft, afterwards archbiſhop of Canterbury. In 1673 he was preſented by Sheldon, biſhop of London, to the rectory of Laingdon in Eſſex; and upon the promotion of that biſhop to the ſee of Canterbury ſoon after, became one of his domeſtic chaplains. He was then doctor of divinity, and expected to be made a dean; but his improvement in the philoſophical and mathematical ſciences was ſo much the bent of his genius, that he did not much purſue his private advantage. The truth is, he was a helpleſs man, as to wordly affairs; and his tenants and relations impoſed upon him, cozened him of the profits of his parſonage, and kept him ſo indigent, that he wanted neceſſaries, even ink and paper, to his dying day. He was for ſome time confined to the King's bench priſon for debt; but in March 1682, was invited by Dr Whitler to live in the college of phyſicians. Here he continued till June following; when he was obliged, by his ill ſtate of health, to remove to the houſe of a grand-child of his in St Margaret's church-yard, Weſtminſter. But he died at the houſe of Mr Cothorne, reader of the church of St Giles's in the Fields, December the 12th, 1685, in the 74th year of his age, and was interred at the expence of Dr Buſhby, maſter of Weſtminſter ſchool, and Mr Sharp, rector of St Giles's, in the rector's vault under that church.—Dr Pell publiſhed ſome other things not yet mentioned; a liſt of which is as follows, *viz.*

1. An Exercitation concerning Eaſter; 1644, in 4to, 2. A Table of 10,000 ſquare numbers, &c.; 1672, folio 3. An Inaugural Oration at his entering upon the Profeſſorſhip at Breda. 4. He made great alterations and additions to Rhonius's Algebra, printed at London 1668, 4to, under the title of An Introduction to Algebra, tranſlated out of the High Dutch into Engliſh by Thomas Branker, much altered and augmented by D. P. (Dr Pell). Alſo a Table of Odd Numbers, leſs than 100,000, ſhewing thoſe that are incompoſite, &c. ſupputated by the ſame Thomas Branker. 5. His Controverſy with Longomontanus concerning the Quadrature of the Circle; Amſterdam, 1646, 4to.

Pell, Pelletier.

He likewiſe wrote a Demonſtration of the 2d and 10th books of Euclid; which piece was in MS. in the library of Lord Brereton in Cheſhire: as alſo Archimedes's Arenarius, and the greateſt part of Diophantus's ſix books of Arithmetic; of which author he was preparing, Auguſt 1644, a new edition, in which he intended to correct the tranſlation, and make new illuſtrations. He deſigned likewiſe to publiſh an edition of Apollonius; but laid it aſide, in May 1645, at the deſire of Golius, who was engaged in an edition of that author from an Arabic manuſcript, given him at Aleppo 18 years before. Letters of Dr Pell to Sir Charles Cavendiſh, in the Royal Society.

Some of his manuſcripts he left at Brereton in Cheſhire, where he reſided ſome years, being the ſeat of William Lord Brereton, who had been his pupil at Breda. A great many others came into the hands of Dr Buſby; which Mr Hook was deſired to uſe his endeavours to obtain for the Society. But they continued buried under duſt, and mixed with the papers and pamphlets of Dr Buſby, in four large boxes, till 1755; when Dr Birch, ſecretary to the Royal Society, procured them for that body, from the truſtees of Dr Buſby. The collection contains, not only Pell's mathematical papers, letters to him, and copies of thoſe from him, &c. but alſo ſeveral manuſcripts of Walter Warner, the mathematician and philoſopher, who lived in the reigns of James I. and Charles I.

Dr Pell invented the method of ranging the ſeveral ſteps of an algebraical calculus, in a proper order, in ſo many diſtinct lines, with the number affixed to each ſtep, and a ſhort deſcription of the operation or proceſs in the line. He alſo invented the character ÷ for diviſion, ⊕ for involution, ɯ for evolution*.

* Hutton's Mathematical Dictionary.

PELLETIER (Bertrand), was born at Bayonne in 1761, and very ſoon began to diſplay an inſatiable thirſt of ſcience. It frequently happens, however, that young men, ſincerely deſirous of inſtruction, have no means or place where they can be aſſiſted in the developement of their natural talents, no maſter who may point out the direct road to ſcience, and that order and method, without which the efforts of the individual too often lead him from the object of his purſuit, inſtead of bringing him nearer to it. This was not the caſe with young Pelletier. He found every advantage in his father's houſe, where he received the firſt elements of the art of which he was afterwards the ornament; and his ſubſequent progreſs was made under Darcet, who having remarked in him that ſagacity which may be called the inſtinct of ſcience, admitted him among the pupils attached to the chemical laboratory of the college of France. Five years of conſtant application and ſtudy under ſuch a maſter, who was himſelf formed by nature, perfected by experience, and affectionately diſpoſed towards his pupil, afforded this young man a ſtock of knowledge very unuſual at his age. He ſoon gave a convincing proof of this, by publiſhing, at the age of 21, a ſet of very excellent obſervations on the arſenical acid. Macquer, by mixing nitre with the oxide of arſenic, had diſcovered in the reſidue of this operation a ſalt ſoluble in water, ſuſceptible of cryſtallization in tetrahedral priſms, which he denominated the neutral arſenical arfenical falt. It is the arfeniat of potafh. He was of opinion that no acid could decompofe it; but Pelletier fhewed, that the fulphuric acid diftilled from it does difengage the acid of arfenic. He fhewed the true caufe why the neutral arfenical falt is not decompofable in clofed veffels; and particularly the order of affinity by which the falt itfelf is formed in the diftillation of the nitrate of potafh, and the white oxide of arfenic. He explains in what refpects this falt differs from what Macquer called the liver of arfenic. Pelletier had been anticipated in this work by Scheele, by Bergman, by the academicians of Dijon, and by Berthollet; but he poffeffed at leaft the merit, in the firft effay of his powers, of having clearly developed all the phenomena of this operation, by retaining and even determining the quantity of gas it was capable of affording. After the fame principles it was that he decompofed the arfenico-ammoniacal falt, by fhewing how, in the decompofition of this laft, the pure arfenical acid is obtained in the form of a deliquefcent glafs. In this work we may obferve the fagacity with which he was enabled to developе all the phenomena of thefe compofitions and decompofitions, by tracing thofe delicate threads of fcientific relation which connect the feries of facts, and are imperceptible to ordinary minds.

Encouraged by the fuccefs of thefe firft works, which he prefented with the fenfibility of grateful attachment to his inftructor, he communicated his obfervations on the cryftallization of fulphur, cinnabar, and the deliquefcent falts; the examination of zeolites, particularly the falfe zeolite of Frihourg in Brifgaw, which he found to be merely an ore of zinc; obfervations on the dephlogifticated or oxygenated muriatic acid, relative to the abforption of oxygen; on the formation of ethers, particularly the muriatic and the acetous; and feveral memoirs on the operation of phofphorus made in the large way; its converfion into phofphoric acid, and its combination with fulphur and moft metallic fubftances.

It was by his operations on that moft aftonifhing production of chemiftry, phofphorus, that he burned himfelf fo dangeroufly as nearly to have loft his life. After the cure of his wound, which confined him to his bed for fix months, he immediately began the analyfis of the various plumbagos of France, England, Germany, Spain, and America, and found means to give novelty and intereft to his work, even after the publication of Scheele on the fame fubject. The analyfis of the carbonet of barytes led him to make experiments on animals; which prove that this earth is a true poifon, whether it be adminiftered in the form of the native carbonat of barytes, or whether it be taken from the decompofition of the fulphat, even though again combined with another acid.

Chemifts have given the name of *ftrontian* to a newly difcovered earth, from the name of the place where it was firft found. Pelletier analyfed it, and difcovered it in the fulphat of barytes. He likewife analyfed the verditer of England, of which painters and paper-hangers make fo much ufe. He difcovered a procefs for preparing it in the large way, by treating with lime the precipitate obtained from the decompofition of nitrat of copper by lime. By his procefs, verditer is afforded equal in beauty to that which comes from England. He was likewife one of the firft chemifts who fhewed the poffibility of refining bell metal, and feparating the tin. His firft experiments were made at Paris; after which he repaired to the foundary at Romilly, to verify them in the large way. The following year he was received a member of the Academy of Sciences at Paris, and fhortly afterwards went to La Fere, with Borda and General Daboville, to affift in experiments upon a new gunpowder. Being obliged, in order to render his experiments more decifive, to pafs great part of the day in the open air during a cold and humid feafon, his health, which was naturally delicate, became confiderably impaired. He began to recover his health, when he again became the victim of his zeal for the fcience he fo fuccefsfully cultivated. He had nearly perifhed by refpiring the oxygenated muriatic acid gas. A violent attack of convulfive afthma, which returned during feveral days, was the firft confequence of this unhappy accident. The diforder then feemed to abate; but it was incurable. The affiftance of art was infufficient to fave him; and he died in Paris, on the 21ft of July 1797, of a pulmonary confumption, in the flower of his age.

PENDULUM (See *Encycl.*). Befides the effects of heat and cold on the length of the pendulum rod, and of courfe on its ifochronifm, it may certainly be worth while, in the conftruction of clocks intended to meafure time with the utmoft poffible exactnefs, to take into confideration the refiftance of the air, which, by its unequal denfity, varying the weight of the pendulum, muft in a fmall degree accelerate or retard its motion. The celebrated David Rittenhoufe, who paid particular attention to this fubject, eftimates the extreme difference of velocity, arifing from this caufe, at half a fecond a day; and he obferves, that a remedy dependent on the barometer will not be ftricty accurate, as the weight of the entire column of air does not precifely correfpond with the denfity of its bafe. He propofes, therefore, as a very fimple and eafy remedy, that the pendulum fhall, as ufual, confift of an inflexible rod carrying the ball beneath, and continued above the centre of fufpenfion to an equal (or an unequal) diftance upwards. At this extremity is to be fixed another ball of the fame dimenfions (or greater or lefs, according as the continuation is fhorter or longer), but made as light as poffible. The ofcillations of this upper ball will be accelerated by its buoyancy by the fame quantity as thofe of the lower would be retarded; and thus, by a proper adjuftment, the two effects might be made to balance and correct each other.

Our author made a compound pendulum on thefe principles, of about one foot in its whole length. This pendulum, on many trials, made in the air 57 vibrations in a minute. On immerfing the whole in water, it made 59 vibrations in the fame time; fhewing evidently, that its returns were quicker in fo denfe a medium as water than in the air. (This is contrary to what takes place with the common pendulum). When the lower bob or pendulum only was plunged in water, it made no more than 44 vibrations in a minute.

PENNANT (Thomas, Efq.), fo well known in the republic of letters as a writer of travels and of natural hiftory, was an ancient Briton by birth, having drawn his firft breath in Flintfhire, in 1726. His family has been fettled in that county for many centuries; we learn from himfelf that he received the rudiments of his education at Wrexham, whence he was removed to Fulham. Soon after this he was fent to Oxford; and ha-

Pennant. ving made a considerable proficiency in the classics, he applied himself within the walls of that university to attain a knowledge of jurisprudence; but we do not find that he ever entered himself of any of the inns of court, or followed the law as a profession.

The ruling passions of mankind are excited, and the future current of their lives frequently directed, by trivial circumstances. One of the greatest painters of our age was attracted with an irresistible impulse towards his art by the perusal of a treatise on it; and we have the authority of the subject of this memoir for asserting, that a present of Willughby's Ornithology, at an early period, first gave him a turn for natural history, which has never once abandoned him through the course of a very long life.

Mr Pennant commenced his travels with great propriety at home, where he made himself acquainted with the manners, productions, and curiosities, of his native country, before he sallied forth to inspect those of other nations. He then repaired to the continent; and not only acquired considerable additional knowledge relative to his favourite studies, but became acquainted, and established a correspondence, with some of the greatest men of the age.

On his return he married, and had two children, but did not come into the family fortune until he was thirty-seven years of age, at which time he was settled at Downing.

Having lost his wife, he appears to have set out once more for the continent, and to have formed an acquaintance with Voltaire, Buffon, Haller, Pallas, &c. He had by this time acquired considerable reputation as a scientific man, having commenced his career as an author so early as 1750. His British Zoology* established his reputation as a naturalist; and this received a fresh accession of celebrity in consequence of his acquaintance with Linnæus, and his intercourse by letters with all the celebrated naturalists in Europe.

* Four vols 4to.

Early in life he had undertaken a most interesting tour to Cornwall; and he now entertained an ardent desire to survey the works of nature in the northern extremities of the island. He accordingly set out for Scotland, and in 1771 favoured the public with an entertaining account of his Tour †, which was so well received as to pass through several editions. Not content with the main land of Great Britain, he was ambitious to survey the islands in the vicinity, and accordingly penetrated to the Hebrides, and visited Man.

† Three vols 4to.

It is not to be supposed that he would leave his own country unexplored; on the contrary, he minutely described all its wonders. He did not fail on this occasion to present the world with the result of his enquiries, for in 1778 he commenced the publication of his Welsh Tour§.

§ Two vol. 4to.

In four years after this (1782) appeared the account of the Journey from Chester to London‡, in which he refutes the vulgar opinion that it is uninteresting; and in two years more his Arctic Zoology, an admirable work, greatly prized both here and in other countries.

‡ One vol. 4to.

In 1790 appeared a quarto volume, simply entitled Of London; in which he observes that this work is composed from observations, originally made without any view of publication. "Let me request (says he in the preface) the good inhabitants of London and Westminster not to be offended at my having stuffed their Iliad into a nutshell; the account of the city of London and liberties of Westminster into a quarto volume. I have condensed into it all I could; omitted nothing that suggested itself; nor amplified any thing to make it a guinea book. In a word, it is done in my own manner, from which I am growing too old to depart.

"I feel within myself a certain monitor that warns me (adds he) to hang up my pen in time, before its powers are weakened, and rendered visibly impaired. I wait not for the admonition of friends. I have the Archbishop of Grenada in my eye; and fear the imbecility of human nature might produce in long worn age the same treatment of my kind advisers as poor Gil Blas had from his most reverend patron. My literary bequests to future times, and more serious concerns, must occupy the remnant of my days. This closes my public labours."

Notwithstanding his parting address, the example of the Archbishop of Grenada, and the concluding sentence of "*Valete & Plaudite*," we find Mr Pennant adventuring once more in the ocean of literature, at a late period of his life, and trying his fortune again with all the eagerness of a young author.

He accordingly published the Natural History of the parishes of Holywell and Downing*, within the precincts of the latter of which he had resided about half a century.

* One vol. 4to.

He also presented the public, a very short time before his death, with a splendid work, consisting of 2 vols. 4to. entitled The View of Hindoostan; in the preface to which he candidly states his motives for this new attempt. "I had many solicitations from private friends (says he), and a few wishes from persons unknown, delivered in the public prints, to commit to the press a part, in the form in which the posthumous volumes might hereafter make their appearance. I might have pleaded the imprudence of the attempt at my time of life, of beginning so arduous an undertaking in my 71st year.

"I happily, till very lately, had scarcely any admonition of the advanced season. I plunged into the sea of trouble, and with my papers in one hand, made my way through the waves with the other, and brought them secure to land. This, alas! is finite boasting. I must submit to the judgment of the public, and learn from thence how far I am to be censured for so grievous an offence against the maxim of Aristotle, who fixes the decline of human abilities to the 49th year.

"I ought to shudder, when I consider the wear and tear of 22 years; and feel shocked at the remark of the elegant Delanty, who observes, 'that it is generally agreed among wise men, that few attempts, at least in a learned way, have ever been wisely undertaken and happily executed after that period!'

"I cannot defend the wisdom: yet from the good fortune of my life I will attempt the execution."

These valuable volumes are drawn up by Mr Pennant in the manner of his introduction to the Arctic Zoology. The plates, 23 in number, are admirably engraved, and one (the Napaul pheasant) is beautifully coloured.

In addition to the list of literary labours already enumerated, is a letter on an earthquake felt at Downing, in Flintshire, in 1753; another inserted in the same publi-

Pennant, Pennatula. publication*, in 1756, on coralloid bodies (κοραλλοειδης) collected by him: his Synopsis of Quadrupeds, published in 1771; a pamphlet on the Militia; a paper on the Turkey: and a volume of Miscellanies.

Phil. Trans.

Mr Pennant attained academical honours of all kinds, having had the degree of LL. D. conferred on him by the university in which he was educated, he was a Fellow of the Royal Society, and a member of the Society of Antiquaries, a Fellow of the Royal Society of Upsal in Sweden, a member of the American Philosophical Society, an honorary member of the Anglo Linnæan Society, &c.

The ample fortune left him by his father enabled Mr Pennant to keep an hospitable table, and also to present the profits of several of his works to public institutions, particularly the Welsh charity-school in Gray's-inn-lane. He encouraged several engravers by his patronage, and was not a little serviceable to the advancement of the fine arts.

In 1776 he married a second time; on which occasion he became united to Miss Mostyn, sister of his neighbour, the late Sir Roger Mostyn, in Flintshire. The latter part of his life was chearful, and he scarcely felt the approaches of old age. He died at his seat at Downing in his 72d year.

He has left several works behind him in MS. under the title of Outlines of the Globe; and as a proof that it will be a very voluminous and interesting publication, it is only necessary to observe, that the View of Hindoostan composed the xivth and xvth volumes.

Mr Pennant possessed a well-compacted frame of body, an open and intelligent aspect, an active and chearful disposition, and a vivacity which rendered him always entertaining, as well in conversation as in writing. Though not without a share of irrascibility, his heart was kind and benevolent. He was examplary in the relations of domestic life, and sensibly felt for the distresses of his poor neighbours, whose relief in seasons of hardship he promoted with great zeal and liberality, His candour and freedom from ordinary prejudices, are sufficiently displayed in his writings; and Scotland was forward to confess, that he was the first traveller from this side the Tweed, who had visited the country with no unfriendly spirit, and had fairly presented it under its favourable as well as its less pleasing aspects. As a writer, his style is lively and expressive, but not perfectly correct. His principles of arrangement in zoology are judicious, and his descriptions characterestic. If in some of his later works a little vanity appears, and a propensity to think that important to the world which was so to himself, it may readily be pardoned to one who has afforded such copious and valuable entertainment to the public. His name will live with honour in the literary history of his country, and his memory will be cherished with respect and affection by his surviving friends.

PENNATULA (See *Encycl.*) A species of this animal, hitherto undescribed, was discovered by La Martiniere near Nootka. Its body is of a cartilaginous substance, and a cylindrical form; its head, armed with two little horns of the same substance, presents a spherical figure flatted at its interior extremity. This part is covered with small papillæ, some of which are visible at D, and which serve the purpose of small mouths, by means of which this animal sucks the blood of fishes, making its way as far as possible into the flesh: the extremity of its body, which always projects from the fish, appears like the feathers of a pen; these feather-like substances serve as excretory vessels: for on making a slight pressure on the animal, from the greater part of these cartilaginous barbs issued small drops of a very limpid liquor: at the base of these barbs, and beneath the body, are placed two large cartilaginous threads, of which our author could not imagine the use, for they are not universally met with in each individual. The circulation of its blood is readily observed, it forms a complete revolution about once in a minute. It is probable that this animal is only able to make its way into the bodies of different fish when it is very young; and when it has once buried itself there, having abundance of nourishment, its head increases considerably, and the two horns with which it is furnished necessarily form an obstacle to its regress, which is a remarkable instance of the foresight of Nature, since it is destined to be nourished at the expence of another. The pennatula, of which we have given from Martiniere a figure, was found by him at the depth of more than an inch and an half in the body of a *diodon*.

Plate XLI.

Pepusch.

PEPUSCH (John Christopher), one of the greatest theoretic musicians of modern times, as we are told, was born at Berlin about 1667; and became so early a proficient on the harpsichord, that at the age of 14 he was sent for to court, and appointed to teach the prince, father of the late King of Prussia. About 1700, he came over to England, and was retained as a performer at Drury Lane: it is supposed that he assisted in composing the operas which were performed there. While he was thus employed, he forbore not to prosecute his private studies; and these led him to enquire into the music of the ancients, and the perusal of the Greek authors upon that subject. The abilities of Pepusch, as a practical composer, were not likely to become a source of wealth to him: his music was correct, but it wanted variety of modulation. Besides, Handel had got possession of the public ear, in the opinion of whose superior merit he readily acquiesced; and chose a tract for himself, in which he was almost sure to meet with no obstruction. He became a teacher of music, not the practice of any particular instrument, but music in the absolute sense of the word, that is to say, the principles of harmony and the science of practical composition; and this, not to children or novices, but in very many instances to professors of music themselves.

In 1713, he was admitted to the degree of Doctor in Music at Oxford, and continued to prosecute his studies with great assiduity. In 1724, he accepted an offer from Dr Berkeley to accompany him to the Burmudas, and to settle as professor of music in his intended college there; but the ship in which they sailed being wrecked, he returned to London, and married Francesca Margarita de l'Epine. This person was a native of Tuscany, and a celebrated singer, who performed in some of the first of the Italian operas that were represented in England. She came hither with one Greber, a German, and from this connection became distinguished by the invidious appellation of *Greber's Peg*. Afterwards she commenced a new connection with Daniel Earl of Nottingham, who had defended the orthodox notion of the Trinity against the heretic Whiston; and to this connection Rowe, in imitation of Horace's

Horace's, "Ne fit ancillæ tibi amor pudori," thus alludes:

> Did not bafe Greber's Peg inflame
> The fober Earl of Nottingham,
> Of fober fire defcended?
> That, carelefs of his foul and fame,
> To play-houfes he nightly came,
> And left church undefended.

She continued to fing on the ftage till about 1718; when having, at a modeft computation, acquired above ten thoufand guineas, fhe retired from the theatre, and afterwards married Dr Pepufch. She was remarkably tall, and remarkably fwarthy; and, in general, fo deftitute of perfonal charms, that Pepufch feldom called her by any other name than Hecate, to which fhe is faid to have anfwered very readily.

The change in Pepufch's circumftances by Margarita's fortune was no interruption to his ftudies: he loved mufic, and he purfued the knowledge of it with ardour. At the inftance of Gay and Rich, he undertook to compofe, or rather to correct, the mufic for the Beggar's Opera. His reputation was now at a great height. He had perufed with great attention thofe feveral ancient treatifes on Harmonics, publifhed by Meibomius, and that of Ptolemy by Dr Wallis; and the difficulties which occurred to him on the perufal, were in a great meafure removed by his friend De Moivre the mathematician, who affifted him in making calculations for demonftrating thofe principles on which the harmonic fcience is founded. In confequence of thefe ftudies, he was efteemed, in matters of theory, one of the beft muficians of his time. In 1737, he was chofen organift of the Charter-houfe, and retired, with his wife, to that venerable manfion. The wife died in 1740, before which he loft a fon, his only child; fo that he had no fource of delight left, but the profecution of his ftudies, and the teaching of a few favourite pupils, who attended him at his apartments. Here he drew up that account of the ancient genera which was read before the Royal Society, and is publifhed in the Philofophical Tranfactions for October, November, and December, 1746; and, foon after the publication of that account, he was chofen a Fellow of the Royal Society.

He died the 20th of July, 1752, aged 85; and was buried in the chapel of the Charter-houfe, where a tablet with an infcription is placed over him.*

* Biog. Dict. new edit.

PERCUSSION, Force of Percussion, is the name by which mechanicians diftinguifh that faculty of producing motion, or making other fenfible mechanical impreffions on bodies, by means of the ftroke of a body in motion. It is nearly the fame with *impulfe;* only, it would feem that the very fcrupulous and refined effect to limit the attention to the *immediate* caufe of the motion, or other effect produced; to the fomething that is different, both from the force fuppofed to be inherent in the moving body (a hammer for example), and the fubfequent motion and penetration of the nail which is driven by it. We may venture to fay that it is needlefs to attempt any inveftigation of this object. It is hid, with all other caufes of all other effects in the univerfe, in impenetrable darknefs. If we reflect on the conftitution of our own mind, fo far as we can know it by experience and obfervation, and on the manner in which we draw conclufions, we muft fee that the knowledge of the efficient caufe of any effect is unattainable; for were the intervening fomething pointed out to us, and clearly conceived by us, we fhould find it juft as neceffary to find out why and how this fomething is connected with each of the events which we obferve it invariably to connect.

But a knowledge of the force of percuffion, in as far as it may or may not be diftinguifhable from other forces, is not unattainable. We can learn as much, and no more, concerning this, as concerning any other force; and we can contemplate that circumftance which, in our opinion, is common to it with all other forces, and may perhaps difcover other circumftances in which it differs from them. But in all this difquifition, it is plain that it is only events, which we conceive to be the characteriftic effects of the caufe, that we contemplate.

Percuffion, confidered as an effect, characteriftic of a particular faculty of moving bodies, became an object of anxious refearch, almoft as foon as philofophers began to think of motion and moving forces at all. The ancients (as has been obferved in the article Impulsion, *Suppl.*) contented themfelves with very vague fpeculations on the fubject. Galileo was the firft who confidered it as a meafurable thing, the object of mathematical difcuffion; being encouraged by his precious difcovery of the laws of accelerated motion, and the very refined meafure which thefe gave him of the power of gravity. It was a meafure of the heavinefs, not of the weight, of the body; and this was meafured by its acceleration, and not by its preffure. Encouraged by this, he hoped to find fome fuch meafure of the force of percuffion, which he faw fo intimately connected with motion; whereas its connection with preffure was far from being obvious. He therefore tried to convert the terms; and as he had found a meafure of the preffure of gravity in the acceleration of motion, he endeavoured to find in preffure a meafure of the force of purcuffion arifing from this acceleration. He endeavoured to find the number of pounds, whofe preffure is equal to the blow of a given body, moving with a given velocity. The velocity was known to him with great precifion, by means of the height from which the ball muft fall in order to acquire it. It feems pretty clear that percuffion may be meafured in this way; for a body falling from a height will pierce an uniformly tenacious body to a certain degree, and no further; and experiment fhews that this degree of penetration is very precife and conftant. The fame body, being merely laid on the tenacious body, will penetrate to a fmall depth by its weight. Laying more weight on it, will make it penetrate deeper; and a certain weight will make it penetrate as deep as the fall did, and no deeper. Thus, percuffion feems very eafily meafurable by weight, or by any preffure fimilar to that of weight. It appears that Galileo made experiments with this view, and that he was difappointed, and obliged to acquiefce in the opinion of Ariftotle, that percuffion and weight are incomparable. He propofes, therefore, another experiment, namely, to drop a body into the fcale of a balance from greater and greater heights, till at laft the blow on the fcale raifes a weight that lies on the other fcale. This offers itfelf fo plaufibly, that we are perfuaded that Galileo tried it: but as he makes no mention

tion of the refults, we prefume that they were unfatisfactory.

Neither of thefe experiments *could* give us a meafure of the force of percuffion, if this force be any thing different from the forces which are excited or brought into action by percuffion, in the manner defcribed in the article Impulsion, *Suppl.* When the ball comes into phyfical contact with the fcale, it begins to comprefs it. This compreffion begins to ftretch the ftrings by which the fcale is fupported. Thefe pull at the arm of the balance, and caufe it to prefs the centre-pin a little harder on its fupport, and to bend the balance a little, and caufe it to pull at the cords which fupport the other fcale. That fcale is pulled upwards, diminifhing a little its preffure on the ground, and preffing it harder to the incumbent weight. Thefe forces are excited *in fucceffion* from the one fcale to the other, and a fmall moment of time elapfes. The re-action of the fcale diminifhes, but does not inftantaneoufly annihilate, the velocity of the falling ball. It therefore compreffes the fcale ftill more, ftretches the threads, preffes the fulcrum, and bends the balance ftill more (becaufe the weight in the other fcale keeps it down). The velocity of the falling ball is rapidly diminifhed ; the balance is more bent, and pulls more ftrongly upwards at the threads of the other fcale ; and thus preffes that fcale more ftrongly againft the incumbent weight, gradually communicating more and more motion to it, removing it farther from the ground, till, at laft, the motion becomes fenfible, or fo confiderable as to difengage fome delicate catch as a fignal. The experiment is now finifhed ; and the mechanician fondly thinks that, at this inftant, the preffure excited by the percuffion, between the oppofite fcale and the under fide of the incumbent weight, is juft equal, or but a very little fuperior, to the preffure of the incumbent weight : and, fince the arms of the balance are equal, and therefore the preffures on the two fcales are equal, he imagines that that weight exerts a preffure equal to the percuffion of the falling ball.

But all this is mifconception, and alfo falfe reafoning. It is not percuffion that we are meafuring, but the preffures excited by percuffion, on the two fcales. And thefe preffures are the forces of elafticity or expanfivenefs, belonging to, or inherent in, the particles of the balls and the fcales ; forces which are brought into action by the approach of thofe bodies to each other. This reafoning is alfo erroneous ; and we fhould be miftaken if we think that the preffure actually exerted is equal to that of the weight in the oppofite fcale. It is greater than the mere preffure of that weight. The re-action of the oppofite fcale on its load was precifely equal to that weight before the ball was dropped from the hand ; and, had the ball been equal to that weight, and fimply laid into the fcale on which it falls, it would have made no change on the mutual preffures of the fcale and the other weight ; it would only have relieved the ground from the preffure of that weight, and would have brought it on the threads which fupport its fcale. The preffure of this fcale upwards muft be increafed, before it can ftart the weight fenfibly from the ground. How much it muft be increafed depends on the fpringinefs of the fcales, cord, and beam. By a proper adjuftment of thefe particulars, the apparatus will give us almoft any meafure of percuffion that we choofe. For this reafon, the improvements made on it by Gravefande are of no value. The fame reafoning, nearly, may be applied to the meafurements of the force of percuffion by means of the penetration of foft bodies.

Galileo mentions another very curious experiment, by which he thought that he had obtained a juft meafure of percuffion. A veffel, filled with water, was fufpended on the arm of a balance, with another veffel hanging from it, a great way below. All was exactly balanced by a weight in the oppofite fcale. By means of a fuitable contrivance, a hole was opened in the bottom of the upper veffel, without difturbing the equilibrium. As foon as the water iffued, and while it was falling through the air, that end of the balance rofe ; but when the water ftruck the lower veffel, the equilibrium was reftored, and continued during the whole time of the efflux. Hence Galileo concluded, that the force of the ftroke was equal to the weight of the falling water. But we apprehend that the obfervations made on this in the article Impulsion, *Suppl.* will convince the reader that this conclufion is far from being legitimate. Befides, the ftroke, in any one inftant, is made by thofe particles only which ftrike in that inftant, while the whole vein of water between the veffels is neither acting by its weight on the upper veffel, nor by its ftroke on the lower ; and we fhould conclude from the experiment, that the force of percuffion is infinitely greater than the weight of the ftriking body. Indeed this is the inference made by Galileo. But if we have recourfe to the experiments and reafonings of Daniel Bernoulli, in the article *Resistance of Fluids*, *Encycl.* we fhall find that the feeming impulfe on the lower veffel is really a moft complicated pure preffure, and of moft uncertain determination. The experiment is valuable, and gives room for curious reflections. We have repeated it, in a great variety of forms, and with great changes of impulfe, and fometimes in fuch a manner that no impulfe whatever can obtain, while at the fame time a quantity of water was filling, unfupported by either veffel. In all the trials the equilibrium remained undifturbed. We were obliged to conclude, therefore, that the experiment afforded no meafure of percuffion. Indeed we were of this opinion before making the trial, for the reafons juft now given.

We cannot fay that the fubfequent labours of philofophers have added much to our knowledge of this matter. Mr Leibnitz had contrived his whimfical doctrine of *living* and *dead* forces. The action of gravity, or of a fpring, is a *vis viva*, when it actually produces motion in the body on which it acts ; but when a ftone lies on a table, and preffes on it, this preffure is a *vis mortua*. Its exertion is made, and in the fame inftant deftroyed, by an oppofite *vis mortua*. Each of thefe exertions would have produced *a beginning* of motion (fomething different from any of the fmalleft local motion) ; and the fum of all would, after a certain time, have amounted to a fenfible motion and velocity. There feems no diftinct conception to accompany, or that can accompany, this language. And, as a proof that Leibnitz had no diftinct conceptions of the matter, he has recourfe to this very experiment of Galileo in fupport of his genefis of a fenfible motion from the continual exertions of the *vis mortua* ; and he concludes that the force of percuffion is infinitely, or incomparably, greater than preffure, becaufe it is the fum total of an infinity of individual

dual exertions of *vis mortua*. Nothing but the authority which Leibnitz has acquired on the continent, by the zealous efforts of his partizans, could excuse our taking up any time in considering this unintelligible discourse. Surely, if there is such a thing as a *vis viva*, it exists in the moving water, and its impulsions are not continual exertions of a *vis mortua*. Nor is it possible to conceive continual impulse, nor a beginning of motion that is not motion, &c. &c. It is paradoxical (and Leibnitz loved to raise the wonder of his followers by paradoxes) to say that percussion is infinitely greater than pressure, when we see that pressure can do every thing that can be done by percussion. Nay, Euler, by far the most able supporter of the doctrines of Leibnitz about the force of bodies in motion, actually compares these two forces; and, in his Commentary on Robins's Artillery, demonstrates, in his way, that when a musket ball, moving with the velocity of 1700 feet per second, penetrates five inches into a block of elm, the force of its percussion is 107,760 times its weight. John Bernoulli restricts the infinite magnitude of percussion to the case of perfectly hard bodies; and, for this reason alone, says, that there can be none such in the universe. But, as this justly celebrated mathematician scouts with scorn the notion of attractions and repulsions, he must allow, that an ultimate atom of matter is unchangeable in its form; which we take to be synonymous with saying that it is perfectly hard. What must be the result of one atom in motion hitting another at rest? Here must be an instantaneous production of a finite velocity, and an infinite percussion. A doctrine which reduces its abettors to such subterfuges, and engages the mind in such puzzling contemplations, cannot (to say the best of it) be styled an EXPLANATION of the laws of Nature. The whole language on the subject is full of paradoxes and obscurities. In order to reconcile this infinite magnitude of percussion with the observed finite magnitude of its effects, they say that the pressure, or instantaneous effort, has the same relation to the force of percussion that an element has to its integral; and in maintaining this assertion, they continually consider this integral under the express denomination of a *sum total*, robbing Leibnitz's great discovery of the infinitesimal calculus of every superiority that it possessed over Wallis's Arithmetic of infinites, and really employing all the erroneous practices of the method of indivisibles. We look upon the strange things which have been inculcated, with pertinacious zeal, in this doctrine of percussion and *vires vivæ*, as the most remarkable example of the errors into which the unguarded use of Cavalerius's Indivisibles, and of the Leibnitzian notion of the infinitesimal calculus, have led eminent mathematicians. It is not true that the pressure, and the ultimate force of percussion, have this relation; nor has the pressure and the resulting motion, which is mistaken for the measure of this ultimate force, any mathematical relation whatever. The relation is purely physical; it is the relation of pure cause and effect: and all that we know of it is their constant conjunction. The relation of fluxion and fluent is not a mathematical or measurable relation, but a connection in thought; which is sufficient for making the one an indication of the other, and the measures of the proportions of the one a mean for obtaining a measure of the proportions of the other. In this point of view, the relation of pressure to motion, as the measure of the force of percussion, *resembles* that of fluxion and fluent, but is not the same.

Much has been said by the partizans of Mr Leibnitz about the incomparableness of pressure and percussion, and many experimental proofs have been adduced of the incomparable superiority of the latter. Bulfinger says, that the pressure of many tons will not cause a spike to penetrate a block of hard oak half so far as it may be driven by a weak man with one blow of a mallet; and that a moderate blow with a small hammer will shiver to powder a diamond, which would carry a mountain without being hurt by its pressure. Nay, even Mr Camus, of the Academy of Paris, a staunch Cartesian, and an eminent mechanician, says that he beat a leaden bullet quite flat with a hammer of one pound weight, without much force; and that he found that 200 pounds weight would not have flattened it more than this blow: and he concludes from thence, that the force of the blow exceeded 200 pounds. These, to be sure, are remarkable facts, and justify a more minute consideration of a power of producing certain effects, which is so frequently and so usefully employed. But, at the same time, these are all very vague expressions, and they do not authorise any precise conclusions from them. Mr Camus saying "without much force," makes his pound weight, and his 200 pound weight, of no use for determining the force of the blow. He would have given more precise and applicable data for his decision, had he told us from what height the hammer should fall in order to flatten the bullet to this degree. But even then we should not have obtained any notion of the force in actual exertion during the flattening of the bullet; for the blow which could flatten the bullet in a longer or a shorter time, would unquestionably have been less or greater.

All the paradoxes, obscurities, and puzzling difficulties, in this subject disappear, if we leave out of our consideration that unintelligible force, which is supposed to preserve a body in motion or at rest; and if we consider both of these states of body as conditions which will continue, unless some adequate cause operate a change; and if we farther grant, that such causes do really exist in the universe, however unknown their nature may be by us; and, lastly, if we acknowledge, that the phenomena of elasticity, expansiveness, cohesion, gravity, magnetism, electricity, are indications of the agency of such causes, and that their actual exertions, and the motions and changes consequent on these exertions, are so invariably connected with particular bodies, that they always accompany their appearance in certain mutual relations of distance and position:—if we proceed thus, all the phenomena of collision will be explained by these causes alone, without supposing the existence and agency of a cause distinct from them all, and incomparable with them, called the FORCE OF PERCUSSION.

For it has been sufficiently demonstrated in the article IMPULSION (*Suppl.*), that that property of tangible coherent matter, which we call *perfect elasticity*, operates as a pressure during a certain small portion of time on both bodies, diminishing more and more the motion of the one, and augmenting that of the other, as the compression of one or both increases, till at last they separate with sensible velocities. In some very simple or perspicuous

Percussion spicuous cases, we know what this pressure is in every instant of the action. We can tell how many pounds weight, at rest, will exert the same pressure. We can tell the whole duration of this pressure, and the space along which it is exerted; and, in such a case, we can say with precision what motion will be generated by this continued and varied pressure on the body which was at rest, and what diminution will be made in the motion of the other. All this can be done in the case Plate XLI. of a ball A (fig. 1.), moving like a pendulum with a small velocity, and striking a slender elastic hoop B, also suspended like a pendulum. We can ascertain by experiment, before the collision, what pressure is necessary for compressing it one inch, one-half, one-fourth, &c. Knowing this, and the weight of the hoop, and the weight and velocity of the ball, we can tell every circumstance of the collision—how long the compression continues—what is the greatest compression—how far the bodies have moved while they were acting on each other—and what will be the final motion of each:—in short, every thing that affords any mark or measure of a force of percussion. And we know that all this is produced by a force, familiarly known to us by the name of elasticity. Which of all these circumstances shall be called the precussion, or the force of percussion? Is it the ultimate or greatest pressure occasioned by the compression? This cannot be, because this *alone* will not be proportional to the final change of motion, which is generally taken as a measure of the percussion when a change of motion is its only observed effect.

We know that another perfectly elastic body, of the same weight, and struck by the same blow, and acquiring the same final velocity by the stroke, may not have sustained the tenth part of the pressure, in any one instant of the collision, if it has only been much more compressible. The greatest mutual pressure in the collision of a billiard ball is perhaps 1000 times greater than it is in a similar collision of a foot ball of the same weight.

We also know what degree of compression will break this hoop, and what pressure will produce this compression. Therefore, should the fracture of the body be considered as the mark and measure of the percussion, we know what blow will just produce it, and be exhausted by so doing. In short, we know every mark and measure of percussion which this hoop can exhibit.

We can increase the strength of this hoop till it becomes a solid disk; and we see clearly, that in all these forms the mode of acting is the same. We see clearly that it is the same when, instead of the solid disk, it is an elastic ball; therefore every thing that can indicate or measure the percussion of an elastic ball, is explained without the operation of a peculiar force of percussion, even when the ball is shivered to pieces by the blow.

Nor is the case materially different when the bodies are soft, or imperfectly elastic. When the struck body is uniformly tenacious, it opposes a uniform resistance to penetration, and its motion will be uniformly accelerated by the action of its own tenacity during the whole time of mutual action, except a trifling variation occasioned by the mere motion of the internal parts, independent of their tenacity. If we knew the weight necessary for merely penetrating this mass, and the weight and velocity of the penetrating body, we can tell how long it must be resisted by this force before Percussion. its initial velocity will be annihilated, and therefore how far it will penetrate. We have tried this with deal, birch, willow, and other soft woods of uniform texture, and with nails having the body somewhat slenderer than the end, that there might not be an irregularity occasioned by a friction on the sides of the nail, continually increasing as the penetration advanced. We made the hammer fall from a considerable height, and hit the nail with great accuracy in the direction of its length, by fixing it to the end of a long lath, moveable round an axis. The results corresponded with the calculation with all the precision that could be desired.

But it does not result from all this agreement, that the force, exertion, or effect, of a blow with a hammer is equal to the pressure of any number of pounds whatever. They are things that cannot be compared; and yet the force operating in the penetration by a blow is no way different from pressure. It is a physical blunder to compare the area of the curve, whose abscissa is the depth of penetration, and the ordinates are as the resistances, with any pressure whatever. This area expresses the square of a velocity, and its slips, bounded by parallel ordinates indefinitely near each other, are as the decrements of this square of a velocity, occasioned by a pressure, acting almost uniformly along a very small space, or during a very small time. It is an absurdity therefore to sum up these slips as so many pressures, and to consider the sum total as capable of expressing any weight whatever. Such a paralogism is peculiar to Leibnitz's way of conceiving his infinitesimal method, and it could have no place in the genuine method of fluxions. It is this misconception that has made Mr Leibnitz and his followers suppose that a body, accelerated by gravity, retains in it a sum total of all the pressures of gravity accumulated during its fall, and now forming a *vis viva*. Supposing that it requires a pressure of twenty pounds to press a six pound shot slowly through a mass of uniformly resisting clay; this pressure would carry it from the top to the bottom of a mountain of such clay. Yet this ball, if discharged horizontally from a cannon, would penetrate only a few yards, even though the clay should resist by tenacity only, independent of the motion lost by giving *motion* to its internal parts. In this experiment the utmost pressure exerted during the motion of the ball did not much exceed the pressure of twenty pounds. In this comparison, therefore, percussion, so far from appearing infinitely greater than pressure, would appear much less. But there is perhaps nobody that resists penetration with perfect uniformity, even though uniformly tenacious. When the ball has penetrated to some depth, the particles which are before it cannot be so easily displaced, even although they had no tenacity, because the particles adjoining are more hemmed in by those beyond them. We have always observed, that a ball impelled by gunpowder through water rises toward the surface (having entered horizontally through the side of the vessel at some depth), and this so much the more rapidly as it entered nearer to the surface. The reason is plain. The particles which must be displaced before the ball, escape more easily upwards than in any other direction. It is for this reason chiefly that a greater weight laid on the head of a nail will cause it sink deeper into the wood; and thus a great weight appears to to be commenſurable with a great force of percuſſion. Alſo while a bullet is flattening more and more under a hammer during the progreſs of a blow, it is ſpreading under the hammer; more particles are reſiſting at once, and they find more difficulty in effecting their eſcape, being harder ſqueezed between the hammer and the anvil. The ſame increaſed reſiſtance muſt obtain while it is flattening more and more under the quiet preſſure of a weight; and thus, too, a great weight appears to be commenſurable with a greater blow.

After all, however, a blow given by a falling body muſt excite a preſſure greater than its mere weight can do, and this in any degree. Thus, ſuppoſe AB (fig. 2.) to repreſent a ſpiral ſpring in its natural unconſtrained dimenſions, ſtanding upright on a table. Let $a\ b$ be the abſciſſa of a line $a\ d\ h\ k$, whoſe ordinates $c\ d$, $g\ h$, $i\ k$, &c. are as the elaſtic reaction of the ſpring when it is compreſſed into the lengths $c\ b$, $g\ b$, $i\ b$, &c. Suppoſe that, when it is compreſſed into the form CD, it will juſt ſupport the weight of a ball lying on C. Then $c\ d$ will be a reaction equal to the weight of the ball, and the rectangle $a\ c\ d\ f$ will expreſs the ſquare of the velocity which this ball would acquire by falling freely through $a\ c$. If therefore the ball be gently laid on the top of the ſpring at A, and then let go, it will deſcend, compreſſing the ſpring. It will not ſtop when the ſpring has acquired the form CD, which enabled it to carry the weight of the ball gently laid on it. For in this ſituation it has acquired a velocity of which the ſquare is repreſented by the figure $a\ d\ f$. (See Dynamics, *Suppl.* n° 95.). It will compreſs the ſpring into the length $g\ b$, ſuch that the area $c\ g\ h\ d$ is equal to the area $a\ d\ f$. If the ball, inſtead of being gently laid on A, be dropped from M, it will compreſs the ſpring into ſuch a length $i\ b$, that the area $a\ i\ k$ is equal to the rectangle $m\ c\ d\ n$; and, if the ſpring cannot bear ſo great compreſſion, it will be broken by this very moderate fall.

Thus we ſee that a blow may do things which a conſiderable preſſure cannot accompliſh. The accounts which are given of theſe remarkable effects of percuſſion, with the view of impreſſing notions of its great efficacy, are generally in very indefinite terms, and often without mentioning circumſtances which are acceſſory to the effect. It would be very unfair to conclude an almoſt infinite power of percuſſion, from obſerving, that a particle of ſand, dropped into a thick glaſs bottle which has not been annealed, will ſhiver it to pieces. When Mr Bulfinger ſays that a moderate blow will break a diamond which could carry a mountain, he not only ſays a thing of which he cannot demonſtrate the truth, and which, in all probability, is not true; but he omits noticing a circumſtance which he was mechanician enough to know would have a conſiderable ſhare in the effect. We mean the rapidity with which the excited preſſure increaſes to its maximum in the caſe of a blow. In the experiment in queſtion, this happens in leſs than the millionth part of a ſecond, if the velocity of the hammer has been ſuch as a man would generate in it by a very moderate exertion. For the blow which will drive a good lath nail to the head in a piece of ſoft deal with an ordinary carpenter's hammer, muſt be accounted moderate. This we have learned by experiment to be above 25 feet per ſecond. The connecting forces exerted between the particles of the diamond may not have time ſufficient for their excitation in the remote parts, ſo as to ſhare the derangement among them all, in ſuch a manner that it may be ſo moderate in each as not to amount to a diſunion in any part of the diamond. We ſee many inſtances of this in the abrupt handling of bodies of tender and friable texture. It is partly owing to this that a ball diſcharged from a piſtol will go through a ſheet of paper ſtanding on edge without throwing it down, which it would certainly do if thrown at it by the hand. The connecting forces, having time to act in this laſt caſe, drag the other parts of the paper along with them, and their union is preſerved. Alſo, when a great weight is laid on the diamond, it is gradually dimpled by it; and thus incloſing many parts together in the dimple, it obliges them to act in concert, and the derangement of each is thus diminiſhed.

We flatter ourſelves that the preceding obſervations and reflections will contribute ſomewhat towards removing the paradoxes and myſteries which diſcredit, in ſome degree, our mechanical ſcience. If we will not pertinaciouſly conjure up ideal phantoms, which, perhaps, *cannot* exiſt, but content ourſelves with the ſtudy of that tangible matter which the Author of Nature has preſented to our view, we ſhall have abundant employment, and ſhall perceive a beautiful harmony thro' the whole of natural operations; and we ſhall gradually diſcover more and more of thoſe mutual adaptations which enable an atom of matter, although of the ſame preciſe nature wherever it is found, to act ſuch an unſpeakable variety of parts, according to the diverſity of its ſituations and the ſcene on which it is placed. If a mind be "not captivated by the harmony of ſuch ſweet ſounds," we may pronounce it, "dark as Erebus, and not to be truſted."

PERFECT Number, is one that is equal to the ſum of all its aliquot parts when added together. Eucl. lib. 7, def. 22. As the number 6, which is $= 1 + 2 + 3$, the ſum of all its aliquot parts; alſo 28, for $28 = 1 + 2 + 4 + 7 + 14$, the ſum of all its aliquot parts. It is proved by Euclid, in the laſt prop. of book the 9th, that if the common geometrical ſeries of numbers 1, 2, 4, 8, 16, 32, &c. be continued to ſuch a number of terms, as that the ſum of the ſaid ſeries of terms ſhall be a prime number, then the product of this ſum by the laſt term of the ſeries will be a perfect number.

PERGUNNA, in Bengal, the ſubdiviſion of a diſtrict.

PERKINISM, the proper name of what we muſt think an impoſition attempted to be put upon the world by Dr Perkins of North America.

Though the phenomena of electricity had been long familiar to the philoſophers of Europe, it is well known that a philoſophical theory of theſe phenomena was firſt formed by a tranſatlantic philoſopher. In like manner, though the diſcovery of Galvani, under the name of *animal electricity* (ſee Galvanism in this *Supplement*), had occupied the attention of many of the firſt phyſicians and philoſophers of the old world, it was reſerved for a phyſician of the new, to apply it to the cure of a number of diſeaſes. Every philoſopher of America, however, has not the ſagacity of the Philadelphian ſage; nor muſt Dr Perkins or his admirers be ſurpriſed, if we treat not incomprehenſible myſticiſm with the reſpect due to a theory founded on facts.

We are told by the son (A) of this rival of Franklin, that before the news of Galvani's discovery had reached America, he had observed several phenomena pointing out the influence of metals in cases of pain. The first remarkable incident that presented itself to his notice was the sudden contraction of a muscle when he was performing a chirurgical operation. This, he observed, regularly took place whenever the point of the metallic instrument was put in contact with the muscle. Struck with the *novelty* of the appearance (Is Mr Perkins sure that the appearance was new?), he was induced to try the points of wood and other substances; and no contraction taking place on these experiments, he thence inferred that the phenomena could be ascribed only to the influence of the metal. About the same time, he observed that, in one or two cases (and if his practice had been great he might have observed that in a thousand cases), a cessation of pain had ensued when a knife or lancet was applied to separate the gum from a tooth previous to extracting it; and in the same year he discovered, that *momentary* ease was given, in a few instances, by the accidental application of a metallic instrument to inflamed and painful tumors previous to any incision.

These are the judicious reasonings and assertions of a dutiful child, who, having probably heard of Leibnitz's claims to some of Newton's discoveries, was determined to put in a similar claim for his father, to a *share*, at least, of the discovery made by the celebrated professor at Bologna. He has not, however, copied with servility the conduct of the Leibnitzians. We do not remember an instance where any of them attempted to elevate the fame or the merits of their master *above* the fame and merits of Newton; but, according to our author, the pursuits of Galvani and his European pupils sink into insignificance, when compared with those of the transatlantic physician.

This is evident; for when the physiologists of Europe were engaged in experimenting on the denuded nerves and muscles of the smaller animals, with a view to ascertain the agency of this incomprehensible property in them, Dr Perkins was prosecuting a series of experiments, which consisted in applying externally, to parts affected with disease, metals, and compounds of metals of every description which occurred to him, and constructed into various forms and sizes. The result proved, that on drawing lightly over the parts affected certain instruments, termed *tractors*, which he formed from metallic substances into pointed shapes, he could remove most of those topical diseases of the human body, where an extra degree of nervous energy or vital heat was present; unless such disease was situated in some of the internal viscera, too remote from the part where the instruments could be applied.

The diseases which have been found most susceptible of the influence of the tractors are, rheumatism, some gouty affections, pleurisy, opthalmias, erysipelas, violent spasmodic convulsions, as epileptic fits and the locked jaw, the pain and swelling attending contusions, inflammatory tumors, the pains from a recent sprain, the painful effects of a burn or scald, pains in the head, teeth, and indeed most kinds of painful topical affections, excepting where the organic structure of the part is destroyed, as in wounds, ulcers, &c. and excepting also where oils or some other non-conducting substances are present.

But we have other testimonies than those of Dr Perkins and his son for the influence of the tractors. Mr Meigs, professor of natural philosophy at Newhaven, in a letter on Dr Perkins's discovery, conceives the principles of metallic irritability as so little understood, that he will not pretend to explain how the tractors produce their effects; but seems satisfied in finding that the effects are produced. After stating an experiment on his own child, eight years of age, very dangerously ill with a peripneumonic complaint, and to which the tractors gave almost instantaneous relief, he says, "I have used the tractors with success in several other cases in my own family; and although, like Naaman the Syrian, I cannot tell why the waters of Jordan should be better than Abana and Pharpar, rivers of Damascus; yet, since *experience* has proved them so, no reasoning can change the opinion. Indeed, the causes of all common facts are, *we think*, perfectly well known to us; and it is very probable, fifty or an hundred years hence, we shall as well know why the metallic tractors should in a few minutes remove violent pains, as we now know why cantharides and opium will produce opposite effects: viz. we shall know but *very little* about either, excepting *facts*."

Mr Woodward, professor of natural philosophy at Dartmouth, in a letter also on the same subject, has stated a number of successful experiments in pains of the head, face, teeth, and in one case of a sprain.

Dr Vaughan, a member of the Philadelphia medical society, has lately published an ingenious tract on Galvanism, the object of which is to account for the influence of the tractors in removing diseases. After a citation of numerous experiments made on the nerves and muscles of animals, he observes, "If we only take an impartial view of the operations of Nature herself, and attend diligently to the analytical investigations of the aforementioned experimentalists on this sublime subject, I think the sceptic must admit that the principle of nervous energy is a modification of electricity. As sensation is dependant on this energy, a pleasurable sensation, or what may be termed a natural or healthy degree thereof; then certainly pain, or supersensation, can only depend on an accumulation of the electric fluid, or extra degree of energy in the part affected. On this principle the problem admits of easy solution; namely, that the metals, being susceptible of this fluid, conduct the extra degree of energy to parts where it is diminished, or out of the system altogether, restoring the native law of electric equilibrium."

We trust we are not sceptics; and yet we feel not ourselves inclined to admit any part of this theory. We have seen no proof that nervous energy is a modification of electricity; and we think that we have ourselves proved, that *galvanism* and *electricity* are in many respects different; but we shall not be much surprised if we soon see a *demonstration* by some American or German philosopher,

(A) See a pamphlet, entitled The Influence of Metallic Tractors on the Human Body, &c. by Benjamin Douglas Perkins, A. M. son to the discoverer; or a very good abridgement of it in the first volume of the Philosophical Magazine.

Perkinism. philosopher, that the foul of man is a compofition of filver and zinc. One of thefe fages has lately difcovered, that the fymptoms of *putrefaction* do not conftitute an *infallible* evidence of death, but that the application of *metals* will in all cafes afcertain it beyond the poffibility of doubt! A proper application certainly will; for when the Perkinift is doubtful whether his patient be dead or alive, he has only to apply the muzzle of a loaded piftol to his temple, and blow out his brains; after which he may fafely fwear that the man is dead.

From the *Philofophical Magazine*, we learn that Profeffor Schumacher at Copenhagen made experiments with tractors of brafs and iron on ten patients in Frederick's hofpital at Copenhagen. He tried alfo tractors of ebony and ivory, which are faid to have cured a pain in the knee; with others of filver and zinc; and fome of copper and lead. By the two laft, pains in the knee, arm, and face, are faid to have been mitigated. According to M. Klingberg's experiments, this remedy was of ufe in *malum ifchiaticum*; and according to thofe of M. Steffens, in *malum ifchiaticum* and megrim. According to M. Bang, the pains in fome cafes were increafed, and in others allayed. According to M. Blech, the tractors were of ufe in *hemicrania* and gouty pains in the head; and, according to M. Hahn, in rheumatic pains in both fhoulders. The principal document in the Danifh collection relating to Perkinifm, appears to be a letter of Profeffor Abilgaard, in whofe opinion Perkins's tractors will never acquire much value in medicine, and fcarcely even have the merit of being a palliative; but, in a phyfical point of view, he thinks they deferve the attention of phyficians, and particularly of phyfiologifts. Mankind (he fays) hitherto have paid too little attention to the influence which electricity has on the human body; otherwife they would know that the effects produced on it by our beds is no matter of indifference. If the feather beds and hair mattreffes, &c. are perfectly dry, the perfon who fleeps on them is in an infulated ftate; but the contrary is the cafe if they are moift. He three times removed a pain in the knee, by fticking the tractors, one on each fide of the knee, fo deep through the ftockings that the points touched the fkin. He removed a rheumatic pain in the head from a lady by the fame means. M. Kafn, by the tractors, relieved, in others, gouty pains of the head and megrim: and in himfelf, a rheumatic pain of the back, which, according to his fenfations, was like a conftriction in the cellular tiffue. M. Herholdt, from his experiments, confiders the effect of the tractors as indefinite and relative as that of other remedies. He, however, faw relief given by them in the ftrangury in a cafe of fyphilis. M. Bang alfo, at Soroe, freed a man from a violent gouty pain in the thigh, by drawing the tractors 200 times over the affected part. M. Jacobfen likewife found benefit derived from thefe tractors feveral times in the common hofpital at Copenhagen. M. Tode tried them alfo in rheumatic pains, toothe-ache, and inflammation of the eyes; and obferved that they neither did good nor harm.

On fome of the attefted cures mentioned in Mr Perkins's pamphlet, an able writer in the Monthly Review has made remarks fo very pertinent, that we cannot refufe ourfelves the pleafure of tranfcribing them.

"At page 54 of the pamphlet, we meet (fays the reviewer) with a ftrong proof of the confidence placed in this remedy by feveral tranfatlantic philofophers. Dr Willard, it feems, applied a red hot piece of iron to a wart on his finger, and burnt himfelf very feverely, in order that he might be relieved by the tractors; which are faid to have given him eafe in two fucceffive experiments. The author adds, 'many have fubmitted to fimilar meafures, in order to *experience* the effects. I once formed one of five, who burned ourfelves fo that blifters were raifed, to make the experiment; we all obtained relief in a few minutes.'

"This zeal for knowledge is truly edifying; efpecially as the tractors are generoufly prefented to the public at *only* five guineas a pair; and it is clear that one pair would fuffice to cure all the burns and fcalds of a large parifh. Why are not fuch luculent experiments repeated here? If Mr Perkins, or any admirer of the difcovery, would fubmit to have a red hot poker run into fome part of his body not neceffary to life (into *that part where honour's lodged*, according to Butler, for example), in any public coffee houfe within the bills of mortality, and would afterward heal the wound in prefence of the company, in ten minutes, or in half as many hours, by means of the tractors, the moft ftony-hearted infidel could not refift fuch a demonftration. Why trifle with internal inflammations, when fuch an outward and vifible fign might be afforded?

"Mr Perkins has taken fome pains, in the firft part of his pamphlet, to fhew that the operation of his rods is not derived from animal magnetifm. In our opinion, this is an unneceffary piece of trouble in England, where there is a conftant fucceffion of fimilar pretenfions. The *virgula divinatoria*, and the *laguette* of the juggler, are the genuine prototypes of this myftery. We were, indeed, rejoiced, on Dr Perkins's account, to find that the Connecticut Society had only denounced him as a Mefmerift: we trembled left he fhould have been put into the inquifitorial hands of the old women as a white witch."

This may be thought too ludicrous a treatment of a difcovery which profeffes to benefit mankind; but to have treated this difcovery with ferioufnefs, would have degraded the profeffion of a fcientific critic. As if the very cures pretended to have been performed did not of themfelves throw fufficient ridicule over the difcovery, Mr Perkins informs us, "that in fome inftances the metallic influence, when excited by different perfons, produces different effects. Experiments made to afcertain the point, proved that there were perfons who might ufe the tractors for any length of time, in difeafes which were fuitable for the operation, and produce no perceptible effect; when by placing them in the hands of another perfon, who fhould perform the operation precifely in the fame manner as before, the pain or inflammation would be removed directly." Hence he endeavours to prove that the influence of the tractors is Galvanic, by an argument as abfurd as the pretended fact on which it is founded.

"On the application (fays he) of zinc and filver to the tongue, the fenfation of tafte is very flight to fome, while with others it is very ftrong:—when the experiment is applied to the fenfe of fight, fome are hardly fenfible of it, while others obferve a ftrong flafh." But, not to mention that neither ebony nor ivory can form part of the excitatory arc in *Galvanifm*, though we have

Perkinifm. have feen them both employed *fuccefsfully* as tractors by a Danifh Perkinift, it is enough to obferve, that the different effects of the Galvanic metals on different perfons depend upon the difference of ftructure of the organs of fenfation in the *patients;* whereas the different effects of the metallic tractors refult, according to this account, from the difference of ftructure in the organs of fenfe of the various *operators!* Nay, what is ftill more extraordinary, if any thing can be more extraordinary than this, is, that the value of the tractors depends, not upon the *materials* of which they are made, or the *fkill* of the manufacturer, but upon fome inconceivable virtue conveyed by Mr Perkins to the *perfon* of him by whom they are *fold.* This we learn from a pamphlet publifhed by Charles Cunningham Longworthy, furgeon in Bath; who informs us, that he fells tractors by *commiffion* from Mr Perkins the original manufacturer in London.

After this article was fent to the prefs, and thus much of it printed, we received, from a friend in London, a copy of Mr Perkins's laft publication on the fubject *; in which he endeavours to repel the objections urged by Dr Haygarth and others againft the influence of the metallic tractors. Had we not been previoufly convinced of the falfity of Perkinifm, the perufal of this pamphlet would have removed from our minds every doubt; for we will venture to fay, that it is not in the power of Dr Haygarth, and the whole faculty united, to bring more complete proof than Mr Perkins has here brought, that what he calls his father's *difcovery* has no claim to rank otherwife than with the difcovery of Mefmer. See *Animal* MAGNETISM, Encycl.

* *The Efficacy of Perkins's Patent Metallic Tractors, &c.* 1800.

He gives indeed 250 cafes, which are attefted to have been fuccefsfully treated by the tractors; but at leaft an equal number of cafes were attefted to have been fuccefsfully treated by Mefmer and his partifans; and fix times that number of cures were faid to have been miraculoufly performed at the tomb of the Abbé Paris (See PARIS in this *Suppl.*) We would willingly allow, however, that thefe atteftations ought to draw the attention of men of fcience to the fubject, did not the author himfelf betray a want of confidence in the tractors, by his own arguments in their favour, and by his caution to the public againft *counterfeits.* He feems indeed to confider their fanative influence as refulting entirely from his *patent.*

Dr Haygarth having faid that he performed cures of the fame kind with thofe of which Mr Perkins boafts, by the proper application of tractors made of *wood;* and having added, that "if any perfon would repeat thefe experiments, it fhould be done with due folemnity," in order to work upon the imagination; our author replies, by putting the following queftion: "Is there a fingle poffeffor of the *patent metallic* tractors in England, who has frequently ufed them, and will fay that this fraud is neceffary to make *them* perform *cures?*" Inftead of anfwering for the Englifh poffeffors of thefe valuable inftruments, we beg leave, in our turn, to afk, If there be a fingle expert chemift in Great Britain who can underftand this queftion in any other fenfe than as implying that the virtue of the tractors refides in the *patent?* This, however, appears ftill more palpable in the caution to the public.

"Among the various artifices (fays Mr Perkins) which have been employed by certain interefted perfons, I have to mention the mean attempt to circulate *falfe tractors,* and from the failure of thefe to throw difcredit upon the difcovery. Three inftances of this kind have occurred lately. Complaints having been made to me that my tractors would not cure the difeafes for which they are recommended, I was led to make inquiry refpecting the cafes alluded to; and conceiving them fit fubjects for the tractors, I called on the patients to apply them myfelf. In *both* inftances (it was juft now in *three* inftances) I found they had been ufing *counterfeit* tractors. Had not this been difcovered, the *merit* of the *patent* tractors muft have fuffered extremely!"

This is very extraordinary. The *character* or *fame* of any thing may indeed be injured by a counterfeit; but we believe this is the firft inftance of the *merit* or *demerit* of one inanimate fubftance being increafed or diminifhed by another at a diftance from it,—of the hardnefs of fteel, for inftance, being diminifhed by the foftnefs of lead! But we beg Mr Perkins's pardon. The *merit* of his tractors confifts in their putting money into his pocket; and *that* merit might certainly be injured by the ufe of *counterfeits.* Hence, with great propriety, he informs the public, that every *genuine fet* is ftamped with the words PERKINS's PATENT TRACTORS, accompanied with a receipt for the five guineas, numbered and figned in the handwriting of the patentee. From thefe facts we infer (and he muft acknowledge the inference to be juft), that the virtue of the tractors refides in the *patent,* reftricting the making of them to *Benjamin Douglas Perkins,* and not to the *metal* of which they are made. This is indeed moft obvious; for he cannot be fuch a ftranger to the ftate of chemical fcience in this country, as to fuppofe that his tractors may not be analyfed into their component principles, and, of courfe, that others may not be made poffeffing all their virtues except fuch as refult from the patent.

We fhall conclude this article in the words of the reviewer already quoted: "To trace the relations and dependencies of projects fimilar to that of Dr Perkins, would now be a work of more labour than utility. The fund of public credulity is an inexhauftible refource for thofe who can refolve to levy contributions on it. In vain is the fpirit of quackery exorcifed in one form; it rifes again immediately, 'with twenty ghaftly murders on its head, to pufh us from our ftools.' We, who have contemplated the progrefs of real knowledge during a long courfe of years, have feen many bubbles like this glitter for a moment, and then difappear for ever. People may talk of Mefmerifm, or Perkinifm, but we confider all fuch varieties as belonging to the old and extenfive clafs of Charlatanifm."

Perouse.

PEROUSE (John Francis Galoup de la), the celebrated, though unfortunate, French navigator, was born at Albi in 1741. Of the rank or condition of his father, M. *Milet-Mureau* has given us no information in that meagre eulogy of Peroufe which he has inferted in the introduction to his laft voyage. It appears, however, that he intended to make his fon a feaman, and fent him, at a very early period of life, to the marine fchool, where the young man became enthufiaftically fond of his profeffion, and laudably ambitious to emulate the fame of the moft celebrated navigators.

Being

Being appointed a midfhipman on the 19th of November 1756, he behaved, we are told, with great bravery in that ftation, and was feverely wounded in the engagement between the admirals Hawke and Conflans, on the 20th of November 1759. The Formidable, in which he ferved, was taken, after a vigorous refiftance; and it is probable that Peroufe reaped fome advantage from his acquaintance with Britifh officers.

On the 1ft of October 1764 he was promoted to the rank of lieutenant; and defpifing a life of eafe and idlenefs, he contrived to be employed in fix different fhips of war during the peace that fubfifted between Great Britain and France. In 1767 he was promoted to the rank of what, in our navy, is called *mafter* and *commander*. In 1779 he commanded the *Amazone*, belonging to the fquadron of Vice-admiral Count d'Eftaing; and when that officer engaged Admiral Byron, the poft of La Peroufe was to carry his Admiral's orders to the whole of the line. He afterwards took the floop *Ariel*, and contributed to the capture of the *Experiment*—exploits which his eulogift feems to confider as inftances of very uncommon heroifm; but he foon after performed a greater.

Being, on the 4th of April 1780, appointed captain of the frigate *Aftrea*, and being on a cruife with the *Hermione*, thefe two frigates attacked fix Englifh veffels of war, of from 28 to 14 guns each, and took two of them. The French certainly reaped more laurels about that period than they have been accuftomed to do in naval wars with Great Britain: but as we have completely forgotten the particulars of this fight, we fufpect that it was not altogether fo very brilliant a bufinefs as M. Milet-Mureau is pleafed to reprefent it.

In the year 1782, La Peroufe was difpatched with the Sceptre of 74 guns, and two frigates of 36 guns each, having fome troops and field pieces on board, to deftroy the Englifh fettlements in Hudfon's Bay. This tafk was eafily accomplifhed; for when he had furmounted the difficulties of navigation in a frozen fea, he found nothing on fhore to oppofe the fmalleft force. Having deftroyed the fettlements, he learned that fome of the Englifh had fled at his approach into the woods; and his eulogift confiders it (fuch are the difpofitions of French republicans) as a moft wonderful inftance of humanity, that he left to thefe unfortunate men provifions to preferve them from perifhing by hunger, and arms to protect them from the fury of the favages! Peroufe, we dare anfwer for him, was confcious of nothing heroic or extraordinary in this act of beneficence, which he certainly could not have omitted, without incurring both infamy and guilt.

In the year 1785, he was appointed to the command of a voyage round the world; which was unfortunately deftined to be his laft. Of this voyage, as far as it was accomplifhed, there is a full account in the hands of every French and Englifh reader; and from that account it appears, that Peroufe was admirably qualified to difcharge fuch a truft. He feems to have been an experienced and fkilful feaman; a man of confiderable mathematical and phyfical fcience, uncorrupted by that philofophifm which difgraced many of his attendants; and capable of the utmoft perfeverance in every laudable purfuit. To thefe qualities he united a proper combination of caution and courage, with a difpofition truly benevolent to the various tribes of favages whom he vifited. The difafters which occurred on the voyages were all, except the laft, of which nothing is known, occafioned by the difobedience of his officers, or their neglecting to follow his advice.

The laft difpatches of this great and good man were dated from Botany Bay, February the 7th, 1788; and fince that period, no account of him has been received which is intitled to the fmalleft confidence. *M. Milet-Mureau* has indeed given us, at fome length, the childifh conjectures of the Society of Natural Hiftory refpecting his fate, which, in language equally childifh, were delivered at the bar of the National Affembly; and he has added the ridiculous decree which that body of legiflative fciolifts paffed in confequence of fo extraordinary a fpeech. We will not difgrace our pages, or infult the memory of Peroufe, by contributing to the circulation of nonfenfe, which, we are perfuaded, would have made him blufh for his country.

PERPENDICULAR, in gunnery, is a fmall inftrument, ufed for finding the centre line of a piece in the operation of pointing it to a given object.

PERSIAN or PERSIC, in architecture, a name common to all ftatues of men, ferving inftead of columns to fupport entablatures.

PERWANNAH, in the language of Bengal, an order of government, or a letter from a perfon in authority.

PETERSBURGH (St), the capital of Ruffia, is a city, of which a pretty full hiftorical detail has been given in the *Encyclopædia*. It is introduced here merely on account of its police, which, according to the anonymous author of the life of Catharine II. has a very fimple and competent organization, and deferves to be adopted in other great capitals. Excepting the governor, whofe office naturally extends to all objects of public welfare, the head police-mafter is the proper chief of the whole fyftem of police. His office takes in the great compafs of this department, but confined to the general objects of public fecurity and order. He is not here, as in fome large towns, the formidable copartner of family fecrets, and the invifible witnefs of the actions of the private man. Under the head police-mafter is the police-office, where fit a police-mafter, two prefidents, the one for criminal, the other for civil cafes, and two confulters, chofen from the burgher clafs. To this is committed the care to maintain decorum, good order, and morals: alfo it is its bufinefs to fee to the obfervance of the laws, that the orders iffued by government, and the decifions of the courts of juftice, are put in force. The attainment of thefe purpofes is effected by the following mechanifm:

The refidence is divided into ten departments. Each of thefe has a prefident, appointed to watch over the laws, the fecurity, and the order of his diftrict. The duties and rights of this office are not lefs extenfive than important. A prefident muft have exact knowledge of the inhabitants of his department, over which a fort of parental authority is committed to him; he is the *cenfor morum* of his department; his houfe muft not be bolted or barred by night or day, but muft be a place of refuge, continually open to all that are in danger or diftrefs; he himfelf may not quit the town for the fpace of two hours, without committing the difcharge of his office to fome other perfon. The police-commando (conftables), and the watchmen of his department, are under

under his orders; and he is attended on all affairs of his office by two ferjeants. Complaints againft unjuft behaviour in the prefident may be brought to the police-office.

Each department is again divided into three, four, or five fubdivifions, called quarters, of which, in the whole refidence, are 42. Each of thefe has a quarter-infpector, in fubordination to whom is a quarter-lieutenant. The duty of thefe police-officers is in harmony with that of the prefident, only that their activity is confined to a fmaller circle. They fettle low affairs and flight altercations on the fpot, and keep a watchful eye on all that paffes.

The number of the nightly watch in the city amounts to 500. They have their ftations affigned them in watch-houfes at the corners of ftreets; and, befides their proper deftination, are to affift in the taking up of offenders, and in any fervice, by day or night, as their commanders fhall require. Befides thefe, for the execution of the police orders, and to act as patroles, there is alfo a commando of 120 men, who, in cafes of emergency, are fupported by a company of kofaks, or a regiment of huffars.

This machine, confifting of fo many fubordinate parts, preferves in its orderly courfe that fecurity and peace which excite the admiration of all foreigners. The activity of every individual member is unobferved in the operation of the whole; and by fuch a diftribution alone is the attainment of fo complicated an aim practicable.—All the quarter-infpectors of a department repair every morning, at feven o'clock, to their infpector's houfe, to lay before him the report of all that has happened in their quarters during the laft 24 hours; and at eight o'clock, all the infpectors bring together thefe feveral reports into the police-office, whereupon they firft and immediately take into examination the cafes of perfons taken into cuftody during the night. On urgent occafions, the police-office affembles at all hours.

This organization, and the extraordinary vigilance of the police, which is found competent to the bufinefs of a numerous and reftlefs people, render all fecret inquifitions unneceffary. The police has knowledge of all perfons in the refidence; travellers who come and go are fubject to certain formalities, which render it extremely difficult to conceal their place of abode, or their departure from the city. To this end, every houfeholder and innkeeper is obliged to declare to the police who lodges with him, or what ftrangers have put up at his houfe. If a ftranger or lodger ftays out all night, the landlord muft inform the police of it at lateft on the third day of his abfence from his houfe. The cautionary rules, in regard to travellers quitting the town, are ftill more ftrict. Thefe muft publifh in the newfpapers their name, their quality, and their place of abode, three feveral times, and produce the newfpapers containing the advertifement, as a credential in the government from which they then received their paffport; without which, it is next to impoffible to get out of the empire. This regulation not only fecures the creditor of the perfon about to depart, but alfo enables the police to keep a clofer infpection over all fufpected inhabitants.

If individuals may be fufpected by the government, becaufe their means of fupport, the company they keep, and their whole courfe of action, are clofely wrapped up in myftery; fo likewife may whole focieties be lefs indifferent to it, if they carefully conceal the object of their connection, or their very exiftence, from the eye of the public. The police watches here, with laudable attention, over fecret focieties of all kinds; and frequently as the fanatical fpirit of religious or political fectaries, or the enthufiafm of pretended myftagogues, have attempted to neftle here, they have never been able to proceed, or only for a very fhort time. Animal magnetifm, Martinifm, Rofycrutianifm, and by whatever other name the conceits of diftempered imaginations may be called, have always been attended with the fame bad fuccefs on this ftage.

From this fketch it will be readily imagined, that the number of impoftors and difturbers of the public peace can be but fmall. Quarrels and affrays in the ftreets or in the cabaks but feldom happen. The perfon attacked calls the neareft watchman; and in a moment both the aggreffor and the aggrieved are taken into cuftody, and led to the next fieja (police-watch-houfe), where the caufe of their quarrel is inquired into, and the aggreffor is punifhed. For matters of fome defcriptions, there is a peculiar tribunal, under the denomination of the oral court, which, on account of its fingularity, deferves to be briefly noticed.

In each quarter of the town are one or more judges of the oral court, who are chofen from the clafs of burghers, and with whom are affociated a few jurats. This court fits daily in the forenoon, and proceeds orally in all the differences that come before it. It, however, keeps a day-book, in which are entered all the caufes and decifions of the court, and which muft be every week laid before the magiftrate. When a charge is brought, the court declares it orally to the prefident of the quarter: whereupon the accufed muft not delay his appearance before the police longer than one day after he has received the fummons. Every caufe muft be determined in one day, or, if the examinations require more time in collecting, in three days. The oral court communicates the decifion to the prefident of the quarter by means of his day-book, in order to its ratification. If either party is not fatisfied with the fentence, he may appeal to the court as appointed in the regulations.

This is a very favourable account of the police of St Peterfburgh; but it is differently reprefented in *Beaujolin's Travels of two Frenchmen through Ruffia*, in 1790—1792. According to him, the police of the capital of that empire is far from being on the moft refpectable footing. There happen, indeed, but few accidents in the night; yet fometimes murders are committed, and efpecially thefts; for which, according to our author, it is exceedingly rare to obtain juftice. When a perfon has been affaffinated in fome place of bad repute, the police-officer is engaged to fecrecy by means of a few rubles; fo that the affair is foon hufhed up, unlefs the deceafed belonged to fome powerful family, whofe intereft makes it neceffary that inquiries fhould be inftituted. When two perfons quarrel, either in the ftreet or in a public houfe, he who *pays* the inquirer is always in the right: the inferior police-officers are never proof againft money; and the *poor* individual, whether he be in the right or wrong, is almoft fure of a beating.

PETIVER (James), a famous Englifh botanift, was con-

Petiver, Phasianus.

contemporary with Plukenet; but the exact time of his birth is not known, nor is much intelligence concerning him at present to be obtained. His profession was that of an apothecary, to which he was apprenticed under Mr Feltham, then apothecary to St Bartholomew's hospital *. When he entered into business for himself, he settled in Aldersgate street, and there continued for the remainder of his life. He obtained considerable business, and after a time became apothecary to the charter-house. After the Tradescants, he appears to have been the only person, except Mr Courten and Sir Hans Sloane, who made any considerable collection in natural history, previous to those of the present day. He engaged the captains and surgeons of ships to bring him home specimens, and enabled them to select proper objects, by printed directions which he distributed among them. By these means his collection became so valuable, that some time before his death Sir Hans Sloane offered him L. 4000 for it. After his death, it was purchased by the same collector. His museum extended his fame both at home and abroad. He was elected into the Royal Society; and becoming acquainted with Ray, assisted him in arranging the second volume of his History of Plants. He died April 20. 1718; and much honour was shewn to him at his funeral, by the attendance of Sir Hans Sloane, and other eminent men, as pall bearers, &c. By future botanists, his name was given to a plant. See PETIVERIA, *Encycl.*

* Pulteney's *Sketches of Botany in England.*

He gave the world several publications on various subjects of natural history: 1. *Musci Petiveriani Centuriæ decem*, 1692—1703, 8vo. 2. *Gazophylacii Naturæ et Artis, Decades decem*, folio, 1702, with 100 plates. 3. A Catalogue of Mr Ray's English Herbal, illustrated with figures, folio, 1713, and continued in 1715. 4. Many small publications, which may be found enumerated in Dr Pultney's book. 5. Many papers in the Philosophical Transactions, and a material article in the third volume of Ray's work, entitled, *Plantæ Rariores Chinenses Madraspatanæ, et Africanæ, a Jacobo Petivero ad opus Consummandum Collatæ*, &c. Many of his smaller tracts having become very scarce, his works were collected and published, exclusive of his papers in the Transactions, in 2 vols folio, and one 8vo, in the year 1764.

PHASIANUS (See *Encycl.*) A species of this genus of birds, formerly not described, was sent from Batavia to England by Lord Macartney, or some of his attendants, when they were on their voyage to China. The species to which it seemed to be most nearly allied, in point of general habit or appearance, was the *phasianus curvirostris*, or Impeyan pheasant; an East Indian bird, described and figured both in Mr Latham's Ornithology, and in the Museum Leverianum. From that bird, however, it differs very considerably. The tail of the latter being in a mutilated state, it was scarce possible to determine, with absolute precision, whether it should be referred to that subdivision of pheasants which contains those with long or cuneiform tails, or those with rounded ones, as in the Impeyan pheasant. The general colour of this most elegant bird was black, with a gloss of blue, or what, in the language of natural history, may be termed chalybean black, or black accompanied by a steel blue lustre. The lower part of the back was of a peculiarly rich colour, which, according to the different directions of the light, appeared either of a deep ferruginous or of the brightest fiery orange red. This beautiful colour passed in the manner of a broad zone round the whole body; but on the abdomen was of a much more obscure appearance than on the back, as well as somewhat broken or irregular, especially on the sides. The throat was furnished with a large, and somewhat angular, pair of wattles, uniting with the bare spaces on the cheeks. The feathers on the top of the head, which was of a lengthened form, ran a little backward, so as to give the appearance of an indistinct occipital crest. The beak was remarkable for a more lengthened and curved aspect than in any other bird of this genus, except the Impeyan pheasant. The feathers on the neck, back, and breast, were rounded, and of the same shell-like or scaly habit as those of the turkey. The legs very stout, and were armed with a pair of extremely strong, large, and sharp spurs. Both legs and beak were of a pale colour. Whether this bird be really new or not to the ornithologists of Europe, it may at least be affirmed with safety, that it had never been properly described; nor can the character of any species, hitherto introduced into the books of any systematic naturalist, be considered as a just or competent specific character of the present bird. It may be called the *fire-backed pheasant*; and its essential character may be delineated in the following terms: Black pheasant with a steel-blue gloss; the sides of the body rufous; the lower part of the back fiery ferruginous; the tail rounded; the two middle feathers pale yellow brown.—*Sir George Staunton's Account of an Embassy to China*, &c.

Phasianus, Philosophist.

PHILOSOPHIST, a lover of sophistry or false reasoning, in contradistinction to *philosopher*, who is a lover of sound reasoning, true science, and practical wisdom.

CRITICAL PHILOSOPHY.

1 Origin of the science.

CRITICAL PHILOSOPHY, is the appellation given to a system of science, of which the founder is *Immanuel Kant*, regius professor of logic and metaphysics in the university of Koenigsberg. Of this system, which is very generally admired in Germany, we promised, in our prospectus, to gratify our speculative readers with a short view; and that promise we are enabled to fulfil, by the kind communication of an illustrious foreigner, who, after acting a conspicuous part on the theatre of the world, and striving in vain to stem the torrent of democratic innovation, is now living an exile from his wretched country, and cultivating the sciences and the arts of peace.

2 Obscurity of its language.

"To explain (says he) the philosophy of Kant in all its details, would require a long and a painful study, without producing any real advantage to the reader. The language of the author is equally obscure, and his reasonings equally subtle, with those of the commentators of Aristotle in the 15th century.

The truth of this assertion will be denied by none, who

who have endeavoured to make themfelves mafters of the works of *Willich* and *Nitfch* on the critical philofophy; and the fource of this obfcurity feems to be fufficiently obvious. Befides employing a vaft number of words of his own invention, derived from the Greek language, Kant ufes expreffions, which have long been familiar to metaphyficians, in a fenfe different from that in which they are generally received; and hence a large portion of time is requifite to enable the moft fagacious mind to afcertain with precifion the import of his phrafeology.

The difficulty of comprehending this philofophy has contributed, we believe, more than any thing elfe, to bring it into vogue, and to raife the fame of its author. Men are afhamed, after fo laborious and fatiguing a ftudy, to acknowledge that all their labour has been thrown away; and vanity prompts almoft every man to raife the importance of that branch of fcience which is underftood but by a few, and in which he is confcious that his own attainments have been great. "We acknowledge, however, that in the fyftem of Kant there is difplayed much genius, combination, and fyftematic arrangement; but this only affords one of the many reafons which it prefents, for our regretting that the author has not directed his mind to more ufeful refearches, and that he has wafted the ftrength of his genius in rendering uncertain the moft comfortable truths, and in giving the appearance of novelty to opinions for the moft part taught long before his day.

The following analyfis, we believe, will fufficiently enable any one, at all converfant with metaphyfical fcience, to form a judgment of this celebrated fyftem; and our correfpondent, on whofe word the reader may rely, affures us, that, in detailing the principles of Kant, he has taken fpecial care to exhibit them with the utmoft poffible exactnefs, having feveral times preferred the obfcurity of the author's reafonings and language, to the danger of a falfe, though more perfpicuous, interpretation.

3 Divifion of human knowledge.

"Kant divides all our knowledge into that which is *a priori*, and that which is *a pofteriori*. Knowledge *a priori* is conferred upon us by our nature. Knowledge *a pofteriori* is derived from our fenfations, or from experience; and is by our author denominated *empyric*. One would at firft be induced, by this account of the origin of human knowledge, to believe that Kant intended to revive the fyftem of *innate ideas;* but we very quickly difcover that fuch is not his fyftem. He confiders all our knowledge as acquired. He maintains, that experience is the *occafional caufe* or *productrice* of all our knowledge; and that without it we could not have a fingle idea. Our ideas *a priori*, he fays, are produced *with* experience, and could not be produced *without* it; but they are not produced *by* it, or do not proceed *from* it. They exift in the mind; they are the *forms* of the mind. They are diftinguifhed from other ideas by two marks, which are eafily difcerned; *i. e.* they appear *univerfal* and *neceffary;* or, in other words, they admit of no exception, and their *converfe* is impoffible. Ideas which we derive from experience have no fuch characters. We can fuppofe, that what we have feen, or felt, or heard once, we may fee, or feel, or hear again; but we do not perceive any impoffibility in its being otherwife. For inftance, a houfe is on fire in my view: I am certain of this fact; but it affords me no *general* or *neceffary* knowledge. It is altogether *a pofteriori;* the materials are furnifhed by the individual impreffion which I have received; and that impreffion might have been very different.

"But if I take twice two fmall balls, and learn to call twice two *four*, I fhall be immediately convinced, that any two bodies whatever, when added to any two other bodies, will conftantly make the fum of bodies *four*. Experience has indeed afforded me the *opportunity* of acquiring this knowledge; but it has not given it to me; for how could experience prove to me that this truth fhall never vary? Experience muft always be *limited;* and therefore cannot teach us that which is *neceffary* and *univerfal*. It is not experience which difcovers to us, that we fhall always have the furface of the whole pyramid by multiplying its bafe by the third part of its height; or that two parallel lines, extended *in infinitum*, fhall never meet.

"All the truths of pure mathematics are, in the language of Kant, *a priori*. Thus, that a ftraight line is the fhorteft of all poffible lines between two fixed points; that the three angles of a triangle are always equal to two right angles; that we have the fame fum, whether we add 5 to 7 or 7 to 5; and that we have the fame remainder when we fubtract 5 from 10 as when we fubtract 10 from 15—are fo many propofitions, which are true *a priori*.

4 Pure knowledge *a priori*.

"Pure *knowledge a priori*, is that which is abfolutely without any mixture of experience. *Two and two men* make *four men*, is a truth, of which the knowledge is *a priori;* but it is not PURE knowledge, becaufe the truth is particular. The ideas of *fubftance*, and of *caufe* and *effect*, are *a priori;* and when they are feparated from the objects to which they refer (we fuppofe from this or that *particular* object), they form, in the language of Kant, *void ideas* (A) It is our knowledge *a priori*, *i. e.* that knowledge which precedes experience as to its origin, which renders experience poffible (B). Our faculty of knowledge has an effect on our ideas of fenfation analogous to that of a veffel, which gives its own form to the liquor with which it is filled. Thus, in all our knowledge *a pofteriori*, there is fomething *a priori* derived from our faculty of knowledge. All the operations of our minds; all the impreffions which our external and internal fenfes receive and retain, are brought into effect by the *conditions*, the *forms*, which exift in us by the pure ideas *a priori*, which alone render all our other knowledge certain.

5 Time and fpace.

"*Time* and *fpace* are the two effential forms of the mind:

(A) In the language of Lock *abftract ideas*.

(B) In our correfpondent's manufcript, this fentence runs thus: "It is our knowledge *a priori*, or that knowledge which *entirely precedes experience* as to its origin, which experience renders poffible;" but here muft be fome miftake, either by the tranflator or by the amanuenfis. Kant's philofophy is abundantly obfcure and paradoxical; but it furely never entered into his head to reprefent the effect as prior in its origin to the very caufe which alone renders it poffible. The context, too, feems to us to agree better with the meaning of the fentence as we have printed it in the text.

mind: the former for impreſſions received by the internal ſenſe; the ſecond for thoſe received by our external ſenſes. Time is neceſſary in all the *immediate* (perhaps *intuitive*) perceptions of objects; and ſpace in all *external* perceptions.

6 Extenſion. "*Extenſion* is nothing real but as the form of our ſenſations. If extenſion were known to us only by experience, it would then be poſſible to conceive that there might be ſenſible objects without ſpace.

7 Impenetrability, &c. "It is by means of the form *ſpace* that we are enabled, *a priori*, to attribute to external objects *impenetrability*, *diviſibility*, *mobility*, &c.; and it is by means of the form *time* that we attribute to any thing *duration*, *ſucceſſion*, *ſimultaneity*, *permanence*, &c.

8 Origin of arithmetic and geometry. "*Arithmetic* is derived from the form of our internal ſenſe, and *geometry* from that of our external.

9 Unifying power of the mind. "Our underſtanding collects the ideas received by the impreſſions made on our organs of ſenſe, confers on theſe ideas *unity* by a particular *force* (we ſuppoſe energy) *a priori*; and thereby forms the repreſentation of each object. Thus, a man is ſucceſſively ſtruck with the impreſſions of all the parts which form a particular garden. His underſtanding unites theſe impreſſions, or the ideas reſulting from them; and in the unity produced by that unifying act, it acquires the idea of the garden. If the objects which produce the impreſſions afford alſo the *matter* of the ideas (c), then the ideas are *empyric*; but if the objects only unfold the *forms of the thought*, the ideas are *a priori*. The act of the underſtanding which unites the perceptions of the various parts of an object into the perception of one whole, is the ſame with that which unites the attribute with its ſubject.

10 Analytic judgments. "Judgments are divided into two ſpecies; *analytic* and *ſynthetic*. An analytic judgment is that in which the attribute is the mere developement of the ſubject, and is found by the ſimple analyſis of the perception; as *bodies are extended*; *a triangle has three ſides*.

11 Synthetic judgments. "A ſynthetical judgment is that where the attribute is connected with the ſubject by a cauſe (or baſis) taken from the faculty of knowledge, which renders this connection neceſſary: as, *a body is heavy*; *wood is combuſtible*; *the three angles of a triangle are equal to two right angles*. There are ſyntheſes *a priori* and *a poſteriori*; and the former being formed by experience, we have the ſure means of avoiding deception.

"It is a problem, however, of the utmoſt importance, to diſcover how ſynthetic judgments *a priori* are poſſible. How comes it, for example, that we can affirm that all the radii of a circle are equal, and that two parallel lines will never meet? It is by ſtudying the *forms* of our mind that we diſcover the poſſibility of making theſe affirmations. In all objects there are things which muſt neceſſarily be THOUGHT (be ſupplied by thought); as, for example, that there is a *ſubſtance*, an *accident*, a *cauſe*, and certain *effects*.

12 Forms of the underſtanding. "The *forms* of the underſtanding are, *quantity*, *quality*, *relation*, *modality*.

"Quantity, Kant diſtinguiſhes into *general*, *particular*, and *individual*; quality, into *affirmation*, *negation*, *infinite*; relation, into *categoric*, *hypothetic*, and *disjunctive*; and modality, into *problematic*, *certain*, and *neceſſary*. He adds alſo to theſe properties of the four principal forms of the underſtanding, a table of *categories* or fundamental ideas *a priori*.

13 Categories. "Quantity, gives *unity*, *plurality*, *totality*. Quality, gives *reality*, *negation*, *limitation*. Relation, gives *inherence*, *ſubſtance*, *cauſe*, *dependence*, *community*, *reciprocity*, Modality, gives *poſſibility*, *impoſſibility*, *exiſtence*, *nothing*, *neceſſity*, *accident*. Theſe categories can only be applied to experience. When, in the conſideration of an object, we abſtract all that regards ſenſation, there remain only the pure ideas of the underſtanding, or the *categories*, by which a *thing* is conceived as a *thing*.

"Pure reaſon is the faculty of tracing our knowledge *a priori*, to ſubject it to principles, to trace it from its neceſſary conditions, till it be entirely without condition, and in complete unity. This pure reaſon has certain fundamental rules, after which the neceſſary connection of our ideas is taken for the determination of the objects in themſelves;—an illuſion which we cannot avoid, even when we are acquainted with it. We can conclude from what we know to what we do not know; and we give an *objective* reality to theſe concluſions from *an appearance* which leads us on.

14 Critique of pure reaſon. "The writings of Kant are multifarious; but it is in his work entitled the *Critique of Pure Reaſon* that he has chiefly expounded his ſyſtem. This work is a treatiſe on a pretended ſcience, of which Kant's ſcholars conſider him as the founder, and which has for its objects the *natural forces*, the *limits of our reaſon*, as the ſource of our pure knowledge *a priori*, the *principles of all truth*. Kant does not propoſe to give even an expoſition of theſe branches of knowledge, but merely to examine their origin; not to extend them, but to prevent the bad uſe of them, and to guard us againſt error. He denominates this ſcience *tranſcendental criticiſm*; becauſe he calls all knowledge, of which the object is not furniſhed by the ſenſes, and which concerns the kind and origin of our ideas, *tranſcendental knowledge*. The Criticiſm of Pure Reaſon, which gives only the fundamental ideas and maxims *a priori*, without explaining the ideas which are derived from them, can lead (ſays Kant) to a complete ſyſtem of pure knowledge, which ought to be denominated *tranſcendental philoſophy*, of which it (the *Criticiſm*, &c.) preſents the *architectonic* plan, *i. e.* the plan regular and well diſpoſed.

"The work entitled *The Critique of Pure Reaſon*, is divided into ſeveral parts or ſections, under the ridiculous titles of *Æſthetic tranſcendental*; of *tranſcendental logic*; of *the pure ideas of the underſtanding*; of *the tranſcendental judgment*; of *the paralogiſm of pure reaſon*; of *the ideal tranſcendental*; of *the criticiſm of ſpeculative theologies*; of *the diſcipline of pure reaſon*, &c.

15 We cannot know objects as they are in themſelves. "But to proceed with our abſtract of the ſyſtem. We know objects only by the manner in which they affect us; and as the impreſſions which they make upon us are only certain *apparitions* or *phenomena*, it is impoſſible for us to know what an *object is in itſelf*. In conſequence of this aſſertion, ſome have ſuppoſed that Kant is an *idealiſt* like Berkeley and ſo many others, who have thought that ſenſations are only *appearances*, and

(c) This is wonderful jargon; but the reader will reflect that it is not ours.

and that there is no truth but in our reafon; but fuch is not the opinion of Kant (D). According to him, our underftanding, when it confiders the apparitions or phenomena, acknowledges the *exiftence* of the objects in themfelves, inafmuch as they ferve for the bafes of thofe apparitions; though we know nothing of their *reality*, and though we can have no certitude but in experience.

" When we apply the *forms* of our underftanding, fuch as *unity*, *totality*, *fubftance*, *caufality*, *exiftence*, to certain ideas which have no object in *fpace* and *time*, we make a fallacious and arbitrary application. All thefe forms can bear only on fenfible objects, and not on the *world of things in itfelf*, of which we can THINK, but which we CAN NEVER KNOW. Beyond things fenfible we can only have *opinions* or a *belief* of our reafon.

16 Objective and fubjective truths.

" The motives to confider a propofition as true, are either *objective*, *i. e.* taken from an *external* object, fo that each man fhall be obliged to acknowledge them; and then there is a truth *evident* and fufceptible of *demonftration*, and it may be faid that we are *convinced:* or the motives are *fubjective*, *i. e.* they exift only in the mind of him who judges, and he is *perfuaded*.

" TRUTH, then, confifts in the agreement of our *notions* with the *objects*, in fuch a manner as that all men are obliged to form the fame judgment; BELIEF confifts in holding a thing for true in a *fubjective manner*, in confequence of a perfuafion which is entirely perfonal, and has not its bafis in an object fubmitted to experience.

17 Belief.

" There is a *belief of doctrine*, of which Kant gives, as an example, this affertion—' there are inhabitants in the planets.' We muft acknowledge (he adds) that the ordinary mode of teaching the exiftence of God belongs to *the belief of doctrine*, and that it is the fame with *the immortality of the foul. The belief of doctrine* (he continues) has in itfelf fomething *ftaggering*; but it is not the fame with *moral belief*. In moral belief there is fomething *neceffary*; it is (fays he), that I fhould obey the law of morality in all its parts. The end is ftrongly eftablifhed; and I can perceive only one condition, by means of which this end may be in accord with all the other ends, *i. e.* that *there is a God*. I am certain that no man knows any other condition which can conduct to the fame unity of end under the moral law; which law is a law of my reafon. I will confequently believe certainly the *exiftence of God*, and a *future life*; becaufe this perfuafion renders immoveable my moral principles—principles which I cannot reject without

18 Proof of the exiftence of God, &c.

rendering myfelf contemptible in my own eyes. I wifh for happinefs, but I do not wifh for it without morality; and as it depends on *nature*, I cannot wifh it with this condition, except by believing that nature depends on a Being who caufes this connection between morality and happinefs. This fuppofition is founded on the *want* (or *neceffity*) of my reafon, and not on my duty.

" We have, however, no *certainty* (fays Kant) in our knowledge of God, becaufe certainty cannot exift except when it is founded on an object of experience. The philofopher acknowledges, that *pure reafon* is too weak to prove the exiftence of a being beyond the reach of our fenfes. The neceffity of believing in God is therefore only *fubjective*, although neceffary and general for all thofe beings who conform to their duty. This is not *knowlege*, but only a *belief* of reafon, which fupplies the place of a knowledge which is impoffible (E).

" The proofs of natural theology (fays our philofopher) taken from the order and beauty of the univerfe, &c. are proofs only in *appearance*. They refolve themfelves into a bias of our reafon to *fuppofe* an Infinite Intelligence as the author of all that is poffible; but from this bias it does not follow that there really is fuch an Author. To fay, that whatever exifts muft have a caufe, is indeed a maxim *a priori*; but it is a maxim applicable only to experience, for one knows not how to fubject to the laws of our perceptions that which is abfolutely independent of them. It is as if we were to fay, that whatever exifts in experience muft have an experience; but the world, taken as a whole, is without experience as well as its caufe. It is much better to draw the proof of the exiftence of God from morality, than to weaken it by fuch reafoning. This proof is relative. It is impoffible to *know* that God exifts; but we can comprehend how it is poffible to act morally on the *fuppofition* of the exiftence (although incomprehenfible) of an intelligent Creator—an exiftence which PRACTICAL REASON forces THEORETICAL *reafon* to adopt. This proof not only *perfuades*, but even acts on the CONVICTION, in proportion as the motives of our actions are conformable to the law of morality.

" Religion ought to be the *means* of virtue and not its object. Man has not in himfelf the idea of religion as he has that of virtue. The latter has its principle in the mind; it exifts in itfelf, and not as the means of happinefs; and it may be taught without the idea of a God, for the pure law of morality is *a priori*.

" He who does good by inclination does not act morally. The converfe of the principle of morality is to make perfonal happinefs the bafis (F) of the will. There are compaffionate minds which feel an internal pleafure in communicating joy around them, and who thus enjoy the fatisfaction of others; but their actions, however juft, however good, have no moral merit, and may be compared to other inclinations; to that of honour 19 Morality.

(D) We muft requeft the reader to obferve that this is the language of our correfpondent. We have fhewn elfewhere, that Berkeley did not deny the reality of fenfations; and we hope to fhew by and bye, that Kant is as much an *idealift* as he was, if this be a fair view of the Critical Philofophy.

(E) We have here again taken the liberty to alter the language of our correfpondent. He makes Kant fay, " It is not this knowledge, but a *belief* of reafon, &c.;" but this is furely not the author's meaning. From the context, it is apparent that Kant means to fay, that we have not, and cannot have, what can be properly called a *knowledge* of the exiftence of God, but only fuch a belief of his exiftence as fupplies the place of this impoffible knowledge.

(F) This is a very abfurd phrafe. We fuppofe Kant's meaning to be, that the principles of him whofe actions and volitions are influenced by the profpect of perfonal happinefs, are the reverfe of the pure principles of morality.

honour (for example), which, whilft it meets with that which is juft and ufeful, is worthy of praife and encouragement, but not of any high degree of efteem. According to Kant, we ought not even to *do good*, either for the pleafure we feel in doing it, or in order to be happy or to render others happy; for any one of thefe additions (perhaps motives) would be *empyric*, and injure the purity of our morals. A reafonable being ought to defire to be exempted from all *inclinations*, and never to do his duty but for his duty's fake.

"We ought to act after the maxims derived *a priori* from the faculty of knowledge, which carry with them the idea of neceffity, and are independent of all experience; after the maxims which, it is to be wifhed, could be erected into GENERAL LAWS for all beings endowed with reafon."

20 Futility of this fyftem

If this be a correct view of the object and the refults of the critical philofophy, and the character of him from whom we received it permits us not to doubt of its being nearly correct, we confefs ourfelves unable to difcover any motive which fhould induce our countrymen, in their refearches after truth, to prefer the dark lantern of Kant to the luminous torch of Bacon. The metaphyfical reader will perceive, that, in this abftract, there is little which is new except the phrafeology; and that what is new is neither unitelligible or untenable.

21 Of which the fundamental principles are not new.

The diftinction between knowledge *a priori* and knowledge *a pofteriori*, is as old as fpeculation itfelf; and the mode in which Kant illuftrates that diftinction differs not from the illuftrations of Ariftotle on the fame fubject. The Stagyrite talked of *general forms*, or *formal caufes*, in the mind, as well as the profeffor at Koenigfberg; and he or his difciples (for we quote from memory) compared them to the form of the ftatue in the rough block of marble. As that form is brought into the view of the fpectator by the chiffel of the ftatuary, fo, faid the peripatetics, are the general *forms* in the mind brought into the view of confcioufnefs by fenfation and experience.

Such was the doctrine of Ariftotle and his difciples, and fuch feems to be the doctrine of Kant and his followers; but it is either a falfe doctrine, or, if it be true, a doctrine foolifhly expreffed. A block of marble is capable of being cut into any form that the ftatuary pleafes; into the form of a man, a horfe, an ox, an afs, a fifh, or a ferpent. Not one of thefe forms therefore can be inherent in it, or effential to it, in oppofition to the reft; and a general form, including all the animals under it, is inconceivable and impoffible. In like manner, the human mind is capable of having the ideas of a circle, a triangle, a fquare, of black, white, red, of four, fweet, bitter, of the odour of a rofe, and the ftench of a dunghill, of proportion, of mufical founds, and of a thoufand other things. None of thefe ideas therefore can be effential to the mind in oppofition to the reft; and every man, who is not an abfolute ftranger to the operations of his own intellect, knows well that he cannot think of a thoufand things at once; or, to ufe the language of philofophers, have in his mind a general idea, comprehending under it a thoufand things fo difcordant as colours and founds, figures, and fmells. If therefore Kant means to affirm, with Plato, that, previous to all experience, there are *actually* in the mind *general forms*, or *general ideas*, to which fenfation, or experience, gives an opportunity of coming into view, he affirms what all men of reflexion know to be falfe. If he means only to affirm, what feems to have been the meaning of Ariftotle, that particular fenfations give occafion to the intellect to form general ideas, he expreffes himfelf indeed very ftrangely; but his doctrine on this fubject differs not effentially from that of Locke and Reid, and many other eminent metaphyficians of modern times. Of abftraction and general ideas we have given our own opinion elfewhere (See METAPHYSICS, *Encycl.* Part I. Chap. iv.), and fhall not here refume the fubject.

22 Improper ufe of terms;

But when Kant fays that his ideas *a priori* are *univerfal* and *neceffary*, and that their converfe is *impoffible*, he feems by the word *idea* to mean what more accurate writers exprefs by the term *propofition*. There are indeed two kinds of propofitions, of which both may be true, though the one kind expreffes neceffary and univerfal truths, and the other fuch truths as are contingent and particular. (See METAPHYSICS, *Encycl.* Part I. Chapter vii.) Propofitions directly contrary to thofe which exprefs particular and contingent truths may be eafily conceived; whilft fuch as are contrary to neceffary and univerfal truths are inconceiveable and impoffible; but we doubt whether *any idea*, in the proper fenfe of the word, has a *contrary* or, as he expreffes it, a *converfe*. *Nothing* is not contrary to *fubftance*, nor *black* contrary to *white*, nor *four* contrary to *fweet*, nor an *inch* contrary to an *ell*. Nothing is the negation of fubftance, and black the negation of white; four is different from fweet, and an inch is lefs than an ell; but between thefe different ideas we perceive no contradiction.

That Kant ufes the term *idea* inftead of *propofition*, or fome word of fimilar import, is farther evident from his inftances of *the houfe on fire*, and the manner in which we learn that any two bodies added to any two other bodies will conftantly make the fum of *four bodies*. If it be his will to ufe the terms *a priori* and *a pofteriori* in the fenfe in which other metaphyficians ufe the terms *neceffary* and *contingent*, we can make no other objection to his diftinction between thefe two propofitions, but that it is expreffed in very improper language. The houfe might certainly be *on fire* or *not* on fire; but twice two bodies *muft* always make the fum of four bodies, and cannot poffibly make any other fum.

The truth of this laft propofition (he fays) we cannot have learned from *experience*, becaufe experience, being always limited, cannot poffibly teach us what is *neceffary* and *univerfal*. But this is egregious trifling. The experience employed here is not limited. A child unqueftionably learns the import of the terms of numeration, as he learns the import of all other terms, by experience. By putting two little balls to two little balls, he learns to call the fum *four* balls. After two or three leffons of this kind with different bodies, his own reflection fuggefts to him, that the fum four has no dependance upon the fhape or confiftence of the bodies, but merely upon the *individuality* of each or their numerical difference; and individuality, or numerical difference, is as compleately exemplified in two bodies of any kind as in two thoufand.

23 With its confequences.

All the truths of pure mathematics (fays Kant) are *a priori*. If he means that they are all *neceffary*, and that the contrary of any one of them is *inconceivable*, he affirms nothing but what is true, and has been known to to all mathematicians theſe two thouſand years. But, if he means that they are *innate* truths, not diſcovered by induction or ideal meaſurement, his meaning is demonſtrably falſe. (See INDUCTION in this *Supplement*.) When he ſays, that it is not *experience* which diſcovers to us that we ſhall always have the ſurface of the pyramid, by multiplying its baſe by the third part of its height, he is right, if by experience he means the actual meaſurement of all poſſible pyramids; but ſurely he cannot mean that the truth of this meaſurement is innate in the mind, for it is in fact not a true but a falſe meaſurement (G). The baſe of a pyramid multiplied by the third part of its height gives, not the ſurface, but the ſolid contents of the pyramid; and he who underſtands the propoſition on which this truth is immediately built, knows perfectly that Euclid proved it by a ſeries of ideal meaſurements of thoſe particulars in which all pyramids neceſſarily agree.

Kant ſeems often to confound ſenſation with experience; and if by experience he means *ſenſation*, when he ſays that *pure knowledge, a priori*, is that which is abſolutely without any mixture of experience, he talks nonſenſe; for the moſt ſpiritual notions which men can form are derived from the operations of the mind on ideas of ſenſation. To the reſt of the paragraph, reſpecting pure knowledge, we have hardly any objection to make. Locke, the great enemy of innate ideas, taught, before Kant was born, that our knowledge depends upon our organization and the faculties of our minds, as much as upon impreſſions made on the ſenſes *ab extra*; that if our organs of ſenſe were different from what they are, the taſte of ſugar might be bitter, and that of wormwood ſweet; and that if we had not memory, and could not modify and arrange our ideas, all progreſs in knowledge would be impoſſible.

24 Groundleſs falſe aſſertions.

When our author talks of *time* and *ſpace* as the two eſſential *forms* of the mind, we are not ſure that we underſtand him. We have ſhewn elſewhere, that a conſcious intelligence may be conceived which has no ideas either of ſpace or of time (ſee METAPHYSICS, *Encycl.* n° 182, &c. and 209, &c.); and he who can affirm, that if extenſion were known to us only by *experience*, it would be poſſible to conceive ſenſible objects *without ſpace*, has never attended to the force of what philoſophers call *the aſſociation of ideas of the mind*. But what is here meant by ſenſible objects? Are they objects of touch, taſte, or ſmell? Objects of touch cannot indeed be conceived without ſpace; but what extent of ſpace is ſuggeſted by the taſte of ſugar or the odour of a roſe?

When Kant talks of the *form* ſpace enabling us to attribute to external objects *impenetrability*, *mobility*, &c. he talks at random; and another man may, with as much propriety, and perhaps more truth, affirm the converſe of his propoſitions, and ſay, that it is the impenetrability and mobility, &c. of external objects that enable us to form the idea called *ſpace*, and the ſucceſſion of ſome objects, compared with the permanence of others, that enables us to form the notion or mode called *time*.

On the two or three next paragraphs it is not worth while to detain the reader with many remarks. They abound with the ſame uncouth and obſcure phraſeology, and the ſame idle diſtinctions between ideas *a priori* and *a poſteriori*. In n° 11. he affirms, that the three 25
following propoſitions (*a body is heavy*, *wood is combuſtible*, and *the three angles of a triangle are equal to two right angles*) are all neceſſary judgments. In one ſenſe this affirmation is true, and in another it is falſe. We cannot, without ſpeaking unintelligibly, give the name *body* to any ſubſtance which is not heavy; and we are not acquainted with any kind of *wood* which is not combuſtible; but ſurely it is not impoſſible to conceive a ſubſtance extended and diviſible, and yet *not* heavy, to which the name *body* might be given without abſurdity, or to conceive wood as incombuſtible as the mineral called *aſbeſtos*. That the three angles, however, of a plane triangle can be either more or leſs than equal to two right angles, is obviouſly impoſſible, and muſt be perceived to be ſo by every intelligence from the Supreme down to the human. The three propoſitions, therefore, are not of the ſame kind, and ſhould not have been claſſed under the ſame genus of *neceſſary* ſynthetic judgments.

Bad logic.

In the critique of pure reaſon, Kant ſeems to teach that all demonſtrative ſcience muſt proceed from general principles to particular truths. Hence his *forms* of the underſtanding, and his *categories*, which, according to one of his pupils*, "lie in our underſtanding as pure notions *a priori*, or the foundation of all our knowledge. They are *neceſſary forms*, *radical* notions, of which all our knowledge *muſt* be compounded." But this is directly contrary to the progreſs of the human mind, which, as we have ſhewn in the article INDUCTION, already referred to, proceeds, in the acquiſition of every kind of knowledge, from particular truths to general principles. This *tranſcendental philoſophy* of Kant's, therefore, inverts the order of nature, and is as little calculated to promote the progreſs of ſcience as the ſyllogiſtic ſyſtem of Ariſtotle, which was likewiſe built on *categories* or *general forms*. His *tranſcendental æſthetic*, which, according to Dr Willich, is the knowledge *a priori* of the *rules of ſenſation*, ſeems to be a contradictory expreſſion, as it implies that a man may know the laws of ſenſation, without paying the ſmalleſt attention to the organs of ſenſe.

* *Dr Willich.*

That we know objects only by the manner in which they affect us, and not as they are in themſelves, is a truth admitted, we believe, by all philoſophers, and certainly by Locke and Reid; but when Kant ſays that we know nothing of the *reality* of the objects which affect our ſenſes, he ſeems to be ſingularly paradoxical. Berkeley himſelf, the moſt ingenious idealiſt perhaps that ever wrote, contends ſtrenuouſly for the exiſtence of a *cauſe* of our ſenſations diſtinct from our own minds; and becauſe he thinks inert matter a cauſe inadequate

---

(G) This may look like cavalling, as the blunder may be either Kant's or our correſpondent's, though neither of them can be ſuppoſed ignorant of the method of meaſuring the ſurface of a pyramid. We aſſure the reader, however, that we do not mean to cavil. We admit that both Kant and our correſpondent know perfectly well how to meaſure the ſurface of a pyramid; but had that knowledge been *innate* in their minds, we cannot conceive the poſſibility of their falling into the blunder. The blunder, therefore, though the offspring of mere inadvertence, ſeems to be a complete confutation of the doctrine.

inadequate to this effect, he concludes, that every ſenſation of which we are conſcious is a proof of the immediate agency of the Deity. But Kant, as we ſhall perceive by and bye, makes the exiſtence of God and of matter equally problematical. Indeed he ſays expreſsly, that beyond things ſenſible we can only have *opinions* or *belief*; but things ſenſible, as every one knows, are nothing more than the *qualities* of objects.

26 Tendency of the ſyſtem towards atheiſm.

It ſhould ſeem that the greater number of wonders which Kant has found in our primitive knowledge and in the faculties of our mind, the greater number of proofs ought he to have found of the exiſtence and attributes of one Firſt Cauſe; but ſo far is this from being the caſe, that we have ſeen him reſting the evidence of this moſt important of all truths, either upon the *moral ſenſe*, which our paſſions and appetites ſo eaſily alter, or upon the intuitive perception of *abſtract moral rectitude*; a perception which thouſands, as virtuous and as profound as he, have conſidered as impoſſible. Our philoſopher's proof of a God is nothing more than his perſuaſion that happineſs is connected with virtue by a being upon whom nature depends; and he ſays expreſsly, that this proof carries conviction to the mind in proportion as the motives of a man's actions are conformable to the law of morality. This being the caſe, the reader cannot be much ſurpriſed, when he is informed that ſeveral of Kant's diſciples on the continent have avowed themſelves Atheiſts or Spinoziſts. We have elſewhere (ſee ILLUMINATI, n° 37.) mentioned one of thoſe gentlemen who was lately diſmiſſed from his profeſſorial chair in the univerſity of Jena, for making GOD nothing more than an *abſtract idea*, derived from our relations with the moral world. His ſucceſſor, a Kantiſt likewiſe, when it was told in his preſence, that, during one of the maſſacres in Paris, David the Painter ſat with his pencil in his hand, enjoying the ſufferings of the unfortunate wretches, and trying to paint the expreſſions of their agonies, exclaimed—"What force of character! What ſublimity of ſoul!" That this wretch muſt be an Atheiſt, likewiſe, follows of courſe from Kant's principles; for it is not conceivable that he perceives any connection between happineſs and virtue.

That Kant is an atheiſt himſelf, we have not learned, though his doctrine leads thus naturally to atheiſm, and though in his work called TUGEND LEHRE, page 180, he makes the following ſtrange obſervation upon oaths: "As it would be abſurd to ſwear that God exiſts, it is ſtill a queſtion to be determined, whether an oath would be poſſible and obligatory if one were to make it thus—*I ſwear on the ſuppoſition that God exiſts*. It is extremely probable (ſays he), that all *ſincere* oaths, taken with *reflection*, have been taken in no other ſenſe!"

It is not our intention to plunge deeper into this mire of atheiſm, or to enter into a formal confutation of the deteſtable doctrines which have been dragged from its bottom. Enough has been ſaid elſewhere to convince the *theoretical* reaſon of the ſound minds of our countrymen of the exiſtence of one omnipotent, infinitely wiſe, and perfectly good Being, the author and upholder of all things (See *Encycl.* METAPHYSICS, Part III. Chap. vi. and THEOLOGY, Part I. Sect. 1.) It may not, however, be altogether uſeleſs to point out to the reader how completely Kant confutes himſelf, even in the ſhort abſtract that we have given of his ſyſtem.

27 Kant confutes himſelf.

Among his *categories*, or fundamental ideas, which are *neceſſarily* formed in the mind, he expreſsly reckons *cauſe* and *effect*: but in various articles of this work, it has been proved beyond the poſſibility of contradiction, that no *ſenſible* object is the *true metaphyſical cauſe* of any one event in nature; and indeed Kant himſelf is at much pains to ſhew that his *categories* or ideas *a priori* are not ideas of ſenſation. There muſt therefore, upon his own principles, be cauſes which are *not* the objects of *ſenſe* or *experience*; and by tracing theſe cauſes backward, if there be a ſucceſſion of them, we muſt arrive at one ſelf-exiſtent cauſe, by a demonſtration as complete as that by which Euclid proves the equality of the three angles of a plane triangle to two right angles. We have no other evidence for the truth of geometrical axioms than the laws of human thought, which compel us to perceive the impoſſibility of ſuch propoſitions being falſe. According to our philoſopher, we have the very ſame evidence for the reality of cauſes and effects which are not the objects of ſenſe. The conſequence is obvious.

28 His morality is extravagant.

Kant's *political* opinions are ſaid to be tolerably moderate, though he betrays, what we muſt think, an abſurd confidence in the *unlimited perfectibility* of the human mind. On his morality our valued correſpondent has beſtowed a much larger ſhare of his approbation than we can allow it of ours. Kant ſeems to contend, that the actions of men ſhould be directed to no end whatever; for he expreſsly condemns, as an end of action, the purſuit either of our own happineſs or of the happineſs of others, whether temporal or eternal; but actions performed for no purpoſe are ſurely indications of the very eſſence of folly. Such actions are indeed impoſſible to beings endued with reaſon, paſſions, and appetites; for if there be that beauty in abſtract virtue, for which Kant and the Stoics contend, it cannot be but that the virtuous man muſt feel an internal pleaſure when he performs a virtuous action, or reflects upon his paſt conduct. He who makes his temporal intereſt the ſole rule of his conduct, has indeed no pretenſions to the character of a virtuous man; but as the morality of the goſpel has always appeared to us ſufficiently pure and diſintereſted, we think a man may, without deviating into vice, have reſpect unto "the recompence of future reward."

P H O

Phoſphorus.

PHOSPHORUS (See CHEMISTRY *Index*, *Supplement*,) has lately been employed as a medicine by Alphonſus Leroi, profeſſor at the Medical School of Paris. Its effects, in a variety of caſes, are thus deſcribed in the *Bulletin de la Societé Philomatique*, 1798.

1. Phoſphorus adminiſtered internally in conſumptive diſeaſes appears to give a certain degree of activity to life, and to revive the patients, without raiſing their pulſe in the ſame proportion. The author relates ſeveral inſtances that occurred to him in the courſe of his practice;

practice; one of which is as follows: Being called to attend a woman, at the point of death, who was quite worn out by a confumptive diforder, with which fhe had been afflicted for three years, in compliance with the earneft defire of her hufband, who requefted him to give her fome medicine, he compofed one of a portion of fyrup diluted with water, in which a few fticks of phofphorus had been kept. Next day the woman found herfelf much better. She was revived for a few days; and did not die till about a fortnight after.

2. He himfelf, as he acknowledges, was fo imprudent as to take two or three grains of folid phofphorus combined only with treacle, and experienced the moft dreadful fymptoms. At firft he felt a burning heat in the whole region of the ftomach. That organ feemed to be filled with gas which efcaped by the mouth. Being dreadfully tormented, he tried to vomit, but in vain; and found relief only by drinking cold water from time to time. His uneafy fenfations were at length allayed: but next morning he feemed to be endowed with an aftonifhing mufcular force, and to be urged, with an almoft irrefiftible impulfe to try its energy. The effect of this medicine at length ceafed, adds the author, *à la fuite d'un priapifme violent*.

3. In many cafes the author employed, and ftill employs, phofphorus internally, with great benefit, to reftore and revive young perfons exhaufted by exceffes. He divides the phofphorus into very fmall particles, by fhaking it in a glafs filled with boiling water. He continues to fhake the bottle, plunging it into cold water, and thus obtains a kind of precipitate of phofphorus, exceedingly fine, which he bruifes flowly with a little oil and fugar, or afterwards employs as liquid electuary, by diluting the whole in the yoke of an egg. By means of this medicine he has effected aftonifhing cures, and reftored the ftrength of his patients in a very fhort time.

4. In malignant fevers the ufe of phofphorus internally, to check the progrefs of gangrene, has fucceeded beyond expectation. The author relates feveral inftances.

5. Pelletier told him, that having left, through negligence, fome phofphorus in a copper bafon, that metal was oxidated, and remained fufpended in the water. Having thoughtlefsly thrown out the water in a fmall court in which ducks were kept, thefe animals drank of it, and all died. *Mais le male* (fays the author) *couvrit toutes fes femelles jufque au dernier inftant de fa vie*. An obfervation which accords with the effect experienced by the author.

6. The author relates a fact which proves the aftonifhing divifibility of phofphorus. Having adminiftered to a patient fome pills, in the compofition of which there was not more than a quarter of a grain of phofphorus, and having had occafion afterwards to open the body, he found all the internal parts luminous; and even the hands of the perfon who had performed the operation, though wafhed and well dried, retained a phofphoric fplendor for a long time after.

7. The phofphoric acid, employed as lemonade, has been ferviceable to the author in the cure of a great number of difeafes.

8. Leroi affures us that he oxidated iron with phofphorus, and obtained, by the common means, a white oxide, almoft irreducible, which he thinks may be employed with advantage in the arts, and particularly in painting with oil, and in enamel, inftead of the white oxide of lead. This white oxide of iron occafioned violent retchings to the author, who ventured to place a very fmall particle of it on his tongue. He does not hefitate, therefore, to confider this oxide as a terrible poifon. He was not able to reduce it but by fixed alkali and the glafs of phofphorus.

9. The author afferts that, by means of phofphorus, he decompofed and feparated from their bafes the fulphuric, muriatic, and nitric acids; that by help of the phofphoric acid he tranfmuted earths; and that with calcareous earth he can make, at pleafure, confiderable quantities of magnefia. He declares, that to his labours on phofphorus he is indebted for proceffes by which he effects the diffipation (*opere la frite*) of rubies, the fufion of emeralds, and the vitrification of mercury.

We agree with the editor of the refpectable Mifcellany *, from which we have immediately taken this article, that Britifh practitioners will do well to ufe their wonted caution in the application of fo powerful a remedy. Indeed we confider it as fo very *hazardous* a remedy, that we had refolved to make no mention of it, till we found it tranfcribed into various journals, both foreign and domeftic, and thence began to fufpect that we might be accufed of culpable negligence, were we to pafs unnoticed what had attracted the attention of fo many of our fellow-labourers in the field of fcience.

* *Philofophical Magazine*, vol. ii.

PHOSPHORUS, in aftronomy, is the morning ftar, or the planet Venus, when fhe rifes before the fun. The Latins call it *Lucifer*, the French *Etoile de berger*, and the Greeks *Phofphorus*.

PHOTOMETER, an apparatus for meafuring the intenfity of light, and likewife the tranfparency of the medium through which it paffes. Inftruments for this purpofe have been invented by Count Rumford, M. de Sauffure, that eminent mathematician and philofopher Mr John Leflie, and others. We fhall content ourfelves with defcribing in this place the photometer of Count Rumford, and the inftrument to which Sauffure gives the name of *diaphanometer*. Mr Leflie's is indeed the fimpleft inftrument of the kind of which we have anywhere met with a defcription; but it meafures only the momentary intenfities of light; and he who wifhes to be informed of its conftruction, will find that information in the third volume of Nicholfon's Philofophical Journal.

Count Rumford, when making the experiments which we have noticed in the article LAMP (*Suppl.*), was led, ftep by ftep, to the conftruction of a very accurate *photometer*, in which the fhadows, inftead of being thrown upon a paper fpread out upon the wainfcot, or fide of the room (See page 64 of this volume), are projected upon the infide of the back part of a wooden box $7\frac{1}{2}$ inches wide, $10\frac{1}{4}$ inches long, and $3\frac{1}{4}$ inches deep, in the clear. The light is admitted into it through two horizontal tubes in the front, placed fo as to form an angle of 60°; their axes meeting at the centre of the field of the inftrument. In the middle of the front of the box, between thefe two tubes, is an opening thro' which is viewed the field of the photometer (See fig. 1.). This field is formed of a piece of white paper, which is not faftened immediately upon the infide of the back of the box, but is pafted upon a fmall pane of very fine ground glafs; and this glafs, thus covered, is

Plate XLI.

Photometer.

is let down into a groove, made to recive it, in the back of the box. The whole inside of the box, except the field of the instrument, is painted of a deep black dead colour. To the under parts of the box is fitted a ball and socket, by which it is attached to a stand which supports it; and the top or lid of it is fitted with hinges, in order that the box may be laid quite open, as often as it is necessary to alter any part of the machinery it contains.

The Count had found it very inconvenient to compare two shadows projected by the same cylinder, as these were either necessarily too far from each other to be compared with certainty, or, when they were nearer, were in part hid from the eye by the cylinder. To remedy this inconvenience, he now makes use of two cylinders, which are placed perpendicularly in the bottom of the box just described, in a line parallel to the back part of it, distant from this back $2\frac{2}{10}$ inches, and from each other 3 inches, measuring from the centres of the cylinders; when the two lights made use of in the experiment are properly placed, these two cylinders project four shadows upon the white paper upon the inside of the back part of the box, or the *field* of the instrument; two of which shadows are in contact, precisely in the middle of that field, and it is these two alone that are to be attended to To prevent the attention being distracted by the presence of unnecessary objects, the two outside shadows are made to disappear; which is done by rendering the field of the instrument so narrow, that they fall without it, upon a blackened surface, upon which they are not visible. If the cylinders be each $\frac{4}{10}$ of an inch in diameter, and $2\frac{2}{10}$ inches in height, it will be quite sufficient that the field be $2\frac{7}{10}$ inches wide; and as an unnecessary height of the field is not only usefess, but disadvantageous, as a large surface of white paper not covered by the shadows produces too strong a glare of light, the field ought not to be more than $\frac{3}{10}$ of an inch higher than the tops of the cylinders. That its dimensions, however, may be occasionally augmented, the covered glass should be made $5\frac{1}{2}$ inches long, and as wide as the box is deep, viz. $3\frac{3}{4}$ inches; since the field of the instrument can be reduced to its proper size by a screen of black pasteboard, interposed before the anterior surface of this covered glass, and resting immediately upon it. A hole in this pasteboard, in the form of an oblong square, $1\frac{7}{10}$ inch wide, and two inches high, determines the dimensions, and forms the boundaries of the field. This screen should be large enough to cover the whole inside of the back of the box, and it may be fixed in its place by means of grooves in the sides of the box, into which it may be made to enter. The position of the opening above mentioned is determined by the height of the cylinders; the top of it being $\frac{1}{10}$ of an inch higher than the tops of the cylinders; and as the height of it is only two inches, while the height of the cylinders is $2\frac{2}{10}$ inches, it is evident that the shadows of the lower parts of the cylinders do not enter the field. No inconvenience arises from that circumstance; on the contrary, several advantages are derived from that arrangement.

That the lights may be placed with facility and precision, a fine black line is drawn through the middle of the field, from the top to the bottom of it, and another (horizontal) line at right angles to it, at the height of the top of the cylinders. When the tops of the shadows touch this last-mentioned line, the lights are at a proper height: and farther, when the two shadows are in contact with each other in the middle of the field, the lights are then in their proper directions.

We have said that the cylinders, by which the shadows are projected, are placed perpendicularly in the bottom of the box; but as the diameters of the shadows of these cylinders vary in some degree, in proportion as the lights are broader or narrower, and as they are brought nearer to or removed farther from the photometer, in order to be able in all cases to bring these shadows to be of the same diameter, which is very advantageous, in order to judge with greater facility and certainty when they are of the same density, the Count renders the cylinders moveable about their axes, and adds to each a vertical wing $\frac{1}{10}$ of an inch wide, $\frac{1}{10}$ of an inch thick, and of equal height with the cylinder itself, and firmly fixed to it from the top to the bottom. This wing commonly lies in the middle of the shadow of the cylinder, and as long as it remains in that situation it has no effect whatever; but when it is necessary that the diameter of one of the shadows be increased, the corresponding cylinder is moved about its axis, till the wing just described, emerging out of the shadow, and intercepting a portion of light, brings the shadow projected upon the field of the instrument to be of the width or diameter required. In this operation it is always necessary to turn the cylinder outwards, or in such a manner that the augmentation of the width of the shadow may take place on that side of it which is opposite to the shadow corresponding to the other light. The necessity for that precaution will appear evident to any one who has a just idea of the instrument in question, and of the manner of making use of it. They are turned likewise without opening the box, by taking hold of the ends of their axes, which project below its bottom.

As it is absolutely necessary that the cylinders should constantly remain precisely perpendicular to the bottom of the box, or parallel to each other, it will be best to construct them of brass; and, instead of fixing them immediately to the bottom of the box (which, being of wood, may warp), to fix them to a strong thick piece of well-hammered plate brass; which plate of brass may be afterwards fastened to the bottom of the box by means of one strong screw. In this manner two of the Count's best instruments are constructed; and, in order to secure the cylinders still more firmly in their vertical positions, they are furnished with broad flat rings, or projections, where they rest upon the brass plate; which rings are $\frac{1}{10}$ of an inch thick, and equal in diameter to the projection of the wing of the cylinder, to the bottom of which they afford a firm support. These cylinders are likewise forcibly pushed, or rather pulled, against the brass plate upon which they rest, by means of compressed spiral springs placed between the under side of that plate and the lower ends of the cylinders. Of whatever material the cylinders be constructed, and whatever be their forms or dimensions, it is absolutely necessary that they, as well as every other part of the photometer, except the field, should be well painted of a deep black dead colour.

In order to move the lights to and from the photometer with greater ease and precision, the observer should provide two long and narrow, but very strong and steady, tables; in the middle of each of which there

there is a ſtraight groove, in which a ſliding carriage, upon which the light is placed, is drawn along by means of a cord which is faſtened to it before and behind, and which, paſſing over pulleys at each end of the table, goes round a cylinder; which cylinder is furniſhed with a winch, and is ſo placed, near the end of the table adjoining the photometer, that the obſerver can turn it about, without taking his eye from the field of the inſtrument.

Many advantages are derived from this arrangement: Firſt, the obſerver can move the lights as he finds neceſſary, without the help of an aſſiſtant, and even without removing his eye from the ſhadows; ſecondly, each light is always preciſely in the line of direction in which it ought to be, in order that the ſhadows may be in contact in the middle of the vertical plane of the photometer; and, thirdly, the ſliding motion of the lights being perfectly ſoft and gentle, that motion produces little or no effect upon the lights themſelves, either to increaſe or diminiſh their brilliancy.

Theſe tables muſt be placed at an angle of 60 degrees from each other, and in ſuch a ſituation, with reſpect to the photometer, that lines drawn through their middles, in the direction of their lengths, meet in a point exactly under the middle of the vertical plane or field of the photometer, and from that point the diſtances of the lights are meaſured; the ſides of the tables being divided into Engliſh inches, and a vernier, ſhewing tenths of inches, being fixed to each of the ſliding carriages upon which the lights are placed, and which are ſo contrived that they may be raiſed or lowered at pleaſure; ſo that the lights may be always in a horizontal line with the tops of the cylinders of the photometer.

In order that the two long and narrow tables or platforms, juſt deſcribed, may remain immoveable in their proper poſitions, they are both firmly fixed to the ſtand which ſupports the photometer; and in order that the motion of the carriages which carry the lights may be as ſoft and gentle as poſſible, they are made to ſlide upon parallel braſs wires, 9 inches aſunder, about $\frac{1}{10}$ of an inch in diameter, and well poliſhed, which are ſtretched out upon the tables from one end to the other.

The ſtructure of the apparatus will be clearly underſtood by a bare inſpection of Plate XLI. where fig. 1. is a plan of the inſide of the box, and the adjoining parts of the photometer. Fig. 2. Plan of the two tables belonging to the photometer. Fig. 3. The box of the photometer on its ſtand. Fig. 4. Elevation of the photometer, with one of the tables and carriages.

Having ſufficiently explained all the eſſential parts of this photometer, it remains for us to give ſome account of the precautions neceſſary to be obſerved in uſing it. And, firſt, with reſpect to the diſtance at which lights, whoſe intenſities are to be compared, ſhould be placed from the field of the inſtrument, the ingenious and accurate inventor found, that when the weakeſt of the lights in queſtion is about as ſtrong as a common wax-candle, that light may moſt advantageouſly be placed from 30 to 36 inches from the centre of the field; and when it is weaker or ſtronger, proportionally nearer or farther off. When the lights are too near, the ſhadows will not be well defined; and when they are too far off, they will be too weak.

It will greatly facilitate the calculations neceſſary in drawing concluſions from experiments of this kind, if ſome ſteady light, of a proper degree of ſtrength for that purpoſe, be aſſumed as a ſtandard by which all others may be compared. Our author found a good Argand's lamp much preferable for this purpoſe to any other lamp or candle whatever. As it appears, he ſays, from a number of experiments, that the quantity of light emitted by a lamp, which burns in the ſame manner with a clear flame, and *without ſmoke*, is in all caſes as the quantity of oil conſumed, there is much reaſon to ſuppoſe, that, if the Argand's lamp be ſo adjuſted as always to conſume a given quantity of oil in a given time, it may then be depended on as a juſt ſtandard of light.

In order to abridge the calculations neceſſary in theſe inquiries, it will always be advantageous to place the ſtandard-lamp at the diſtance of 100 inches from the photometer, and to aſſume the intenſity of its light at its ſource equal to unity; in this caſe (calling this ſtandard light A, the intenſity of the light at its ſource $= x = 1$, and the diſtance of the lamp from the field of the photometer $= m = 100$), the intenſity of the illumination at the field of the photometer $(= \frac{x}{m^2})$ (See Lamp, p. 67. of this volume) will be expreſſed by the fraction $\frac{1}{100^2} = \frac{1}{10000}$; and the relative intenſity of any other light which is compared with it, may be found by the following proportion: Calling this light B, putting $y =$ its intenſity at its ſource, and $n =$ its diſtance from the field of the photometer, expreſſed in Engliſh inches, as it is $\frac{y}{n^2} = \frac{x}{m^2}$, as was ſhewn in the article Lamp referred to; or, inſtead of $\frac{x}{m^2}$, writing its value $= \frac{1}{10000}$, it will be $\frac{y}{n^2} = \frac{1}{10000}$; and conſequently y is to 1 as n^2 is to 10000; or the intenſity of the light B at its ſource, is to the intenſity of the ſtandard light A at its ſource, as the ſquare of the diſtance of the light B from the middle of the field of the inſtrument, expreſſed in inches, is to 10000; and hence it is $y = \frac{n^2}{10000}$.

Or, if the light of the ſun, or that of the moon, be compared with the light of a given lamp or candle C, the reſult of ſuch compariſon may beſt be expreſſed in words, by ſaying, that the light of the celeſtial luminary in queſtion, *at the ſurface of the earth*, or, which is the ſame thing, at the field of the photometer, is equal to the light of the given lamp or candle, *at the diſtance found by the experiment*; or, putting $a =$ the intenſity of the light of this lamp C at its ſource, and $p =$ its diſtance, in inches, from the field, when the ſhadows correſponding to this light, and that correſponding to the celeſtial luminary in queſtion, are found to be of equal denſities, and putting $z =$ the intenſity of the rays of the luminary at the ſurface of the earth, the reſult of the experiment may be expreſſed thus, $z = \frac{a}{p^2}$; or the real value of a being determined by a particular experiment, made expreſly for that purpoſe with the ſtandard-lamp, that value may be written inſtead of it. When the ſtandard-lamp itſelf is made uſe of, inſtead of the lamp C, then the value of A will be 1.

The Count's firſt attempts with his photometer were to determine how far it might be poſſible to aſcertain, by by direct experiments, the certainty of the affumed law of the diminution of the intenfity of the light emitted by luminous bodies ; namely, that the intenfity of the light is everywhere as the fquares of the diftances from the luminous body inverfely. As it is obvious that this law can hold good only when the light is propagated through perfectly tranfparent fpaces, fo that its intenfity is weakened merely by the divergency of its rays, he inftituted a fet of experiments to afcertain the tranfparency of the air and other mediums.

With this view, two equal wax candles, well trimmed, and which were found, by a previous experiment, to burn with exactly the fame degree of brightnefs, were placed *together*, on one fide, before the photometer, and their united light was counterbalanced by the light of an Argand's lamp, well trimmed, and burning very equally, placed on the other fide over againft them. The lamp was placed at the diftance of 100 inches from the field of the photometer, and it was found that the two burning candles (which were placed as near together as poffible, without their flames affecting each other by the currents of air they produced) were juft able to counterbalance the light of the lamp at the field of the photometer, when they were placed at the diftance of 60,8 inches from that field. One of the candles being now taken away and extinguifhed, the other was brought nearer to the field of the inftrument, till its light was found to be juft able, fingly, to counterbalance the light of the lamp; and this was found to happen when it had arrived at the diftance of 43,4 inches. In this experiment, as the candles burnt with equal brightnefs, it is evident that the intenfities of their united and fingle lights were as 2 to 1, and in that proportion ought, according to the affumed theory, the fquares of the diftances, 60,8 and 43,4 to be; and, in fact, $\overline{60,8}^2 = 3696,64$ is to $\overline{43,4}^2 = 1883,56$ as 2 is to 1 very nearly.

Again, in another experiment, the diftances were,

With two candles = 54 inches.	Square	= 2916
With one candle = 38,6	- -	= 1489,96

Upon another trial,

With two candles = 54,6 inches.	Square	= 2981,16
With one candle = 39,7	- -	= 1576,09

And, in the fourth experiment,

With two candles = 58,4 inches.	Square	= 3410,56
With one candle = 42,2	- -	= 1780,84

And, taking the mean of the refults of thefe four experiments,

	Squares of the Diftances With two Candles.		With one Candle.
In the Experiment N° 1.	3696,64	—	1883,56
N° 2.	2916	—	1489,96
N° 3.	2981,16	—	1576,09
N° 4.	3410,56	—	1780,84
	4) 13004,36		4) 6730,45
Means	3251,09	and	1682,61

which again are very nearly as 2 to 1.

With regard to thefe experiments, it may be obferved, that were the refiftance of the air to light, or the diminution of the light from the imperfect tranfparency of air, fenfible within the limits of the inconfiderable diftances at which the candles were placed from the photometer, in that cafe the diftance of the two equal lights united ought to be, to the diftance of one of them fingle in a ratio lefs than that of the fquare root of 2 to the fquare root of 1. For if the intenfity of a light emitted by a luminous body, *in a fpace void of all refiftance*, be diminifhed in the proportion of the fquares of the diftances, it muft of neceffity be diminifhed in a ftill higher ratio when the light paffes thro' a refifting medium, or one which is not perfectly tranfparent ; and from the difference of thofe ratios, namely, that of the fquares of the diftances, and that other higher ratio found by the experiment, the refiftance of the medium might be afcertained. This he took much pains to do with refpect to air, but did not fucceed ; the tranfparency of air being fo great, that the diminution which light fuffers in paffing through a few inches, or even through feveral feet of it, is not fenfible.

Having found, upon repeated trials, that the light of a lamp, properly trimmed, is incomparably more equal than that of a candle, whofe wick, continually growing longer, renders its light extremely fluctuating, he fubftituted lamps to candles in thefe experiments, and made fuch other variations in the manner of conducting them as he thought bid fair to lead to a difcovery of the refiftance of the air to light, were it poffible to render that refiftance fenfible within the confined limits of his machinery. But the refults of them, fo far from affording means for afcertaining the refiftance of the air to light, do not even indicate any refiftance at all ; on the contrary, it might almoft be inferred, from fome of them, that the intenfity of the light emitted by a luminous body in air is diminifhed in a ratio *lefs* than that of the fquares of the diftances ; but as fuch a conclufion would involve an evident abfurdity, namely, that light moving in air, its abfolute quantity, inftead of being diminifhed, actually goes on to *increafe*, that conclufion can by no means be admitted.

Why not ? Theories muft give place to facts ; and if this fact can be fairly afcertained, inftead of rejecting the conclufion, we ought certainly to rectify our notions of light, the nature of which we believe no man fully comprehends. Who can take it upon him to fay, that the fubftance of light is not latent in the atmofphere, as heat or caloric is now acknowledged to be latent, and that the agency of the former is not called forth by the paffage of a ray through a portion of air, as the agency of the latter is known to be excited by the combination of oxygen with any combuftible fubftance? See CHEMISTRY, n° 293, *Suppl.*

The ingenious author's experiments all confpired to fhew that the refiftance of the air to light is too inconfiderable to be perceptible, and that the affumed law of the diminution of the intenfity of light may be depended upon with fafety. He admits, however, that means may be found for rendering the air's refiftance to light apparent ; and he feems to have thought of the very means which occurred for this purpofe to M. de Sauffure.

That eminent philofopher, wifhing to afcertain the tranfparency of the atmofphere, by meafuring the diftances at which determined objects ceafe to be vifible, perceived at once that his end would be attained, if he fhould find objects of which the difappearance might be accurately determined. Accordingly, after many trials, he found that the moment of difappearance can be obferved with much greater accuracy when a black object

object is placed on a white ground, than when a white object is placed on a black ground; that the accuracy was still greater when the observation was made in the sun than in the shade; and that even a still greater degree of accuracy was obtained, when the white space surrounding a black circle, was itself furrounded by a circle or ground of a dark colour. This last circumstance was particularly remarkable, and an observation quite new.

If a circle totally black, of about two lines in diameter, be fastened on the middle of a large sheet of paper or pasteboard, and if this paper or pasteboard be placed in such a manner as to be exposed fully to the light of the sun, if you then approach it at the distance of three or four feet, and afterwards gradually recede from it, keeping your eye constantly directed towards the black circle, it will appear always to decrease in size the farther you retire from it, and at the distance of 33 or 34 feet will have the appearance of a point. If you continue still to recede, you will see it again enlarge itself; and it will seem to form a kind of cloud, the darkness of which decreases more and more according as the circumference becomes enlarged. The cloud will appear still to increase in size the farther you remove from it; but at length it will totally disappear. The moment of the disappearance, however, cannot be accurately ascertained; and the more experiments were repeated the more were the results different.

M. de Saussure, having reflected for a long time on the means of remedying this inconveniency, saw clearly, that, as long as this cloud took place, no accuracy could be obtained; and he discovered that it appeared in consequence of the contrast formed by the white parts which were at the greatest distance from the black circle. He thence concluded, that if the ground was left white near this circle, and the parts of the pasteboard at the greatest distance from it were covered with a dark colour, the cloud would no longer be visible, or at least almost totally disappear.

This conjecture was confirmed by experiment. M. de Saussure left a white space around the black circle equal in breadth to its diameter, by placing a circle of black paper a line in diameter on the middle of a white circle three lines in diameter, so that the black circle was only surrounded by a white ring a line in breadth. The whole was pasted upon a green ground. A green colour was chosen, because it was dark enough to make the cloud disappear, and the easiest to be procured.

The black circle, surrounded in this manner with white on a green ground, disappeared at a much less distance than when it was on a white ground of a large size.

If a perfectly black circle, a line in diameter, be pasted on the middle of a white ground exposed to the open light, it may be observed at the distance of from 44 to 45 feet; but if this circle be surrounded by a white ring a line in breadth, while the rest of the ground is green, all sight of it is lost at the distance of only $15\frac{1}{2}$ feet.

According to these principles, M. de Saussure delineated several black circles, the diameters of which increased in a geometrical progression, the exponent of which was $\frac{3}{2}$. His smallest circle was $\frac{1}{5}$ or 0·2 of a line in diameter; the second 0·3; the third 0·45; and so on to the sixteenth, which was 87·527, or about 7 inches $3\frac{1}{2}$ lines. Each of these circles was surrounded by a white ring, the breadth of which was equal to the diameter of the circle, and the whole was pasted on a green ground.

M. de Saussure, for his experiments, selected a straight road or plain of about 1200 or 1500 feet in circumference, which towards the north was bounded by trees or an ascent. Those who repeat them, however, must pay attention to the following remarks: When a person retires backwards, keeping his eye constantly fixed on the pasteboard, the eye becomes fatigued, and soon ceases to perceive the circle; as soon therefore as it ceases to be distinguishable, you must suffer your eyes to rest; not, however, by shutting them, for they would when again opened be dazzled by the light, but by turning them gradually to some less illuminated object in the horizon. When you have done this for about half a minute, and again directed your eyes to the pasteboard, the circle will be again visible, and you must continue to recede till it disappear once more. You must then let your eyes rest a second time in order to look at the circle again, and continue in this manner till the circle becomes actually invisible.

If you wish to find an accurate expression for the want of transparency, you must employ a number of circles, the diameters of which increase according to a certain progression; and a comparison of the distances at which they disappear will give the law according to which the transparency of the atmosphere decreases at different distances. If you wish to compare the transparency of the atmosphere on two days, or in two different places, two circles will be sufficient for the experiment.

According to these principles, M. de Saussure caused to be prepared a piece of white linen cloth eight feet square. In the middle of this square he sewed a perfect circle, two feet in diameter, of beautiful black wool; around this circle he left a white ring two feet in breadth, and the rest of the square was covered with pale green. In the like manner, and of the same materials, he prepared another square; which was, however, equal to only $\frac{1}{12}$ of the size of the former, so that each side of it was 8 inches; the black circle in the middle was two inches in diameter, and the white space around the circle was two inches also.

If two squares of this kind be suspended vertically and parallel to each other, so that they may be both illuminated in an equal degree by the sun; and if the atmosphere, at the moment when the experiment is made, be perfectly transparent, the circle of the large square, which is twelve times the size of the other, must be seen at twelve times the distance. In M. de Saussure's experiments the small circle disappeared at the distance of 314 feet, and the large one at the distance of 3588 feet, whereas it should have disappeared at the distance of 3768. The atmosphere, therefore, was not perfectly transparent. This arose from the thin vapours which at that time were floating in it. M. de Saussure, as we have observed, calls his instrument a *diaphanometer;* but as it answers one of the purposes of a photometer, we trust our readers will not consider this account of it as a digression.

To return to Count Rumford. From a number of experiments made with his *photometer*, he found that, by passing through a pane of fine, clear, well polished glass, such as is commonly made use of in the construction of looking-glasses, light loses ,1973 of its whole

quantity,

quantity, *i. e.* of the quantity which impinged on the glafs; that when light is made to pafs through two panes of fuch glafs ftanding parallel, but not touching each other, the lofs is ,3184 of the whole; and that in paffing through a very thin, clear, colourlefs pane of window-glafs, the lofs is only ,1263. Hence he infers that this apparatus might be very ufefully employed by the optician, to determine the degree of tranfparency of glafs, and direct his choice in the provifion of that important article of his trade. The lofs of light when reflected from the very beft plain glafs mirror, the author afcertained, by five experiments, to be $\frac{1}{3}$d of the whole which fell upon the mirror.

PHYSIOGNOMY is a fcience, if it be entitled to that name, on which we may be thought to have faid enough in the *Encyclopædia.* Since that period we have been favoured with a fhort view of a new fyftem by Dr Gall of Vienna, who calls it the *Craniognomic* fyftem, becaufe he infers the powers and difpofitions of the mind from the *exterior form of the cranium.*

Having obferved that the brain is the material organ of the action of the mind, and that it increafes in direct proportion to the faculties of animals, he endeavours to prove that the faculties are *diftinct* and *independent* on each other; that each has its proper material organ; and that the expanfion of the organ is in proportion to the ftrength of the faculty. This, which is the foundation of his fyftem, looks very like materialifm; and affords one of many proofs that might be brought of the readinefs of the German philofophers to teach fciences which they have never learned. Let us attend, however, to the reafoning by which he endeavours to fupport this foundation.

" The internal faculties do not always exift in the fame proportion to each other. There are fome men who have a great deal of genius without having a memory, who have courage without circumfpection, and who poffefs a metaphyfical fpirit without being good obfervers. Befides, the phenomena of dreaming, of fomnambulifm, of delirium, &c. prove to us that the internal faculties do not always act together; that there is often a very great activity of one, while the reft are not fenfible. Thus in old age, and fometimes in difeafe (fuch, for example, as madnefs), feveral faculties are loft, while others fubfift; befides a continued employment of the fame faculty fenfibly diminifhes its energy: if we employ another, we find it has all the force of which it is fufceptible: and if we return to the former faculty, it is obferved that it has refumed its ufual vigour. It is thus that, when fatigued with reading an abftract philofophical work, we proceed with pleafure to a poetical one, and then refume with the fame attention our former occupation. All thefe phenomena prove, continues our author, that the faculties are diftinct and independent on each other; and we are inclined to believe that the cafe is the fame with their material organs *."

* *Phil. Mag.* vol. xiv. p. 77, &c.

Have Dr Gall and his friend Dr Bojanus, the author of this view, never paid attention to their own confcioufnefs? or do they fuppofe that the teftimony of confcioufnefs is not to be regarded? To us nothing can be more evident than that the fame individual being fees, and hears, and reafons, and remembers, and conceives, fometimes fober truths, and fometimes paradoxical abfurdities. If *they* think otherwife, it would be extremely kind in them to explain the procefs by which the *thirty-two diftinct and independent faculties,* which operate in the cranium of Dr Gall, came to unite in the compofition of this fyftem of fcience; to compare their different operations together; or indeed to know, each, that his one-and-thirty brothers have any exiftence! To us fuch a union in fyftem-building, among diftinct and independent beings, in the fame cranium, appears juft as impoffible as a mutual confcioufnefs among fo many men, diftant, each from the others, a thoufand miles; and it would be as eafy to perfuade us that Dr Gall is privy to the thoughts of the Emperor of China, as that a collection of independent faculties, refiding in his fkull, know what each other is doing.

If we examine the reafoning upon which this abfurd theory is built, nothing will appear lefs conclufive. Granting that there may be a great deal of genius without memory, that there may be courage without circumfpection; a metaphyfical fpirit without a talent for obfervation; and that, in old age and madnefs, feveral faculties may feem to be loft, while others remain in full vigour —may not all this refult from the perfection or imperfection of the material organs in the brain? If one portion of the brain be the organ of genius, and another the organ of memory, and if the former of thefe organs be in a ftate of high perfection when compared with the other--it is obvious that the man, whofe brain is fo conftituted, muft appear to poffefs a great deal of genius with little memory, though his efforts of genius and memory be the efforts of one individual being. A man with his left hand, aided by a lever in the proportion of three to one, will raife a much greater weight than he could raife with his right hand, aided by a lever equally divided; but it would be very ridiculous, from this fact, to infer, that the mufcular ftrength of his left arm is greater than that of his right.

His next principle is, that "*the expanfion of the organs contained in the cranium is in the direct ratio of the force of their correfponding faculties.* This principle (he fays), dictated by analogy, refts on this axiom, that throughout all nature the faculties are always found to be proportioned to their relative organs." This feems to be reafoning in a circle; and it takes for granted what we have proved to be falfe. The mind does not confift of fo many diftinct and independent faculties; and if it did, the affertion which is here ftyled an *axiom* would authorife us only to infer the ftrength of the faculty from the fize of the organ, and by no means the fize of the organ from the ftrength of the faculty.

But how does our author know, that throughout all nature the faculties are always found to be proportioned to their organs? Why, he does *not* know it; for he admits, that " exercife has a great influence on the force of the faculties; and that an organ moderately expanded, but often exercifed, can give a faculty fuperior to that which accompanies a very extenfive organ never put in action." If this be true, there feems to be an end of the fyftem; for its object is to afcertain, from the external appearance of the cranium, the internal powers and difpofitions of the mind. Now, the external appearance or conformation of the cranium depends on that of the brain. " Obfervation (fays the author of the View) has proved to Dr Gall, that we cannot judge of the ftrength of the faculties, but by the

the developement of the *ſeparate organs which form diſtinct eminences in the cranium*; and that a cranium perfectly round, of whatever ſize it may be, is never a proof of many or of great faculties." But if it be true that an organ moderately expanded, but often exerciſed, indicates a faculty ſuperior to that which accompanies a very extenſive organ never put in action, it follows incontrovertibly, that no man, however well acquainted with the organic ſtructure of the brain, can infer with certainty, from the eminences of the cranium, what faculties or diſpoſitions predominate in the mind. Nay it follows, that a cranium perfectly round (if there be ſuch a cranium) may contain many and great faculties; for if the moderately expanded organs be moſt exerciſed, their faculties will acquire ſtrength, while the preſſure on the ſkull is equally balanced on all ſides.

PIANO FORTE, otherwiſe called FORTE PIANO, a well known muſical inſtrument, of which we need make no apology for conſidering the peculiarities with ſome attention. If we look on muſic from no higher point of view than as the *laborum dulce lenimen*, the innocent, the ſoothing, the cheering ſweetener of toil, we muſt acknowledge that it is far from being the meaneſt of thoſe enjoyments with which the Bountiful Father of Men has embelliſhed this ſcene of our exiſtence. But there is a *ſcience* in muſic, independent of that artificial half mathematical doctrine which we have contrived to unite with it, and which really enables us to improve pure muſical pleaſure. Hence in the Engliſh univerſities degrees are conferred in muſic.

The voice is the original muſical inſtrument, and all others are but imitations. The voice of man obeys the impulſe of the heart with wonderful promptitude, and ſtill more wonderful accuracy. A very coarſe ear is hurt by an error in its tone, amounting to what is called a *comma*. A very limited voice can execute melodies extending to 12 notes, or an octave and a fifth. The motion of the glottis between theſe extremes does not amount to $\frac{1}{11}$th of an inch. This muſt therefore be divided, by the moſt ordinary finger, into more than a thouſand parts; and this muſt be done in an inſtant, and repeated with rapidity, without ever miſtaking one of theſe diviſions; and this is done everywhere, and without any ſeeming effort or thought. The mechaniſm of the human organ for effecting this with eaſe and preciſion is very remarkable, and ſeems to prove that the Author of our being meant to give us this pleaſure.

When, in the cultivation of this fruit of our own ſoil, the moderns diſcovered the beauties of harmony or conſonance, and inſtruments of fixed ſounds were employed, by means of which theſe beauties could be exhibited in their utmoſt richneſs and variety; and particularly when the organ, that " magic world of ſound," was invented, the immenſe advantages of the ingenious ſpeculations of the ancient Greeks about the diviſion of the monochord were now perceived, and muſic became a deep intellectual ſtudy. It fell into the hands of men of letters, and, for a long while, counterpoint occupied all their attention. Inſtruments of fixed ſounds were now made, not only with pipes, but with ſtrings, bells, rings, and every thing that could make a noiſe in tune.

But all theſe inſtruments were far inferior to the voice, the ſpontaneous gift of Nature, in promptitude, and in the power of obeying every call of ſentiment, every degree, as well as every kind of emotion, with which the heart was agitated. The pleaſures of harmony, though great, were monotonous, and could not expreſs the momentary variations of ſentiment, which are as fleeting as the light and ſhade of a proſpect while the dappled clouds ſail acroſs the ſky. The violin, and a ſmall number of the ſimple wind inſtruments, were found to be the only ones which could fully expreſs thoſe momentary gradations of ſentiment that give muſic its pathos, and enable it to thrill the very ſoul.

Attempts were made to remove this defect of the harmonic inſtruments, and the SWELL was added to the organ. The effect was great, and encouraged the artiſts to attempt ſimilar improvements on other inſtruments of the ſame kind. This was firſt done in the ſame way as in the organ. The harpſichord was ſhut up, like the ſwell organ, and was opened by means of pedals when the performer wiſhed to enforce the ſound. But the effect was far inferior to that of the ſwell organ; for this was (at leaſt in all great organs) a real addition of another properly ſelected ſound. But the effect of the pedal on the harpſichord could not be miſtaken; it was juſt like opening the door of a room where muſic was performing. Other methods were tried with better effect. Uniſons were added to each note, which were brought on either by means of pedals or by another ſet of keys.

This method ſucceeded perfectly well, and the power of the harpſichord was greatly improved. But ſtill it was imperfect, becauſe it was only the more conſiderable changes of force which could be exhibited, and this only in one or two degrees. Other artiſts, therefore, attempted to conſtruct the inſtrument, ſo that the jacks (the moveable upright pieces which carry the quills) can be made to approach nearer to the wires, ſo that the quills ſhall give them a ſtronger twang. The mechaniſm was ſuch, that a very conſiderable motion of the pedal produced but a moſt minute motion of the quill; ſo that the performer was not reſtricted to the utmoſt preciſion in the degree of preſſure. Some of thoſe inſtruments, when freſh from the hand of the artiſt, gave full ſatisfaction. But, though made in the moſt accurate manner, at an enormous expence, they very ſoon become unfit for the purpoſe. The hundredth part of an inch, more or leſs, in the place of the quill, will make a great odds in the force of the ſound. Nor does the ſame change of diſtance produce an equal alteration of ſound on different quills. Other inſtrument makers have therefore tried baked or prepared leather (buffalo hide) in place of quills; and it is found much more uniform, in the tone which it produces, and alſo remains longer in the ſame ſtate; but the tone is not ſo powerful, nor in general ſo much reliſhed.

But all theſe contrivances, both in the organ and harpſichord, were ſtill very deficient. Whatever change they could produce in the ſtrength of the ſound, was produced through the whole inſtrument, or at leaſt through two or three octaves. But the captivating expreſſion of muſic frequently reſults from the momentary ſwelling or ſoftening of a ſingle phraſe, or a ſingle note, in one of the parts. Hence ariſe the unrivalled powers of the harp, and the acknowledged ſuperiority of the theorbo, the lute, and even the guitar, over all keyed inſtruments, notwithſtanding their great limitations in harmony and in practicable melodies. Theſe inſtruments ſpeak, while the harpſichord only plays.

Many attempts have been made to enable the performer to produce, by the intervention of the key, all the gradations of ſtrength, and even the varieties of ſound, which the finger can bring forth by the different manner of pinching, bruſhing, or, as it were, careſſing the ſtring; but we have no diſtinct account of any attempt that has ſucceeded. Such a thing would quickly ſpread over Europe. The compiler of the article Luthier, in the *Encyclopedie Methodique*, ſays a great deal about a harpſichord fitted with prepared buffalo leather inſtead of crow quills; and aſſerts expreſsly, that, by the mere preſſure on the key, without the aſſiſtance of pedals or ſtops of any kind, the leather is made to act with greater or leſs force on the ſtring. But he gives no account by which we can comprehend how this is brought about; and indeed he writes in terms which ſhew plainly that he has not ſeen the inſtrument, and is merely puffing ſomething that he does not underſtand.

The attempt has been made with more ſucceſs on keyed inſtruments, when the ſtrings are not pinched, but are rubbed by a wheel or band, in the manner of the vielle (hurdygurdy), or ſtruck with a plectrum, like the dulcimer. The celestina (deſcribed by Merſennus by the name of archiviola) is of this kind. A fine band of horſe hair or ſilk, filled with roſin, is extended under the ſtrings, and drawn ſmoothly along by a wheel. By a particular mechaniſm of the keys, this band is made to preſs or rub on any ſtring tranſverſely, as the ſtrings of a violin are touched by the bow. The preſſure on the key regulates the ſtrength of the tone. This inſtrument is not without conſiderable beauties, and will execute ſoft *cantabile* muſic in eaſy modulation, with great expreſſion and juſtneſs. But the artiſts have not yet been able to give it either clearneſs or brilliancy of tone, nor ſufficient force for concert muſic, nor that promptitude of touch that is indiſpenſibly neceſſary for figurative muſic or quick movements.

The ſame improvements have been made on the pulſatile inſtruments; and indeed they are here the moſt obvious and eaſy. When the key is employed merely as the means of cauſing a plectrum to give a blow to the ſtring, the performer will hardly fail to give that degree of force which he feels proper for his intended expreſſion. Accordingly, many inſtruments of this kind have been made in Germany, where the artiſts have long been eminent for mechanical knacks. But all their inſtruments of the dulcimer kind are feeble and ſpiritleſs, and none of them have been brought into general uſe, if we except the clavichord. This is indeed an inſtrument of feeble, and not the moſt pleaſing ſound; but is well fitted for giving every momentary gradation of ſtrength by the preſſure of the finger. It is therefore a good inſtrument for forming the muſical taſte by chamber practice, and was much uſed by compoſitors in their ſtudies. It is alſo an ingenious, though ſeemingly an obvious and ſimple contrivance, and is capable of much more force, and even brilliancy of ſound, than has generally been given to it.

The conſtruction is ſhortly this. The inner end of the key is furniſhed with an upright piece, which terminates in an edge of braſs, ſomewhat like the end of a narrow blunt chiſel, whoſe line of direction is athwart the ſtrings. When the key is preſſed down, this edge ſtrikes the ſtring, and forces it out of the ſtraight line in which it is ſtretched between its pins. Thus the ſtring is ſhaken or jogged into vibration, in the ſame manner as we obſerve a tight rope ſet a vibrating by a ſudden jerk given to any part of it. The ſtring, thus agitated, gives a ſound, which will continue for ſome little time if the key be held down. As the tone depends on the length of the vibrating ſtring, as well as on its tenſion, it is of importance that the ſtroke be made on the preciſe point of the ſtring which terminates the proper length. The ſtring does not give the note correſponding to its whole length, but that which is produced by the part between the edge and the pin. And becauſe the parts of the ſtring on each ſide of the edge are equally thrown into vibration, the ſhorter portion of it muſt be wrapped up in a liſt of cloth, to prevent it from diſturbing the ear by its ſonorous vibrations. This, however, greatly diminiſhes the ſweetneſs of the ſound given by the other part.

The clavichord gives a fretful waſpiſh kind of ſound, not at all ſuited to tender expreſſion. If the bridge (for the end of the key is really a bridge during the ſound) were placed at an exact third of the length of the ſtring, and if both parts were free, and if the ſtroke be of a proper ſtrength, the ſtring would ſound its twelfth with great ſweetneſs, and with much more force and brilliancy than it does by the preſent conſtruction, and the clavichord would be a charming inſtrument for a leſſon and for private ſtudy. We ſay this from experience of the power of one conſtructed under the direction of the great mathematician Euler, who was alſo an excellent judge of muſic and muſical compoſition. The tones of the upper part of that inſtrument had a ſort of pipe or vocal ſound, and were ſuperior in clearneſs and ſweetneſs to any ſtringed inſtrument we ever heard. But as this conſtruction required every ſtring to be one half longer than a harpſichord wire of the ſame pitch, and as this would have made the inſtrument of a moſt inconvenient ſize, the baſſes were made ſhorter, by placing the bridge at one-ſixth of the length, and loading the ſhorter portion of the ſtring with wire twiſted round it. But although this was executed by a moſt dexterous artiſt, the tones were far inferior to thoſe of the trebles, and the inſtrument was like the junction of a very fine one and a very bad one, and made but hobbling muſic. This was probably owing to the impoſſibility of connecting the metal wire and its covering with ſufficient cloſeneſs and ſolidity. An upright clavichord, where the length would be no inconvenience, would be indeed a capital inſtrument for muſical ſtudy. It is worthy of remark, that Mr Euler tried other diviſions of the ſtring by the bridge. When it is ſtruck preciſely in the middle, it ſhould ſound its octave; when it is ſtruck at one-fourth, it ſhould give the double octave, &c. But the maker found that theſe diviſions give very indifferent, and even uncertain tones; ſometimes not ſounding at all, and ſometimes ſounding beautifully. Our readers will find this well explained in a future article of this *Supplement*, (Trumpet, *Marine*). They may pleaſe to reflect on the very different tone of the violin as it is bowed on different parts of the ſtring, and on the very different tones of the fore and back uniſons, and particularly of the Cornet ſtop of the harpſichord. The harpſichords of Rucker are noted for the grand fulneſs of their tone; thoſe of Haſſe of Dreſden for their mellow ſweetneſs, and thoſe of Kirkmann of London for their unequalled brilliancy. Theſe makers differed greatly in the placing of their quills.

But

Piano Forte.

But the English Piano Forte, by its superior force of tone, its adequate sweetness, and the great variety of voice of which our artists have made it susceptible, has withdrawn all farther attention from the clavichord, so that it is no longer probable that the learned contribution of the great Euler to public amusement will be followed up. The Piano-forte corresponds to its name with great precision: For, without any other attention or effort than what sentiment spontaneously dictates, and what we practise (without knowing it) on the harpsichord, where it is ineffectual, we make the Piano-forte give every gradation of strength to the sound of the string, and give it every expression that an instrument, purely pulsatile, is capable of. It is also susceptible of a very considerable variety of tone by the clothing of the mallets, which may be acute or obtuse, hard or soft. And we see, by the effect of what are called the grand Piano fortes, that they are fully equal to the harpsichord in fulnese or body of tone. Nothing seems to be wanting to it but that sliding, or (as the French call it) *caressing* touch of the string, by which a delicate finger, guided by fine taste, causes the harp or lute to melt the heart, and excite its finest emotions. We trust that the ingenuity of our British artists will accomplish even this, and make this national instrument rival even the violin of Italy.

We call it a *national instrument*, not doubting but that this is a recommendation to a British heart, and because we are very well assured that it is an English contrivance; the invention of a most excellent man and celebrated poet, Mr William Mason. His Caractacus and Elfrida may convince any person who is a judge of music, that he had a mind exquisitely sensible of all its charms; and we cannot be surprised that it was one of his chief delights. No man enjoyed the pleasures of music with more rapture; and he used to say, that his speediest recruit from the fatigue of a long walk was to sit down for a few minutes to the harpsichord. He had seen several of the German attempts to make keyed dulcimers, which were, in some measure, susceptible of the *forte* and *piano*: But they were all on one principle, and required a particular touch of the finger, of difficult acquisition, and which spoiled it for harpsichord practice. We have also seen of those instruments, some of very old date, and others of modern improvement. Some had very agreeable tones; but all were deficient in delicacy and justness. The performer was by no means certain of producing the very strength of sound that he intended. And, as Mr Mason observed, they all required an artificial peculiarity of fingering; without which, either the intended strength of tone was not brought out, or the tone was destroyed by repeated rattling of the mallet on the wire.

Mr Mason removed all those imperfections by detaching the mallet entirely from the key, and giving them a connection quite momentary. The sketch in Plate XL. will give the reader a clear view of Mr Mason's general principle, by which the English piano forte is distinguished from all others. The parts are represented in their state of inaction. The key ABK turns, as usual, on the round edge of the bar B, and a pin *b*, driven into the bar, keeps it in its place. The dot F represents a section of the string. ED is the mallet, having a hinge of vellum, by which it is attached to the upper surface of the bar E. At the other end is the head D, of wood, covered with some folds of prepared leather. The mallet lies in the position represented in the figure, its lower end resting on a cushion-bar K, which lies horizontally under the whole row of mallets. The key AR has a pin C, tipt with a bit of the softest cork or buckskin. This reaches to within $\frac{1}{10}$th of an inch of the shank of the mallet, but must not touch it. The distance E*e* is about $\frac{1}{3}$d or $\frac{1}{4}$th of the length of the shank. When the end A of the key is pressed down on the stuffing (two or three thicknesses of the most elastic woollen list) it raises the mallet, by means of the pin C, to the horizontal position E *d*, within $\frac{1}{8}$th or $\frac{1}{10}$th of an inch of the wire F; but it cannot be so much pressed down as to make the mallet touch the wire. At the same time that the key raises the mallet by means of the pin C, it also lifts off the damper G (a bit of spunge) from the wire. This damper is fixed on the end of a little wooden pin G *g*, connected with the lever *g* H, which has a vellum hinge at H. This motion of the damper is caused by the pin I, which is fixed into the key near to R. These pieces are so adjusted, that the first touch of the key lifts the damper, and, immediately after, the pin C acts on the shank of the mallet. As it acts so near to its centre of motion, it causes the head D to move briskly through a considerable arch D *d*. Being made extremely moveable, and very light, it is thus *tossed* beyond the horizontal position E *d*, and it strikes the wire F, which is now at liberty to vibrate up and down, by the previous removal of the damper G. Having made its stroke, the mallet falls down again, and rests on the soft substance on the pin C. It is of essential importance that this mallet be extremely light. Were it heavy, it would have so much force, after rebounding from the wire, that it would rebound again from the pin C, and again strike the wire. For it will be recollected, that the key is, at this time, down, and the pin C raised as high as possible, so that there is very little room for this rebound. Lessening the momentum of the mallet by making it very light, making the cushion on the top of the pin C very soft, and great precision in the shape and figure of all the parts, are the only securities against the disagreeable rattling which these rebounds would occasion. In respect to the solidity and precision of workmanship, the British instruments are unrivalled, and vast numbers of them are sent to all parts of the continent.

As the blow of so light a mallet cannot bring much sound from a wire, it has always been found necessary to have two strings for each note. Another circumstance contributes to enfeeble the sound. The mechanism necessary for producing it makes it almost impossible to give any considerable extent to the belly or sound board of the instrument. There is seldom any more of it than what occupies the space between the tuning pins and the bridge. This is the more to be regretted, because the basses are commonly covered strings, that they may be of a moderate length. The bass notes are also of brass, which has a considerably lower tone than a steel wire of the same diameter and tension. Yet even this substitution for steel in the bass strings is not enough. The highest of them are much too slack, and the lowest ones must be loaded, to compensate for want of length. This greatly diminishes the fulness, and still more the mellowness and distinctness of the tone, and frequently makes the very lowest notes hardly appreciable. This inequality of tone about the

Pigments.

the middle of the inftrument is fomewhat diminifhed by conftructing the inftrument with two bridges; one for the fteel, and the other for the brafs wires. But ftill the bafs notes are very much inferior to the treble. It would furely be worth while to conftruct fome piano fortes, of full fize, with naked baffes. If thefe were made with all the other advantages of the grand piano forte, they would furpafs all other inftruments for the regulating power of their thorough bafs. We wifh that the artifts would alfo try to conftruct them with the mechanifm of mallets, &c. above the found board. This would allow to it the full extent of the inftrument, and greatly improve the tone. It does not feem impoffible, nor (we think) very difficult.

For directions how to tune this pleafing inftrument, fee TEMPERAMENT in this *Supplement*.

PIGMENTS, or PAINTS, are furnifhed by both the mineral and vegetable kingdoms. The former are the moft durable, and are generally prepared from the OXIDES of metals (fee CHEMISTRY-*Index* in this *Suppl.* and *COLOUR-Making*, Encycl.); but Fourcroy thinks that chemiftry furnifhes a method of fixing vegetable colours completely. From a number of experiments, which we need not detail, as they will be noticed in the article *Vegetable* SUBSTANCES; he draws the following conclufions:

1. That oxygen, when combined with vegetable fubftances, changes their colour.

2. That different proportions of this principle produce different fhades in coloured vegetable matter.

3. That thefe fhades pafs, by a fort of degradation, from the darkeft colours to the lighteft; and that the extreme point of the latter may be confidered as a complete deprivation of colour.

4. That in many vegetable fubftances this degradation does not take place, as M. Berthollet has obferved.

5. That many red, violet, purple, chefnut, and blue vegetable colours, are produced by different proportions of oxygen; but that none of thefe are completely faturated with this principle.

6. That the complete faturation here fpoken of generally produces yellow colours, which are the leaft changeable of all.

7. That vegetable fubftances coloured by oxygen, not only change their colour according to the proportion of oxygen they have imbibed, but that they alfo change their nature in the fame proportion, and approach more to a refinous ftate as they become nearer to a yellow colour.

Laftly, that the caufe of the changeability of the red, brown, and violet colours, procured from vegetables, is fuch as has been ftated above; that there exifts a method of fixing them, or rendering them permanent, by impregnating them with a certain quantity of oxygen, by means of the oxygenated muriatic acid; imitating, by this procefs, the method purfued by nature, who never forms fixed and permanent colours, except in fubftances which have been long expofed to the open air.

Pitch, Plague.

PITCH. See *Encycl.*—The beft black pitch is made of the refufe of rofin and turpentine, fuch as will not pafs through the ftraw filter, and the cuttings around the incifion on the tree. Thefe materials are put into a boiler fix or feven feet in circumference, and eight or ten high. Fuel is laid around the top, and the materials as they melt flow through a channel cut in the fire-place into a tub half filled with water. It is at that time very red, and almoft liquid. To give this a proper confiftence, it is put in a cauldron placed in a furnace, and boiled down in the fame manner as rofin, but it requires much lefs precaution and double the time. It is then poured into moulds of earth, and forms the beft kind of black pitch. See ROSIN and TURPENTINE in this *Suppl.*

BASTARD PITCH, is a mixture of colophony, black pitch, and tar boiled down together, and caft in moulds.

PLAGUE (fee MEDICINE-*Index*, Encycl.), is a difeafe which has been lately afferted by Dr Mofeley to be not contagious. In fupport of this opinion, he quotes many paffages from medical writers, ancient and modern; but he feems to place the greateft confidence (as is indeed natural) in his own obfervations on peftilential fevers in the Weft Indies, and on what is faid of the plague in Berthier's account of Buonaparte's expedition into Syria.

"At the time of our entry into Syria (fays this Frenchman), all the towns were infected by the plague; a malady which ignorance and barbarity render fo fatal in the Eaft. Thofe who are affected by it give themfelves up for dead; they are immediately abandoned by every body (A), and are left to die, when they might have been faved by medicine and attention.

"Citizen Degenettes, principal phyfician to the army, difplayed a courage and character which entitle him to the national gratitude. When our foldiers were attaked by the leaft fever, it was fuppofed that they had caught the plague, and thefe maladies were confounded. The fever hofpitals were abandoned by the officers of health and their attendants. Citizen Degenettes repaired in perfon to the hofpitals, vifited all the patients, felt the glandular fwellings, dreffed them, declared and maintained that the diftemper was not the plague, but a malignant fever with glandular fwellings, which might eafily be cured by attention, and keeping the patient's mind eafy."

Degenette's views in making this diftinction were highly commendable; but certainly, fays Dr Mofeley, this fever was the plague. The phyfician, however, carried his courage fo far, as to make two incifions, and to inoculate the fuppurated matter from one of thefe buboes above his breaft and under his arm-pits, but was not affected with the malady. He thus eafed the minds of the foldiers, the firft ftep to a cure; and, by his affiduity and conftant attendance in the hofpitals, a number of men attacked with the plague were cured. His example was followed by other officers of health.

The lives of a number of men Citizen Degenettes was

(A) This can hardly be true. Every one knows that Mahometans are fatalifts in the ftricteft fenfe of the word; and Mr Browne, whofe knowledge of Syria and its inhabitants muft be at leaft equal to that of Berthier, affures us, that, far from abandoning his friend in the plague, "the Moflem, awe-ftruck, and refigned to the unalterable decrees of fate, hangs over the couch of his expiring relative."

Plague.

was thus instrumental of saving. He dismissed those who had been ill with the fever and buboes, without the least contagion being communicated to the army.

"There are (says Dr Moseley) annual or seasonal disorders, more or less severe, in all countries; but the plague, and other great depopulating epidemics, do not always obey the seasons of the year. Like comets, their course is eccentric. They have their revolutions; but from whence they come, or whither they go after they have made their revolutions, no mortal can tell.

"To look for the cause of an epidemic in the present state of the air, or weather, when it makes its appearance, is a very narrow contracted method of scrutiny. The cause of pestilential epidemics cannot be confined, and local. It must lie in the atmosphere, which surrounds, and is in contact with every part of us; and in which we are immersed, as bodies in fluids.

"These diseases not appearing in villages and thinly inhabited places, and generally attacking only great towns and cities, may be, that the atmosphere, which I conceive to be the universal propagator of pestilence, wants a commixture, or union, with some compounded and peculiar air, such as is generated in populous communities, to release its imprisoned virulence, and give it force. Like the divided seminal principles of many plants, concealed in winds and rains until they find suitable materials and soil to unite their separated atoms, they then assume visible forms in their own proper vegetation.

"Diseases originating in the atmosphere seize some, and pass by others; and act exclusively on bodies graduated to receive their impressions; otherwise whole nations would be destroyed. In some constitutions of the body the access is easy, in some difficult, and in others impossible.

"The air of confined places may be so vitiated as to be unfit for the purposes of the healthy existence of any person. Hence gaol, hospital, and ship fevers. But, as these distempers are the offspring of a local cause, that local cause, and not the distempered people, communicate the disease.

"Plagues and pestilences, the produce of the great atmosphere, are conveyed in the same manner, by the body being in contact with the cause; and not by its being in contact with the effect. If pestilences were propagated by contagion, from infected persons, the infection must issue from their breath or excrements, or from the exhalations of the bodies of the diseased. The infection, if it were not in the atmosphere, would be confined within very narrow limits; have a determinate sphere of action; and none but physicians and attendants on the sick would suffer; and these must suffer; and the cause and the effects would be palpable to our senses. Upon this ground the precaution of quarantine would be rational. But who then would visit and attend the sick, or could live in hospitals, prisons, and lazarettos?"

From these reasonings and facts, the author is convinced, that the bubo and carbuncle, of which we hear so much in Turkey, and read so much in our own history of plagues, arise from heating food and improper treatment; that they contain no infection; and consequently that they are not the natural deposit of the morbific virus separated from the contagion.

He is equally confident that no pestilential or pandemic fever was ever imported or exported; and hence he considers the fumigating of ship-letters, and shutting up the crews and passengers of vessels, on their arrival from foreign places, several weeks, for fear they should give diseases to others which they have not themselves, as an ignorant barbarous custom. Whence was the importation of the plague at Naples in 1656; by which 20,000 people died in one day? Can any person, for a moment reflecting, believe, that the great plague of London in 1665, which imagination traced from the Levant to Holland, and from Holland to England, was caused by opening a bag of cotton in the city, or in Long Acre; or a package of hemp in St Giles's parish? Quarantine, always expensive to commerce, and often ruinous to individuals, is a reflection on the good sense of countries.

That Dr Moseley is a man of learning, and a lively writer, is known to every one who has looked into his works, and is not himself a stranger to letters. On this account, and still more on account of the opportunities which he has possessed of making accurate observations on various kinds of pestilential diseases, we have detailed at some length his notions of the plague; but as it does not appear that he ever *saw* the disease which is *known* by the name of *the plague*, justice requires that we give some account of it from a man who had the best possible opportunities of obtaining correct information on the subject.

"The facts that appear to be chiefly ascertained relative to the plague (says Mr Browne), are, 1. That the infection is not received but by actual contact. In this particular, it would seem less formidable than several other disorders. 2. That it is communicated by certain substances, by others not; as by a woollen cloth, or rope of hemp, but not by a piece of ivory, wood, or rope made of the date tree; nor by any thing that has been completely immersed in water. It would appear from the report of the Kahirines *, that no animal but man is affected with this disorder; though, it is said, a cat passing from an infected house has carried the contagion. 3. That persons have often remained together in the same house, and entirely under the same circumstances, of whom one has been attacked and died, and the others never felt the smallest inconvenience. 4. That a person may be affected any number of times. 5. That it is more fatal to the young than the old. 6. That no climate appears to be exempt from it; yet, 7. That the extremes of heat and cold both appear to be adverse to it. In Constantinople it is often, but far from being always, terminated by the cold of winter, and in Kahira by the heat of summer; both circumstances being, as may be conjectured, the effect of indisposition for absorption in the skin, unless it be supposed that in the latter case it may be attributed to the change the air undergoes from the increase of the Nile.

* The inhabitants of *Cairo*, which Mr Brown uniformly calls *Kahira*.

"The first symptoms are said to be thirst; 2. Cephalalgia; 3. A stiff and uneasy sensation, with redness and tumor about the eyes; 4. Watering of the eyes; 5. White pustules on the tongue. The more advanced symptoms of buboes, fœtor of the breath, &c. &c. are well known; and I have nothing authentic to add to them. Not uncommonly, all these have successively shewn themselves, yet the patient has recovered; in which case, where suppuration has had place, the skin always remains discoloured, commonly of a purple hue. Many who have been bleeded in an early stage of the disorder,

disorder, have recovered without any fatal symptoms; but whether from that or any other cause, does not appear certain (B). The same operation is reported to have been commonly fatal in a late stage. It is said that embrocating the buboes continually with oil has sometimes wrought a cure; but this remedy is so difficult and dangerous for the operator, that it would appear experiments must yet be very defective."

They are not, perhaps, so defective as Mr Browne supposes. In the hospital of St Anthony at Smyrna, it has been the practice for many years past to rub over with warm olive oil the bodies of persons infected by the plague; and that practice has been attended with wonderful success. It was first suggested by Mr Baldwin the English consul; and from him adopted by *P. Luigi di Pavia*, who for upwards of 27 years has exposed himself to infection by his unremitting attendance on those who are labouring under this dreadful distress. This excellent man, whose philanthropy equals that even of "Marseilles' good bishop," declares, that during the long period mentioned, he has found no remedy comparable to that of rubbing olive oil, with the strongest friction, into the whole body of the infected person. When the body is thus rubbed, the pores being opened, imbibe the oil, and a profuse perspiration takes place, by which the poisonous infection is again thrown out. This operation must be performed the first day of the infection; and if only a weak perspiration ensues, it must be repeated till it is observed that every particle of infection is removed, and that the whole body of the patient is covered with a profuse sweat. Neither the patient's shirt nor bed-clothes must be changed till the perspiration has entirely ceased. The operation must be performed in a very close apartment; and at every season of the year there must be kept in it a fire-pan, over which sugar and juniper must be thrown from time to time, that the vapour which thence arises may promote the perspiration. The whole body of the patient, the eyes alone excepted, must in this manner be anointed, or rather rubbed over, with the greatest care.

This practice of the pious monk is mentioned by Mr Howard in his work on Lazarettos; but a more satisfactory account of it is given by Count *Leopold von Berchtold*, who adds the following remarks by way of illustration: 1. The operation of rubbing in the oil must be performed by means of a sponge, and so speedily as not to last more than about three minutes. 2. The interval between the first and the second rubbing, if a second be necessary, must be determined by circumstances, as the second must not be performed till the first perspiration is over, and this will depend on the constitution of the patient. If any sweat remains upon the skin, it must be wiped off with a warm cloth before the second rubbing takes place. This strong friction with oil may be continued for several days successively, until a favourable change is remarked in the disease; after which the rubbing may be performed in a more gentle manner. The quantity of oil requisite each time cannot be determined with accuracy; but, in general, a pound may be sufficient. The purest and freshest oil is the best for this operation: it must not be hot, but only lukewarm. The breast and privities must be rubbed softly. In a cold climate such as ours, those parts only into which the oil is rubbed must be exposed naked. The other parts must be covered with warm clothing. In this manner each part of the body must be rubbed with oil in succession, as quickly as possible, and be then instantly covered. If the patient has boils or buboes, they must be rubbed over gently with the oil till they can be brought to suppurate by means of emollient plasters. The persons who attend the patients to rub in the oil must take the precaution to rub themselves over in the like manner, before they engage in the operation. They must, if possible, avoid the breath of the patient, and not be under any apprehensions of catching the infection.

P. Luigi then says: "In order to prevent the patients from losing their strength, I prescribed for them, during four or five days, soup made of vermicelli boiled in vinegar without salt. I gave them six or seven times a-day a small spoonful of preserved sour cherries; preserved not with honey, but with sugar, as the former might have occasioned a diarrhœa. When convinced that the patients were getting better, I usually gave them the fifth morning a cup of good Mocha coffee, with a piece of toasted biscuit (*biscotto*) prepared with sugar; and I doubled the latter according to the strength and improvement of my patients."

In the course of five years, during which friction with oil was employed in the hospital at Smyrna, of 250 persons attacked by the plague the greater part were

(B) Dr Moseley, we think, has assigned a very sufficient reason why bleeding should generally prove effectual, if recourse be had to it at the commencement of the disease. "In the common order of pestilential fevers (says he), they commence with coldness and shivering; simply demonstrating, that something unusual has been in contact with the skin, agonizing cutaneous sensibility. Sickness at the stomach, and an immoveable pressure about the præcordia, follow. These demonstrate, that the blood cannot pervade the extremities of the body, and that the quantity which ought to dilate through the whole machine is confined to the larger organs, and is crowding and distending the heart and central vessels.

"The restraining power of the remoter blood vessels being destroyed, the thinner parts of the blood escape their boundaries; hence arises yellowness in the skin in some climates; in others, the extravasated grosser parts of the blood stagnate, forming black lodgements, bubo, anthrax, and exanthemata.

"The object in these fevers is, to decide the contest between the solids and the fluids; and this appears to me to be only practicable, when spontaneous sweats do not happily appear, or cannot be raised by a cooling regimen; and by draining the vital parts, by bleeding and purging, before the fluids have burst their confines, and dissolved their bond of union with the solids. The next step is to regain the lost energy of the surface of the body, by exciting perspiration; and then of the whole system, by tonics.

"When these things are not done in the first hours of attack, in pestilential fevers, and the conflict is not *extinguished* at once, attempting to extort sweats from the body, by heating alexapharmacs, will do mischief; and bark, wine, stimulants, and cordials, may be called on, like undertakers, to perform an useless ceremony."

Planetary-hours, Planets.

were cured; and this would have been the cafe with the reft had they not neglected the operation, or had it not been employed too late after their nervous fyftem had been weakened by the difeafe fo as to render them incurable. Immenfe numbers of people have been preferved from the effects of this malady by the above means; and of all thofe who have anointed themfelves with oil, and rubbed it well into their bodies, not one has been attacked by the plague, even though they approached perfons already infected, provided they abftained from heavy and indigeftible food.

Thus we fee, if this account may be depended on, that oil rubbed into the fkin acts as a preventative, as well as a cure. When the operation is performed to prevent infection, and it is fuccefsfully performed with that view at Smyrna, as often as the plague makes its appearance in the city, as it is not done for the purpofe of promoting perfpiration, it is not requifite that it fhould be performed with the fame fpeed as when for curing the diforder; nor is it neceffary to abftain from flefh and to ufe foups; but it will be proper to ufe only fowls or veal for ten or twelve days, boiled or roafted, without any addition or feafoning (*condimento*). In the laft place, it will be neceffary to guard againft fat and indigeftible food, and fuch liquors as might put in motion or inflame the mafs of the blood.

This important difcovery deferves the ferious confideration of all medical men; for if olive oil has been found efficacious in curing or preferving againft one fpecies of infection, it is not abfurd to fuppofe that the fame or other kinds of oil might be productive of much benefit in other malignant infectious difeafes. We hope foon to hear of fome trial being made with it in this country. Would it be of any fervice in the yellow fever, fo prevalent in the weftern world? See the *Philofophical Magazine*, Vol. II.

PLANETARY HOURS, are twelfth parts of the artificial day and night; being each double in length to the hour ufed in civil computation in Europe. They are ftill ufed by the Jews as they were among their forefathers; and hence are called *Jewifh* hours. The reafon of their being called *planetary* hours, is, that according to the aftrologers, a new planet comes to predominate every hour, and that the day takes its denomination from that which predominates the firft hour of it; as Monday from the moon, &c.

PLANETS have been fufficiently defcribed in the articles ASTRONOMY in the *Encyclopædia* and this *Supplement*. The word is introduced here merely to notice the difcovery of two new planets fince thofe articles were written. The firft was difcovered in January 1801, by Piazzi of Palermo; and the other, if it be indeed a planet, on the 28th of March 1802, by Mr Olbars an aftronomer of Bremen. Of the exiftence of Piazzi's planet there is no doubt, as it has been obferved by almoft all the eminent aftronomers of Europe. Its orbit is between that of Mars and Jupiter, and its appearance like that of a ftar of the feventh or eighth magnitude. It has been called *Juno*, *Hera*, and *Ceres Ferdinandea*. The laft of thefe names feems to be generally adopted; and it was impofed by the difcoverer in allufion to Sicily, and the monarch who reigns over that country. Dr Herfchel does not think the ftar of Olbars intitled to the rank of a planet; and hitherto we believe it has received no name. *Ceres Ferdinandea* revolves in four years; and the following are the elements found by Bruckhardt and Gaufs, and admitted by Lalande:

Plants.

PLANTS, organifed bodies, of which a full account has been given in the *Encycl.* under the title BOTANY, PLANTS, SEXES, &c. The eftablifhment of the fexual fyftem in vegetables, and the acknowledged analogy between vegetable and animal bodies, has fuggefted a method of improving plants, as animals are confeffedly improved, by what is called *croffing the breed*. This thought incurred firft, we believe, to Andrew Knight, Efq; and in the Tranfactions of the Royal Society for 1799, we have an account of fome very curious experiments made by him, with the view of afcertaining whether the improvement which he had conceived be actually practicable. Thofe were chiefly made on the garden pea, of which he had a kind growing in his yard; which having been long cultivated in the fame foil, had ceafed to be productive, and did not appear to recover the whole of its former vigour when removed to a foil of a fomewhat different quality. On this his firft experiment in 1787 was made. Having opened a dozen of its immature bloffoms, he deftroyed the male parts, taking great care not to injure the female ones; and a few days afterwards, when the bloffoms appeared mature, he introduced the farina of a very large and luxuriant grey pea into one half of the bloffoms, leaving the other half as they were. The pods of each grew equally well; but he foon perceived that of thofe into whofe bloffoms the farina had not been introduced, the feed remained nearly as they were before the bloffom expanded, and in that ftate they withered. Thofe in the other pods attained maturity, but were not in any fenfible degree different from thofe afforded by other plants of the fame variety; owing, he imagines, to the external covering of the feed (as he had found in other plants) being furnifhed entirely by the female. In the fucceeding fpring, the difference, however, became extremely obvious; for the plants from them arofe with exceffive luxuriance, and the colour of their leaves and ftems clearly indicated that they had all exchanged their whitenefs for the colour of the male parent: the feeds produced in autumn were dark grey. By introducing the farina of another white variety (or in fome inftances by fimple culture), he found this colour was eafily difcharged, and a numerous variety of new kinds produced; many of which were in fize and every other refpect much fuperior to the original white kind, and grew with exceffive luxuriance, fome of them attaining the height of more than twelve feet.

The diffimilarity he obferved in the offspring, afforded by different kinds of farina in thefe experiments, pointed out to him an eafy method of afcertaining whether fuperfœtation (the exiftence of which has been admitted among animals) could alfo take place in the vegetable world. For as the offspring of a white pea is always white, unlefs the farina of a coloured kind be introduced into the bloffom, and as the colour of the grey one is always transferred to its offspring, though the female be white, it readily occurred to Mr Knight, that if the farina of both were mingled or applied at the fame moment, the offspring of each could be eafily diftinguifhed.

His firft experiment was not altogether fuccefsful; for the offspring of five pods (the whole which efcaped the birds) received their colour from the coloured male. There was, however, a ftrong refemblance to the other male in the growth and character of more than one of the plants; and the feeds of feveral in the autumn very clofely refembled it in every thing but colour. In this experiment he ufed the farina of a white pea, which poffeffed the remarkable property of fhrivelling excef-fively when ripe; and in the fecond year he obtained white feeds from the grey ones above mentioned, perfectly fimilar to it. He is therefore ftrongly difpofed to believe that the feeds were here of common parentage; but doth not conceive himfelf to be in poffeffion of facts fufficient to enable him to fpeak with decifion on this queftion. We have no right to form a decided opinion on this part of the fubject, having paid to it very little attention; but at prefent we are inclined to think differently from the author. We admit, indeed, that if the female afford the firft organized atom, and the male act only as a ftimulus, it is by no means impoffible that the explofion of two veficles of farina, at the fame moment (taken from different plants), may afford feeds of common parentage; but whether the female or the male affords the firft organized atom, is the queftion which to us appears not yet decided.

Another fpecies, however, of fuperfœtation, in which one feed appears to have been the offspring of two males, has occurred to Mr Knight fo often, as to remove, he fays, all poffibility of doubt as to its exiftence. In 1797, the year after he had feen the refult of the laft mentioned experiment, having prepared a great many white bloffoms, he introduced the farina of a white and that of a grey nearly at the fame moment into each; and as in the laft year the character of the coloured male had prevailed, he ufed its farina more fparingly than that of the white one; and now almoft every pod afforded plants of different colours. The majority, however, were white; but the characters of the two kinds were not fufficiently diftinct to allow him to judge with precifion whether any of the feeds were produced of common parentage or not. In the year 1798 he was more fortunate; having prepared bloffoms of the little early frame pea, he introduced its own farina, and immediately afterwards that of a very large and late grey kind, and fowed the feeds thus obtained in the end of fummer. Many of them retained the colour and character of the fmall early pea, not in the flighteft degree altered, and bloffomed before they were eighteen inches high; whilft others (taken from the fame pods), whofe colour was changed, grew to the height of more than four feet, and were killed by the froft before any bloffoms appeared.

It is evident, that in thefe inftances fuperfœtation took place; and it is equally evident that the feeds were not all of common parentage. Should fubfequent experience evince, that a fingle plant may be the offfpring of two males, the analogy between animal and vegetable nature may induce fome curious conjectures relative to the procefs of generation in the animal world.—It certainly may; but either we do not perfectly underftand the author's meaning, or this experiment is not conclufive. There were here feeds of different colours produced by the farina of different males, operating on the fame female plant; and there are well attefted inftances of twin children being born of different colours, in confequence of the coition of different males, a negro and a white man, with the fame woman. Had Mr Knight difcovered, not that the fame pod, but that the fame individual *pea*, was the offspring of two males, his difcovery would indeed have led to fome curious conjectures refpecting animal generation. But to proceed with his experiments.

By introducing the farina of the largeft and moft luxuriant kinds into the bloffoms of the moft diminutive, and by reverfing this procefs, he found that the powers of the male and female, in their effects on the offspring, are exactly equal. The vigour of the growth, the fize of the feeds produced, and the feafon of maturity, were the fame, though the one was a very early and the other a late variety. He had in this experiment a ftriking inftance of the ftimulative effects of croffing the breeds; for the fmalleft variety, whofe height rarely exceeded two feet, was increafed to fix feet; whilft the height of the large and luxuriant kind was very little diminifhed. By this procefs it is evident, that any number of new varieties may be obtained; and it is highly probable, that many of thefe will be found better calculated to correct the defects of different foils and fituations than any we have at prefent.

The fuccefs of Mr Knight's experiments on the pea induced him to make fimilar experiments on wheat; but thefe did not anfwer his expectations. The varieties indeed which he obtained, efcaped the blights of 1795 and 1796; but their qualities were not otherwife good, nor were they permanent. His experiments on the apple, the improvement of which was the firft object of his attention, have, as far as he could judge from the cultivated appearance of trees which had not borne fruit when he wrote his memoir, been fully equal to his hopes. The plants which he obtained from his efforts to unite the good qualities of two kinds of apple, feem to poffefs the greateft health and luxuriance of growth, as well as the moft promifing appearance in other refpects. In fome of thefe the character of the male appears to prevail; in others that of the female; and in others both appear blended, or neither is diftinguifhable. Thefe variations, which were often obfervable in the feeds taken from a fingle apple, evidently arife from the want of permanence in the character of this fruit, when raifed from feed. Many experiments of the fame kind were tried on other plants; but it is fufficient to fay, that all tended to evince, that improved varieties of every fruit and of efculent plants may be obtained by this procefs, and that Nature intended that a fexual intercourfe fhould take place between neighbouring plants of the fame fpecies. For the nutrition of plants, fee VEGETABLE SUBSTANCES in this *Suppl.*

PLATINUM, or PLATINA (See CHEMISTRY, *Suppl.* Part I. Chap. iii. Sect. 3.), is a metal, of which every chemift regrets the difficulty of making it malleable. Of the different proceffes adopted to accomplifh this end, we have reafon to believe that of Mr Richard Knight the moft fuccefsful; and, with the ſpirit of a true philoſopher, he wiſhes to make that proceſs as generally known as poſſible. We ſhall give it in his own words:

"To a given quantity of crude platinum, I add (ſays he) 15 times its weight of nitro-muriatic acid (compoſed of equal parts of nitric and muriatic acids) in a tubulated glaſs retort, with a tubulated receiver adapted to it. It is then boiled, by means of an Argand's lamp, till the acid has aſſumed a deep ſaffron colour: it is then poured off; and if any platina remains undiſſolved, more acid is added, and it is again boiled until the whole is taken up. The liquor, being ſuffered to reſt till quite clear, is again decanted: a ſolution of ſal-ammoniac is then added, by little and little, till it no longer gives a cloudineſs. By this means the platina is thrown down in the form of a lemon-coloured precipitate, which having ſubſided, the liquor is poured off, and the precipitate repeatedly waſhed with diſtilled water till it ceaſes to give an acid taſte (too much water is injurious, the precipitate being in a certain degree ſoluble in that liquid); the water is then poured off, and the precipitate evaporated to dryneſs."

Thus far our author's method, as he candidly obſerves himſelf, differs not from that which has been followed by many others; but the remainder of the proceſs is his own. "A ſtrong, hollow, inverted cone of crucible earth being procured, with a correſponding ſtopper to fit it, made of the ſame materials, the point of the latter is cut off about three-fourths from the baſe. The platina, now in the ſtate of a light yellow powder, is preſſed tight into the cone, and, a cover being fixed ſlightly on, it is placed in an air furnace, and the fire raiſed gradually to a ſtrong white heat. (The furnace uſed by Mr Knight is portable, with a chamber for the fire only eight inches in diameter.) In the mean time the conical ſtopper, fixed in a pair of iron tongs ſuitable for the purpoſe, is brought to a red, or to a bright red, heat. The cover being then removed from the cone, the tongs with the heated ſtopper is introduced through a hole in the cover of the furnace, and preſſed at firſt gently on the platina, at this time in a ſtate nearly as ſoft as dough, till it at length acquires a more ſolid conſiſtence. It is then repeatedly ſtruck with the ſtopper, as hard as the nature of the materials will admit, till it appears to receive no farther impreſſion. The cone is then removed from the furnace; and being ſtruck lightly with a hammer, the platina falls out in a metallic button, from which ſtate it may be drawn, by repeatedly heating and gently hammering, into a bar fit for flatting, drawing into wire, planiſhing, &c.

"Beſides the comparative facility of this proceſs, it has the farther advantage of rendering the platina much purer than when red hot iron is obliged to be had recourſe to; for platina, when of a white heat, has a ſtrong affinity for iron, and, with whatever care it may have been previouſly ſeparated from that metal, will be found to have taken up a portion of it, when it is employed of a red heat, to ſerve to unite the particles of the platina."

PLATONIC Bodies, ſee *Regular Bodies*, *Suppl.*

PLUVIAMETER, a machine for meaſuring the quantity of rain that falls, otherwiſe called Ombrometer; which ſee, *Encycl.*

POLLARDS, the name of a coarſe kind of wheaten flour. When the flour of wheat is ſeparated into three degrees of fineneſs, the third is the pollards. There is nothing between it and the bran.

PORCELAIN, a kind of earthen or ſtone ware, of the manufacture of which a full account is given in the *Encyclopædia* from Groſier and Reaumur. It may be proper, however, to add here, from Sir George Staunton, that one of the principal ingredients in the Chineſe porcelain called *pe-tun-tſe*, is a ſpecies of fine granite, or compound of quartz, feldſpath, and mica, in which the quartz bears the largeſt proportion. "It appears (ſays Sir George) from ſeveral experiments, that *pe-tun-tſe* is the ſame as the growan-ſtone of the Corniſh miners. The micaceous part in ſome of this granite from both countries, often contains ſome particles of iron; in which caſe it will not anſwer the potter's purpoſe. This material can be calcined and ground much finer by the improved mills of England, than by the very imperfect machinery of the Chineſe, and at a cheaper rate, than the prepared *pe-tun-tſe* of their own country, notwithſtanding the cheapneſs of labour there. The *kao-lin*, or principal matter mixed with the *pe-tun-tſe*, is the growan clay alſo of the Corniſh miners. The *wha-ſhe* of the Chineſe is the Engliſh ſoap rock; and the *ſhe kan* is aſſerted to be gypſum.

"The manufacture of porcelain is ſaid to be precarious, from the want of ſome preciſe method of aſcertaining and regulating the heat within the furnaces, in conſequence of which, their whole contents are baked ſometimes into one ſolid and uſeleſs maſs." If this be ſo, Wedgewood's thermometer would be a preſent highly valuable to the Chineſe potter, if that arrogant and conceited people would condeſcend to be taught by a native of Europe.

POSITION, Centre of, is a point of any body, or ſyſtem of bodies, ſo ſelected, that we can eſtimate with propriety the ſituation and motion of the body or ſyſtem by the ſituation and motion of this point. It is very plain that, in all our attempts to accurate diſcuſſion of mechanical queſtions, eſpecially in the preſent extended ſenſe of the word *mechaniſm*, ſuch a ſelection is neceſſary. Even in common converſation, we frequently find it neceſſary to aſcertain the diſtance of objects with a certain preciſion, and we then perceive that we muſt make ſome ſuch ſelection. We conceive the diſtance to be mentioned, neither with reſpect to the neareſt nor the remoteſt point of the object, but as a ſort of average diſtance; and we conceive the point ſo aſcertained to be ſomewhere about the middle of the object. The more we reflect on this, we find it the more neceſſary to attend to many circumſtances which we had overlooked. Were it the queſtion, to decide in what preciſe part of a country pariſh the church ſhould be placed, we find that the geometrical middle is not always the moſt proper. We muſt conſider the populouſneſs of the different quarters of the pariſh, and ſelect a point ſuch, that the diſtances of the inhabitants on each ſide, in every direction, ſhall be as equally balanced as poſſible.

In mechanical diſcuſſions, the point by whoſe poſition and diſtance we eſtimate the poſition and diſtance of the whole, muſt be ſo ſelected, that its poſition and diſtance, eſtimated in any direction whatever, ſhall be the average of the poſitions and diſtances of every particle of the aſſemblage, eſtimated in that direction.

This will be the caſe, if the point be ſo ſelected that, when a plane is made to paſs through it *in any direc-*

Position. *tion whatever*, and perpendiculars are drawn to this plane from every particle in the body or syſtem, the ſum of all the perpendiculars on one ſide of this plane is equal to the ſum of all the perpendiculars on the other ſide. If there be ſuch a point in a body, the poſition and motion of this point is the average of the poſitions and motions of all the particles.

Plate XL. For if P (fig. 1.) be a point ſo ſituated, and if QR be a plane (perpendicular to the paper) at any diſtance from it, the diſtance Pp of the point from this plane is the average of the diſtances of all the particles from it. For let the plane APB be paſſed through P, parallel to QR. The diſtance CS of any particle C from the plane QR is equal to DS—DC, or to Pp—DC. And the diſtance GT of any particle G, lying on the other ſide of APB, is equal to HT+GH, or to Pp+GH. Let n be the number of particles on that ſide of AB which is neareſt to QR, and let o be the number of thoſe on the remote ſide of AB, and let m be the number of particles in the whole body, and therefore equal to $n+o$. It is evident that the ſum of the diſtances of all the particles ſuch as C, is n times Pp, after deducting all the diſtances, ſuch as DC. Alſo the ſum of all the diſtances of the particles, ſuch as G, is o times Pp, together with the ſum of all the diſtances, ſuch as GH. Therefore the ſum of both ſets is $\overline{n+o}\times Pp +$ ſum of GH—ſum of DC, or $m\times Pp+$ ſum of GH—ſum of DC. But the ſum of GH, wanting the ſum of DC, is nothing, by the ſuppoſed property of the point P. Therefore $m\times Pp$ is the ſum of all the diſtances, and Pp is the mth part of this ſum, or the average diſtance.

Now ſuppoſe that the body has changed both its place and its poſition with reſpect to the plane QR, and that P (fig. 2.) is ſtill the ſame point of the body, and α P β a plane parallel to QR. Make $p\,\pi$ equal to p P of fig. 1. It is plain that Pp is ſtill the average diſtance, and that $m\times Pp$ is the ſum of all the preſent diſtances of the particles from QR, and that $m\times \pi p$ is the ſum of all the former diſtances. Therefore $m\times P\pi$ is the ſum of all the changes of diſtance, or the whole quantity of motion eſtimated in the direction π P. Pπ is the mth part of this ſum, and is therefore the average motion in this direction. The point P has therefore been properly ſelected; and its poſition, and diſtance, and motion, in reſpect of any plane, is a proper repreſentation of the ſituation and motion of the whole.

It follows from the preceding diſcuſſion, that if any particle C (fig. 1.) moves from C to N, in the line CS, the centre of the whole will be transferred from P to Q, ſo that PQ is the mth part of CN; for the ſum of all the diſtances has been diminiſhed by the quantity CN, and therefore the average diſtance muſt be diminiſhed by the mth part of CN, or PQ is $=\frac{CN}{m}$.

But it may be doubted whether there is in every body a point, and but one point, ſuch that if a plane paſs through it, *in any direction whatever*, the ſum of all the diſtances of the particles on one ſide of this plane is equal to the ſum of all the diſtances on the other.

It is eaſy to ſhew that ſuch a point may be found, with reſpect to a plane parallel to QR. For if the ſum of all the diſtances DC exceed the ſum of all the diſtances GH, we have only to paſs the plane AB a little nearer to QR, but ſtill parallel to it. This will diminiſh the ſum of the lines DC, and increaſe the ſum of Position the lines GH. We may do this till the ſums are equal.

In like manner we can do this with reſpect to a plane LM (alſo perpendicular to the paper), perpendicular to the plane AB. The point wanted is ſomewhere in the plane AB, and ſomewhere in the plane LM. Therefore it is ſomewhere in the line in which theſe two planes interſect each other. The line paſſes through the point P of the paper where the two lines AB and LM cut each other. Theſe two lines repreſent planes, but are, in fact, only the interſection of thoſe planes with the plane of the paper. Part of the body muſt be conceived as being above the paper, and part of it behind or below the paper. The plane of the paper therefore divides the body into two parts. It may be ſo ſituated, therefore, that the ſum of all the diſtances from it to the particles lying above it ſhall be equal to the ſum of all the diſtances of thoſe which are below it. Therefore the ſituation of the point P is now determined, namely, at the common interſection of three planes perpendicular to each other. It is evident that this point alone can have the condition required in reſpect to theſe three planes.

But it ſtill remains to be determined whether the ſame condition will hold true for the point thus found, in reſpect to *any other* plane paſſing through it; that is, whether the ſum of all the perpendiculars on one ſide of *this fourth* plane is equal to the ſum of all the perpendiculars on the other ſide. Therefore

Let AGHB (fig. 3.), AXYB, and CDFE, be three planes interſecting each other perpendicularly in the point C; and let CIKL be any other plane, interſecting the firſt in the line CI, and the ſecond in the line CL. Let P be any particle of matter in the body or ſyſtem. Draw PM, PO, PR, perpendicular to the firſt three planes reſpectively, and let PR, when produced, meet the oblique plane in V; draw MN, ON, perpendicular to CB. They will meet in one point N. Then PMNO is a rectangular parallelogram. Alſo draw MQ perpendicular to CE, and therefore parallel to AB, and meeting CI in S. Draw SV; alſo draw ST perpendicular to VP. It is evident that SV is parallel to CL, and that STRQ and STPM are rectangles.

All the perpendiculars, ſuch as PR, on one ſide of the plane CDFE, being equal to all thoſe on the other ſide, they may be conſidered as compenſating each other; the one being conſidered as poſitive or additive quantities, the other are negative or ſubtractive. There is no difference between their ſums, and the ſum of both ſets may be called 0 or nothing. The ſame muſt be affirmed of all the perpendiculars PM, and of all the perpendiculars PO.

Every line, ſuch as RT, or its equal QS, is in a certain invariable ratio to its correſponding QC, or its equal PO. Therefore the poſitive lines RT are compenſated by the negative, and the ſum total is nothing.

Every line, ſuch as TV, is in a certain invariable ratio to its correſponding ST, or its equal PM, and therefore their ſum-total is nothing

Therefore the ſum of all the lines PV is nothing; but each is in an invariable ratio to a correſponding perpendicular from P on the oblique plane CIKL. Therefore the ſum of all the poſitive perpendiculars on this plane is equal to the ſum of all the negative perpendiculars, and the propoſition is demonſtrated, *viz.* that in in every body, or system of bodies, there is a point such, that if a plane be passed through it *in any direction whatever*, the sum of all the perpendiculars on one side of the plane is equal to the sum of all the perpendiculars on the other side.

The point P, thus selected, may, with great propriety, be called the CENTRE OF POSITION of the body or system.

If A and B (fig. 4.) be the centres of position of two bodies, whose quantities of matter (or numbers of equal particles) are a and b, the centre C lies in the straight line joining A and B, and $AC : CB = b : a$, or its distance from the centres of each are inversely as their quantities of matter. For let $\alpha C \beta$ be any plane passing through C. Draw $A\alpha$, $B\beta$, perpendicular to this plane. Then we have $a \times A\alpha = b \times B\beta$, and $A\alpha : B\beta = b : a$, and, by similarity of triangles, $CA : CB = b : a$.

If a third body D, whose quantity of matter is d, be added, the common centre of position E of the three bodies is in the straight line DC, joining the centre D of the third body with the centre C of the other two, and $DE : EC = a + b : d$. For, passing the plane $E\kappa$ through E, and drawing the perpendiculars $D\delta$, $C\kappa$, the sum of the perpendiculars from D is $d \times D\delta$; and the sum of the perpendiculars from A and B is $\overline{a+b} \times C\kappa$, and we have $d \times D\delta = \overline{a+b} \times C\kappa$; and therefore $DE : EC = a + b : d$.

In like manner, if a fourth body be added, the common centre is in the line joining the fourth with the centre of the other three, and its distance from this centre and from the fourth is inversely as the quantities of matter; and so on for any number of bodies.

If all the particles of any system be moving uniformly, in straight lines, in any directions, and with any velocities whatever, the centre of the system is either moving uniformly in a straight line, or is at rest.

For let m be the number of particles in the system. Suppose any particle to move uniformly in any direction. It is evident, from the reasoning in a former paragraph, that the motion of the common centre is the mth part of this motion, and is in the same direction. The same must be said of every particle. Therefore the motion of the centre is the motion which is compounded of the mth part of the motion of each particle. And because each of these was supposed to be uniform and rectilineal, the motion compounded of them all is also uniform and rectilineal; or it may happen that they will so compensate each other that there will be no diagonal, and the common centre will remain at rest.

Cor. 1. If the centres of any number of bodies move uniformly in straight lines, whatever may have been the motions of each particle of each body, by rotation or otherwise, the motion of the common centre will be uniform and rectilineal.

Cor. 2. The quantity of motion of such a system is the sum of the quantities of motion of each body, reduced to the direction of the centre's motion. And it is had by multiplying the quantity of matter in the system by the velocity of the centre.

The velocity of the centre is had by reducing the motion of each particle to the direction of the centre's motion, and then dividing the sum of those reduced motions by the quantity of matter in the system.

By the selection of this point, we render the investigation of the motions and actions of bodies incomparably more simple and easy, freeing our discussions from numberless intricate complications of motion, which would frequently make our progress almost impossible.

POSITION, in arithmetic, called also *False Position*, or *Supposition*, or *Rule of False*, is a rule so called, because it consists in calculating by false numbers supposed or taken at random, according to the process described in any question or problem proposed, as if they were the true numbers, and then from the results, compared with that given in the question, the true numbers are found.

Thus, take or assume any number at pleasure for the number sought, and proceed with it as if it were the true number, that is, perform the same operations with it as, in the question, are described to be performed with the number required: then if the result of those operations be the same with that mentioned or given in the question, the supposed number is the same as the true one that was required; but if it be not, make this proportion, *viz.* as your result is to that in the question, so is your supposed false number to the true one required.

Example. What number is that, to which if we add $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, and $\frac{1}{6}$ of itself, the sum will be 240?

Suppose 99
$$
\begin{array}{rl}
49.5 & = \frac{1}{2} \\
33. & = \frac{1}{3} \\
24.75 & = \frac{1}{4} \\
16.5 & = \frac{1}{6} \\
\hline
222.75 & = \text{result}
\end{array}
$$

Then, as $222.75 : 240 :: 99 : 106.6 =$ Answer.
$$
\begin{array}{rl}
53.\dot{3} & = \frac{1}{2} \\
35.5 & = \frac{1}{3} \\
26.\dot{6} & = \frac{1}{4} \\
17.\dot{7} & = \frac{1}{6} \\
\hline
240. & = \text{proof.}
\end{array}
$$

This is *single* position.

Sometimes it is necessary to make two different suppositions or assumptions, when the same operations must be performed with each as in the single rule. If neither of the supposed numbers solve the question, find the differences between the results and the given number; multiply each of these differences into the other's position; and if the errors in both suppositions be of the same kind, *i. e.* if both suppositions be either less or greater than the given number, divide the differences of the products by the differences of the errors. If the errors be not of the same kind, *i. e.* if the one be greater and the other less than the given number, divide the sum of the products by the sum of the errors. The quotient, in either case, will be the answer.

Example. Three partners, A, B, and C, bought a sugar-work which cost them L. 2000; of which A paid a certain sum unknown; B paid as much as A, and L. 50 over; C paid as much as them both, and L. 25 over: What sum did each pay?

(1.) Suppose A paid L. 500
B —— 550
C —— 1075

2125
2000

125 = error of excess.

(2.) Sup-

Pottery.

(2.) Suppose A paid L.400
B —— 450
125 = excess. C —— 875
———
400 = 2d position. 1725
——— 2000
50000 ———
275 = error of defect.
500 = 1st position.
———
1st error, 125 137500
2d —— 275 50000
——— ———
400)187500
———
Answers. { 468.75 = sum paid by A.
518.75 = ——— B.
1012.5 = ——— C. }
———
2000 . . . = proof.

This is called double position.

POTTERY is an art of very considerable importance; and in addition to what has been said on it in the *Encyclopædia*, the following reflections, by that eminent chemist Vauquelin, will probably be acceptable to many of our readers.

Four things (says he) may occasion difference in the qualities of earthen-ware: 1*st*, The nature or composition of the matter; 2*d*, The mode of preparation; 3*d*, The dimensions given to the vessels; 4*th*, The baking to which they are subjected. By composition of the matter, the author understands the nature and proportions of the elements of which it is formed. These elements, in the greater part of earthen ware, either valuable or common, are silex, argil, lime, and sometimes a little oxide of iron. Hence it is evident that it is not so much by the diversity of the elements that good earthen-ware differs from bad, as by the proportion in which they are united. Silex or quartz makes always two-thirds at least of earthen-ware; argil or pure clay, from a fifth to a third; lime, from 5 to 20 parts in the hundred; and iron from 0 to 12 or 15 parts in the hundred. Silex gives hardness, infusibility, and unalterability; argil makes the paste pliable, and renders it fit to be kneaded, moulded, and turned at pleasure. It possesses at the same time the property of being partially fused by the heat which unites its parts with those of the silex; but it must not be too abundant, as it would render the earthen-ware too fusible and too brittle to be used over the fire.

Hitherto it has not been proved by experience that lime is necessary in the composition of pottery: and if traces of it are constantly found in that substance, it is because it is always mixed with the other earths, from which the washings and other manipulations have not been able to separate it. When this earth, however, does not exceed five or six parts in a hundred, it appears that it is not hurtful to the quality of the pottery; but if more abundant, it renders it too fusible.

The oxide of iron, besides the inconvenience of communicating a red or brown colour, according to the degree of baking, to the vessels in which it forms a part, has the property of rendering them fusible, and even in a greater degree than lime.

As some kinds of pottery are destined to melt very penetrating substances, such as salts, metallic oxides, glass, &c. they require a fine kind of paste, which is obtained only by reducing the earths employed to very minute particles. Others destined for melting metals, and substances not very penetrating, and which must be able to support, without breaking, a sudden transition from great heat to great cold, require for their fabrication a mixture of calcined argil with raw argil. By these means you obtain pottery, the coarse paste of which resembles *breche*, or small grained pudding-stone, and which can endure sudden changes of temperature.

The baking of pottery is also an object of great importance. The heat must be capable of expelling humidity, and agglutinating the parts which enter into the composition of the paste, but not strong enough to produce fusion; which, if too far advanced, gives to pottery a homogenuousness that renders it brittle. The same effect takes place in regard to the fine pottery, because the very minute division given to the earths reduces them nearly to the same state as if this matter had been fused. This is the reason why porcelain strongly baked is more or less brittle, and cannot easily endure alternations of temperature. Hence coarse porcelain, in the composition of which a certain quantity of calcined argil is employed, porcelain retorts, crucibles, tubes, and common pottery, the paste of which is coarse, are much less brittle than dishes and saucers formed of the same substance, ground with more labour.

The general and respective dimensions of the different parts of vessels of earthen-ware have also considerable influence on their capability to stand the fire.

In some cases the glazing or covering, especially when too thick, and of a nature different from the body of the pottery, also renders them liable to break. Thus, in making some kinds of pottery, it is always essential, 1*st*, To follow the best proportion in the principles; 2*d*, To give to the particles of the paste, by grinding, a minuteness suited to the purpose for which it is intended, and to all the parts the same dimensions as far as possible; 3*d*, To carry the baking to the highest degree that the matter can bear without being fused; 4*th*, To apply the glazing in thin layers, the fusibility of which ought to approach as near as possible to that of the matter, in order that it may be more intimately united.

C. Vauquelin, being persuaded that the quality of good pottery depends chiefly on using proper proportions of the earthy matters, thought it might be of importance, to those engaged in this branch of manufacture, to make known the analysis of different natural clays employed for this purpose, and of pottery produced by some of them, in order that, when a new earth is discovered, it may be known by a simple analysis whether it will be proper for the same object, and to what kind of pottery already known it bears the greatest resemblance.

	Hessian Crucibles.	Argil of Drenx.	Porcelain Capsules.	Wedgwood's Pyrometer's.

Raw

Porcelain, Poules.

Raw kaolin 100 parts.—Silex 74, argil 16·5, lime 2, water 7. A hundred parts of this earth gave eight of alum, after being treated with the fulphuric acid.

Washed kaolin 100 parts.—Silex 55, argil 27, lime 2, iron 0·5, water 14. This kaolin, treated with the fulphuric acid, gave about 45 or 50 *per cent.* of alum.

Petuntzé.—Silex 74, argil 14·5, lime 5·5. lofs 6. A hundred parts of this fubftance, treated with the fulphuric acid, gave feven or eight parts of alum. But this quantity does not equal the lofs fuftained.

Porcelain of retorts.—Silex 64, argil 28·8, lime 4·55, iron 0·50, lofs 2·77. Treated with the fulphuric acid, this porcelain gave no alum.

There is a kind of earthen veffels, called *Alcarrezes*, ufed in Spain for cooling the water intended to be drunk. Thefe veffels confift of 60 parts of calcareous earth, mixed with alumina and a little oxyd of iron, and 36½ of filiceous earth, alfo mixed with alumina and the fame oxide. The quantity of iron may be eftimated at almoft one hundredth part of the whole. This earth is firft kneaded into a tough pafte. being for that purpofe previoufly diluted with water; formed into a cake of about fix inches in thicknefs, and left in that ftate till it begin to crack. It is then kneaded with the feet, the workman gradually adding to it a quantity of fea falt, in the proportion of feven pounds to a hundred and fifty; after which it is applied to the lath, and baked in any kind of furnace ufed by potters. The alcarrezes, however, are only about half as much baked as the better kinds of common earthen ware; and being exceedingly porous, water oozes through them on all fides. Hence the air, which comes in contact with it by making it evaporate, carries off the caloric contained in the water in the veffel, which is thus rendered remarkably cool.

POULES, or FOULQUES, one of the principal nations which inhabit the banks of the Senegal. They poffefs an extent of more than fixty leagues along the river, and exact heavy cuftoms from the Senegal traders with the interior of the country. They are not fo black as the other negroes, but of a copper colour, much inclining to red. It is remarkable, however, that their children who are fent to Senegal, and refide there for fome years, become much blacker. The females are very handfome, and the whites of Senegal generally take care to procure fome of them. But they are of a bad difpofition, and utterly incapable of attachment. When a man has a miftrefs of this nation, he muft watch her conduct very narrowly, and even chaftife her, that fhe may not be guilty of infidelity to him whom fhe honours with her favours. The dread of the baftinado will, in fuch cafe, effect what attention and complaifance can never bring about.

Although the Poules inhabit one of the fineft fpots in Africa, they are neverthelefs a wretched people; they are bafe, cruel, thievifh, and fanatic in the extreme. They are commanded by a chief of their religion, which is a contemptible mixture of Mahometanifm and idolatry. This chief is called the *Almamy*; he is always chofen from among the Tampfirs, who are twelve in number. The Tampfirs are the interpreters of the law, and are the moft learned, or rather the moft fanatical among them. The Almamy has the power of life and death over his fubjects; yet he may be depofed by an affembly of Tampfirs: it is therefore his intereft to keep on good terms with them. The payment of cuftoms is made to the Almamy, and is afterwards diftributed among the Tampfirs; and although a part belongs to the former, he neverthelefs requires a feparate prefent for himfelf.

Printing

PRINTING. (See that article, *Encycl.* and TYPOGRAPHY in this *Supplement.*) We fhall here only defcribe a *PRINTING Prefs*, for the invention of which a patent was granted, in 1790, to Mr William Nicholfon of New North-ftreet, Red Lion Square, London. This machine, with fome flight varieties, is adapted for printing on *paper*, *linen*, *cotton*, *woollen*, and other articles, in a more neat, cheap, and accurate method, the author thinks, than the printing preffes now in ufe.

The invention confifts in three particulars, 1*ft*, The manner of preparing and placing the types, engravings, or carvings, from which the impreffion is to be made; 2*dly*, In applying the ink or colouring matter to types or engravings; and, 3*dly*, In taking off the impreffion.

1*ft*, Mr Nicholfon makes his moulds, punches, and matrices, for cafting letters, in the fame manner, and with the fame materials, as other letter-founders do, excepting that, inftead of leaving a fpace in the mould for the ftem of one letter only, he leaves fpaces for two, three, or more letters, to be caft at one pouring of the metal; and at the lower extremity of each of thofe fpaces (which communicate by a common groove at top) he places a matrix, or piece of copper, with the letter punched upon its face in the ufual way. And moreover, he brings the ftem of his letters to a due form and finifh, not only by rubbing it upon a ftone, and fcraping it when arranged in the finifhing-ftick, but likewife by fcraping it, on one or more fides, in a finifhing-ftick whofe hollowed part is lefs deep at the inner than the outer fide. He calls that fide of the groove which is neareft the face of the difpofed letter, the outer fide; and the purpofe accomplifhed by this method of fcraping is, that of rendering the tail of the letter gradually fmaller the more remote it is, or farther from the face. Such letters may be firmly impofed upon a cylindrical furface, in the fame manner as common letters are impofed upon a flat ftone.

2*dly*, He applies the ink or colouring matter to the types, forms, or plates, by caufing the furface of a cylinder, fmeared or wetted with the colouring matter, to roll over the furfaces of the faid forms or plates, or by caufing the forms or plates apply themfelves fucceffively to the furface of the cylinder. The furface of this colouring cylinder is covered with leather, or with woollen, linen, or cotton-cloth. When the colour to be ufed is thin, as in calico-printing, and in almoft every cafe, the covering is fupported by a firm elaftic ftuffing, confifting of hair, or wool, or woollen cloth wrapped one or more folds round the cylinder. When the covering confifts of woollen cloth, the ftuffing muft be defended by leather, or oilfkin, to prevent its imbibing too much colour. and by that means lofing its elafticity. It is abfolutely neceffary that the colouring matter be evenly diftributed over the furface of the cylinder; and for this purpofe, when the colour is thick and ftiff, as in letter-prefs printing, he applies two, three, or more fmall cylinders, called diftributing-rollers, longitudinally againft the colouring cylinders, fo that they may be turned by the motion of the latter; and the effect of this application is, that every lump or mafs of colour

which

Printing. which may be redundant, or irregularly placed upon the face of the colouring cylinder, will be pressed, spread, and partly taken up, and carried by the small rollers to the other parts of the colouring cylinder; so that this last will very speedily acquire and preserve an even face of colour. But if the colouring matter be thinner, he does not apply more than one or two of these distributing-rollers; and, if it be very thin, he applies an even blunt edge of metal, or wood, or a straight brush, or both of these last, against the colouring cylinder, for the purpose of rendering its colour uniform. When he applies colour to an engraved plate, or cylinder, or through the interstices of a perforated pattern, as in the manufacturing of some kinds of paper-hangings, he uses a cylinder entirely covered with hair or bristles in the manner of a brush.

3dly, He performs all his impressions, even in letter-press printing, by the action of a cylinder or cylindrical surface. The construction of this machine, and the manner of using it, will be intelligible to every reader who shall attentively consider Plate XL: where fig. 1. represents a printing-press, more especially applicable to the printing of books. A and E are two cylinders, running or turning in a strong frame of wood, or metal, or both. The cylinder A is faced with woollen cloth, and is capable of being pressed with more or less force upon HI, by means of the lever M. HI is a long table, which is capable of moving endwise, backwards and forwards, upon the rollers E and K. The roller A acts upon this table by means of a cog-wheel, or by straps, so as to draw it backwards and forwards by the motion of its handle L. The table is kept in the same line by grooves on its sides, which contain the cylinder A. D is a chase, containing letter set up and imposed. B is a box, containing a colouring-roller, with its distributing-rollers CC; it is supported by the arm N. O is a cylinder faced with leather, and lying across an ink-block; this cylinder is fixed by the middle to a bended lever moveable on the joint Q.

The action. When D, or the letter, is drawn beneath the cylinder B, it receives ink; and when it has passed into the position R, a workman places or turns down a tympan with paper upon it (this tympan differs in no respect from the usual one, except that its hinge opens sidewise); it then proceeds to pass under the cylinder A, which presses it successively through its whole surface. On the other side, at S, the workman takes off the paper, and leaves the tympan up. This motion causes the cylinder B to revolve continually, and consequently renders its inked surface very uniform, by the action of its distributing-rollers CC; and, when the table has passed to its extreme distance in the direction now spoken of, the arm G touches the lever P, and raises the cylinder O off the ink-block, by which means it dabs against one of the distributing-rollers, and gives it a small quantity of ink. The returning motion of the table carries the letter again under the roller B, which again inks it, and the process of printing another sheet goes on as before.

Fig. 2. is another printing-press. In this, B is the inking-roller; A is a cylinder, having the letter imposed upon its surface; and E is a cylinder, having its uniform surface covered with woollen cloth: these three cylinders are connected, either by cogs or straps at the edges of each. The machine is uniformly turned in one direction by the handle L. The workman applies a sheet of paper to the surface of E, where it is retained, either by points in the usual manner, or by the apparatus to be described in treating of fig. 4. The paper passes between E and A, and receives an impression; after which the workman takes it off, and applies another sheet; and in the mean time the letter on the surface of A passes round against the surface of B, and receives ink during the rotation of B. The distributing-rollers CC do their office as in the machine fig. 1.; and once in every revolution the tail F, affixed to B, raises the inking-piece G, so as to cause it to touch one of the distributing-rollers, and supply it with ink. In this way therefore the repeated printing of sheet after sheet goes on. Printing.

Fig. 3. is a printing-press, more particularly adapted to print cottons, silks, paper-hangings, or other articles which run of a considerable length. A is a cylinder covered with woollen cloth, or other soft substance. The web or piece of cotton, or other goods, is passed round this cylinder, from the carrying-roller F to the receiving-rollers GH; which are connected by a piece of linen, woollen, or hair-cloth, in the manner of a jack-towel sewed round them; the rotation of this towel carries away the printed stuff or goods, and deposits them at I. KL is a moveable box, containing three rollers, which move against each other in rotation. The lowest roller C revolves in a mass of colour, contained in a trough or vessel in the bottom part of the box KL; the surface of this colour is represented by the line MN. The next roller B is stuffed and covered as described in section 2. The pressure of B against C prevents the cylinder B from receiving too much colour. D is a cut or carved cylinder, which receives colour, during the rotation, from the roller B, and impresses it upon the web as it passes round the cylinder A; in this way the constant and effectual action of the machine is sufficiently obvious. It must be observed, that the cylinders ADB and G are connected together by cog-wheels, straps, or other well-known equivalent contrivances; so that the handle P drives the whole, without their necessarily depending on any adhesion or friction at their surfaces. The pressure of B against D is governed by an adjustment of the axis of D, whose sockets are capable of a small motion; and the pressure of D against A is governed by the position of the whole box KL. When it is required to print more than one colour upon a piece, Mr Nicholson causes it to pass two or more times through the machine; or, in those cases where the materials are liable to change their dimensions, he applies, at one and the same time, two or more such boxes as KL, with their respective cylinders, so that the pattern cylinder of each may make its impression upon the web or material to be printed on.

Fig. 4. is a printing-press, chiefly of use for books and papers. 1, 2, 3, 4, represents a long table, with ledges on each side; so that the two cylinders A and B can run backwards and forwards without any side shake. In one of these ledges is placed a strip or plate of metal cut into teeth, which lock into correspondent teeth in each cylinder; by which means the two cylinders roll along, without the possibility of changing the relative positions of their surfaces at any determinate part of the table. This may also be effected by straps, and

Printing. and may indeed be accomplished, with tolerable accuracy, by the mere rolling of the cylinders on the smooth or flat ledges without any provision. A is the printing-cylinder, covered with woollen cloth, and B is the inking cylinder, with its distributing rollers. The table may be divided into four compartments, marked with a thicker bounding line than the rest, and numbered 1, 2, 3, 4. At 1 is placed a sheet of paper; at 2 is the form or chase, containing letter set and imposed; at 3 is an apparatus for receiving the printed sheet; and 4 is employed in no other use than as a place of standing for the carriage E, after it has passed through one operation, and when it takes ink at F. Its action is as follows: the carriage is thrust forward by the workman, and as the roller A passes over the space numbered 1, it takes up the sheet of paper previously laid there, while the roller B runs over the form and inks the letter. The sheet of paper, being wrapped round the cylinder A, is pressed against the form as that cylinder proceeds, and consequently it receives an impression. When A arrives at the space numbered 3, it lets go the sheet of paper, while the prominent part of the carriage G strikes the lever P, and raises the inking-piece, which applies itself against one of the distributing rollers. In this manner therefore the cylinder A returns empty, and the cylinder B inked, and in the mean time the workman places another sheet of paper ready in the space numbered 1. Thus it is that the operation proceeds in the printing of one sheet after another.

The preceding description is not incumbered with an account of the apparatus by which the paper is taken up and laid down. This may be done in several ways: Fig. 9. and 10. represent one of the methods. DE is a lever, moving on the centre pin C, and having its end D pressed upwards by the action of the spring G. The shoulder which contains the pin C is fixed in another piece F, which is inserted in a groove in the surface of the cylinder A (fig. 4.), so that it is capable of moving in and out, in a direction parallel to the axis of that cylinder. As that cylinder proceeds, it meets a pin in the table; which (letter P, fig. 9.) acting on the inclined plane at the other end of the lever, throws the whole inwards, in the position represented in fig. 10.; in which case the extremity D shoots inwards, and applies itself against the side of the cylinder.

In fig. 11. is a representation of part of the table; the dotted square represents a sheet of paper, and the four small shaded squares denote holes in the board, with pins standing beside them. When the lever DE (fig. 10.) shoots forward, it is situated in one of these holes, and advances under the edge of the paper, which consequently it presses and retains against the cylinder with its extremity D. Nothing more remains to be said respecting the taking up, but that the cylinder is provided with two pair of these clasps or levers, which are so fixed as to correspond with the four holes represented in fig. 11. It will be easy to understand how the paper is deposited in the compartment n° 3. (fig. 4.). A pin P (fig. 10.) rising out of the platform or table, acts against a pin E, projecting sidewise out of the lever, and must of course draw the slider and its lever to the original position; the paper consequently will be let go, and its disengagement is rendered certain by an apparatus fixed in the compartment numbered 3. (fig. 4.) of exactly the same kind as that upon the cylinder, and which, by the action of a pin duly placed in the surface of the cylinder A, takes the paper from the cylinder in precisely the same manner as that cylinder originally took it up in the compartment numbered 1 (fig 4.)

Figs. 5, 6, and 7, represent a simpler apparatus for accomplishing the same purpose. If A a B b (fig. 7.) be supposed to represent a thick plate of metal of a circular form, with two pins, A and B, proceeding sidewise or perpendicularly out of its plane, and diametrically opposite to each other, and G another pin proceeding in the direction of that plane, then it is obvious that any force applied to the pin A, so as to press it into the position a (by turning the plate on its axis or centre X), will at the same time cause the pin G to acquire the position g; and, on the other hand, when B is at b, or the dotted representation of the side-pin, if any pressure be applied to restore its original position at B, the pin g will return back to G. Now the figures 5 and 6 exhibit an apparatus of this kind, applied to the cylinder A; and that cylinder, by rolling over the pins P and p, properly fixed in the table to re-act upon the apparatus, will cause its prominent part G either to apply to the cylinder and clasp the paper, or to rise up and let it go. The compartment numbered 3 (fig. 4.) must of course have an apparatus of the same kind to be acted upon by pins from A, in order that it may take the paper from that cylinder.

There is one other circumstance belonging to this machine which remains to be explained. When the carriage E (fig. 4.) goes out in the direction of the numbers 1, 2, 3, 4, both rollers, A and B, press the form of letter in their passage; but in their return back again the roller A, having no paper upon it, would itself become soiled, by taking a faint impression from the letter, if it were not prevented from touching it: the manner of effecting this may be understood from fig. 12. The apparatus there represented is fixed upon the outside of the carriage E, near the lower corner, in the vicinity of the roller A; the whole of this projects sidewise beyond the ledge of the table, except the small truck or wheel B. The irregularly-triangular piece, which is shaded by the stroke of the pen, carries this wheel, and also a catch moveable on the axis or pin E. The whole piece is moveable on the pin A, which connects it to the carriage. CD, or the part which is shaded by dotting, is a detent, which serves to hold the piece down in a certain position. It may be observed, that both the detent and the triangular piece are furnished each with a claw, which holds in one direction, but trips or yields in the other, like the jacks of a harpsichord, or resembling certain pieces used in clock and watch making, as is clearly represented in the figure. These claws overhang the side of the table, and their effect is as follows: There is a pin C (fig. 4) between the compartments of the table numbered 2 and 3, but which is marked F in fig. 12. where GH represents the table. In the outward run of the carriage these claws strike that pin, but with no other effect than that they yield for an instant, and as instantly resume their original position by the action of their respective slender back-springs. When the carriage returns, the claw of the detent indeed strikes the pin, but with as little effect as before, because its derangement is instantly removed by the action of the back spring of the detent itself;

 but,

but, when the claw of the triangular piece takes the pin, the whole piece is made to revolve on its axis or pin A, the wheel B is forced down, fo as to lift that end of the carriage, and the detent, catching on the piece at C, prevents the former pofition from being recovered. The confequence of this is, that the carriage runs upon the truck B (and its correfpondent truck on the oppofite fide) inftead of the cylinder A, which is too much raifed to take the letter, and foil itfelf; but as foon as the end of the carriage has paffed clear of the letter, another pin R (fig. 4.) takes the claw of the detent, and draws it off the triangular piece; at which inftant the cylinder A fubfides to its ufual place, and performs its functions as before. This laft pin R does not affect the claw of the triangular piece, becaufe it is placed too low; and the claw of the detent is made the longeft, on purpofe that it may ftrike this pin.

Fig. 8. reprefents an inftrument for printing floor-cloths, paper-hangings, and the like, with ftiff paint and a brufh. D is a copper or metallic cylinder fixed in a frame A, like a garden roller; its carved part is thin, and is cut through in various places, according to the defired pattern. A ftrong axis paffes through the cylinder, and its extremities are firmly attached to the frame A. To this axis is fixed a veffel or box of the fame kind, and anfwering the fame purpofe as the box KL in fig. 3. It carries a cylinder P, which revolves in the colour; another cylinder E, which revolves in contact with P; and a third cylinder B, whofe exterior furface is covered with hair, after the manner of a brufh, and revolves in contact with E. This cylinder B is adjufted by its axis, in fuch a manner that its brufh-part fweeps in the perforated parts of the metallic cylinder D. The circle C reprefents a cog-wheel, fixed concentric to the cylinder D, and revolving with it; this wheel takes another wheel concentric to, and fixed to, B; hence the action is as follows: When the metallic cylinder is wheeled or rolled along any furface, its cog-wheel C drives the brufh B in the contrary direction; and this brufh-cylinder, being connected by cogs or otherwife with E and P, caufes thofe alfo to revolve and fupply it with colour. As the fucceffive openings of the cylinder, D, therefore, come in contact with the ground, the feveral parts of the brufh will traverfe the uncovered part of that ground, and paint the pattern upon it. The wheel G, being kept lightly on the ground, ferves to determine the line of contact, that it fhall be the part oppofite to B, and no other.

PRINTS (fee *Encycl.*) are valuable on many accounts; but they are liable to be foiled by fmoke, vapour, and the excrements of infects. Different methods have, of courfe, been practifed to clean them. Some have propofed fimple wafhing with clear water, or a ley made of the afhes of reeds, and then expofing the prints to the dew. Others have cleaned prints with *aqua fortis* (fulphuric acid); but both thefe methods are attended with a degree of rifk at leaft equal to their advantages. The following method of cleaning prints is recommended in the fecond volume of Nicholfon's Journal of Natural Philofophy, &c. as at once fafe and efficacious:

"Provide a certain quantity of the common muriatic acid, for example three ounces, in a glafs bottle, with a ground ftopper, of fuch a capacity that it may be only half full. Half an ounce of minium muft then be added; immediately after which the ftopper is to be put in, and the bottle fet in a cold and dark place. The heat, which foon becomes perceptible, fhews the beginning of the new combination. The minium abandons the greateft part of its oxygen with which the fluid remains impregnated, at the fame time that it acquires a fine golden yell w, and emits the deteftable fmell of oxygenated muriatic acid. It contains a fmall portion of muriat of lead; but this is not at all noxious in the fubfequent procefs. It is alfo neceffary to be obferved, that the bottle muft be ftrong, and the ftopper not too firmly fixed, otherwife the active elaftic vapour might burft it. The method of ufing this prepared acid is as follows:

"Provide a fufficiently large plate of glafs, upon which one or more prints may be feparately fpread out. Near the edges let there be raifed a border of foft white wax half an inch high, adhering well to the glafs and flat at top. In this kind of trough the print is to be placed in a bath of frefh urine, or water containing a fmall quantity of ox-gall, and kept in this fituation for three or four hours. The fluid is then to be decanted off, and pure warm water poured on; which muft be changed every three or four hours until it paffes limpid and clear. The impurities are fometimes of a refinous nature, and refift the action of pure water. When this is the cafe, the wafhed print muft be left to dry, and alcohol is then to be poured on and left for a time. After the print is thus cleaned, and all the moifture drained off, the muriatic acid prepared with minium is to be poured on in fufficient quantity to cover the print; immediately after which another plate of glafs is to be laid in contact with the rim of wax, in order to prevent the inconvenient exhalation of the oxygenated acid. In this fituation the yelloweft print will be feen to recover its original whitenefs in a very fhort time. One or two hours are fufficient to produce the defired effect; but the print will receive no injury if it be left in the acid for a whole night. Nothing more is neceffary to complete the work than to decant off the remaining acid, and wafh away every trace of acidity by repeated affufions of pure water. The print being then left to dry (in the fun if poffible) will be found white, clear, firm, and in no refpect damaged either in the texture of the paper or the tone and appearance of the impreffion."

The judicious editor of the Journal fubjoins the following note, to which collectors of prints will do well to pay attention: "As I have not repeated this procefs, I cannot eftimate how far the prefence of the lead may weaken the corrofive action of the acid on the paper; but I fhould be difpofed to recommend a previous dilution of the acid with water. Whoever ufes this procefs will of courfe make himfelf mafter of the proportion of water required to dilute the acid, by making his firft trials with an old print of no value."

PRISM, in geometry, is a body or a folid, whofe two ends are any plane figures which are parallel, equal, and fimilar; and its fides, connecting thofe ends, are parallelograms. The definition of this figure in the *Encyclopædia* we muft, in candour, acknowledge to be unaccountably indiftinct, if not unintelligible.

PRISMOID, is a folid or body, fomewhat refembling a prifm, but that its ends are any diffimilar parallel plane figures of the fame number of fides; the up-

right ſides being trapezoids.—If the ends of the priſmoid be bounded by diſſimilar curves, it is ſometimes called a *cylindroid*.

PRISON is ſaid, in the *Encyclopædia*, to be only a place of ſafe cuſtody, not a place of puniſhment. Such was, no doubt, the original intention of Engliſh priſons; but now temporary confinement is, in England as well as elſewhere, inflicted as a puniſhment for certain crimes. Perhaps it would be expedient to ſubſtitute this puniſhment more frequently than is yet done in Great Britain, for tranſportation and death; proportioning the length of the confinement, as well as its cloſeneſs, to the heinouſneſs of the crime. In no country, we believe, is this more accurately done, or to better purpoſe, than in Pennſylvania; and ſurely in no country has impriſonment been more abuſed than in Venice under the old government.

By the laws of Pennſylvania, puniſhment by impriſonment is impoſed, not only as an expiation of paſt offences, and an example to the guilty part of ſociety, but alſo for another important purpoſe—the reformation of the criminal's morals. The regulations of the gaol are calculated to promote this effect as ſoon as poſſible; ſo that the building deſerves the name of a *penitentiary houſe* more than that of a *gaol* (ſee PHILADELPHIA, *Encycl*). As ſoon as a criminal is committed to the priſon, he is made to waſh; his hair is ſhorn; and, if not decently clothed, he is furniſhed with clean apparel. He is then thrown into a ſolitary cell, about nine feet long and four wide, where he remains debarred from the ſight of every living being except his gaoler, whoſe duty is to attend to his bare neceſſities, but who is forbidden on any account to hold converſation with him. If a priſoner be at all refractory, or if the offence for which he is committed be of a very atrocious nature, he is then confined to a cell ſecluded even from the light of heaven. The treatment of each priſoner, during his confinement, is varied according to his crime and his ſubſequent repentance. Solitary confinement in a dark cell is looked upon as the ſevereſt uſage; next, ſolitary confinement in a cell with the admiſſion of light; next, ſolitary confinement in a cell, where the priſoner is allowed to do ſome ſort of work; and, laſtly, labour in company with others. The longeſt period of confinement is for a rape, which is not to be leſs than ten years, nor more than twenty-one; for high treaſon it is not to exceed twelve, nor fall ſhort of ſix years.

The priſoners are obliged to bathe twice every week, proper conveniences for that purpoſe being provided within the walls of the priſon, and alſo to change their linen, with which they are regularly ſupplied. Thoſe in ſolitary confinement are kept upon bread and water; but thoſe who labour are allowed broth, porridge, puddings, and the like. Meat is diſpenſed only in ſmall quantities, twice in the week; and on no pretence whatever is any other beverage than water ſuffered to be brought into the priſon. Thoſe who labour are employed in the trade to which they have been accuſtomed; and for thoſe acquainted with no particular trade, ſome kind of work is deviſed which they can perform. One room is ſet apart for ſhoemakers, another for tailors, a third for carpenters, and ſo on. In the yards are ſtone-cutters, ſmiths, nailers, &c. In a word, this priſon has all the advantages of the raſping houſe of Amſterdam, without any of its enormous defects. See *Correction-Houſe* in this *Suppl*.

The priſon of Venice is of a very different deſcription, and is worthy of notice here only as a curioſity in the annals of tyranny, which has, we hope, paſſed away with the government which contrived it. Dr Moſeley, in conſequence of his being an Engliſh phyſician (a character then highly reſpected in Venice), was permitted, on the 16th of September 1787, to viſit the common priſon, but was abſolutely refuſed admittance into the *Sotto Piombi*, where the ſtate priſoners were kept. As the Doctor believes that no foreigner beſides himſelf ever witneſſed the ſcenes, even in the common priſon, which he relates, we ſhall give his relation in his own words.

"I was conducted (ſays he) through the priſon by one of its inferior dependants. We had a torch with us. We crept along narrow paſſages as dark as pitch. In ſome of them two people could ſcarcely paſs each other. The cells are made of maſſy marble; the architecture of the celebrated Sanſovini.

"The cells are not only dark, and black as ink, but being ſurrounded and confined with huge walls, the ſmalleſt breath of air can ſcarcely find circulation in them. They are about nine feet ſquare on the floor, arched at the top, and between ſix and ſeven feet high in the higheſt part. There is to each cell a round hole of eight inches diameter, through which the priſoner's daily allowance of twelve ounces of bread and a pot of water is delivered. There is a ſmall iron door to the cell. The furniture of the cell is a little ſtraw and a ſmall tub; nothing elſe. The ſtraw is renewed and the tub emptied through the iron door occaſionally.

"The diet is ingeniouſly contrived for the perduration of puniſhment. Animal food, or a cordial nutritious regimen, in ſuch a ſituation, would bring on diſeaſe, and defeat the end of this Venetian juſtice. Neither can the ſoul, if ſo inclined, ſteal away, wrapt up in ſlumbering deluſion, or ſink to reſt, from the admonition of her ſad exiſtence, by the gaoler's daily return.

"I ſaw one man who had been in a cell thirty years; two who had been twelve years; and ſeveral who had been eight and nine years in their reſpective cells.

"By my taper's light I could diſcover the priſoners horrid countenances. They were all naked. The man who had been there thirty years, in face and body was covered with long hair. He had loſt the arrangement of words and order of language. When I ſpoke to him, he made an unintelligible noiſe, and expreſſed fear and ſurpriſe; and, like ſome wild animals in deſerts, which have ſuffered by the treachery of the human race, or have an inſtinctive abhorrence of it, he would have fled like lightning from me if he could.

"One whoſe faculties was not ſo obliterated; who ſtill recollected the difference between day and night; whoſe eyes and ears, though long cloſed with a ſilent blank, ſtill languiſhed to perform their natural functions—implored, in the moſt piercing manner, that I would prevail on the gaoler to murder him, or to give him ſome inſtrument to deſtroy himſelf. I told him I had no power to ſerve him in this requeſt. He then entreated I would uſe my endeavours with the inquiſitors to get him hanged, or drowned in the Canal' Orfano..

fano. But even in this I could not ferve him: death was a favour I had not intereft enough to procure for him.

"This kindnefs of death, however, was, during my ftay in Venice, granted to one man, who had been 'from the cheerful ways of man cut off' thirteen years.

"Before he left his dungeon I had fome converfation with him; this was fix days previous to his execution. His tranfport at the profpect of death was furprifing. He longed for the happy moment. No faint ever exhibited more fervour in anticipating the joys of a future ftate, than this man did at the thoughts of being releafed from life, during the four days mockery of his trial.

"It is in the Canal' Orfano where veffels from Turkey and the Levant perform quarantine. This place is the watery grave of many who have committed political or perfonal offences againft the ftate or fenate, and of many who have committed no offences at all. They are carried out of the city in the middle of the night, tied up in a fack with a large ftone faftened to it, and thrown into the water. Fifhermen are prohibited, on forfeiture of their lives, againft fifhing in this diftrict. The pretence is the plague. This is the fecret hiftory of people being loft in Venice.

"The government, with age, grew feeble; was afraid of the difcuffion of legal procefs and of public executions; and navigated this rotten Bucentaur of the Adriatic by fpies, prifons, affaffination, and the Canal' Orfano."

This is indeed a frightful narrative, and, we doubt not, true as well as frightful; but when, from the ftate of the Venetian prifons, the author infinuates that Howard was not actuated by genuine benevolence, and infers, or wifhes his reader to infer, that the propofal of that celebrated philanthropift for fubftituting folitary confinement, in many cafes, for capital punifhment, muft have refulted from his not taking into confideration the *mind* of the criminal—the infinuation, to fay the leaft of it, is ungenerous, and the conclufion is at war with the premifes. That there was fomething romantic and fuperfluous in Howard's wanderings, we readily admit; but it feems impoffible to doubt of the reality of his benevolence; and though the horrid prifon of Venice, into which, as the Doctor affures us, Mr Howard never entered, was calculated to injure the body without improving the mind of the criminal, it does not follow but that folitary confinement, under fuch regulations as at Philadelphia, is the beft means that have yet been thought of for obtaining the object neareft Howard's heart, the reformation of the morals of the criminal.

PROCYON, in aftronomy, a fixed ftar of the fecond magnitude, in Canis Minor, or the little Dog.

PROSTHAPHERESIS, in aftronomy, the difference between the true and mean motion, or between the true and mean place, of a planet, or between the true and equated anomaly; called alfo *equation of the orbit*, or *equation of the centre*, or fimply the *equation*; and it is equal to the angle formed at the planet, and fubtended by the eccentricity of its orbit.

PROTRACTING, or Protraction, in furveying, the act of plotting or laying down the dimenfions taken in the field, by means of a protractor, &c. Protracting makes one part of furveying.

Protracting-Pin, a fine pointed pin or needle, fitted into a handle, ufed to prick off degrees and minutes from the limb of the protractor

PRUNING. Under this title *(Encycl.)* it is obferved, that when large branches of trees bearing ftone-fruit are taken off, the trees are fubject to gum and decay. For this a remedy has been invented by *Thomas Skip Dyot Bucknall*, Efq; of Conduit-ftreet, which, notwithftanding many objections made to it at firft, experience has proved to be fuccefsful, and for the difcovery of which the Society for the Encouragement of Arts, &c. voted the filver medal to the difcoverer. It is as follows:

Cut every branch which fhould be taken away clofe to the place of its feparation from the trunk; fmooth it well with a knife; and then with a painter's brufh fmear the wound over with what Mr Bucknall calls *medicated tar*. This medicated tar is compofed of one quarter of an ounce of corrofive fublimate, reduced to fine powder by beating with a wooden hammer, and then put into a three pint earthen pipkin, with about a glafs full of gin or other fpirit, ftirred well together, and the fublimate thus diffolved. The pipkin is then filled by degrees with vegetable or common tar, and conftantly ftirred, till the mixture be blended together as intimately as poffible; and this quantity will at any time be fufficient for two hundred trees. To prevent danger, let the corrofive fublimate be mixed with the tar as quickly as poffible after it is purchafed; for, being of a very poifonous nature to all animals, it fhould not be fuffered to lie about a houfe, for fear of mifchief to fome part of the family.

By the application of this compofition, Mr Bucknall can, without the fmalleft danger, ufe the pruning hook on all kinds of trees much more freely than we have recommended its ufe in the article referred to. "I give no attention (fays he) to fruit branches, and wood-branches; but beg, once for all, that no branch fhall ever be fhortened, unlefs for the figure of the tree, and then conftantly taken off clofe to the feparation, by which means the wound foon heals. The more the range of the branches fhoots circularly, a little inclining upwards, the more equally will the fap be diftributed, and the better will the tree bear; for, from that circumftance, the fap is more evenly impelled to every part. Do not let the ranges of branches be too near each other; for remember all the fruit and the leaves fhould have their full fhare of the fun; and where it fuits let the middle of the tree be free from wood, fo that no branch fhall ever crofs another, but all the extreme ends point outwards."

PULO, the name of feveral iflands of Afia, in the Indian Ocean; the principal of which alone, according to Dr Brookes, is inhabited. This is the ifland

Pulo-Condore, which, being vifited by Lord Macartney as he failed to China, is thus defcribed by Sir George Staunton. "It has the advantage of convenient anchoring places in either monfoon. The fquadron accordingly ftopped on the 17th of May, in a fpacious bay on the eaftern fide of the ifland; and came to anchor at the entrance of its fouthern extremity, as the water fhoaled there to five fathoms and a half occafioned by a bank which ftretches acrofs two-thirds of the entrance. It was found afterwards, that beyond the bank there is a fafe paffage to the inner part of the bay,

bay, the north of which is ſheltered by a ſmall iſland lying to the eaſtward. The whole of the bay is formed by four ſmall iſlands, which approach ſo nearly to each other, as to appear, from ſeveral points, to join. They all ſeem to be the rude fragments of primitive mountains, ſeparated from the great continent in the lapſe of time. The principal iſland is eleven or twelve miles in length, and about three in breadth. It is in the form of a creſcent, and conſiſts of a ridge of peaked hills. Its latitude, as calculated from a meridional obſervation, is 8° 40′ north from the equator; and its longitude, according to a good chronometer, is 105° 55′ eaſt from Greenwich.

"The Engliſh had a ſettlement on Condore until the beginning of the preſent century, when ſome Malay ſoldiers in their pay, in reſentment for ſome unjuſtifiable treatment, murdered their ſuperiors, with the exception of a very few who eſcaped off the iſland, where no Europeans have ſince reſided. At the bottom of the bay was a village ſituated cloſe to a fine ſandy beach, with a long range of cocoa-nut trees before it, and it was defended from the north eaſt ſea by a reef of coral rocks, within which was good anchorage for ſmall veſſels, and an eaſy landing for boats. A party went on ſhore from Lord Macartney's ſquadron, with the precaution, however, of being armed, as large canoes were eſpied within the reef, which might have been Malay pirates. Several of the inhabitants came to the beach, and with the appearance of much urbanity of manners welcomed them on ſhore, and conducted them to the houſe of their chief. It was a neat bamboo cabin, larger than the reſt. The floor was elevated a few feet above the ground, and ſtrewed with mats, on which were aſſembled as many men as the place could hold. It was apparently on the occaſion of ſome feſtival, or pleaſurable meeting. There was in one of the apartments an altar decorated with images, and the partitions hung with figures of monſtrous deities; but the countenances and deportment of the people conveyed no idea of religious awe, and no perſon was ſeen in the poſture of prayer or adoration. A few ſpears ſtood againſt the wall with their points downwards, together with ſome matchlocks and a ſwivel gun. The dreſs of thoſe people was compoſed chiefly of blue cotton worn looſely about them; and their flat faces and little eyes denoted a Chineſe origin or relation. Several long ſlips of paper, hanging from the ceiling, were covered with columns of Chineſe writing. One of the miſſionaries, who was of the party, could not, however, in any degree, underſtand their converſation; but when the words were written, they inſtantly became intelligible to him. Though their colloquial language was altogether different from what is ſpoken in China, yet the characters were all Chineſe; and the fact was clearly aſcertained on this occaſion, that thoſe characters have an equal advantage with Arabic numbers, of which the figures convey the ſame meaning wherever known; whereas the letters of other languages denote not things but elementary ſounds, which combined variouſly together, form words, or more complicated ſounds, conveying different ideas in different languages, though the form of their alphabet be the ſame.

"The inhabitants of Pulo Condore were, it ſeems, Cochin-Chineſe, with their deſcendants, who fled from their own country, in conſequence of their attachment to one of its ſovereigns, dethroned by ſeveral of his own ſubjects. It was propoſed to purchaſe proviſions here; and the people promiſed to have the ſpecified quantity ready, if poſſible, the next day, when it was intended, if the weather ſhould be favourable, to land the invalids. The next morning was fair in the beginning; and a party of pleaſure was made from the Hindoſtan to a ſmall iſland cloſe to Pulo Condore. They were ſcarcely arrived upon it when the weather began to lower; and the boat ſet off on its return, in order to reach the ſhip before the impending ſtorm ſhould begin.

"With difficulty it reached the ſhip; and as ſoon as the weather became fair, meſſengers were diſpatched on ſhore to receive and pay for the proviſions promiſed. When they arrived at the village, they were aſtoniſhed to find it abandoned. The houſes were left open, and none of the effects, except ſome arms, that had on the firſt viſit been perceived within them, or even of the poultry feeding about the doors, were taken away. In the principal cabin a paper was found, in the Chineſe language, of which the literal tranſlation purported, as nearly as it could be made, 'that the people of the iſland were few in number, and very poor, yet honeſt, and incapable of doing miſchief; but felt much terror at the arrival of ſuch great ſhips and powerful perſons, eſpecially as not being able to ſatisfy their wants in regard to the quantity of cattle and other proviſions, of which the poor inhabitants of Pulo Condore had ſcarcely any to ſupply, and conſequently could not give the expected ſatiſfaction. They therefore, through dread and apprehenſion, reſolved to fly to preſerve their lives. That they ſupplicate the great people to have pity on them; that they left all they had behind them, and only requeſted that their cabins might not be burnt; and conclude by proſtrating themſelves to the great people a hundred times.'

"The writers of this letter had probably received ill treatment from other ſtrangers. It was determined that they ſhould not continue to think ill of all who came to viſit them. On their return they were perhaps as much ſurpriſed to find their houſes ſtill entire, as their viſitors had been who found they were deſerted. Nothing was diſturbed; and a ſmall preſent, likely to be acceptable to the chief, was left for him in the principal dwelling, with a Chineſe letter, ſignifying, that 'the ſhips and people were Engliſh, who called merely for refreſhment, and on fair terms of purchaſe, without any ill intention; being a civilized nation, endowed with principles of humanity, which did not allow them to plunder or injure others who happened to be weaker or fewer than themſelves."

Pulo Lingen, another of this cluſter, is likewiſe a conſiderable iſland, remarkable for a mountain in its centre, terminating in a fork like Parnaſſus; but to which the unpoetical ſeamen beſtow the name of *aſſes ears*. Every day preſented new iſlands to the view, diſplaying a vaſt variety in form, ſize, and colour. Some iſolated, and ſome collected in cluſters. Many were clothed with verdure; ſome had tall trees growing on them; others were mere rocks, the reſort of innumerable birds, and whitened with their dung.

PUNCTUATION, in grammar, is an art with which we have ſaid, in the *Encyclopædia*, that the ancients were entirely unacquainted. Candour obliges us to

Punctuation. to confess that this was said rashly. A learned writer, in the Monthly Magazine for September 1798, who subscribes J. Warburton, has proved, we think completely, that the art is not wholly modern; and we shall lay his proofs, in his own words, before our readers.

"Some species of pauses and divisions of sentences in speaking and writing must have been coeval with the knowledge of communicating ideas by sound or by symbols. Suidas * says, that the *period* and the *colon* were discovered and explained by Thrasymacus, about 380 years before the Christian æra. Cicero † says, that Thrasymacus was the first who studied oratorical numbers, which entirely consisted in the artificial structure of periods and colons. It appears from a passage in Aristotle ‡, that punctuation was known in his time. The learned Dr Edward Bernard § refers the knowledge of pointing to the time of that philosopher, and says, that it consisted in the different positions of one single point. At the bottom of a letter, thus, (A.), it was equivalent to a comma; in the middle (A·) it was equal to a colon; at the top (A˙) it denoted a period, or the conclusion of a sentence.

* Qui primus periodum et colon monstravit. *Suidas de Thrasymacho.*
† *Cicero Orat.* § 33.
‡ *Rhet.* lib. iii. c. 9.
§ *Bern. Orbis erud. Literat.* tab. 30. edit. 1689.

"This mode was easily practised in Greek manuscripts, while they were written in capitals. But when the small letters were adopted, that is, about the 9th century, this distinction could not be observed; a change was therefore made in the scheme of punctuation. *Unciales literas hodierno usu dicimus eas in vetustis codicibus, quæ priscam formam servant, ac solutæ sunt, nec mutuo colligantur. Hujus modi literæ unciales observantur in libris omnibus ad nonum usque sæculum.*—Montf. Palæog. Recens. p. xii.

"According to Cicero, the ancient Romans, as well as the Greeks, made use of points. He mentions them under the appellation of *librariorum notæ;* and in several parts of his works he speaks of '*interpunctæ clausulæ in orationibus*,' of '*clausulæ atque interpuncta verborum*,' of '*interpunctiones verborum*,' &c. *.

"Seneca, who died A. D. 65, expressly says, that Latin writers, in his time, had been used to punctuation. '*Nos* †, *cum scribimus interpungere consuevimus.*' Muretus and Lipsius imagined that these words alluded to the insertion of a point after each word: but they cetainly were mistaken; for they must necessarily refer to marks of punctuation in the division of sentences, because in the passage in which these words occur, Seneca is speaking of one Q. Haterius, who made no pauses in his orations.

* *Cic. de Orat.* l. iii. § 26. ibid. 7. *Orat pro Murena*, § 25.
† *Sen. Epist.* 40.

"According to Suetonius, in his *Illust. Gram.* Valerius Probus procured copies of many old books, and employed himself in correcting, pointing, and illustrating them; devoting his time to this and no other part of grammar. *Multa exemplaria contracta emendare, ac distinguere et adnotare curavit; soli huic, nec ulli præterea, grammatices parti deditus.*

"It appears from hence, that in the time of Probus, or about the year 68, Latin manuscripts had not been usually pointed, and that grammarians made it their business to supply this deficiency.

"Quintilian, who wrote his celebrated treatise on Oratory about the year 88, speaks of commas, colons, and periods; but it must be observed, that by these terms he means clauses, members, and complete sentences, and not the marks of punctuation ‡.

"Ælius Donatus § published a treatise on Grammar in the 4th century, in which he explains the *distinctio*, the *media distinctio*, and the *subdistinctio;* that is, the use of a single point in the various positions already mentioned.

"Jerom *, who had been the pupil of Donatus, in his Latin Version of the Scriptures, made use of certain distinctions or divisions, which he calls *cola* and *commata*. It has, however, been thought probable, that these divisions were not made by the addition of any points or stops; but were formed by writing, in one line, as many words as constituted a clause, equivalent to what we distinguish by a comma or a colon. These divisions were called στιχοι or ρηματα; and had the appearance of short irregular verses in poetry. There are some Greek manuscripts still extant which are written in this manner †."

‡ *Quint.* l. ix. c. 4.
§ A.D. 340.
* *Hieron. Præf. in E. f..ian. Vide etiam. Præf. in Josuam*, &c. tom. iii. p. 26.
† *Vide Montf. Palæog. Græca*, lib. iii. c. 4.

Mr Warburton says, that the best treatise upon punctuation that he has seen, was published some years since by an anonymous author, and dedicated to Sir Clifton Wintringham, Bart. With that treatise we are not acquainted; but we do not think that the art of punctuation can be taught by rules. The only way to acquire it is to observe attentively how the most perspicuous writers dispose of their periods, colons, semicolons, and commas. This will make us acquainted with the importance of each; and then every writer, who knows his own meaning, must be capable of pointing his own pages more correctly than any other man.

PYRAMIDOID, is sometimes used for the parabolic spindle, or the solid formed by the rotation of a semiparabola about its base or greatest ordinate. See *Parabolic Spindle.*

Pyrites.

PYRITES. See Mineralogy in this *Supplement.*—In the third volume of Mr Nicholson's Philosophical Journal, we have a method of making artificial pyrites, which we shall give in the words of the author.

"I impregnated water (says he) very strongly with carbonic acid, and introducing some iron filings, I continued the impregnation for a day or two, and afterwards allowed the water to stand in a well-corked bottle for some days, till the acid had taken up as much iron as possible. I then poured it into an aerating apparatus; threw up the hepatic gas from sulphuret of potash and sulphuric acid; and after having agitated the water till it had got a good dose of the gas, I poured the water into a large bason: this was in the evening, and next morning when I looked at it, I found it covered with a pretty thick film of a most beautiful variegated pyrites. I had so little of it, that the only proof I had of its being this substance was, that it was ignited on its being placed on a hot poker."

QUADRATURE,

Q.

QUADRATURE, in geometry (fee that article, and likewife FLUXIONS, *Encycl.*), has employed the time and ingenuity of fome of the moft eminent mathematicians both of ancient and of modern times. Dr Halley's method of computing the ratio of the diameter of the circle to its circumference, was confidered by himfelf, and other learned mathematicians, as the eafieft the problem admits of. And although, in the courfe of a century, much eafier methods have been difcovered, ftill a celebrated mathematician of our own times has expreffed an opinion, that no other aliquot part of the circumference of a circle can be fo eafily computed by means of its tangent as that which was chofen by Dr Halley, viz. the arch of 30 degrees. Without taking upon him to determine whether this opinion be juft or not, the Rev. John Hellins has fhewn how the feries by which Dr Halley computed the ratio of the diameter to the circumference of the circle may be transformed into others of fwifter convergency, and which, on account of the fucceffive powers of $\frac{1}{80}$ which occur in them, admit of an eafy fummation. We fhall give the memoir in the author's own words.

"1. The propofed transformation is obtained by means of different forms in which the fluents of fome fluxions may be expreffed; and to proceed with greater clearnefs, "I will here (fays Mr Hellins) fet down the fluxion in a general form, and its fluent, in the two feries which are ufed in the following particular inftance, and may be applied with advantage in fimilar cafes.

"2. The fluent of $\frac{x^{m-1}\dot{x}}{1-x^n}$ is $= \frac{x^m}{m} + \frac{x^{m+n}}{m+n} + \frac{x^{m+2n}}{m+2n} + \frac{x^{m+3n}}{m+3n}$, &c. which feries, being of the fimpleft form which the fluent feems to admit, was firft difcovered, and probably is the moft generally ufeful. But it has alfo been found, that the fluent of the fame fluxion may be expreffed in feries of other forms, which, though lefs fimple than that above written, yet have their particular advantages. Amongft thofe other forms of feries which the fluent admits of, that which fuits my prefent purpofe is $\frac{x^m}{m.\overline{1-x^n}} - \frac{nx^{m+n}}{m.\overline{m+n}.\overline{1-x^n}|^2} + \frac{n.2n.x^{m+2n}}{m.\overline{m+n}.\overline{m+2n}.\overline{1-x^n}|^3} - \frac{n.2u.3n.x^{m+3}}{m.\overline{m+n}.\overline{m+2n}.\overline{m+3n}.\overline{1-x^n}|^4}$ + &c. which, to fay nothing of other methods, may eafily be inveftigated by the rule given in p. 64. of the third edition of *Emerfon's Fluxions;* or its equality with the former feries may be proved by algebra.

"3. On account of the fign — before x^n, in the laft feries, it may be proper to remark, that its convergency, by a geometrical progreffion, will not ceafe till $\frac{x^n}{1-x^n}$ becomes $= 1$, or x becomes $= \sqrt[n]{\frac{1}{2}}$; and that when x is a fmall quantity, and n a large number, this feries will converge almoft as fwiftly as the former. For inftance, if x be $= \sqrt{\frac{1}{3}}$, and $n = 8$, which are the values in the followiug cafe, the former feries will converge by the quantity $x^n = \sqrt{\frac{1}{3}}|^8, = \frac{1}{81}$, and this feries by the quantity $\frac{x^n}{1-x^n} = \frac{\frac{1}{81}}{1-\frac{1}{81}} = \frac{1}{80}$; where the difference in convergency will be but little, and the divifions by 80 eafier than thofe by 81.

"4. With refpect to the indices m and n, as they are here fuppofed to be affirmative whole numbers, and will be fo in the ufe I am about to make of them, the reader need not be detained with any obfervations on the cafes in which thefe fluents will fail, when the indices have contary figns.

"5. It may be proper further to remark, that by putting $\frac{x^n}{1-x^n} = z$, and calling the firft, fecond, third, &c. terms of the feries $\frac{x^m}{m.\overline{1-x^n}} - \frac{nx^{m+n}}{m.\overline{m+n}.\overline{1-x^n}|^2} + \frac{n.2nx^{m+2n}}{m.\overline{m+n}.\overline{m+2n}.\overline{1-x^n}|^3}$ + &c. A, B, C, &c. refpectively, the feries will be expreffed in the concife and elegant notation of Sir Ifaac Newton, viz. $\frac{x^m}{m.\overline{1-x^n}} - \frac{nzA}{m+n} + \frac{2nzB}{m+2n} - \frac{3nzC}{m+3n}$ + &c. which is well adapted to arithmetical calculation.

"6. I come now to the transformation propofed, which will appear very eafy, as foon as the common feries, expreffing the length of an arch in terms of its tangent, is properly arranged.

"If the radius of a circle be 1, and the tangent of an arch of it be called t, it is well known that the length of that arch will be $= t - \frac{t^3}{3} + \frac{t^5}{5} - \frac{t^7}{7} + \frac{t^9}{9} - \frac{t^{11}}{11} +$ &c. Now, if the affirmative terms of this feries be written in one line, and the negative ones in another, the arch will be

$$= \begin{cases} t + \frac{t^5}{5} + \frac{t^9}{9} + \frac{t^{13}}{13} + \frac{t^{17}}{17} + \text{\&c.} \\ -\frac{t^3}{3} - \frac{t^7}{7} - \frac{t^{11}}{11} - \frac{t^{15}}{15} - \frac{t^{19}}{19} - \text{\&c.} \end{cases}$$

And if, again, the firft, third, fifth, &c. term of each of thefe feries be written in one line, and the fecond, fourth, fixth, &c. in another, the fame arch will be expreffed thus:

$$= \begin{cases} + \begin{cases} t + \frac{t^9}{9} + \frac{t^{17}}{17} + \frac{t^{25}}{25} + \frac{t^{33}}{33} + \text{\&c.} \\ \frac{t^5}{5} + \frac{t^{13}}{13} + \frac{t^{21}}{21} + \frac{t^{29}}{29} + \frac{t^{37}}{37} + \text{\&c.} \end{cases} \\ - \begin{cases} \frac{t^3}{3} + \frac{t^{11}}{11} + \frac{t^{19}}{19} + \frac{t^{27}}{27} + \frac{t^{35}}{35} + \text{\&c.} \\ \frac{t^7}{7} + \frac{t^{15}}{15} + \frac{t^{23}}{23} + \frac{t^{31}}{31} + \frac{t^{39}}{39} + \text{\&c.} \end{cases} \end{cases}$$

All which feries are evidently of the firft form in article 2. and therefore their values may be expreffed in the fecond form there given, or more neatly the Newtonian notation mentioned in art. 5. In each of thefe feries the value of n is 8:

And the value of m, $\left\{\begin{array}{l}\text{in the first series, is } 1\,; \\ \text{in the second series, is } 5\,; \\ \text{in the third series, is } 3\,; \\ \text{in the fourth series, is } 7.\end{array}\right.$

" If now we take $t = \sqrt{\frac{1}{3}}$, the tangent of 30°, which was chosen by Dr Halley, we shall have the arch at 30°

$$= \left\{\begin{array}{l} + \left\{\begin{array}{l} \frac{1}{\sqrt{3}} \times : 1 + \frac{1}{9.81} + \frac{1}{17.81^3} + \frac{1}{25.81^3} + \frac{1}{33.81^4}, \text{ \&c.} \\ \frac{1}{9\sqrt{3}} \times : \frac{1}{5} + \frac{1}{13.81} + \frac{1}{21.81^2} + \frac{1}{29.81^3} + \frac{1}{37.81^4}, \text{ \&c.} \end{array}\right. \\ \hline - \left\{\begin{array}{l} \frac{1}{3\sqrt{3}} \times : \frac{1}{3} + \frac{1}{11.81} + \frac{1}{19.81^2} + \frac{1}{27.81^3} + \frac{1}{35.81^4}, \text{ \&c.} \\ \frac{1}{27\sqrt{3}} \times : \frac{1}{7} + \frac{1}{15.81} + \frac{1}{23.81^2} + \frac{1}{31.81^3} + \frac{1}{39.81^4}, \text{ \&c.} \end{array}\right. \end{array}\right.$$

Six times this quantity will be = the semicircumference when radius is 1, and = the whole circumference when the diameter is 1. If therefore we multiply the last series by 6, and write $\sqrt{12}$ for $\frac{6}{\sqrt{3}}$, and express their value in the form given in art. 5. we shall have the circumference of a circle whose diameter is 1,

$$= \left\{\begin{array}{l} + \left\{\begin{array}{l} \frac{81\sqrt{12}}{80} - \frac{8A}{9.80} + \frac{16B}{17.80} - \frac{24C}{25.80} + \frac{32D}{33.80}, \text{ \&c.} \\ \frac{81\sqrt{12}}{5.9.80} - \frac{8A}{13.80} + \frac{16B}{21.80} - \frac{24C}{29.80} + \frac{32D}{37.80}, \text{ \&c.} \end{array}\right. \\ \hline - \left\{\begin{array}{l} \frac{81\sqrt{12}}{3.3.80} - \frac{8A}{11.80} + \frac{16B}{19.80} - \frac{24C}{27.80} + \frac{32D}{35.80}, \text{ \&c.} \\ \frac{81\sqrt{12}}{7.27.80} - \frac{8A}{15.80} + \frac{16B}{23.80} - \frac{24C}{31.80} + \frac{32D}{39.80}, \text{ \&c.} \end{array}\right. \end{array}\right.$$

" 7. All these new series, it is evident, converge somewhat swifter than by the powers of 80. For in the first series, which has the slowest convergency, the coefficients $\frac{8}{9}$, $\frac{16}{17}$, $\frac{24}{25}$, &c. are each of them less than 1; so that its convergency is somewhat swifter than by the powers of 80.

" 8. But another advantage of these new series is, that the numerator and denominator of every term except the first, in each of them is divisible by 8: in consequence of which the arithmetical operation by them is much facilitated, the division by 80 being exchanged for a division by 10, which is no more than removing the decimal point. These series, then, when the factors which are common to both numerators and denominators are expunged, will stand as below (each of which still converging somewhat quicker than by the powers of 80), and we shall have the circumference of a circle whose diameter is 1,

$$= \left\{\begin{array}{l} + \left\{\begin{array}{l} \frac{81\sqrt{12}}{80} - \frac{A}{9.10} + \frac{2B}{17.10} - \frac{3C}{25.10} + \frac{4D}{33.10}, \text{ \&c.} \\ \frac{9\sqrt{12}}{400} - \frac{A}{13.10} + \frac{2B}{21.10} - \frac{3C}{29.10} + \frac{4D}{37.10}, \text{ \&c.} \end{array}\right. \\ \hline - \left\{\begin{array}{l} \frac{9\sqrt{12}}{80} - \frac{A}{11.10} + \frac{2B}{19.10} - \frac{3C}{27.10} + \frac{4D}{35.10}, \text{ \&c.} \\ \frac{3\sqrt{12}}{7.80} - \frac{A}{15.10} + \frac{2B}{23.10} - \frac{3C}{31.10} + \frac{4D}{39.10}, \text{ \&c.} \end{array}\right. \end{array}\right.$$

" By which series the arithmetical computation will be much more easy than by the original series."

Quadrature Lines, or *Lines of Quadrature*, are two lines often placed on Gunter's sector. They are marked with the letter Q, and the figures 5, 6, 7, 8, 9, 10; of which Q denotes the side of a square, and the figures denote the sides of polygons of 5, 6, 7, &c. sides. Also S denotes the semidiameter of a circle, and 90 a line equal to the quadrant or 90° in circumference.

QUADRIPARTITION, is the dividing by 4, or into four equal parts. Hence *quadripartite*, &c. the 4th part, or something parted into four.

QUADRUPLE, is four fold, or something taken four times, or multiplied by 4; and so is the converse of quadripartition.

QUART, a measure of capacity, being the quarter or 4th part of some other measure. The English quart is the 4th part of the gallon, and contains two pints. The Roman quart, or quartarius, was the 4th part of their congius. The French, besides their quart or pot of two pints, have various other quarts, distinguished by the whole of which they are quarters; as *quart de muid*, and *quart de boisseau*.

QUARTILE, an aspect of the planets when they are at the distance of three signs or 90° from each other; and is denoted by the character □.

QUELPAERT, an island lying in the mouth of the channel of Japan, and subject to the king of Corea (See that article *Encycl.*) Till the last voyage of La Perouse, this island was known to Europeans only by the wreck of the Dutch ship Sparrow-hawk in 1635. On the 21st of May 1787, the French Commodore made this island, and determined the south point of it to be in Lat. 33° 14′ north, and in Lon. 124° 15′ east from Paris. He ran along the whole south-east side, at six leagues distance, and says that it is scarcely possible to find an island which affords a finer aspect; a peak of about a thousand toises, which is visible at the distance of eighteen or twenty leagues, occupies the middle of the island, of which it is doubtless the reservoir; the land gradually slopes towards the sea, whence the habitations appear as an amphitheatre. The soil seemed to be cultivated to a very great height. By the assistance of glasses was perceived the division of fields; they were very much parcelled out, which is the strongest proof of a great population. The very varied gradation of colours, from the different states of cultivation, rendered the view of this island still more agreeable. Unfortunately, it belongs to a people who are prohibited from all communication with strangers, and who detain in slavery those who have the misfortune to be shipwrecked on these coasts. Some of the Dutchmen of the ship Sparrow-hawk, after a captivity of eighteen years there, during which they received many bastinadoes, found means to take away a bark, and to cross to Japan, from which they arrived at Batavia, and afterwards at Amsterdam.

QUEUE d'aronde, or *Swallow's Tail*, in fortification, is a detached or outwork, whose sides spread or open towards the campaign, or draw narrower and closer towards the gorge. Of this kind are either single or double tenailles, and some horn-works, whose sides are not parallel, but are narrow at the gorge, and open at the head, like the figure of a swallow's tail. On the contrary, when the sides are less than the gorge, the work is called *contre queue d'aronde*.

Queue, Quintal. *Queue d'aronde*, in carpentry, a method of jointing, called alſo *dove-tailing*.

QUINTAL, the weight of a hundred pounds, in moſt countries: but in England it is the hundred weight, or 112 pounds. Quintal was alſo formerly uſed for a weight of lead, iron, or other common metal, uſually equal to a hundred pounds, at 6 ſcore to the hundred.

Quintile. QUINTILE, in aſtronomy, an aſpect of the planets when they are diſtant the 5th part of the zodiac, or 72 degrees; and is marked thus, C, or O.

R.

Rachitis. RACHITIS, RICKETS (See MEDICINE-*Index*, *Encycl.*), is a diſeaſe ſo formidable to children that we believe no parent will think the following abſtract of *Bonhomme's* memoir on the nature and treatment of it too long even for this *Supplement*.

The change which the bones undergo in this diſorder, has long been attributed to the action of an acid on their ſubſtance; but this ſuppoſition was grounded on mere conjecture and remote analogy. Bonhomme holds the ſame opinion on better grounds; and the principal notions which conſtitute the baſis of his memoir are the following:

1. According to him, the nature of the rachitic diſorder ariſes, on the one hand, from the developement of an acid approaching in its properties to the vegetable acids, particularly the oxalic; and, on the other, from the defect of phoſphoric acid, of which the combination with the animal calcareous earth forms the natural baſis of the bones, and gives them their ſolidity. Whence it follows, that the indication reſulting from this propoſition, if once adopted, would be, that the treatment of rachitis muſt depend on two principal points, namely. to prevent the developement of the oxalic acid, and to re-eſtabliſh the combination of the phoſphoric acid with the baſis of the bones to which they owe their ſolidity.

2. The author proves, by experiments and obſervations, in the firſt place, that alkaline lotions of the parts affected with rachitis contribute to their cure; next, that the calcareous phoſphate taken internally is really tranſmitted by the lymphatic paſſages, and contributes to oſſification; and, laſtly, that the internal uſe of calcareous phoſphate, whether alone or combined with the phoſphate of ſoda, powerfully contributes to reſtore the natural proportions in the ſubſtance of the bones, and accelerate the cure of rachitis.

With regard to the author's endeavours to prove that the calcareous acid is wanting in the bones of thoſe who are diſordered with rachitis, and that the developement of oxalic acid contributes to the diſeaſe, we muſt not conceal that his memoir contains views rather than abſolute proofs of theſe two poſitions, He declares, himſelf, he was not provided with the neceſſary means to eſtabliſh an exact and complete analyſis. He therefore preſents his ideas, in this reſpect, merely as conjectures approaching to the truth.

The effect of the action of acids upon bones was before known; that is to ſay, that when deprived of calcareous phoſphate, and reduced to the gelatinous parenchyma which forms one of their elements, they loſe their conſiſtence, and become flexible. Hence it was already conjectured by various phyſicians, that the rachitis was the effect of a peculiar acid.

A diſpoſition to aſceſcence in the firſt paſſages is obſervable in all infants. The odour which characterizes this aceſcence is often manifeſt in their breath, and even their perſpiration. The bile corrects this diſpoſition; but in general the bile is wanting in rachitic infants. It does not colour their excrements, and the acids accordingly are developed in a very decided manner. They diſturb the circulation, and attack and ſoften the bones. As it is by defect of animalization that theſe acids develope themſelves, it follows that their character is analagous to the fermenteſcible vegetable acids, and more or leſs to the oxalic acid; and that, on the contrary, the animal acid or phoſphoric acid ceaſes to be formed, and to unite with the animal calcareous earth; whence they are deprived of the principle of their ſolidity. This is the theory of Citizen Bonhomme.

In order to eſtabliſh this doctrine upon preciſe experiments, it was requiſite to analyſe rachitic bones comparatively with thoſe of healthy individuals of the ſame age; and as it is known that the urine of rachitic ſubjects depoſites a great quantity of a ſubſtance of ſparing ſolubility and earthy appearance, it would have been advantageous to have joined a complete analyſis of this urine and its ſediment. Citizen Bonhomme, not being provided with the means ſufficient to make theſe analyſes, and being beſides of opinion that ſuch rachitic bones as are deſtroyed by this malady exiſt in a progreſſive ſtate of change, which might render their analyſis ſcarcely ſuſceptible of compariſon, limited himſelf to a collection of ſome of the moſt remarkable phenomena of the urine, of the aged, the adult, and infants in the healthy ſtate, of infants in the rachitic ſtate, and of patients after the perfect cure of this diſorder. From theſe obſervations he has deduced ſeveral important reſults.

It is known, that when the urine contains diſengaged phoſphoric acid, as happens to aged individuals, and in ſome peculiar circumſtances of the ſyſtem, if lime water be poured in, there is a ſpeedy depoſition of calcareous phoſphate. It is alſo known, that when a ſolution of the nitrate of mercury is poured to the freſh urine of adults, a roſe-coloured precipitate is formed, which is a phoſphate of mercury produced by the decompoſition of the phoſphates contained in the urine. Theſe two proofs are therefore extremely proper to aſcertain the preſence of phoſphoric acid, whether free or combined, in a fluid which in its natural ſtate contains a remarkable proportion. Beſides this principle, the urine depoſits more or leſs of ſediment, either gelatinous or of an earthy appearance; and, laſtly, by evaporation, a ſaponaceous and ſaline extract, in greater or leſs abundance, is obtained by evaporation. By means of theſe four methods of examination, the author has aſcertained the following facts:

1. In the healthy ſtate, the ſediment naturally depoſited by urine is almoſt totally gelatinous in the infant and the adult, and in the aged individual it is ſurcharged with an abundant ſediment of an earthy appearance ſimilar to the earth of bones, which conſequently is calcareous phoſphate. 2. The quantity of brown ſaponaceous ſaline extract afforded by evaporation is greater in proportion to the age. 3. The preſence of diſengaged phoſphoric acid, as ſhewn by lime water, is none in the urine of infants, ſcarcely perceptible in that of adults, but very remarkable in that of old men. For two ounces of this laſt urine afforded by this means ten grains of phoſphate of lime. 4. The decompoſition of the phoſphates by nitrate of mercury is not ſeen in the urine of infants; an abundant precepitate of a light roſe-colour is produced in this way from the urine of adults; and in that of old men this precipitate is always of a grey colour, and very abundant. Hence Citizen Bonhomme concludes, that the phoſphoric acid, whether at liberty or combined, does exiſt in the urine of healthy individuals in proportion to the deſtruction of the ſolids by age, and that it increaſes with the age.

With regard to the urine of rachitic ſubjects, the moſt remarkable facts are, 1. The abundant and apparently earthy ſediment it depoſits (ſpontaneouſly) is different from that of old men, by its colour, which is grey, and does not reſemble phoſphate of lime, and alſo by its much greater quantity. For a pound of this urine let fall two gros, whereas the ſame quantity of the urine of old men depoſited only 45 grains. 2. The extract left by evaporation is likewiſe much more conſiderable than in other urine. It is one third more in quantity than the extract afforded even by the urine of aged perſons.

From theſe two firſt obſervations it follows, that the ſolids in rachitic ſubjects are deſtroyed with much more rapidity than even in old men; and that they afford a much more abundant portion of waſte to the urine.

3. The light depoſition occaſioned by lime water in the urine of rachitic ſubjects is very ſmall in quantity, brown, gelatinous when freſh, and pulverulent when dry. It does not at all reſemble calcareous phoſphate. 4. The depoſition formed by the ſolution of mercurial nitrate is not abundant, neither of a roſe colour as in the urine of adults, nor grey like that of old men. It is always white, and conſequently has no external reſemblance to the phoſphate of mercury. The author affirms that it reſembles a mercurial oxalate. Laſtly, the urine of the ſame rachitic ſubjects, when cured, exhibits again all the characters obſerved in the urine of healthy children. We ſhall not add to the reflections of the author. In effect, though theſe firſt obſervations are curious, they are incomplete. We offer them to phyſicians ſimply as the elements of an inveſtigation which it is of importance to continue and bring to perfection. We ſhall therefore proceed to the curative and experimental parts of the memoir.

One of the facts which it was of the utmoſt importance to eſtabliſh, was the tranſition of the calcareous phoſphate from the inteſtinal paſſages, into thoſe of circulation and ſecretion. Fourcroy had already well aſcertained that the ſerum of milk contains the ſalt naturally. Vauquelin had proved its exiſtence, as well as that of pure ſoda, in the ſeminal fluid; but was it poſſible that it could paſs unaltered from the ſtomach and inteſtines into the veſſels which contain the blood and lymph? Could it by this means apply itſelf to the bones? This was to be aſcertained by experiments; and the following are the experiments made by Bonhomme for that purpoſe. We give them in a tranſlation of his own words.

"I cauſed (ſays he) ſeveral young fowls of the ſame incubation to be fed in different manners. Some received the uſual food without any mixture; others received daily a certain quantity of calcareous phoſphate mixed in the ſame paſte as formed the ſupport of the others; and, laſtly, one of them was fed with variations in the uſe of the mixture; the calcareous phoſphate was ſometimes given and ſometimes ſuſpended. When theſe fowls, after two months, had acquired their ordinary growth, I examined and carefully compared the ſtate of their bones. The progreſs of the oſſification in the epiphyſes was various according to the nature of the food the animal had received. The bones of the laſt fowl, which had received the phoſphate only from time to time, were rather more advanced than the bones of thoſe which had been fed without mixture. The bones of thoſe fowls which had been habitually fed with the mixture were evidently more ſolid, and their epiphyſes were much leſs perceptible. Simple inſpection was ſufficient to ſhew theſe differences when the bones were mixed together.

"I had fed ſeveral young fowls of the ſame incubation according to another plan. Some were fed on a ſimple paſte, without mixture; for others it was mixed with pulveriſed madder-root; and a third compoſition was made of this laſt paſte and calcareous phoſphate. This was alſo given habitually to other fowls. When after two months I examined the progreſs of oſſification in the bones of theſe different animals, I eaſily perceived the red traces of the madder in the oſſified parts of all thoſe which had uſed it; but I obſerved, that the oſſification was not more advanced by the ſimple mixture of this root than by the ordinary food: on the contrary, the bones of thoſe fowls which had ſwallowed the phoſphate mixed with madder were much more ſolid than the others. The red colour ſerved admirably to diſtinguiſh the extremities of the long bones from their epiphyſes. After an exact compariſon, there could be no doubt of the efficacy of calcareous phoſphate in favour of the progreſs of oſſification. The virtue of the madder ſeemed confined to that of giving colour to the oſſified parts."

From theſe experiments, it was natural to make the trial of calcareous phoſphate in addition to the remedies made uſe of in the treatment of rachitic ſubjects. Here follows what the author himſelf ſays of two remarkable inſtances in which the calcareous phoſphate was adminiſtered with ſucceſs:

"The daughter of Mr Ranchon watch-maker, aged two years and a half, walked with a feeble and tottering pace, and the extremities of all her bones preſented epiphyſes very

very prominent. In this fituation fhe exhibited the appearance of imperfect rachitis, or the firft period of this diforder. Alkaline lotions, which I immediately advifed, were attended with a good effect. Her fleep became more firm; and as the firft paffages were in a good ftate, I gave, without internal preparation, one fcruple of a mixture of equal parts of phofphate of lime and phofphate of foda twice a day. In the courfe of three weeks her legs were perfectly reftored; and this amiable infant has ever fince had the fatisfaction to run with fpirit and agility.

" A female infant, of the name of Boiard, aged four years, had experienced from her birth the moft decided fymptoms of rachitis. The protuberance of the epiphyfes and tumefaction of the abdomen firft indicated the difeafe. The impoffibility of fupporting herfelf and walking at the ufual age confirmed thefe unfortunate fymptoms. By degrees the glands of the neck and of the mefentary became fwelled; the teeth were blackened, became carious, and were not replaced. This fituation became ftill more afflicting by crifes almoft periodical at an interval of three or four weeks. At thefe afflicting periods, a fever of confiderable ftrength, cardialgia, and even convulfions, particularly in the night, were obferved. The termination of each paroxyfm was announced or afcertained by abundant ftools, and the evacuation of urine ftrongly charged with an earthy fediment. The imprudent exhibition of a purge at the beginning of one of thefe crifes had nearly deprived the patient of her life. In this ftate it was that I beheld her for the firft time in the month of January 1791. The alkaline lotion was the only remedy the mother adopted in the firft inftance, and it produced a remarkable effect. After eight days the infant was fo much better as to be able to fupport herfelf. The remedy was then laid afide, and eight days afterwards the child was incapable of ftanding without fupport. The ufe of the alkaline folution being renewed, was attended with the fame fuccefs, and its difcontinuance was again followed by the complete return of all the fymptoms. In the firft days of March, the other remedies I had advifed were exhibited. The conftipation which had always exifted became lefs, and the following crifis was effected without pain. And at length the convulfions, the pains, and the crifes difappeared; but the impoffibility of walking ftill remained. At this time, namely, on the fecond of May, I gave the child the phofphate of foda and calcareous phofphate mixed together, in the dofe of half a dram twice a-day. At the end of the month fhe was able to ftand upright, leaning againft a chair, and the fwellings began to diminifh. She continued for a long time afterwards to take the mixture of the phofphates. I likewife gave her occafionally one grain of the extract of bile, prepared with fpirit of wine; and at length in the month of July I had the pleafure to fee the patient run and play in the middle of the ftreet with the other children of her own age, &c."

The author gives other inftances of this medicine being adminiftered with complete fuccefs to rachitic children, and one in which it was attended with the beft effects in a cafe of incurvated fpine. Thefe it is needlefs to infert, becaufe we truft that none of our lefs learned readers will have recourfe to the medicine without the advice of a phyfician; and to him an enumeration of cafes could ferve no purpofe. It may be proper, however, as alkaline lotions and their beneficial effects are mentioned, to give here the author's account of the lotion which he ufed.

" In ordinary cafes of rachitis, particularly at the commencement of the diforder, it is of advantage to ufe a fimple folution of pot-afh to wafh the parts affected. This folution is made by diffolving from half an ounce to an ounce of purified pot-afh in a pound of diftilled or very pure fpring-water. When it is to be ufed, the fkin muft firft be rubbed with a dry cloth, or a piece of fine flannel. After this precaution, the difeafed extremities are to be wafhed carefully with the warm folution, and at length wiped, fo as to leave no trace of moifture. This practice and wafhing muft be repeated at leaft twice a-day. I can affirm, from repeated trials, that it will foon be attended with fuccefs."

In a note on this paffage, M. Hallé, who analyfed the memoir at the defire of the Society of Medicine at Paris, juftly obferves, that as pure potafs, or the vegetable alkali, is a moft powerful cauftic, it cannot be ufed in thefe proportions; adding, that he found one-eighth part of the falt here indicated to form too ftrong a lotion for the fkin of an infant. M. Bonhomme, upon enquiry being made, informed him that the potafs which he ufed was that of the fhops, which is very far from being pure; and Mr Nicholfon conjectures that it was the common falt of tartar of our fhops. This, we think, extremely probable, efpecially as M. Bonhomme affures us that even a lixivium of wood-afhes, fuch as is ufed for wafhing fine linen, may anfwer the purpofe extremely well.

For a fuller account of this interefting memoir our readers are referred to the 17th volume of the *Annals de Chimie*, or to the firft volume of *Nicholfon's Philofophical Journal*.

RAJA, the *ray fifh*. See *Encyclopædia*, where it is faid that the *oxyrinchus* or fharp nofed ray, is fuppofed to be the *bos* of the ancients; but if there be any truth in the following narrative, which we confefs has much the air of fiction, this is probably a miftake. It is the narrative of Vaillant, and we fhall give it in his own words.

" In the latitude of 10° 15′ north, and longitude 355°, an enormous flat fifh of the ray genus (fays he), came and fwam round our veffel. It differed from the common ray, however, in the fhape of its head, which, inftead of being pointed, formed a crefcent, and from the extremities of the femicircle iffued two arms as it were, which the failors called horns. They were two feet wide at the bafe, and only five inches at the extremity. This monfter they told me was called the *fea-devil*.

" A few hours after, we faw two others with this, one of which was fo extremely large, that it was computed by the crew to be *fifty* or *fixty* feet wide. Each fwam feparately, and was furrounded by thofe fmall fifh which ufually precede the fhark, and which are therefore called by feamen *pilot-fifh*. Laftly, all three carried on each of their horns a white fifh, about the fize of a man's arm, and half a yard long, which appeared to be ftationed there on duty.

" You would have faid they were two fentinels placed to keep watch for the fafety of the animal, to inform him of any approaching danger, and to guide his movements. If he approached too near the veffel, they quitted their pofts, and, fwimming brifkly before, led him

him away. If he rofe too high above the water, they paffed backward and forward over his back till he had defcended deeper. If, on the contrary, he fwam too low, they difappeared, and we faw no more of them, becaufe, no doubt, they were paffing underneath, as in the preceding inftance they had paffed above him. Accordingly we found him reafcend towards the furface, and then the two fentinels reaffumed their pofts, each on his horn."

Thefe manœuvres continued three days; and to give our author the better opportunity of obferving them, the fhip moft fortunately was becalmed the whole time. He was naturally very defirous of catching one of them that he might examine it at leifure; and, by bribing the feamen with a dozen of bottles of wine, he accomplifhed his object. One of the fifh was ftruck with twelve or fifteen harpoons; feveral halfers were paffed round his body, and he was hoifted on board.

"This (fays our author) was the leaft of the three, being only *eight-and-twenty* feet in its extreme breadth, and *one-and-twenty* in length from the extremity of the horns to that of the tail. The tail, which was thick in proportion to the body, was *twenty-two inches* long. The mouth, placed exactly like that of the ray, was wide enough to fwallow a man with eafe. The fkin was white under the belly, and brown on the back, like that of the ray. We reckoned the animal to weigh not lefs, certainly, than a ton."

We think it was fortunate that they chanced to ftrike the fmalleft fifh; for an addition of eight or ten ton weight, which the largeft ray muft have weighed, as certainly as the fmalleft weighed one ton, might have been very inconvenient on board a fhip already loaded. We do not remember to have anywhere met with a defcription of this ray before, and we think it fhould be confidered as a new fpecies; but we fhall not give it a name till its exiftence be better afcertained, when we fubmit to the pupils of Linnæus, whether it may not be proper to give it the ancient name *bos*.

RAJAH (See *Encycl.*) We learn from Sir Charles Roufe Boughton's *Differtation concerning the Landed Property of Bengal*, that this title is conferred upon Hindoos by the Emperor, and frequently given out of courtefy to the greater zemindars. It would appear therefore that the Rajahs can never be independent of the Mogul but by a fuccefsful rebellion.

RAYEL UL-MULK, in the language of Bengal, the ufage of the country, the common law

RATIO (See *Encycl.*) has been defined by Euclid, in the 5th book of his Elements, in terms to which many mathematicians have objected; and his definition of proportion, which is fo ultimately connected with it, is ftill more objectionable. The Rev. Abraham Robertfon of Oxford, in a fmall tract publifhed in 1789, demonftrates the truth of the two definitions in queftion in feven propofitions, of which the fubftance is as follows. He firft lays down thefe four definitions:

"1. Ratio is the relation which one magnitude has to another, of the fame kind, with refpect to quantity.

"2. If the firft of four magnitudes be exactly as great when compared to the fecond, as the third is when compared to the fourth, the firft is faid to have to the fecond the fame ratio that the third has to the fourth.

"3. If the firft of four magnitudes be greater, when compared to the fecond, than the third is when compared to the fourth, the firft is faid to have to the fecond a greater ratio than the third has to the fourth.

"4. If the firft of four magnitudes be lefs, when compared to the fecond, than the third is when compared to the fourth, the firft is faid to have to the fecond a lefs ratio than the third has to the fourth."

He then demonftrates, by reafoning ftrictly geometrical, the following propofitions:

Prop. 1. If the firft of four magnitudes have to the fecond the fame ratio which the third has to the fourth; then, if the firft be equal to the fecond, the third is equal to the fourth; if greater, greater; if lefs, lefs.

Prop. 2. If the firft of four magnitudes be to the fecond as the third to the fourth, and if any equimultiples whatever of the firft and third be taken, and alfo any equimultiples of the fecond and fourth; the multiple of the firft will be to the multiple of the fecond as the multiple of the third to the multiple of the fourth.

Prop. 3. If the firft of four magnitudes be to the fecond as the third to the fourth, and if any like aliquot parts whatever be taken of the firft and third, and any like aliquot parts whatever of the fecond and fourth, the part of the firft will be to the part of the fecond as the part of the third to the part of the fourth.

Prop. 4. If the firft of four magnitudes be to the fecond as the third to the fourth, and if any equimultiples whatever be taken of the firft and third, and any whatever of the fecond and fourth; if the multiple of the firft be equal to the multiple of the fecond, the multiple of the third will be equal to the multiple of the fourth; if greater, greater; if lefs, lefs.

Prop. 5. If the firft of four magnitudes be to the fecond as the third is to a magnitude lefs than the fourth, then it is poffible to take certain equimultiples of the firft and third, and certain equimultiples of the fecond and fourth, fuch, that the multiple of the firft fhall be greater than the multiple of the fecond, but the multiple of the third not greater than the multiple of the fourth.

Prop. 6. If the firft of four magnitudes be to the fecond as the third is to a magnitude greater than the fourth, then certain equimultiples can be taken of the firft and third, and certain equimultiples of the fecond and fourth, fuch, that the multiple of the firft fhall be lefs than the multiple of the fecond, but the multiple of the third not lefs than the multiple of the fourth.

Prop. 7. If any equimultiples whatever be taken of the firft and third of four magnitudes, and any equimultiples whatever of the fecond and fourth; and if when the multiple of the firft is lefs than that of the fecond, the multiple of the third is alfo lefs than that of the fourth; or if when the multiple of the firft is equal to that of the fecond, the multiple of the third is alfo equal to that of the fourth; or if when the multiple of the firft is greater than that of the fecond, the multiple of the third is alfo greater than that of the fourth: then, the firft of the four magnitudes fhall be to the fecond as the third to the fourth.

RATIONAL, in arithmetic, &c. the quality of numbers, fractions, quantities, &c. when they can be expreffed by common numbers; in contradiftinction to irrational or furd ones, which cannot be expreffed in common numbers.

RAYNAL (William Thomas), commonly called the Abbé Raynal, was educated among the Jefuits, and had become one of the order. The learning of that Society is univerfally

Raynal. universally known as well as the happy talents which its superiors possessed, of assigning to each member his proper employment. Raynal, however, after having acquired among them a taste for literature and science, had probably become refractory, for he was expelled from the order; and the cause of his expulsion, according to the Abbé Barruel, was his impiety.

With the real cause of his expulsion M. Barruel is surely much better acquainted than we can pretend to be; but we have a strong suspicion that his impieties had not then reached farther than to call in question the supreme authority of the church; for our author himself assures us, that he did not utter his atrocious declarations against Christianity 'till he had ceased to be a member of the order of Jesuits. He then associated himself with Voltaire, D'Alembert, and Diderot, and was by them employed to furnish the theological articles for the *Encyclopédie*. But though his religious opinions were certainly lax, and his moral principles very exceptionable, he could not even then be what, in a Protestant country, would be deemed a man remarkable for impiety; for he employed the Abbé Yvon, whom M. Barruel calls an odd metaphysician, but an inoffensive and upright man, to write the articles which he was engaged to furnish. In the conducting of this transaction, he shewed, indeed, that he possessed not a proper sense of honour; for he paid poor Yvon with twenty-five louis d'ores for writing theological articles, for which he received himself six times that sum. This trick was discovered, Raynal was disgraced, and compelled to pay up the balance to Abbé Yvon; but tho' he had thus shewn himself to be without honour, it is difficult to believe that he had yet proceeded so far as to blaspheme Christ, since he had employed a Christian divine to supply his place in the *Encyclopédie*.

His first work of eminence, and that indeed upon which his fame is chiefly built, is his "Political and Philosophical History of the European Settlements in the East and West Indies." That this history is written in an animated style, and that it contains many just reflections, both political and philosophical, is known to all Europe; for it has been translated into every European language. Its beauties, however, are deformed by many sentiments that are irreligious, and by some that are impure. It was followed, we think, in 1780, by a small tract entitled "The Revolution of America;" in which the author pleads the cause of the revolted colonists with a degree of zeal, censures the conduct of the British government with a keenness of asperity, and displays a knowledge of the principles and intrigues of the different factions which at that period divided the English nation, that surely was not natural to the impartial pen of a philosophic foreigner. Hence he has been supposed to have been incited to the undertaking, and to have been furnished with part of his materials, by that desperate faction which uniformly opposed the measures of Lord North, and secretly fomented the rebellion in America. Be this as it may, he propagated, both in this tract and in his history, a number of licentious opinions respecting government and religion, of which he lived to regret the consequences.

A prosecution was instituted against him by the French government on account of his history of the East and West Indies; but it was conducted with so little severity that he had sufficient time to retire to the dominions of Raynal. the King of Prussia, who afforded him the protection he solicited, although his Majesty's character was treated by the author in his book with no great degree of veneration. Raynal also experienced the kindness of the Empress of Russia; and it is not a little remarkable of this singular personage, that although he was always severe in discussing the characters of princes, yet the most despotic among these heaped upon him many marks of favour and generosity. The Abbé also received a very unusual mark of respect from a British House of Commons. It was once intimated to the speaker that Raynal was a spectator in the gallery. The business was immediately suspended, and the stranger conducted to a more convenient and honourable situation. How different was the conduct of Dr Johnson, who, when a friend advanced to him with our author, saying, "Will you give me leave, Doctor, to introduce to you the Abbé Raynal?" turned on his heel, and vociferated, "No, Sir!" We are far from wishing to vindicate the rudeness of the sage; but it was perhaps as proper as the politeness of the House of Commons.

The great trait of Raynal's character was a love of liberty, which, in his earlier writings, he did not properly define; but when he lived to see some of the consequences of this, in the progress of the French Revolution, he made one glorious effort to retrieve his errors. In the month of May 1791, he addressed to the constituent assembly one of the most eloquent, argumentative, and impressive letters that ever was written on any subject; a letter which, if the majority of them had not been intoxicated with their newly acquired consequence, must have given some check to their mad career. After complimenting them upon what they had done, he proceeds thus: "I have long dared to speak to kings of their duty; suffer me now to speak to the people of their errors, and to their representatives of the dangers which threaten us. I am, I own to you, deeply afflicted at the crimes which plunge this empire into mourning. Is it true that I am to look back with horror at myself for being one of those who, by feeling a noble indignation against arbitrary power, may perhaps have furnished arms to licentiousness? Do then religion, the laws, the royal authority, and public order, demand back from philosophy and reason the ties which united them to the grand society of the French nation, as if, by exposing abuses, and teaching the rights of the people and the duties of princes, our criminal efforts had broken those ties? But, no!—never have the bold conceptions of philosophy been represented by us as the strict rule for acts of legislation.

"You cannot justly attribute to us what could only be the result of a false interpretation of our principles. Alas! now that I stand on the brink of the grave; now that I am about to quit this immense family, whose happiness I have ardently desired, what do I see around me? Religious troubles, civil dissensions, consternation on the one hand, tyranny and audacity on the other; a government the slave of popular tyranny; the sanctuary of the laws surrounded by unruly men, who alternately dictate or despise those laws; soldiers without discipline; leaders without authority; ministers without means; a king, the first friend of his people, plunged into bitterness, insulted, menaced, stripped of all authority; and the public power no longer existing but in in clubs, in which ignorant and rude men dare to decide all political queftions."

He then proceeds to prove, which he does very completely, that it was not the bufinefs of the affembly to abolifh every ancient inftitution; that the genius of the French people is fuch, that they never can be happy or profperous but under a well regulated monarchical government; and that, if they wifhed not the nation to fall under the worft kind of defpotifm—the defpotifm of a low faction, they muft increafe the power of the king. "Alas! (continues he) what are my fufferings, when in the heart of the capital, in the centre of knowledge, I fee this mifguided people welcome, with a ferocious joy, the moft criminal propofitions, fmile at the recital of murder, and celebrate their crimes as conquefts."

He had then feen comparatively but little; but he lived to fee more—to fee his countrymen celebrate, as virtues, crimes, compared with which the atrocities of 1790 appear almoft as harmlefs. Being ftripped of all his property, which was large, by the robbers of the revolution, he died in poverty in March 1796, and in the 84th year of his age.

Befides the works which we have already mentioned, he wrote "A Hiftory of the Parliament of England," and a "Hiftory of the Stadholderate;" but thefe are both of them more remarkable for a fpecious ftyle and loftinefs of invention than for ufeful obfervation or folid argument. He wrote likewife "The Hiftory of the Divorce of Catharine of Arragon by Henry the Eighth," which is not fo much a recital of, and commentary upon, the fact from which he takes the title, as it is an able picture of univerfal Europe at that period, of the views, interefts, and power, of all the different potentates. At the time of his death he was preparing a new edition of all his works, in which were to be made many alterations; and he is faid to have left among his manufcripts a "Hiftory of the Revocation of the Edict of Nantes," in four volumes; but it is alfo very certain, that, during the fanguinary reign of Robefpierre, he burnt a great part of his papers.

REAPING, the well-known operation of cutting corn either by the fickle or by the fcythe. Reaping by the fickle is by much the moft common practice, and that which, we believe, prevails univerfally in Scotland; yet the other method, where it is practicable, is certainly the leaft laborious, and by much the moft expeditious. To the fcythe, as an inftrument of reaping, many objections are urged.

It is faid that it fhakes the ear, fo that many of the grains are loft; that it lets the corn fall, after cutting it, in a confufed and fcattered ftate, fo that either much of it is loft, or a great deal of time is confumed in gathering it together; that it can only be made ufe of in land which is very even and free from ftones; that it does not leave fufficient length of ftubble in the ground to lay the corn on when cut; that it mixes bad weeds with the corn, the feeds of which are fown the next year; and, laftly, that the ufe of the fcythe is prejudicial to the health of the reaper.

Thefe objections, however, are either of no weight, or they are made by thofe who are not acquainted with the fcythes which have been adapted to this purpofe, and with the proper manner of ufing them. With a good fcythe, properly managed, the corn, after being cut, remains at firft upright, and then falls very gently upon the rake fixed to the fcythe, without any fhake or jolt; or at leaft with lefs than that which it receives when reaped with a fickle. With refpect to the lofs of grain, that proceeds chiefly from the corn being too dry; confequently it fhould be reaped only upon proper days, and proper times of the day, which is much more eafily done with the fcythe than with the fickle, becaufe the work is fo much fhorter. The ftalks, kept together by the rake, may be laid upon the ground, or rather againft the corn not yet cut, in fo regular and collected a ftate, that thofe who gather and tie the fheaves, whether they are women or children, have nothing but their own negligence to accufe if any thing is left behind. When land is properly ploughed and harrowed, it is fufficiently even; and in fuch as is ftony, the only precaution neceffary is to keep the fcythe a little higher in ufing it, that it may not ftrike againft the ftones. If the ftubble left in the ground be fhort, the ftraw which is cut off will be the longer; and the latter is certainly of more value than the former, which only ferves to incommode the cattle which afterwards go to feed in the field.

Thefe confiderations, and others of a like nature, induced the patriotic fociety of Milan to fend, fome years ago, to thofe parts in which fcythes are made ufe of for reaping; and having procured a model of a fcythe from Silefia, they caufed one to be made of a proper fize. It was firft tried upon corn, and afterwards upon millet; and although the firft fcythe was not accurately made, and the reaper had never before made ufe of fuch an inftrument, yet it was found that nearly half the ufual time was faved, and that the labour and fatigue were much diminifhed; the corn alfo was cut without receiving any fhock that could be hurtful to it, and fell in an even and regular ftate, fo that it was afterwards eafily bound up in compact fheaves. They were afterwards prefented with a fcythe fomewhat different from the Silefian, which is very geneally ufed in Auftria.

Thefe inftruments are fo fimple, that the figure of one of them renders the defcription of either almoft unneceffary. In fig. 1. is fhewn the Silefian fcythe tried by the Society; the difference between that and the Auftrian one we fhall mention in our defcription. The firft, or Silefian fcythe, differs very little from the fcythe we commonly ufe for mowing grafs, except that the blade is rather fmaller; to it are added four teeth of wood, parallel to the blade, fixed and fecured in a proper manner, and intended to keep the corn together after being cut, fo that inftead of its falling in a confufed ftate, the reaper may lay it down in a regular and compact one. The fecond, or Auftrian fcythe, is fimilar to the former, except that the blade is larger; confequently the wooden teeth, of which there are five, are longer; the handle is alfo more flat, and rather crooked. Plate XLII.

In the *firft*, the handle *a b* (fee fig. 1.) is two Milanefe braffes (A), and nine inches and a half in length; the

(A) One hundred Milanefe *braffes* are equal to fifty-eight Englifh yards and a half.

the blade $b\,c$ is one brafs three inches and a half; the piece of wood in which the teeth are fixed, one brafs one inch and a half. In the *fecond*, the handle is two braffes, and feven inches long; the blade, one brafs eleven inches; the piece in which the teeth are fixed, eleven inches and a quarter. The proportions of the other parts may be conceived from the figure.

The difference in the conftruction of thefe two fcythes makes it requifite to ufe them in a different manner; but that will be better acquired in practice than by precept. Such of our countrymen as are accuftomed to the ufe of the common fcythe will very foon find out the moft convenient and advantageous manner of ufing thefe new kinds of fcythe, and of laying down the corn properly when cut.

It fhould, however, be obferved, that in mowing grafs the feet are kept almoft parallel to each other, whereas in reaping corn they fhould be kept upon a line, one behind the other, thrufting the right foot forward, and drawing the left towards it. This is neceffary, becaufe when grafs is mowed it is left to fall juft where it is cut; but when corn is cut, it is to be carried and laid in a proper manner againft that which is not yet cut, and which is at the left hand of the reaper; and if the feet were kept parallel to each other, the reaper would be obliged to extend and turn his body in a very inconvenient manner.

After having made public thefe obfervations, the fociety made farther experiments upon the fubject; in which it was found, that when, on account of very wet weather, the ftalks of the corn are bent down, the wooden teeth of the forementioned fcythes are apt to lay hold of fome ears, to the ftalks of which the iron does not reach, and confequently not being cut below, they are pulled fo that the grain is fcattered. This happens chiefly when the reapers, not being yet fufficiently accuftomed to that kind of fcythe, do not know how to adapt it to particular circumftances.

To remedy this inconvenience, it occurred to an ingenious blackfmith to add to the common fcythe a *gatherer* or *collector* made of cloth, as may be feen at fig. 2. where $a\,b\,c$ is a common fcythe; $c\,d\,m\,l\,o\,f\,n\,e$ is the gatherer; which at $c\,d\,e$ is compofed of a thin plate of iron, having at its extremity a hollow for receiving the point of the blade. At $e\,d$ are holes for fewing in the cloth, which is coarfe, light, and of low price; it is alfo fixed to two thick iron wires, of which the upper one is continued to f, where it terminates in a hole in the handle; the other is fixed to the back of the blade. The manner of fixing this gatherer to the blade of the fcythe will be better underftood by referring to fig. 3. which reprefents one of the irons which, by means of a fcrew, are faftened to the back of the fcythe. Thefe irons proceed from, and make part of, the upright irons $m\,n$, $l\,o$, which ferve to keep the gatherer extended.

This is a very fimple and cheap contrivance; but an attempt was made to render it ftill more fimple, by fubftituting for the gatherer two iron hoops, which are fhewn in fig. 2. by the dotted lines $h\,g$, $k\,i$, with a crofs piece p which connects them. Experience, however, has fhewn, that the gatherer is in general preferable to thefe hoops, as it does not leave an ear of corn behind.

RECTIFICATION OF ETHER, a procefs for depriving ether of its fulphureous acid (See CHEMISTRY-*Index* in this *Suppl.*) It has been ufual to add an alkali for this purpofe; but Dizé has found it much more advantageous to add a fubftance which might afford the requifite quantity of oxygen to convert the fulphureous into the fulphuric acid; in which ftate it is not difpofed to rife and come over. Various metallic oxides were tried, among which the black oxide of manganefe proved the beft and the cheapeft. His procefs is as follows:

The fulphureous acid contained in unrectified ether being neutralized with oxide of manganefe, the fluid is decanted into a pewter veffel of the capacity of fifty ounces, which is placed on a water bath. To this veffel a head and worm are adapted, the latter of which paffes through a refrigeratory conftantly fupplied with water in a ftream from below, which caufes the heated water to flow off above. The diftillation is then performed by raifing the bath to a temperature of 36° (113° Fahrenheit, if the decimal thermometer be here meant). The rectification by this treatment ufually requires a day to complete it. The flavour of the ether is of the beft kind, and the product about one fixth more than in the ufual method with retort and receiver. Dizé has practifed this method with fuccefs for three years.—*Journal de Phyfique, April*, 1798.

RECTIFICATION, in geometry, is the finding of a right line equal to a curve. The rectification of curves is a branch of the higher geometry, a branch in which the ufe of the inverfe method of fluxions is efpecially ufeful.

TURKEY-RED, *Levant-Red*, and *Adrianople-Red*, the names indifferently given to that beautiful red dye which diftinguifhes the cotton manufactured in the Ottoman empire, and at *Aftracan* in the dominions of Ruffia. We have two accounts of the procefs of communicating this dye to the ftuffs; one by Profeffor Pallas as he faw it practifed at Aftracan; the other in the 92d number of the *Annales de Chimie* by Citizen Felix. As every thing relating to ufeful manufactures is of general importance, we fhall give pretty copious extracts from both papers.

According to Dr Pallas, the dye-ftuffs employed at Aftracan are, madder, fumach, gall-nuts, alum, an inferior kind of foda, and fifh-oil. The procefs of dyeing is as follows:

The roots of the madder, when frefh gathered, are placed above each other in a ftove, or in a pit dug in vifcous earth which has been ftrongly heated. Earth is then thrown over the madder, and it muft fweat until the ftove or pit becomes cold; when the roots, the fecond or third day, are taken from it, and either fpread out or hung up to dry. When it is thoroughly dried in the fun, the madder is ground to a very fine powder, as are likewife the round leaves of the fumach (*rhus cotinus*). The fifh oil is boiled from the entrails of the fturgeon and other large fifhes; and the proof of its being proper for dyeing is, that when mixed with a lixivium of foda, it muft immediately affume a milky appearance. Should that not be the cafe, it cannot be ufed by the dyers.

The cotton to be dyed red is firft wafhed exceedingly clean in running water; and when the weather is clear, hung up on poles to dry. If it does not dry before the evening, it is taken into the houfe, on account of

Turkey-Red.

of the ſaline dews ſo remarkable in the country around Aſtracan, and again expoſed to the air next morning. When it is thoroughly dry it is laid in a tub, and fiſh-oil is poured over it till it is entirely covered. In this ſtate it muſt ſtand all night; but in the morning it is hung up on poles, and left there the whole day; and this proceſs is repeated for a week, ſo that the cotton lies ſeven nights in oil, and is expoſed ſeven days to the atmoſphere, that it may imbibe the oil, and free itſelf from all air. The yarn is then again carried to a ſtream, cleaned as much as poſſible, and hung up on poles to dry.

After this preparation a mordant is made of three materials, which muſt give the grounds of the red colour. The pulveriſed leaves of the ſumach are firſt boiled in copper kettles; and when their colouring matter has been ſufficiently extracted, ſome powdered galls are added, with which the liquor muſt be again boiled; and by theſe means it acquires a dark dirty colour. After it has been ſufficiently boiled the fire is taken from under the kettle, and alum put into the ſtill hot liquor, where it is ſoon diſſolved. The proportion of theſe three ingredients cannot be aſcertained, as the dyers vary that proportion at pleaſure. The powder of the ſumach leaves is meaſured into the kettle with laddles; the water is poured in according to a gauge, on which marks are made to ſhew how high the water muſt ſtand in the kettle to ſoak ſix, eight, ten, &c. puds of cotton yarn. The galls and alum are added in the quantity of five pounds to each pud of cotton. In a word, the whole mordant muſt be ſufficiently yellow, ſtrong, and of an aſtringent taſte.

As ſoon as the alum is diſſolved, no time muſt be loſt in order that the mordant may not be ſuffered to cool. The yarn is then put into hollow blocks of wood ſhaped like a mortar, into each of which ſuch a quantity of the mordant has been poured as may be ſufficient to moiſten the yarn without any of it being left. As ſoon as the workman throws the mordant into the mortar, he puts a quantity of the yarn into it, and preſſes it down with his hand till it becomes uniformly moiſtened, and the whole cotton yarn has ſtruck. By this it acquires only a pale yellow colour, which, however, is durable. It is then hung up on poles in the ſun to dry; again waſhed in the ſtream, and afterwards dried once more.

The next part of the proceſs is to prepare the madder dye. The madder, ground to a fine powder, is ſpread out in large troughs, and into each trough is poured a large cupful of ſheep's blood, which is the kind that can be procured with the greateſt facility by the dyers. The madder muſt be ſtrongly mixed in it by means of the hand, and then ſtand ſome hours in order to be thoroughly ſoaked by it. The liquor then aſſumes a dark red appearance, and the madder in boiling yields more dye.

After this proceſs water is made hot in large kettles, fixed in brickwork; and as ſoon as it is warm, the prepared red dye is put into it, in the proportion of a pound to every pound of cotton. The dye is then ſuffered to boil ſtrongly; and when it is enough, which may be tried on cotton threads, the fire is removed from under the kettle, and the prepared cotton is depoſited near it. The dyer places himſelf on the edge of the brickwork that incloſes the kettle; dips the cotton yarn, piece by piece, into the dye; turns it round backwards and forwards; preſſes it a little with his hands; and lays each piece, one after the other, in pails ſtanding ready for the purpoſe. As ſoon as all the cotton has received the firſt tint, it is hung up to dry; as the red, however, is ſtill too dull, the yarn, which has been already dyed once, and become dry, is put once more into the dyeing-kettle, and muſt be left there to ſeethe for three hours over a ſtrong fire; by which it acquires that beautiful dark red colour which is ſo much eſteemed in the Turky yarn. The yarn is now taken from the dye with ſticks; the ſuperfluous dye which adheres to it is ſhaken off; the hanks are put in order, and hung up, one after another, to dry. When it is thoroughly dry, it is waſhed in the pure ſtream, and again dried.

In the laſt place, the above-mentioned ſoda is diſſolved with boiling water in tubs deſtined for that purpoſe, and it is uſual at Aſtracan to allow 20 pounds of ſoda to 40 pounds of cotton, or half the weight. Large earthen jars, which are made in Perſia of very ſtrong clay, a yard and a half in height, almoſt five ſpans wide in the belly, and ending in a neck a ſpan and a half in diameter, incloſed by means of cement in brickwork over a fire-place, in ſuch a manner that the necks only appear, are filled with the dyed cotton yarn. The ley of diſſolved ſoda, which is blackiſh and very ſharp, is then poured over it till the jars be filled; and ſome clean rags are preſſed into their mouths, that the uppermoſt ſkains of yarn may not lie uncovered. A fire is then made in the fire-place below, and continued for 24 hours; and in the mean time the ſteam which ariſes from the jars is ſeen collected among the rags in red drops. By this boiling the dye is ſtill more heightened, and is made to ſtrike completely; every thing ſuperfluous is removed, and all the fat matter which ſtill adheres to the yarn is waſhed out. Nothing more is then neceſſary for completing the dye of the yarn but to rinſe it well ſeveral times in running water, and then to dry it.

Cotton cloth is dyed with madder at Aſtracan in the ſame manner; but many purſue a fraudulent proceſs, by dyeing with red wood, and then ſell their cloth as that which has been dyed in the proper manner.

The proceſſes followed in the Grecian manufactories in the Levant, as deſcribed by M. Felix, varies in ſome particulars from this. The firſt proceſs is that of cleaning the cotton: for which purpoſe three leys are employed; one of ſoda, another of aſhes, and a third of lime. The cotton is thrown into a tub, and moiſtened with the liquor of the three leys in equal quantities: it is then boiled in pure water, and waſhed in running water.

The ſecond bath given to the cotton is compoſed of ſoda and ſheep's dung diſſolved in water. To facilitate the ſolution, the ſoda and dung are pounded in a mortar. The proportions of theſe ingredients employed, are one occa of dung, ſix of ſoda, and forty of water; each occa being equal to about fifty ounces. When the ingredients are well mixed, the liquor expreſſed from them is ſtrained; and being poured into a tub, ſix occas of olive oil are added to it, and the whole is well ſtirred till it becomes of a whitiſh colour like milk. The cotton is then beſprinkled with this water; and when the ſkains are thoroughly moiſtened, they are wrung, Turkey-Red.

wrung, preſſed, and expoſed to dry. The ſame bath muſt be repeated three or four times, becauſe it is this liquor which renders the cotton more or leſs fit for receiving the dye. Each bath is given with the ſame liquor, and ought to continue five or ſix hours. It is to be obſerved that the cotton, after each bath, muſt be dried without being waſhed, as it ought not to be rinſed till after the laſt bath. The cotton is then as white as if it had been bleached in the fields.

It may be ſuppoſed that the dung is of no utility for fixing the colours; but this ſuppoſition would be raſh; for, as M. Felix obſerves, it is well known that this ſubſtance contains a great quantity of volatile alkali in a diſengaged ſtate, which has the property of giving a roſy hue to the red. It is therefore probable that it is to this ingredient that the red dyes of the Levant are indebted for their ſplendour and vivacity. This much, at any rate, is certain, that the Morocco leather of the Levant is prepared with dogs dung; becauſe it has been found that this dung is proper for heightening the colour of the lack.

The proceſs of galling, which follows the bath of dung, is performed by immerſing the cotton in a bath of warm water, in which five occas of pulveriſed gall-nuts have been boiled. This operation renders the cotton more fit for being ſaturated with the colour, and gives to the dye more body and ſtrength. After the galling comes aluming, which is performed twice, with an interval of two days, and which conſiſts in dipping the cotton into a bath of water in which five occas of alum have been infuſed, mixed with five occas of water alkaliſed by a ley of ſoda. The aluming muſt be performed with care, as it is this operation which makes the colouring particles combine beſt with the cotton, and which ſecures them in part from the deſtructive action of the air. When the ſecond aluming is finiſhed, the cotton is wrung; it is then preſſed, and put to ſoak in running water, after being incloſed in a bag of thin cloth.

The workmen then proceed to the dyeing. To compoſe the colours, they put in a kettle five occas of water, and 35 occas of a root which the Greeks call *ali-zari*, or painting colour, and which in Europe is known under the name of *madder*. The madder, after being pulveriſed, is moiſtened with one occa of ox or ſheep's blood. The blood ſtrengthens the colour, and the doſe is increaſed or leſſened according to the ſhade of colour required. An equal heat is maintained below the kettle, but not too violent; and when the liquor ferments, and begins to grow warm, the ſkains are then gradually immerſed before the liquor becomes too hot. They are then tied with packthread to ſmall rods placed croſſwiſe above the kettle for that purpoſe; and when the liquor boils well, and in an uniform manner, the rods from which the ſkains were ſuſpended are removed, and the cotton is ſuffered to fall into the kettle, where it muſt remain till two-thirds of the water is evaporated. When one-third only of the liquor remains, the cotton is taken out and waſhed in pure water.

The dye is afterwards brought to perfection by means of a bath alkaliſed with ſoda. This manipulation is the moſt difficult and the moſt delicate of the whole, becauſe it is that which gives the colour its tone. The cotton is thrown into this new bath, and made to boil over a ſteady fire till the colour aſſumes the required tint. The whole art conſiſts in catching the proper degree: a careful workman, therefore, muſt watch with the utmoſt attention for the moment when it is neceſſary to take out the cotton; and he will rather burn his hand than miſs that opportunity.

Turkey-Red ‖ Reflector.

It appears that this bath, which the Greeks think of ſo much importance, might be ſupplied by a ley of ſoap; and it is probable that ſaponaceous water would give the colour more brightneſs and purity.

M. Felix ſeems doubtful whether the ali-zari of the Greeks be the ſame plant with the European madder. If it be, its ſuperiority muſt ariſe from the mode in which it is cultivated, and the method employed to dry it. The ali-zari is not collected till the fifth or ſixth year of its growth, when it has acquired its full ſtrength; and as it is the woody part of the roots which affords the greateſt quantity of colouring particles, this muſt give it an obvious ſuperiority over madder, which is collected before it has arrived at maturity. The mode of deſiccation contributes alſo, in the opinion of our author, to improve the quality of the ali-zari. The Levantines dry it in the open air; and this operation is eaſy in a country where great dryneſs prevails in the atmoſphere, while in our damp climates we are obliged to dry the madder by ſtoves. Hence it happens that the ſmoke, which mixes itſelf with the cold air, and penetrates the roots, impregnates them with fuliginous particles, which alter the colouring ſubſtance; an accident which does not take place when the madder is dried without the aſſiſtance of fire.

For the philoſophical principles of theſe proceſſes of dyeing, ſee *Animal and Vegetable* SUBSTANCES in this *Supplement*.

REDINTEGRATION, is the taking or finding the integral or fluent again from the fluxion. See FLUXIONS, *Encycl.*

REFLECTOR FOR A LIGHT-HOUSE, is compoſed of a number of ſquare plane glaſs mirrors, ſimilar to thoſe with which Archimedes is ſaid to have ſet fire to the Roman fleet at the ſiege of Syracuſe (See BURNING, *Encycl.*) Each of theſe mirrors is about an inch ſquare; and they are all diſpoſed cloſe to each other in the concave of a parabolic ſegment, formed of ſtucco or any other proper bed. Stucco has been found to anſwer the purpoſe beſt; and is accordingly employed in all the reflectors of the light-houſes erected by Mr Thomas Smith tinplate worker, Edinburgh, at the expence, and by the authority, of government. This ingenious and modeſt man ſeems to have conceived the idea of illuminating light-houſes by means of lamps and reflectors inſtead of coal-fires, without knowing that ſomething of the ſame kind had been long uſed in France; he has therefore all the merit of an inventor, and what he invented he has carried to a high degree of perfection.

His parabolic moulds are from three to five or ſix feet in diameter; and in the centre or apex of each is placed a long ſhallow lamp of tin-plate, filled with whale oil. In each lamp are ſix cotton wicks, almoſt contiguous to each other, which are ſo diſpoſed as to burn without trimming for about ſix hours. The light of theſe is reflected from each mirror ſpread over the concave ſurface, and is thus multiplied, as it were, by the number of mirrors. The ſtucco moulding is covered on the back with tin-plate, from which a tube, immediately over the lamp, proceeds to the roof of the

 light

light room, and serves as a funnel, through which the smoke escapes without sullying the faces of the mirrors. The light-room is a cupola or lantern of from eight to twelve sides, composed entirely of glass, fixed in cast-iron frames or sashes, and roofed with copper. On circular benches passing round the inside of this lantern, at about eighteen inches from the glass frames, are placed the reflectors with their lamps, so as that the concave surfaces of two or three of the reflectors front every point of the compass, and throw a blaze of light in all directions. In the roof immediately over the centre of the room is a hole, through which pass all the funnels already mentioned, and which serves likewise to admit fresh air to the lamps. This light room is firmly fixed on the top of a round tower so as to be immoveable by the weather; and the number of the reflectors, and the height of the tower, are less or greater according as it is the intention that the light should be seen at a less or a greater distance.

A man judging from mere theory would be very apt to condemn light-houses of this kind; because the firmest building shakes in a violent storm, and because such shaking, he might think, would sometimes throw the whole rays of light into the air, and thus mislead the bewildered seaman. This opinion, we know, was actually entertained of them by one of the profoundest philosophers and most scientific mechanicians of the age. Experience, however, has convinced him, as well as the public at large, that such apprehensions are groundless, and that light-houses with lamps and reflectors are, in every point of view, preferable to those with fires burning in the open air. They are supported at much less expence; their light is more brilliant, and seen at a greater distance, whilst it can never be obscured by smoke, or beaten down on the lee-side by a violent gust of wind; and what is perhaps of still greater importance, the reflectors with their lamps may be so variously placed, that, as Mr Smith observes, one light-house cannot be mistaken for another. If we add to all this, that the lamps do not stand in need of trimming so often as open fires require fuel, and that the light man is never exposed either to cold or to wet by attending to his duty, we must be convinced that light-houses with reflectors are much less liable to be neglected in stormy weather than those with open fires, and that this circumstance alone would be enough to give the former a preference, almost incalculable, over the latter.

It has been proposed to make the concave surface of the parabola one speculum of metal, instead of covering it over with a multitude of plain glass mirrors; or to diminish the size of each mirror, if they are to be retained in preference to the metallic speculum. To every man who has but dipped into the science of optics, it must be obvious, that either of these alterations would be wrong. The brightest metal does not reflect such a quantity of light as well foliated clear glass; and were the size of the mirrors to be diminished, the number of joinings would be increased, in each of which some light is lost, not merely in the seam, but from its being almost impossible to foliate glass perfectly at its edge.

REFLEXITY, a word employed by Mr Brougham to denote a property of light which causes the different rays to be acted upon by bodies, and to begin to be refracted, reflected, inflected, and deflected, at different distances. This property follows the same law that the other optical properties of light follow: the red ray having most reflexity, and the violet least (See *Philosophical Transactions*, 1797, p. 360.) Mr Brougham has denoted this property by the three words, *refrangity*, *reflexity*, and *flexity*; but as the power is the same there is no occasion for different names. Some philosophers have refused to admit this as a new property; we have not verified it by experiment.

REFRACTION OF ALTITUDE, is the arc or portion of a vertical circle, by which the altitude of a star is increased by the refraction of light.

Refraction of Ascension and Descension, is an arc of the equator, by which the ascension and descension of a star, whether right or oblique, is increased or diminished by the refraction.

Refraction of Declination, is an arc of a circle of declination, by which the declination of a star is increased or diminished by refraction.

Refraction of Latitude, is an arc of a circle of latitude, by which the latitude of a star is increased or diminished by the refraction.

Refraction of Longitude, is an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of the refraction.

Terrestrial Refraction, is that by which terrestrial objects appear to be raised higher than they really are, in observing their altitudes. The quantity of this refraction is estimated by Dr Maskelyne at one tenth; by Le Gendre at one-fourteenth; by De Lambre at one-eleventh; and by others at a twelfth of the distance of the object observed, expressed in degrees of a great circle. But it is obvious that there can be no fixed quantity of this refraction, since it depends upon the state of the atmosphere, which is extremely variable. Hence some very singular effects of it are related, of which the following is worthy of notice. It is taken from the Philosophical Transactions of London 1798; being an extract of a letter, dated Hastings, August 1. 1797.

"On Wednesday, July 26, about five o'clock in the afternoon, while I was sitting in my dining room at this place, which is situated upon the Parade, close to the sea shore, nearly fronting the south, my attention was excited by a number of people running down to the sea-side. Upon enquiring the reason, I was informed that the coast of France was plainly to be distinguished by the naked eye. I immediately went down to the shore, and was surprised to find that, even without the assistance of a telescope, I could very plainly see the cliffs on the opposite coast; which, at the nearest part, are between 40 and 50 miles distant, and are not to be discerned, from that low situation, by the aid of the best glasses. They appeared to be only a few miles off, and seemed to extend for some leagues along the coast. I pursued my walk along the shore eastward, close to the water's edge, conversing with the sailors and fishermen upon the subject. They at first could not be persuaded of the reality of the appearance; but they soon became so thoroughly convinced, by the cliffs gradually appearing more elevated, and approaching nearer, as it were, that they pointed out and named to me the different places they had been accustomed to visit; such as the Bay, the Old Head or Man, the Windmill, &c. at Boulogne; St Vallery, and other places on the coast of Picardy; which they afterwards confirmed when they

they viewed them through their telefcopes. Their obfervations were, that the places appeared as near as if they were failing, at a fmall diftance, into the harbours."

The writer of this extract was W. Latham, Efq; F. R. S. and A. S. who adds, that the day was extremely hot, that it was high water at Haftings about two o'clock P. M. and that not a breath of wind was ftirring the whole day.

REGIS (Peter Sylvain), a French philofopher, and great propagator of Cartefianifm, was born in Agenois 1632. He cultivated the languages and philofophy under the Jefuits at Cahors, and afterwards divinity in the univerfity of that town, being defigned for the church. He made fo uncommon a progrefs, that at the end of four years he was offered a doctor's degree without the ufual charges; but he did not think it became him to accept of it till he had ftudied alfo in the Sorbonne at Paris. He went thither, but was foon difgufted with theology; and as the philofophy of Des Cartes began at that time to make a noife through the lectures of Rohault, he conceived a tafte for it, and gave himfelf up entirely to it. He frequented thefe lectures; and becoming an adept, went to Toulonfe in 1665, and read lectures in it himfelf. Having fine parts, a clear and fluent manner, and a happy way of making himfelf underftood, he drew all forts of people; the magiftrates, the learned, the ecclefiaftics, and the very women, who now all affected to abjure the ancient philofophy. In 1680 he returned to Paris; when the concourfe about him was fuch, that the fticklers for Peripateticifm began to be alarmed. They applied to the Archbifhop of Paris, who thought it expedient, in the name of the king, to put a ftop to the lectures; which accordingly were difcontinued for feveral months. The whole life of Regis was fpent in propagating the new philofophy. In 1690 he publifhed a formal fyftem of it, containing logic, metaphyfics, phyfics, and morals, in 3 vols 4to, and written in French. It was reprinted the year after at Amfterdam, with the addition of a difcourfe upon ancient and modern philofophy. He wrote afterwards feveral pieces in defence of his fyftem; in which he had difputes with M. Huet, Du Hamel, Malebranche, and others. His works, though abounding with ingenuity and learning, have been difregarded, in confequence of the great difcoveries and advancement in philofophic knowledge that have been fince made. He died in 1707. He had been chofen member of the academy of fciences in 1699*.

* *Biog. Dict.* new edit.

REGULAR BODY, called alfo *Platonic Body*, is a body or folid comprehended by like, equal, and regular plane figures, and whofe folid angles are all equal.

The plane figures by which the folid is contained are the faces of the folid; and the fides of the plane figures are the edges, or linear fides of the folid

There are only five regular folids, viz.

The tetrahedron, or regular triangular pyramid, having four triangular faces;

The hexahedron, or cube, having fix fquare faces;

The octahedron, having eight triangular faces;

The dodecahedron, having twelve pentagonal faces;

The icofahedron, having twenty triangular faces.

Befides thefe five, there can be no other regular bodies in nature. See PLATONIC *Body*, Suppl.

REGULUS, in aftronomy, a ftar of the firft magnitude, in the conftellation Leo; called alfo, from its fituation, *Cor Leonis*, or the *Lion's Heart*; by the Arabs, *Albabor*; and by the Chaldeans, *Kalbeleced*, or *Karbeleceid*; from an opinion of its influencing the affairs of the heavens.

REID (Thomas, D. D.), fo well known to the public by his moral and metaphyfical writings, was the fon of the Rev. Lewis Reid, minifter of the parifh of Strachan, in the county of Kincardine, North Britain. His mother was the daughter of David Gregory, Efq; of Kinardie, of whom fome account has been given in this *Supplement*, and fifter to David, James, and Charles Gregories, who were at the fame time profeffors of aftronomy, or mathematics, in the univerfities of Oxford, Edinburgh, and St Andrews.

He was born at the parfonage-houfe of Strachan in April 1710, and received the rudiments of his education at the parifh fchool of Kincardine-oniel. At that period the parochial fchools of Scotland were very fuperior to what they are now; and young men went from them to the univerfity well furnifhed with philological learning. The progrefs of young Reid muft have been rapid; for he was removed from fchool to the Marifchal College, Aberdeen, when not more than twelve years of age; and we have never heard that he was admitted into the univerfity before he was qualified to profit by the lectures of the profeffors. On the contrary, he foon difplayed the genius of his mother's family, and fhone confpicuous among the ftudents of mathematics in a college where that fcience has been at all times cultivated with ardour and fuccefs.

After the ufual courfe of four years employed in the ftudy of Latin, Greek, Mathematics, and Philofophy, he probably took his degree of M. A. which at that period, and for a long time fubfequent to it, was the univerfal practice in the univerfity of Aberdeen, and then commenced the ftudy of theology. In due time he was licenfed to preach the gofpel according to the forms of the church of Scotland; but continued to refide for fome years in Aberdeen, cultivating his favourite fcience, mathematics.

The mathematical chair in Marifchal College was then filled by Mr John Stuart, a man of great eminence in his profeffion; but who, like many other profound mathematicians, was not happy in his mode of communicating fcience, at leaft to the duller part of his pupils. Mr Reid occafionally read lectures for the profeffor; and a friend of our's, by no means dull, has often been heard to exprefs great fatisfaction that Mr Stuart was kept a whole winter from the fchools, when he was a ftudent, and that the clafs was taught by Mr Reid. "Had it not been for this circumftance (faid he) I fhould never have underftood more of mathematics than the firft fix books of Euclid's elements; but Mr Reid had the faculty of making every thing intelligible to the ftudents which he clearly apprehended himfelf."

He could not, however, fpend his life in the ftudy of mathematics, and in reading barren lectures for other men. He had been educated for the church; and it was in the church only that he had the profpect of gaining a livelihood. He was accordingly prefented, we know not in what year, to the church of *New Machar* in Aberdeenfhire, at the time when the good people of Scotland were very far from being reconciled to the rights of patronage; and the confequence was, that

that his fettlement met with much popular oppofition. Even a little riot took place in the church at his ordination; but he foon gained the affections of his flock by his good fenfe, his acknowledged worth, and his unwearied attention to all their wants, which he was ever ready to relieve to the utmoft extent of his abilities. So deeply rooted indeed was their regard for him at laft, that, though it is now almoft half a century fince his relation to the parifh of New Machar ceafed, his memory continues to be revered in that parifh even at the prefent day; and the following anecdote evinces that it is not revered without reafon.

A man who, from being in decent circumftances, and a member of the kirk feffion (See PRESBYTERIANS, *Encycl.*), when Dr Reid was minifter, had become, in his old age, poor and infirm, obferved to the then minifter of the parifh, that if he were able to go to Glafgow, and make his cafe known to his old friend and paftor, he was fure that he would get fomething done for him. This obfervation was reported to the Doctor, who inftantly recollected the man, though, in all probability, he had not thought of him for thirty years; and he fettled upon him an annual penfion of ten pounds, which was punctually paid as long as they both lived. The pride of fcience had not from the mind of this great man eradicated the amiable fympathies of humanity, nor had his philofophic fame made him overlook the unafpiring duties of the Chriftian paftor.

In the year 1751, about the beginning of the feffion or annual term, one of the profeffors of philofophy in King's College, Aberdeen, died; and his death being unexpected, prefented to the other members of that learned body fome difficulty in carrying on the ufual courfe of education for that year. At this our readers will not be furprifed, when they reflect on the modeon which fcience was taught in that univerfity; for he who could with propriety be placed in the vacant chair, muft have been qualified, without much previous preparation, to read lectures on LOGIC, ONTOLOGY, PNEUMATICS, MORALS, POLITICS, MATHEMATICS, and NATURAL PHILOSOPHY (See GERARD, in this *Suppl.*) In fuch a place as Aberdeen, it is hardly to be fuppofed that there was a fingle man unemployed, fo completely mafter of all thefe branches of fcience, as to take up the clafs where it was dropt by the deceafed profeffor, and carry it fuccefsfully through that fcience, whatever it might be, in which, at his death, he chanced to be lecturing. It occurred, however, to the principal, and fome of the profeffors, that the minifter of New Machar was fully equal to the tafk; and the late Dr John Gregory, then profeffor of medicine, and the Rev. Dr Macleod, the prefent fubprincipal of King's College, were deputed to vifit Mr Reid, and requeft his immediate acceptance of the vacant profefforfhip. He yielded to the requeft not without fome hefitation, and was admitted profeffor of philofophy on the 22d of November.

He was now in the very fituation for which Nature feemed to have intended him. He had not only an opportunity, but it was his duty to cultivate the fcience to which his attachment was fo ftrong; and the duties of his office made him turn his attention more clofely than he had hitherto done to another fcience, in which he was deftined to make a more confpicuous figure than he ever made even in his favourite mathematics.

It was during his profefforfhip in the univerfity of Aberdeen that he wrote his "Effay on Quantity," which was publifhed in the 45th volume of the Philofophical Tranfactions, and is perhaps the fineft fpecimen of metaphyfical mathematics, if we may ufe fuch an expreffion, that is extant in our own or in any other language (See QUANTITY, *Encycl.*). It was during the fame period that he publifhed his "Inquiry into the Human Mind on the Principles of Common Senfe;" a work of unqueftionable merit, which has contributed more than any other work whatever to give a rational turn to metaphyfical fpeculations. It was about this period that the degree of D. D. was conferred upon him by his mother-college.

The well-earned fame of Dr Reid attracted the attention of the univerfity of Glafgow to him as the fitteft perfon to fucceed the celebrated Dr Adam Smith; and he was admitted profeffor of moral philofophy in that univerfity on the 11th of June 1764. There his attention was not diftracted by a multitude of fciences, which it was his duty to teach; and he had leifure to improve his metaphyfical fyftem, though he continued through life to amufe himfelf occafionally with mathematical fpeculations.

In the year 1773 appeared, in Lord Kames's "Sketches of the Hiftory of Man, a brief Account of Ariftotle's Logic; with remarks by Dr Reid." It would feem that he had entered upon this tafk rather reluctantly, and merely in compliance with the folicitations of his friend, the author of the Sketches. "In attempting (fays he) to give fome account of the analytics, and of the topics of Ariftotle, ingenuity requires me to confefs, that though I have often purpofed to read the whole with care, and to underftand what is intelligible, yet my courage and patience always failed before I had done. Why fhould I throw away fo much time and painful attention upon a thing of fo little ufe? If I had lived in thofe ages when the knowledge of Ariftotle's Organon intitled a man to the higheft rank in philofophy, ambition might have induced me to employ upon it fome years of painful ftudy; and lefs, I conceive, would not be fufficient. Such reflections as thefe always got the better of my refolution, when the firft ardour began to cool. All I can fay is, that I have read fome parts of the different books with care, fome flightly, and fome perhaps not all. I have glanced over the whole often; and when any thing attracted my attention, have dipped into it till my appetite was fatisfied."

Notwithftanding this modeft acknowledgment, we are not fure that any one of Dr Reid's publications does him greater honour than his very perfpicuous view of this ftupendous fyftem. Having ourfelves occafionally looked into the writings of Ariftotle, we fhould not hefitate to fay, that it is by much the beft analyfis of thefe writings that we have any where met with, even though we could not corroborate our own opinion by that of other men much more converfant than we are with the oracular language of the Stagyrite. But when it is known that the late Dr Doig of Stirling, to whom Greek was as familiar as his mother tongue, and an equally learned Doctor of Oxford, who has been reading Ariftotle ever fince he was fourteen years of age, agreed in opinion, that a more accurate view of his logic could not be given in the fame compafs than had been

been given by Dr Reid, we may furely affirm, with fome degree of confidence, that this fmall work adds much to the fame of our celebrated countryman.

Though Dr Reid's health continued good, and his mental faculties unimpaired, till a very fhort time before his death, he ceafed for fome years to read lectures from his profeffional chair, employing that time in preparations for eternity, and in fitting his lectures for the prefs. Thefe were publifhed in two volumes 4to: the firft in 1785, under the title of "Effays on the Intellectual Powers of Man," dedicated to his friends Dr Gregory and Profeffor Stewart, both of the univerfity of Edinburgh; and the fecond in 1788, under the title of "Effays on the Active Powers of Man," without any dedication or preface. He continued to enjoy the fame acquired by this work, as well as the affection of his friends and the reverence of the public, for eight years, dying at Glafgow in the end of September, or the beginning of October 1796, in the 87th year of his age. He had been married, and he left behind him one daughter.

To do juftice to the biography of fuch a man as this, we fhould here attempt to draw his intellectual character, and to appreciate the merits of his works; but to perform this tafk in a manner at all worthy of him, or we hope of ourfelves, would require more room than our limits permit us to allot to any article of the kind; and our readers will be pleafed to learn, that they may confidently expect an account of his life, with a critique on his works, by a man better qualified to do juftice to both, than the writer of this fhort fketch pretends to be. His works are in the hands of the fpeculative public; and by that public will be duly valued, as long as found fenfe fhall be preferred to impious jargon. How long that may be, God only knows; but if any thing can guard the minds of our youth againft that fophiftry of which the object is to attribute real agency to material fluids, and to reprefent the elective attractions of chemiftry as perfectly fimilar to human volitions, it will be the unbiaffed ftudy of Dr Reid's "Effays on the Intellectual and Active Powers of Man." They will there find metaphyfics divefted of myftery, and the profoundeft fpeculations rendered intelligible by the conftant ufe of words in one determined fenfe. We think, indeed, that in this confifts the Doctor's chief merit; for, except when treating of our notions of power, he feems not to have added much to what certainly *may be* found in the writings of Locke.

Let not our readers fuppofe, that by this obfervation we wifh to detract in the fmalleft degree from our author's fame, or to leffen him by comparifon with the Englifh philofopher. If on mere topics of fpeculative fcience, he appears to us to have thought as Locke thought, it is on the other hand certain, that the greater part of Locke's doctrines may be gleaned from the logical and metaphyfical writings of Bacon, Hobbes, and Des Cartes. Nor need this furprife any one; for he who reflects a moment on the fubject, muft perceive that fuch a coincidence of thought in metaphyfical fcience is among men of eminence almoft inevitable. Of mind and its powers—the fubject of that fcience—we neither know, nor can know any thing, but by patiently attending to the operations of our own minds, when we fee, hear, feel, think, reafon, and will, &c.: and it is obvious, that every man who is capable of fuch patient attention, and does not labour under the bias of fome prejudice, muft view thefe operations in the fame way. The great fuperiority of Dr Reid over his predeceffors, in this department of fcience, appears to have been this, that he apprehended the operations of his own mind with a clearnefs, which gave to his language a precifion and perfpicuity which the language of Locke certainly does not poffefs.

In the Effay on the Human Underftanding, the term *idea* fometimes fignifies a material fubftance, fometimes the qualities of that fubftance, fometimes the conception of thefe qualities, fometimes the power or faculty of the mind by which we conceive a thing, fometimes a perception of fenfe, and fometimes an intellectual notion. Hence the ambiguity of terms which runs thro' the whole of that immortal work, has furnifhed both the author's friends and his enemies with an opportunity of attributing to him pernicious doctrines, which we are perfuaded he did not maintain, and which, we think, a patient analyfis of the effay muft *convince every man* that he did not maintain. From this ambiguity the writings of Dr Reid are perfectly free. His doctrines, whether well or ill-founded, can never be mifunderftood by him who is defirous to underftand them; and he who knows how much perfpicuity of ftyle depends upon accuracy of thinking, will not deem us enemies to his fame for having faid that his chief merit confifts in the precifion of his language.

He has been much cenfured by fome, and much applauded by others, for introducing the phrafe *common fenfe* into fpeculative philofophy, as the proper name of that faculty of the mind by which we apprehend firft truths: but he is on this account entitled neither to praife nor to cenfure. He adopted the phrafe from others; and has proved, by the moft unexceptionable authorities, both ancient and modern, that it may with great propriety be ufed as he has ufed it. Whether the adopting of it into works of fcience was neceffary, is another queftion, on which we have given our opinion elfewhere; it is fufficient in this place to vindicate his ufe of it, efpecially in his latter works, from ambiguity.

Candour obliges us to acknowledge, that he has advanced fome doctrines which we cannot admit as true. Though not in general partial to Locke, he has adopted his notions refpecting our power of abftraction with hardly any other variation than the fubftituting of the term *conceptions* for Locke's favourite phrafe *ideas*. He has likewife endeavoured to prove, that we may diftinctly conceive what cannot poffibly exift. Thefe miftakes, for fuch they appear to us, we have pointed out elfewhere (See Metaphysics, Part I. Chapt. iii. and iv. *Encycl.*); but they are infinitely more than counterbalanced by his clear, accurate, and fatisfactory difquifitions on our notions of active power. Had Dr Reid never written a fentence but the effay which treats of this delicate and important fubject, he would have been entitled to a place in the very firft rank of ufeful metaphyficians; for, previous to the appearance of his works, we had nothing written directly on *power* but contradictory and unintelligible jargon. We recommend the ferious perufal of this effay, the firft in his fecond volume, to fuch of our readers as fancy that they diftinctly conceive the powers of chemical agents, and that intelligence and volition may refult from any mechanical organization, Reiske. organization, or any combination whatever of matter and motion.

REISKE (John James), a most profound scholar and sagacious critic, was born in 1706 at a small town of the duchy of Anhalt. After struggling with some difficulties in his school education, in which, however, he, by perseverance, obtained considerable advantages, he went, in 1733, to Leipsic; where he continued, for the sake of study, five years. Here he accomplished himself in Arabic, and translated and published a book from that language. In order to prosecute his study of Arabic with greater effect, he travelled on foot, and with many difficulties, to Leyden. Here he was employed in arranging the Arabic manuscripts, for which, however, he received a very scanty compensation; and here also he translated from the German and French, into Latin, various essays set him by Dorville, whom he had visited in his journey, and who afterwards inserted these papers in the *Miscellanea Critica*. Dorville was so well pleased with his skill and diligence, that he employed him in more important concerns. At his desire, Reiske translated the whole of the Chariton from the Greek, and the Geography of Abulfeda from the Arabic, into Latin. At Leyden he continued for the space of eight years; where a storm of jealousy and calumny, excited against him by the younger Burman, finally induced him to change his residence. This was principally owing to the freedom he used with respect to the edition of Petronius, edited by the younger Burman at Leyden; however, before he quitted it, he took the degree of doctor of physic, which was given him in a manner which did him the highest honour. He then visited different parts of Germany, till he at length settled at Leipsic a second time. Here, for twelve years, notwithstanding he was made professor of Arabic, he experienced all the inconveniences of poverty, and was obliged to undergo a great deal of drudgery for booksellers, and the editors of periodical publications, to procure a subsistence; at this period, in particular, the *Acta Eruditorum* were greatly indebted to him. Amidst all these hardships, however, he found opportunity to write, and to publish, his *Animadversiones in Auctores Græcos*, in five volumes; a work of extraordinary learning and merit. In 1758, by the death of Haltausius, he obtained a situation at once honourable and lucrative, which placed him above want, and enabled him to follow his favourite pursuits at ease. He was made rector of the academy at Leipsic, in which office he continued till the time of his death. In 1764, he married Ernestina Christina Muller, a woman of wonderful attainments, whose knowledge was hardly inferior to his own, and particularly in Greek literature. She assisted him in all his literary labours, and especially in his immortal work of the "Edition of the Greek Orators." Thus, in the manner most grateful to himself, Reiske consumed the remainder of his life, which continued till 1774, when he died possessed of the highest reputation. The number of works which he superintended and published is very great; but it will be sufficient to name those which are most sought after and esteemed. These are, the "Remarks upon Greek Authors," before mentioned. An "Edition of the Greek Orators," in 12 vols 8vo, which was finished by his widow. "Dionysius Halicarnassensis," in 7 vols. "Plutarch's Works," in 9 vols. "Theocritus, &c. &c." This John James Reiske must not be confounded with *John Reiske*, rector of the college of Wolfenbuttel, who was also a learned man, and published various works *.

Remonstrants || Republicans.

REMONSTRANTS, in church history, a title given to the ARMINIANS (See that article, *Encycl.*) by reason of the remonstrance which, in 1610, they made to the States of Holland, against the sentence of the synod of Dort, which condemned them as heretics. Episcopius and Grotius were at the head of the *Remonstrants*, whose principles were first openly patronised in England by Archbishop Laud. In Holland, the patrons of Calvinism presented an address in opposition to the remonstrance of the Arminians, and called it a counter-remonstrance. Hence the Dutch Calvinists were termed *Counter Remonstrants*. Much controversy was carried on by these rival sects, which, on the side of the Calvinists, was extremely illiberal.

* *Biog. Dict.* new edit.

REMORA, or SUCKING FISH, a species of ECHENEIS (See *Encycl.*), M. Vaillant found, upon different parts of his enormous *ray* (See RAJA in this *Suppl.*) about twenty small sucking fish, or *remoras*, fastened so firmly that they did not drop off when he was hoisted on board. Some naturalists have said, that the head of the sucking fish is viscous on the lower part, and furnished with rough points similar to the teeth of a file; and, according to them, it is by means of these two qualities, its roughness and viscosity, that it is enabled to adhere to other fish.

"Figure to yourself (says one of them) a row of nineteen sharp-edged and dentated laminæ, placed crosswise, and issuing immediately from the rim of the lower jaw, and you will have a just idea of the part with which the remora makes itself fast."

This description (says Vaillant) is exact as far as relates to the figure and number of the dentated laminæ; but it places them on the lower part of the head, whereas they are, in reality, on the upper. Accordingly, when the remora fixes itself, it is obliged to turn upon its back, with its belly upward.

If the two white fish, however, that posted themselves on the arms of the *ray*, and served him as pilots, be of the remora species, as he is inclined to think, the laminæ by which that variety adheres to other fishes must be on the lower part of the body, since the two pilots continued in their natural position, and had no occasion to turn over to fix themselves at their post.

REPETEND, in arithmetic, denotes that part of an infinite decimal fraction, which is continually repeated *ad infinitum*. Thus in the numbers $2{\cdot}13\ 13\ 13$, &c, the figures 13 are the repetend, and marked thus $\dot{1}\dot{3}$.

REPUBLICANS, the name given by Vaillant, with some propriety, to a kind of birds which were observed in South Africa, both by him and Paterson, to inhabit apparently the same enormous nest. Cutting one of these nests in pieces with a hatchet, he perceived that the principal and fundamental piece consisted of a mass of strong coarse grass (called by the Hottentots *Boshmen's grass*), without any mixture, but so compact and firmly knit together as to be impenetrable to the rain. This nucleus is the commencement of the structure; and each bird builds and applies to it its particular nest. But these cells are formed only beneath and around the mass; the upper surface remains void, without, however, being useless; for, as it has a projecting

Republicans, Residual.

jecting rim, and is a little inclined, it ferves to let the water run off, and preferves each dwelling from the rain. Figure to yourfelf a huge irregular mafs, the fummit forming a kind of roof, and all the other parts of the furface completely covered with cells fqueezed one againft another, and you will have a tolerably accurate idea of thefe fingular edifices.

Each cell is three or four inches in diameter, which is fufficient for the bird. But as they are all in contact with one another through the greater part of the furface of the mafs, they appear to the eye to form but one building, and are diftinguifhable from each other only by a little external aperture, which ferves as an entrance to the neft; and even this is fometimes common to three different nefts, one of which is fituated at the bottom, and the other two at the fides.

The neft which he examined contained 320 inhabited cells, which, fuppofing a male and female to each, announce a fociety of 640 individuals. Such a calculation, however, would not be exact; for whenever our author fired at a flock of thefe birds, he always killed four times as many females as males. "For the reft (fays he), thefe birds have nothing very remarkable in their plumage. It is an uniform brown grey, diverfified by a few black fpots on the fides, and a large patch of the fame colour on the throat. The male is a little larger than the female; in other refpects they exactly refemble each other."

RESIDUAL ANALYSIS, a calculus propofed by the inventor, Mr Landen, as a fubftitute for the method of fluxions. The object of this fubftitution was to avoid introducing the idea of motion, and of quantities infinitely or indefinitely fmall, into mathematical inveftigation. The refidual analyfis accordingly proceeds, by taking the difference of the fame function of a variable quantity in two different ftates of that quantity, and expreffing the relation of this difference to the difference between the two ftates of the faid variable quantity itfelf. This relation being firft expreffed generally, is then confidered in the cafe when the difference of the two ftates of the variable quantity is $= 0$; and by that means it is evident, that the fame thing is done as when the fluxion of a function of a variable quantity is affigned by the ordinary methods.

The evolution of the functions, confidered in this very general view, requires the affiftance of a new theorem, difcovered by Mr Landen, and remarkable for its fimplicity, as well as its great extent. It is, that if x and v are any two variable quantities, $\frac{x^{\frac{m}{n}} - v^{\frac{m}{n}}}{x - v}$

$$= x^{\frac{m}{n}-1} \times \frac{1 + \frac{v}{x} + \frac{v^2}{x^2} + \frac{v^3}{x^3} + \cdots (m)}{1 + \left(\frac{v}{x}\right)^{\frac{m}{n}} + \left(\frac{v}{x}\right)^{\frac{2m}{n}} + \left(\frac{v}{x}\right)^{\frac{3m}{n}} \cdots (n)}$$

where m and n are any integer numbers.

This theorem is the bafis of the calculus; and from the expreffions $x^{\frac{m}{n}} - v^{\frac{m}{n}}$, and $x - v$ having the form of what algebraifts call *refiduals*, the ingenious inventor gave to his whole method the name of the *refidual analyfis*.

Refidual, Revivification.

The firft account of this method was publifhed by Mr Landen in 1758, under the title of a *Difcourfe concerning the Refidual Analyfis*. The firft book of the Refidual Analyfis itfelf was publifhed in 1764; and contained an explanation of the principles of the new calculus, with its application to feveral of the moft confiderable problems belonging to the direct method of fluxions. The fecond book was intended to give the folution of many of the moft difficult problems that belong to the inverfe method of fluxions, or to the integral calculus; but it has never been publifhed: a circumftance which every one, who has taken the trouble to ftudy the firft part of the work, will very much regret.

If we eftimate the value of the refidual analyfis from the genius, profound knowledge, and extenfive views required to the difcovery of it, it will rank high among works of invention: but if, on the other hand, we eftimate its value by its real practical utility, as an inftrument of inveftigation, we muft rate it much lower. When compared with the fluxionary calculus, which it was intended to fuperfede, its principles, though in appearance more rigorous, are much lefs eafily apprehended, much lefs luminous, and lefs direct in their application: and therefore, as a means of extending the bounds of mathematical fcience, it muft ever be regarded as vaftly inferior to the latter (A.)

RETICULA, or RETICULE, in aftronomy, a contrivance for meafuring very nicely the quantity of eclipfes, &c. This inftrument, introduced fome years fince by the Paris Academy of Sciences, is a little frame, confifting of 13 fine filken threads, parallel to, and equidiftant from, each other, placed in the focus of object glaffes of telefcopes; that is, in the place where the image of the luminary is painted in its full extent. Confequently the diameter of the fun or moon is thus feen divided into 12 equal parts or digits: fo that, to find the quantity of the eclipfe, there is nothing to do but to number the parts that are dark, or that are luminous. As a fquare reticule is only proper for the diameter of the luminary, not for the circumference of it, it is fometimes made circular, by drawing fix concentric equidiftant circles, which reprefents the phafes of the eclipfe perfectly. But it is evident that the reticule, whether fquare or circular, ought to be perfectly equal to the diameter or circumference of the fun or ftar, fuch as it appears in the focus of the glafs; otherwife the divifion cannot be juft. Now this is no eafy matter to effect, becaufe the apparent diameter of the fun and moon differs in each eclipfe; nay, that of the moon differs from itfelf in the progrefs of the fame eclipfe. Another imperfection in the reticule is, that its magnitude is determined by that of the image in the focus; and of confequence it will only fit one certain magnitude. See MICROMETER, *Encycl.*

REVETEMENT, in fortification, a ftrong wall built on the outfide of the rampart and parapet, to fupport the earth, and prevent its rolling into the ditch.

REVIVIFICATION, in phyfiology, the recalling to

(A) For this view of the *Refidual Analyfis*, we are obliged to Mr Playfair profeffor of Mathematics in the Univerfity of Edinburgh.

to life of animals apparently dead. There are many kinds of inſects which may be revivified, after all the powers of animation have been ſuſpended for a conſiderable time. Common flies, ſmall beetles, ſpiders, moths, bugs, &c. after being drowned in ſpirit of wine, and continuing apparently dead for more than a quarter of an hour, have been reſtored to life merely by being thrown among wood aſhes ſlightly warm.

While Dr Franklin reſided in France, he received from America a quantity of Madeira wine which had been bottled in Virginia. In ſome of the bottles he found a few dead flies, which he expoſed to the warm ſun, it being then the month of July; and in leſs than three hours theſe apparently dead animals recovered life which had been ſo long ſuſpended. At firſt they appeared as if convulſed; they then raiſed themſelves on their legs, waſhed their eyes with their fore feet, dreſſed their wings with thoſe behind, and began in a little time to fly about.

But the moſt extraordinary inſtance of revivification that we ever heard of, is the following: In the warmer parts of France there is an inſect very deſtructive to rye, which ſeems to begin its operations at the root of the plant, and gradually to proceed upwards to the ear. If the plant be completely dried while the inſect is in the root or ſtem, the animal is irrecoverably killed; but after it has reached the grain, the caſe is very different. There have been inſtances, which are noticed in the Academy of Sciences, of theſe inſects being brought to life in a quarter of an hour, by a little warm water, after the grains, in which they were lodged, had been kept dry for 30 years.

What is the metaphyſician to think of theſe phænomena, or what concluſion is he to draw from them with reſpect to the mind or ſentient principle? If he be a ſober man, he will draw no concluſion; and for this very good reaſon, that of the ſentient principle of inſects, and indeed of every animal but man, he knows nothing. He is conſcious that it is the ſame individual being, which, in himſelf, thinks, and wills, and feels; he knows, that part of his thought is not in one place and part of it in another; and therefore he rationally concludes that this thinking being is not matter, whilſt experience teaches him that it quits the material ſyſtem as ſoon as that ſyſtem becomes completely unfit to diſcharge its functions, and that when it has once taken its flight, it cannot be recalled. Experience teaches him, on the other hand, that the ſentient principle of theſe inſects does not quit the material ſyſtem as ſoon as that ſyſtem ſeems unfit for its functions; and hence he ought to infer, that the minds of men and of inſects (if we may uſe ſuch language), though probably both immaterial are very different ſubſtances; and that the bond which unites the material and immaterial parts of an inſect, is certainly different from that which unites the mind and body of man. This is the only inference which can be legitimately drawn from theſe phenomona; and he who makes them the baſis of materialiſm, muſt have his judgment warped by ſome paſſion or prejudice.

216 Narrative continued. REVOLUTION of France. We formerly preſented to our readers a conciſe ſtatement of the commencement and progreſs of this extraordinary event (See Revolution, *Encycl.*). The ſingularity of its nature, and the important place which it muſt hereafter occupy in the moral and political hiſtory of mankind, require that we ſhould now reſume and continue the detail of its wide waſting career. We left the ſubject towards the commencement of the year 1795, at the cloſe of that wonderful campaign, during which the armies of the Republic had exerted themſelves with ſuch unparalleled ſucceſs in every direction. On the one ſide they had croſſed the Pyrenees, and ſhaken the Spaniſh monarchy to its centre; while on the other they had driven the united forces of Auſtria, Pruſſia, and Britain, from the walls of Landrecies acroſs the Rhine, at all points from Hageneau to the ſea, and had finally cloſed their efforts by the conqueſt of Holland. At that period, though a prolongation of hoſtilities was threatened, we ſcarcely expected that Europe was ſo ſoon to witneſs, or we to record, a ſucceſſion of military enterpriſes of a ſtill more romantic and extraordinary nature, the ſcene of which was even to extend into barbarous countries, where the opinions and the quarrels of the European nations had hitherto remained unknown.

217 Diminiſhed energy of the Convention, The campaign of 1794, however, was not immediately followed by any important military exertions. The Britiſh troops were recalled home, Pruſſia had been gradually withdrawing from the coalition, and the Auſtrian armies remained upon the defenſive. Neither was the French government in a ſituation which could enable it to renew its enterpriſes with vigour, or to give much trouble to the allies. The Convention ſtill exiſted; but it was no longer that terrible aſſembly which, under Robeſpierre and his aſſociates, had, in the ſhort period of fifteen months, reduced two thirds of France under its dominion, and ſent forth armies which the combined ſtrength of the reſt of Europe ſeemed unable to reſiſt. While its authority remained almoſt concentrated in one man, and while the fear of foreign invaſion, and the new born enthuſiaſm for freedom, induced the people to ſubmit to every meaſure of government, however oppreſſive or arbitrary, the power of the Convention, and the number of its armies, were unbounded. The dreadful price, however, which they had paid for liberty, and the facility with which they ſaw it might be loſt, had now diminiſhed the political zeal of all claſſes of citizens. The removal of the foreign armies had diſpelled the dread of invaſion, and the death of Robeſpierre, by diſſolving the unity of its efforts, and ſuffering it to fall into contending factions, had greatly weakened the authority of the Convention, and diminiſhed its efficiency as a government.

The fall of Robeſpierre had been accompliſhed by two ſeparate conſpiracies. At the head of one of theſe were, Barrere, Billaud Varennes, and Collot d'Herbois, who had been members of the Committee of public ſafety. The other conſpiracy conſiſted of members of the Convention who did not belong to the committees, and had no immediate ſhare in the adminiſtration. Among theſe, Tallien, Bourdon de l'Oiſe, and Lecointre of Verſailles, were conſpicuous. After the deſtruction of their mutual tyrant, a conteſt for power took place between theſe parties. The popularity of Robeſpierre had once been ſo conſiderable, and all men had ſubmitted ſo tamely to his dominion, that both parties accounted it neceſſary, in their ſpeeches and writings, to juſtify to the nation the ſhare they had taken in accompliſhing his ruin. It was eaſy to be eloquent upon ſuch a topic; but its diſcuſſion naturally operated to the diſcredit of the members of the committee, and of the 219 And diſcredit of the Jacobins, the more violent Jacobins, who had been the immediate instruments for carrying into effect his sanguinary measures. They nevertheless retained possession, for some time, of a considerable portion of power. The current of public opinion, however, ran so strongly against them, and the restoration to their seats in the Convention of the seventy one imprisoned members of the Girondist party, added so much to the strength of their antagonists, that they gradually lost their influence, and were threatened to be brought to trial for their conduct.

As early as August 1794, Lecointre of Versailles had denounced the members of the old committee of safety; but his accusation at that time produced little effect. Towards the end of that year, however, their approaching fall became evident. On the 26th of December the Convention ordered, on the motion of Clauzel, that the committees should immediately report upon the conduct of the representatives denounced by Lecointre and all France. Accordingly, on the following day, Merlin of Douay reported, in the name of the committees, that there was no cause for inquiry into the conduct of Vouland, Amar, and David; but that there was room for examining the conduct of Barrere, Billaud Varennes, Collot d'Herbois, and Vadier.

219
Whose leaders were accused,

In consequence of this report, a committee of twenty-one members was appointed to make the enquiry. On the 2d of March this year (1795), Saladin presented the report of the commission; in which these four deputies were accused of having participated, as members of the governing committee, in the tyranny and atrocious measures of Robespierre. Their trial commenced before the Convention on the 22d of March; but previous to that period, Vadier had made his escape. The others remained, and rested their defence upon this ground, that although members of the committee of safety, they had no power to resist Robespierre, and that they were not more culpable in having acquiesced in his tyranny than the other members of the Convention, who had all been overpowered for the time by the knowledge that instant destruction awaited every man who should dare to oppose his measures. Except in the case of the cruelties committed by Collot d'Herbois at Lyons, this defence was probably by no means destitute of foundation. It had much weight with the nation at large; in whose eyes it tended, not to exculpate the three persons now accused, but to criminate and degrade the character of the whole Convention.

220
and defended by their faction;

Carnot, Lindet, Cambon, Duhem, and the other members of what was now called the *Jacobin party*, defended their leaders with considerable ability, and with much vehemence. Nor was the party less active without doors than within the hall of the Convention. For some time they had drawn their friends to the capital from all quarters of the country; and in the morning sitting of the first of April, they commenced their operations by an open insurrection. An immense multitude having assembled in the suburbs, proceeded to the hall of the Convention. A real or factitious scarcity existed at the time. Taking advantage of this circumstance, they pretended they were going to petition for bread; and this pretence drew numbers along with them who had no share in their designs.

Boissy d'Anglas, a conspicuous member of the moderate party, was addressing the Convention upon the means of removing the present scarcity when the insurgents arrived, drove the centinels from their posts, and suddenly filled the hall. They tumultuously demanded "Bread, and the Constitution." The Jacobin party supported the insurgents; and one of the multitude, in a vehement harangue, exclaimed, "We are men of the 14th of July, of the 10th of August, and of the 31st of May." He demanded, that the Convention should change its late measures, that the people should no longer be the victims of mercantile rapacity, and that the accused patriots should not be sacrificed to the passions of their antagonists. The Convention ordered the tocsin to be rung, and the people of Paris to be called to arms. General Pichegru was in Paris at the time; and, upon the motion of Barras, he was appointed to the command of the military force.

221
Which is quelled by Pichegru.

The citizens of Paris, who remembered with horror the domination of Robespierre and his adherents, and now saw themselves menaced with its return, instantly called each other to arms, and assembled, by six in the evening, for the protection of the Convention, to the amount of 20,000 men. Till that time the assembly had remained under no small disquietude, surrounded by the insurgents, and listening to the addresses of their orators, and the speeches of the Jacobin minority in their favour. The majority was now rescued from this state of constraint; and, on the motion of Dumont, without proceeding farther in the trial, it was decreed that Barrere, Collot d'Herbois, and Billaud Varennes, should immediately be transported to Guiana.

222
Victory of the Convention.

During the following day the insurgents were completely subdued; and the majority of the Convention, taking advantage of their victory, decreed the arrest and confinement, in the castle of Ham in Picardy, of several of the most obnoxious of their antagonists. Among these were Leonard Bourdon, Duhem, Chasles, Choudieu, Ruamps, Foussedoire, Huguet, Bayle, Lecointre, Cambon, Thuriot Maignet, Heutz, Crassous, and Levasseur. By departing from the punishment of death, and adopting that of banishment on this occasion, the Convention expected to diminish the ferocity of the contending factions in the state, by rendering the result of a political defeat less fatal than formerly. The design was good; but in attempting to accomplish it, they established the pernicious precedent of inflicting punishment without a trial, which could scarcely fail to prove highly dangerous, if not ultimately fatal, to all their prospects of a free and just government.

223
Proposal for a new constitution.

The Convention now followed up its victory with the popular measure of preparing for its own dissolution, by endeavouring to frame a fixed constitution for the Republic. The constitution which had been decreed in 1793, under the auspices of Robespierre, was considered as impracticable, and a committee was appointed to report upon the measures which ought now to be adopted. It consisted of Sieyes, Cambaceres, Merlin of Douay, Thibaudeau, Mathieu, Le Sage of Eure and Loire, and Latouche. On the 19th of April, Cambaceres reported, that it was the opinion of this committee that a commission should be appointed to frame an entirely new constitution. The Convention accordingly appointed the following persons to this important office, Le Sage, Louvet, Boissy d'Anglas, Creuze, Latouche, Bertier, Daunow, Baudin, Durand, Maillane, Languinais, La Reveillere Lepaux, and Thibaudeau. All other citizens of every description were at at the same time invited to communicate projects upon the subject, and the committee was required to order the best conceived of these to be printed.

The Convention farther gratified the feelings of the great majority of the nation, by bringing to trial Fouquier Jenville the president, and fifteen judges and jurors of the late revolutionary tribunal. They were convicted on the 8th of May, and executed on the following day, amidst the execrations of a multitude of spectators.

224
New insurrection of the Jacobins,

In the mean time, though defeated on the 1st and 2d of April, the Jacobins by no means considered themselves as subdued. On the contrary, they were preparing a new and more extensive insurrection, which should not, like the former, be confined to the capital. They fixed upon the 20th of May as the day of revolt. Thuriot, and Robespierre's financier Cambon, had found means to escape from the castle of Ham in Picardy, and to come to Paris. They concealed themselves in the suburb St Antoine, and from thence gave counsel to their party, and urged them to action. The scarcity of bread had increased, and advantage was again taken of this circumstance. For some days the walls were covered in various places of Paris with printed accusations against the Convention of withholding bread from the people, and attempts were made to excite the troops in the city to join the disaffected party. On the evening of the 19th, a paper was openly distributed in the different sections, explaining the object of the approaching insurrection. It declared insurrection to be the most sacred duty of the people, and called upon the citizens of Paris to proceed in a mass to the Convention, to demand from it bread and the establishment of Robespierre's constitution, together with a new election of national representatives.

On the morning of the 20th, the tocsin was rung, and drums beat to arms in the suburb St Antoine, which had always been the quarter of the city in which the Jacobins possessed the greatest strength. Upon this alarm the Convention assembled; but although the intended insurrection was no secret, and though the committee of public and general safety now made a report, in which they confessed their previous knowledge of it, yet it does not appear that any vigorous measures of precaution had been taken; for it was only at the instant when the insurgents were actually approaching that General Hoche was appointed to command the armed force, and was sent forth to assemble the military and the citizens for the defence of the Convention. In the mean time, the multitude surrounded the hall. They soon overpowered the guards, and burst into the midst of the assembly. In all the turbulent days of the revolution, the women of Paris have never failed to act a conspicuous part. On this occasion they greatly augmented the crowd by their numbers, and the tumult by their cries of "Bread, and the constitution of 1793," which was the rallying exclamation of the party. After some fruitless efforts to restore tranquillity, Vernier the president, an old man, resigned the chair to Boissy d'Anglas, who remained in it with much firmness during the day. The whole strength of the insurgents had not arrived at once; for the first party that approached, although they forced their way into the hall, were soon repulsed by the aid of a few soldiers and citizens, who came to the assistance of the Convention. A short interval of tranquillity was thus obtained; but the attack was speedily renewed with double fury by armed men, who subdued all opposition, and entered the hall with cockades, on which was written the inscription, "Bread, and the constitution of 1793." While things were in this state, a citizen of the party of the Convention rashly tore off the hat of one of the insurgents, and was immediately assaulted with swords by the multitude. He fled towards the president's chair, and was killed at the side of it by a musket shot. Ferand, one of the members, having attempted to rescue him, was also attacked. He escaped into one of the passages, where he was also killed, and his head was brought into the Convention upon a pike. The greater number of the members now gradually departed, and left the hall in possession of the insurgents, who acted with some regularity, and proposed a variety of laws favourable to their party, which were instantly decreed. Duroi, Duquesnoi, Bourbotte, and Goujon, were the members who stood most openly forward on this occasion, and appeared as chiefs of the insurrection. But their triumph only lasted a few hours. Towards the evening a large body of citizens joined the military, and marched to the aid of the Convention. Having overcome the insurgents, they entered the hall in great force, and restored the powers of the majority. The decrees that had been forced upon them were repealed as speedily as they had been enacted, and the deputies who had proposed or supported them were arrested.

225
Who murder some of the Convention, and drive it from its hall.

The citizens of Paris, and even the members of the Convention, appear now to have fancied their victory complete; for they adopted no adequate measures to prevent a new disturbance. But the Jacobins did not so easily give up their own cause. On the following day they once more assembled in the suburbs, and in the afternoon they returned to the attack. They took possession of the Carousal without opposition, and pointed some pieces of cannon against the hall of the Convention. This assembly was now unprotected, and attempted not to subdue, but to flatter, the insurgents. A deputation of the members was sent forth to fraternise with them, and to carry forth two decrees passed at that instant, which ordained that bread should abound, and that Robespierre's constitution of 1793 should immediately be put in force. The insurgents, in return, sent a deputation to the Convention, to express their satisfaction with the decrees, to demand the release of the imprisoned patriots, and the punishment of those who preferred money to assignats. The Convention pretended to agree to all their demands, and the president was ordered to give to the deputation the fraternal embrace.

226
Meanness of the Convention.

The 22d, which was the third day of the insurrection, appears to have been passed by both parties in a strange degree of inaction. The Convention proceeded in its ordinary business; and the Jacobins, at their head quarters in the suburb St Antoine, were occupied in consultations and preparations for new movements. But on the following day the citizens assembled at their sections, and hastened from thence to the Thuilleries to defend the Convention. Considerable bodies of the military were also collected, and the assembly at last resolved to act upon the offensive. A decree was passed, declaring, that if the suburb St Antoine did not instantly surrender its arms and cannon, together with the

the murderer of Ferand, it ſhould be conſidered as in a ſtate of rebellion. The conventional generals were at the ſame time ordered to reduce it by force. The in-
227 ſurgents now found themſelves unequal to the conteſt, and were compelled to ſurrender without conditions by the inhabitants of the ſuburb, who dreaded the deſtruction of their property by military operations. Several ſoldiers being found among the priſoners, were put to death; and ſix members of the Convention were tried and condemned on this occaſion by a military commiſſion. Three of theſe periſhed by ſelf-ſlaughter, and three were executed. The majority of the Convention, elated by their victory, ordered back Collot D'Herbois, Billaud Varennes, and Barrere, to take their trial; but the two former had ſailed before the arrival of the courier. Barrere only remained, and he was brought back and impriſoned.

Its victory over the Jacobins;

In the mean time, the Jacobins in the ſouth were not leſs active than their brethren at Paris. On the 20th of May they formed a vigorous inſurrection at Toulon. They ſeized the gates and mounted them with cannon; they liberated ſuch of their aſſociates as had been impriſoned, and detained the fleet which was about to ſail. Having begun their operations in this ſucceſsful manner, they marched from Toulon towards Marſeilles. Their force amounted to three thouſand men and twelve pieces of cannon. They were encountered on their way, however, and defeated by Generals Charton and Pactod. Three hundred of them were carried priſoners to Marſeilles, and Toulon was ſpeedily retaken.

The party of the *Mountain*, as it had been called, or of the violent Jacobins, who wiſhed to revive the reign of terror and the meaſures of Robeſpierre, was now reduced very low both in the Convention and out of it. Thoſe who adhered to it were even in many places, and more eſpecially in the ſouth, expoſed to very violent perſecution. Aſſociations were formed, called Companies of *Jeſus* and of the *Sun*, for the purpoſe of avenging the crimes committed by them during the period of their power. At Lyons ſeveral of them were maſſacred in priſon, and many of them in all places periſhed by aſſaſſination. On conſidering the mercileſs character of the government of Robeſpierre and his aſſociates, and the perſecution which was ſuffered under it, not merely by the nobles and the rich, but by every man who was diſtinguiſhed by integrity, talents, or literature, it may appear ſurpriſing that it ſhould have obtained admirers, or that any number of individuals ſhould have been found willing to hazard their lives to procure its reſtoration. Accordingly, from the period of the fall of its leader, the party had gradually been forſaken by its adherents; and the more cloſely its conduct was conſidered, it loſt ground the more rapidly in the eſtimation of the public. After the unſucceſsful inſurrections of the 20th of May, it was treated with the utmoſt contempt, and its unpopularity was extreme. Still, however, a party remained. It was ſmall,
228 indeed, but its members compenſated the inferiority of their numbers by ſuperior enterpriſe and activity. They conſiſted of outrageous republicans, whoſe heated imaginations beheld royalty and ariſtocracy in every propoſal for ſober and regular government. In the conduct of Robeſpierre, they remembered only the energy of his meaſures, by which France was enabled to triumph over the combined efforts of the kings of Europe; and overlooked the atrocities by which he had brought diſgrace upon their cauſe, and rendered his party odious to their own countrymen, as well as to the neighbouring nations. Amidſt the univerſal odium, however, the Jacobins did not deſpair of riſing once more into power; and it is not a little ſingular, that we muſt date the revival of their ſtrength from the period of the unſucceſsful inſurrections which we have juſt recorded, and which ſeemed to have extinguiſhed their hopes for ever.

[W]ho ſtill [re]tain their [ſp]irit;

The unpopularity under which the Jacobins laboured ſoon began to affect the Convention itſelf. The tame ſubmiſſion of that body to the government of Robeſpierre was now remembered. It was recollected, that the majority of its members had been the inſtruments of his power, and had applauded, or at leaſt acquieſced in, his crimes. As the preſs was now free, and the reins of government unſteadily held, their conduct was repreſented to the public in the moſt odious colours. A celebrated ſong, *Le Reveil du Puple*, became extremely popular, as the means of marking diſlike both to the Convention and to the Jacobins; and their conduct was canvaſſed with the utmoſt bitterneſs in a great variety of publications, but more eſpecially in a journal that at this time attracted much notice, and which was conducted by Freron, who had himſelf been a Jacobin, but had now abondoned his party.

In this ſtate of things, the majority of the Convention ſpeedily began to repent of their late victory over the Jacobins. In the firſt efforts of their zeal, they had taken meaſures for the immediate formation and eſtabliſhment of a ſettled conſtitution to ſuperſede their own authority; but they now regretted their raſhneſs, when they perceived, from the temper the nation was in, that the men, the moſt avowedly hoſtile to their character and meaſures, would without doubt be elected as their ſucceſſors. They, and their friends, had ariſen to great diſtinction and wealth under the revolutionary government; and they now began to dread, not only the loſs of power, but alſo a ſevere inveſtigation of their conduct. Theſe conſiderations ſoon produced their natural effects. The decrees for forming and putting in force the conſtitution could not decently be recalled; but the majority of the Convention ſet about deviſing means for rendering them of little importance, ſo far as they themſelves were concerned. 229

And terrify the Convention.

On the 23d of June, Boiſſy D'Anglas preſented the report of the committee that had been appointed to prepare the plan of a conſtitution. It began, like the former conſtitutions, with a declaration of the rights of man; and in addition to this, conſiſted of fourteen chapters, upon the following ſubjects:—The extent of the territorial poſſeſſions of the Republic, the political ſtate of citizens, the primary aſſemblies, the electoral aſſemblies, the legiſlature, the executive power, the municipal bodies, the judicial authority, the public force, public inſtruction, the finances, foreign treaties, the mode of reviſing the conſtitution, and, laſtly, an enactment, that no rank or ſuperiority ſhould exiſt among citizens, excepting what might ariſe from the exerciſe of public functions. 230

New conſtitution, conſiſting of

The primary aſſemblies were to poſſeſs the right of electing the members of the electoral aſſemblies, and alſo the juſtices of the peace. The electoral aſſemblies were to nominate the judges and the legiſlators of the ſtate,

French Revolution, 1795.

ftate. The legiflature was divided into two affemblies; the one of which confifted of 250 members, and was called the *Council of the Ancients*, as none but married men and widowers above 40 years of age could be members of it. The other affembly or council confifted of 500 members, and poffeffed the exclufive privilege of propofing the laws; the Council of Ancients being only intitled to reject or approve, without power to alter the decrees prefented to it. To this rule there was one exception, which was afterwards employed as the means of overturning the whole fabric of the conftitution; the Council of the Ancients might decree the removal of the legiflature from its ordinary place of fitting. To this decree the approbation of the Council of Five Hundred was not neceffary; and when once enacted, it could not be confidered even by the Council of Ancients itfelf. One-third of the members of the two Councils was to be elected annually. A member might he once re-elected but he could not be elected a third time till an interval of two years had elapfed.

231 Two Councils and an

232 Executive Directory.

The executive power was intrufted to five perfons of forty years of age at leaft, to be ftyled the *Executive Directory*. Its members were elected by the two Councils; the Council of Five Hundred electing ten times the number of candidates that might be neceffary to fill up the vacancies, and the Council of Two Hundred and Fifty nominating the directors from this lift of candidates. One member of the Directory was to go out annually; fo that the whole might be changed every five years. The Executive Directory had no vote in the enactment of laws; but it fuperintended their execution, regulated the coining of money, and difpofed of the armed force. Foreign treaties made by it were not binding till ratified by the legiflative body, nor could it make war without the authority of a decree of the two affemblies. The public functionaries were to receive falaries, and to appear dreffed in an appropriated habit.

Each article of this conftitution was feparately difcuffed; and on the 23d of Auguft the whole was declared to be complete, and ordained to be tranfmitted to the primary affemblies for their approbation. Previous to this refolution, however (that is, on the 22d of the fame month), the majority of the Convention had brought forward the grand meafure by which they meant to provide for their own fafety, and the fafety of their friends and adherents, againft the change which the public opinion had undergone concerning them. They decreed, that at the approaching general election, the electoral bodies fhould be bound to choofe *two-thirds* of the new legiflature from among the members of the prefent convention; and they afterwards decreed, that, in default of the election of two-thirds of the Conventioo, the Convention fhould fill up the vacancies themfelves.

233 The convention fetters the freedom of election.

Thefe decrees were tranfmitted, along with the Conftitution, to the primary affemblies, to be accepted or rejected by them. Many of the primary affemblies underftood, that they could not accept of the conftitution without accepting along with it the law for the re-election of the *two-thirds*. The point had, in all probability, been purpofely left under a certain degree of ambiguity; and as the people were now weary of this Convention, they acquiefced in any conditions that gave them the profpect of one day getting quit of it. But at Paris, and in the neighbouring departments, where the fubject was more accurately inveftigated, the public difapprobation of the Convention difplayed itfelf with great vehemence.

234 Confequences of this conduct.

There was indeed fomething extremely aukward in the decree about the re-election of two-thirds of the Convention. That body might, if neceffary, have continued its own exiftence for fome time longer, or it might have difmiffed one third of its number by ballot or otherwife, and allowed a new election only to that extent; but a compulfory election was an abfurdity fo new, and fo obvious, that it gave their antagonifts every advantage againft them. Accordingly, at the meetings of the fections of Paris, the laws for the re-election were rejected with contempt, and their abfurdity demonftrated with much acrimony. In confequence of the debates which took place at thefe meetings, the minds of men were gradually inflamed, and it became obvious that a political convulfion approached. On the one fide, the Convention took care to publifh daily the approbation of the decrees, along with the conftitution, by the majority of the primary affemblies, by moft of which the two had been confounded and accepted in the grofs. Its committees alfo called in the aid of the troops of the line for its protection. On the other hand, the language of the fections became every day more violent. The whole Convention was reprefented as a band of tyrants and of murderers, the affociates of all the cruelty of Robefpierre and the Mountain party. It was even propfed to bring to trial every individual member of the affembly before a new revolutionary tribunal, and to punifh him according to his demerits.

For fome time much anxiety prevailed on both fides. Numerous deputations were repeatedly fent from the fections to the Convention to remonftrate againft the obnoxious decrees. But the eagernefs with which thefe remonftrances were made, ferved only to convince more ftrongly the members of the Convention of the danger to themfelves as individuals which would attend a refignation of their power, and confirmed the refolution they had taken to retain it. The deputies of the fections having obtained infpection of the records of the convention, afferted, that the national majority, if rightly numbered, had rejected the decrees, as every affembly that voted in oppofition to them was only numbered as one vote, however numerous its members might be; which enabled the primary affemblies of remote diftricts to outvote the more populous fections of Paris and other great towns. Whereas it was faid, that if the individual voters were counted, it would be found that the decrees were difapproved of by a confiderable majority. All this was difregarded by the Convention, and the fections prepared to decide the difpute by arms. The firft ftep taken by them, however, was ill concerted. A notion was propagated, that as foon as the primary affemblies or fections had chofen the electors who were to choofe the members of the new legiflature, the national fovereignty became vefted in thefe electors, and that they had a right to affume the government in their various diftricts. Accordingly, about 100 of the electors of Paris affembled in the hall of the French theatre in the fuburb St Germain, previous to the day of meeting appointed by the Convention. Having chofen

De

French Revolution, 1795.

De Nivernois (formerly the Duke de Nivernois) their prefident, they began their debates. The Convention was alarmed, and inftantly fent a body of the military to difmifs the meeting as illegal. This was eafily accomplifhed, as the citizens had not been unanimous with regard to it, and no meafures were taken for its protection.

Notwithftanding this firft advantage on the fide of the Convention, the fections regarded its power with contempt, and imagined themfelves fecure of ultimate fuccefs. In every political conteft that had hitherto occurred fince the commencement of the revolution, the immenfe population of the capital had given a decifive fuperiority to the faction whofe fide it efpoufed. The citizens alfo regarded with indifference the armed force with which the Convention had furrounded itfelf, from a notion, which they fondly entertained, that the military would in no cafe be brought to act againft the people. It would appear that the Convention itfelf entertained fome jealoufy upon this head, and did not account itfelf entirely fafe under the protection of the foldiers. On this occafion, therefore, it had recourfe to a new ally, and befought the aid of thofe very Jacobins whom it had almoft crufhed on the 24th of May. The members of the Convention were odious to the fections of Paris, on account of their participation in the revolutionary crimes and meafures of Robefpierre; but this very circumftance endeared them to the Jacobins, whofe character it was to imagine that they had never enough of war abroad or of revolution at home. It was eafy therefore to bring about a reconciliation between the Convention and thefe men. Several hundreds of them were difmiffed from the prifons, where they had been confined fince the two laft infurrections, and they were now put in requifition to defend the legiflative body.

235 The Convention courts the Jacobins.

When the fections of Paris beheld the Convention furrounded by thofe Jacobins who had been the unrelenting agents of the government of Robefpierre, and who were now denominated *terrorifts* and *men of blood*, their ardour for action became unbounded. They affembled in arms at their different fections on the 12th Vendemaire (October 4th); but they do not feem to have acted with much concert, or upon any well digefted plan of operations. The general defign of their leaders was to feize the members of the Convention, and imprifon them in the church of the Quatre Nations till they could be brought to trial. As this would occafion a vacancy or interregnum in the government, it was refolved that all affairs fhould be conducted by committees of the fections, till a new legiflature could be elected. General Miranda, a Spaniard, a native of the Carraccas in South America, who had ferved in the republican armies, was to be appointed to the chief command of the armed force after the overthrow of the Convention. This man, in his eagernefs for preferment, had alternately courted all parties, and he now feems to have joined the Parifians upon the fuppofition of their being the ftrongeft. As he entertained fome doubts of their fuccefs, however, he adopted the crooked and timid policy of avoiding the ftorm by retiring from the city till the combat fhould be finifhed, refolving to return immediately on its conclufion to fhare the rewards and the triumph of victory.

The Convention, in the mean time, refolved to ftrike the firft blow. For this purpofe they fent General Menou to the fection of Le Pelletier to difperfe the citizens, whofe greateft force was affembled there. But this officer difliking the fervice which he was employed to perform, inftead of proceeding to action, began to negociate with the leaders of the fections, and fpent the evening of this day in fruitlefs conferences. The fections on their fide appointed General Danican, who had diftinguifhed himfelf in the war againft the Royalifts in La Vendee, to act as their military leader. It would appear, however, that this officer, from the moment that he affumed the command, began to defpair of the caufe of the fections. He found them totally deftitute of cannon, whereas the Convention was furrounded by regular troops and a numerous artillery. This inequality in point of weapons appears to have been confidered by him as a fufficient reafon for avoiding an engagement. Occupied in vifiting and arranging the different pofts, he was unacquainted with the difaffection of the conventional generals. He therefore thought he had done much when he had prevented bloodfhed for another day, and thus the favourable moment for attack was loft. Whether the fections would have been fuccefsful had they been inftantly led to battle on this important occafion, cannot now be known. Though the fuperior officers of the Convention were unfaithful, yet the fubalterns and the troops in general might have ftood firm, confirmed as they were by the perfuafion of their Jacobin auxiliaries. Even in this cafe, however, the fate of a battle might have at leaft been doubtful. The battalions of Paris were very numerous, their contempt of danger was great, and their ardour unbounded. The mere poffeffion of cannon might not in a conteft againft fuch men have afforded fecurity to the Convention. But the firft moments of popular enthufiafm were fuffered to pafs away, and that diftruft and diffenfion, which delay never fails to introduce among great and irregular affemblages of men, foon began to render the conduct of the fections undecided and weak.

The conventional committees, during the night of the 12th Vendemaire (October 4th), difmiffed Generals Menou, Raffet, and fome others, from their ftations, and gave the command of the troops to Barras. He immediately collected around him a variety of able officers, among whom we find the names of Generals Brune and Bonaparte. With their affiftance he began to provide for a moft vigorous defence. Troops with cannon were ftationed in all the avenues leading to the Thuilleries. In cafe any of thefe pofts fhould be forced, mafked batteries were planted in more retired fituations. Nor was this all; meafures were taken for conveying the public magazines of provifions and military ftores to St Cloud, whither the Convention prepared to retreat if they fhould fuffer a defeat at Paris.

On the 13th Vendemaire (October 5th), from which the infurrection was afterwards named, both parties remained for many hours upon the defenfive. At laft, about three o'clock in the afternoon, General Danican made advances to an accommodation by a letter to the committee of public fafety; in which he ftated, that the only caufe on account of which the citizens had taken arms was the dread of a maffacre being intended by the armed terrorifts who furrounded the Convention, and that if thefe men were removed, tranquillity would immediately be re-eftablifhed. A civil meffage was returned;

French Revolution, 1795. turned; but the Jacobin party in the Convention, being now more confident of victory, and wishing to strengthen themselves, by the defeat and punishment of their antagonists, it was resolved that the dispute should be decided by arms. It is not correctly known how the contest commenced, but the armed Jacobins are most generally understood to have begun the attack. The citizens on the southern side of the river attempted to reach the Convention by the Quay de Voltaire, but were speedily repulsed by the conventional cannon; but on the northern side of the river, near the Convention, the combat was extremely obstinate. The cannon were repeatedly seized by the citizens, and repeatedly retaken by the troops and the armed Jacobins. It was not till after a contest of four hours that the sections were repulsed and driven to the post of St Roch. This post was also taken after great slaughter, and the sections were driven to their head quarters at the section of Le Pelletier. After a short interval they were pursued thither by the troops of the Convention, who by midnight were masters of the whole city.

236 Subdues the citizens of Paris.

This insurrection was ascribed by the victorious party to the exertions of the Royalists. It is no doubt true, that by this time Royalty was become less unpopular even among the rabble of France than the extreme of Republicanism, as it had appeared in the conduct of the Mountain party. It is also probable, that the Royalists mingled in a contest that had the overthrow of the present Convention for its object; but the insurgents in general seem neither to have avowed nor entertained any farther view than the disarming of the Jacobins, and the obtaining an immediate election of new representatives. The failure of the attempt had the effect of placing the Mountain party once more at the head of the state. This party at first thought of adjourning the new constitution, and of renewing all the terrors of the revolutionary government. This project, however, was opposed in the Convention with so much vehemence and ability by Thibaudeau, that it was renounced. Indeed it was become unnecessary to the safety or ascendency of the men who proposed it, as the decrees for the re-election of two-thirds of the Convention enabled them to retain the full possession of their power. A few members of the moderate party, such as Boissy D'Anglas, Languinais, and Le Sage, were elected by almost every place in France, though they could only sit for one place. Hence the Convention itself had the re-election of nearly two-thirds of its own members; and the Mountain party, which now commanded the majority, was thus enabled to fill the new legislature with its own leaders.

237 Mountain party, or the most violent Jacobins, again at the head of the state.

On the 27th of October the Convention terminated its sittings, and was succeeded by the new legislature as appointed by the Constitution. By its last decrees, a general amnesty was granted for all revolutionary crimes and proceedings. From this amnesty, however, were excepted the emigrants, the transported priests, and all persons concerned in the last insurrection; so that in fact it was merely a pardon granted by the Mountain party to its own friends for all the excesses they had committed. The members of the Convention, who had been imprisoned in the castle of Ham since the Jacobin insurrection in May, were now set at liberty. The members of the revolutionary committees, and other agents of Robespierre in Paris and the departments, were all dismissed from their prisons, and advanced to the most important offices under the new government.

238 First sitting of the new legislature.

As soon as the new legislature had divided itself into two councils, it proceeded to the election of an Executive Directory. Here the genius of the French nation for intrigue instantly displayed itself. The Council of Five Hundred was bound to present to the Council of Two Hundred and Fifty a list of ten times the number of candidates necessary for the office. It fulfilled this duty in the following manner. The majority of the Council of Five Hundred made out a list, consisting of the five following persons, upon whom they wished the election ultimately to fall: Sieyes, Barras, Rewbell, La Revellere Lepaux, and Letourneur de la Manche. To complete the list, they added the names of 45 obscure persons, country justices, farmers, and even peasants. Thus there was nothing left to the Council of Ancients but the mere form of an election; and from the want of other qualified candidates, they were under the necessity of nominating to the office of directors the five persons at the head of the list presented by the Council of Five Hundred. The crafty Sieyes, however, who had been the adviser of all parties, but the ostensible agent of none, did not yet think fit to venture upon the possession of power. He had disapproved of the constitution which was now put in force, and had even framed one of his own in opposition to it, which, however, was rejected by the Convention. The most remarkable circumstance in his plan of government was a national jury, upon which he proposed to confer the power of dismissing from their offices, without a cause being assigned, any of the public functionaries whom they might account dangerous to the state. Sieyes having refused to accept the office of director, Carnot was elected in his stead. But on this occasion the Council of Ancients was treated with a little, and but a little, more decency than formerly; as the name of Cambaceres, a man of considerable eminence, appeared along with that of Carnot in the list of candidates voted by the Council of Five Hundred.

239 The Council of Five Hundred outwits the Council of Ancients.

The republican government that was now attempted to be established promised little tranquillity to the nation. This great misfortune attended it, that the chief offices in the state were intrusted to men who were disliked by the people. The members of the Executive Directory, with the exception of Reveillere Lepaux, had always belonged to the Mountain or most violent Jacobin party. As they now owed their power to that party, they employed its members in almost every official department. The government was therefore necessarily unpopular. Things might have been gradually altered, indeed, by successive elections, which would in time bring other men into power: But by the forms of the constitution, the executive power was more permanent than the legislative body, without possessing any influence over it. Hence it was to be feared that a contest for power might speedily occur between a directory nominated by the Jacobin party and the new legislators appointed by the people, in which the Constitution might suffer shipwreck; an event which actually occurred.

240 New government not popular.

While the possession of power continued to fluctuate in the manner we have already stated, between the Moderate and the Jacobin or Mountain parties, the armies of the state were suffered to languish; but upon the credit

French Revolution, 1795.

credit of its former military succefs, the Republic was treated with refpect by fome of the neighbouring powers. On the 10th of April, a treaty of peace with Pruffia, which had been negociated by the committees through the medium of Barthelemi the French refident at Bafle, was prefented to the Convention for ratification. By this treaty, it was ftipulated, that the French troops fhould immediately evacuate the Pruffian territory on the right bank of the Rhine, but fhould retain the territory belonging to that power on the left bank till a general peace. Prifoners of war were to be mutually reftored, and the commerce of the two countries was to be placed on its ancient footing. Meafures were alfo to be taken to remove the theatre of war from the north of Germany by treaties between France and thofe princes for whom the king of Pruffia might interpofe.

241 Treatment of the Republic by foreign powers.

During the fame month of April, the French Republic was acknowledged by the king of Sweden; and Baron Stael his ambaffador was received at Paris with great folemnity. In the month of May a fecond treaty with Pruffia was concluded. It chiefly regarded the line of neutrality. It is worthy of remark, that thefe treaties contained fecret articles which were to be revealed only to a felect committee. By authorifing this mode of procedure, the Convention fufficiently demonftrated its refolution, that no form of popular government to be adopted in France fhould ftand in the way of the national aggrandifement. The Swifs cantons now followed the example of Sweden, and acknowledged the French Republic. A treaty of peace with Spain was alfo concluded at Bafle on the 22d of July. France, on this occafion, relinquifhed all the conquefts fhe had made in the territory of that country, and reftored the ancient frontier. She received in return all the Spanifh part of the ifland of St Domingo. The Dutch Republic was included in this treaty; and France agreed to accept of the king of Spain's mediation in favour of Portugal and the Italian princes.

242 Death of Louis XVII.

On the 9th of June, the Dauphin, fon of the unfortunate Louis XVI. died in the prifon of the Temple, where he had been confined, along with his fifter, fince the executions of his father, mother, and aunt. His death, which was probably produced by difeafes arifing from long confinement, if not by more unjuftifiable means, excited in the French nation fuch a degree of intereft in favour of his family, that the Convention found it neceffary to liberate his fifter from imprifonment. The committee of public fafety propofed to the Emperor to exchange this princefs for the members of the Convention whom Dumourier had delivered up to Auftria, along with two ambaffadors, Semonville and Maret, who had been feized on their way to Turkey. This propofal was accepted, and the exchange took place at Bafle in Switzerland.

243 Naval fuperiority of Britain.

On the fide of Britain the war maintained its former character. The Britifh retained their fuperiority by fea, and were unfortunate in their efforts on the continent. On the 14th of March the Britifh fleet in the Mediterranean, under Admiral Hotham, engaged the French fleet, and took two fail of the line, the Ca-Ira and the Cenfeur; but as the French fleet, four days before the engagement, had captured the Berwick, a Britifh fhip of the line, when detached from the fleet, and as the Illuftrious, another Britifh fhip of the line, was fo feverely injured in the action that fhe run afhore and was loft at Avenza, the fubftantial lofs on both fides was nearly equal. On the 23d of June another Britifh fleet under Lord Bridport attacked the French off Port L'Orient, and took three fhips of the line, the reft of the fleet efcaping into that port.

This evident fuperiority of the Britifh fleet in every conteft, induced the government to take advantage of the command which it had of the fea, to give affiftance to the French Royalifts in the weftern departments. Thefe Royalifts, hitherto unaffifted by foreign powers, had, by repeated defeats, been reduced very low. The Convention had at laft offered them a treaty, which was accepted and figned at Nantes on the 3d of March, on the one fide by deputies from the Convention, and on the other by Charette, Sapineau, and other chiefs of the infurgents of La Vendée, and by Cormartin, as reprefenting the party called *Chouans* or Night Owls. Stofflet, another chief, held out for fome weeks longer; but at laft, on the 20th of April, he too was under the neceffity of fubmitting by treaty to the Republic.

244 Expedition to Quiberon Bay.

In a fhort time, however, the hopes of the Royalifts were revived by the countenance of the Britifh government, and thefe treaties were ill obferved. In the beginning of June the Britifh expedition was ready to fail for the French coaft. The troops to be employed confifted of emigrants in the pay of Great Britain, and many of them had been prifoners of war, who now agreed to join the royal caufe. The command during the voyage, and the felection of the place of landing, were intrufted to the Count D'Hervilly. The command on fhore was given to Puifaye, who had been employed under the Girondifts in the military fervice of the Republic, but had now become a royalift. The Count de Sombreuil was afterwards fent to join them with a fmall reinforcement.

On the 25th of June the expedition arrived in the Bay of Quiberon, and on the 27th 2500 emigrants made good their landing, after difperfing a fmall party of republican troops. The emigrant army foon after diftributed itfelf into cantonments along the fhore, and gave arms to the inhabitants of the country, who appeared to receive them with joy. It was foon found, however, that the Chouans, though well qualified for a defultory warfare, could not be of much ufe to regular troops. They had little fubordination. They were eafily difperfed, and never fought unlefs every advantage was on their fide. When it was found that their unfteady aid could not be depended on, a refolution was taken to withdraw the emigrant army within the peninfula of Quiberon. The fort of that name was taken on the 3d of July. Its garrifon confifted of five or fix hundred men, and it was now occupied by the emigrants. A republican army, in the mean time, under General Hoche, advanced, and attacked all the pofts that had been left without the peninfula. Thefe were fpeedily taken. The emigrants and Chouans efcaped into the boats of the Britifh fleet, or fled under the cannon of the fort of Quiberon. The republicans then began to conftruct formidable works on the heights of St Barbe, at the entrance of the peninfula. To prevent their operations, a fally was made from the fort on the 7th of July; but without fuccefs. On the 15th, another fally was attempted in greater force. The whole

whole troops in the peninfula amounted to about 12,000, including Chouans. Out of thefe a detachment of 5000 was fent to attack the heights of St Barbe. The republicans were entrenched in three camps. The two firft of thefe were eafily taken, and the detachment preffed eagerly forward to attack the third. But here a mafked battery opened upon them with grape fhot. A dreadful carnage enfued; and very few of the detachment could have efcaped, had not the fire of the Britifh fhips foon compelled the republicans to defift from the purfuit.

245 Its failure.

It now became obvious that the expedition muft ultimately fail. Defertion became extremely common among the emigrants. Thofe men in particular who had been prifoners of war, and received their liberty on condition of joining the expedition, feized every opportunity of going over to their countrymen; and a correfpondence feems even to have been eftablifhed between the republicans and the difcontented troops in the fort of Quiberon. On the evening of the 20th of July, the weather was extremely tempeftuous, which produced a fatal fecurity in the emigrant army. Sufpicious patroles were remarked; but as they repeated the watchword for the night, they were allowed to pafs. The republican troops were conducted in filence along an unguarded quarter of the fhore, till they were enabled to furprife one of the pofts of the garrifon, where they found the artillery men faft afleep. Their matches were feized, and the lanthorn intended to give the alarm to the Britifh fleet was extinguifhed. The fort was fpeedily in confufion. Some regiments threw away their arms, and went over to the republicans; others even maffacred their own officers. A confiderable number, however, maintained a violent conflict for fome time before they furrendered. Puifaye efcaped on board the fleet. The Count de Sombreuil was taken; and this accomplifhed young man was foon after put to death, along with the other emigrant officers and all the Chouans that were found in the fort. The bifhop of Dol was alfo put to death, with his clergy who accompanied him; but many of the private foldiers of the emigrant army made their peace with the republicans, by pretending they had been compelled to engage in the expedition.

The Britifh fleet, with tranfports and troops, ftill hovered upon the French coaft, and made an unfuccefsful attempt upon the ifland of Noirmoutier. In confequence of the feafon of the year, however, it returned home in December, after evacuating a fmall ifland called *L'Ifle Dieu*, which the troops had for fome time occupied.

246 Succeffes of the French in Germany.

On the fide of Germany the fortrefs of Luxembourg furrendered on the 7th of June, after having been in a ftate of blockade fince the preceding campaign. The French were now in poffeffion of the whole left bank of the Rhine excepting the city of Mentz, which they attacked in vain, becaufe the Auftrians could at all times throw fuccours into it from Fort Caffel on the oppofite bank of the river. Finding the capture of Mentz impoffible in thefe circumftances, the French refolved to crofs the Rhine to inveft the city on all fides. The enterprife, however, was delayed for fome time, till the refult of the Britifh expedition to Quiberon fhould appear. In the month of Auguft, General Jourdan forced the paffage of the Rhine at Duffeldorf, at the head of what was called the army of the Sambre and Meufe. After driving before him three Auftrian pofts upon the Lahn, he croffed the Mein, and completely invefted Mentz and Caffel. Pichegru, in the mean time, croffed the river, with the army of the Rhine and Mofelle, near Manheim, of which city he immediately took poffeffion. But the French generals foon found their forces inadequate to the undertaking in which they were engaged. A confiderable detachment of Pichegru's army, after driving the Auftrians under General Wurmfer from a poft of fome importance, began to plunder, and went into confufion. The Auftrians being informed of this circumftance, returned to the charge, and defeated the French. General Clairfait alfo, having violated the line of neutrality, came upon the rear of Jourdan's army, and took a confiderable part of his artillery. Both the French generals now retreated. Jourdan was rapidly purfued by Clairfait till he returned to Duffeldorf, where he maintained his ground. Pichegru recroffed the Rhine near Manheim, leaving a garrifon of 8000 men in that city. The Auftrians advanced in all directions. Manheim was taken after a vigorous fiege. The French were driven from the neighbourhood of Mentz. The Palatinate became the theatre of war, and the Auftrians feized the country called the *Hundfruck*, fouth of the Rhine as far as Landau and Treves. After various engagements, in which little more ground was loft or won, the two parties entered into an armiftice for three months. 247 They receive a check.

On the 28th of Auguft a treaty of peace was concluded between the French Republic and the Landgrave of Heffe Caffel, on condition that he fhould lend no more troops to Great Britain for the profecution of the war. It is not a little fingular, that peace was concluded with the Elector of Hanover at this period upon fimilar terms. The Duke of Wirtemberg, and fome other princes of the empire, alfo began to treat; but the negociations were broken off in confequence of the reverfe of fortune now experienced by the French. 248 Treaties with German princes.

The Directory, however, refolved to continue the war with vigour, and vaft preparations for the approaching campaign were made during the winter. The Mountain party being once more poffeffed of power, its members exerted themfelves with their ufual energy. Such, however, was the turbulent character of thefe men, that they could not long fubmit peaceably to any government, and foon became weary of that Directory whom they themfelves had eftablifhed. They held clubs in all quarters, and were continually difturbing the public tranquillity. For fome time the government fupported them. The Parifians, after the 5th October, no longer dared to avow openly their diflike to the Jacobins; but they were underftood to exprefs this fentiment by wearing green filk cravats, and by applauding with much vehemence at the public fpectacles the air called *Le Reveil du Peuple*. The Directory now prohibited, by an edict, as tokens of royalifm, the wearing of green cravats, or the performing at any of the theatres the air now mentioned, though the fentiments it contained were entirely republican. The Directory alfo ordered in its ftead, that the Marfeillois hymn, and other popular fongs, fhould be performed every evening at all the theatres. The Parifians fhewed their difapprobation of the Directory by maintaining a profound filence during the performance of thefe fongs, 1796. 249 Ridiculous conduct of the Directory.

French Revolution, 1796.

ſongs, which had never failed till that period to excite burſts of applauſe. The Directory ſoon became aſhamed of this ridiculous conteſt, and in a few weeks recalled their edict. Indeed they found it impoſſible to give countenance for any long period to the reſtleſs and innovating ſpirit of the Jacobins, who continually wiſhed and attempted to return to revolutionary, that is, to violent meaſures againſt their antagoniſts. In the ſouth, in particular, the preſent ſupremacy of the Jacobins produced very pernicious effects. Freron, who had deſerted them after the death of Robeſpierre, and became one of their moſt violent adverſaries, thought fit to return to their party before the 5th October, and was ſent to Toulon with full powers of adminiſtration. Here he diſmiſſed the municipality that had been elected by the people, reſtored the Jacobin clubs, and proceeded to impriſon all ſuſpected perſons, as in the days of Robeſpierre. Theſe meaſures produced a violent reaction on the part of the enemies of the Jacobins. Aſſaſſinations became frequent, and many perſons began to leave the country. The Directory was alarmed by the many complaints againſt the Jacobins or terroriſts that came from all quarters, and reſolved to aim at popularity by deſerting a ſet of men who could not be prevailed upon to act with moderation. Freron was recalled from Toulon, and more manageable men were ſought out to replace the more violent Jacobins, who were in general diſmiſſed from the ſervice of government.

250 Meaſures taken againſt the Jacobins.

The Directory proceeded farther, and acknowledged, by a public reſolution, that its confidence had been abuſed. The miniſter of police was ordered to remove from Paris the members of former revolutionary tribunals, and others who now acted as leaders of the Jacobins, or *anarchiſts* as they were called. A body of troops, amounting to 10,000 men, called the *legion of police*, that had acted againſt the Pariſians on the 5th October, and was now devoted to the Jacobins, was ordered by the Directory, with the authority of the legiſlature, to join the armies on the frontiers. Theſe men refuſed to obey the order; but they were reduced to ſubmiſſion by ſome troops that had been brought to the neighbourhood to provide againſt ſuch an event. The more violent Jacobins were enraged, but not intimidated, by theſe meaſures, and began to organize a plot for the overthrow of the Directory and of the majority of the councils, who had now deſerted them. They were not prepared for action, however, before the month of May, and by that time their deſigns were diſcovered and counteracted. On the 10th of that month the guards were increaſed, and bodies of cavalry ſtationed around the Luxembourg and the Thuilleries. The Directory at the ſame time informed the Council of Five Hundred, by a meſſage, that a dreadful conſpiracy was prepared to burſt forth on the following morning. At the ſound of the morning bell, which is every day rung, the conſpirators were to proceed in ſmall parties of three or four men to the houſes of ſuch perſons as they had marked out for deſtruction. After aſſaſſinating thoſe perſons, the whole parties were to unite, and to act againſt the Directory, whoſe guard they apprehended they could eaſily overpower. The conſpirators had appointed a new Directory and a new legiſlature, to conſiſt of the moſt violent of their own party. Among the leaders of this conſpiracy, who were now arreſted by order of the Directory, was Drouet the poſtmaſter of Varennes, whom we formerly mentioned as having arreſted the unfortunate Louis XVI. when attempting to eſcape to the frontiers. Along with him were Babeuf, Antonelle, Pelletier, Gaudet, Julien, General Roſſignol, Germain, D'Arthe, Laignelot, and Amar, who had been a member of the committee of general ſafety along with Robeſpierre. Vadier and Robert Lindet were alſo engaged in the conſpiracy, but they made their eſcape. Drouet alſo eſcaped by the connivance of the Directory, as was generally underſtood; but the reſt of the conſpirators were removed for trial to the high national court at Vendome, where they were condemned. At the period of their removal thither, a new attempt was made by their party for their reſcue. About 600 men entered the camp at Grenelle near Paris, and endeavoured to prevail with the ſoldiers to join them in an inſurrection. This attempt was altogether unſucceſsful. A few of the inſurgents were killed, and the reſt fled.

These defeats of the Jacobins, and the diſcredit under which they were again brought, encouraged the moderate party in the two legiſlative councils to attempt to repeal the laſt decrees of the Convention, which had at once granted them an amneſty, and confirmed all the laws which, by confiſcating the property of emigrants, excluded their relations from the ſucceſſion. The diſcuſſion laſted many days; but the reſult was, that the law with regard to emigrants remained on the former footing; and the only point which the moderate party were yet able to carry was a modification of the decree to this extent, that thoſe terroriſts were declared incapable of holding public offices who owed their ſafety to the amneſty. 251 Moderate party.

The ſtate of the finances now began to occupy the French government in a very ſerious manner. During the government of Robeſpierre, while the credit of the aſſignats was preſerved by the influence of terror, or by the ſale of the church lands, and the property of emigrants, little attention was beſtowed upon this ſubject. When money was wanted, more aſſignats were fabricated; and as few or no taxes were demanded from the people, no enquiry was made about the public expenditure. But when the boundleſs extravagance of the agents of government had loaded the circulation with aſſignats till they became of little or no value, it became a very difficult queſtion how the public ſervice was hereafter to be ſupported. A new paper currency, called *reſcripts*, was firſt adopted. Theſe were orders on the treaſury for caſh, payable at certain periods. But their credit ſoon paſſed away, as the treaſury had no means of fulfilling its engagements. The Directory complained very bitterly, in a meſſage to the Councils, of its diſtreſſes, and of the want of funds to carry on the approaching campaign. In conſequence of this meſſage, a law was paſſed, on the 25th of March, authoriſing the ſale of the remainder of the national domains for the price that had been fixed upon them at an early period of the revolution, amounting to about twenty-two years purchaſe. A new paper currency, called *mandats*, was to be received in payment. But the credit of government was now gone. The mandats inſtantly loſt in all private tranſactions one-fourth of their value, and they ſoon fell ſtill lower. This, however, produced a great demand for national property, 252 Diſtreſſed ſtate of the finances.

French Revolution, 1796.

perty, which was thus about to be fold far below its value. To prevent this effect, the legiflature broke its engagements, and decreed, that one-fourth of every purchafe fhould be paid, not in mandats, but in cafh. This decree put a ftop both to the fale of national property and to the circulation of mandats.

Recourfe was next had to taxation; but this was attended with much difficulty. By the war, and the violent government of Robefpierre, the French commerce had been in a great meafure ruined. Induftrious men, who poffeffed any capital, had therefore turned their attention to the cultivation of land. Many circumftances led to this. By the emigration of the nobles, and the confifcation of the church lands, the farmers were left with no landlord but the government; which, being fupported by affignats, paid little attention to any other fource of revenue. Hence they paid no rent, and fpeedily rofe into opulence. The revolutionary government, which kept the inhabitants of the towns under dreadful bondage, was fcarcely felt by the inhabitants of the country, who thus enjoyed the advantage of exciting no fufpicion in the rulers, and of paying neither rent nor taxes. The law which declared affignats to be a legal tender of payment, was a great fource of profit to the cultivators of the foil. They contrived to fell the produce of their farms only to fuch as offered them ready fpecie; while, at the fame time, they paid their rents, where the landlord had not emigrated, in affignats, which they obtained at a trifling price. Hence it ufually happened, that while the tenant enjoyed affluence, his miferable landlord was reduced to the neceffity of felling his moveables to buy a portion of the grain that grew upon his own eftate, or was tempted to fell the eftate itfelf at an undervalue, to obtain the means of emigration. By thefe and other circumftances, the whole induftry of the French nation came to be directed towards agriculture. Their country was accordingly well cultivated; but as the riches of agricultural nations are not eafily fubjected to taxation, the French Directory now found it impoffible to carry on the fchemes of ambition and of conqueft, which they had already formed, without relying for refources upon the plunder of the neighbouring ftates, which fpeedily rendered their armies odious in all thofe quarters of Europe to which they penetrated.

253 Reafons of the flourifhing ftate of agriculture.

254 National Inftitute.

Amidft their preparations for the approaching campaign, the Directory attempted to increafe their own reputation at home, by eftablifhing what is called the *National Inftitute*; which is a fociety of men of letters, under the protection of the government *. Into this body were collected the moft celebrated literary characters in the nation that had efcaped the fury of the Mountain Party. Among thefe were La Place, Lalande, Fourcroy, Berthollet, Volney, Dolomieu, and others, well known throughout Europe. The firft public meeting of the Inftitute was held, with great fplendour, on the 4th of April, in the hall of the Louvre, called the *Hall of Antiques*. The ambaffadors of Spain, Pruffia, Sweden, Denmark, Holland, America, Tufcany, Genoa, and Geneva, were prefent. The members of the Directory attended in their robes, and their prefident made a fpeech of inftallation, declaring the determination of the executive power to protect and encourage literature and the arts. Dufaulx, the prefident of the Inftitute, replied, in a fpeech in which he declared the refolution of the members to labour to give luftre to the republican government by their talents and productions. Fifteen hundred fpectators applauded the fpeeches with enthufiafm, and vainly imagined that all the evils of the revolution were terminated, and that their country was now entering upon a career of unexampled glory and profperity.

* See INSTITUTE, *Suppl.*

255 Overtures of the Britifh government

At this period the Britifh government made an approach towards a negociation with France. On the 8th of March Mr Wickham, the minifter plenipotentiary to the Swifs Cantons, tranfmitted to Barthelemy, ambaffador from the French Republic to the Helvetic body, a note containing three queftions: Whether France would be difpofed to fend minifters to a congrefs to negociate peace with his Britannic Majefty and his allies? Whether France would be difpofed to communicate the general grounds on which fhe would be willing to conclude peace, that his Majefty and his allies might confider them in concert? and, laftly, Whether France would defire to communicate any other mode of accomplifhing a peace? The note concluded with a promife to tranfmit to the Britifh court whatever anfwer fhould be returned; but declared, that Mr Wickham was not authorifed to enter into any difcuffion upon thefe fubjects.

256 Infolently rejected by the Directory.

On the 26th of the fame month Barthelemy returned an anfwer in name of the French Directory. This anfwer began by complaining of infincerity in the propofal made by the Britifh court, feeing its ambaffador was not authorifed to negociate, and that a congrefs was propofed, which muft render negociation endlefs. It proceeded to ftate the ardent defire of the Directory for peace; but afferted, that it could liften to no propofal for giving up any territory that had been declared by the conftitutional act to form a part of the Republic (alluding to the Auftrian Netherlands); declaring, however, that other countries occupied by the French armies, and political or commercial interefts, might become the fubject of negociation. Upon thefe points the Directory declared its readinefs to receive reafonable propofals.

To this anfwer no reply was fent; but the Britifh court publifhed a note, of which copies were prefented to the foreign minifters refiding at London; and in it the fpirit of the Directors anfwer was complained of, and alfo the refufal even to negociate about the retention of foreign territory, under pretence of an internal regulation. It was added, with truth, that while fuch difpofitions were perfifted in, nothing was left but to profecute a war equally juft and neceffary; but that, when more pacific fentiments fhould be manifefled, his Majefty would be ready to concur with his allies in taking meafures for eftablifhing a juft, honourable, and permanent peace.

The French Directory had fucceeded, during the winter, in reducing the weftern departments into fubjection. The emigrant expedition from England had induced the royalifts once more to try the fortune of war; but, after various defeats, their leaders, Charette and Stofflet, were taken, and put to death on the 29th of March, and the infurgents were fuppreffed in all quarters. The French government being thus left without an enemy at home, was enabled to make great efforts on the frontiers. The military force of the Republic was divided into three armies. On the Lower Rhine, the army of the Sambre and Meufe was chiefly ftationed about Duffel.

257 French armies.

French Revolution, 1796. Duſſeldorf and Coblentz, and was commanded by Jourdan. Moreau commanded the army of the Rhine and Moſelle, in the room of General Pichegru, who had been diſmiſſed from his command. This army was ſtationed on the Upper Rhine, and from Landau to Treves. The third and laſt army was ſtationed on the coaſt of Italy, from Nice towards Genoa, and now received Bonaparte as its commander. The name and the actions of this man muſt hereafter fill ſo large a ſpace in the detail of this eventful period, that it is neceſſary to pay ſome attention to his perſonal hiſtory.

258 Bonaparte. A Corſican gentleman, a lawyer by profeſſion, but who had appeared in arms under the celebrated Paoli in defence of the independence of his native iſland, was the father of Napolone Bonaparte. Napolone was born at Ajaccio in 1767; aad by the intereſt of M. de Marboeuf, the French governor of the iſland, he was placed for his education at the celebrated military academy of France (*Ecole Militaire*), which has produced ſo many accompliſhed men. At a very early period of life he preſented himſelf as candidate for a commiſſion in the artillery, and was ſucceſsful, being the 12th on the liſt out of 36 victorious candidates. In conſequence of this event he ſerved two or three years in the French army as a lieutenant in the regiment of La Fere. Bonaparte having riſen to the rank of Captain of artillery, returned to Corſica after the revolution, and was there elected lieutenant-colonel of a corps of Corſican national guards. Here he formed a connection, which had nearly proved fatal to him, with General Paoli, the friend of his father. He reſented the treatment which Paoli received from Robeſpierre's government, and entered ſo far into his intereſts as to write the remonſtrance, which was tranſmitted by the municipality to the Convention, againſt the decree which declared the general an enemy to the Republic. In conſequence of this, a warrant was at one time iſſued for his arreſt by the commiſſioners of the Convention. He made his peace, however, on this occaſion; and reſolved to adhere to the intereſts of France, in oppoſition to Great Britain, which at this period formed the deſign of taking poſſeſſion of Corſica. He embarked with the other members of his family for France, and arrived there at the time when Lord Hood was in poſſeſſion of Toulon. Salicetti, a deputy from Corſica to the Convention, introduced him to Barras, who was now ſuperintending the ſiege of Toulon. Here Bonaparte was advanced to the rank of general of artillery; and, under Dugommier, directed the attack of the various fortified poſts around the city. He was afterwards employed for a ſhort time againſt the royaliſts in the weſt of France; and we have already mentioned, that he was at the capital, and aſſiſted Barras in the conteſt between the Convention and the Pariſians on the 5th October. Hence he was regarded with diſlike by the moderate party, and repreſented as an unprincipled adventurer, brought forward to ſupport the terroriſt faction. He had mauy enemies, therefore, at the commencement of his career, and his character was treated with much freedom. The ſcandal of the times went ſo far as to aſſert, that he owed his preſent preferment, not ſo much to any talents he had yet had an opportunity to diſplay, as to his marriage with Madame Beaucharnois, a beautiful French woman whom Barras had taken under his protection.

The French army of Italy amounted at this time to 56,000 men. Bonaparte at his arrival found it ill equipped, and the troops mutinous for want of pay and neceſſaries. He addreſſed them, however, in the true ſtyle of military enterpriſe, "If we are to be vanquiſhed, we have already too much; and if we conquer, we ſhall want nothing;" and ordered them to prepare for immediate action. His opponents, however, anticipated him in the attack. The Auſtrians employed in the defence of Italy, under General Beaulieu, are ſaid to have more than equalled the French in numbers. To theſe were united the King of Sardinia's army, under Count Colli, of 60,000 regular troops, beſides the militia of the country, which was now embodied, and a ſmall body of Neapolitan cavalry, amounting to about 2500 men. General Beaulieu began the campaign, on the 9th of April, by attacking a poſt called Voltri, which the French poſſeſſed, within ſix leagues of Genoa. They defended themſelves till the evening, and then retreated to Savona. Next morning Beaulieu, at the head of 15,000 men, preſſing upon the centre of the French army, was completely ſucceſsful till one o'clock afternoon, when he reached a redoubt at Montennote, which was the laſt of their entrenchments. This redoubt contained 1500 French. Their commander, Rampon, prevailed with them, in a moment of enthuſiaſm, to ſwear that they would not ſurrender; and the conſequence was, that they arreſted the progreſs of Beaulieu for the remainder of the day. During the night, Bonaparte ſtationed his right wing under La Harpe, a Swiſs exile, in the rear of the redoubt of Montenotte, which ſtill held out, while he himſelf, with Maſſena, Berthier, and Salicetti, advanced by Altara, to take the Auſtrians on their flank and rear. Beaulieu, in the mean time, had received powerful reinforcements, and on the morning of the 11th renewed the attack on the French under La Harpe; but Maſſena ſoon advancing upon the flank of the Auſtrians and Sardinians, they gave way on all ſides. Two of their generals, Roccavina and Argentau, were wounded. They loſt 2500 priſoners, and were purſued beyond Cairo, of which the French took poſſeſſion on the following day.

French Revolution, 1796.

259 Takes the command of the army of Italy.

260 His ſucceſs.

On the 13th at day-break, the defiles of Mileſimo, were forced by the French General Augereau; and, by a ſudden movement, General Provera, a knight of the order of Maria Thereſa, at the head of 1500 Auſtrian grenadiers, was ſurrounded; a circumſtance which proved not a little embarraſſing to the French army. For this reſolute officer, inſtead of ſurrendering, inſtantly withdrew to a ruined caſtle on the top of the mountain, and there entrenched himſelf. Augereau brought up his artillery, and ſpent many hours in attempting to diſlodge him. At laſt he divided his troops into four columns, and endeavoured to carry Provera's entrenchments by ſtorm. The French loſt two generals, Banel and Quenin, and Joubert was wounded in this attempt, which proved unſucceſsful. Provera paſſed the night in the midſt of the French army, which had been prevented by his obſtinate reſiſtance from coming to battle. On the 14th the hoſtile armies faced each other, but a diviſion of the French troops was ſtill occupied in blockading General Provera. The Auſtrians attempted to force the centre of the French, but without ſucceſs. Maſſena, in the mean time, turned the left flank of their left wing near the village of

Dego;

French Revolution, 1796.

Dego; while La Harpe, with his division in three close-columns, turned the right flank of the same wing. One column kept in awe the centre of the Austrians, a second attacked the flank of their left wing, while the third column gained its rear. Thus was the left wing of the combined army completely surrounded and thrown into confusion. Eight thousand men were, on this occasion, taken prisoners, and General Provera at last also surrendered.

These victories were not gained over a timid or an inactive adversary. On the morning after his fatal defeat at Millesimo, Beaulieu made one of those spirited efforts which often retrieve and alter the fortune of war. At the head of 7000 chosen Austrian troops he attacked, at day-break, the village of Dego, where the French reposed in security after their success. He took the village; but the French having rallied under General Massena, spent the greater part of the day in attempting to retake it. They were thrice repulsed, and one of their Generals, Causse, was killed. Towards evening, however, Bonaparte in person having brought up reinforcements, the post was retaken, and the Austrians retired with the loss of 1400 made prisoners.

Bonaparte had now thrown himself between the Austrian and Sardinian armies. By the possession of the strong post of Dego, his right was secured against the efforts of Beaulieu, while he was enabled to act with the mass of his force against the Piedmontese troops. His enterprises in this quarter were facilitated by the exertions of Augereau, who had opened a communication with the valley of the Tanaro, where Serrurier's division was approaching the town of Ceva, near which the Piedmontese had an entrenched camp defended by 8000 men.

On the 16th Augereau attacked the redoubts which covered this camp, and took most of them; which induced the Piedmontese to evacuate it during the night, and on the 17th Ceva was entered by Serrurier. Count Colli now retreated to cover Turin; making choice, however, of the strongest posts, and fighting in them all. He was able, on the 20th, to repulse Serrurier; but on the 22d Bonaparte, still pressing on the Piedmontese general, defeated him near Mondovi, and entered that place. The retreating army next endeavoured to make a stand, with its head quarters at Fossano, and its wings at Coni and Cherasco. On the 25th Massena advanced against Cherasco, which was speedily evacuated. Fossano surrendered to Serrurier, and Alba to Augereau.

261 Armistice with Sardinia succeeded by

Previous to these last movements, however, Count Colli, on the 23d of April, had written to Bonaparte, requesting an armistice, to allow the King of Sardinia an opportunity of negociating a peace. The French army was now within 26 miles of Turin; and that prince saw himself suddenly reduced to the necessity of standing a siege in his capital, or of accepting such terms as the conqueror might think fit to impose. Bonaparte granted an armistice, on condition that the three fortresses of Coni, Ceva, and Tortona, should be delivered up to him, with their artillery and magazines, and that he should be allowed to cross the Po at Valentia. The armistice was signed on the 29th, and it was followed by a formal treaty with the French Republic, which was concluded at Paris on the 17th of May. The conditions imposed by this treaty upon the King of

262 A formal treaty.

Sardinia were humiliating and severe. He gave up to France for ever the duchy of Savoy, and the counties of Nice, Jenda, and Breteuil. He gave an amnesty to all his subjects that were prosecuted for political opinions. He agreed that the French troops should have free access to Italy through his territory; and, in addition to the fortresses surrendered by the armistice, he gave up those of Exiles, Susa, Brunette, Assiette, Chateau Dauphin, and Alexandria, to be possessed by the French during the war; and they were authorised to levy military contributions in the territory occupied by them. He agreed to erect no fortresses on the side of France, to demolish the fortresses of Brunette and Susa, and to disavow his disrespectful conduct towards the last French ambassador.

In the mean time the French army advanced towards the Po. Beaulieu was deceived by the arcicle in the armistice; which stipulated, that the French should be allowed to cross that river at Valentia, and made all his preparations for resistance in that quarter. Bonaparte laboured, by several evolutions, to confirm this error; and while the Austrian general waited for him near Valentia, in various well fortified positions, he advanced hastily into Lombardy, and had proceeded sixty miles down the river to Placentia, where he arrived on the 7th of May, before the direction of his march was discovered. He immediately seized whatever boats or other craft he could find, and affected his passage without difficulty, there being only a small party of Austrian cavalry accidentally on the opposite bank, and they fled at his approach. Beaulieu in the meanwhile had sent, when too late, a body of 6000 infantry and 2000 cavalry, to prevent if possible the French from passing the river; but Bonaparte, now on the same side of the river with themselves, met and defeated them on the 8th at the village of Fombio. Another body of 5000 Imperialists, advancing to the assistance of those at Fombio, was met at Codogno, and repulsed by General La Harpe; but this officer was killed on the occasion. On the 9th Bonaparte granted an armistice to the Duke of Parma, on condition of his paying a contribution of 2,000,000 of French money, and delivering 10,000 quintals of wheat, 5,000 quintals of oats, and 2,000 oxen, for the use of the army. This prince also agreed to deliver up 20 of his best paintings, to be chosen by the French. This last stipulation was no sooner known in France, than many men of letters and artists remonstrated against it as both impolitic and useless. They contended, that it would render the French Republic odious to all Italy, without producing any advantage to compensate this evil, as the progress of the arts could not be promoted by removing their best productions from the scenes in which they originated. But the Directory was too much occupied by views of national aggrandisement to listen to considerations of this kind, and similar stipulations were ordered to be inserted in every future treaty; by which means the most valuable curiosities of Italy were gradually transferred to the French capital.

263 Armistice with the Duke of Parma.

Beaulieu, now driven from the Po, crossed the Adda at Lodi, Pizzighitone, and Cremona. He left some troops, however, to defend the approaches to Lodi. The advanced guard of the French attacked these on the 10th, and drove them into the town; which was entered in such close pursuit, that the Imperialists, on leaving

French Revolution, 1796. ving it, had not leifure to break down the bridge over the Adda. At the other end of the bridge the Imperial army was drawn up, and thirty pieces of cannon defended the paffage. The French generals, after a confultation, agreed that it could not be forced. But Bonaparte having demanded of his grenadiers if they were willing to make the attempt, they applauded the propofal, and he formed them into a clofe column. Taking advantage of a cloud of fmoke which iffued from the hoftile artillery, they rufhed along the bridge, which was about 100 yards in length, and were at the middle of it before they were difcovered. Here a general difcharge from the Auftrians deftroyed 700 men. The French column hefitated, and the carnage became terrible; but Maffena, Berthier, Dallemagne, Cervoni, Lafnefs, Dupat, and other officers, flying to the head of the column, urged on the foldiers, and preffing forward, broke into the ranks of the Imperial army, which immediately gave way, and fled in all directions. This exploit has been much celebrated. The intrepidity of the troops by whom it was accomplifhed is unqueftionable; but how far the leader who urged them to fuch an enterprife is entitled to approbation may well be doubted. He had paffed the Po with fcarcely the lofs of a man. The Adda is a very inferior ftream, which has fords both above and below the town of Lodi. The river was actually croffed at one of thefe by Augereau with the cavalry, during the attack upon the bridge. With the delay of one day therefore the paffage might have been effected without difficulty by the whole army, and there was no adequate motive to juftify the lavifh expenditure of blood which was here made; for the French army no longer preffed forward in purfuit of Beaulieu, but, after the furrender of Pizzighitone and Cremona on the 12th, returned upon Pavia and Milan on its left (A). Thefe places opened their gates without refiftance, though the citadel of Milan held out for a fhort time.

264 Victory at Lodi.

It would feem that, in the original plan of Bonaparte's campaign, the utmoft expected from his efforts was to gain fuch an afcendancy in Italy as might induce the princes and ftates of that country to defert the coalition againft France, which all of them affifted with money and provifions, if not with troops. To accomplifh this object, though he fent Maffena in purfuit of Beaulieu as far as Verona, yet he himfelf now turned afide into Modena and the territories of the Pope. He took Ferrara, Bologna, and Urbino; and at laft granted an armiftice to his holinefs and the Duke of Modena, on the ufual conditions of large contributions of money, paintings, and curiofities. From the Pope he farther exacted the ceffion of the legations of Bologna and Ferrara, and poffeffion of the citadel of Ancona. His march into the Roman territory fo alarmed the Neapolitan cabinet, that it now folicited peace; and Bonaparte granted an armiftice, without attempting to add to it the humiliating conditions to which the other Italian ftates were fubjected. From the territories of the Pope, Bonaparte haftily advanced with a body of troops to Leghorn, in the neutral ftate of Tufcany, under pretence of driving out the Englifh, whofe property there he confifcated. By thefe meafures the tafk affigned to Bonaparte was completed by the time the campaign upon the Rhine was begun. Mantua was ftill indeed in the hands of the Imperialifts, but it was blockaded, and all Italy was now fubmiffive to France.

265 Its confequences.

French Revolution, 1796.

266 Succeffes of the French in Germany.

To diminifh, if poffible, the efforts of the French on the fide of Italy, the Imperialifts thought it neceffary to renew the conteft in Germany. An intimation was therefore fent to General Jourdan, that the armiftice would terminate and hoftilities commence on the 31ft of May. At this time General Wartenfleben oppofed Jourdan; and the Archduke Charles commanded the army in the Hundfruck, which covered Mentz and Manheim, and was ftationed againft Moreau on the Upper Rhine. The French began their operations with a very artful ftratagem, intended to draw the whole Auftrian force to the Lower Rhine, that Moreau might have an opportunity of fuddenly penetrating into Swabia, and confequently of carrying the war towards the hereditary territories of Auftria. For this purpofe Moreau remained quiet, while Jourdan began to act vigoroufly. On the 31ft of May his left wing, under Kleber, iffued from the lines of Duffeldorf, on the right bank of the Rhine, and, advancing towards the Sieg, defeated the Imperialifts. Thereafter they were driven fucceffively from the ftrong pofitions of Ukareth and Altenkirchen, and retreated acrofs the Lahn, Jourdan, in the mean time, having advanced with his centre and right wing, forced the Auftrian pofts on the Nahe, croffed the Rhine, formed the blockade of the fortrefs of Ehrenbreitftein, and haftened forward as if about to form the blockade or fiege of Mentz. By thefe movements the Archduke found himfelf in the hazardous fituation of having Moreau in his front, while Jourdan, with a victorious army, commanded his rear. He therefore haftily croffed the river, leaving the fortreffes of Mentz and Manheim to keep Moreau in check. Having joined the retreating army, he encountered Jourdan's advanced guard, which he compelled to retire after an obftinate conflict. Jourdan did not hazard a general engagement, but withdrew to his former pofitions, the Archduke preffing hard upon him, till he raifed the blockade of Ehrenbreitftein, and croffed the Rhine in its neighbourhood, till Kleber, on the 20th of June, entered the lines of Duffeldorf, from which he had fet out.

Thefe movements were forefeen. For the inftant that the Archduke withdrew from the Palatinate to drive Jourdan down the Rhine, Moreau afcended rapidly towards Strafburgh; fo that thefe hoftile armies feemed to be flying from each other with all poffible fpeed. On the 24th of June, Moreau effected the paffage of the river oppofite to fort Kehl. This was an enterprife of confiderable difficulty; for a fudden fwell, by covering a part of the iflands with which the river abounds, had prevented the Auftrians from being taken by furprife, as was originally intended. The entrenchments on fuch iflands as were occupied by troops were fpeedily carried by the bayonet, and 2600 French landed on the oppofite fhore, but without cavalry or artillery. Here they were expofed to the attacks of the Auftrian

(A) We think this conduct cannot be accounted for, but by the fuppofition of a very improper correfpondence between Bonaparte and the Auftrian officers.

French Revolution, 1796.

Auſtrian horſe from the camp of Wilſtedt, and to the fire of the cannon of the fort. They maintained their ground, however, and even acted on the offenſive, till the boats, which had been ſent back, returned with a reinforcement. The whole redoubts and the fort were then inſtantly taken by ſtorm, or with the aſſiſtance of ſuch cannon as had been found in the firſt redoubts at which the French arrived, and the Imperialiſts fled towards Offenburgh.

The departure of the Archduke to the Lower Rhine in purſuit of Jourdan, and the large detachments which had recently been ſent towards Italy to oppoſe Bonaparte, now enabled Moreau to enter Swabia with a great ſuperiority of force. The ſtrong military poſitions, however, which the country affords, preſented to him conſiderable difficulties. On the 26th of June he drove the Auſtrians from their camp of Wilſtedt; and on the 27th he advanced with his army, in three columns, againſt another camp of 15,000 men in front of Offenburgh. General Wurmſur ſent a ſtrong reinforcement from Manheim to the aſſiſtance of theſe troops; but having encountered two of the French columns on its way, the reinforcement was defeated, and the camp at Offenburgh was evacuated during the night. The Auſtrians made an obſtinate ſtand at Renchen, near Philipſburgh, on the 29th, but were at laſt compelled to retire with the loſs of 1200 men taken priſoners, and ſeveral pieces of cannon. On the 2d of July a diviſion of the French army, under General Laroche, ſucceeded in ſeizing the mountain Knubis, which is the higheſt point of the ridge of mountains called the Black Foreſt. On the 3d, after an obſtinate conflict, the Auſtrians were driven from the paſs of Friedenſtadt; in conſequence of which they loſt all communication with the emigrant troops under the Prince of Condé, and other Imperial troops ſtationed on the Rhine towards Switzerland. On the 6th, the left wing of the French, under Defaix, encountered the Imperialiſts at Raſtadt, where the Auſtrians, who had received ſome reinforcements from the Lower Rhine, made a very determined reſiſtance; but were at laſt compelled to give way, and to retire to Ettingen.

The Archduke Charles now arrived in perſon with his army from the Lower Rhine, where he had left Wartenſleben, but with inferior force, to oppoſe Jourdan. The French, under this general, had inſtantly reſumed the offenſive upon the departure of the Archduke. Kleber advanced from the lines of Duſſeldorf, as formerly; while the centre and right wing croſſed the Rhine near Coblentz. The poſts of Ukareth and Altenkirchen were forced, and on the 9th of July the whole of Jourdan's army croſſed the Lahn. On the 10th, Wartenſleben was defeated near this river, after great ſlaughter on both ſides, with the loſs of 500 priſoners; and the French on the 12th entered Franckfort. The ſituation of the hoſtile armies was now become extremely important. The two Imperial armies were at no great diſtance from each other, and were placed in the centre between the armies of Moreau and Jourdan. Could the Archduke, who was commander in chief, have reſiſted one of theſe armies for a ſhort time, at any ſtrong poſition, by a detachment of his troops, while he precipitated himſelf with the maſs of his force upon the other, is is probable that any farther invaſion of Germany might have been prevented. But the activity of the French generals, whoſe progreſs could nowhere be reſiſted by partial efforts, prevented the poſſibility of executing ſuch a plan. He was therefore under the neceſſity of making his final exertion for the preſent ſafety of Germany againſt Moreau at Ettingen, on the 9th of July, without having formed any junction with Wartenſleben. The battle was moſt obſtinately fought. The French were four times repulſed in their attempts to force the heights of Rollenſolhe; and it was not till they had experienced a dreadful ſlaughter that they at laſt carried the field by the bayonet.

The loſs of the battle of Ettingen compelled the two Imperial armies to retire eaſtward. After placing ſtrong garriſons in Mentz, Manheim, and Philipſburg, the Archduke retreated through Swabia towards Ulm, where his magazines were placed. At every ſtrong poſition, however, he made an obſtinate ſtand; thus endeavouring to render the progreſs of the French under Moreau as tardy as poſſible. Wartenſleben, with the other Imperial army, retired through Franconia, reſiſting Jourdan in the ſame manner. Many bloody battles were fought, of which it is here unneceſſary to give a minute deſcription. It is ſufficient to remark, that the French were long ſucceſsful in them all. They gradually preſſed forward till Moreau's army compelled the Archduke to croſs the Neckar, and afterwards the Danube, leaving the whole circle of Swabia in the rear of the French. Wartenſleben was in like manner driven through Aſchaffenburgh, Wurtzburg, Schweinfurt, and found it neceſſary to croſs the Rednitz, on the 6th of Auguſt, at Bamberg, to avoid the preſſure of Jourdan's army in his rear. This army continued to advance till its right wing, under Bernadotte, was poſted at Neumarck, with his advanced poſts at Teining, while the body of the army had driven Wartenſleben beyond the Nab, and had reached Amberg on the 22d of Auguſt. 267

Alarm throughout Germany.

Excepting a part of the mountains of Tyrol, three French armies, under Jourdan, Moreau, and Bonaparte, now occupied the whole country reaching from the frontiers of Bohemia to the Adriatic Sea. The alarm throughout Germany was extreme. The Duke of Wirtemberg obtained peace from the French on condition of paying 4,000,000 of French money. The circle of Swabia did the ſame, on engaging to pay 12,000,000 of livres, and to deliver 8,400 horſes 5,000 oxen, 100,000 quintals of wheat, 50,000 quintals of rye, 100,000 ſacks of oats, 100,000 pairs of ſhoes, and a large quantity of hay. The Margrave of Baden obtained peace on ſimilar terms. The elector of Bavaria and the circle of Franconia negociated, and offered large payments; and even the diet of Ratiſbon ſent a deputation to treat with the French generals for neutrality. The King of Pruſſia now entered into a new treaty with the French; the conditions of which were concealed, but its nature appeared in the advantage which he took of the progreſs of their arms to take poſſeſſion of certain territories in Germany, and particularly of the ſuburbs of Nuremberg, under pretence of ſome antiquated title. Spain alſo entered into a treaty offenſive and defenſive with France, which was afterwards followed up by a declaration of war again Britain. 268

Danger of the houſe of Auſtria.

The danger of the houſe of Auſtria was now very great; and had Bonaparte, inſtead of being detained in Italy, by events of which we ſhall immediately take notice,

French Revolution, 1796.

tice, been able to croſs the Tyrol by Inſpruck, and to reach the banks of the Danube, there is little doubt that the Emperor muſt have ſubmitted to ſuch conditions as the French thought fit to impoſe. Deſerted in all quarters by the members of the coalition, he ſtill, however, retained an ally in Great Britain, whoſe riches, liberally beſtowed in the form of a loan, extricated him from the preſent difficulties. Having the command of abundance of money, he was enabled to ſend one army after another to oppoſe Bonaparte in Italy, while he recruited his armies in Germany by extenſive levies, and by taking into his pay the troops of thoſe ſtates that made peace with France.

269 Maſterly conduct of the Archduke.

The Archduke, having received powerful reinforcements, reſolved to make a ſtand, on the 11th of Auguſt, againſt Moreau at Umenheim. A ſevere battle was fought during ſeventeen hours, and one of the wings of the Auſtrian army, under General Rieſe, even ſucceeded in occupying four leagues of territory in the rear of the French army; but the Archduke having received intelligence, in the mean time, that Wartenſleben could not maintain his ground againſt Jourdan, he thought it neceſſary to continue his retreat, and to adopt new meaſures. On the 17th of Auguſt he left General La Tour, with a part of his numerous army, to oppoſe Moreau, and having croſſed the Danube at Neuburg and Ingolſtadt, he marched to Wartenſleben's aſſiſtance to fall upon Jourdan with united forces. On the 23d he attacked Bernadotte at Teining, and forced him to retire towards Nuremberg. The Archduke was thus upon the right of Jourdan, while Wartenſleben was ſtationed on his front. The French general, finding his poſition dangerous, began to retreat on the 24th. From the ſtate of the finances, the French armies, at the commencement of this campaign, had been extremely ill equipped and ill paid. Hence the two armies of Moreau and Jourdan plundered, without decency or mercy, every place into which they entered. In Jourdan's army, more eſpecially, the want of diſcipline was extreme (A). Hence, when they began to retreat, loaded as they were with ſpoil, they ſuffered not leſs from the enraged inhabitants of the countries through which they paſſed, than from the military efforts of the hoſtile army. The Archduke having joined Wartenſleben, was enabled to ſend off Nauendorf with reinforcements to La Tour, who oppoſed Moreau, and, in the mean time, he continued in perſon to purſue Jourdan towards Wurtzburg. Here the French made a ſtand, on the 3d of September, and a general engagement took place. Both parties ſuffered great loſs, but more eſpecially the French, who retreated during the night. Jourdan now fled by Fuldaw to Wetzlaer. Having croſſed the Lahn, where he made ſome reſiſtance, he deſcended along the banks of the Rhine, till his army, on the 17th, reached Coblentz and Duſſeldorf, from which it had originally departed.

270 Critical ſituation of Moreau.

The ſituation of Moreau's army was now uncommonly dangerous. He maintained his poſition, however, till the 17th of September; but he was undecided in his movements, and was obviouſly at a loſs how he ought to proceed. He attempted, without ſucceſs, to withdraw the Archduke from the purſuit of Jourdan, by detaching a part of his troops towards Nuremberg. Many attacks were made upon him, but all of them without ſucceſs; and the Imperial generals at laſt gave way to him wherever he turned. Finding at laſt that Jourdan's defeat was irretrievable, and that Bonaparte did not arrive from Italy, he reſolved to retreat. He had recroſſed the Lech to prepare for this event; but now ſuddenly paſſing it again, as if determined to advance farther into Auſtria, he drove back General La Tour as far as Landſberg. Having thus obtained freedom for his future movements, he ſet out in full retreat, proceeding between the Danube at Ulm and the lake of Conſtance. La Tour, however, ſoon preſſed upon his rear. He found the paſſes of the Black Foreſt occupied by large bodies of Auſtrians and armed peaſants, while Generals Nauendorf and Petrarſch haraſſed his right flank with 24,000 men. Once more therefore he turned upon La Tour, at Biberach, on the 3d of October, with great impetuoſity, and having defeated him, took no leſs than 5000 priſoners; whom he was able to carry to France. He now continued his retreat; his right wing, under General Deſaix, keeping Nauendorf and Petrarſch in check, while the reſt of the army cleared the paſſages in front till he arrived at what is called the Valley of Hell (*Val d'Enfer*), a narrow defile, running for ſome leagues between lofty mountains, and in ſome places only a few fathoms in breadth. The centre of his army, advancing in a maſs, forced this paſſage, while the wings reſiſted the Imperial troops under La Tour and Nauendorf. After this deſperate effort he reached Fribourg on the 13th of October, and was ſoon compelled by the Archduke Charles, who had now arrived from the purſuit of Jourdan, to evacuate all his poſitions on the Swabian ſide of the Rhine, with the exception of Kehl, and a temporary fortification erected at Huningen, called a

271 His ſkilful retreat.

(A) It would be improper to interrupt our military detail with the following information reſpecting the morals of Jourdan's army at this time; which, however, it is of importance for our reader's to know. We have it from a German Count, who ſaw with his own eyes a conſiderable extent of the march and countermarch of the French through Franconia.

Almoſt every officer in Jourdan's army had a miſtreſs; and ſuch of them as by plunder could ſupport the expence, gave balls, acted plays, and exhibited every ſpecies of gaiety when the army was not in actual motion. In all this there was nothing wonderful. The ladies, however, were not unfrequently pregnant; and as nurſing would keep them from theſe aſſemblies, where their company could not be diſpenſed with by the ſoldiers of liberty, they drowned their new-born infants—*they drowned them publicly!* Our correſpondent (the Count) ſaw two of the little victims, and he heard, from unqueſtionable authority, of ſeveral more. At a place within ſix miles of Nuremberg, a Pruſſian pariſh-miniſter, who was alſo a ſort of juſtice, endeavoured to ſave one innocent, and was thrown into the river and fired at by the French, when his pariſhioners endeavoured to ſave him. He had the happineſs, however, to ſave the child, and was allowed to keep it, the mother never enquiring after it!

French Revolution, 1796.

bridge-head (*tete de pont*), though there was no bridge at that place.

The Imperial troops, in the mean time, had taken advantage of the defenceless state of the French frontier to cross the Rhine at Manheim, and to advance in various detachments to Weissemburg, Seltz, Hagenau, and almost to the gates of Strasburgh, levying contributions and taking hostages wherever they came. These detachments being now recalled, the Archduke resolved to terminate the campaign by the capture of Kehl, and of the fortification at Huningen. But this proved no easy task. As the communication with the French side of the river was open at both places, the divisions of Moreau's army did duty at them by turns. A great part of the winter was spent in fruitless attempts, on the part of the Austrians, sometimes to take them by storm, and sometimes to reduce them by the forms of regular siege. Different sallies were made by the French, and immense numbers of men were lost on both sides by the sword, and by the severity of the season. It was not till the 10th of January that the French agreed to evacuate Kehl, and the fortification at Huningen was not given up till the succeeding month.

During the invasion of Germany that has been now mentioned, and the reverses that were suffered by the French armies there, Bonaparte still continued to gain victories in Italy. The success and the wonderful fortune of this man, require that we should give some account of the arts by which he was enabled, so unexpectedly, to triumph over the most experienced military commanders of the age in which he lived. In the military art three orders of battle, or forms of drawing up an army, have been chiefly adopted by those nations whose force has principally consisted of foot soldiers.

272 Reflections on the different orders of battle.

The first form or mode consists of arranging the troops in a deep line; that is, with from 16 to 30 men placed close behind each other. This is the most ancient and the simplest order of battle. It was carried to perfection by the Greeks, under the name of the *Phalanx*; and, when the soldiers were armed with the long spear, it was extremely formidable. It left little to the skill of the general, except the choice of the ground where he was to fight, and made all to depend upon the steadiness of the troops. It was attended with these disadvantages, however, that an army thus drawn up commanded very little territory, and that if its ranks happened to be broken by unequal ground, or an uncommon effort of the enemy at a particular quarter, its parts could not easily be re-united, and it infallibly went into confusion. In modern times, this order of battle cannot be adopted with success on account of the facility with which it is broken by artillery, and the slaughter to which it exposes the troops from every kind of fire arms. The second, or modern order of battle, consists in forming a front of an immense extent, with only two or three men in depth, and usually supporting these by another, and perhaps a third equally slender line, at a considerable distance in the rear. Troops thus drawn up derive the greatest possible benefit from their own fire arms, and suffer the least loss from those of the enemy. They provide for their own subsistence by covering an immense tract of country. Their battles are not sanguinary, as they are seldom very closely engaged; and in case of a defeat, little loss is suffered, because they can scatter themselves over a wide space, as the rear protects the advanced body; and as the troops in a long line can seldom all be engaged at once, they are supported by each other in a retreat. This order of battle, however, is easily broken; and the moment the flank of an army is turned, it is under the necessity of retreating, as troops cannot speedily be brought from other quarters to face the enemy there. The last order of battle consists of dividing an army into columns of a narrow front and very great depth, and of stationing the columns at some distance from each other, with a second set of columns opposite to the intervals between the first. This arrangement is superior to the phalanx, in this respect, that it does not expose an army to disorder by inequalities of ground, by the turning of its flank, or even by the defeat of one of its parts. The celebrated Epaminondas won the battles of Leuctra and Mantinea, by forming a part of his troops, on each of these occasions, into a strong column, which, by its great depth, and the mechanical weight of its shock, broke through the Spartan phalanx. The Romans are known to have owed their military success, in a great measure, to the arrangement of their legion. It was drawn up upon the principle now mentioned; and tho' the columns were only 16 men in depth, it was confessedly superior to the phalanx. In modern times, however, this order of battle is attended with great difficulties. It must reduce an army to embarrassment with regard to provisions from the smallness of territory which is thus occupied, and it exposes the troops in an engagement to dreadful destruction from the powerful missile weapons which are now employed. In every enterprise they must instantly carry their point or be undone, as the fire of a few guns from a single battery or redoubt would exterminate them by thousands. With all its imperfections, however, this last order of battle has at times been employed by enterprising men. It was the favourite arrangement of Gustavus Adolphus; and his troops were drawn up according to it at the battle of Lutzen, where he himself was killed, while his army was victorious. The celebrated Marquis of Montrose also used it on more than one occasion, and it was now adopted in all important cases by Bonaparte.

273 The order adopted by Bonaparte.

Trusting to its success, he pushed his columns into the midst of the Austrian army at Millesimo, and fairly captured one of its wings. He ventured farther to throw himself into the centre, between the Austrian and Sardinian armies, and to vanquish the one, by acting against it with his whole troops while separated from the other. Being careless about the shedding of blood, he never hesitated to expose his whole army to utter ruin in case of a failure. The success of his battles, by enabling him to lay almost all Italy under contribution, gave him the means of maintaining the most steady and severe discipline over a well paid army. Filled with high notions of military glory, which he is said to have derived from the writings of Plutarch, he laboured to inflame, with the same spirit, the minds of his soldiers by proclamations, expressed in a very different style from the formal and more modest language of modern times. "Soldiers (said he, when he first entered Lombardy), you have rushed like a torrent from the summit of the Appenines, you have driven back and dispersed all who opposed your march. Your fathers, your mothers, your wives, your sisters, your sweethearts, rejoice in your success, and boast with pride of being related to you. But

274 His pompous proclamation.

French Revolution, 1796.

But remains there nothing more for you to effect? Shall pofterity reproach us with having found a Capua in Lombardy? But I already fee you rufhing to arms; an unmanly repofe fatigues you, and the days loft to glory are loft to your felicity. But let the people be tranquil; we are the friends of all nations, and more particularly of the defcendants of the Brutufes, the Scipios, and the illuftrious perfonages whom we have chofen as models. To reftore the Capitol, to replace with honour the ftatues of the heroes who rendered it renowned, and to roufe the Roman people, become torpid by fo many ages of flavery, fuch will be the fruit of your victories; they will form an epoch to pofterity, and you will have the immortal glory of renovating the faireft portion of Europe. The French nation, free and refpected by all the world, will give to Europe a glorious peace. You will then return to your homes and your fellow-citizens; who, when pointing to you, will fay, *He was of the army of Italy.*"

275 Marfhal Wurmfer attacked. At the commencement of the French invafion of Germany, Marfhal Wurmfer was fent into Italy to replace Beaulieu, who was removed from his command. On his arrival, he collected the wrecks of the Auftrian army, and prepared, till he fhould receive reinforcements, to confine the French within as narrow limits as poffible, by lines drawn from the lake of Garda to the river Adige. At the end of June, however, thefe lines were attacked and carried by Maffena's divifion, which induced Wurmfer to avoid farther exertion till he fhould receive an increafe of force. In the mean time Bonaparte was not a little difturbed by partial infurrections of the Italians. Soon after his arrival in Lombardy, the inhabitants of Milan and of Pavia had rifen in concert againft his troops; but they were reduced to fubjection with little bloodfhed. In the beginning of July, farther infurrections broke out in the Romagna. The infurgents eftablifhed their head quarters at Lugo, and repulfed a party of French cavalry that was fent againft them. It was not till Augereau had overcome them, on the 6th, in a battle in which he loft 200 men, that they could be fubdued. The flaughter of thefe unhappy people was very great. Their town was given up to pillage, and all found in arms deftroyed.

276 Mantua befieged. The firft part of the month of July was fpent by Bonaparte in commencing the fiege of Mantua in regular form; and towards the clofe of that month he expected its capture. In this, however, he had ill-calculated the immenfe military efforts which Auftria, aided by the money of Britain, was capable of making. Twenty thoufand troops had been fent from the Rhine, and other reinforcements were marching towards Italy from all quarters; fo that Bonaparte, inftead of being able to take Mantua, had fpeedily to defend himfelf againft the force of a fuperior army to his own, that approached to raife the fiege, and even threatened to drive him out of Italy. Wurmfer's army defcended from the Tyrol

277 Partial fucceffes of Wurmfer. in two divifions. One half of it proceeded along the eaft fide of the lake of Garda, and the other came by the weft to cut off the retreat of the French, who were thus enclofed by the Auftrians. On the 29th of July, at three o'clock in the morning, Maffena was driven from the ftrong poft of La Corona, on the eaft of the lake, while, at the fame time, 15,000 Auftrians drove the French from Salo, and afterwards from Brefcia, with all the magazines and hofpitals of Bonaparte's army. There was a fatal error, however, in the general plan of operations that had been formed by the Imperialifts. Their army united was an overmatch for the French; but they had voluntarily divided it into two parts, placing Bonaparte between them. The error was inftantly difcerned, and taken advantage of by their antagonift. On the night of the 30th, he fuddenly raifed the fiege of Mantua, and leaving a fmall body of troops to keep in check the Imperialifts on that fide, he marched rapidly weftward, and on the firft of Auguft retook Brefcia, with the magazines and hofpitals. Having the mafs of his army united, Bonaparte furpaffed his antagonifts in numbers wherever he encountered them. He prepared to attack the Imperialifts on the 3d at Salo, Lonado, and Caftiglione, but was anticipated by them. Having formed a large body of his troops into clofe columns, the Auftrians, who were not yet aware of the nature of his mode of fighting, extended their line to furround them; a movement which enabled the columns to penetrate the Imperial army in all directions, and throw it into complete diforder. The French took 4000 prifoners, and 20 pieces of cannon. The Imperial troops 278 He is defeated. were here fo completely defeated, that a confiderable divifion of them having in vain attempted to retreat by Salo, which they found occupied by the French, wandered about in fearch of a road by which to efcape; and having next day come to Lonado, they fummoned it to furrender, upon the fuppofition that the greater part of the French army had gone eaftward to encounter Wurmfer. This was actually the cafe; but it fo happened, that Bonaparte was in perfon at Lonado with only 1200 men. He was fufficiently perplexed by this accident; but having ordered the meffenger to be brought into his prefence, he threatened to deftroy the whole divifion for having dared to infult the French army, by fummoning its commander in chief to furrender. The ftratagem was fuccefsful. The Imperial officers imagined that the whole army was in the place, and immediately, with their troops, laid down their arms, to the number of 4000 men.

Such is the account of this tranfaction, which we have from the partial pen of the panegyrift of Bonaparte, who writes the hiftory of his campaigns in Italy; but we believe that the General has himfelf affigned the true reafon of his fuccefs on this occafion, and others, where fuccefs could not be reafonably expected. In one of his intercepted letters, Bonaparte informs his correfpondent, that the Auftrian armies in Italy coft him more money than his own; and indeed it is not within the compafs of fuppofition, that a body of veteran foldiers could have been intimidated to lay down their arms by fo vain-glorious a threat as this, had not their officers been corrupted by French gold and French principles. The ftratagem might have its effect upon the common foldiers, but it could not poffibly impofe upon their leaders, or upon the meffenger who fummoned Lonado to furrender.

On the 5th and 6th, Bonaparte attacked Marfhal Wurmfer, and drove him from Pefchiera and the river Mincio. On the 7th, the Auftrians were compelled to quit Verona, and to retire once more to the mountains of Tyrol. The conteft, which had lafted more than 279 Again defeated. fix days, coft the Imperialifts more than 20,000 men, upwards of 15,000 of whom were made prifoners. A part of the Emperor's troops had been levied in Gal-

 licia,

French Revolution, 1796.

licia, the part of Poland which, in the partition of that country, had been allotted to Auſtria. Theſe men ſeized the moment of defeat to quit a ſervice which they diſliked, and to go over to the French; a circumſtance which greatly ſwelled the liſt of priſoners.

It was now neceſſary for the French to commence the ſiege of Mantua anew. The garriſon in their abſence had deſtroyed their works, and carried into the place 140 pieces of heavy cannon which they had left behind them, and procured a conſiderable quantity of proviſions. The blockade was renewed; but the French, by the loſs of their artillery, were unable to proceed to a regular ſiege; and by the beginning of the month of September, Marſhal Wurmſer, having received new reinforcements, was again enabled to attempt the relief of the place. Bonaparte having information of his intended approach, left ſufficient troops to keep up the blockade, while he advanced northward with his army; and on the 4th of September drove the Auſtrians from the paſſes of St Marco and the city of Roveredo to the
280 paſs of Calliano, where they made their principal ſtand.

His maſterly conduct after a third defeat.

Here a battle enſued, in which the French took no leſs than 6000 priſoners, and entered Trent as conquerors. Upon ſuffering this defeat, Marſhal Wurmſer adopted a meaſure which cannot be ſufficiently approved of. Inſtead of retiring before the conqueror, who might have driven him to Inſpruck, and arrived at a critical moment at the Danube, where Moreau, after much heſitation, had only commenced his retreat, he ſuddenly threw himſelf with his vanquiſhed army into Baſſano, upon the flank and rear of Bonaparte, and then advanced by haſty marches towards Mantua. He attempted to make a ſtand at Baſſano on the 8th, but was defeated, and 5000 of his men were taken priſoners. He had ſtill a conſiderable body of troops however. With theſe he puſhed forward; and having fought different ſcattered diviſions of the French at Cerea, Caſtellano,
280 and Due Caſtello, he effected the paſſage of the Adige at

He enters Mantua.

Porto Legnano, entered Mantua with the wreck of his army, amounting to about 4000 infantry and 4500 cavalry. In this enterpriſe the Imperialiſts loſt altogether 20,000 men; but the effect of it was, that it fixed Bonaparte in Italy, where he was obliged to remain watching and keeping under blockade the numerous garriſon of Mantua. He hoped that its numbers would ſoon reduce it by famine to the neceſſity of a capitulation; but in this he was deceived, as the fleſh of the horſes, carried into it by Wurmſer, afforded ſubſiſtence to the troops during a very long period.

In the mean time, the fame which their countryman Bonaparte gained by theſe victories, produced in the
281 Corſicans a deſire to change the Britiſh government for

Corſica revolts from Britain, and unites with France.

that of France. They accordingly diſplayed ſo mutinous a ſpirit, that the Britiſh Viceroy thought fit to evacuate the iſland, which was no longer of any value to his government after all Italy had, in a great meaſure, ſubmitted to the French. The Imperial ſubjects in Italy alſo, along with the inhabitant of Bologna, Ferrara, and Modena, who were completely corrupted by the falſe philoſophy of the age, began now to republicaniſe themſelves under the patronage of the French general. They ſent deputies to a convention, levied troops, and aboliſhed all orders of nobility.

The Emperor ſoon ſent into the field a new army to attempt the relief of Mantua. In the beginning of November this army advanced under the command of Field Marſhal Alvinzi, who advanced towards Vizenza on the eaſt, ſeconded by General Daviduvich, who deſcended with another diviſion from Tyrol. Alvinzi had already croſſed the Piava, when he was met by the French, and compelled to repaſs that river. But Da- 282

Partial ſucceſſes of the Auſtrians.

vidovich, in the mean time, after ſeveral engagements, having ſucceeded in driving the French down the Adige towards Verona, Bonaparte was under the neceſſity of concentrating his forces. He now adopted his uſual expedient of keeping one diviſion of the hoſtile army in check, while he contended with the maſs of his forces againſt the other. He left Vaubois with ſome troops to detain Davidovich, while he advanced in perſon againſt Alvinzi, who was now haſtening towards Verona. He was met, on his way, by the Auſtrians at the village of Arcole. To ſeize this village, which could not be ſpeedily turned on account of a canal, the French were under the neceſſity of paſſing a narrow bridge in the face of the fire of the Auſtrians. They made the attempt without ſucceſs. Their officers ruſhed to the head of the column, and in vain attempted to rally the troops. Generals Verdier, Bon, Verne, and Laſnes, were carried off the field. Augereau advanced with a ſtandard to the extremity of the bridge, but nobody followed him. At laſt Bonaparte, who in the mean time had ſent Guieux with 2000 men to turn the village at two miles diſtance, haſtened to the bridge of Arcole. Seizing a ſtandard, he advanced at the head of the grenadiers, crying, "Follow your general." They accordingly followed him to within 30 yards of the bridge, when they were intimidated by the terrible fire of the Auſtrians; and their leader found it neceſſary to retire. Attempting to mount his horſe to rally the column, leſt the Auſtrians ſhould advance to the purſuit, he was thrown into a moraſs, while ſtill under the fire of the troops in the village; but here he again eſcaped, as the Auſtrians did not attempt to follow up their advantage.

The village of Arcole was taken towards the evening by Guieux, and afterwards evacuated by the French. On the following day (the 16th of November) an obſtinate conflict enſued in its neighbourhood, at which nothing deciſive was accompliſhed. On the 17th the 283

They are defeated.

Auſtrians, having preſſed impetuouſly forward upon the centre of the French army, were taken by ſurpriſe upon their flank by the left wing of the French, which had been ſtationed for that purpoſe in ambuſcade. Their left wing, however, maintained its ground till Bonaparte ſent round a party of horſe with twenty-five trumpeters to their rear, who, by the noiſe they made, induced the Auſtrians to believe themſelves ſurrounded, and to fly on all ſides in confuſion.

Here again appear evidences of treachery among the Auſtrian officers, though the battle of Arcole was the moſt ſevere which the French had yet fought in Italy, and extremely fatal to their officers, as well as to a multitude of their troops. During its continuance, Davidovich had ſucceeded in defeating Vaubois, who was oppoſed to him and Rivoli, and the blockade of Mantua was actually uncovered for a time. But Bonaparte now returned, after having driven Alvinzi acroſs the Brenta, and the poſitions of Rivoli and La Corona were retaken, and Davidovich repulſed into Tyrol. General Wurmſer, however, ſtill held out in Mantua during

French Revolution, 1796.

during the remaining part of the year; and the only fruit hitherto derived from so many victories was, that the French nation was led to look towards Bonaparte as its only invincible commander, upon whom all its hopes of conquest were to depend.

284 Negociation between Britain and France.

During these military transactions, Great Britain had entered into a negociation with France. In consequence of passports obtained from the Directory, Lord Malmesbury arrived in Paris, and began the negociation with De la Croix the minister for foreign affairs. Tho' the Directory could not decently refuse to negociate, yet they were unwilling seriously to conclude a peace with Britain. On the other hand, the British ministry have since declared that, as individuals, they actually disapproved of a peace at this time, but that they thought it necessary both to negociate, and even to conclude a treaty, if proper terms could be obtained. In judging thus, they were certainly right; for the country at large, not seeing the danger of peace, was very desirous of it, whilst a desperate faction was constantly ascribing the continuance of the war to the criminal obstinacy of the British government. The negociation which was now set on foot opened the eyes of all but those who wished to sell their country to French regicides. Lord Malmesbury proposed, that the principle of mutual restitutions should be agreed upon as the basis of the treaty. After much useless altercation, and many notes had passed upon this subject, and also upon the question, how far Lord Malmesbury could negociate for the allies of Great Britain, from whom he had received no official powers, the Directory at last agreed to the general principle of mutual restitutions, and required that the objects of these should be specified. Accordingly, the British ambassador proposed, in two memorials, that France should relinquish the Austrian Netherlands, and offered to give up the French foreign settlements in return. An offer was also made to restore a great part of the Dutch foreign possessions,

285 Suddenly broke off by the Directory.

on condition that the Stadtholder's ancient authority should be acknowledged in that country. The Directory now required Lord Malmesbury to present the ultimatum of his conditions within twenty-four hours. On his complaining of this demand, he was informed, on the 19th of December, that the Directory would agree to no conditions contrary to the French constitution; and it was added, that his farther residence at Paris was unnecessary!

286 Cape of Good Hope with a Dutch squadron, taken by the British.

During this year, Great Britain retained her usual superiority by sea. A British squadron, under Admiral Elphinston, had taken possession of the Dutch settlement at the Cape of Good Hope, on the 16th of September 1795. This settlement the Dutch wished eagerly to recover; and for this purpose they advanced money to enable the French to fit out a squadron to co-operate with them in an attack upon it. The French government took the money, but the squadron was never equipped. The Dutch themselves this year sent a squadron of seven ships of war, under Admiral Lucas, to attempt to reconquer the Cape; but being no match for the British squadron, and being likewise caught between two fires, without the possibility of escaping, the Dutch fleet, without firing a gun, was delivered up to the British admiral.

Notwithstanding the superiority of Great Britain by sea, the French, towards the close of this year, attempted an invasion of Ireland; but the plan was ill concerted, and, of course, unsuccessful. The whole conduct of it was intrusted to one man, General Hoche, and no second was prepared to occupy his place in case of any accident. The disaffected faction with whom the French meant to co-operate was not warned of their approach, and the fleet was sent towards a quarter of the country where the people were little disposed, or, at least, by no means prepared to receive them.

French Revolution, 1796.

287 Unsuccessful attempt by the French on Ireland.

Eighteen ships of the line, thirteen frigates, twelve sloops, and some transports, having 25,000 land forces on board, were employed in this expedition. When about to sail, it was detained for some time by a mutiny which arose in consequence of the enlistment of about 1,200 galley slaves. The fleet sailed on the 10th of December; but a ship of the line was lost in going out of Brest, and some of the rest were damaged. The frigate in which the commander in chief had embarked was separated from the fleet in a gale of wind; and the consequence was, that when the greater part of the fleet arrived at Bantry Bay, on the west coast of Ireland, nobody had instructions how to proceed. The troops and their officers wished to land, but the admiral, Bouvet, refused to comply with their request. Having remained several days upon the coast, he sailed for France, and arrived at Brest with a part of the fleet on the 31st of December. General Hoche did not reach Bantry Bay till it was too late, and therefore could not land. The fleet suffered great losses in its return. One ship of the line and two frigates foundered at sea, a frigate was taken by the British, and a ship of the line, after an engagement with two British ships, was run ashore to prevent her being captured.

1797.

At the commencement of the year 1797, the Archduke Charles was still occupied in the reduction of Kehl, and of the French fortifications opposite to Huningen. Moreau still commanded the army that opposed the Archduke; but General Hoche, after his return from the expedition to Ireland, was appointed to succeed Jourdan on the Lower Rhine. Bonaparte was still engaged in the blockade of Mantua, while the Austrian government was making vast efforts to recruit the army of Alvinzi after its defeat at Arcole, and to enable that General to make a last and desperate effort for the relief of Mantua. The young men of Vienna were urged to give their assistance on this important occasion, and 6000 of them marched into Italy as volunteers. Alvinzi's army amounted now to nearly 50,000 men; and he commenced his operations on the 8th of January, by skirmishing along the whole of the French line from below Porto Legnago upwards, to La Corona near the Lake Garda. He continued for some days to alarm the French at all points, and thus to conceal the plan of his future efforts. On the 10th Bonaparte was still at Bologna, on the other side of Mantua, taking precautions against the escape of Wurmser by that quarter, which, from an intercepted letter, he had learned was in contemplation. Being now informed of the approach of the Austrian army, he hastened to Mantua, and from thence to Verona, which was the centre of the line of his army that opposed Alvinzi. He arrived at Verona on the morning of the 12th; but as the Austrians continued to make their attacks upon all quarters at once, he was unable to penetrate the design of their leader. At last, on the 13th, the

288 Successes of the Austrians.

French Revolution, 1797. the efforts of the Auftrians began to affume a more formidable afpect on the lower part of his line near Porto Legnago; but on the evening of the fame day he received intelligence, that the upper extremity of his line, where Joubert commanded, had been attacked by fuch an immenfe fuperiority of numbers, that there could be no doubt that the greateft number of the Imperial troops was concentrated there. The poft of La Corona had even been forced, and Joubert compelled to withdraw to Rivoli, which he alfo abandoned.

298 They divide their army; The Auftrians ftill perfifted in their unfortunate plan of dividing their army, that they might have two chances of fuccefs. Ten thoufand chofen troops, among whom were the Vienna volunteers, were deftined under General Provera to penetrate to Mantua by Porto Legnago, at the lower extremity of the French line; while Alvinzi in perfon advanced with the mafs of the army againft Joubert at its other extremity. On the 13th all went well; Joubert was compelled to retreat; and he was fo fituated, that the eafy capture of his whole divifion on the following day appeared a very probable event.

Bonaparte, in the mean time, having learned the ftate of affairs, left Verona in the evening of the 13th, having firft ordered the whole centre of his army under Maffena to follow him to the neighbourhood of Rivoli with all poffible fpeed. Here he fpent the night with his officers in arranging the order of battle for next day, and in occupying proper pofitions. At day-break of the 14th the attack was begun by Joubert's divifion, to the no fmall furprife of the Imperialifts, who were not aware of the arrival of Bonaparte with reinforcements. The battle, however, was long and obftinate. The fuperiority of numbers on the fide of the Auftrians enabled them to defeat all the efforts of the French to turn their divifions. They at laft fucceeded in driving back upon the centre the two wings of the French army in confiderable diforder. Alvinzi now attacked the centre, which fcarcely maintained its pofition; and the Auftrian wings advancing on both fides, completely furrounded the French army. The victory feemed already won; and it is faid that Alvinzi difpatched a courier to Vienna to announce the approaching capture of Bonaparte and his army. Bonaparte indeed confidered his own fituation as very alarming; and is faid to have meditated his efcape acrofs the Auftrian right wing. From the nature of his order of battle, his troops had rather been concentrated than fcattered by the repulfe they had received, and it was therefore ftill in his power to make a defperate effort. Having formed three ftrong columns, he fent them againft the Auftrian right wing. They fucceeded in penetrating it at different points; and it fled in fuch confufion, that having encountered a party of French that had not arrived in time to join the body of the army, 4000 Auftrians laid down their arms in a panic, and furrendered themfelves prifoners of war. Night put an end to any farther conteft; but Bonaparte, confidering this quarter of his line as no longer in danger, departed to oppofe General Provera, leaving Joubert to profecute the victory now gained. This fervice he performed with great fuccefs. A detachment under General Murat having marched all the night of the 14th after the battle, feized Montebaldo in the rear of the pofition at Corona, to which a confiderable divifion of the Auftrians had retreated, while Joubert, next morning, attacked them in front. Finding themfelves furrounded, they foon fell into confufion. Six thoufand men were made prifoners, many were drowned in attempting to crofs the Adige, and the remainder fled to Tyrol. French Revolution, 1797. 290 And are defeated.

During this fanguinary conteft on the upper part of the Adige, General Provera had forced his paffage acrofs the lower part of that river at Angiara near Porto Legnago, and compelled the French General Guieux to retire to Ronco. Augereau collected all the troops in the neighbourhood, and marched to attack Provera; but as he haftened towards Mantua, Augereau could only come up with his rear; of which, after an engagement, he took 2000 prifoners. On the 15th, however, General Provera arrived in the vicinity of Mantua. The city, which ftands in a lake, was blockaded at the two points, by which it has accefs to the main-land called *St George* and *La Favorite*. Alvinzi was to have formed his junction with Provera at the poft of St George. Receiving no intelligence of him, General Provera fummoned the French commander here to furrender; and on his refufal, endeavoured to carry the pofition by affault. Having failed in this attempt, he turned his attention towards the poft of La Favorite, which he attacked on the morning of the 16th: while Wurmfer, who had perceived his arrival, advanced with the troops of the garrifon againft the fame point. But by this time Bonaparte had arrived with reinforcements. General Wurmfer was repulfed (B); and Provera being completely furrounded by the French, was under the neceffity of furrendering himfelf with his troops prifoners of war. The refult of all thefe battles at Rivoli and Mantua was the capture of 23,000 prifoners and 60 pieces of cannon; and thus four Imperial armies had perifhed in Italy in the attempt to preferve Mantua. The capture of this city, however, was now inevitable, in con-
fequence of famine. It furrendered by capitulation on the 2d of February. Bonoparte on this occafion endeavoured to acquire the reputation of humanity. To allow the French emigrants in the garrifon to efcape, he confented to an article in the capitulation that General Wurmfer fhould be allowed to felect and carry out of the garrifon 700 men, who were not to be examined 291 Mantua furrenders.

(B) Marfhal Wurmfer had before this time begun to fufpect that his plans were betrayed to the enemy. When he refolved to make his laft fally to co-operate with Alvinzi, he kept his plan to himfelf; and in the morning of that day on which the army was to march out, he gave to each of the generals commanding the divifions (which we think were feven) his orders in a fealed packet. The troops marched at the hour fixed on, in fo many divifions; and they were inftantly attacked at all points by the enemy. Upon this the old General faid to a Britifh officer of high rank, who was with him in the fortrefs, We are betrayed, make your efcape by any means that you can. This anecdote was communicated to us through a channel which leaves no doubt of its truth in our own minds; but not being authorifed to give the *names* of our informers, we thought it not right to infert it in the text. Its truth or falfehood may be eafily afcertained.

French Revolution, 1797. mined nor confidered as prifoners; and the General himfelf was allowed to depart unconditionally.

292 The Pope perfeveres in hoftilities; In the meanwhile, the Pope, who of all the European princes had the beft reafon for difliking the French caufe, uncautioufly perfevered in hoftility, in the hope that fome one of the Imperial armies might fucceed in driving Bonaparte from Italy. Having recovered from the panic which induced him to folicit an armiftice when the French firft entered Lombardy, he had avoided concluding a treaty of peace, and attempted to enter into a clofe alliance with the court of Vienna. He procured officers to be fent from thence to take the command of his troops, and flattered himfelf with the vain hope of being able to make an important diverfion in favour of the Imperial troops.

As the Emperor and the French were both preparing with all poffible fpeed to renew their bloody conteft on the frontiers of Germany, it was of importance to Bonaparte to leave all Italy in peace on his rear. On the 1ft of February he fent a divifion of his troops under General Victor, along with what was called the *Lombard Legion*, confifting of Italians, to enter the territory of the Pope; and upon the furrender of Mantua Bonaparte followed in perfon. The troops of his Holinefs made feeble refiftance. The new raifed Lombard legion was made to try its valour againft them on the river Senis on the 2d. After ftorming their entrenchments, it took their cannon and 1000 of themfelves pri-

293 But is conquered. foners. Urbino, Ancona, and Loretto, fucceffively fell an eafy prey to the French. From the chapel at Loretto the papal General Colli had carried moft of the treafure; but the French ftill found gold and filver articles worth 1,000,000 of livres, and the image of the virgin was conveyed as a curiofity to Paris. Bonaparte now proceeded through Macerata to Tolentino. He was here met by a meffenger from the Pope with offers of peace, and concluded a treaty with his Holinefs on the 19th. By this treaty the conditions of the armiftice were confirmed; and in addition to the payments then ftipulated, the Pope promifed to pay 15,000,000 of livres, and to deliver 800 cavalry horfes, with as many draught horfes and oxen. He alfo engaged to pay 300,000 livres to the family of the French envoy Baffeville, who had been murdered at Rome, and to apologife by his minifter at Paris for that event.

294 Bonaparte reinforced. The French had been fo unfuccefsful in their late irruption into Germany, through Swabia and Franconia, that they now refolved to make their principal effort from Italy under Bonaparte. For this purpofe, the Directory detached great bodies of the veteran troops that had fought under Moreau as fecretly as poffible through Savoy into Italy. The court of Vienna, however, was aware of the approaching danger, and gave the command on the fide of Italy to the Archduke Charles, who of all their military leaders had alone of late been fuccefsful againft the French. He brought along with him his beft troops from the Rhine, and numerous levies were endeavoured to be made in all the hereditary ftates for his farther fupport. The war was now about to be carried into new territories, on which the houfe of Auftria had fcarcely hitherto beheld a foe. It was neceffary that Bonaparte fhould once more attempt to fcale the fummit of the Alps. This immenfe chain of mountains, which takes its rife in the vicinity of Toulon, at firft ftretches northward under the names of *Piedmont* and *Savoy*. It then runs towards the eaft, forming the countries of Switzerland, Tyrol, Carinthia, and Carniola. The three laft of thefe, paffing along the head of the Adriatic, form the frontier in this quarter of the hereditary ftates of Auftria. Between the mountains and the fea lies the level and fertile tract of territory which belonged to Venice. It is croffed by many large ftreams, which are fed by the melting fnows of the Alps, and whofe nature is this, that they are greateft in fummer, and that their waters diminifh during the frofts of winter.

295 Blunder of the Court of Vienna. The council of war at Vienna now committed an important error in the plan of defence which it adopted. Inftead of making a ftand in the defiles of the mountains, the Archduke was fent down into the plain to defend the paffages of the rivers. War is effentially an offenfive art. Whatever the general purpofe of hoftility may be, it is always conducted with moft fuccefs when the detail of its operations is fo managed as to affume the form of enterprife and of vigorous attack. This arifes not from any thing in the nature of the art of war, but from the immutable conftitution of the human character. The ftrength of men who are fixed without motion in a particular fpot, is fubdued by the depreffing paffion of fear, and by the defpair of accomplifhing any important object; whereas, when urged to action and to enterprife, their energy is increafed by hope, and by that prefumption of their own fuperiority which all men readily entertain. Hence we have fo few inftances in hiftory of nations fuccefsfully defended by rivers or extenfive fortified lines; whereas mountainous countries have ufually fet bounds to the progrefs of armies. In fuch fituations, the defending party can always act upon the offenfive. He finds his adverfaries divided, by their fituation, into fmall parties. He hopes to vanquifh them in detail, and he acquires ftrength and courage from the profpect of fuccefs.

While Bonaparte was advancing into the territory of the Pope, the Auftrian army was arranging itfelf along the eaftern bank of the Piava. The French were on the oppofite bank, and Bonaparte haftened to join them after he had concluded his treaty with the Pope. The beginning of March was fpent in preparations; but at laft the troops advanced, that the point of refiftance might be difcovered. Having croffed the Piava on the 12th of March, the Auftrians retired, fkirmifhing for fome days till they had croffed the Tagliamento, where they made a ftand with their whole force. 296 Progrefs of the French army. Early on the 17th the French army arrived at Valvafone, on the oppofite bank; and after fome hefitation, refolved to force the paffage of the river. To have accomplifhed this object very fpeedily would have been difficult, had not a recent froft diminifhed the ftream, by which means the French were enabled to crofs it in the face of the enemy in columns at various points. The army of Bonaparte was now in three divifions. Joubert, with the left wing, advanced along the courfe of the Adige into Tyrol, and was ordered to crofs over from thence, and to defcend along the valley of the river Drave, which is beyond the higheft chain of what the Romans called the *Noric Alps*. Maffena, with the centre, after croffing the Tagliamento, advanced into the defiles of thefe mountains; while the right divifion, which was attended by Bonaparte in perfon, proceeded along the coaft of the Adriatic.

French Revolution, 1797.

After forcing the paſſage of the Tagliamento on the 17th, the French had eaſily defeated the Auſtrians on the oppoſite bank, and compelled them everywhere to retreat. The other rivers were eaſily paſſed; and on the 19th, the town of Gradiſca, on the river Liſonzo, ſurrendered to the right wing of the army, and its garriſon, amounting to 3000 men, were made priſoners of war. On the 21ſt Goritz was entered by the ſame diviſion, who found there the principal Auſtrian magazines and hoſpitals. Trieſte was entered on the 23d; and the French ſent off in waggons, from the quickſilver mines of Ydria, materials worth 2,000,000 of livres. In the mean time, the Auſtrians, in their haſty retreat, entangled themſelves and their baggage among the mountains. On the 24th, a large body of them was hemmed in between Maſſena, who had reached Tarvis, and a part of the French right wing under Guieux. Reinforcements, however, having found means

297 The Auſtrians defeated.

to reach them from the Archduke's head quarters at Clagenfurt, they hazarded an engagement on the following day, but were defeated, with the loſs of 5000 taken priſoners, and 400 waggons loaded with baggage. The French left wing under Joubert, Baraguay D'Hilliers, and Delmas, was equally ſuccesſful. On the banks of the Lavis, after an obſtinate engagement, 4000 Auſtrians were taken; and thereafter at Clauzen they were again defeated, with the loſs of 1500 taken priſoners. Having entered Brixen, this diviſion turned eaſtward, and deſcended the valley of the Drave towards Clagenfurt, the capital of Carinthia, where it was met by General Maſſena; the Archduke, after a ſlight conteſt, having evacuated the place, and advanced farther towards the capital of the empire, which was now ſeriouſly menaced, and in which great conſternation

298 Wonderful ſucceſs of Bonaparte.

prevailed. In 15 days Bonaparte had taken 20,000 priſoners, and croſſed the Alps; and though the country ſtill preſented ſome difficulties, there was no fortified place capable of reſiſting his progreſs towards Vienna. He did not, however, conſider his own ſituation as deſtitute of hazard, and ſeized the preſent moment of unbounded ſucceſs to make propoſals of peace. On the 31ſt of March he ſent a letter to the Archduke, in which he depricated the uſeleſs prolongation of the war, and intreated him to interpoſe his good offices to put a ſtop to its farther ravages. But this prince, who ſeems to have doubted his own influence at the court of Vienna, returned a cold anſwer, ſtating, that it belonged not to him to inveſtigate the principles on which the war was carried on, and that he had no powers to negociate.

299 Partial ſucceſſes of the Auſtrians.

The Auſtrian chiefs made a laſt effort, by raiſing the peaſants of the Tyrol in a maſs to embarraſs the rear of the French. They accordingly gained ſome ſucceſſes under General Laudohn, and drove out the French troops that had been left at Botzen and Brixen. The inhabitants of the Venetian ſtates alſo roſe againſt the troops that remained in their country; and being joined by ten regiments of Sclavonians, which had been in the pay of the government of Venice, they put the French to death wherever they were found, without excepting the ſick in the hoſpitals, of whom 500 were maſſacred at Verona. A party of Imperialiſts alſo drove the French garriſon out of Trieſte, and thus attempted to ſurround the invading army. Bonaparte, however, knew that the court of Vienna muſt be at leaſt as much embarraſſed as himſelf. His army amounted to 95,000 men. It had hitherto proved irreſiſtible; and the Auſtrians knew, that to ſurround was not to conquer it. He therefore perſiſted in advancing. On the 2d of April he ſucceeded in forcing the ſtrong defiles between Freiſach and Newmark, after a bloody battle, in which he took 600 priſoners. On the 4th, his advanced guard reached Hunſmark, where the Auſtrians were again defeated; and his army occupied Kintenfeld, Murau, and Judenbourg. Theſe advantages compelled the Auſtrian cabinet to treat for peace, as there was no longer any point at which the Archduke's army could hope to make a ſtand till it came to the mountains in the vicinity of Vienna. Meaſures were taken for removing the public treaſure and effects into Hungary, while Generals Bellegarde and Morveld were ſent to requeſt from Bonaparte a ſuſpenſion of hoſtilities. On being ſuffered to take poſſeſſion of Gratz and Leoben, within little more than 50 miles of Vienna, he conſented, on the 7th of April, to an armiſtice, which was only to endure till the night of the 13th, but was afterwards renewed for a longer period. It was followed on the 19th by a preliminary treaty, ſigned at Leoben; by which it was agreed that the Auſtrian Netherlands ſhould belong to France, and that the new republic in Lombardy ſhould continue under the name of the *Ciſalpine Republic*, and ſhould include the Milaneſe, the duchy of Mantua, and the territories of Modena, Ferrar, and Bologna. There is reaſon to ſuſpect that ſomething hoſtile to the independence of Venice was here alſo ſtipulated.

300 The Auſtrian cabinet treats for peace.

301 Unjuſt and cruel conduct of Bonaparte.

Bonaparte agreed to withdraw without delay into Italy, on receiving ſubſiſtence for his army during its march; and it was reſolved, that all farther diſputes ſhould be afterwards ſettled by a definitive treaty of peace. On his return he accuſed the Venetian government of connivance at the inſurrection which had taken place againſt the French in his abſence; and having ſeized their city and whole territory, he diſſolved that ancient and ſingular, but now feeble, ariſtocracy.

While Bonaparte was advancing towards Vienna, the French armies on the Rhine had begun to preſs upon the Auſtrians, to prevent farther reinforcements from being ſent againſt him from that quarter. The Auſtrians offered an armiſtice; but as the French demanded the fortreſs of Ehrenbreitſtein as the price of it, both parties prepared for action. The left wing of the army of General Hoche advanced rapidly from Duſſeldorf, while the centre and right wing croſſed the Rhine near Coblentz. The Auſtrians under General Wernecht retreated to the Lahn, where they waited the arrival of the French. Here a violent conteſt enſued on the 18th of April, in which 4000 Auſtrians were taken priſoners. The French took poſſeſſion of Wetzlaer, and drove their antagoniſts to the gates of Francfort. In the mean time, General Moreau, on the Upper Rhine, forced the paſſage of the river near Straſburg, and attacked the village of Dierſheim, of which he at laſt retained poſſeſſion, after having been more than once driven out, and the village nearly deſtroyed. The following day, however, the Auſtrians renewed the attack, and forced the French for ſome time to give way; but powerful reinforcements having croſſed the river,

302 Succeſſes of the French on the Rhine.

French Revolution, 1797.

river, the French were at laſt enabled to renew the battle with ſuch vigour, that they took Fort Kehl, together with 5000 priſoners. The Imperialiſts in this quarter were now purſued towards the Danube; when all military operations were ſuddenly arreſted by meſſengers ſent through Germany by the Archduke Charles and Bonaparte, announcing that peace was concluded. These meſſengers found the army of Hoche violently attacking Francfort on the Maine, which General Wernecht was endeavouring to defend. The news was diffuſed in an inſtant through both armies; and the contending troops, throwing aſide their weapons, congratulated each other upon the event.

303 Peace concluded.

304 Power of France at this period.

France now held a very elevated rank, and a formidable character, among the nations of Europe. Spain, Italy, and Holland, were held in dependence; while her victorious armies had compelled the laſt continental member of the coalition to accept of peace from an army that approached his capital. Had the Auſtrian officers been faithful, and the court of Vienna leſs ſelfiſh, ſubſequent events have indeed ſhewn that the affairs of the Emperor were not yet deſparate, and that Bonaparte was not that invincible hero which his rapid ſucceſſes gave ſome reaſon to ſuppoſe him. After the peruſal of his letters from Egypt, his victories loſe much of their brilliancy; nor does any action, or all the actions of his life, diſplay ſuch military ſkill, as the retreat of Moreau through Swabia, when preſſed on the rear by a victorious army, and ſurrounded on all hands by an incenſed populace. But Bonaparte had been ſucceſsful; the Archduke knew not whom to truſt: there is reaſon to believe that his plans were continually thwarted by a corrupt council at home; and the court of Vienna was bribed to make a peace. Of all the enemies of the French revolution, Britain alone remained in hoſtility. From her command of the ocean, ſhe was enabled indeed to retain the feeble ſtate of Portugal, attached to her cauſe; but on land, ſuch was the terrible energy of France, that, with this exception, which ſeemed only to exiſt by tolerance, the Britiſh trading veſſels were excluded, by her influence, from all approach to the continent, from the Elbe to the Adriatic; and the Britiſh government was once more induced, in theſe circumſtances, to try the effect of a new negociation. All theſe external advantages, however, were ſpeedily loſt by the French nation; and it ſeemed the unhappy deſtiny of this people to be conſtantly deprived of the fruits of all their ſufferings, and their courage, by the turbulence of their domeſtic factions, and the profligacy and unprincipled conduct of their rulers.

305 Britain continues the war.

306 Conteſt between the Directory and Councils.

A ſerious conteſt between the executive power and the legiſlature was now approaching. We already remarked, that the Directory was originally ſelected by thoſe men who had been the aſſociates of Robeſpierre; and though deſerted of late by ſome of the more violent ſpirits, who were termed *Anarchiſts*, it was ſtill conſidered as the head of the Mountain party. By the victory obtained over the ſections of Paris on the 5th of October, all oppoſition had been ſet at defiance for a time; but the nation at large had never been reconciled to theſe men. The period now arrived when a third of the legiſlative body was to be changed. On the 19th of May, Letourneur went out of the Directory by lot. On the 20th, the new third took their ſeats in the Councils, a third of their predeceſſors having evacuated their ſeats by lot; and on the following day, Barthelemi, the ambaſſador to Switzerland, was choſen to ſucceed Letourneur in the Directory. The election of the members of the new third had almoſt entirely fallen upon men who were underſtood to be hoſtile to the Directory. Many Generals out of employment were choſen; ſuch as Pichegru, Jourdan, and Willot, and many repreſentatives of the families of the ancient nobility who had not emigrated (among whom was the Prince of Conti) were now elected into the legiſlature. The moderate or oppoſition party in the two Councils now poſſeſſed a complete majority. Carnot and Barthelemi were underſtood to be favourable to them in the Directory; the former having made his peace with them, and the latter being eſtabliſhed by themſelves. The effect of this change in the ſtate of the Councils ſpeedily appeared in their adopting every meaſure that could embarraſs the Directory, or caſt odium upon the Mountain party, and alter the ſtate of things which it had eſtabliſhed.

On the 14th of June, Gilbert Deſmolieres brought forward a report from a committee upon the ſtate of the finances; in which he exhibited and reprobated in the ſtrongeſt terms the prodigality of the Directory, and the profuſion and rapacity of its agents. On the 18th the ſame committee propoſed a new plan of finance, the object of which was to deprive the Directory of any ſhare in the adminiſtration of the public money. In the mean time, on the 17th of the ſame month, Camille Jourdan had preſented a long report on the ſubject of religion; in which he endeavoured to demonſtrate the impropriety of prohibiting the public diſplay of its ceremonies, and the injuſtice of the perſecution which its miniſters had undergone for refuſing to take oaths preſcribed by the legiſlature. This report was afterwards, on the 15th of July, followed up in the Council of Five Hundred, by a decree, repealing all the laws againſt refractory prieſts, or which aſſimilated them to emigrants. On the following day, another decree, requiring from them a declaration of fidelity to the conſtitution, could only be carried by a majority of 210 againſt 204. A propoſal was now brought forward in the Council of Five Hundred by Emery, a new member, to repeal the laws which confiſcated the property of emigrants, and to allow their relations to ſucceed to them as if they had died at the period of their emigration. Thoſe who had fled into foreign countries from Toulon and other places, during the reign of terror, were alſo encouraged to return, and allowed to expect that their names would be erazed from the liſt of emigrants. The conduct of the Directory towards foreign powers was attacked on different occaſions; and Dumoullard propoſed the appointment of a committee to enquire into the external relations of the republic. This was a delicate ſubject; as it involved the character of the armies and their leaders, and as it might ſubvert the intereſts of the Directory with ſome of their friends of the Mountain party. The Venetian republic, though a neutral ſtate, had been overturned by Bonaparte on account of a popular inſurrection, for which the government apologiſed. Little account had been given of the immenſe ſums of money that had been levied in Italy. The armies in the preceding year had entered Germany in the character of plunderers;

307 Mild meaſures of the Councils.

plunderers; which had diſguſted all thoſe in that country who had once been friendly to their cauſe, and longed for their arrival. The Directory, at the ſame time, inſtead of encouraging the progreſs of revolution, which the Jacobins eagerly deſired, had ſuddenly made peace with the German princes, upon receiving pecuniary contributions, which were left to be exacted according to the ancient laws of the different ſtates (which exempt the nobles and the clergy) and thus fell heavieſt upon thoſe very perſons who had cheriſhed the new republican principles.

The diſcuſſion of theſe ſubjects brought the majority of the Directory and of the Councils into a ſtate of complete hoſtility. Both parties reſolved to violate the conſtitution, under the pretence of preſerving it. The one wiſhed to change the Directory before the time preſcribed by law, and the other to deprive of their ſeats a great number of the new legiſlators elected by the people. Barras was the moſt obnoxious of the directors; and an attempt was made to deprive him of his office, upon the footing that he was leſs than 40 years of age. But his colleagues aſſerted that he was born in the year 1755; and as no proof to the contrary could be brought, this abortive attempt ſerved only ſtill farther to irritate the contending parties, and they began to prepare for more effectual meaſures. Had not force been ſpeedily uſed on the ſide of the Directory, the Councils muſt naturally have prevailed.

308 Their popularity.

The majority of the people confided in them. The national purſe was in their hands; and they hoped to ſubdue the Directory, as the conſtituent aſſembly had done the king, by avoiding to vote the neceſſary ſupplies. They could enact what laws they pleaſed. They had not indeed the command of the armies; but to remedy their weakneſs in this reſpect, General Pichegru, on the 20th of July, preſented a plan for reorganiſing the national guard, and placing it more at the diſpoſal of the Councils, by depriving the Directory of the nomination of the officers.

In the mean time the Directory was by no means deſtitute of adherents. The reſolutions of the Councils in favour of the prieſts, and the relations of emigrants, looked ſo like a deſertion of former maxims, that many perſons expected an immediate counter revolution. The royaliſts gained courage, and a multitude of journals or newſpapers, favourable to their cauſe, began to be publiſhed. Emigrants obtained paſſports, and haſtened to Paris in the hope of being ſtruck off the liſt, upon alledging that they fled to avoid proſcription during the power of the Jacobins. The effect of all this was, that the purchaſers of national property, and thoſe who had become rich by the revolution, were alarmed. The whole Mountain party, and all thoſe who had been active in oppoſition to royalty, rallied round the Directory. The armies, whoſe chiefs found themſelves involved in ſome of the accuſations brought againſt that body, ſent addreſſes, in which they declared their reſolution to ſupport its power. The Councils declared theſe addreſſes, which the Directory had received from armed bodies, unconſtitutional, and procured counter-addreſſes from different departments. At laſt the partizans of the two contending powers began to diſtinguiſh themſelves in Paris by their dreſs, and every thing preſaged an approaching appeal to force. On the 20th of July the Councils received intelligence that a diviſion of the army of General Hoche had advanced within a few leagues of Paris; whereas, by the conſtitution, the Directory incurred the penalty of ten years impriſonment if it authoriſed troops to approach nearer to the reſidence of the legiſlative body than twelve leagues, without its own conſent. An explanation of this event was immediately demanded. The Directory denied that they had ordered the march, and aſcribed it to a miſtake of the officer by whom it was conducted. Their explanation was treated with contempt, and much angry debate took place in the Councils concerning it; the Directory all the while conducting themſelves with much ſeeming moderation, and even ſubmiſſiveneſs. In the mean time their antagoniſts acted a very undecided part.

309 The Directory victorious.

They long hoped to gain Lareveillere Lepaux to their ſide; in which caſe they would have had a majority in the Directory. This vain expectation rendered their conduct indeciſive. At length the majority of the Directory procured an addreſs of adherence from the ſuburb St Antoine, which in all the tempeſtuous days of the revolution had been the rallying point of the Mountain party. Encouraged by this addreſs, they proceeded to immediate action. General Augereau had been ſent from Italy under pretence of preſenting ſome Auſtrian ſtandards to the Directory, and he was employed as their tool upon this occaſion. They commanded the garriſon of Paris, and they had managed to bring over to their party the ſoldiers compoſing the guard of the two councils. Before day-break, on the morning of the 4th, Augereau ſurrounded the Thuilleries with a diviſion of the troops. The guard of the Councils refuſed to reſiſt, and their commander, Ramel, was taken priſoner. Having entered the hall, he found Pichegru and other twelve of the chiefs of the oppoſite party ſitting in conſultation, and immediately ſent them priſoners to the Temple. Some other obnoxious members of the Councils were alſo put under arreſt. The director Carnot had made his eſcape on the preceding evening, but Barthelemi remained, and was impriſoned.

All this was accompliſhed without noiſe, and in an inſtant. Many members of the Councils, when they came to the hall at the uſual hour were ſurpriſed to find that ſeals were put upon the doors, and that they could not obtain admittance. They were invited, however, to go to the Surgeons Hall and the theatre of the Odeon, where they were told the Directory had appointed the Councils to aſſemble. At theſe places, about forty of the Council of Ancients, and double that number of the other Council, aſſembled about noon, and ſent to demand from the Directory an account of the proceedings of the morning. They received an anſwer, declaring, that what had been done was neceſſary to the ſalvation of the Republic, and congratulating the Councils *on their eſcape* from the machinations of royaliſts.

310 Pretended conſpiracy.

Being ſtill at a loſs how to act, the Council of Five Hundred appointed a committee of four members (of whom Sieyes was one) to report upon the meaſures to be adopted. On the following day Boullay de la Meurth preſented a report from this committee, in which he announced, that a vaſt royaliſt conſpiracy, whoſe centre was in the boſom of the Councils, had been formed to overturn the conſtitution, but that it had been baffled by the wiſdom and activity of the Directory. The report concluded, by propoſing the immediate tranſportation of the conſpirators without a trial.

trial. Accordingly, theſe degraded repreſentative bodies proceeded, after ſome debate, on hearing the names of the accuſed perſons read over, to vote the tranſportation to Guiana in South America, of fifty-three of their own members, and twelve other perſons, among whom were the directors Carnot and Barthelemi. They annulled the elections in forty-nine departments, repealed the laws lately enacted in favour of the diſaffected clergy and the relations of emigrants; and even ſo far aboliſhed the liberty of the preſs, as to put all periodical publications under the inſpection of the police for one year. New taxes were voted without heſitation, Francis de Neufchauteau and Merlin were elected to fill the vacancies in the Directory, and affairs were endeavoured to be conducted in their ordinary train.

All this while the city of Paris remained tranquil. That turbulent capital, which had made ſo many ſanguinary efforts in favour of what it accounted the cauſe of freedom, had been ſo completely ſubdued ſince its unfortunate ſtruggle on the 5th of October, that it now permitted the national repreſentation to be violated, and the moſt obvious rules of practical

311 Employed by the Directory to juſtify their conduct.

liberty to be infringed, without an effort in their defence. The Directory, in the mean time, attempted to juſtify their conduct to the nation at large, by publiſhing various documents intended to prove the exiſtence of a royaliſt conſpiracy. The moſt remarkable of theſe was a paper, ſaid to be written by M d'Antraigues, and found by Bonaparte at Venice; in which a detail was given of a correſpondence between General Pichegru and the Prince of Condé in the year 1795. The correſpondence itſelf was alſo, at the ſame time, ſaid to be found by General Moreau among papers taken by him at the late paſſage of the Rhine. It ſtated, that Pichegru had offered to the Prince of Condé to croſs the Rhine with his army, and having joined the Auſtrians under General Wurmſer, and the emigrants under the Prince of Condé, to return with the united armies and march to Paris, where they were to re-eſtabliſh royalty. The Prince is ſaid to have refuſed to accept of the offer, from jealouſy of the participation of the Auſtrians in the honour of the tranſaction. He therefore inſiſted that it ſhould be conducted without their aid; but Pichegru thought the attempt too hazardous in this form, and, being ſoon after removed from his command, the project failed. At the time of its publication, the genuineneſs of this correſpondence, and alſo of the paper found by Bonaparte, was denied; and nothing has appeared ſince to induce an unprejudiced man to think otherwiſe at preſent. Moreau, who was certainly involved in this conſpiracy, if real, has been intruſted ſince that period with the command of the armies of the republic; and though defeated by Marſhal Suwarrow, he is ſo far from being now conſidered as a royaliſt, that the revolutionary government ſeems inclined to intruſt to his military ſkill and fidelity its laſt efforts for the continuance of its exiſtence.

From the violation of the repreſentative government that has been now ſtated, it became obvious to ſurrounding nations, that France had paſſed under the dominion of a ſmall faction at variance with the majority

312 The Directory all powerful.

of the people. The Directory was all powerful. Its members, however, ſeem very ſoon to have become giddy by the elevated nature of their ſituation, and to have adopted a notion that there was no project of ambition or rapacity in which they might not venture to engage. During their conteſt with the Councils, they had protracted the negociations with Lord Malmeſbury at Liſle, and had ſuffered thoſe to relax which had been entered into between Bonaparte and the Imperial ambaſſadors at Campo Formio near Udine. Great Britain had offered to conſent to peace, on condition of being allowed to retain the Dutch ſettlement of the Cape of Good Hope, and the Spaniſh iſland of Trinidad, which had been taken in the month of February this year. The Directory now recalled their former negociators Letourneur and Maret, and ſent two others, Treilhard and Bonnier, in their ſtead; who immediately demanded whether Lord Malmeſbury had full power to reſtore all the ſettlements taken from France and her allies during the war? Upon his Lordſhip's declining to anſwer ſuch a queſtion, becauſe it implied an enquiry, not into his powers, which were in the uſual form, but into his inſtructions, which would preclude all negociation, he was required to return home to procure more ample powers. The negociations with the Emperor, however, were now ſpeedily brought to a concluſion. On the 17th of October, a definitive treaty was ſigned at Campo Formio. By it the Emperor gave up the Netherlands to France, the Milaneſe to the Ciſalpine republic, and his territories in the Briſgaw to the Duke of Modena, as an indemnification for the loſs of his duchy in Italy. The Emperor alſo conſented that the French ſhould poſſeſs the Venetian iſlands in the Levant of Corfu, Zante, Cephalonia, Santa Maura, Cerigo, and others. On the other hand, the French Republic conſented that the Emperor ſhould poſſeſs in full ſovereignty the city of Venice, and its whole other territory, from the extremity of Dalmatia round the Adriatic as far as the Adige and the lake Garda. The Ciſalpine Republic was to poſſeſs the remaining territory of Venice in this quarter, along with the city and duchy of Mantua, and the eccleſiaſtical ſtates of Ferrara and Bologna.

313 Treaty of Campo Formio.

Upon whatever principles the war might have hitherto been conducted, the terms of this treaty ſufficiently demonſtrated to all Europe, that its leſſer ſtates had no better reaſon to expect ſecurity from the houſe of Auſtria than from that of the new republic. This truth would have been ſtill more evident, had the articles of a convention, which was ſigned by theſe parties at the ſame period at Campo Formio, been publiſhed to the world. Fearing, however, to alarm too much the Germanic body, theſe articles were kept ſecret, and the parties agreed to prevail with the German princes, at a congreſs to be opened at Raſtadt, to conſent, in conſequence of an apparently fair negociation, to what France and Auſtria had determined ſhould take place. By the ſecret convention or treaty now alluded to, it was ſtipulated, that the Rhine, including the fortreſs of Mentz, ſhould be the boundary of the French Republic; that the princes, whoſe territories were alienated by this agreement, ſhould be indemnified by the ſecularization of church lands in Germany; that the Stadtholder of Holland ſhould be indemnified for the loſs of his eſtates in that country, by receiving German territory; that the Emperor ſhould receive the Archbiſhopric of Saltzburg, and the part of the circle of Bavaria ſituated between that archbiſhopric, the rivers Inn and Saltz, and the Tyrol; that the Imperial troops ſhould immediately withdraw to the confines of the hereditary ſtates beyond

French Revolution, 1797. yond Ulm; and if the Germanic body ſhould refuſe peace on the above terms, it was ſtipulated, that the Emperor ſhould ſupply to it no more troops than his contingent as a co-eſtate amounted to, and that even theſe ſhould not be employed in any fortified place.

Theſe treaties were immediately begun to be put in execution. The Auſtrians left the Rhine, which enabled the French to ſurround the fortreſſes of Mentz and Ehrenbreitſtein. Of the former, they ſpeedily obtained poſſeſſion; but the latter coſt them a very tedious blockade, before the garriſon, conſiſting of troops of the Palatinate, would agree to ſurrender. The Imperial troops, at the ſame time, entered Venice; the French having evacuated that city after carrying off or deſtroying its whole navy. The Ciſalpine Republic was eſtabliſhed, and Bonaparte left Italy; leaving, however, an army of 25,000 men to garriſon Mantua, Breſcia, Milan, and other places, and to retain this new

313 Violent meaſures of the Directory. republic in dependence upon France. Genoa was, at the ſame time, brought under a ſimilar dependence by means of popular commotion, inſtigated by the French, and a revolution in its government which took place at this period. And thus the French Directory, without the excuſe of hoſtility, as in the caſes of Holland and Spain, began a ſyſtem of interference in the affairs of weaker neighbouring ſtates, which was ſpeedily carried to an height that once more alarmed all Europe. Theſe men even attempted, at this time, to compel the ſtates of North America to purchaſe with money their forbearance from war. This was done through a circuitous channel, and in the form of an intrigue, by private perſons, who were inſtructed to inform the American miniſters at Paris, that a large loan on the part of America would be the beſt means of ſecuring peace; and it was hinted, that it would be rendered more acceptable if accompanied with a private preſent of L. 50,000 ſterling to the members of the Directory. This laſt propoſal was indeed denied by the French miniſter Tallyrand, who had given his countenance to this crooked negociation: but the general impreſſion produced by the tranſactions could not be removed; and its effect was to injure very deeply the character of the French government in the opinion of thoſe diſtant nations that were otherwiſe diſpoſed to regard it in the moſt favourable light. Nor was its reſpectability increaſed by a law which the two Councils, at the deſire of the Directory, thought fit to enact, declaring the ſhips of all neutral ſtates bound for Britain, or returning from thence, liable to capture. This law was not leſs impolitic than unjuſt. It placed the whole carrying trade of the weſtern world in the hands of the Britiſh, and thus enriched the very people whom it was intended to injure.

For at this period Britain had acquired over the

314 Invaſion of Wales. ocean a degree of uncontrouled dominion that was altogether unexampled in former times. During the whole year the French fleet lay blockaded in its owns ports, and no enterpriſe was attempted by ſea, excepting in one ſolitary but ſingular inſtance. We have already mentioned that a number of galley ſlaves were ſent as ſoldiers with Hoche in his attempt upon Ireland. On the failure of that expedition, the Directory were at a loſs how to diſpoſe of theſe men. They could not now with propriety be ſent back to puniſhment, the troops would not ſerve along with them in the army; and as the new laws of France allow no remiſſion of crimes, they could not receive a pardon, nor was it ſafe to let looſe upon the country 1400 criminals. In this dilemma, the Directory reſolved to throw them into England. Accordingly, they were ſent in two frigates and ſome ſmall veſſels to the coaſt of Wales, and there landed with muſkets and ammunition, but without artillery. In the evening of the very day on which they landed, the 23d of February, they ſurrendered themſelves priſoners of war to a party of militia, yeomanry, cavalry, colliers, and others, under the command of Lord Cawdor. The Directory boaſted that, by this enterpriſe, they had demonſtrated the poſſibility of landing troops on the Britiſh coaſt in ſpite of the vigilance of the navy; but this aſſertion was ill ſupported by the fate of the two frigates accompanying the expedition; both were captured in attempted to return to Breſt.

Though the French navy remained in port, and conſequently ſafe during the reſt of the year, their allies, the Spaniards and Dutch, ſuffered ſeverely. On the 14th of February, a Britiſh fleet of 15 ſail of the line, under the command of Sir John Jervis, engaged the Spaniſh fleet, amounting to 27 ſail of the line, off Cape St Vincent. In this action, the Spaniſh force, if it be eſtimated by the number of men, the number of guns, and the weight of metal, was more than double that of the Britiſh; but by the ſkilful manœuvres of its heroic commander, the Britiſh fleet twice croſſed through the line of the Spaniards, and ſucceeded in cutting off a part of their fleet from the reſt. Four ſhips of the line were taken, and the Spaniſh admiral's own ſhip eſcaped with difficulty. The fleet had been on its way to Breſt to join the French fleet there; but in conſequence of this action, it returned to Cadiz, where it was blockaded by the Britiſh. 315 Brilliant victory of Sir John Jervis over the Spaniſh fleet,

For his gallant conduct in this engagement, which, when every circumſtance is taken into conſideration, is perhaps unparalleled in the annals of naval war, Sir John Jervis was immediately created Earl St Vincent, and received the thanks of both houſes of the Britiſh Parliament.

The Dutch were ſtill more unfortunate. The Texel, within which their fleet lay, was blockaded during the whole ſummer by Admiral Duncan. The French intended, by means of the Dutch fleet, to make another attempt upon Ireland. Troops were accordingly embarked, under the command of General Daendels; but a reſolution having at laſt been adopted of hazarding an engagement with the Britiſh, the Dutch admiral De Winter, in oppoſition to his own remonſtrances, was ordered to put to ſea. The Britiſh admiral had by this time left his ſtation near the Texel, and gone to Yarmouth to refit. On receiving intelligence, however, that the Dutch had ſailed, he inſtantly proceeded in queſt of them. On the 11th of October the Britiſh fleet, amounting to 16 ſail of the line and 3 frigates, came in ſight of the Dutch fleet, which in force was nearly equal, within about nine miles of Camperdown in Holland. Admiral Duncan immediately run his fleet through the Dutch line, and, though on a lee ſhore, began the engagement between them and their own coaſt. A moſt bloody and obſtinate conflict enſued, which laſted nearly three hours. By that time, it is ſaid that almoſt the whole Dutch fleet had ſtruck. The ſhips could not all be approached and ſeized, however, 316 And of Admiral Duncan over the Dutch.

French Revolution, 1798. ever, on account of the shallowness of the water upon the coast, to which the fleets were now very near. Eight ships of the line, with two of 56 guns, and one of 44, were taken, besides a frigate, which was afterwards lost near the British coast, and one of the ships of 56 guns foundered at sea. Admiral de Winter was taken with his ship, and also the Vice-admiral Rentjies.

Similar honours were conferred upon Admiral Duncan as upon Sir John Jervis, and both admirals had each a pension of L.2000 *per annum* conferred upon him for life, with the full approbation, we may venture to say, of every well affected man in the kingdom.

1798. The internal history of France now ceased to be very interesting. Political freedom could not be said to
317 Decline of public spirit in France. exist after so many of the representatives chosen by the people had been driven from the legislature, and the departments reduced to the necessity of electing men more acceptable to their present rulers. Public spirit therefore rapidly declined. The high notions of the freedom and felicity it was about to enjoy, which had once been so eagerly cherished by a great part of the nation, now gave way to a growing indifference about political questions, and the future destiny of the republic; for the people at large found themselves little interested in a government which existed independent of their will, which consisted of a narrow circle of persons, and whose conduct was surely not less crooked, intriguing, and unprincipled, than that of the ancient royalty, and its attending court, from which they had escaped; whilst its ferocious cruelty, and total disregard even of the forms of justice, were infinitely greater. But though the Directory was all-powerful, yet its power was limited by the present state of things, which denied it the possession of an abundant revenue. It had not yet been found possible to re-establish a system of productive taxation. The legislative councils, indeed, who now complied with every wish of the Directory, voted abundance of taxes; but these were scantily paid; partly on account of the total loss of the national commerce, and partly because the people were not disposed to make great exertions in this way for the support of government. By the constitution, they still possessed the election of the judges and other magistrates; the country was filled with veteran soldiers, who at different
318 Measure of the Directory. times had returned from the armies after the lapse of the usual period of service. The Directory, kept in awe by these circumstances, turned its attention abroad, and found means to establish an extensive patronage, by dividing among its adherents the plunder of neighbouring states, in whose welfare the people of France were little interested. The Girondist party had formerly proposed to propagate their principles by establishing a number of petty republics in the vicinity of France. The Directory now adopted the same project; that, under the pretence of diffusing liberty, they might obtain new sources of revenue and of power, by the dominion which they meant to exercise over these new governments. Holland and the Cisalpine republic were already placed in dependence upon them; and Rome and Switzerland readily afforded them opportunities for extending their plan.

319 Embassy to Rome. After the treaty with the Emperor had been concluded at Campo Formio, Joseph Bonaparte, brother of the General, had entered Rome as ambassador from the French Republic. The Pope, now deprived of all hope of foreign aid, and accustomed to humiliations, had submitted to every demand made by him for reducing the number of his troops, and setting at liberty persons imprisoned on account of political opinions. But an event soon occurred to afford the Directory a pretence for accomplishing the ruin of this decayed government. On the 26th of December 1797, three persons had waited upon the French ambassador, and solicited the protection of his government to a revolution which a party at Rome meant to accomplish. He rejected their proposals, and dissuaded them from the attempt; but did not, as was certainly his duty, communicate these proposals to the papal government, to which he was sent on a friendly embassy. On the following day, however, a tumult took place, in which the French cockade was worn by about 100 insurgents. They were speedily dispersed, but two of the Pope's dragoons were killed. The ambassador, who probably knew the disposition of the Directory towards the Pope, seems to have resolved that his own personal conduct should be blameless on the occasion. He therefore went on the 28th of December to the secretary of state, and presented a list of the persons under his protection who were entitled to wear the French cockade, consenting that all others adopting it should be punished. He also agreed to surrender six of the insurgents who had taken refuge in his palace. Towards the evening of this day, however, the popular tumult became more serious, particularly in the courts and neighbourhood of the French minister's palace. The Pope appears to have been personally unacquainted with the state of affairs; but the governor of the city sent parties of cavalry and infantry to disperse the insurgents. About twenty persons, having a Frenchman at their head, had, in the mean time, rushed into the palace, and demanded aid towards accomplishing a revolution. A number of French officers, and others who were with the ambassador, proposed to drive the whole insurgents by force from the jurisdiction of the palace. This was certainly a salutary advice, and such as could not have been rejected by the ambassador, had not his designs been hostile to the established government. Rejected, however, it was; for, pretending to believe that his authority would be sufficient to accomplish the object in a peaceable manner, he went out into the court to address the multitude. He was prevented from doing so by a discharge of musquetry from the military, who were firing within the jurisdiction of the palace. He interposed with his friends between the military and the insurgents; and while a part of the French officers in his train drove back the insurgents with their sabres, the ambassador advanced towards the soldiers, and demanded why they presumed to violate his jurisdiction? as if the jurisdiction of a foreign ambassador were a legal asylum for men in open rebellion against the government of the state. It is not, therefore, surprising, that no attention was paid to this arrogant and absurd demand; and the nature of the ground being such, that the troops could fire over his head upon the multitude in the rear, they made a second discharge, which killed several of the insurgents. Upon this the ambassador advanced close upon the soldiers, to prevail with them to depart; but they remained in a menacing attitude, and prepared for another discharge. Eager to prevent this, the French General Duphot, who was with the ambas-

French Revolution, 1798.

ambaſſador, and was next day to have married his ſiſter, ruſhed into the ranks of the military, intreating them to deſiſt. Here a petty officer of the Pope's troops
321 A French general killed. diſcharged his muſket into the body of Duphot. Upon this, the ambaſſador and his other friends found it neceſſary to make their eſcape through a bye-way into the palace. The Spaniſh miniſter hearing of this event, ſent to the ſecretary of ſtate to proteſt againſt this violation of the privileges of ambaſſadors But the government, equally alarmed and perplexed by the fear of a revolution, and of French vengeance, remained during many hours totally inactive. All this while the palace of the French ambaſſador remained cloſely beſet by the military, who occupied the whole of its juriſdiction, and all its courts and paſſages. He at laſt ſent to demand paſſports, to enable him to leave the territories of the Pope. They were granted; but with many proteſtations of the innocence of the government, and its regret on account of this unfortunate occurrence.

Joſeph Bonaparte retired to Florence, and from thence to Paris. The Pope ſolicited the protection of the courts of Vienna, Naples, Tuſcany, and Spain; but they all ſtood aloof from his misfortunes: and this government, which had once poſſeſſed the moſt uncontrouled dominion over the minds of men, now fell without a ſtruggle. General Berthier, at the head of a body of French and Ciſalpine troops, encountered no oppoſition in his march
322 The papal government overturned. to Rome, where he overturned the government of the Pope, and proclaimed the ſovereignty of the Roman people, with circumſtances of wanton inſult; which convey a ſtriking example of French humanity and French delicacy.

"That the head of the church might be made to feel with more poignancy his humiliating ſituation, the day choſen for planting the tree of liberty on the Capitol was the anniverſary of his election to the ſovereignty. Whilſt he was, according to cuſtom, in the Siſtine chapel celebrating his acceſſion to the papal chair, and receiving the congratulations of the cardinals, Citizen Haller, the commiſſioner-general, and Cervoni, who then commanded the French troops within the city, gratified themſelves in a peculiar triumph over this unfortunate potentate. During that ceremony they both entered the chapel, and Haller announced to the ſovereign Pontiff on his throne, that his reign was at an end.

"The poor old man ſeemed ſhocked at the abruptneſs of this unexpected notice, but ſoon recovered himſelf with becoming fortitude; and when General Cervoni, adding ridicule to oppreſſion, preſented him the national cockade, he rejected it with a dignity that ſhewed he was ſtill ſuperior to his misfortunes. At the ſame time that his Holineſs received this notice of the diſſolution of his power, his Swiſs guards were diſmiſſed, and republican ſoldiers put in their place." 323 Cruel treatment of the Pope.

He was himſelf removed to the territory of Tuſcany, where he reſided in much obſcurity, till his enemies, driven from Rome in their turn, thought fit to carry him ſtill farther from his capital, to end his days beyond the Alps.

In the mean time, the Roman ſtates were converted into a republic after the French model; excepting that the ancient appellations of *conſuls*, *ſenators*, and *tribunes*, were adopted, inſtead of the new names of a *Directory* and *two Councils* (D). But this oſtentatious grant of freedom was rendered completely illuſory, by a condition 324 Roman republic.

(D) The character of a nation, like that of an individual, will not perhaps admit of a ſudden and total change. This remark is exemplified in the French; who, even when they affect to aſſume the ſtern manners of Republicans, cannot diveſt themſelves of their frivolous and fantaſtical turn, and of that fondneſs for pomp and ſhow by which they were always diſtinguiſhed. The following account of the re-eſtabliſhment of the Roman Republic, by an author of reſpectability who witneſſed the ſolemn farce, will amply confirm the truth of our aſſertion.

"That the regenerated Roman people might be conſtitutionally confirmed in their newly-acquired rights, a day was ſet apart ſolemnly to renounce their old government, and ſwear fidelity to the new. For the celebration of this ſolemnity, which took place on the 20th of March, an altar was erected, in the middle of the piazza of St Peter's, with three ſtatues upon it, repreſenting the French, Ciſalpine, and Roman Republics. Behind the altar was a large tent, covered and decorated with ſilk of the Roman colours, ſurmounted with a red cap, to receive the deputies from the departments who had been ſummoned to aſſiſt. Before the altar was placed an open orcheſtra, filled with the ſame band that had before been employed to celebrate the funeral honours of Duphot. At the foot of the bridge of St Angelo, in the piazza di Ponte, was erected a triumphal arch, upon the general deſign of that of Conſtantine, in the Campo Vacino, on the top of which was alſo placed three coloſſal figures, repreſenting the three republics. As a ſubſtitute for bas-reliefs, it was painted in compartments in *chiara ſcura*, repreſenting the moſt diſtinguiſhed actions of Bonaparte in Italy. Before this arch was another orcheſtra.

"The ceremony in the piazza began by the marching in of the Roman legion, which was drawn up cloſe to the colonnade, forming a ſemicircular line; then came French infantry, and then cavalry, one regiment after another alternately, drawn up in ſeparate detachments round the piazza. When all was thus in order, the conſuls made their entrance, on foot, from the Vatican palace, where they had robed themſelves, preceded by a company of national troops and a band of muſic; and if the weather had permitted, a proceſſion of citizens, ſelected and dreſſed in *gala* for the occaſion, from the age of five years to fifty, were to have walked two and two carrying olive branches; but an exceſſively heavy rain prevented this part of the ceremony.

"Before the high altar, on which were placed the ſtatues, there was another ſmaller one with fire upon it. Over this fire the conſuls, ſtretching out their hands, ſwore eternal hatred to monarchies. and fidelity to the republic; and at the concluſion, one of them committed to the flames a ſcroll of paper he held in his hand, containing a repreſentation of all the inſignia of royalty, as a crown, a ſceptre, a tiara, &c.; after which the French troops fired a round of muſketry; and, at a ſignal given, the Roman legion raiſed their hats in the air upon the points of their bayonets, as a demonſtration of attachment to the new government: but there was no ſhouting—no

French Revolution, 1798. tion annexed to it, that for ten years the French General should possess a negative upon all laws and public acts. At first, however, the conquerors took care to place the government in the hands of the most respectable persons in the state favourable to democracy. But these men finding that they were merely to be employed as tools to plunder their fellow-citizens, for the emolument of their northern masters, soon renounced their odious dignities, and were succeeded by men of more compliant characters, and less scrupulous integrity. The whole public property was seized by the invaders, and contributions were levied without end. The property of the cardinals and others who fled was confiscated, and those members of the sacred college who remained were thrown into prisons, from which they could only escape by purchasing their freedom at a high price.

When this was done, and Generals and Commissaries had glutted themselves with wealth, quarrelled about a *just* division of the spoil, mutinied, and dispersed, other unpaid, unclothed, unprovisioned armies from the north, with new appointments, succeeded; and when at length, even by these *constitutional* means, nothing more was to be obtained, and artifice had exhausted every resource, the mask was put under the feet that had been long held in the hand; liberty was declared dangerous to the safety of the republic, the constituted authorities in-

325 Superseded by military despotism. capable of managing the affairs of the state, and military law the only rational expedient to supply their place. Thus at once the mockery of consular dignity was put an end to, the senators sent home to take care of their families, and the tribunes to blend with the people whom they before represented. This new and preferable system began its operations with nothing less important for the general welfare, than seizing the whole annual revenue of every estate productive of more than ten thousand crowns; two-thirds of every estate that produced more than five, but less than ten; and one-half of every inferior annual income.

Even the degenerated Romans could not have submitted to all this, or at least would not have assisted in forging their own chains, had not the same means been employed to eradicate from their minds every moral and religious principle, which had been formerly employed for the same purpose in Paris. In order that the spirit of equality might be more extensively diffused, a constitutional democratic club was instituted, and held in the hall of the Duke d'Altemp's palace. Here the new-born sons of freedom harangued each other on the blessings of emancipation; talked loudly and boldly against all constituted authority; and even their own consuls, when hardly invested with their robes, became the subjects of censure and abuse. The English were held as particularly odious, and a constant theme of imprecation; and this farce was so ridiculously carried on, that a twopenny subscription was set on foot to reduce what they were pleased to call the proud Carthage of the North.

French Revolution, 1798. 326 Methods employed to corrupt the Roman youth.

If this foolish society had had no other object in view than spouting for each other's amusement, bowing to and kissing a bust of Brutus which was placed before the rostrum (a ceremony constantly practised before the evening's debate), it would have been of little consequence to any but the idle, who preferred that mode of spending their time; but it had other objects of a very different tendency, more baneful, and more destructive to the peace and morals of society—that of intoxicating young minds with heterogeneous pinciples they could not understand, in order to supersede the first laws of nature in all the social duties; for there were not wanting men who knew how to direct the folly and enthusiasm of those who did not know how to direct themselves. Here they were taught, that their duty to the Republic ought ever to be paramount to every other obligation; that the illustrious Brutus, whose bust they had before them, and whose patriotic virtue and justice ought never to be lost sight of, furnished them with the strongest and most heroic example of the subordination of the dearest ties of humanity to the public good; and that, however dear parental affection might be, yet, when put in competition with the general welfare of society, there ought not to be a moment's hesitation which was to be preferred.

This sort of reasoning might perhaps have done no harm to the speculative closet metaphysician, who might have had neither father, nor mother, nor brother, nor sister, nor a chance of ever being thrown in the way to reduce his theory to practice; but with a people who knew of no other ties but such as depended on their religion and their natural feelings, without having been previously educated to discriminate, how far their reason might be deluded by sophistry, or upon what causes

no voluntary signs of approbation; nor do I believe that there ever was a show, in which the people were intended to act so principal a part, where so decided a tacit disapprobation was given as on this occasion.

"After the ceremony was concluded, the French officers, with the consuls and deputies from the departments, dined together in the papal palace on Monte Cavallo, and in the evening gave a magnificent ball to the exnobles and others, their partizans, which was numerously attended, yet with an exception to the houses Borghese, Santacroce, Altemp, and Cesarini: I believe not one distinguished family was present from desire or inclination: but it was now no longer time to accumulate additional causes for oppression: and he who hoped to save a remnant of his property, avoided giving occasion for personal resentment. At night the dome of St Peter's was illuminated, with the same splendour as was customary on the anniversary of St Peter's day. This was the second time of its illumination since the arrival of the French, having been before displayed on the evening of the solemn fete to honour the manes of Duphot, which, though not quite so opportune, was done to gratify the officers that were to leave Rome on the morrow.

"The day after this federation, the French published the Roman constitution in form, which was only a repetition of the one given to the unfortunate Venetians, consisting of 372 articles, and which I think unnecessary to transcribe, as it would only be giving what we have already had from time to time in translations made from their own."—*Duppa's Journal of the most remarkable occurrences that took place in Rome*, upon the Subversion of Ecclesiastical Government in 1798.

French Revolution, 1798.

causes the permanent good of society depended, it had the most direct tendency to generate the worst passions, and to annihilate the best.

Young men were thus initiated to lose all respect for their parents and relations, and even encouraged to lodge information against them, with the hopeful prospect of being considered as deserving well, of what they were pleased to denominate, the republic; and by thus weakening or destroying the bonds of affection, the way was made smooth and easy to the destruction of every thing like what, in a state of civilization, is called character; doubtless, in order to prepare them the better to become the faithful agents of those whom they were thus educated to serve.

327 Monuments of ancient art exposed to sale.

The most remarkable curiosities of this celebrated city had already been conveyed to Paris; and as national vanity had now given place to avarice in the minds of the Directory, the remaining monuments of ancient or of modern art, with which Rome abounded, were sold by public auction. Advertisements (E) were sent through Europe, offering passports to the natives of countries at war with France, if they should wish to become purchasers; and thus the wealthier inhabitants of the Roman territory not only saw themselves subjected to severe exactions, but they beheld with cruel mortification those objects now given up as a prey to vulgar speculation, and dispersed over the world, which had so long rendered their city the resort of all nations.

Such was the progressive conduct of the *Great Nation* towards an injured and oppressed people, whose happiness and dearest interests were its first care, and to whom *freedom* and *liberty* had been restored, that they might know how to appreciate the virtue of their benefactors, and the inestimable blessings of independence.

328 French ingratitude to Switzerland.

More sanguinary scenes were, in the meanwhile, taking place in Switzerland. That country had remained neutral during the contest in which France had lately been engaged; and had thus protected the weakest portion of her frontier, while the rest of it was assailed by the combined forces of Europe. The merit of this service was now forgotten, and the Directory resolved to render Switzerland one of their tributary states. Ambitious nations have in all ages found it an easy matter to devise apologies for invading the territory of their neighbours. The wealthier branches of the Swiss confederacy were in general governed by hereditary aristocracies. Some of the cantons had no government within themselves, but were the subjects of neighbouring cantons. In consequence of this circumstance, and of the contending privileges of different orders of men, popular insurrections were more frequent in Switzerland than in any country in Europe, though none was more equitably governed. When an insurrection took place in one canton, its government was frequently under the necessity of soliciting the aid of the government of an adjoining canton, or even of the neighbouring monarchs of France or Sardinia, to enable it to subdue its own rebellious subjects. A dangerous precedent was thus established; and as the French kings had formerly interfered in favour of the rulers, the republican Directory now interfered in favour of the subjects. The canton of Berne was sovereign of the territory called the *Pays de Vaud*. In this district discontents had always existed; and an insurrection, under the countenance of the French Directory, broke out towards the end of the year 1797. The government of Berne saw the dangerous nature of its own situation; and on the 5th of January issued a proclamation, commanding the inhabitants of the Pays de Vaud to assemble in arms, to renew their oath of allegiance, and to reform every abuse that might appear to exist in their government. A commission was at the same time appointed by the Senate or Sovereign Council at Berne to examine all complaints, and to redress all grievences. The proceedings of this commission, however, did not keep pace with the popular impatience; and the insurgents began to seize the strong places in their country. The government of Berne now resolved to reduce them by force, and sent troops against them; but their commander Weiss appears to have acted with much hesitation, if not with treachery, In the mean time, a body of French approached under General Menard. He sent an aid de camp with two hussars, with a message to General Weiss. On the return of the messengers, an accidental affray took place, in which one of the hussars was killed. This was magnified into an atrocious breach of the law of nations. The French advanced; and by the end of January obtained possession of the whole Pays de Vaud. Still, however, the government of Berne attempted to preserve peace, while it endeavoured to prepare for war. The soldiers who had killed the French hussar were delivered up, negociations were begun, and a truce entered into with General Brune, who succeeded Menard in the command of the French troops in the Pays de Vaud. As internal commotions were breaking out in all quarters, an attempt was made to quiet the minds of the people, that they might be induced to unite against the threatened invasion. Fifty two deputies from the different districts were allowed to sit in the Supreme Council of Berne, and a similar measure was adopted by the cantons of Zurich, Lucerne, Fribourg, Soleure, and Schaff hausen. An army of 20,000 men was at the same time assembled, and entrusted to the command of M. d'Erlach, formerly field marshal in the French service. But disaffection greatly prevailed in this army, and the people could not be brought to any tolerable degree of union. The French knew all this, and demanded a total change of government. M. d'Erlach, dreading the increasing tendency to desertion among his troops, requested leave to dissolve the armistice. It was granted by the government, and immediately recalled. But the French now refused to negociate; and on the 2d of March, General Schawenberg, at the head of 13,000 men, entered Soleure.

329 Undecided conduct of the magistrates of Berne.

(A) A copy of an advertisement, issued on this occasion by what was called *The Administration of Finances and Contributions of the French Republic in Italy*, is to be found in *Nicholson's Journal of Philosophy, Chemistry, and the Arts, for May* 1798. The advertisement is dated at Rome, 28th Feb. 1798. A copy of it was sent by Hubert, the agent of the French administrators, to Mr Trevor the British minister at Turin, and by him was transmitted to England.

French Revolution, 1798.

Solcure. Friburg was afterwards reduced by Brune, and the Swifs army retreated. The government of Berne was in confternation, and decreed what was called the *landfturm*, or rifing of the people; which, in cafes of emergency, was authorifed by their ancient cuftoms.

330 Conſternation of the government, and capitulation of Berne.

The people accordingly affembled; and their firft act was to diffolve the government, and to offer to difmifs the army, on condition that the French troops fhould proceed no farther. This offer was refufed, unlefs a French garrifon fhould be received into Berne, and the invaders continued to advance. The regular troops under M. d'Erlach were reduced by defertion to 14,000. The rifing of the people had indeed fupplied him with numbers, but there was no time for arranging them. On the 5th of March he was attacked, and driven from the pofts of Newenbeg and Favenbrun. He rallied his troops, however, at Uteren, where they made a ftand for fome time. They renewed the conteft at Grauholtz without fuccefs, and were driven from thence about four miles farther to the gates of their capital. Here the Swifs army made a laft and bloody effort. Being completely routed, they murdered many of their officers in defpair, and among others their commander M. d'Erlach. The flaughter on both fides is faid to have been nearly equal; but the French fucceeded in obtaining poffeffion of Berne by capitulation on the evening of the day on which thefe battles were fought. Upon the capture of this city, the other more wealthy and populous ftates fubmitted to the French; but the poorer cantons, who had leaft to lofe, made a terrible effort in defence of their fmall poffeffions, and the independence of their country. They even at firft compelled Schawenberg to retire with the lofs of 3000 men; but were at laft overpowered by the fuperior numbers and military fkill of the French army.

331 Switzerland treated as a conquered country.

Switzerland was treated as a conquered country. Its public magazines were feized by the French, heavy contributions were levied, and a new conftitution, in imitation of that of France, was impofed.

While the Directory continued to encroach upon the independence of other nations, they were not likely to refpect the freedom of their countrymen at home. In the month of April, a third of the legiflature was changed. Francis de Neufchateau went out of the Directory by ballot, and Treilhard was chofen in his ftead. The Directory had made great efforts to influence the elections in favour of their friends, but with little fuccefs. They prepared therefore to preferve the legiflature in fubjection to them by a new violation of the conftitution.

332 The Directory violates the conftitution.

On the 2d of May they complained to the Council of Five Hundered of the plots of anarchifts and royalifts; by which they alleged that the elections had in many places been made to fall on men hoftile to the Republic. On the 7th a committee made a report upon this meffage, and propofed that the proceedings of many electoral affemblies fhould be totally or partially annulled, according to the characters of the perfons they had chofen. General Jourdan, and fome others, ventured to oppofe this plan as utterly inconfiftent with the freedom of election, and as proceeding upon alleged intrigues of confpirators againft the Republic, while no confpiracy had been proved to exift. But the majority agreed to the propofal of the committee, and arbitrarily annulled the whole elections in fix or feven departments, befides the particular elections of a great number of individuals.

333 Plan an expedition to Egypt and India.

The Directory now carried into effect the moft fatal of all their projects, that of fending a powerful army to the eaft to feize upon Egypt, and from thence to attack the empire which Britain has acquired in India. The treaty with Auftria had no fooner been figned at Campo Formio, than the Directory excited the expectation of France and of all Europe, by loudly proclaiming their determination to invade Great Britain. They fent troops into their own weftern departments, called them the *Army of England*, and appointed Bonaparte their commander in chief. This officer, in the mean time, had refided during the winter at Paris. Here he feems to have endeavoured to guard againft the jealoufy of government, and the envy of individuals, by paffing his time in retirement, and affuming the character of a man of letters. He procured himfelf to be elected a member of the National Inftitute; but fo feldom did he appear abroad, that when he attended fome of its public fittings his perfon was altogether unknown to the fpectators. Greedy of renown, but aware that it ultimately depends upon the labours and the approbation of the learned, he never failed, when called into military fervice, to remind this order of men of his alliance with them, by adding to his name at all proclamations and difpatches the defignation of *Member of the National Inftitute*.

Whether the expedition to Egypt was now fuggefted by Bonaparte himfelf, or whether it was not a fnare by which the prefent rulers of France impofed upon the vanity of an enterprifing young man, to enable them to get quit of him and his veteran army, is not known. It is very poffible, however, that Bonaparte might neither be the devifer nor the unconfcious victim of this plan; but that he might account himfelf more fafe abroad, upon the moft hazardous expedition, than expofed at home to the malice of a government that had become jealous of his reputation, and was by no means fcrupulous in its conduct.

334 Preparations for it conducted with fecrecy.

The projected invafion of Egypt was conducted with much fecrecy. The world was amufed with tales of monftrous rafts to be conftructed to convey the army of England over into Britain. To favour the deception, Bonaparte made a journey to the weftern coaft. In the mean time, the fleet was preparing at Toulon, and troops affembling in its neighbourhood. When all was in readinefs, Bonaparte embarked with 40,000 of the troops that had fought in Italy. On the 9th of June he arrived at the ifland of Malta, and contrived to quarrel with the Grandmafter, becaufe he refufed to admit fo large a fleet all at once into his ports to water. The French General immediately landed his troops in different quarters, and endeavoured to reduce the ifland. The knights were divided into factions. Many of them, as is now well known, were of the order of Illuminati, and of courfe prepared to act the part of traitors.

335 Conqueft of Malta.

After making a very feeble refiftance, the Grandmafter propofed a capitulation; and thus was treacheroufly furrendered, in a few days, a fortrefs which, if defended by faithful troops, might have held out for as many weeks againft all the forces of the French Republic. Bonaparte, after leaving a garrifon of 4000 men in the ifland, failed on the 21ft of June for Alexandria.

336 Admiral Nelfon fails in queft of Bonaparte.

In the mean time, Rear admiral Nelfon, who, in the ftation of Commodore, had fignalized himfelf in a very high degree under Lord St Vincent, had been difpatched in queft of him from the Britifh fleet, which ftill blockaded Cadiz. Not knowing the object of the French expedition, the Britiſh Admiral ſailed firſt to Naples; and having there been informed of the attack upon Malta, he directed his courſe to that iſland. By the time he arrived there, however, Bonaparte had departed. Conjecturing now that Alexandria might be the deſtination of the French troops, he ſailed thither; but they had not been ſeen in that quarter, and he therefore went eagerly in ſearch of them to other parts of the Mediterranean Bonaparte, in the mean while, inſtead of ſteering in a direct line for Alexandria, had proceeded ſlowly with his immenſe train of nearly 400 tranſports, along the coaſt of Greece, till he arrived at the eaſtern extremity of the iſland of Candia. Here he ſuddenly turned ſouthward; and in conſequence of his circuitous courſe, did not arrive at the coaſt of Egypt till Admiral Nelſon's fleet had left it. He landed his troops; and on the 5th of July took by ſtorm the city of Alexandria. The inhabitants defended themſelves very deſperately, but without ſkill; and for ſome time a ſcene of barbarous pillage and maſſacre enſued. The tranſports that had conveyed the army were now placed within the inner harbour of Alexandria, and the ſhips of war under Admiral Brueys caſt anchor in a line cloſe along the ſhore of what proved to them the fatal Bay of Aboukir. The army proceeded to the Nile, and aſcended along the banks of that river, ſuffering great hardſhips from the heat of the climate. They were met and encountered by the Mamalukes, or military force that governed Egypt; but theſe barbarians could not reſiſt the art and order of European war. Cairo was taken on the 23d of July. On the 25th another battle was fought; and on the 26th the Mamalukes made a laſt effort in the neighbourhood of the celebrated pyramids for the preſervation of their empire. Two thouſand of them were killed on this occaſion, 400 camels laden with their baggage were taken, along with 50 pieces of cannon.

337 Conqueſts of Bonaparte in Egypt.

A proviſional government was now eſtabliſhed in Egypt. Proclamations were iſſued in the Arabian tongue, declaring that the French were friendly to the religion of Mahomet, that they acknowledged the authority of the Grand Signior, and had only come to puniſh the crimes committed by the Mamalukes againſt their countrymen trading to Egypt. Thus far all had gone well; but on the 1ſt of Auguſt the Britiſh fleet appeared at the mouth of the Nile; and the ſituation of the French fleet having been diſcovered, Admiral Nelſon prepared for an attack. In number of ſhips the fleets were equal; but in the number of guns and weight of metal the French ſquadron had the ſuperiority. It was drawn up, too, in a form which ſuggeſted to its ill-fated commander the idea of its being invincible; but remaining at anchor, the Britiſh Admiral was enabled, by running ſome of his ſhips between thoſe of the enemy and the ſhore, to ſurround and engage one part of their fleet, while the reſt remained unemployed and of no ſervice. In executing this plan of attack, a Britiſh ſhip, the Culloden, run aground; but this accident only ſerved as a beacon to warn the others of the ſpot that ought to be avoided. The battle commenced at ſunſet, and was continued at intervals till daybreak. At laſt, nine ſail of the French line were taken; one ſhip of the line was burned by her own commander; a frigate was burned in the ſame manner, to prevent her being taken. The French Admiral's ſhip L'Orient took fire, and blew up during the action, and only a ſmall number of her crew of 1000 men eſcaped deſtruction. Two French ſhips of the line and two frigates were ſaved by a timely flight (F).

338 Admiral Nelſon attacks and deſtroys the French fleet.

339 Conſequences of his victory.

No naval engagement has in modern times produced ſuch important conſequences as this. The unexampled military efforts made by France had gradually diſſolved the combination which the princes of Europe formed againſt her. By the train of victories which Bonaparte had gained, the houſe of Auſtria, her moſt powerful rival, had been humbled and intimidated. The whole continent looked towards the new Republic with conſternation; and when the Directory ſeized upon Rome and Switzerland, none were found hardy enough to interpoſe in their favour. The current of affairs was now almoſt inſtantaneouſly altered. Europe beheld Bonaparte, with his *invincible* army, exiled from its ſhores, and ſhut up in a barbarous country, from which the triumphant navy of Britain might for ever prevent his return. The enemies of France could not beforehand have conceived the poſſibility of the event which was now realiſed; and the hope was naturally excited of being able to form a new and more efficient coalition againſt a government which had ſo groſsly abuſed the temporary proſperity it had enjoyed. The northern powers began to liſten to the propoſals made to them by Great Britain for commencing hoſtilities anew, and the Italian ſtates prepared to make another effort for independence. The court of Naples in particular openly avowed its joy on account of the recent deſtruction of the French fleet. The king himſelf put to ſea to meet Admiral Nelſon on his return from the Nile. Illuminations took place in the capital, and vigorous preparations were made for war. The Grand Signior, who had poſſeſſed of late little authority in Egypt, and might perhaps have been induced to relinquiſh his claims on that province rather than engage his decaying empire in war, now entered into cloſe alliance with Britain, and engaged in hoſtilities againſt the French. Tippo Sultan had ſtipulated for the aid of a French army againſt the Britiſh in India; but Bonaparte, on taking poſſeſſion of Suez and the other Egyptian ports on the Red Sea, found no ſhipping there fit to tranſport his army to the Indian peninſula. Inſtead of proceeding therefore upon any ſplendid ſcheme of farther conqueſt, he was compelled to remain in his preſent ſituation, and to contend for exiſtence againſt the whole force of the Ottoman empire.

340 Rebellion in Ireland.

The French at this time did not venture to ſend forth any large fleet upon the ocean; but wherever their ſmaller ſquadrons appeared, the fortune of Britain overpowered them there no leſs than it had done in the Mediterranean. They had long promiſed aid to the diſaffected party in Ireland; but weary of fruitleſs expectation, the Iriſh had during this ſummer broken out into rebellion, without waiting the arrival of the troops whom the Directory had engaged to ſend to their aſſiſtance. While the rebellion was at its height, and although the inſurgents for ſome time occupied the ſea port of Wexford, the French did not arrive. Afterwards,

---

(F) The two ſhips of the line and one of the frigates have been ſince taken.

French Revolution, 1798. wards, however, when the rebellion had been totally subdued, they attempted to elude the vigilance of the British fleet, and to land men in small parties. On the
341 22d of August, General Humbert came ashore at Killala, at the head of about 1100 men. Even this small party might have been dangerous had it arrived a month earlier; and it actually produced very serious alarm. It consisted of men selected with great care, and capable of enduring much fatigue. They were joined by a few of the most resolute of the discontented Irish in the neighbourhood, and speedily defeated General Lake, who advanced against them with a superior force, taking from him six pieces of cannon. They next marched in different directions, for the purpose of raising the people, and maintained their ground in the country during three weeks. Finding, however, that he was not seconded by additional troops from France, that the rebellion in Ireland had been fully subdued, and that 25,000 men under Lord Cornwallis were closing round him, Humbert dismissed his Irish associates; and four days thereafter, having encountered one of the British columns in his march, he laid down his arms. Now, when it was too late, the Directory was very active in sending troops towards Ireland; but all their efforts
342 were defeated by the superiority of the British navy. On the 12th of October, Sir John Borlase Warren took La Hoche, a ship of 84 guns, and four frigates, attempting to reach Ireland with nearly 3000 men on board. The other ships belonging to the French squadron, which conveyed 5000 men in all, contrived to make their escape by sailing round by the north of the island. On the 20th of the same month another frigate bound for Ireland was taken; and the French finding that the sea was completely occupied by the British fleet, were at last compelled to desist from their enterprise.

Feebly supported by the Directory.

Whose efforts are defeated by the British navy.

Ever since the treaty of Campo Formio had been concluded, a congress of ministers from the French Directory, and from the German princes, had been negociating at Rastadt a treaty between France and the empire. As these negociations terminated in nothing, and were tedious and uninteresting during their progress, it is unnecessary to enter into a detail of the steps by which they were conducted. The intended result of them had been previously arranged between the Emperor and the Directory in the secret convention of
343 Campo Formio, which has been already mentioned. That the articles of this convention might be concealed, the French ministers at Rastadt formerly brought forward their proposals in succession for the discussion of the German deputies. The French demanded that the Rhine should be the boundary of their Republic. The Germans resisted this. References were made to the diet of Ratisbone, and long discussions and negociations took place among the different princes. When it was found that little was to be expected from the protection of Austria, the German deputies at Rastadt were instructed to offer one half of the territory demanded. This offer was refused, and new negociations took place. The other half was at last yielded up, and a long discussion commenced about the debts due by the ceded territory, which the French refused to pay. The tolls upon the river, and upon the rivers flowing into the Rhine, also gave rise to much altercation. It was even a matter of no small difficulty, after all, to determine the precise boundary of France; whether her territory should extend to the left bank, the right bank, or the thalweg, that is, the middle of the navigable channel of the river. It became also a question how those princes ought to be indemnified who lost their revenues or territories by the new acquisitions of France; and it was at length agreed that they should receive portions of the ecclesiastical estates in Germany.

Negociations at Rastadt.

These discussions, conducted with endless formality and procrastination, still occupied the congress at Rastadt: but it now became gradually more probable that 344
no treaty would be concluded at that place. Austria began to strengthen her armies in all quarters. Russia, that had hitherto avoided any active interference in the contest, placed a large body of troops in British pay, and sent them towards the German frontiers. The king of Naples avowedly and eagerly prepared for war. This impatient monarch, resolving to attack without delay the French troops who occupied the Roman territory, procured General Mack and other officers from the court of Vienna to assume the command of his army. Without waiting, however, till Austria should commence the attack, he rashly began the war alone and unaided, excepting by the British fleet, and thus drew upon himself the whole force of the French Republic. The Directory did not suspect such imprudent conduct on the part of this prince; and accordingly, when General Mack entered the Roman territory, at the head of 45,000 men, the French troops in that quarter were altogether unequal to the contest. A French ambassador still resided at Naples when this event took place, and war was not declared. When the French General Championet complained of the attack made upon his posts under these circumstances, he was informed in a letter by General Mack, that the king of Naples had resolved to take possession of the Roman territory, having never acknowledged its existence as a Republic; he therefore required the French quietly to depart into the Cisalpine states; declaring, that any act of hostility on their part, or their entrance into the territory of Tuscany, would be regarded as a declaration of war. Championet finding himself unable to resist the force 345
now brought against him, actually evacuated Rome. He left, however, a garrison in the castle of St Angelo, and endeavoured to concentrate whatever troops he could hastily collect in the northern extremity of the Roman state. Towards the end of November, General Mack entered Rome without opposition.

Preparations for war on the Continent.

The Neapolitans take possession of Rome.

When these events came to be known at Paris, war was immediately declared against the king of Naples, and also against the king of Sardinia. This last prince had made no attack upon France; but he was accused by the Directory, in their message to the Councils, of *disaffection* to the Republic, and of *wishing* to join the king of Naples in his hostile efforts. This accusation could not well be false. From the period of Bonaparte's successful irruption into Italy, the king of Sardinia had felt himself placed in the most humiliating circumstances; his most important fortresses were occupied by the French; they levied in his country what contributions they thought fit; and when they recently required him to receive a garrison into his capital, he 346
found himself unable to resist the demand. Even now, when they performed the useless ceremony of declaring war, he could make no effort in his own defence, and quietly

Hard fate of the king of Sardinia.

French Revolution, 1798. quietly gave them a formal resignation in writing of his whole continental dominions, consenting to retire to the island of Sardinia.

In the mean time, the contest with Naples was soon decided. The French on their retreat were much harassed by the people of the country. The Neapolitan troops regarded them with such animosity, that they scarcely observed the modern rules of war towards the prisoners who fell into their hands. Even their leaders seemed in this respect to have forgotten the practice of nations; for when General Bouchard, by order of General Mack, summoned the castle of St Angelo to surrender, he declared, that he would consider the prisoners of war and the sick in the hospitals as hostages for the conduct of the garrison; and that for every gun that should be fired from the castle, a man should be put to death. It cannot well be imagined that the Neapolitan officers would have acted in this vehement manner, had they not expected countenance and support from the immediate co-operation of Austrian troops. In their hopes from this quarter, however, they were completely disappointed.

347 Naples conquered by the French.

Mindful of her recent calamities, and attentive only to her own aggrandisement, Austria seems still to have expected more from negociation than from war, and the territory of Naples soon fell into the hands of the French. Such indeed was the terror of the French name in Italy, or such was the disaffection or cowardice of the Neapolitan troops themselves, that they were beaten by one-fourth of their number in different engagements, at Terni, Porto Fermo, Civita Castellana, Otricoli, and Calvi. At the commencement of the contest a body of Neapolitans, with the assistance of the British fleet, had been landed at Leghorn, for the purpose of taking the French in the rear: but they, disregarding this attempt on the part of such an enemy, pressed on towards Naples. By degrees, General Mack's army being reduced by the result of the battles which it fought, and by desertion, to 12,000 men, he found it necessary to advise the king and royal family of Naples to take refuge on board the British fleet. They did so; and arrived at Palermo, in Sicily, on the 27th of December, in the British Admiral Lord Nelson's ship. General Mack, in the mean time, requested an armistice, to afford an opportunity for making peace; but this was refused. Being driven from Capua, which is the last military post of any strength in the Neapolitan territory, and his life being in no small danger from the disaffection of his own troops, he at last found it necessary to seek for safety, by surrendering himself, along with the officers of his staff, to the French General. The governor of Naples, in the mean time, offered to the French a contribution in money, if the commander in chief would consent to avoid entering that city. The offer was accepted, and the invading army remained at Capua. General Serrurier, on the 28th of December, at the head of a column of French troops, expelled the Neapolitans from Leghorn, and took possession of that place. So far as the efforts of regular armies are to be considered, the war might now therefore be regarded as brought to a termination; but the French had speedily a new and unusual enemy to contend against.

1799. From the mildness of the climate, and the fertility of the soil, human life can be sustained in the southern parts of Italy with fewer efforts of industry than in almost any other country in Europe. Hence arises a general propensity to idleness, which is increased by the numerous charitable institutions to which the Roman Catholic religion gives rise. In the city of Naples there had long existed a body of persons under the denomination of *Lazzaroni* or Beggars, amounting to the incredible number of from thirty to forty thousand men, who did nothing, and subsisted merely by charity, or by such shifts as occasionally occurred to them. One of these frequently was the menacing the state with an insurrection, in case their wants were not instantly supplied; which usually drew from a feeble administration very liberal distributions of money and provisions. On the present occasion they demonstrated abundance of loyalty; but the king had thought fit to avoid entrusting his safety to such defenders. During the confusion which followed the flight of the court and the approach of the French army, the Lazzaroni became mutinous. They heard that the French abolished, wherever they came, all those monasteries and other religious establishments which are the great sources of public charity. The Lazzaroni, therefore, conceived the most violent hatred against them, and against all who were suspected of favouring opinions hostile to royal government. In the beginning of January they began to shew symptoms of discontent, and in a few days broke out into open insurrection. The members of the government left by the king, overcome by habitual terror of the Lazzaroni, consulted merely their own personal safety, and made no effort to preserve the public tranquillity. Prince Militorni had gained considerable applause on account of his vigorous defence of Capua against the French. The Lazzaroni therefore elected him their commander in chief; but he attempted in vain to restrain their violence and love of plunder. They declared hostility against the French and all the advisers of the armistice. They broke open the prisons, and put to death all those who were confined on account of political offences against the royal government.

348 The Lazzaroni rise against the French.

349 Their outrages.

They next spread themselves over the city in search of those persons whom they considered as favourable to the invaders, and committed murder and robbery in all quarters, concluding by burning the houses of those accounted disaffected. An attempt was made by a considerable body of the inhabitants, who thought themselves in the greatest danger, to resist their fury, by fortifying the Convent of the Celestins, and retiring thither; but the Lazzaroni, after encountering the fire of cannon and of musketry, succeeded in storming the place, and destroyed all who had taken refuge there. Their power and their fury were now equally boundless, and the city became in many quarters a scene of massacre and pillage. Prince Militorni, therefore, went to Capua, and requested Championet to rescue Naples from utter ruin by occupying it with his army. For this purpose it was arranged, that a column of French troops should secretly advance by a circuitous march, and suddenly enter the city from the opposite quarter. Before this plan could be fully executed, the Lazzaroni had adopted the daring resolution of attacking the French within the fortifications of Capua. Accordingly two-thirds of them marched out upon this enterprise, and spent the 19th and 20th of January in attempting to take Capua by assault. Multitudes of these men here perished by the artillery of the place; for the French,

French Revolution 1799.

French, to favour the capture of Naples by the party that had been ſent eaſtward for that purpoſe, avoided making any ſally, and remained upon the defenſive. The Lazzaroni at Capua, however, having learned on the 21ſt that a French column had marched to Naples, and approached the gates, ſuddenly returned to the aſſiſtance of their brethern in the capital. They were cloſely purſued by the French; but they had leiſure, nevertheleſs, to barricade the ſtreets, and to form themſelves into parties for the defence of different quarters. A dreadful and ſanguinary conteſt now enſued, which laſted from the morning of the 22d to the evening of the 23d of January. The Lazzaroni, with ſome peaſants who had joined them, diſputed obſtinately every ſpot of ground; and by the energy which they diſplayed, caſt a ſevere reproach upon the feeble and unſkilful government, which had not been able to direct in a better manner the courage of ſuch men. At length, after having been gradually driven from ſtreet to ſtreet, the Lazzaroni rallied for the laſt time at one of the
350 gates of the city, where they were nearly exterminated. The inhabitants rejoiced on account of their own eſcape from immediate ruin; and while the French armies found themſelves become odious in all the other countries which they had entered, they here found themſelves, from the peculiar circumſtances of the caſe, received with unfeigned welcome, in a city which holds the third place in population and ſplendour among the capitals of Europe.

They are nearly exterminated.

This may be regarded as the laſt triumph enjoyed by the Directory. The conſequences of their conduct were now gathering faſt around them. They were deſervedly unpopular at home; not only from the violations they had offered to the conſtitution of their country, but alſo from the manner in which they conducted public affairs in detail. They ſet no bounds to their profuſion, or to the exactions with which their agents vexed the conquered countries. Championnet, aſhamed of the extortions of which the Commiſſaries of the Directory were guilty, attempted in Italy to reſtrain them; and the conſequence was, that, upon the complaint of the commiſſary Taypoult, he was deprived of his command, and thrown into priſon. Scherer, the miniſter of war, was appointed his ſucceſſor. Under him
351 the rapacity of the agents of government, and the embezzlement of the public ſtores, was carried to its height. The members of the armies were ſuffered to decline, that the Directory, the commiſſaries, and the generals, might become rich. Thus the ſtate was left totally unprepared againſt the ſtorm which was now rapidly gathering from abroad. Still, however, France was feared by the neighbouring nations, to whom the preſent ſtate of her internal affairs was obſcurely known. Though an army of 45,000 Ruſſians had advanced to the aid of Auſtria, yet that Cabinet heſitated to declare war. Pruſſia was eagerly ſolicited by Britain to take up arms againſt France, and large pecuniary aid was offered; but Sieyes, the Directory's ambaſſador at Berlin, artfully contrived to defeat this negociation, and to counteract the unpopularity of his country in Germany, by publiſhing the ſecret convention at Campo Formio, which we have already mentioned. This treaty demonſtrated ſo clearly to the German princes the utter unconcern with which their independence and their intereſts were regarded by the head of the empire, that no ſteady co-operation with Auſtria could henceforth be expected from them. The greater number of them, therefore, reſolved to maintain their neutrality under the protection of Pruſſia.

Rapacity of the Directory.

On the 2d of January, the French miniſters at Raſtadt preſented a note to the congreſs, in which they intimated, that the entrance of Ruſſian troops into Germany, if not reſiſted, would be regarded by them as a declaration of war. Some negociation took place in conſequence of this note, but no ſatisfactory anſwer was returned. On the 26th of that month, the ſtrong fortreſs of Ehrenbreitſtein ſurrendered, after having remained under blockade ſince the concluſion of the treaty of Campo Formio. By the poſſeſſion of this place, and of Mentz and Duſſeldorf, France was now rendered very formidable on the Rhine. As ſhe poſſeſſed alſo the ſtrong country of Switzerland, and all the fortified places of Italy, ſhe was well prepared, not only for defence, but for active operation; for it is now known, that the conferences of Raſtadt were purpoſely protracted, by orders from the Directory, till the French armies ſhould be ready to take the field with advantage againſt an enemy whoſe conduct betrayed the moſt culpable tardineſs. At this time Jourdan commanded 352
on the Upper Rhine from Mentz to Huningen; Maſſena occupied with an army the eaſtern frontier of Switzerland towards the Griſon country; Scherer was commander in chief in Italy; Moreau acted as general of a diviſion under him; and Macdonald commanded the troops that occupied the territory of Rome and Naples. But theſe armies that kept in ſubjection, and were now to defend ſo many countries, ſcarcely amounted to 170,000 men in all, and were far outnumbered by the armies which Auſtria alone, without the aid of Ruſſia, could bring into the field. The Directory, however, confiding in the unity of its own plans, in the undecided politics of the court of Vienna, and in the conſequent ſlow movements of the Imperial armies, was eager to renew the war; and the two Councils, on the 13th of March, declared France to be at war with the Emperor of Germany and the Grand Duke of Tuſcany. The war, however, had already been begun. On the 1ſt of March Jourdan croſſed the Rhine at Straſburgh, and occupied ſeveral ſtrong poſitions in Swabia. Manheim was taken, and Philipſburg ſummoned to ſurrender by Bernadotte (G), while St Cyr entered Stutgard. On the 4th of March the Auſtrians croſſed the Lech, under the command of the Archduke Charles, to oppoſe this army. Maſſena advanced into the territory of

War renewed on the Rhine.

(G) This ſummons was conceived in very extraordinary terms, and cannot be accounted for but upon the ſuppoſition that Bernadotte believed the Auſtrian officers infected with French principles. He calls upon the commander of the fortreſs to ſurrender without reſiſtance, and thus violate the truſt repoſed in him by his ſovereign. He tells him, that a diſcharge of his duty would produce the *defection of his officers and men.* He warns him of the folly and danger of leading troops to action *againſt their will;* and, laſtly, he threatens him with *vengeance* if he ſhould *dare to reſiſt!*

French Revolution, 1799. of the Grifons; and furprifing a ftrong body of Auftrians, took them all prifoners, together with their General Auffenburgh, and the whole of his ftaff, after a defperate refiftance under the walls of *Coire*. The reduction of the Grifons was the confequence of this victory.

353 And in Switzerland.

But in order to complete the plan of the French, which was to effect a junction with their two armies, that of Maffena in Switzerland with that of Jourdan in Germany, it was neceffary to carry the important poft of Feldkirch, which was occupied by the Auftrian General Hotze, whofe line extended from the frontiers of the Grifons, to the north eaft by the Vorelberg, to the eaftern extremity of the Lake Conftance. Vigoroufly repulfed in his firft attack, Maffena renewed it, five different times, with frefh forces, and increafed impetuofity. But all could not avail againft the fteady bravery of the Auftrians, who drove back the affailants with immenfe flaughter. The French, however, being in poffeffion of the Grifons, the invafion of the Engadine, and the county of Bormio, by a divifion of the army of Italy cantoned in the Valteline, under the orders of General Cafabianca, was facilitated. The Auftrians, too weak in that quarter to refift them, retreated into the Tyrol, whither they were purfued by the French, who forced fome of the defiles by which the entrance of that country was defended, and extended their deftructive incurfions as far as Glurenz and Nauders.

Meanwhile the van-guard of the main army of the Imperialifts pufhed forward to meet the enemy. On the 20th of March it was attacked by Jourdan, who drove in the outpofts; but on the following day that general was himfelf attacked in the centre of his army, driven from his pofition, and compelled to retire during the night to Stockach. Both parties now prepared for a decifive engagement. On the 24th, the Archduke encamped before Stockach, with his right wing towards Nellenburgh, and his left near Wallenweis. On the 25th at day-break, the French army began the attack. They directed their chief efforts againft the right wing of the Auftrians commanded by General Meerfeldt. The battle was long and obftinate. From five o'clock in the morning till paft one of the afternoon, its termination remained extremely doubtful. The French fucceeded in their attempt againft General Meerfeldt. His pofition was forced, and he retreated into a wood between Liptingen and Stockach. Here he renewed the combat

354 The French are defeated in Swabia,

without fuccefs. He was gradually driven to the extremity of the wood, though it is a German mile in breadth. The left wing of the Auftrians, however, had in the mean time maintained its ground, and reinforcements were fent from it to General Meerfeldt. With the affiftance of thefe he at laft fucceeded in making a ftand, and even obliged the French to retire in their turn. At length, about two o'clock, the French found it neceffary to withdraw from this quarter. The battle, however, was continued in different points till night came on. The French remained upon the ground where they had begun the attack, and they even retained 4000 prifoners whom they had taken during the various movements of the day. The refult of the battle, upon the whole, however, was fatal to their affairs. Their lofs was fo great, and the fuperiority of the Auftrians fo manifeft, that Jourdan dared not to hazard another engagement. On the following day he retired to Weiller near Dutlingen; and finding his army altogether unequal to offenfive operations, he fent back one part of it to cover Kehl and Strafburgh, while he withdrew with the other towards Switzerland. This event compelled Maffena, who was preffing upon Tyrol and the Engadine, to return to the defence of Switzerland. He was immediately intrufted with the chief command of the troops in this quarter, in the room of Jourdan, who was removed. The Auftrians continued to advance in every direction, and immediately occupied the whole of the right, or German fide of the Rhine, from the lake of Conftance to Mentz.

355 And in Italy.

In Italy the fuccefs of the Auftrians was equally confpicuous, notwithftanding the treachery of the French in attacking them before the expiration of the truce. The attempt of the latter to force the advanced pofts of the former, on the 26th of March, at Santa Lucia and Buffelango, was rendered abortive; and at Legnago, the Auftrian general, Kray, obtained a complete victory, and compelled them to feek protection under the walls of Mantua. On the 5th of April, the Auftrians again attacked them in their pofition at Memiruolo, which lies on the road from Mantua to Pefchiera, and compelled them, after an obftinate conflict, once more to retreat. The lofs of the French in thefe different actions was undoubtedly great; but it is probably overrated at 30,000 men killed, wounded, and taken.

The fuccefs of the Auftrians, however, was not cheaply purchafed. Scherer, who commanded the French army, gained over them, at firft, fome advantages, which, had he known how to improve them, might have given a different turn to the tide of affairs. One divifion of his army had actually forced the Auftrian pofts on the 26th of March, and taken 4000 prifoners; but the other divifion being repulfed, he withdrew his troops from their advanced pofition, and thus relinquifhed the advantage which he had gained. Even on the 5th of April, Moreau's divifion performed prodigies of valour, and took, it has been faid, 3000 prifoners; but from the injudicious difpofitions which had been made by Scherer, that general was not fupported, and the victory of the Auftrians was complete. Kray now quickly drove the French from the Mantuan, and compelled them, after having fuftained new loffes, to relinquifh their ftrong holds on the Mincio and the Adige, and to retreat to the Adda.

356 Moreau fortifies his camp.

On the banks of this river, rendered remarkable for the dear bought victories which Bonaparte had obtained at the bridge of Lodi, the French general Moreau, to whom the Directory had given the chief command of their army, prepared to make a vigorous defence. The military talents of this man had been rendered unqueftionable by his celebrated retreat through a hoftile country, and before a victorious army ably commanded. On the prefent occafion he did not belie his former character. Nothing that could give courage or confidence to his troops was neglected. Entrenchments were thrown up wherever the river was confidered as paffable; and a fituation, remarkably ftrong by Nature, was ftrengthened by every means which art could fupply.

Before this period, a confiderable body of Ruffians had joined the Imperialifts; and the chief command of the allied army was now affumed by Field Marfhal Suwarrow Rimnifki. This celebrated leader, whofe character

French Revolution, 1799.

racter every democrate labours to miſrepreſent, had entered into the army at the age of twelve, and riſen from the ranks to the ſtation which he now holds, of Generaliſſimo of the Ruſſian armies. Poſſeſſed of ſtrong natural talents, he had likewiſe the benefit of an excellent education, and is ſaid, by thoſe who are perſonally known to him, as well as acquainted with the ſtate of literature in Ruſſia, to be one of the beſt claſſical ſcholars of all the natives of that great empire. He had ſtudied, in early life, mathematics and natural philoſophy, as branches of ſcience abſolutely neceſſary to the man whoſe higheſt ambition is to become a great commander; and his knowledge of the learned, as well as of the faſhionable languages, has enabled him to avail himſelf of all that has been written either by the ancients or the moderns on the art of war. This art has indeed been his chief ſtudy from his youth; it has been at once his buſineſs and his amuſement.

357 [M]arſhal [S]uwarrow

Poſſeſſed with his countrymen, in general, of the moſt undaunted courage, and formed by Nature to endure the greateſt fatigue, it is not ſurpriſing, that with all theſe advantages Suwarrow ſhould have long ago acquired the character of one of the ableſt generals of his time. It is indeed true, that, till the opening of the campaign of 1799, he had diſtinguiſhed himſelf only againſt the Turks, whom we are too apt to deſpiſe, and againſt the Poles when divided among themſelves; but let it be remembered, that the enthuſiaſtic courage of thoſe ſame Turks had found employment for the talents of ſome of the ableſt generals in Europe, a Laudohn and a Cobourg; and that the Poliſh armies which Suwarrow ſubdued were united by the ſtrongeſt of all ties—the knowledge that they muſt conquer or periſh. All this was ſo well known to Frederic the Great, that he held the military talents of the Ruſſian hero in the higheſt eſteem; and the attention of all Europe was now turned towards the quarter where thoſe talents were to be exerted in the ſupport of ſocial order, and of every thing which ennobles man. His operations in Italy did not diſappoint the higheſt expectations which had been formed of them. At an age conſiderably above ſixty, he began a campaign not leſs remarkable for its activity than any which had gone before it ſince the commencement of the French revolution. We are by no means prepared, however, to do juſtice to the various military efforts which were now made, or to explain clearly the means employed to inſure ſucceſs. If the work entitled the *Hiſtory of Suwarrow's Campaigns* be deſerving of credit, the ſuperiority of that commander over his rivals and opponents ſeems to have at all times conſiſted principally in the promptitude with which he formed his plans, and the rapidity with which he carried them into execution. It is likewiſe ſaid to be a maxim of his, always to *commence* the attack when he ſees a battle inevitable, from the perſuaſion that the ardour of the attacking army more than counterbalances the advantage of ground, if that advantage be not very great. Such was certainly the principle upon which he acted at preſent.

358 [At]tacks [hi]m in his [e]ntrench[me]nts,

On the 24th of April the combined army advanced to the Adda; and having driven in Moreau's outpoſts, Suwarrow reſolved, on the 26th, to attack him in his entrenchments. For this purpoſe, while the ſhew of an attack was maintained along the whole line, a bridge was ſecretly thrown over among the rocks at the upper part of the river, where the French had thought ſuch an enterpriſe unlikely or impoſſible. A party of the combined army was thus enabled, on the following morning, after croſſing the river, to turn the French fortifications, and to attack their flank and rear, while the reſt of the army forced the paſſage of the river at different points. The French fought obſtinately, but were ſpeedily driven from all their poſitions, and compelled to retire to Pavia, leaving 6000 men on the field; while upwards of 5000 priſoners, including 4 generals, fell into the hands of the allies, together with 80 pieces of cannon.

359 And defeats him with great ſlaughter.

The advantage thus obtained over the French, in conſequence of the addreſs with which the Adda was croſſed, is ſaid to have gained for Suwarrow more eſtimation from his antagoniſts than they had originally been diſpoſed to grant to any military officer coming from Ruſſia, and who had never before had perſonal experience of the mode in which war is conducted in the ſouth of Europe. But this is probably affectation. The French had ſurely no cauſe to deſpiſe Ruſſian generals, ſince they could not but know that Laudohn was born in Ruſſia, that he had his military education there, and that he had riſen to a high rank in the army before he entered into the ſervice of the Empreſs Queen Maria Thereſa. Indeed it is evident, that while their orators were declaiming againſt Suwarrow and his Ruſſians as mercileſs barbarians, they were ſecretly trembling at his proweſs and reſources, which they could not but remember had more than once ſaved the armies of the Prince of Cobourg in the Turkiſh war.

Moreau now eſtabliſhed the wreck of the French army, amounting to about 12,000 men, upon the Po, between Aleſſandria and Valentia. On the 11th of May he compelled a body of Auſtrians to retire, though they had already paſſed the river, and took a great number of them priſoners. On the following day, 7000 Ruſſians croſſed the Po at Baſignano, and advanced on Pecetto. Moreau immediately fell upon them with his army. They maintained a long and deſperate conflict; but being at laſt thrown into confuſion, and refuſing to lay down their arms, about 2000 of them were drowned in recroſſing the river, and the French, with difficulty, took a ſmall number of them priſoners. But Suwarrow ſoon advanced, and terminated this active, but petty warfare, which was all that the French could now maintain. Moreau was under the neceſſity of retiring with his troops to occupy the Bochetta, and other paſſes which lead to the Genoeſe territory; and the combined army commenced vigorouſly, and at once, the ſiege of all the fortreſſes in the part of Italy which is now occupied. Peſchiera, Mantua, Ferrara, Tortona, Aleſſandria, and the citadels of Turin and Milan, were all attacked. The French were driven from the Engadine by Bellegarde; Maſſena, cloſely preſſed in Switzerland by the Archduke Charles, was compelled to retreat to the neighbourhood of Zurich, and almoſt all Piedmont had riſen in inſurrection againſt the French; ſo that in every quarter their affairs ſeemed deſperate. Few or no reinforcements arrived from the interior, and their generals were left to act upon the defenſive, and to detain the enemy at a diſtance from the frontiers of France as long as poſſible. One effort of offenſive war only remained, and, after ſome delay, it was made with much vigour.

Macdonald

French Revolution, 1799.

360 Macdonald and Moreau concert meaſures for attacking the allies.

Macdonald was ſtill with a conſiderable French army in the ſouthern parts of Italy, and occupied the territories of Rome and Naples. No attempt was made on the part of the combined powers to cut of his retreat; probably from the conviction that ſuch an enterpriſe could not be accompliſhed with ſucceſs in the mountainous countries of Tuſcany and Genoa, through which it would be in his power to paſs. Aware of this circumſtance, he was in no haſte to remove, though the combined army now occupied almoſt the whole territory between him and France. He gradually concentrated his forces, however, and drew near to the ſcene of action. His army amounted to 30,000 men; and he was ordered by the Directory to evacuate the new born republics of Rome and Naples, and to form a junction, if poſſible, with the army of Moreau. The preſent ſituation of the allies, however, tempted Macdonald to hazard an action by himſelf. Marſhal Suwarrow had extended his forces over Lombardy and part of Piedmont, in order to afford protection to the well diſpoſed inhabitants of theſe countries; and Macdonald and Moreau had concerted between them a plan for dividing their antagoniſts, and vanquiſhing them, as the French generals had often vanquiſhed their enemies in detail. It was only by Macdonald, however, that any important blow could be ſtruck; but it was neceſſary that Moreau ſhould draw upon himſelf a great part of the Auſtro-Ruſſian forces, that the remainder might be more completely expoſed to his colleague's attack. For this purpoſe he had recourſe to a ſtratagem.

361 Junction of the French and Spaniſh fleets.

Towards the end of April, the French fleet, amounting to 16 ſhips of the line, had ventured out of Breſt harbour. Ireland was ſuppoſed to be the place of its deſtination; and the Britiſh fleet was ſtationed in the ſituations moſt likely to prevent its arrival there. The French, however, intending to form a junction with the Spaniſh fleet, which was ſtill blockaded in the port of Cadiz, ſailed ſouthward. When they approached Cadiz, a ſtorm aroſe, which prevented any attempt on their part to enter the harbour, and any effort on the part of the Britiſh admiral, Lord Keith, to bring them to an engagement. On the 4th and 5th of May, therefore, they paſſed the Strait of Gibraltar, and ſteered for Toulon. Lord Keith kept his ſtation near Cadiz till the 9th of May, and then entered the Mediterranean in queſt of the French fleet. The Spaniards immediately put to ſea, and went into the Mediterranean alſo. The French fleet entered Toulon, and afterwards went out in queſt of the Spaniſh fleet. They ſailed towards Genoa, and afterwards to Carthagena, where they met their allies. The two fleets being now united once more, paſſed Gibraltar, and ſailed round to Breſt, where they arrived in ſafety, without being overtaken by the Britiſh.

362 Partial ſucceſſes of Macdonald.

Moreau, in the mean time, took advantage of the arrival of the French and Spaniſh ſquadrons in the vicinity of Genoa, to ſpread a report that they had brought him a powerful reinforcement of troops, in the hope of withdrawing from Macdonald the attention of Suwarrow. This laſt officer was himſelf at Turin. His advanced troops poſſeſſed the paſſes of Suſa, Pignerol, and the Col d'Aſſiette; while, at the lower extremity of the vaſt track of country over which his army was ſcattered, General Hohenzollern was poſted at Modena with a conſiderable force, and General Ott was at Reggio with 10,000 men. On the 12th of June, Macdonald began his operations. His advanced diviſions attacked Hohenzollern at Modena on that day, defeated him, and took 2000 of his men priſoners. The French, at the ſame time, attacked General Ott; and, after obliging him to retreat, they entered Parma on the 14th of June. On the 17th, General Ott was again attacked, and compelled to retire upon Caſtel St Giovanni. But here the progreſs of Macdonald was arreſted.

363 He is completely defeated by Suwarrow.

Suwarrow had been informed of his approach and alarming ſucceſſes; and with that preſence of mind, and that promptitude of energy, which ſo ſtrongly mark the whole of his conduct, he ſuddenly left Turin on the 15th of June, at the head of 20,000 men; and having marched ſeventeen leagues in eight-and-forty hours, came up with Macdonald's army on the banks of the Tidone. The Ruſſian Generals Roſenberg and Foerſter commanded the right and the centre; the left wing was commanded by the Auſtrian General Melas; the Ruſſian General Prince Procration commanded the advanced guard, and Prince Lichtenſtein the reſerve. A deſperate action now commenced, which, conteſted with equal obſtinacy on both ſides, was fought during three ſucceſſive days. At length victory, ſtill faithful to the ſtandard of Suwarrow, declared for the allies. The French, driven on the 1ſt day from the Tidone to the Trebbia, were there ultimately defeated on the 19th, after a carnage on both ſides, ſuch as ſome of the oldeſt officers in the army declared that they had never before ſeen. The Ruſſians and French repeatedly turned each others line, and were mutually repulſed. Suwarrow, who appeared in perſon wherever the fire was heavieſt, and his troops moſt cloſely preſſed, is ſaid to have had ſeven horſes killed under him, and to have ſtript himſelf to the ſhirt on the 19th, running on foot from rank to rank, to urge the troops forward by his preſence and example (H). With all theſe exertions of heroiſm, however, and greater have ſeldom been made, the iſſue of the conteſt continued doubtful, till the gallant Kray, in direct diſobedience to the pernicious orders of the Aulic Council at Vienna, arrived at the head of a large detachment from the army beſieging Mantua, and, on the 19th, decided the fate of the day.

The French fled during the night; and on the morning of the 20th, Suwarrow purſued them with his army in two columns. It ſeldom happens that German troops can overtake the French in a march. The Ruſſians now did ſo, however; and at Zena, the rear guard of the French, being ſurrounded, laid down their arms. The

(H) We had this information from an officer of high rank, now reſiding in Weimar, who was preſent in the action; and who added, that the Coſſacs, as ſoon as they ſaw their old commander in his *ſhirt*, ruſhed upon the enemy with an impetuoſity which nothing could withſtand. The ſtory is by no means incredible; for Suwarrow, who deſpiſes coſtume, is known to have fought repeatedly in his ſhirt againſt the Turks; and he would be as hot on the Trebbia as ever he was on the Danube.

French Revolution, 1799.

The reſt of the French army found ſafety in the paſſes of the Appennines and the Genoeſe territory, after having loſt on this occaſion, in killed, wounded, and priſoners, not leſs than 17,000 men.

Moreau, in the mean time, had attacked the Auſtrians under General Bellegarde in the vicinity of Alexandria. Though ſuperior to him in numbers, they were completely beaten; but Suwarrow having returned with infinite rapidity after his victory over Macdonald, the temporary advantage gained by Moreau became of no importance. Suwarrow complained loudly of the conduct of the Aulic Council on this occaſion; while they, in return, imputed their diſaſter under Bellegarde to his unſkilful diſtribution of the whole troops, which had expoſed an immenſe army to great danger from the enterpriſes of an handful of men. It is not our buſineſs to decide between them. The inſtructions of the Council to Kray not to co-operate with the commander in chief of the combined army, ſeem to us in the higheſt degree abſurd, if not treacherous; and we have heard a general officer, whoſe name, were we at liberty to give it, would do honour to theſe pages, ſay, that the diſtribution of the troops, of which that council complained, was the moſt maſterly thing that has been done during the war. Be this as it may, a diſtruſt and mutual miſunderſtanding thus commenced, or, at leaſt, made its firſt open appearance, which gave good reaſon to ſuſpect that little cordiality of co-operation would long exiſt between theſe allies. They continued, however, for ſome time to enjoy uninterrupted proſperity under the command of Suwarrow. The sieges of the different Italian fortreſſes were very cloſely preſſed. They all ſurrendered in ſucceſſion; and the period appeared faſt approaching when it would be in the power of the allied armies to enter the ancient territory of France.

364 Mutual complaints of Suwarrow and the Aulic Council.

If we turn our eyes to a different quarter, we ſhall find the French as much humbled at this time in Paleſtine by Britiſh valour, as they were in Italy by the united armies of Ruſſia and Auſtria. The hero of France, the conqueror of Italy, the boaſted legiſlator of Europe, after having defeated the Mamalukes, taken poſſeſſion of Alexandria and Cairo, and profeſſed himſelf a Mahometan in Egypt, led an army into Paleſtine with the avowed purpoſe, it has been ſaid, to take poſſeſſion of Jeruſalem, and by rebuilding the temple, and reſtoring the Jews, to give the lie to the prophecies of the Divine founder of the Chriſtian religion. At the head of a choſen band, exceeding 12,000 in number, and poſſeſſed of a ſtaff eminent for military ſkill and experience, he arrived at the ſmall town of Acre, ſituated on the ſea-coaſt, 28 miles ſouth of Tyre, and 37 north of Jeruſalem. To this town, which was wretchedly fortified, and defended only by a ſmall garriſon of Muſſelmans, he laid ſiege in form; and the governor would have ſurrendered unconditionally, had he not been, we ſay not *perſuaded*, but *decoyed*, by an Engliſh *naval* officer, to make a vigorous reſiſtance. We need not add, that the naval officer was Sir Sidney Smith, or that the beſieging general was Bonaparte.

365 Bonaparte's unſucceſsful attack of Acre.

The command of the garriſon being entruſted to Sir Sidney Smith, who was not to be bribed by French gold, or corrupted by French philoſophy, the hero who, by the aid of theſe allies, had ſo quickly routed armies, and conquered ſtates in Italy, was detained before the town of Acre *ſixty-nine* days; hough the number of the allies who defended that town exceeded not 2000 men! Foiled in *eleven* different attempts to carry it by aſſault, one of which was made during the truce which he himſelf had ſolicited to bury the dead, he was ultimately obliged to retreat, leaving eight of his generals, eighty-five of his officers, and *one half* of his army behind him. The ſuperiority of the Britiſh over the Corſican hero was, during this ſiege, more fully diſplayed in conduct than even in courage. The true magnanimity evinced by the former; his temperate replies to the audacious calumnies and atrocious falſehoods of his adverſary; and the moderation and humanity which characteriſed his diſpatches, and invariably marked his behaviour to thoſe whom the fortune of war ſubjected to his power—give additional luſtre to the brilliant victory which his valour, his energy, and his perſeverance, ſo eſſentially contributed to ſecure.

But while we pay a tribute of juſtice to the merits of our gallant countryman, we muſt not omit to notice the high deſerts of the brave, the loyal, the virtuous Philipeaux, his gallant comrade, the partner of his toils, and the partaker of his glory. The ſkill of this French officer as an engineer was moſt ſucceſsfully diſplayed in the defence of Acre; and, indeed, his exertions on that memorable occaſion ſo far ſurpaſſed his ſtrength, that he actually periſhed through fatigue.

366 His vaſt projects, had he ſucceeded.

The defeat of Bonaparte at Acre, which effectually ſtopped his deſtructive career, will be conſidered as important indeed, when it is known that his arts of intrigue had ſo far ſucceeded as to prevail on the numerous tribe of the Druſes to join his ſtandard with *ſixty thouſand* men immediately after the reduction of that town. Had this junction been effected, it was intended to proceed to Conſtantinople, and, after plundering the city, to lay it in aſhes! It is ſcarcely poſſible to calculate the dreadful conſequences of ſuch an event on the political ſtate of Europe. If ſervices are to be eſtimated in proportion to their effects, we know of none, during the preſent war, fertile as it has been in brilliant atchievements, that deſerves a higher reward than the defeat of Bonaparte at Acre.

During theſe reverſes abroad, France had begun to ſuffer much internal agitation, and the Directory found itſelf in a very difficult ſituation. The elections, as uſual, were unfavourable to them; and amidſt the contempt with which they now began to be regarded, it was no longer poſſible to ſecure a majority in the Councils, by unconſtitutionally annulling the elections of their political opponents. They demanded money, and were anſwered by reproaches, on account of their profuſion, and the rapacity of their agents. The royaliſts in the ſouth and the weſt began to form inſurrections. They were ſubdued with much difficulty, on account of the abſence of the troops. The people had totally loſt that enthuſiaſm which, in the earlier periods of the revolution, induced them to ſubmit to ſo many evils, and to make the moſt violent efforts without murmuring. They beheld the renewal of the war with regret, and were unwilling to aſſiſt by their exertions to reſtore power and ſplendour to the faction which had trampled upon their freedom.

Amidſt all theſe difficulties, an event occurred which, for a time, gave the Directory the hope of being once more able to rouſe the dormant energies of their countrymen. After the defeat of Jourdan, a detachment from

from the army of the Archduke Charles had occupied Rastadt, where the Congress still sat. On the 28th of April an order was sent by an Imperial officer to the French ministers, requiring them to quit Rastadt in 24 hours. They demanded a passport from Colonel Barbasey, who had sent the order; but this he could not grant, none having that power but the commander in chief. They declared themselves determined to depart without delay, although the evening approached. They were detained about an hour at the gate of the town, in consequence of general orders which had been received by the military to suffer none to pass. In consequence of an explanation, however, and of the interposition of superior officers, they were allowed to depart. The three ministers, Bonnier, Roberjot, and Jean Debry, were in carriages. The wife of Roberjot, and the wife and daughters of Jean Debry, were along with them; and they were attended by the ministers of the Cisalpine republic. When they had advanced to a very short distance from Rastadt, they were met by about 50 hussars of the regiment of Szeckler, who made the carriages to halt, and advancing to the first of them, containing Jean Debry, demanded his name. He told them his name, and added that he was a French minister returning to France. On receiving this answer, they immediately tore him from his carriage, wounded him in several places with their sabres, and cast him into a ditch, on the supposition that he was killed. They treated in the same manner the two other ambassadors, Bonnier and Roberjot, whom they murdered upon the spot. They offered no personal violence, however, to the rest of the company, who were allowed to return to Rastadt; but they robbed the carriages of whatever effects they contained; and the papers of the ambassadors were conveyed to the Austrian commander. After the departure of the soldiers, and the return of the carriages to Rastadt, Jean Debry wandered about the woods all night, and returned also to Rastadt on the following day. He claimed the papers belonging to the legation from the Austrian commander, but they were refused to be restored.

367 Assassination of the French envoys,

During the whole of the long period that the Congress had sat, Rastadt and its vicinity had been occupied by French troops, and it was only a few days since the Austrians had obtained possession of it. This event therefore cast, at least, a severe reproach upon the discipline of the Austrian army. It did more; it made every honest man regret, that troops, engaged in the support of a good cause, should think to promote that cause by the murder even of the greatest villains. The Archduke Charles made haste to disclaim all knowledge of it in a letter to Massena; but the French Directory, regarding it as a fortunate occurrence, from its tendency to rouse the resentment of the nation, addressed to the two Councils, on the 5th of May, a message, in which they ascribed it to a deliberate purpose on the part of the Austrian government to insult France by the assassination of her ambassadors. They thus converted the private act of a few desperate individuals into a measure of public policy; as if the death of those wretched miscreants could have been of consequence to the enemies of the *great* nation. The unpopularity of the Directory, however, and the obvious inutility of so gross a crime, prevented this accusation from obtaining much credit, or producing great effects upon the people. In a private letter which a friend of our's received at that period from the Continent, he was assured that the murder of the envoys "*fait plus de bruit que de sensation*;" and that the general opinion was, that the Directory itself knew more of the authors of that crime than the Archduke or the Austrian government.

368 Turned by the Directory to its own advantage.

369 Dissensions in France.

Upon the introduction of the new third of this year into the Councils, a violent opposition to the Directory commenced. Sieyes, who was ambassador at Berlin, and who had enjoyed, during the whole progress of the revolution, a very considerable influence over all the parties that had successively enjoyed the supreme authority, was elected into the Directory. At the first establishment of the constitution he had refused to occupy this station, and it excited much surprise when he readily accepted the office in the present calamitous state of the Republic. His admission into the Directory, however, did not reconcile the pulic or the two Councils to that body. A violent contest for power betwixt the Moderate and the Jacobin parties seemed to approach; but they soon came to a compromise. Treilhard was removed from the Directory, under the pretence that he had held an office in the state within less than a year previous to his nomination. Merlin and Reveillere were compelled to resign, to avoid an impeachment with which they were threatened; but Barras still contrived to retain his station. Moulins, Gohier, and Ducos, men little known, and by no means leaders of the contending parties, were appointed Directors. The power was understood to be divided, and that neither party greatly predominated. An attempt was made to revive public spirit, by encouraging anew the institution of clubs, which had been suppressed by the Directory. The violent Jacobins were the first to take advantage of this licence. They resumed their ancient style, their proposals for violent measures, and their practice of denouncing the members and the measures of government. But the Directory becoming alarmed by their intemperance, obtained leave from the Councils to suppress their meetings before they were able to interest the public in their favour.

370 Warlike efforts of the Directory.

Considerable efforts were now made by the French government to recruit their armies; but the deranged state of the finances, which the votes of the Councils could not immediately remedy, prevented the possibility of their gaining a superiority during the present campaign. The difficulty was also increased by the necessity of resisting immense armies in different quarters at the same time, France being assailed at once on the side of Holland, Switzerland, and Italy. Such, however, were the exertions of the Directory, that they seemed not destitute of the hope of being able speedily to assume, on the frontier, a formidable, and even menacing posture. In the beginning of August, their Italian army amounted to 45,000 men. The different bodies of troops of which it consisted had been drawn together, and concentrated nearly in the same positions which Bonaparte had occupied before his battles of Montenotte and Millesimo. The command of the whole was given to Joubert, a young man, who had been much distinguished under Bonaparte; and who, in the style of gasconade employed by that general, assured his government of victory, declaring, that he and Suwarrow should not both survive the first battle. In this boasting declaration he seems to have been in earnest;

371 Joubert assumes the command in Italy.

earneſt; for, on taking the command, he prevailed with Moreau to remain in the army as a volunteer till the firſt battle ſhould be fought. The allies had now taken Turin, Aleſſandria, Milan, Peſchiera, and Ferrara, with a rapidity which would lead one to ſuppoſe that
372 ſome new mode had been invented of materially abrid-
Succeſſes of the allies. ging the duration of ſieges. The ſtrong citadel of Turin opened its gates, to the aſtoniſhment of Europe, after a bombardment of only *three days;* the citadel of Aleſſandria ſurrendered to the Auſtrian General Bellegarde, on the 22d of July, after a ſiege of *ſeven days;* and the ſtill more important fortreſs of Mantua ſurrendered to the brave General Kray, on the 29th of the ſame month, after a ſiege of only *fourteen days.* The garriſon of Aleſſandria amounted to 2400 men; that of Mantua to 13,000. The former were detained priſoners of war, and the latter were allowed to return to France on their *parole;* a parole which the commanders of the allied armies could not reaſonably expect to be kept. This has given riſe to a ſuſpicion, that the fortreſs was voluntarily ſurrendered to the Auſtrians, in order that the Directory might recruit its armies with the garriſon.

The allies next began to beſiege Tortona, and Joubert reſolved to attempt its relief. He hoped to accompliſh this object, and to gain ſome advantage over their army, before General Kray could arrive to the aſſiſtance of Suwarrow with the troops that had been occupied in the ſiege of Mantua. On the 13th of Auguſt the French drove in the whole of the Auſtrian poſts, and took poſſeſſion of Novi. Here they encamped on a long and ſteep, but not high, ridge of hills, with their centre at Novi, their right towards Seravalle, and their left towards Baſaluzzo. On the 14th they remained quiet; and on the 15th they were attacked by Suwarrow, whoſe army was now reinforced by the arrival of General Kray from Mantua. The right wing of the allied army was commanded by Kray, its left by Melas, and its centre was occupied by the
373 Suwarrow's victory over Joubert, who is killed. Ruſſians, under Prince Pongrazion (Pracration) and Suwarrow in perſon, The attack began at 5 o'clock in the morning, and was continued during many hours. Soon after the commencement of the battle, while the French commander in chief, Joubert, was urging his troops forward to a charge with the bayonet, he received a muſquet ſhot in his body, and, falling from his horſe, immediately expired. Moreau inſtantly reſumed the command. After an obſtinate conteſt, the allied army gave way, and was compelled to fall back in all quarters. The attack, however, was repeatedly renewed, and much blood was ſhed. From the obſtinate manner in which they fought, the Ruſſians, in particular, ſuffered very ſeverely. They made three unſucceſsful efforts againſt the centre of the French army, and on each occaſion thoſe immediately engaged were rather deſtroyed than repulſed. The laſt attack along the whole line was made at three in the afternoon. The French remained unbroken; and the day muſt have terminated in the defeat of the allies, had not General Melas ſucceeded in turning the right flank of the French line. Their right wing was thus thrown into confuſion. Melas purſued his advantage till he obtained poſſeſſion of Novi, and the whole French army made a rapid retreat under the direction of Moreau.

According to the accounts given by the Auſtrians, the French loſt in this battle 4000 killed and an equal number taken priſoners. They acknowledged their own loſs in killed to be equal to that of the French, but the loſs ſuſtained by the Ruſſians was never publiſhed. The general reſult of the battle was the total ruin of the French affairs in this quarter. The allies retained their decided ſuperiority; and there was no enterpriſe which, on the preſent theatre of the war, they might not have ventured to undertake. The French renounced all hope of defending Genoa, and prepared to evacuate that city and its territory. The Directory expected an immediate invaſion of the ſouth of France, and addreſſed a proclamation to the people, urging them to act with firmneſs and energy amidſt the calamities with which the country was now menaced.
But theſe apprehenſions were unneceſſary. The court 374 Unaccountable conduct of the allies.
of Vienna had other objects in view that were leſs dangerous to their enemy. They neither invaded Genoa nor France, but quietly proceeded in the ſiege of Tortona. The vanquiſhed army was ſurpriſed to find itſelf unmoleſted after ſuch a defeat; and in a few days ventured to ſend back parties to inveſtigate the movements of the allies. The new Commander Championnet, who had ſucceeded Joubert, found to his no ſmall aſtoniſhment that they had rather retreated than advanced; and he immediately occupied the ſame poſitions which his army had held before the battle of Novi.

Inſtead of purſuing the advantages they had gained in Italy, the Aulic council, or council of war at Vienna, now perſuaded Suwarrow to leave that country with his Ruſſians, and to ſet out for Switzerland to drive the French from thence. In the early part of the campaign, the Archduke Charles had ſucceeded, after various attacks, in driving the French from the eaſtern part of Switzerland beyond Zurich, of which laſt city he retained poſſeſſion. The Directory, however, had ſent their new levies chiefly towards this quarter; ſo that in the middle of the month of Auguſt Maſſena's army amounted to 70,000 men. The Archduke was now ſo far from being able to purſue the advantages he had gained, that of late the French had reſumed the offenſive, and threatened to endanger his poſition. Their right wing under Lecourbe had even ſucceeded in taking poſſeſſion of Mount St Gothard, which is the great paſs that leads from the centre and eaſtern part of Switzerland into Italy. The cabinet of Vienna probably wiſhed to throw the ſevereſt duties of the
war upon their northern aſſociates. The veteran Suwar- 375 Suwarrow leaves Italy and marches to Switzerland.
row had never, during his long military career, ſuffered a ſingle defeat. His preſumption of ſucceſs was therefore high; and he perhaps felt himſelf not a little flattered by the requeſt to undertake an enterpriſe in which the Auſtrians had failed, though led by their moſt fortunate commander. It is indeed certain that he conſidered himſelf as called out of Italy too ſoon. Though confident of being properly ſupported, he agreed to proceed with his troops from Piedmont to Switzerland, where another Ruſſian army had lately arrived. Delays however were thrown in his way. Tortona did not fall quite ſo ſoon as was expected; and when he was ready to march, the Auſtrian commander in Italy refuſed to ſupply him with mules for the tranſport of his baggage. Unable to reply to the indignant expoſtulations of the Ruſſian hero, this man deſcended to a pitiful falſehood, by aſſuring him that he would find a

French Revolution, 1799.

sufficient number of mules at Bellinzone, where, when he arrived, not one was to be had. He had now no other resource but to dismount the cavalry, and employ their horses to drag along the baggage. Under all these difficulties, he arrived, by forced marches, on the confines of Switzerland, on the day appointed by him and the Archduke; but the Austrian cabinet had, in the mean time, taken a step which made all his exertions useless.

376 Is deserted, if not betrayed, by the Austrians.

Thinking it degrading to a Prince of the Imperial house, who had so long held the highest military rank, to serve under the Russian General, and not having the confidence to require the most experienced leader in Europe to receive the orders of a man so young as the Archduke, they sent that prince with his army to attack the French, who, in a small body, had entered into Swabia. He began accordingly to draw off his troops in the beginning of September, before Suwarrow was in readiness to leave Italy. The number which he took with him has been differently estimated, the lowest computation stating it at 48,000, and the highest at 60,000. The former is the most probable; since it is well known that 20,000 would have been fully adequate to the purpose for which he marched. The army which he left behind him is more perfectly ascertained: it consisted of 21,000 Russians, 18,900 Austrians, Bavarians, and other auxiliaries, forming a total of 39,900 men.

Upon what principle of military tactics the Aulic council could suppose that a skilful and intrepid commander like Massena, with a force nearly double that of the allies, would remain in a state of inactivity, it is not easy to conceive. He perceived at once the advantage which might be derived from this unaccountable movement of the Archduke. The French troops in Swabia were therefore ordered to advance rapidly, and to threaten the rear of the Archduke's army. As the repulse of these troops and the invasion of France towards Alsace, formed a part of the Austrian commander's plan of operations, he marched against them with his army. The French made as much resistance as the smallness of their force would permit. The Archduke however, gradually drove them towards the Rhine. The better to carry on their plan of deception, they made a serious stand in the neighbourhood of Manheim, and were defeated with the loss of 1800 men. The Austrians entered Manheim, and seemed ready to cross the Rhine in this quarter.

All this while Switzerland was left completely exposed to the enterprises of Massena. General Hotze, with the Austrians, occupied the right wing of the allied army there. The newly arrived Russian army was stationed in the centre at Zurich under the command of General Korsakof; and the left, consisting chiefly of Bavarians and other troops of the empire, was commanded by Nauendorf. Massena remained quiet till he learned that the Archduke had entered Manheim, and that Suwarrow, having taken Tortona, was on his march towards Switzerland by Mount St Gothard.

377 The allies defeated in Switzerland.

This last position was defended by Lecourbe; and Massena resolved, in the mean time, to anticipate the arrival of Suwarrow. On the 24th of September, having drawn the attention of the Russians to another quarter by a false attack, he suddenly crossed the Limmat, a river which divided the two armies near the convent of Far, which is three leagues distant from Zurich. A part of the French troops engaged the Austrians, while the greater part of the army marched against the Russians at Zurich. The Austrian General Hotze was killed in the commencement of the action. General Petrarch, who succeeded him in the command, contrived to avoid a total rout, and retired during the night with the loss of about 4000 men. The contest with the Russians was singularly obstinate. In a mountainous country, to which they were strangers, and contending against the most skilful military leaders that the south of Europe had been able to produce, they laboured under every disadvantage. They could not be put to flight however; and even when different divisions of them were surrounded, they refused to lay down their arms, and were slaughtered upon the spot. By the retreat of the Austrians on the evening of the 25th, they found themselves on the 26th nearly surrounded in Zurich. They now began to retreat also; and we are only surprised at the ability of the Russian General in effecting his retreat in such good order, and with such little loss; for if the official accounts deserve credit, his loss in killed, wounded, and taken, did not exceed 3000 men. He was obliged, however, to abandon his baggage and cannon to the enemy. 378

Suwarrow's march.

During these operations, Suwarrow was advancing on the side of Italy with an army rated, in some accounts, at 18,000, in others at only 15,000; and forcing the French from their strong positions on Mount St Gothard, descended, on the very day on which Massena made his general attack, into the valley of Ursern; and driving Lecourbe before him, with considerable slaughter, advanced as far as Altorf. He even penetrated on the next day into the canton of Glaris, and took 1000 of the French prisoners; while the Russian General Rosemberg was equally successful in the canton of Schwitz, where General Auffenberg had effected a junction with him; and General Linken defeated and took another corps of French, consisting of 1300 men.

379 His admirable conduct.

Massena, however, now turned upon the Field-marshal with the greater part of his army; and, by hemming him in on all sides, expected to have made him, and the Grand Duke Constantine, prisoners. Suwarrow, however, defended himself against every attack with unexampled vigour and address. A single pass among the mountains was all that remained unoccupied by the French. He discovered this circumstance, and escaped, though closely pursued. He lost his cannon, baggage, and provisions, among the dreadful mountains and precipices with which that country abounds. He made his way, however, eastward through the Grison country, and at length arrived at Ceire with about 6000 men in great distress.

380 His indignation at the court of Vienna.

Nothing could exceed the indignation of this old warrior when he discovered the manner in which affairs had been conducted, the hazardous state in which the Russians had been abandoned by the Archduke, and the consequent ruin which they had encountered. He considered himself and his countrymen as treacherously exposed to destruction; he loudly complained of the Commander of the allied forces in Switzerland; publicly taxed the Council of Vienna with selfishness and injustice; and refused all farther co-operation with the Austrian army. He sent an account of the whole transaction

French Revolution, 1799. action to St Peterſburgh in a letter, of which the compoſition would do honour to the fineſt writer of the age, and withdrew with his troops to the neighbourhood of Augſburg to wait for farther orders.

380 Invaſion of Holland

In the mean time, Great Britain prepared to invade Holland with an army of 40,000 men, conſiſting of Britiſh troops and Ruſſian auxiliaries. The firſt diviſion under General Sir Ralph Abercromby, failed in the month of Auguſt, under the protection of a fleet commanded by Admiral Lord Duncan. Bad weather prevented a landing from being attempted till the 27th. On the morning of that day the troops landed without oppoſition upon the ſhore of Helder Point in north Holland, at the entrance to the Zuyder Sea. They had not been expected in this quarter, and the troops in the neighbourhood were conſequently few. The Britiſh, however, had no ſooner begun to move forward, than they were attacked by a conſiderable body of infantry, cavalry, and artillery, who had been haſtily aſſembled from the neareſt towns. The Dutch troops maintained the conteſt with much obſtinacy; but they were gradually fatigued by the ſteady oppoſition they encountered, and retired to the diſtance of two leagues. In the night they evacuated the fort of Helder, of which the Britiſh took poſſeſſion on the morning of the 28th. A detachment from the Britiſh fleet, commanded by Vice Admiral Mitchell, now entered the Zuyder Sea

381 Capture of the Dutch fleet.

by the ſtrait of the Texel, to attack the Dutch fleet under Admiral Story. This laſt officer, inſtead of retiring for ſafety to any of the ports, or to the ſhallow water with which that ſea abounds, ſurrendered the whole fleet on the 30th of Auguſt without firing a gun, under pretence that his ſeamen were mutinous, and would not fight.

Had the expedition terminated here, it might have been regarded as extremely fortunate, and as eſtabliſhing the power of the Britiſh navy without a rival. But it was reſolved to follow up this firſt ſucceſs by an effort on land to reſtore the authority of the Stadtholder, and the ancient government of the United Provinces. Many circumſtances were hoſtile to this enterpriſe. The whole army had not been ſent at once from Britain. As no more than the firſt diviſion had arrived, the troops could only reſt upon the ground they had gained till reinforcements ſhould be ſent. The terror ariſing from the firſt appearance of an invading army was thus allowed to paſs away, the enemies of the preſent Dutch government were diſcouraged, and leiſure was afforded to adopt effectual meaſures of defence. The place where the landing was effected was well choſen for an attack upon the Dutch fleet; but for an invaſion, with a view to the reſtoration of the Stadtholder, it was the worſt that could have been ſelected. North Holland, at the extremity of which it was made, is a narrow peninſula, everywhere interſected by canals and ditches, of about 40 miles in length. Here the invaders might be detained, and even ſucceſsfully reſiſted, by a force greatly inferior to their own. This alſo is the quarter of the country the moſt unfavourable to the cauſe of the Stadtholder. In Zealand, where his eſtates are ſituated, and in Rotterdam, which is full of Scotchmen and of families of Scottiſh extraction, his friends are numerous and powerful; but in Amſterdam, and in North Holland, which is under its influence, his enemies abound, and the reſiſtance to his power has been very great during every period of the Dutch hiſtory. When to all this it is added, that the rainy ſeaſon was approaching, and that a winter campaign in Holland is almoſt impoſſible, it will not appear ſurpriſing that this expedition was attended with little ultimate ſucceſs. It is ſaid that, amidſt the preſſure of the many difficulties which ſurrounded them, the French Directory heſitated much about undertaking the defence of Holland; but the place, and the time of landing the invading army, at once brought them to a determination. General Brune was ſent thither, with whatever troops could be haſtily collected, to ſupport the Dutch General Daendels. 382

Progreſs of the invaders.

General Abercromby, in the mean time, remained upon the defenſive at Schager Brug, waiting for reinforcements. His inactivity encouraged the enemy on the 10th of September to venture an attack upon his poſition. They advanced in three columns, two of which conſiſted of Dutch and one of French troops. They were repulſed, however, in all quarters, and retired to Alkmaer. On the 13th the Duke of York arrived with additional troops, and aſſumed the chief command. The Ruſſian auxiliaries having alſo arrived, offenſive operations were immediately reſolved upon. On the 19th the army advanced. General Abercromby commanded the left, which proceeded along the ſhore of the Zuyder Sea againſt Hoorne. The centre columns were commanded by Generals Dundas and Pultney; and the right wing, conſiſting of Ruſſians, was commanded by their own General D'Herman. In conſequence of ſome ſtrange miſunderſtanding, the Ruſſians advanced to the attack ſoon after three o'clock in the morning, which was ſome hours previous to the movement of the reſt of the army. They were ſucceſsful in their firſt efforts, and obtained poſſeſſion of the village of Bergen; but preſſing eagerly forward, and being unſupported by the other columns, they were nearly ſurrounded. Their commander was taken priſoner; and though the Britiſh came in time to protect their retreat, they loſt at leaſt 3000 men. This failure on the right obliged the Britiſh Commander in Chief to recal his troops from the whole advanced poſitions they had gained, though General Abercromby had actually taken Hoorne with its garriſon, and although General Pultney's column had carried by aſſault the principal poſition of the Dutch army called *Ourds Carſpel*.

The ſeverity of the weather prevented another attack till the 2d of October, when, after an engagement that laſted from ſix in the morning till the ſame hour in the evening, the Britiſh army ſucceeded in driving the united Dutch and French troops from Alkmaer and the villages in its neighbourhood. The conteſt was chiefly conducted among the ſand hills in the vicinity of the ocean; and the battle was maintained with ſuch obſtinacy, that the fatigue of the troops, together with the difficult nature of the country, prevented the Britiſh from gaining any great advantage in the purſuit. The retreating army immediately occupied a new poſition between Baverwyck and Wyck op-zee. The Duke of York once more attacked them on the 6th; and after an obſtinate and bloody engagement, which was maintained till night, he remained in poſſeſſion of the field of battle. But this was the laſt ſucceſs of the invaders. Finding himſelf unable to make farther progreſs, in conſequence of the increaſing numbers of the enemy, the impracticable nature of the country, and the badneſs of

383 Stopped by the enemy and the inclemency of the weather.

French Revolution, 1799.

of the weather, which, during the whole of this year, was unuſually ſevere, the Duke of York retired to Schager Brug, and there waited for orders from England to return home. He was, in the mean time, cloſely preſſed by the United Dutch and French forces, ſo that his embarkation muſt have been attended with much hazard. He therefore entered into a convention with the French and Dutch generals; by which it was agreed, that they ſhould no farther moleſt him in his retreat, and that, in return, he ſhould not injure the country by breaking down any of the dykes which protect it againſt the ſea, and that Great Britain ſhould reſtore to France and Holland 8000 priſoners of war, taken previous to the preſent campaign.

In conſequence of theſe events, the affairs of France now began to aſſume a leſs unfavourable aſpect They were indeed driven to the extremities of Italy, Championet was defeated in every effort which he there made againſt the Auſtrians during the reſt of the year, and Ancona, which was the laſt place of any ſtrength poſſeſſed by the French, alſo ſurrendered on the 13th of November to General Frolich; but they retained the Genoeſe territory, and Switzerland and Holland continued under their power. The new coalition againſt them ſeemed once more ready to diſſolve. From the commencement of the French Revolution, a ſpirit of ſelfiſhneſs had mingled with all the efforts made by the continental powers of Europe againſt it, and had rendered them fruitleſs. To prevent the aggrandiſement of Auſtria, Pruſſia had early withdrawn, and ſtill ſtood aloof. Spain and Holland were retained under the influence of France by the efforts of her arms, and by the univerſal diffuſion of her wild principles among the people. Even the Britiſh cabinet, which of all the European powers has remained moſt true to the original purpoſe of the war, ſometimes forgot that object. Thus, when invading Holland, the Dutch were informed, by a proclamation, that their ancient government was to be reſtored; but no offer was made to reſtore their diſtant poſſeſſions. Of all the coaleſced powers, however, Auſtria purſued her ſeparate intereſts with the leaſt diſguiſe. With much facility ſhe relinquiſhed the Netherlands, and ſuffered the principal bulwarks of Germany, Mentz, and Ehrenbreitſtein, to fall into the hands of the French, upon obtaining in exchange the Venetian territories, which Bonaparte had conquered, and thought himſelf authoriſed to ſell. During the preſent campaign, the whole conqueſts made by the united efforts of the Auſtrian and Ruſſian forces were ſeized by Auſtria in her own name, and none of the princes of Italy obtained leave to reſume the government of their own territories. This conduct on the part of the allies gave every advantage to the French. They broke off the negociations at Liſle, under the pretence of defending the Dutch and Spaniſh ſettlements which the Britiſh government refuſed to relinquiſh. They found it eaſy to alarm the King of Pruſſia, by diſplaying the unbounded ambition of the houſe of Auſtria; and the Emperor of Ruſſia, having publicly declared to the members of the German empire, that the purpoſe for which he had taken up arms was not to diſmember France, but to reſtore peace to Europe, became jealous of the Court of Vienna, when he ſaw it purſue a conduct ſo very different. This jealouſy was encreaſed by the misfortunes of the Ruſſian troops; and all circumſtances ſeemed now to promiſe that the new coalition would ſpeedily be deſerted by its northern auxiliary.

384 Coalition againſt France ready to be diſſolved.

While affairs were in this ſtate, an event occurred which exhibited the French Revolution under a new aſpect. When Bonaparte found himſelf compelled to retreat baffled and diſgraced, from the ruins of Acre, he learned that a Turkiſh army was ready to invade Egypt by ſea. He returned, therefore, with his uſual celerity, by way of Suez, acroſs the deſart of Arabia Petrea, which divides Syria from that country, and was in the neighbourhood of the Pyramids on the 11th of July, when an army of 18,000 Turks landed from 100 ſhips at Aboukir. They took this fort by aſſault, and gave no quarter to the French garriſon of 500 men that it contained. On the 15th, Bonaparte began to march down the country againſt them. On the 25th he came in ſight of them, at ſix o'clock in the morning.

385 Bonaparte vanquiſhes the Turks in Egypt.

It is not wonderful that thoſe barbarians afforded him an advantage which had ſo often been preſented by the armies of Auſtria. They had divided their force into two parts, which were encamped on the oppoſite ſides of a beautiful plane. He had now formed a conſiderable body of cavalry, by obtaining for his men fleet horſes from Arabia. Theſe advanced rapidly into the centre of the Turkiſh army, and cut off the communication between its different parts. His infantry then attacked the right, which was the weakeſt diviſion of the Turks. They being ſpeedily panic ſtruck, attempted to fly to their ſhips, and every man was drowned in the ſea. The left diviſion of the Turks was next attacked. It made a more obſtinate reſiſtance, but was ſoon alſo put to flight. Some caſt themſelves into the ſea, and periſhed in attempting to reach the boats of their fleet; the reſt took refuge in the fort of Aboukir. The news of this battle reached France towards the end of September, and revived the memory of Bonaparte's victories, contraſted with the reverſes which the Republican armies had lately experienced. On the 10th of October a diſpatch was received from him by the Directory, and read to the Councils, giving an account of the capture of the fort of Aboukir, with the whole remains of the Turkiſh army. On the 14th of the ſame month a meſſage from the Directory announced, to the aſtoniſhment of all men, that Bonaparte, along with his principal officers, had juſt arrived in France, and that they left the army in Egypt in a proſperous ſtate. This laſt part of the meſſage was ſoon afterwards proved, by the intercepted letters of Kleber, and the other generals left behind, to be a ſcandalous falſehood. In one of theſe letters, Pouſſielgue ſays, "Every victory carries off ſome of our beſt troops, and their loſs cannot be repaired. A defeat would annihilate us all; and however brave the army may be, it cannot long avert that fatal event."

386 Arrives with his principal officers in France,

Bonaparte, however, was received at Paris with diſtinction, though nobody could tell why he had deſerted his army and come thither. The parties in the government were equally balanced; and both the Jacobins, and what were called the *Moderates*, ſolicited his aſſiſtance The Jacobins ſtill poſſeſſed a majority in the Council of Five Hundred; but in the other Council their antagoniſts were ſuperior. The Director Sieyes was underſtood to be of the party of the Moderates; and the Jacobins had of late unſucceſsfully attempted to to remove him from his office, under the pretence that the interval appointed by the constitution had not elapsed between his going out of the Council of Five Hundred and his election to the office of director. Neither party was satisfied with the existing authorities; but none of the usual indications of approaching hostilities appeared. The Jacobins were far from suspecting that Sieyes had a plot ripe for execution, which was to overwhelm them in an instant. They were even in some measure laid asleep by an artful scene of festivity, in which the whole members of the Councils were induced to engage, on the 6th of November, under pretence of doing honour to the arrival of Bonaparte. On the morning of the 9th, one of the committees of the Council of Ancients, called the committee of Inspectors of the Hall, presented a report; in which they asserted that the country was in danger, and proposed to adjourn the sitting of the legislature to St Cloud, a village about six miles from Paris. We have already mentioned, that the constitution entrusted to the Council of Ancients the power of fixing the residence of the legislative bodies, and that this Council could in no other case assume the initiative, or propose any law; their powers of legislation being otherwise limited to the unconditional approbation or disapprobation of the decrees passed by the Council of Five Hundred. The Council of Ancients now suddenly decreed, that both Councils should meet next day at St Cloud. As the Council of Five Hundred had no constitutional right to dispute the authority of this decree, and as the ruling party in it was completely taken by surprise, its members silently submitted, and both Councils assembled on the 10th of November at the place appointed.

387 And seizes the reins of government.

The Council of Five Hundred exhibited a scene of much agitation. They received a letter from Legarde, secretary to the Directory, stating, that four of its members had sent resignations of their offices, and that the fifth (Barras) was in custody by order of General Bonaparte, who had been appointed commander of their guard by the Council of Ancients. While the Council were deliberating, Bonaparte entered the hall, attended by about twenty officers and grenadiers. He advanced towards the chair, where his brother Lucien Bonaparte sat as president. Great confusion ensued; he was called a Cromwell, a Cæsar, an usurper. The members began to press upon him, and his countryman Arena attempted to stab him with a dagger. He was rescued by his military escort. Lucien Bonaparte then left the chair, and cast aside the badge of office which he wore as a member of the Council. The confusion did not diminish; but in a short time a party of armed men rushed into the hall, and carried off Lucien Bonaparte. A tumultuous debate now began; in which it was proposed that Bonaparte should be declared an outlaw. The debate was soon terminated, however. The doors of the hall were once more burst open. Military music was heard; and a body of troops proceeding into the hall in full array, the members were compelled to disperse. The Council of Ancients, in the mean time, setting aside the constitution, passed a variety of decrees. They abolished the Directory, and appointed in its stead an Executive Commission; to consist of Bonaparte, Sieyes, and Roger Ducos, under the appellation of Consuls. They adjourned the sittings of the legislative bodies till the 20th of February, and appointed two committees, consisting of twenty-one members, selected from each of the two councils, to act as legislators in the mean time. They also expelled a great number of members from their seats in the councils.

Most of the members of the Council of Five Hundred returned to Paris, after having been driven from their hall by the military; but a part of them remained at St Cloud, and, on the evening of the same day, confirmed all the decrees of the Council of Ancients. The new government entered upon its functions at Paris on the following day. That city remained tranquil, and the public funds even rose upon the occasion. On the 17th of November the consuls decreed the transportation of a great number of the leading Jacobins and zealous republicans to Guiana, and ordered many others to be imprisoned; but these decrees were speedily recalled, and affairs went on as quietly as if nothing unusual had occurred.

388 Motions of Tippoo Sultan in India.

While Bonaparte was thus obtaining boundless personal aggrandisement in Europe, the African expedition in which he had been engaged was utterly unsuccessful in all its objects. The circumstances which led to it, so far as concerned foreign nations, now came to light, and were shortly these: Tippoo Sultan, the son and successor of the celebrated Hyder Ally, and sovereign of the Mysore country, which forms a part of the peninsula of India, had been compelled to conclude a treaty of peace in the year 1792 with the British governor general, Lord Cornwallis, under the walls of Seringapatam his capital. By this treaty he resigned to the invaders a part of his territory, and agreed to pay a large sum of money. He was, moreover, under the humiliating necessity of consenting that two of his sons should be delivered as hostages, to remain with the British till the pecuniary payments could be completed.

A war thus concluded could not become the foundation of much cordial amity between the parties. Tippoo had inherited from his father a deep sentiment of hostility against the growing power of Britain in India. Though he submitted on the occasion now mentioned to the necessity of his circumstances, yet he only waited a more fortunate opportunity to endeavour to recover what he had lost; and even, if possible, to accomplish the favourite object of all his enterprises, the complete expulsion of the British from India. At a former period, almost the whole of the native princes of this vast continent had entered into a combination against the power of Britain; but their designs had been defeated by the talents and exertions of Warren Hastings, Esq. The ascendency of the British government in this quarter was now so great, that no such combination could again be formed, and Tippoo felt that its power could only be shaken by the aid of an European army. France was the only country from which he could hope to obtain an adequate force. By the events of the revolution, however, and by the pressure of the war at home, the rulers of France had been prevented from attending to distant views and interests. Their settlements in India had been seized by the British, and they had ceased to retain any possessions beyond the Cape of Good Hope, excepting the islands of Mauritius and Bourbon.

389 He renews his intercourse with the French.

In the year 1797, Tippoo resolved to endeavour to renew his intercourse with the French by means of these islands. One Repaud, who had once been a lieutenant in the French navy, and had resided for some time at Seringapatam, French Revolution, 1799. gapatam, had misled Tippoo into a belief that the French had a great force at the Mauritius, which could immediately be sent to his aid in case of a war. He therefore fitted out a ship, of which he gave the command to Ripaud, and sent two persons in it as his ministers, with powers to negociate with the French leaders at the Mauritius. But, at the same time, to avoid exciting the suspicions of the British government in his neighbourhood, he directed his messengers to assume the character of merchants, to act in that capacity in public, and to conduct their political negociations with secrecy. They arrived at the Mauritius towards the close of the year 1797, and opened their proposals to Malartic the governor, for an alliance between Tippoo and the French nation, with the view of obtaining the aid of an European army. They were received with great joy, and vessels were instantly dispatched to France to communicate their proposals to the Directory.

In the mean time, Malartic the governor of the Mauritius, from folly, from treachery, or from a desire to involve Tippoo, at all hazards, in a quarrel with the British, took a step which ultimately was in a great measure the means of defeating the plans, and accom-

390 His conduct watched by the British. plishing the ruin of that prince. On the 30th of January 1798, he published and distributed a proclamation, in which he recited the whole private proposals of Tippoo, and invited all French citizens to enlist in his service. Copies of this proclamation were speedily conveyed by different vessels, touching at the Mauritius, to the continent of India, to Britain, and to all quarters of the world. Accordingly, as early as the 18th of June 1798, the secret committee of the Court of Directors of the East India Company in London wrote to their governor general in India, requiring him, in consequence of this proclamation, to watch the conduct of Tippoo, and even to engage in hostilities, if the measure should appear necessary. Before that period, however, the government in India had been alarmed, by the same means, and was making preparations for war. This, however, was no easy matter. It is the nature of European power, in these countries, gradually to decline. The nature of the climate, the view of returning home, and the distance from the seat of government, speedily introduce a relaxation of the efforts and the vigilance by which dominion was originally acquired. The troops require to be continually renewed by levies from the parent country; and if this precaution is neglected for a very short time, or negligently attended to, they become unable to protect the extensive territories such as Britain now possessed in India. When Lord Mornington, the governor-general, enquired into the state of the British army at Madras, and whether he might hazard an offensive war against Tippoo; he was informed that three, if not six months would be necessary to assemble the scattered divisions of the army, and to prepare them to defend their own territory. It was added, that such was the feeble state of the British forces in that quarter, that it might even be unsafe to excite suspicion in Tippoo by military preparations, as he might, in that case, ruin them by a sudden attack. Lord Mornington, however, resolved to encounter every hazard, and ordered immediate and active preparations in every quarter.

In the mean while, Tippoo did not trust for success to the aid of France alone. He endeavoured to bring an attack upon the British and their allies, or subjects in India, from the north west, by inviting Zemaun Shah to invade the country. This prince is at the head of a formidable kingdom, made up of provinces torn from both Persia and India. It was founded about sixty years ago by Ahmed Khaun Abdalla, an Affghan chief, who followed Nadir Shah on his invasion of India in 1739. He himself afterwards invaded India no less than seven times; and, in particular, he overthrew, with dreadful slaughter, the united forces of the Mahratta empire, in the year 1761, on the plains of Panipat. He was succeeded, in 1773, by his son Timmur Shah, who died, and was succeeded by his own son, the present prince. The dominions of Zemaun Shah extend from the left bank of the river Indus, on the sea-coast, as far northward as the latitude of Cashmeer; and from east to west they are 650 English miles in length, comprehending the provinces of Cabal, Candahar, Peishere, Ghizni, Gaur, Sigistan, and Korasun. He usually keeps in pay an army of 150,000 horse, besides infantry to garrison his fortresses. In expectation of direct aid from France, by Bonaparte's expedition to Egypt, and of an important diversion to be made by Zemaun Shah, Tippoo endeavoured to remain quiet, and to temporise with the British.

Since the first victories of Lawrence and of Clive, the native princes of India have been eager to introduce the European art of war among their subjects. For this purpose they retain European adventurers to command and discipline a part of their troops, and even endeavour to form a guard for their persons of European soldiers. The Nizam, a prince in alliance with the British, though in a great measure under their influence, had long retained around his person a considerable body of French, and of troops under their management. These, under the command of one Perou, now possessed great influence at Hydrabad, the capital of the Nizam. It was of much importance that these should be removed out of the way, to enable the British to obtain the aid of this prince as an ally in the approaching contest with Tippoo. Lord Mornington procured this object to be accomplished with so much success, that, on the 22d of October 1798, the French corps under Perou was surrounded and disarmed without bloodshed, and a British force was substituted as a guard to the Nizam in its stead. The military preparations being in a considerable state of forwardness, Lord Mornington next warned Tippoo Sultan, in a letter dated the 8th of November 1798, of his having a knowledge of his hostile designs and connection with the French. He also proposed to send an ambassador to treat about the means of restoring a good understanding between the states. Tippoo avoided returning an answer till the 18th of December, and then merely denied the accusation, and refused to receive the ambassador. On the 9th of January 1799, the British governor again urged in writing that the ambassador should be received. No answer was returned for a month; and, in the mean time, an army of 5000 men having arrived from England, orders were issued to General Harris to advance at the head of the Madras army against the kingdom of Mysore. Tippoo now offered to receive the ambassador, providing he came without an attendance; but this concession was not accounted sufficient, and the army advanced. An army from

391 General Harris advances against him.

French Revolution, 1799.

from Bombay was, at the fame inftant, advancing on the oppofite fide of his dominions. A part of Tippoo's forces encountered this army and were defeated; and within a few days thereafter, on the 27th of March, the reft of his army was defeated by General Harris. When an European army in India is tolerably numerous, the detail of its military operations againft the natives is by no means interefting; for the inhabitants of thefe enfeebling and fertile regions can never be made, by any kind or degree of difcipline, to poffefs that moral energy which enables men to encounter danger with coolnefs and felf-command. They can rufh on death under the influence of rage or defpair, but they cannot meet the hazard of it with calmnefs and recollection. It is fufficient to remark that, on the 7th of April, General Harris fat down before Seringapatam. On the 9th Tippoo fent a letter to this officer, alleging his own adherence to treaties, and enquiring into the caufe of the war. He was anfwered by a reference to Lord Mornington's letters. On the 20th he made another attempt to negociate, by writing to General Harris, requefting him to nominate commiffioners to treat of a peace. In anfwer to this propofal, certain articles were fent to him as the only conditions that would be granted. By thefe he was required to furrender half his dominions, to pay a large fum of money, to admit refident ambaffadors from the Britifh and their allies, to renounce all connection with the French, and to give hoftages for the fulfilment of thefe ftipulations.

On the 28th of April Tippoo again wrote to General Harris, requefting leave to treat by ambaffadors; but his propofal was refufed, upon the footing that he was already in poffeffion of the only terms of peace which would be granted. Could Seringapatam have held out for little more than a fortnight longer, the invading army muft have retreated. The rainy feafon was about to commence; and, by fome ftrange effect of negligence or treachery, provifions were fo deficient in the camp, that it was only by reducing the troops to

392 And takes Seringapatam.

half allowance that they could be made to laft till the 15th of May. On the 30th of April, the befiegers began to batter the walls of Seringapatam; and a breach being made, the city was taken by affault on the 4th of May. One o'clock afternoon had been chofen for this purpofe, as the hotteft hour of the day, and confequently the time when it would be leaft expected. Tippoo was in his palace; but on being informed of the attack, he haftened to the breach, and fell undiftinguifhed in the conflict. His treafures, and the plunder of the city, which was immenfe, went to enrich the conquering army, after deducting a fhare for the Britifh government and Eaft India Company. His kingdom immediately fubmitted. The part of it which formed the ancient kingdom of Myfore was beftowed upon a defcendant of the former race of its kings, whom Hyder Ally had deprived of the fovereignty; the additional territories that had been conquered by Hyder Ally were divided between the Britifh and their allies, the Nizam and the Mahrattas. The family of Tippoo were either taken in the capital, or voluntarily furrendered themfelves to the conquerors. They were removed from that part of the country, and allowed a confiderable penfion.

In the mean time, Zemaun Shah had actually invaded India from the north-weft. He advanced to the vicinity of Delhi, fpreading terror and defolation wherever he came. Had the French army in Egypt been able to detach a body of 15,000 men to the affiftance of Tippoo, while all India was in the ftate of alarm naturally produced by the approach of this northern invafion, it is extremely probable that the Britifh forces might fpeedily have found themfelves deferted by every ally, and funk under an unequal conteft. But the actual refult was very different. Satisfied with the plunder he had obtained, Zemaun Shah foon withdrew; and the French army being detained in Egypt by the war with the Turks, and by the want of veffels at Suez wherewith to reach India, Tippoo was left to contend, unaffifted, againft the whole power of Britain, and of its allies in the eaft. By the conqueft and divifion of his territory, the Britifh power was left without a rival in that quarter of the world, and raifed to fuch a ftate of impofing fuperiority, that if affairs are only preferved in their prefent fituation, by periodical fupplies of European troops, no native prince, or even combination of princes, can henceforth bring it into danger. Thus, notwithftanding the vaft military efforts made by the people of France during this revolutionary war, yet all foreigners who trufted to their aid were ruined by placing confidence in them. In Italy, Germany, Switzerland, and Holland, the rapacity of the commiffaries of the French government foon rendered odious and intolerable the prefence of thofe armies whofe arrival had been eagerly defired. In Ireland and in India, the promife and the hope of affiftance which they were never able to beftow, only ferved to produce premature hoftility, and to increafe and eftablifh the power of the Britifh government.

393 Immenfe power of Britain in India.

But to return to the domeftic hiftory of France, which has now become only an hiftory of the ufurpation of Bonaparte.

394 New conftitution of France.

In the middle of the month of December, the Confuls, with their legiflative committees, produced to the public their plan of a new conftitution, which they prefented to the primary affemblies, and which is faid to have been accepted by them without oppofition, like all the former conftitutions. It is a very fingular production, and neither admits of reprefentative government, nor indeed of any other form of political freedom. Eighty men, who elect their own fucceffors, poffefs, under the appellation of a *Confervative Senate*, the power of nominating the whole legiflators and executive rulers of the ftate; but cannot themfelves hold any office in either of thefe departments. The fovereignty is concentrated in one man, who, under the title of *Chief Conful*, holds his power for ten years, and may be re-elected. The whole executive authority is entrufted to him, and he enjoys the exclufive privilege of propofing new laws. He is affifted by two other confuls, who join at his deliberations, but cannot controul his will. The legiflative power is entrufted to two affemblies: the one, confifting of 100 members, called a *Tribunate*; and the other, of a *Senate*, of 300 members. When a law is propofed by the Chief Conful, the Tribunate may debate about it, but have no vote in its enactment. The Senate votes for or againft its enactment, but cannot debate about it. Neither the Confuls, nor the members of the legiflative bodies, nor of the confervative fenate, are refponfible for their conduct. The minifters of ftate, however, who are appointed by the

French Revolution, 1799.

the Chief Consul, are responsible for the measures they adopt.

The people in the primary assemblies elect one tenth of their number as candidates for inferior offices; persons thus chosen, elect one-tenth of themselves as candidates for higher offices; and these again elect a tenth of themselves as candidates for all the highest offices of the state. Out of this last tenth the Conservative Senate must nominate the consuls, legislators, and members of their own body. But this last regulation is to have no effect till the ninth year of the republic. In the mean time, the same committees that framed the constitution, appointed also the whole persons who were to exercise the government. Bonaparte was appointed Chief Consul, and Cambaceres and Lebrun second and third Consuls. Sieyes, with his usual caution, avoided taking any active share in the management of public affairs, and was appointed, or appointed himself, a member of his own Conservative Senate; the whole being regarded as produced by him. As a gratuity for his services, the Chief Consul and his legislators presented to him an estate belonging to the nation, called *Crosne*, in the department of Seine and Oisne.

395 Absolute power of Bonaparte.

Thus, after all their sanguinary struggles for freedom, did the son of a Corsican drive from their stations the representatives of the French nation, and assume quiet possession of the government of that country, with a power more absolute than ever belonged to its ancient monarchs. The established privileges of the clergy, the nobles, and the parliaments, always restrained, in some degree, the despotism of the kings of France; these being now destroyed, the will of Bonaparte could meet with no controul.

396 Proposals for peace made by the Consul,

One of the first measures of his government was to transmit to the allied powers, then at war with France, proposals for negociating peace; but in these proposals it was easy to discover that a *general* peace was not the object of his wishes. He was, indeed, under the necessity of making some kind of pacific overtures, that he might keep the promise by which he had bribed the people to submit tamely to his usurpation; but he addressed each of the belligerent powers *separately*, with the obvious view of dissolving the coalition; and he repealed not the decrees of the Convention, which declared war against all the governments of Europe. Deviating from the forms long established for transacting business between independent states, he addressed the British government, not, as usual, through the medium of the minister for foreign affairs, but in a letter directed immediately to the King; to that letter he prefixed a motto, which proved his own adherence to the revolutionary decrees that were the chief cause of the rupture with England; and it is difficult to believe that he did not actually *mean* to insult the monarch whom he so addressed.

He certainly did not expect a proposal made in such a manner to be listened to, or that the King would deign to answer a letter which began with proclaiming *liberty*, *equality*, and the *sovereignty of the people*. Besides this revolutionary jargon, the letter contained nothing more than the two simple questions—"Whether the war, which had, for eight years, ravaged the four quarters of the globe, was to be eternal?" and "whether there were no means for Britain and France of coming to a good understanding?" His Majesty's ministers would have been perfectly justified had they returned, to the former of these questions, the laconic answer, *No;* and to the letter, *Yes:* but they condescended to assign the reasons which prevented the King from listening to overtures coming, in so questionable a shape, from so novel an authority.

397 Rejected by Britain

Those reasons were unanswerable; for they rested on past experience of the bad faith of the revolutionary rulers of France; on the instability of the consular government; and on the obligation of treaties, by which his Majesty was bound not to abandon his allies by concluding a separate peace.

That the revolutionary rulers of France had been remarkable for bad faith, was completely proved in both houses of parliament, by an enumeration of the treaties which Bonaparte himself, when commanding the armies of the republic, had first entered into with foreign states, and then violated. That the consular government was then unstable, will be questioned by no man, who, reflecting on the means by which it was formed, adverts to the circumstance of the letter to the King being written on the very day on which the Consuls were installed in their office, and long before it could be known that the primary assemblies would accept the constitution which had been dictated to them. That constitution had, indeed, deviated so far from all republican forms, as to excite discontent even among its own creatures; and, in the first meeting of the tribunate, one of the members, obviously comparing the new with the old government, talked of the idol of fourteen days, which, he observed, might as readily be overthrown as the idol of fourteen ages. That the First Consul was sincere in wishing to restore peace to *Europe*, will hardly be supposed by him who calls to mind, that the French minister, in his reply to Lord Grenville, took not the smallest notice of the *allies*, although he had been assured by his Lordship, that his Majesty could not treat without them. It is likewise worthy of remark, that in the last official paper on the subject, the same minister proposed, not any specific terms of peace, but merely an *immediate suspension* of hostilities between the two nations, and the naming of plenipotentiaries, who should repair to some convenient place, and apply themselves, with all possible dispatch, to the effecting of a good understanding between the French republic and England! Had that proposal been agreed to, the ports of France, which were then blocked up by the British fleet, would have been opened for the importation of naval stores; the negociation might have been 1800.
protracted from day to day; and when the Consul had conquered the Austrians in Italy and on the Rhine, he might have suddenly broken it off, and directed the whole force of the republic against the British empire.

All this was foreseen by those who at that period so ably guided the helm of state, and the insidious overture was with dignity rejected.

398 And the court of Vienna.

A similar overture had been made to the court of Vienna, and treated in the same manner; but early in this year, the Emperor of Russia withdrew from the coalition. He had been highly and justly offended by the conduct of Austria during the last campaign: he is said to have demanded Malta of the British court as soon as it should surrender to the combined forces of Russia and England, and to have received, with the utmost indignation, the refusal which was given to so unreasonable

French Revolution, 1800. reasonable a demand; but such was his caprice, that the motives which induced him to abandon his allies may have been much more trifling than either of these. Whatever they were, he issued the most peremptory orders to Suwarrow to retire with the army under his command into Poland; and with these orders the old man reluctantly complied about the middle of January. The Emperor continued, indeed, to express the utmost abhorrence of the French revolution, and of the principles whence it had sprung; but his warlike operations were now at an end; and the Consuls heard, with indifference, of his prohibiting the importation of French books into the Russian empire.

399 Defection of the Emperor of Russia.

In the mean time, Bonaparte succeeded in suppressing an insurrection, more formidable, if credit be due to the papers which were said to be found in the possession of the chief insurgents, than any that had yet been raised in behalf of the house of Bourbon; and being thus relieved from the anxiety inseparable from a civil war, he found leisure to turn his attention to his foreign enemies.

On the 7th of March he sent a message to the legislative body, in which, after misrepresenting, in the grossest manner, the conduct and views of the court of London, he assured them, that in the midst of battles and triumphs, he would invoke peace, and swear to fight only for the happiness of France, and the repose of the world! This message was followed immediately by two decrees: the one calling, in the name of honour, upon every soldier who was absent on leave from the armies in Italy and on the Rhine, or who, on account of his age, had retired from the service, to join his regiment before the 5th of April, if able to serve another campaign; and the other, appointing a fresh army of reserve, consisting of 60,000 men, to be assembled at Dijon, and to be placed under the command of the First Consul in person.

400 Preparations of France for opening the campaign.

Amid these warlike preparations, which were carried on with vigour, the government did not neglect the administration of justice, or the internal economy of the state. Hitherto the several departments, into which the constituent assembly had divided the kingdom of France, were under the controul of what were called *central administrations*; but they were now subjected to the government of magistrates styled *præfects*, who were nominated to their office by the Chief Consul. In every department there was appointed one præfect, with three or four sub-prefects, according to the population; and one of the offices of the council of præfecture was to decide on the remonstrances of the citizens against their quota of taxation. A reformation was likewise introduced into the civil and criminal courts of justice, of much greater importance to the inhabitants of France than the institution of præfects. The judges were to be no longer chosen by the people for a limited time, but to be appointed, with decent salaries, by the Chief Consul; nor were they to be liable to such interruptions as formerly in the discharge of their duty. The good effects of this reformation were quickly seen in the more prompt and equal administration of justice, and in the less frequent employment of the guillotine.

401 Internal regulations.

The campaign was now ready to be opened both in Italy and on the Rhine. The only territory of any importance which, in Italy, remained in the possession of France, was that of the Genoese republic; and the army which they had to defend it was greatly reduced in numbers since the preceding year, and, for want of clothes, provisions, and pay, was in a state little short of mutiny. It was the great object of the Austrians to get possession of Genoa, with all its dependencies; while the Genoese, who beheld in the French only the destroyers of their commerce and their consequence, were disposed to lend every aid to measures calculated to drive them effectually from their country. French Revolution, 1800.

The command of the French army in Genoa was given to Messena; who, having received from the Consuls extraordinary powers, displayed, in that command, all the abilities of a consummate general. Carrying with him from Lyons and Marseilles a supply of troops, and, by a proper distribution of rewards and punishments, reducing to order and obedience those whom he found ready to desert their standards, he was soon at the head of a force able, not only to overawe the inhabitants, but to stop the progress of the Austrians. After many battles and skirmishes, however, he was at last obliged to retire into the city, where famine would have compelled him to surrender immediately, had he been immediately blockaded by the army under the command of the Imperial General Melas. 402 Messena

The appearance of the British fleet, on the 5th of April, was the signal for that general to attack the place. The communication between Genoa and France by sea was now cut off; but a few days preceding the arrival of Lord Keith, a quantity of wheat, and other provisions, had entered the port, and rescued the inhabitants and the army from the last pressure of famine. The Austrians soon made themselves masters of the surrounding country; but Messena, in hopes of receiving succour from France, obstinately refused to give up the city. Although reduced to act on the defensive, he neglected no opportunity of making sallies on the enemy, sometimes with considerable slaughter on both sides: but he is said to have tarnished the laurels which his bravery would have gained, by exhibiting his prisoners to the contempt of the citizens. An engagement of this kind, in which he lost three of his best commanders, terminated all further operations on his part; and General Melas, having nothing more to apprehend from the army cooped up in Genoa, left General D'Ott to continue the blockade, and turned his own forces against *Sauchet*, who commanded a separate division of the French army. 403 Blocked up in Genoa.

On the 7th of May was fought, between Ceva and St Lorenzo, a decisive battle, in which the French were totally defeated, with the loss of 19 pieces of cannon, and 1200 prisoners, among whom were 357 officers, one of whom was a general of division. Soon after this action, Sauchet was compelled to abandon the strong position of Col di Tenda, leaving behind him four pieces of cannon and 200 prisoners; and advancing towards Niece, he was driven from post to post, till at last he was obliged to take shelter behind the Var, leaving Melas in possession of the whole department of the Maritime Alps. 404 Sauchet defeated.

The opening of the campaign on the Rhine was not so favourable to the Austrians. For reasons, which we pretend not to know, the Archduke Charles had been directed by the court of Vienna to resign the command of the army to General Kray, who had so much distinguished himself in Italy during the campaign 1799. 405 The campaign opened on the Rhine.

French Revolution, 1800.

The military talents of Kray were unqueſtionable; and he had gained ſufficient evidence of his integrity and zeal for the cauſe, both when ſerving under Suwarrow, and when acting independent of him; but, unfortunately, he was a ſtanger to the army which he now commanded, and he was not ſo *noble* as ſome of the other generals! Our attachment to democracy will not be ſuſpected; but the principles of no democrate have been more abſurd than the prejudices of part of the Germans in behalf of *nobility*. Becauſe one of the generals ſerving under Kray was more noble than his commander, he had the folly and inſolence to declare, that he would obey no order of which he was not himſelf convinced of the propriety (A); whilſt many of the inferior officers, who had riſen from the ranks, and were deeply tinctured with the principles of Jacobiniſm, refuſed to fight againſt thoſe whoſe object it was to level nobility with the duſt.

That an army, thus commanded, would make effectual head againſt the French veterans, led on by the gallant Moreau, could not reaſonably be expected; and the reader will not be ſurpriſed, that the Hungarian ſoldiers, though they had given repeated proofs of their bravery, made no reſiſtance to the enemy, when they ſaw themſelves ready to be ſacrificed to the diſſentions of their own officers.

406 The Auſtrian General Kray

Kray had received, at the opening of the campaign, orders from the Aulic council how to diſpoſe of the forces under his command; and being unſupported by the generals under him, he had no other alternative than to obey theſe orders, whether he approved of them or not. Similar inſtructions had been ſent by the Conſul to Moreau, containing a detailed plan of operations which he was commanded to execute; but he ſpiritedly refuſed to fight in ſuch fetters.

Conſcious, it may be preſumed, that his own knowledge of the art of war was at leaſt equal to that of Bonaparte, while his experience of the country was infinitely greater, he diſpatched a courier to Paris to inform the Conſuls, that if the orders which he had received were to be rigidly followed, he muſt beg leave to reſign his command, and take a ſecondary rank. His reſignation was accompanied with the plan of operations which he had formed for himſelf; and the Firſt Conſul, inſtantly perceiving its propriety, continued him in the command, with inſtructions to carry on the war according to his own judgment.

407 Driven from poſt to poſt by Moreau.

Moreau, thus left to act according to circumſtances, eaſily croſſed the Rhine, and drove the Auſtrians from poſt to poſt, till Kray, finding it impoſſible to act offenſively with a mutinous army, commanded by diſaffected officers, determined to maintain his poſition at Ulm, and wait for ſuccours from Vienna. He had been defeated at Stokach, at Engen, and at Moſkirch; but, though he had on theſe occaſions diſplayed all the talents of an able general, we enter not into a minute detail of battles, in which no talents could counteract the effects of treachery. On one occaſion, 7000 men, who were ordered to advance, immediately threw down their arms; and on the night previous to one of theſe actions, ſeveral officers were heard to ſay, that the ſoldiers whom they commanded *would not fight!* With ſuch a ſpirit in the army, offenſive operations were no longer practicable; but Ulm, as it commanded both ſides of the Danube, was of ſo much importance, that the gallant veteran, having ſtrongly entrenched himſelf, reſolved, if poſſible, to maintain his poſition.

408 Makes a ſtand at Ulm;

Moreau, who penetrated into his deſigns, determined to attempt the paſſage of the Danube, and by cutting him off from his magazines at Donavert, to force him to a general action. Accordingly he ordered Lecourbe, who commanded one of the wings of his army, to advance, and take poſſeſſion of a bridge between Donavert and Dillingen. This was accompliſhed with difficulty; for the Auſtrians, perceiving, when too late, that all was at ſtake, diſputed every inch of ground with the French general. During the interval of marching to the Danube and croſſing it, Kray, who perceived the intentions of his enemy, had ſent conſiderable reinforcements to the left bank to oppoſe the paſſage. In conſequence of this, a battle took place at the celebrated poſition of Hochſtet, near Blenheim, which ended in favour of the French, who took 4000 priſoners, without counting the killed and wounded.

Kray, who ſaw the danger of his poſition, aſſembled his forces, and leaving a ſtrong garriſon in Ulm, marched againſt the French; and paſſing by Hochſtet, croſſed the Danube at Newburg, with the ſeeming intention of forcing his enemy to abandon the ground which he occupied on the left bank of the river near Ulm.

409 But, defeated at Newburg, falls back to Ingolſtadt.

The French army received his attack at Newburg; and the engagement, which commenced early in the day, was continued, with the moſt determined bravery on both ſides, till night; when the Auſtrians, obliged to retreat, fell back on Ingolſtadt.

This battle decided the fate of Germany. The French became maſters of the electorate Bavaria, and of various territories of leſs extent; and as they approached the hereditary dominions of the Emperor, the Jacobins, not only of the capital, but of the whole of Upper Auſtria, behaved with ſuch audacity, that the court could not but perceive that no dependence was to be placed on armies compoſed of ſuch men. The Imperial family, and the Britiſh ambaſſador, were publicly inſulted in the theatre; whilſt a hired rabble vociferated "Peace! Peace!"

410 The army of reſerve,

This ſpirit was not rouſed by the ill ſucceſs of Kray alone; for the affairs of Auſtria were now more deſperate in Italy than even on the Danube. About the ſame period that the campaign opened on the Rhine, the army of reſerve, which had been for ſome time forming at Dijon, began its march. The French government had given official notice, that this army was already compoſed of more than 50,000 men; that it was receiving reinforcements every day; and that it was prepared to march either to the right or left, as the chance of war, or the plans of government, ſhould render the one route or the other neceſſary. This account was not generally credited. Thoſe who wiſhed well to the cauſe of the allies, were unwilling to allow ſuch vigour

---

(A) This man afterwards boaſted of his diſobedience at Vienna: "Je ne voulois pas etre commandé par un roturier," ſaid he. "Non! (replied the gentleman to whom he ſpake) vous aimiez mieux etre battu par un roturier."

gour to the French government ; while the Jacobins of Germany induſtriouſly circulated a report, both through Italy and the empire, that the army of reſerve amounted to little more than 6000 men.

On the 5th of May, the Firſt Conful left Paris to take upon himſelf the command of this army ; and after receiving the troops cantoned at Dijon, he paſſed on towards Genoa. Remaining a ſhort time in the
411 Pays de Vaud, he joined the army of reſerve at the foot of Mount St Bernard, and inſtantly aſſumed the command. A very ſmall force would have been ſufficient to ſtop that army in its aſcent ; but General Melas either heard not of its being in motion, or believed implicitly the inſidious report circulated by the Jacobins of Italy and the empire. The French, therefore, met with no reſiſtance till they reached the town of Aoſt, of which, after a very ſlight ſkirmiſh, they took quiet poſſeſſion. Having, with incredible perſeverance and addreſs, paſſed by the fortreſs of Bard, they purſued their route down the valley of Aoſt, with little oppoſition till they reached the town of Yorea. There, indeed, the Auſtrians had aſſembled a force, but a force which, as it was inadequate to the defence of the place, the impetuoſity of the French ſoon compelled to give way, and take poſt on the heights of Romano behind the Chinſella. That poſt was of great importance, as it commanded the paſſage of the river ; but it was occupied by no more than 5000 infantry, 4000 cavalry—of little uſe in ſuch a ſituation, and a few pieces of artillery. The conſequence was, that on the 26th of May it was forced, with conſiderable ſlaughter, indeed, on both ſides ; and ſoon afterwards the fort Brunette, which commanded the entrance to Piedmont on the ſide of Suſa, capitulated to another diviſion of the army under the command of General Turreau ; ſo that the road to Turin was now open.

Under the command of the Firſt Conſul, croſſes the Alps.

412 While the French were paſſing the St Gothard, the main body of the Auſtrian army was occupied in the remoteſt parts of Piedmont, celebrating their victories over the French at Nice. It is difficult to decide whether the raſh confidence of Bonaparte, or the thoughtleſs ſecurity of General Melas, ought, on this occaſion, to excite the greateſt aſtoniſhment ; for it is certain, that a proper diſpoſition of a very ſmall portion of the Auſtrian forces among the paſſes of the Alps, would have cruſhed at once the army, and all the proud proſpects, of the Conſul.

Thoughtleſs ſecurity of the Auſtrian commander.

Rouſed at length from his dreams of ſafety, by the news of an invaſion, of which he had been often warned, and which he would even yet ſcarcely believe, Melas flew to Turin, recalling, by haſty marches, the main body of his army, to defend the Po, and prevent the enemy from getting poſſeſſion of the capital. It was natural for him to ſuppoſe that Turin would be the firſt place of importance attacked by the French ; and the Conſul gave countenance to that ſuppoſition, by ſeeming to menace the paſſage of the Po. He had formed, however, a different plan of operations ; and while the Auſtrian commander was preparing to diſpute with him the paſſage of the river, he ſuddenly turned to the left, and, croſſing the Seſia and the Teſſino, entered Milan on the 2d of June.

413 Whilſt Bonaparte marched to Milan, General Lannes, with the advanced guard, filed off towards Pavia. The French army, though ſtrong in numbers, had neither magazines, artillery, nor ſtores of any kind ; and learning that Pavia was the great depot of the Auſtrian army, the Conſul was determined to make himſelf maſter of it. This was eaſily accompliſhed ; and Lannes 414
found in the place upwards of 200 pieces of artillery, 8000 muſkets, 2000 barrels of gunpowder, and an immenſe quantity of all kinds of proviſions.

Bonaparte enters Milan; Takes Pavia;

The religious profeſſions of Bonaparte had, at all times, been accommodated to the principles or prejudices of thoſe whom he wiſhed to attach to his cauſe. In Egypt he had kept the feſtival of Mohammed, and declared himſelf ſent by the Moſt High to enforce obedience to the laws of the prophet ; and, with equal ſincerity, he now ſung *Te Deum* in the cathedral church of Milan, for the happy deliverance of Italy from *heretics* and *infidels !* He then proceeded to the formation 415
of a proviſionary conſtitution for the Ciſalpine republic ; which, in a few days, was re-organized as a free and independent ſtate.

And reſtores the Ciſalpine republic.

Whilſt the Conſul was diſplaying his talents as a conſtitution-monger, one of his generals, with a detachment of the army, croſſed the Po at Stradella, and, cutting off the communication between General Melas and the country of Piedmont, made himſelf maſter of the Auſtrian magazines at Piacenza, Cremona, and various other depots on the banks of the river. 416

It was at this time that Bonaparte, by means of intercepted letters, was firſt informed of the capitulation of Genoa. Maſſena had done every thing in the power of valour and perſeverance to defend the place ; but after he had ſeen 15,000 of the inhabitants periſh by hunger, he was obliged, on the 5th of June, to ſurrender to the Britiſh and Auſtrian commanders. Conſidering his utter inability to hold out longer, the terms which he obtained were favourable. The right wing of his army, to the number of 8110 men, were to march into France by the road of Nice, and the remainder was to be tranſported by ſea, at the expence of Britain, to Antibes ; no man was to be held reſponſible for having exerciſed any public function under the government of the Ligurian republic ; and all officers made priſoners from the beginning of the campaign, were to return to France on their parole, and not to ſerve till regularly exchanged.

Genoa ſurrendered to the allies.

The ſurrender of Genoa left the Auſtrian army, by which it had been inveſted, at liberty to co-operate with the commander in chief ; and General D'Ott marched, with thirty battalions, to oppoſe the progreſs of the 417
French in Piedmont. He was met, on the 9th of June, at a place called Montebello, by a large detachment of the French army under the command of the Generals Lannes and Victor. The battle raged long with great fury, and the village of Caſteggio, which at its commencement was in the poſſeſſion of the Auſtrians, was taken and retaken ſeveral times ; but at laſt victory declared for the French, and General D'Ott retired with great loſs.

The Auſtrian General D'Ott defeated at Montebello.

Unable to ſtop the progreſs of the French by partial detachments, Melas, who was now blockaded in Piedmont, aſſembled the whole of his forces between Aleſſandria and Tortona, in order, by one ſtroke, either to cruſh the enemy, or at leaſt open to himſelf a way to the Auſtrian diviſions on the Mincio. This produced, on the 14th of June, the memorable battle of Marengo ; of which we ſhall attempt no detail, becauſe we could

could give none for the truth of which we would chooſe to be anſwerable. The French accounts, which are faithfully copied by our own Jacobinical writers of
418 The battle of Marengo. periodical hiſtory, repreſent the army under the command of Melas as more numerous than that of the Conſul; while they attribute the ſucceſs of the latter wholly to the conduct and intrepidity of its leader. The fact, however, we believe to be far otherwiſe; for we think it might be proved, by comparing together the different bulleteins of the army of reſerve, that from the beginning the French had a decided ſuperiority. Be this as it may, the Auſtrians were, for nine hours, victorious; and the fate of the battle was at laſt turned, not by any uncommon exertions of the Conſul, but partly by the provident conduct of Deſſaix, and ſtill more by the ſituation of the Auſtrian commander, whoſe faculties ſeem wholly to have forſaken him in the latter part of the day. When he was in this ſtate, one falſe movement, which weakened his centre, afforded an opportunity to Deſſaix to make a vigorous and ſucceſsful charge with a body of cavalry that had not yet been engaged; and General Zach, who was about to take the command of the army from Melas, worn out with age and fatigue, unfortunately falling, at that critical moment, into the hands of the enemy, the French remained maſters of the field of battle.

The ſpirit of the Auſtrians, however, was not broken. They had loſt indeed 9000 men, with ſome of their beſt generals; but the loſs of the French was confeſſedly greater, amounting by their own account to at leaſt 12,000 men. The Auſtrians, enraged at having had the victory ſo wreſted out of their hands, were eager to renew the conteſt on the following day; but, inſtead of ſeconding the ardour of his troops, General Melas concluded a capitulation, unparalleled, we will venture to affirm, in the annals of war; a capitulation by which he voluntarily ſurrendered into the hands of
419 Its conſequences. the enemy nearly all the fruits of one of the moſt glorious and ſucceſsful campaigns recorded in hiſtory. We wiſh not to throw any undue aſperſion on the character of the Auſtrian commander. His behaviour at the battle of Novi renders his bravery unqueſtionable; and we are aſſured, by letters from Germany, that his integrity has never been ſuſpected; but thoſe letters repreſent him as qualified, not to command a great army, but only to execute the orders of a ſuperior mind. It may have been in conſequence of ſome previous general inſtructions from the Aulic Council that he ſigned ſuch a capitulation; or the fortreſſes which he ſurrendered may have been deſtitute of proviſions, and of courſe incapable of ſuſtaining a ſiege. On the former ſuppoſition, the Aulic Council muſt be conſidered as decided enemies to the cauſe in which the allies were embarked; on the latter, General Melas was the leaſt provident commander that was ever perhaps entruſted with the defence of a country.

420 An armiſtice in Italy. Be this as it may, he gave up to the French the whole of Piedmont and Genoa; and, concluding an armiſtice which was to laſt till an anſwer agreeing to the conditions could return from the court of Vienna, he retired with his army into the territory of Mantua, Tuſcany, and Ancona.

The gallant Kray wiſhed to take advantage of this armiſtice in Italy to ſtop the progreſs of the troops under Moreau; but the French general would not liſten to his overture, till he received inſtructions from Paris, in conſequence, as was ſuppoſed, of the arrival of Count St Julien with propoſals of peace from the Imperial Cabinet. The armiſtice was then concluded in Germany as well as in Italy, leaving for the line of demarcation the poſts occupied at the time by the reſpective armies; but if the French adhered to the letter of theſe treaties, they almoſt inſtantly violated the ſpirit of both. They reinforced their army in Italy in direct contradiction to what was obviouſly the meaning of their ſtipulations with Melas; they filled the conquered countries with their licentious hordes; they levied enormous contributions, and even raiſed troops in ſtates of which they had formally proclaimed the *independence*; and their armies in Germany ſubſiſted on the plunder of the neighbouring countries. 421 And Germany.

Whilſt France was thus everywhere victorious in Europe, her troops were ſuffering hardſhips and diſgrace in Africa. They complained loudly of being deſerted by their chief; and Kleber, on whom the command devolved, declared, in the impious jargon of the Jacobins, that the ſame *univerſe* ſhould not contain him and Bonaparte. He felt it expedient, however, to continue the negociations into which that general had entered with the Grand Viſier for the evacuation of Egypt; and after many letters had paſſed between them, a convention was concluded on the 24th of January 1800, to which Sir Sydney Smith acceded on the part of Great Britain. By that convention the French army was to be collected with its arms, baggage, and effects, at Alexandria, Roſetta, and Aboukir, and thence be tranſported into France, as well in its own veſſels as in ſuch as ſhould be furniſhed to it by the Sublime Porte. 422 State of the war in Egypt.

To the cauſe of the allies it is obvious that nothing could have happened apparently more injurious than the evacuation of Egypt on ſuch conditions as this, which would have furniſhed the Conſul with ſixteen or eighteen thouſand veteran troops to be employed by him either in Italy or on the Rhine. How the gallant Commodore came to overlook this circumſtance, or indeed how he came to act as a Britiſh Plenipotentiary, we pretend not to know. That he exceeded any powers with which he could reaſonably conceive himſelf veſted, was completely proved in the Houſe of Commons by the war-miniſter Mr Dundas; who juſtly obſerved, that the powers of Sir Sidney and his brother as plenipotentiaries, had ceaſed upon the arrival of Lord Elgin in that capacity at Conſtantinople; and that, as a Britiſh officer, he had no right to accede to ſuch a convention while he held only a ſubordinate command under Vice-admiral Lord Keith.

In December 1799, miniſters had reaſon to believe that a negociation would be entered into by General Kleber and the Grand Viſier for the evacuation of Egypt by the French troops. As ſuch a negociation was deſirable, they ſent inſtructions, not to Sir Sidney Smith, but to Lord Keith, to accede to it; on the expreſs condition, however, that Kleber and his forces ſhould not be ſent back to France to fight againſt the Auſtrians, but ſhould be detained as priſoners of war till regularly exchanged. Theſe inſtructions reached the noble admiral in February 1800, when he immediately appriſed General Kleber of them; aſſuring him, at the ſame time, that he would permit no ſhips to ſail with French troops, in conſequence of any partial capitulation,

French Revolution, 1800.

pitulation, or of paſſports from ſuch as had no right to grant them.

This conduct, which was perfectly fair on the part of Britain, and of which the contrary might have been juſtly complained of by the court of Vienna, produced a violent outcry, not only in France but even in England, among thoſe who, from the commencement of the war, had uniformly pleaded the cauſe of the enemies of their country. Government, it was ſaid, had broken faith both with its allies and with its enemies; yet Kleber himſelf accuſed the cabinet of St James's of no ſuch crime. He talked, indeed, of Lord Keith's *inſolence*, and called upon his ſoldiers to anſwer it by their victories; but ſo little did he dream of treachery on the part of Britain, that in his letter to the directory, he ſpoke of his convention as made with the Grand Viſier alone. Accordingly, on the 20th of March, he attacked the Turks in the neighbourhood of Cairo; and though the Janizaries diſplayed ſomething of their wonted bravery, they were forced to yield to the ſuperiority of European tactics, when the Turks fled in all directions, leaving upwards of 8000 dead and wounded on the field of battle.

This victory reſtored to the French the poſſeſſion of Cairo, which they had abandoned in conſequence of the convention; but they were ſtill much haraſſed by ſome of the Beys, who during the battle had paſſed the rear of the army, and maſſacred ſuch of the Copts as favoured their cauſe. Kleber, therefore, again propoſed to evacuate Egypt on the terms agreed to by the Grand Viſier and Sir Sidney Smith; and the court of London having authoriſed Lord Keith to accede to thoſe terms, a ſuſpenſion of hoſtilities took place, and
423 the Turks were about to be freed from enemies whom they were unable to expel, when the French commander was ſuddenly aſſaſſinated.

Aſſaſſination of General Kleber.

This was a ſerious misfortune, as well to the allies as to the French in Egypt; for Kleber appears to have been the moſt honourable, as well as the ableſt, commander of the republicans in that part of the world. By whom, or at whoſe inſtance, he was murdered, is not certainly known; but, at Conſtantinople, ſuſpicion attached ſtrongly to his ſucceſſor Menou, who had thwarted all his meaſures; who reſolutely oppoſed the evacuation of Egypt on any terms; and who, having embraced the Mahommedan faith, prefixed *Abdullah Bey* to his name. He no ſooner ſucceeded to the command of the army, than he broke off the negociation which was almoſt concluded by his predeceſſor; and informed the Engliſh Commodore, on the 19th of June, that he could enter into no treaty without inſtructions from the Conſuls, who, as he truly obſerved, then *governed* the French nation.

In the mean time, meaſures were taken by the Britiſh government to drive him from that country, which he would not leave by capitulation. Early in the campaign, a body of 12,000 men had been put under the command of Lieutenant-general Sir James Pulteney, to act in the Mediterranean in ſuch a manner as might moſt annoy the enemy, and divide their force. The deſign was ſplendid; but it was completely diſconcerted by the fatal iſſue of the battle of Marengo. The force under Sir James, however, might ſtill be employed with advantage to the common cauſe; and as there was reaſon to believe that France and Spain had formed the plan of marching an army into Portugal, the lieutenant-general was directed to reconnoitre Ferrol, and make an attempt upon the place, ſhould he deem ſucceſs probable, with little loſs of men and of time. He landed 424
his troops on the 25th of Auguſt, and got poſſeſſion of the heights which overlooked the town; but finding it better fortified, and occupied by a ſtronger garriſon, than he had expected, he judged ſucceſs unattainable, without ſuch a loſs of men as would render the army incapable of carrying into effect the objects of its future deſtination. He therefore reimbarked, on the morning of the 27th, without having ſummoned the garriſon, thrown a ſhell into the town, or fired a ſhot againſt the ramparts.

Sir James Pulteney at Ferrol.

425
Sir Ralph Abercromby had been ſent to ſuperſede Sir James Pulteney, and take upon himſelf the command of the army acting in the Mediterranean. Having carried reinforcements with him, beſides a train of artillery from Gibraltar, he touched at Minorca and Malta, whence he proceeded towards the coaſt of Egypt. Meeting, however, with unexpected delays on the coaſt of Aſia Minor, the forces, under the joint command of Lord Keith and him, did not arrive at Alexandria till the 1ſt of March 1801. On the following day the fleet made ſail for the Bay of Aboukir, where it anchored. The ſea running high, no diſembarkation could be attempted till the 7th, when, at 10 426
o'clock A. M. the firſt diviſion made good its landing in the face of the French, who, to the number of 4000 men, were poſted ſo advantageouſly, that, in the opinion of an eye-witneſs *, they might have reſiſted the world. Our limits permit us not to dwell on the maſterly plan of the commander in chief, or on the cool intrepidity of General Moore in carrying it into execution. Suffice it to ſay, that by 2000 Britiſh troops the enemy were driven from their poſition with the loſs of ſome field pieces, which were immediately turned againſt them; and that the diſembarkation was continued during that and the following day.

Sir Ralph Abercromby

Lands in Egypt:

* Mr Baldwin. See his *Political Reflections relative to Egypt.*

On the 12th the whole army moved forwards, and coming in ſight of the main body of the French, attacked them on the 13th, when, after an obſtinate conteſt, and conſiderable loſs on both ſides, victory declared 427
for the gallant Abercromby. The blow was followed up with vigour; and on the 21ſt a ſtill more deciſive battle was fought, with a ſimilar event, at the diſtance of about four miles from Alexandria. It commenced early in the morning, and was continued long; victory leaning ſometimes to one ſide and ſometimes to the other; but at laſt the French gave way in all directions. The heroiſm diſplayed in this brilliant action raiſed the military character of the Britiſh nation as high as its naval character; and the magnanimous conduct of the commander in chief, who, that the ardour of his troops might not be damped, concealed, for two hours, the 428
bitter anguiſh of a mortal wound, has ſeldom been equalled, and can hardly be ſurpaſſed. The loſs on our ſide, in killed, wounded, and miſſing, was upwards of 1500, among whom were ſeveral gallant officers beſides the general. The loſs of the French was computed at 4000.

Fights the battle of Alexandria.

In which he is mortally wounded.

As theſe two battles may be ſaid to have decided the fate of Egypt, we ſhall return to Europe, where events had taken place of as great importance as any which had occurred during the war. The northern powers,

powers, long envious of the naval superiority of Britain, and influenced by the Emperor Paul, who seemed now to be leagued with the Conful of France, had re-
429 The northern confederacy. vived the armed neutrality firft formed by Catharine II. during the American war; and claimed the right of treading to the ports of France, without having their veffels fearched by the Englifh cruifers. That confederacy the Britifh minifters had determined to break, when, to the furprife of the whole nation, and the deep regret of the better part of it, they fuddenly retired from office.

Of a meafure fo little expected, various caufes have been affigned; but that which was in a manner avowed
430 The refignation of the miniftry. in parliament, was a difference in the cabinet refpecting Catholic emancipation. With much addrefs the miniftry had accomplifhed a legiflative union between Great Britain and Ireland (See IRELAND, in this *Suppl.*); and it has been faid, but certainly not proved, that the Lord Lieutenant had been authorifed, to hold out to the Irifh Catholics a repeal of the *teft act*, as an inducement to them to comply with the meafure. Such a bribe as this, clandeftinely offered, is very unlike the fpirit as well of Mr Pitt as of the Marquis Cornwallis; and we do not believe that the offer was ever made. There feems, however, to be no doubt but that the minifter propofed the meafure in the cabinet after the union; that the king, with that confcientious regard which he has uniformly difplayed to the conftitution, put his negative upon it; and that in confequence Mr Pitt and his friends immediately gave in their refignation.

Their places were fupplied by men who had generally fupported their meafures during the war; and it
431 The new miniftry has even been fuppofed that thofe who retired from office recommended their fucceffors. Mr. Addington, then fpeaker of the Houfe of Commons, was appointed firft lord commiffioner of the treafury and chancellor of the exchequer; Lord Eldon, lord high chancellor; the Earl of St Vincent, firft lord commiffioner of the admiralty; Lord Hawkefbury and Lord Pelham, fecretaries of ftate for the foreign and home departments; and the Hon. Colonel Yorke, fecretary at war. The old miniftry was diffolved on the 11th of February; but, owing to a fevere illnefs of his Majefty, it was the middle of March before any of the new minifters, except Lord St Vincent and Lord Hawkefbury, entered upon their offices; and during that period of difmay, Mr Pitt and his friends guided the helm of ftate.

The new minifters began their career with pledging themfelves to leave nothing unattempted to bring about a fafe and honourable peace with the French republic; but in the mean time they proceeded with vigour to carry into effect the warlike plans of their predeceffors.

432 Fit out an armament againft the powers of the North, The northern confederacy had by this time adopted meafures the moft hoftile. A Danifh army under the command of Charles Prince of Heffe took poffeffion of the free and imperial city of Hamburgh, for the exprefs purpofe of hurting the Britifh commerce; and the King of Pruffia, with that unaccountable policy which has marked the whole of his conduct, ordered a large army into the electorate of Hanover. To chaftife this infolence and diffolve the confederacy, an armament was fitted out in the Britifh ports, confifting of feventeen fail of the line, four frigates, four floops, and fome bomb veffels. This fleet, under the command of Admiral Sir Hyde Parker, Vice-Admiral Lord Nelfon, and Rear-Admiral (now Sir Thomas) Graves, failed from Yarmouth on the 12th of March; and paffing the Sound, appeared on the 30th before Copenhagen. The Danes feemed undifmayed; for neither the town nor their fleet could be annoyed, but by the Britifh admiral's conducting their force through a channel of fuch intricate navigation, that, thirty years before, it was thought hardly fafe to attempt it with a fingle fhip oppofed to no enemy. Lord Nelfon, however, having founded the channel, undertook to pilot through it a large divifion of the fleet, of which he requefted and obtained the command from Sir Hyde Parker, with Rear-Admiral Graves commanding immediately under him.

433 Which deftroys the Danifh fleet, &c. at Copenhagen. As the fecond rates were thought to draw too much water for fuch a navigation, the twelve fhips felected for the attack carried each from 74 to 50 guns, to which were added four frigates, four floops, two fire-fhips, and feven bombs. The force oppofed to this armament was tremendous, confifting of fix fail of the line; eleven floating batteries, mounting each from 26 twenty-four pounders to 18 eighteen pounders; one bomb-fhip, and feveral fchooner veffels in the line. Thefe were fupported by the Crown Iflands, mounting eighty-eight cannon; by four fail of the line, moored in the harbour's mouth; and by fome batteries on the Ifland of Amak. This force Lord Nelfon attacked on the 2d of April; and after an obftinate action for four hours, filenced the batteries, and took, burnt, or funk feventeen fail, among which were feven fail of the line. On both fides the carnage was great, the Britifh having 943 men, including officers, killed and wounded; whilft the lofs of the Danes was at leaft double that number.

434 The refult of this action. The refult of this brilliant action, to which nothing will be found fuperior in the annals of naval war, was a fufpenfion of hoftilities, and, on the part of Denmark, of the treaty of armed neutrality, for fourteen weeks.

As foon as the difabled fhips were repaired, the Britifh fleet failed for Carlfcrona, off which it appeared on the 19th of April. The admiral immediately acquainted the governor with what had been tranfacted at Copenhagen, requefting from his Swedifh majefty an explicit anfwer whether he meant to adhere to or abandon the hoftile meafures which he had taken in conjunction with the court of Peterfburgh. The anfwer returned was extremely equivocal; but intelligence be- 435
And of the death of the Emperor Paul. ing received of the fudden death of the Emperor Paul on the 23d of March; and Lord Nelfon, who had fucceeded Sir Hyde Parker in the command of the Britifh fleet, writing in more decided terms than his predeceffor, the court of Stockholm followed the example of that of Copenhagen. The young Emperor Alexander foon afterwards, actuated by a fenfe of juftice, reftored the Britifh property which his father had confifcated; relinquifhed his ill founded claims to the ifland of Malta, 436
Surrender of Malta. which by this time had furrendered to the Britifh forces; and agreed to a fearch of neutral fhips bound to the ports of a nation at war with another. It was indeed to fuch a fearch only by fhips employed entirely in the fervice of government that his Imperial Majefty thus agreed; but this is perhaps all that the Britifh government could reafonably afk; and the granting of it put an end to the northern confederacy.

At the figning of the armiftice between the Auftrian and French generals in 1800, the Republican troops were

French Revolution, 1800.

were maſters of Germany almoſt to the banks of the Inn, and of Italy almoſt to the confines of Venice. The ſpirit of the Emperor, however, was not yet broken, and he refuſed to abandon his allies by confirming the preliminaries of peace to which Count St Julian, exceeding his powers, had agreed at Paris. General Kray having retired from the ſervice, the command of his army was given to the Archduke John, and the Emperor in perſon repaired to it with him; but they ſoon found it incapable of acting offenſively againſt Moreau, and another armiſtice was agreed to, including Italy as well as the empire. The conduct of the Emperor was, on this occaſion moſt honourable. He wiſhed to comprehend Great Britain in any treaty of peace to be negotiated between himſelf and the Conſul; and the Cabinet of St James's had agreed to ſend a plenipotentiary to a congreſs to be held for that purpoſe, at any place agreed upon by the courts of Vienna and Paris. The Conſul however would not admit a Britiſh plenipotentiary unleſs a naval armiſtice ſhould be previouſly agreed to between France and England; and becauſe the court of London rejected a propoſal unprecedented, and in itſelf ſo very unreaſonable that even he who made it did not expect it to be agreed to,

438 Moreau received orders to recommence hoſtilities.

Hoſtilities renewed between the Auſtrians and French.

The Auſtrian army was now under the command of Generals, whoſe names had ſcarcely reached beyond their own country, and who ſoon ſhewed that they had little experience in the art of war. While Moreau was meditating the plan of his winter campaign, the right wing of his army was attacked by the Auſtrians with ſuch ſpirit and ſucceſs, as ſeemed to reduce him to the neceſſity of acting on the defenſive; and he would have been completely ruined, had Klenau made a temperate uſe of his victory. This, however, he did not; for, elated with his good fortune, he quitted his ſtrong poſition on the Inn, and attacking his vigilant and able antagoniſt near the village of Hohenlinden, was completely defeated, with the loſs of 80 pieces of cannon, 200 caiſſons, and, if any credit be due to the French official papers, no leſs than 10,000 priſoners, beſides an immenſe number left dead on the field of battle.

Moreau, without ſuffering the Auſtrian commander to rally his ſcattered forces, marched directly to the Inn, which he croſſed on the 9th of December 1800; and driving his enemies before him, ſtruck the court of Vienna with terror and diſmay. Prince Charles was ſuddenly recalled to the command of the army; and after making one fruitleſs effort to retrieve the affairs, not only of Auſtria, but of Europe, he propoſed an armiſtice, which on the 27th of December the French general was glad to accept, on condition that peace ſhould, without farther delay, follow this third ceſſation of hoſtilities. Could the Archduke have depended on his army, weakened as it was, this armiſtice would probably not have taken place; for the poſition held by Moreau was tremendous. He had plunged himſelf into the very heart of Auſtria, leaving behind him, on his right, the Tyrol, filled with troops to the amount of 30,000; beſides the diviſions of Klenau, Simbſchen, and Riſkenfield, with the legion of Bohemia, forming more than 50,000, on his left. But the ſpirit of the Auſtrians was broken, and the principles of too many of their officers were corrupted.

This armiſtice was followed by a treaty of peace concluded at Luneville on the 9th of February 1801, between the Emperor in his own name and in the name of the Germanic body, and the Firſt Conſul of the French republic in the name of the French people. The terms of this peace differed little from thoſe of the treaty of Campo Formio; only, the Emperor bound himſelf to cede to the Duke of Modena, as an indemnity for the countries which that prince had loſt in Italy, the Briſgau, and to find in the Germanic empire indemnities to all thoſe princes who, by the fate of war, had been deprived of their dominions; while the Grand Duke of Tuſcany was to renounce, for himſelf and his ſucceſſors, the Grand Dukedom, and that part of the Iſle of Elbé which depends on it, in full ſovereignty to the infant Duke of Parma, obtaining a full and complete indemnity in the empire! On the juſtice or injuſtice of ſuch a treaty we make no remarks: the facts will ſpeak for themſelves to every one of our readers.

French Revolution, 1801.

439 Peace between Auſtria and France;

440 Between France and Naples;

On the 28th of March a treaty of peace was likewiſe concluded between the King of the two Sicilies and the French republic; in which his Sicilian Majeſty bound himſelf to ſhut all the ports of Naples and Sicily againſt Turkiſh and Engliſh ſhips, as well merchantmen as ſhips of war, till the concluſion of a definitive treaty of peace between thoſe two powers and the French republic, and likewiſe between England and the powers of the north. He renounced likewiſe, for himſelf and his ſucceſſors, Porto Longano in the Iſle of Elbe, and every thing belonging to it in that iſland; together with the ſtates of the Preſides in Tuſcany, which, with the Principality of Piombino, he ceded to the French government, to be by it diſpoſed of at its pleaſure. In both theſe treaties the French plenipotentiaries took upon themſelves to act for the Batavian, Helvetic, Ligurian, and Ciſalpine republics, as if theſe ſtates were provinces of France.

Great Britain was now left to carry on the war without a ſingle ally but the Turks in Egypt and the Portugueſe in Europe; and theſe, inſtead of being able to lend her aid, contributed only to diminiſh her force by

441 dividing it. At the inſtigation of France, Spain had attacked Portugal, and conquered ſome of her provinces; but on the 6th of June a treaty of peace was concluded between thoſe two powers; by which the king of Spain reſtored all his conqueſts except the fortreſs of Olivenza with its territory and inhabitants from the Guardiana, which was henceforth to be the boundary on that ſide between the two kingdoms. On the other hand, the Prince Regent of Portugal and Algarva engaged to ſhut the ports of his whole territories againſt the ſhips of Great Britain, and to make good to his Catholic Majeſty all damages or injury which his ſubjects might have ſuſtained, during the war, from the Britiſh navy or the ſubjects of the Queen of Portugal, and for which indemnification could rightfully be claimed.

And between Spain and Portugal.

The Conſul having made peace with all his other enemies, menaced the kingdom of Great Britain with invaſion; and the people, or at leaſt part of them, were weak enough to be alarmed at his empty threats. To baniſh this panic from the public mind, Lord Nelſon was ſent to deſtroy the ſhipping and harbour of Boulogne. His ſucceſs was not equal to the goodneſs of his cauſe; but, on the 4th of Auguſt, he made ſuch an impreſſion on the enemy, as put an end to their dreams

French Revolution, 1801.

dreams of invaſion, and ſhewed the inhabitants of Britain that they were abler to annoy the French coaſt, than the Conſul and his myrmidons were to annoy their's. It was ſeen, too, about this time, that the ſpirit of the Britiſh navy was not attached excluſively to the hero of the Nile; for in the month of July rear-admiral Sir James Saumarez came up with a ſquadron of French and Spaniſh ſhips of war bound for Cadiz; and though their force was ſuperior to his own, he took one of them, and two others were burnt.

442 Negotiations between Britain and France.

Early in this ſummer negotiations had been entered into between the Britiſh and French courts for the reſtoration of peace to Europe. The diſſolution of the northern confederacy had ſhewn the ambitious Conſul that he could not annihilate the Engliſh trade, and that of courſe all the treaties which he had made for the excluſion of our ſhips from the ports of neutral powers were of no validity. His heart, however, was ſet upon the retention of Egypt, which every maxim of juſtice as well as of ſound policy impelled the cabinet of St James's to wreſt from his gripe. The negotiation was therefore protracted from day to day, till intelligence arrived at London and Paris of the complete conqueſt of that country.

On the death of Sir Ralph Abercromby, the command of the Britiſh forces devolved upon General Hutchinſon, who ſoon ſhewed that he was not unworthy to ſucceed ſo great a man, and who, as he was probably acquainted with the plan of operations formed by his deceaſed friend, ſeems to have been actuated by the ſame ſpirit. Marching with the main body of the army towards Alexandria, which was occupied by Menou, he ſent Colonel Spencer with a diviſion of the Britiſh forces, aided by a body of Turks, to attack Roſetta; which ſoon ſurrendered to the Britiſh commander.

443 Conqueſt of Egypt.

The ſurrender of Cairo followed, on the 22d of June, on terms favourable to the beſieged; and Menou, accepting of the ſame terms for Alexandria, the allies became maſters of the whole of Egypt, from which the French army, with its baggage, was to be tranſported, in ſhips of the allied powers, to the neareſt French ports in the Mediterranean. The intelligence of theſe events forwarded the negociation for peace between Great Britain and France; and on the 1ſt of October, the preliminary articles were ſigned at London by Lord Hawkeſbury on the part of his Britannic Majeſty, and M. Otto on that of the French Republic. By this treaty Great Britain agreed to the reſtoration of all the conqueſts ſhe had made during the war; the iſland of Trinidad and the Dutch poſſeſſions in Ceylon excepted: The French Republic agreed to the reſtitution of nothing! The Cape of Good Hope, though reſtored to the Batavian Republic, was to remain a free port to the other contracting parties, who were to enjoy there the ſame advantages of trade with the Dutch themſelves. The iſland of Malta was to be reſtored to the Knights of the order of St John of Jeruſalem; its independence was to be guaranteed by Great Britain, Auſtria, Ruſſia, Pruſſia, and France; and it was to be evacuated by the Britiſh forces as ſoon as it ſhould be taken poſſeſſion of by the Knights, and garriſoned by 2000 Neapolitan troops. Egypt was to be reſtored to the Ottoman Porte; and the territory of Portugal was to be maintained in its integrity, with the exception of the fortreſſes and its dependencies, ceded by the Prince Regent to the King of Spain. The French were to evacuate the kingdom of Naples, and the Roman ſtates—the Britiſh, Porto Ferrajo, and all the ports and iſlands that they occupied in the Mediterranean and Adriatic. The republic of the Seven Iſlands was recogniſed by France; the fiſhery on the banks of Newfoundland was eſtabliſhed on its former footing; and, finally, plenipotentiaries were to repair to Amiens, and there proceed to the formation of a definitive treaty in concert with the allies of the contracting parties.

French Revolution, 1802.

444 Treaty of Amiens.

That treaty was concluded on the 22d of March 1802 by the plenipotentiary of his Britannic Majeſty on the one part, and the plenipotentiaries of the Catholic King and the French and Batavian Republics on the other; but it differs in ſome particulars, as well from the letter as from the ſpirit of the preliminaries agreed on and ſubſcribed by Lord Hawkeſbury and M. Otto. The territorial poſſeſſions of the Queen of Portugal were *not* maintained in their integrity; for the boundaries of French and Portugueſe Guiana are, by the ſeventh article of the definitive treaty, fixed by the river Arowary; the free navigation of which gives to France the abſolute command of all her faithful Majeſty's dominions in that part of the world. The French troops were indeed to be withdrawn from the kingdom of Naples and the Roman ſtates; but during the interval which paſſed from the ſigning of the preliminaries to the concluſion of the definitive treaty, the firſt Conſul took poſſeſſion of the iſland of Elba; and having got himſelf elected preſident of the Italian republic, which he had lately formed, he has ſecured a pretext for pouring French troops into Italy whenever his ambition may impel him to ſuch a meaſure. In the view of abſtract juſtice, ſuch deviations from the ſpirit of the preliminaries, agreed to at London by the accredited miniſter of the French Republic, would have been a ſufficient reaſon for breaking off the treaty; but the Britiſh government, ſtudying immediate expediency and the temper of the people, directed the Marquis Cornwallis to ſign it. Thus was the French revolution completed, and the republic acknowledged by all Europe.

445 French revolution completed.

---

446 Errors in the former part of the article corrected.

We cannot, however, diſmiſs the momentous ſubject without correcting ſome errors into which we fell in the account of the riſe and progreſs of this revolution which was publiſhed in the *Encyclopædia*. We do not conſider theſe errors as diſgraceful to ourſelves; for in the midſt of commotions which have convulſed all Europe, it is hardly poſſible to arrive at the truth. When time ſhall have cooled the paſſions of men, and annihilated the parties which now divide the nation, the calm voice of Truth may be everywhere heard; but when the article referred to was written, the ears of every man was ſtunned with the clamour of faction.

So ſenſible of this are the editors of the only impartial periodical hiſtory * which we have, that they venture not to publiſh their volumes till ſeveral years have elapſed from the era of the tranſactions which theſe volumes record; whilſt their rivals—the panders of faction—ſeize the earlieſt opportunities of obtruding their partial ſtatements and falſe reaſonings on the public mind.

* *Old Annual Regiſter.*

It cannot be ſuppoſed that one or two men, ſuperintending the publication of a work ſo extenſive, and treating of ſubjects ſo various, as ours, have leiſure or opportunity to examine with much attention the correſpondence of ambaſſadors, or to expiſcate truth from the contradictory publications of the day. We are therefore

French Revolution.

therefore obliged to draw our materials from ſuch works as profeſs to give a ſummary, but impartial, detail of what is acting on the theatre of the world; and by theſe works we have often been miſled. For the firſt error, however, which we ſhall notice in our former account of the riſe of the revolution, we cannot plead even this excuſe. We ought to have known, that the French clergy and French nobleſſe were not exempted from the payment of taxes; and, of courſe, we ought not to have aſſigned ſuch exemption as one of the cauſes of the REVOLUTION. See that article, *Encycl.* n 8. and 9.

447 First error.

By a writer, to whoſe patriotic exertions this country is deeply indebted, it has been proved, with a force of argument which precludes all poſſibility of reply, that the exemption from taxes ſo loudly complained of was very trifling, that it was not confined to the nobility and clergy, and that it did not extend over the whole kingdom of France. "The *vingtiemes*, which may be conſidered as an impoſt merely territorial, was paid alike by the nobility and the *tiers-etat*. A great part of the clergy was indeed exempted; but their contributions, under a different form, conſtituted an ample equivalent. The duties upon the different articles of conſumption were of courſe paid by all the conſumers, except that in the *pays d'etat*, ſuch as Artois and Brittany; the two firſt orders were exempted from paying the tax upon liquors. But theſe exemptions cannot be deemed very important, when it is known, that in the province of Artois they did not exceed 800 guineas annually, even including the exemptions enjoyed by the privileged members of the *tiers-etat*." The Britiſh officers ſerving on board ſhips of war are exempted from the taxes paid by the other members of the ſtate on wine; and we believe no good ſubject has ever murmured at that exemption. The French nobility were ſubject to the pole-tax.

"Of the *teilles*, the impoſt from which it has been falſely aſſerted that the nobility and clergy enjoyed a total exemption, there were two ſpecies; the one *perſonal*, the other *real*. In one part of the kingdom, the right of exemption was annexed to the property; in the other, to the quality of the proprietor. In the firſt caſe, the privilege was enjoyed by every claſs of perſons, by the tenants as well as the proprietor of a fief; whilſt the gentleman, whoſe eſtate was holden by a different tenure, was obliged to pay the tax. In thoſe provinces where the other cuſtom obtained, the exemption was confined to a certain extent of property, and to *that* only while it continued in the actual occupation of the privileged perſon; but as it very ſeldom happened that the French nobility kept any land in their own hands, and as the tax payable by the farmers was of courſe deducted from the rent, the *teilles* was, in this caſe, ultimately paid by the landlord. The ſame obſervations apply, with ſtill greater force, to the clergy, who always let their eſtates."

In a word, it appears from a formal declaration made by M. Necker to the Conſtituent Aſſembly, that all the pecuniary exemptions enjoyed by the privileged claſſes did not exceed L. 292,000; that the exemptions appertaining to the privileged perſons of the *tiers-etat* amounted to one half of that ſum; and the *drôits de controle*, or duty impoſed upon public deeds, and the high capitation tax (proportioned to their rank), paid by the nobility and clergy, made ample amends to the revenue for the partial exemptions which they enjoyed from other taxes. So far, indeed, were the *tiers-etat* from murmuring at the exemptions of the privileged orders, that, previous to the illuminiſm of the 18th century, they diſplayed, at every convention of the ſtates-general, the greateſt anxiety to maintain the rights of the nobility and clergy; and humbly ſupplicated their ſovereign to ſuffer no invaſion thereof, but to reſpect their franchiſes and immunities *.

We muſt likewiſe acknowledge, that in n° 11. of our article REVOLUTION, we have drawn a very overcharged picture of the miſeries and oppreſſion of the French peaſants under the old government. It is indeed true that they were obliged to ſerve in the militia, the eſtabliſhment of which was conducted in France nearly on the ſame principles as it is in England. The men were called out by ballot only for a few days in the year during peace, when they received regular pay; but if a militia forms the beſt conſtitutional defence of a ſtate, this ſurely ought not to have been conſidered as a grievance, eſpecially ſince married men were exempted from the ſervice. The nobility, too, were exempted from the riſk of being drawn, for the beſt of all reaſons—becauſe moſt of them had commiſſions in the regulars, and becauſe ſuch as had not were engaged in profeſſions, which rendered it impoſſible for them to ſerve in the militia. In France, as elſewhere, the peaſants would no doubt be averſe from this ſervice, and might look perhaps with an anxious eye to the ſuppoſed immunities of their privileged ſuperiors; but if mirth, good humour, and ſocial eaſe, may be conſidered as ſymptoms of felicity and content, theſe men ſurely were not miſerable; for theſe ſymptoms never appeared in any people ſo ſtrong as among the French peaſants. They were indeed liable to be called out by the intendants of the provinces to work a certain number of days every year on the public roads; but to this ſpecies of oppreſſion, if ſuch it muſt be called, the Scotch peaſants are liable, and were ſtill more ſo than at preſent, during that period when our parliamentary orators declare that the inhabitants of Britain enjoyed as much freedom as is conſiſtent with the public tranquillity. It ought to be remembered, too, that Louis XVI. whoſe higheſt gratification ſeems to have conſiſted in contributing to the eaſe and welfare of his ſubjects, thought he ſaw the neceſſity of aboliſhing the cuſtom of the *corvée*, and had made conſiderable advances towards the accompliſhment of that object ſome years before the commencement of the revolution.

448 Second error.

449 The French monarch not deſpotic.

That the French monarch was deſpotic; that no man in the kingdom was ſafe; that nothing was unknown to the jealous inquiſition of the police; and that every man was liable, when he leaſt expected it, to be ſeized by *lettres de cachet*, and ſhut up in the gloomy chambers of the Baſtile—has long been common language in England, and language which we muſt confeſs that we have adopted (REVOLUTION, n° 12.) without due limitations. The French government was certainly not ſo free as that of Britain; but he who underſtood it better than we do, and whoſe writings betray no attachment to arbitrary power, expreſsly diſtinguiſhes between it and *deſpotiſm*. "If (ſays Monteſquieu) France has, for two or three centuries paſt, inceſſantly augmented her power, ſuch augmentation muſt not be aſcribed to fortune, *but to the excellence of her laws* †."

* See *Giſford's Letter to the Earl of Lauderdale*, 2d ed.

† *De l'Eſprit des Loix*, liv. 20. c. 20.

This, surely, is not the language of a man who thought himself governed by an arbitrary tyrant whose *caprice* is the law; nor will it be said to be the language of one who was either afraid to speak the truth or not master of his subject.

450 No change of the old constitution wished by the people of France.

The instructions of all the different orders to their representatives, before the fatal meeting of the States General under the unfortunate Louis, are drawn up in language similar to that of this illustrious magistrate, and furnish a complete proof that they knew themselves to be safe under the government of their monarchs. "The constitution of the state (say the clergy) results from the *fundamental laws*, by which the respective *rights* of the *king* and of the *nation are ascertained*, and from which not the smallest deviation can be made. The first of these laws is, that the government of France is purely monarchical. The nation must preserve inviolate the form of its government, which it acknowledges to be a *pure monarchy regulated by the laws*; and such it will have it to remain."

On the 28th of November 1788, in a general committee of the nobles assembled at Versailles, the Prince of Conti delivered a note to the president, which was sanctioned by the concurrence of most of the other princes of the blood, and was supposed to speak the general sense of the nobility; in which it was insisted, that the *proscription of all* NEW SYSTEMS *was necessary* to insure the stability of the throne, of *the laws*, and of *order*; and that the constitution, *with the ancient forms*, should be preserved entire. In their instructions to their representatives, they insist that it shall be expressly and solemnly proclaimed, that the constitution of the French empire is such, that its government is, and must remain, monarchical; that the king, as supreme chief of the French, is only subordinate to the fundamental law of the kingdom, according to which the constitution must be established on the sacred and immutable principles of monarchy, tempered by the laws; and this form of government cannot be replaced by any other constitution.

"Let our deputies (says the third estate), before they attend to any other object, assist in giving to France a truly monarchical constitution, which must invariably fix the *rights* of the *king* and of the *nation*. Let it be declared, that the monarchical is the only form of government admissible in France; and that in the *king alone*, as chief of the nation, is vested the power of *governing according to the laws*." Is this the language of men groaning under the iron rod of despotism, or wishing to reduce the power of the crown?

Even after the power of the crown was almost annihilated, and the order of nobility done away, so far were these innovations from being acceptable to the enlightened part of the French nation, that in many departments of the kingdom they excited open insurrections, whilst the members of all the provincial parliaments opposed them with unanswerable arguments furnished by the law. The chamber of vacation of the parliament of Toulouse, in particular, protested against the proceedings of the States General, because the deputies, who were empowered only to put an end to the ruinous state of the finances, could not change the constitution of the state without violating their instructions, and the faith sworn to their constituents *.

* See the protest at large in *Bertrand's Memoirs*, vol. iii. c. 13.

That *lettres de cachet* were liable to abuse, and that occasionally they were grossly abused, is certain. The use of them ought therefore to have been either annulled, or, which would have been infinitely better, subjected to such rules as should prevent all danger from them to the real liberties of the people; for the government would be of no use whatever which should possess no power capable of being abused by despotism. Yet after all the noise that has been made about *lettres de cachet*, it is but justice to observe, that in the towers of the Bastile, when it was taken by the mob, were found no more than seven prisoners; of whom four were confined for forgery; one was confined at the request of his family on charges of the most serious nature; and two were so deranged that they were sent next day, by those philanthropists who had taken them out of comfortable chambers, to the mad house! That the chambers of the Bastile were as comfortable as the chambers of a prison could be, we are assured by M. Bertrande de Moleville, who can be under no inducement to deceive the British public, and whose opportunities of discovering the truth were such as no man will call in question.

451 Lettres de cachet.

452 Blunder of Necker.

In our account of the opening of the States General, we have expressed too much deference to the character of M. Necker. To that man's irresolute, if not treacherous, conduct, may, with truth, be attributed all the subsequent miseries of France. It was about the mode of verifying their powers that the three orders of the state first differed; but that mode should have been defined by the ministry in the letters sent to the different bailiwicks for the convention of the states. Even this omission might have been repaired after the arrival of the deputies at Versailles; for none of them should have been admitted into the hall of the states, far less should the king have met them there, till the Council had been satisfied of their being duly elected. Had either of these cautions been observed, the *tiers-etat* never could have got the ascendant over the other two orders, and the business of the nation would have been conducted as formerly in three different chambers. M. Necker's rejection of Mirabeau's advances shewed him to be very ill qualified to conduct the helm of affairs at such a crisis; and his absenting himself from the royal session, a measure which he had advised, betrayed the utmost ingratitude to his gracious master.

In our account of the royal session, we were led into a mistake, which calls loudly for correction. The circumstances of that session were very different from what they appeared to us when we wrote n° 24. and 25. of the article REVOLUTION. The royal session was proclaimed in consequence of the violent usurpations of the *tiers-etat*, and the irreconcileable differences which subsisted between that body and the two higher orders; and so far is it from being true that the president and members of the third state found their hall *unexpectedly* surrounded by a detachment of guards, that their sittings were only *suspended*, for the best of all reasons, with those of the other orders. To be convinced of this, we need but to attend to the following proclamation which was made by the heralds, on the 20th of June, between seven and eight o'clock in the morning, in the streets and cross-ways of Versailles: 453 Royal Session.

"June 20th. (By order of the King.) The King having resolved to hold a royal sitting in the States General, on Monday next the 22d of June, the preparations to be made in the three halls used by the assemblies

French Revolution.

blies of the orders, make it neceſſary that thoſe aſſemblies ſhould be ſuſpended until after the ſaid ſitting. His Majeſty will give notice, by another proclamation, of the hour of his going to the Aſſembly of the States on Monday."

M. Bailly, the preſident of the *tiers-etat*, had been made acquainted with the object of this proclamation, by a private letter which was ſent to him by the Marquis de Brezé at ſeven o'clock in the morning; and to which he replied, "that having received no orders from the King, and the aſſembly having been announced for eight o'clock, he ſhould attend where his duty called him."

He repaired, accompanied by a great number of the members of the *tiers-etat*, to the door of the hall of the States, demanded admiſſion; and on being refuſed by the officer on guard, according to his orders, with which he acquainted him, he declared that he proteſted againſt ſuch orders, and that he ſhould give a report of them to the Aſſembly. To do this he had not far to go, as three-fourths of the deputies of the *tiers-etat*

454 Factious insolence of the assembly.

were already collected round him, or in the avenue leading to the palace. There it was that, ſurrounded by an immenſe crowd of people, they declaimed in the moſt violent manner againſt this pretended act of deſpotiſm. "The National Aſſembly is to be diſſolved (ſaid they), and the country to be plunged into the horrors of a civil war. *Want* reigns every where; every where the people ſee *famine* ſtaring them in the face. This we were about to put an *end to*, by rending the veil which covers the manœuvres of the monopoliſts, the engroſſers, and the whole tribe of miſcreants. The Louiſes XI. and XIII. the Richelieus, the Mazarins, the Briennes, attacked with their deſpotiſm only individuals or ſmall bodies; but here it is the whole nation that is made the ſport of the whims of a deſpotic miniſtry. "Let us meet upon the *Place d'Armes* (ſaid one of thoſe orators); there we ſhall recal ſome of the nobleſt days of our hiſtory, *the National Aſſemblies of the field of May*." "Let us aſſemble in the gallery of the palace (ſaid another); there we ſhall preſent a new ſight, by ſpeaking the language of liberty, in that corrupt hall, where a little while ſince the head of him who ſhould have uttered that ſacred word would have been devoted to the executioner.—"No, no (ſaid a third), let us go to Marli, and hold our ſitting on the Terrace:—let the King hear us; he will come from his palace, and will have nothing more to do than to place himſelf in the midſt of his people to hold the royal ſitting."

At the concluſion of theſe declamations, the ſole object of which was to alarm and exaſperate the people, the Aſſembly decided upon transferring their ſitting to the Tennis-court, in the ſtreet called *Rue du Vieux Verſailles*. There M. Bailly read the letter which he had received from M. de Brezé, and his anſwer to it; which he had ſcarcely done, when a ſecond letter from M. de Brezé was put into his hands, the contents of which were as follows:

"It was by the King's poſitive order, Sir, that I did myſelf the honour of writing to you this morning, to acquaint you that, his Majeſty purpoſing to hold a royal ſitting on Monday, and ſome preparations being requiſite in the three halls of the aſſemblies of the orders, it was his intention that no perſon ſhould be admitted into them, and that the ſittings ſhould be ſuſpended till after that to be held by his Majeſty."

French Revolution.

In this there was ſurely no marked diſrepect to the repreſentatives of the people; but ſuch notions were countenanced by M. Necker, who appears indeed, on this occaſion, to have been in cloſe compact with the leaders of the mob. The popular violence that was employed to compel the majority of the clergy to join the *tiers-etat* is well known; and we have, in *Bertrand's Annals of the Revolution*, what amounts to evidence almoſt *legal*, and quite ſufficient to enforce conviction, that Necker directed that violence.

In our account of the commotions which were excited in Paris on the firſt diſmiſſion of that miniſter and his baniſhment from the kingdom, we have been led by our democratic journaliſts to give circulation to a groſs calumny publiſhed by them againſt the Prince de Lambeſc. (See Revolution, n° 36. and 37.) The truth, which is ſo much diſguiſed in theſe two numbers, is as follows:

455 Conduct of the Prince de Lambeſc vindicated.

"A detachment of the Royal Allemand, ſent to diſperſe the mob which was patrolling the ſtreets in proceſſion with the buſts of Necker and the infamous Orleans, received a volley from the French guards as they were paſſing their quarters on the *Chauſſée d'Antin*, ſtopped to return it, and continued their march without quickening their pace. There were ſome ſoldiers killed and wounded on both ſides, but fewer of the regiment of Royal Allemand than on that of the French guards.

"The detachment marched to the place Louis XV. and there found a body of dragoons who had been diſperſing the proceſſion. The two buſts were broken to pieces; and the populace in their fright taking refuge in the garden of the Thuilleries, the Prince de Lambeſc purſued them thither, at the head of the detachment of Royal Allemand, according to the orders which he received. This ſmall troop coming up to the head of the *Pont-tournant* (or turning bridge), at the extremity of the garden, found a kind of barricade, haſtily formed by chairs heaped upon one another: while they were removing this obſtacle, they received a ſhower of ſtones, broken chairs, and bottles, from the two terraces, between which the Prince de Lambeſc drew up his troop, keeping conſtantly at their head. Some guns and piſtols were diſcharged at them, which did no hurt; but ſeveral of the troopers were much bruiſed by the things that had been thrown at them, and an officer was ſeverely wounded by a ſtone.

"The Prince de Lambeſc, keeping at ſix paces from the bridge, oppoſed only a ſteady front to the aggreſſions of the populace. Seeing that this poſt became untenable, and that it was impoſſible for him any longer to reſtrain his troopers from repelling force by force, he gave the order for retreating out of the garden. At the ſame inſtant a cry was heard from all ſides of, *turn the bridge, turn the bridge*; and ſome perſons, in conſequence, ran and began to do it. The Prince de Lambeſc, juſtly fearing that a moſt bloody carnage would be the inevitable conſequence of it, ordered ſome piſtols to be fired in the air towards the bridge, to awe thoſe who were ſtriving to turn it. As the report of this volley did not deter them, he rode up himſelf, and with his ſabre ſtruck one of thoſe who were working hardeſt. The man ran off; and the Prince paſſing the bridge with

French Revolution.

with his detachment into the Place Louis XV. drew up near the Statue, and being foon joined by the Swifs regiment of Chateauvieux, took his poft with this force near the *Gardemeuble*, where he remained fome time, having placed the infantry before him. At ten at night part of the troops were difmiffed to their quarters, and the reft fent to Verfailles." Thefe facts being all judicially confirmed, prove how much the Prince de Lambefc's conduct was calumniated by thofe journalifts whofe detail we rafhly adopted.

456 True account of the taking of the Baftile,

In our account of the taking of the Baftile, mifled by our treacherous guides, the journalifts, we have greatly magnified the military fkill and prowefs of the affailants. That celebrated fortrefs was defended by a garrifon confifting of no more than 114 men, of whom 82 were invalids. It was attacked by 30,000 men and women, armed with mufkets and pikes, and furnifhed with a train of artillery which they had found at the *Hotel des Invalids*, given up to them by the timidity of the governor. Even this multitude would have been quickly repulfed from the Baftile, if the governor of that ftate-prifon, who had received no orders from the court, had been lefs reluctant to fhed the blood of his rebellious countrymen; for the Parifian mob had then difplayed nothing of determined courage. A few difcharges of mufquetry, and one of canifter fhot from a fingle cannon, had thrown them into confufion, and made them fkulk behind the walls, when the ill-timed humanity of the governor made him enter into a treaty with the rebels, ftipulating only that the garrifon fhould not be maffacred. How the ftipulation was obferved with refpect to the governor himfelf, we have faithfully related; but we were miftaken when we faid that the "French guards fucceeded in procuring the fafety of the garrifon." The guards, with the utmoft difficulty, faved indeed fome of them, but moft of the invalds remaining in the courts of the caftle were put to death in the moft mercilefs manner.

457 And of the murder of M. de Fleffelles.

Our account of the murder of M. de Fleffelles (n° 40.) appears likewife to be very incorrect. This man was prefident of the affembly of Electors at Paris (See Revolution, n° 45.), and had not quitted the *Hotel de Ville*, where their rebellious meetings were held, during the whole time of thefe dreadful commotions. He had even figned all their atrocious refolutions, but became fuddenly fufpected from the confternation which he manifefted at the fight of fo many horrors, and efpecially at the cruel and treacherous murder of the governor of the Baftile. The confequence was, that he was treacheroufly murdered himfelf by one of the villains compofing that affembly in which he prefided. "The electors (fays M. Bertrand de Molleville) hoped to extenuate the horror of this affaffination, by caufing it to be confidered as a natural and almoft lawful vengeance for a treachery, the proof of which they pretended to have. In fact, they declared, that when M. de Launay, the governor of the Baftile, was arrefted, a letter had been found in his pocket from M. de Fleffelles, containing this expreffion: 'I am amufing the Parifians with cockades and promifes; hold out till night, and you will receive a reinforcement.' But this fuppofed letter, which, had it exifted, they would not have failed to preferve very carefully, was never feen by any body; and I heard M. Bailly himfelf fay, in a vifit he paid me when he left the mayoralty, that he had no knowledge of it, and that it was not in his power to refer to any one who had told him that he had read it."

458 Ambition and cowardice of the Duke of Orleans.

In our account of the earlier tranfactions of the Revolution, we omitted to mention a very extraordinary inftance of ambition to which the Duke of Orleans was incited by Count Mirabeau, but which that unnatural monfter wanted courage to carry into effect. During the commotions which prevailed in the capital on the difmiffal of M. Necker from the miniftry, Orleans was perfuaded by Mirabeau to offer his fervices as mediator between the king and his rebellious fubjects; but to ftipulate, at the fame time, for his appointment to the high office of lieutenant-general of the kingdom as neceffary to give his mediation due weight with the rebels. The real object of the profligate Count, in this dangerous propofal, and which he did not deign even to conceal, was to pave the way for the infamous Duke ftepping into the throne of his relation and virtuous fovereign. He even went fo far as to compofe the fpeech with which Orleans was to addrefs the king on the occafion; but that coward, when he arrived at the palace, was fo embarraffed by the confcioufnefs of his own wicked defigns, that inftead of afking the office of lieutenant general, he only requefted permiffion to retire into England!! A requeft which was inftantly granted.

This brought upon him the contempt and indignation of Mirabeau; but ftill there was a party defirous of placing him on the throne. This we think evident from an atrocious fact mentioned in all the journals, and confirmed by M. Bertrand. "When the king, on his firft vifit to Paris (See n° 44.) had arrived at the *Champ Elifées*, three or four guns were fired at once. It was never known whence they proceeded; but it is certain that an unfortunate woman in the crowd, who was in the direction of his Majefty's carriage, was fhot at the time, and fell dead on the fpot." As the King's carriage held at the time exactly four perfons, M. Bertrand very naturally concludes that thefe four fhots, fired at once in its direction, had been ordered and paid for; and we are unwilling to believe that at that period of the revolution there was any party difpofed to *pay* for the murder of the fovereign but the Duke of Orleans and his infamous adherents. That he was equal to this wickednefs cannot be doubted, when it is known that legal evidence was afterwards produced that he, with fome other members of the Affembly, fecretly directed the infurrection of the 5th of October, and promoted the outrages of that and the fucceeding day by the diftribution of money and bread *.

459 M. Memmay vindicated.

We have faid (n° 48.), the origin of the report of a train of gunpowder being laid by M. de Memmay, to blow into the air a number of patriots, has never been well explained. It was proved judicially, that at the period when the feaft was given by M. Memmay to the inhabitants of Vefoul, he was fetting vines in a ftony foil, where he was often obliged to blow up the greater rocks. Some foldiers running through, and ferreting every where in the houfe and out-houfes, unfortunately took a candle to the dark corner where the barrel of gunpowder was lodged, and fet it on fire, in trying to fee if it contained wine. Thefe facts, reported and attefted in a memorial drawn up by M. Courvoifier, fo completely juftified M. de Memmay, that the Affembly

* *Bertrand's Annals*, vol. ii. ch. 13.

French Revolution.

bly could not avoid teftifying his innocence by a decree iffued the 4th of June.

460 The powers of the affembly in danger of being recalled by its conftituents.

In n° 70 we have faid that the National Affembly, after its removal from Verfailles to Paris, was in tolerable fecurity; but M. Bertrand has proved, by evidence the moft incontrovertible, that it did not think itfelf fecure; and that if the minifters had been capable of employing events to their own advantage, the powers of that factious body muft have been recalled by its own conftituents. The horrible outrages committed on the 5th and 6th of October had fhocked all France. The wanton confifcation of the property of the church, had demonftrated to every man of found judgment, that under the new order of things no property could be fecure: and by the defertion of its more virtuous and moderate members, the Affembly had become *a rump affembly*. It was therefore much alarmed when the intermediate commiffion of the ftates of Cambrefis entered, on the 9th of November, into a refolution, in which, confidering—"that certain decrees of the National Affembly are paving the way for the ruin of the kingdom, and the annihilation of religion; that if they have been able to place one fpecies of property at the difpofal of the nation, men of all kinds of property may expect the fame fate; they declare from this moment, the power of the deputies of Cambrefis to the National Affembly to be null and revoked." Had M. Necker and his colleagues had addrefs to get fimilar refolutions entered into at the fame time by the electors of all the bailiwicks of the kingdom, the Affembly muft have been diffolved, and France, even then, might have been faved; but thofe minifters were themfelves nothing more than the humble and docile agents of the Affembly.

461 True account of the red book,

There is no part of our former narrative more incorrect, or more likely to miflead the public, than our account of the *red-book* (n° 75). It is fuch, however, as was then current, without any addition or aggravation by us. The villains (K) who, in direct contradiction to their own folemn promife, as well as to every principle of honour, made part of that book public, had the impudence to affirm, that by the fuppreffion of the fuperfluous penfions regiftered in it, a faving would be made to the public *of near a fifth in the bulk of the expences of every year*. M. Bertrand, taking for granted the accuracy of their ftatements, for the exaggeration of which, however, he urges arguments more than plaufible, proves, if arithmetical calculation affords proof, that by the fuppreffion of fuch penfions as even *they* called fuperfluous, the faving in the bulk of the annual expences could not poffibly have amounted to more than *the two hundredth part!* It was not therefore without reafon that M. Necker, in anfwer to their publication, faid, "I know not whether the books of the finances of any fovereign in Europe can fhew a fimilar total."

462 And of the mutiny at Nancy.

Our account of the mutiny of the foldiers at Nancy (n° 83.) is very inaccurate. Far from being excited by the officers that mutiny was the natural confequence of the abfurd decrees of the Affembly; which having declared *all men equal*, and made it criminal to punifh difobedient foldiers in that fummary way, without which no armed force can be commanded, had completely diforganifed the army, and fubftituted for martial law patriotic exhortations, legiflative decrees, and the novel jurifdiction of municipalities. The foldiers knew their own ftrength, of which indeed they were continually informed by the friends of the revolution; and while they fhook off the authority of their military commanders, they laughed at the impotent decrees of the Affembly. At Nancy they had imprifoned two general officers, and committed other outrages of the moft ferious nature. It was the duty of the Marquis de Bouillé, as governor of the province, to reduce the infurgents by force, if force fhould be found neceffary; but he had accomplifhed his object without fhedding blood, and was congratulating the two liberated generals, and fome of the principal inhabitants, upon fo happy a termination of the affair, when the populace, and many foldiers who had not followed their colours, fired upon the troops under his command, and killed fifty or fixty men. The troops immediately returned the fire; and a great number of the rebellious mob and mutinous garrifon were of courfe put to the fword. That fuch able and firm conduct in Bouillé excited indignation among the Jacobins of Paris, is very probable; but even the king himfelf did not exprefs higher approbation of it than the National Affembly, who were duly fenfible that it faved themfelves from deftruction, which, had he failed in his enterprife, would have been inevitable. Three months afterwards, indeed, when the fabrication of counter-revolutionary plots became part of the daily bufinefs of this enlightened Affembly, fome cenfures were thrown by the Jacobins upon the Marquis's conduct on this occafion; and thofe cenfures were loudly applauded. 463

M. de Bouillé vindicated.

We have likewife been led, by our fallacious guides, to accufe this gallant officer (n° 91.) of having laid open the country to the inroads of foreign armies; and we have given an incorrect account of the king's flight from Paris. There is no evidence whatever for the truth of the charge againft the Marquis de Bouillé, and it is directly contrary to his general character. He was indeed a royalift, and would doubtlefs have cooperated with the Prince of Condé and the other emigrants in reftoring the king to his lawful authority; but he was likewife a Frenchman and a patriot in the beft fenfe of the word; and he would have died in defence of the rights and independence of his country. He certainly meant to protect the king in his journey from Paris to Montmedi, where it was to terminate; and he had ftationed troops of dragoons on the road for that purpofe; but the unfortunate Louis had delayed his journey a day longer than was agreed upon; and even when he fet out, neglected to fend couriers before him to warn the troops of his approach. He thus travelled unprotected; and the confequence was fuch as we have related. Yet the gallant Bouillé, tho' this journey was undertaken contrary to his advice, declared himfelf the author of it, in that letter in which he threatened the Affembly with vengeance of all Europe

(K) Thefe were the Marquis de Montcalm-Gozon, Baron Felix de Wimpfen, de Menou, Freteau L. M. de Lepeaux, the Abbé Expilly, Camus, Goupil de Prefeln, Gautier de Biauzat, Treilhard, Champeaux-Palafuc, and Cottin.

French Revolution. rope if they ſhould dare to touch a hair of the heads of the royal family.

464 Erroneous account in nº 90. corrected. In nº 90. we have moſt unaccountably ſaid, that the king was permitted to continue his journey to St Cloud. This is directly contrary to truth. The preſident, after hearing his complaint againſt thoſe who had prevented it, replied indeed in a ſpeech, containing ſome expreſſions of gratitude and affection, mixed with reflections on the refractory prieſts; but the Aſſembly determined nothing reſpecting the propriety of the journey. They did not even ſuffer a ſingle motion to be made on the ſubject; and threatened with impriſonment one of the members who propoſed to take it into conſideration! The king was therefore obliged to abandon this excurſion, though it was firſt undertaken from religious motives; and it was then that he ſeriouſly thought of attempting to elude the vigilance of his rebellious guards, and of taking up his reſidence at Montmedi.

465 Treaty of Pavia a forgery. In nº 96. we have publiſhed, with doubts indeed of its authenticity, what was called the *treaty of Pavia* and the *convention at Pilnitz*. The terms in which we introduced that ſcandalous fabrication to the notice of our readers, and the principles which we have uniformly avowed through the whole of this voluminous work, furniſh, we hope, ſufficient evidence that we could have no intention to deceive the public. Truth, however, demands of us to acknowledge, in the moſt explicit terms, that the pretended treaty of Pavia is not only a forgery, but a bungling forgery, defective in ſome of the moſt uſual diplomatic forms; and that the conferences at Pilnitz between the Emperor, the King of Pruſſia, and the Count d'Artois, related to objects very different from a partition of the French territories.

So early as the month of May 1791, a plan had been digeſted by the Emperor, the King of Pruſſia, and the King of Spain, with the concurrence of Louis XVI. for liberating that unfortunate Monarch from the confinement in which he was kept in his own capital. The means to be employed were a coalition among the principal powers on the continent to lead armies in every quarter to the borders of France. During the alarm which ſo menacing an appearance could not but excite in that kingdom, a declaration by the houſe of Bourbon, complaining of the cruel and iniquitous treatment of its head, was to be circulated through France, and to be immediately followed by the manifeſto of the combined powers. This, it was preſumed, would furniſh a ſufficient reaſon, even to the National Aſſembly, for the king's going to the frontiers, and placing himſelf at the head of the army; but if it ſhould not, petitions were to be procured from the army and the provinces, requeſting his preſence, as the only means left of preventing a civil as well as foreign war. Had this meaſure, which was partly ſuggeſted by Mirabeau and partly by Montmorin and Calonne, been ſteadily purſued, there can be little doubt but it would have proved completely ſucceſsful. It was defeated, however, by the king's ill concerted attempt to eſcape to Montmedi, and by a very imprudent and degrading letter which he was afterwards perſuaded to ſend to every foreign power.

466 Real convention at Pilnitz. At Pilnitz, where the Emperor and the King of Pruſſia met, on the 25th of Auguſt, to ſettle between themſelves ſome intereſts too delicate to be adjuſted by the uſual diplomatic modes, an agreement was entered into by them to ſupport the cauſe of the French princes, to liberate the king, and to ſave, if poſſible, the monarchy. They delivered, accordingly, to the Count d'Artois the following declaration:

"His Majeſty the Emperor, and his Majeſty the King of Pruſſia, having heard the deſires and the repreſentations of Monſieur and his Royal Highneſs the Count d'Artois, declare, conjointly, that they conſider the ſituation in which his Majeſty the King of France is at preſent placed, as a matter which concerns the intereſt of every ſovereign of Europe.—They hope that that intereſt will not fail to be acknowledged by the powers whoſe aſſiſtance is required; and that conſequently they will not refuſe to employ, in conjunction with their Majeſties, the moſt efficacious means, according to their abilities, to put the King of France in a ſituation to eſtabliſh, in perfect liberty, the foundations of a monarchical government, equally agreeable to the rights of ſovereigns and the welfare of the French: then, and in that caſe, their Majeſties are determined to act promptly and by mutual conſent, with the forces neceſſary to obtain the end propoſed by all of them. In the mean time they will give orders for their troops to be ready for actual ſervice.

"*Pilnitz, Auguſt* 27. 1791.

"Signed by the Emperor and the King of Pruſſia."

Such was the agreement entered into at Pilnitz, which was ſo groſsly miſrepreſented by the French Jacobins, and by their zealous partizans in this country. Had not Louis XVI. accepted the conſtitution ſimply and unconditionally, the conſequence of this convention might have been the ſaving of the French monarchy, and the preſervation of peace in Europe; but that acceptance, ſo little looked for by the high contracting powers, completely thwarted their meaſures for a time; and before their armies were put in motion, the monarchy was overturned, and the monarch a priſoner.

467 The French the aggreſſors in the war with Britain. In our account of the origin of the war between Great Britain and France (nº 147, 148.), we have proved, by evidence which to ourſelves appears irreſiſtible, that the French regicides were the aggreſſors, and that the Britiſh miniſtry did all that could be done, conſiſtently with the independence of their own country, to maintain the relations of amity between the two nations. That we have interpreted fairly that decree of the Convention by which this kingdom was forced into the war, is rendered incontrovertible by a ſubſequent decree on the 15th of December, by which their generals were ordered to regulate their conduct in the countries which their armies then occupied, or *might afterwards occupy*. In the preamble to this decree, they expreſsly declared, that *their principles would not permit them to acknowledge any of the inſtitutions militating againſt the ſovereignty of the people;* and the various articles exhibit a complete ſyſtem of demolition. They inſiſt on the immediate *ſuppreſſion of all exiſting authorities*, the *abolition of rank and privilege* of every deſcription, and the *ſuppreſſion of all exiſting impoſts*. Nay, theſe friends to freedom even declare, that they will treat as enemies *a whole nation* (un peuple entier) which ſhall preſume to *reject liberty and equality*, or enter into *a treaty with a prince or privileged caſts!*

It is worthy of remark, that *the very day* on which this decree, containing a ſyſtematic plan for diſorganizing all lawful governments, paſſed the Aſſembly, the provi-

French Revolution

provisional executive council wrote to their agent, Chauvelin, instructing him to disavow all hostile intentions on the part of France, and to proclaim her detestation of the idea of a war with England! Yet the same provisional council, in their comments on the 11th article of this decree, thus express themselves: "The right of natural defence, the duty of securing the preservation of our liberty, and the success of our arms, the universal interest of restoring to Europe a peace, *which she cannot obtain but by* THE ANNIHILATION OF THE DESPOTS *and their satellites*, every thing imposes on us the obligation of exercising all the *rigours of war*, and the *rights of conquest*, towards a people so fond of their chains, so obstinately wedded to their degradation, as to refuse to be restored to *their rights*, and who are the accomplices, not only *of their own despots*, but even of all the *crowned usurpers*, who divide among themselves the dominion of the earth and its inhabitants" That Britain is one of those countries which the Assembly thought their armies might afterwards occupy, and that the great majority of Britons were a people towards whom their principles obliged them to exercise all the rigours of war, and the rights of conquest, is evident from the following extract of a letter, written on the 31st of December 1792, by Monge, a member of the council, and minister of the marine to the sea-ports. "The King and his parliament mean to make war upon us. Will the *English republicans suffer it?* Already these free men shew their discontent, and the repugnance which they have to bear arms against *their brothers the French*. Well! we will fly to their succour. We will make a descent on the island; we will lodge there 50,000 *caps of liberty*; we will plant there *the sacred tree*; and we will stretch out our arms to our REPUBLICAN BRETHREN. *The tyranny of their government will be destroyed.*"

As these two decrees of November and December 1792 have never been repealed, and as their object is so plainly avowed in the commentaries of the executive council, and in this letter of the minister of marine, they would alone sufficiently authorise us to adopt as our own the following reflections of M. Bertrand de Moleville*. With these, as they give a concise but perspicuous view of the rise and progress of that revolution, or, to speak more correctly, that series of revolutions which has for seven long years oppressed, not France alone, but all Europe, we shall conclude this

468 long article.

Introduction to the *Annals of the French Revolution.*

Bertrand's view of the rise and progress of the revolution.

"Popular insurrections, and an army (says this able and useful writer), have hitherto been the usual means, or chief instruments, of every revolution; but those insurrections being of the most ignorant and unthinking class of the people, were always fomented by a certain number of factious men, devoted to, and dependent upon, some ambitious chief, daring, brave, of military talents, sole and absolute conductor of every step of the revolt, and master of all the means of the insurrection. In the hands of this chief, the soldiers, or people armed, were but machines, which he set in motion or restrained according to his pleasure, and of which he always made use to put an end to revolutionary disorders and crimes, as soon as the object of the revolution was gained. So Cæsar and Cromwell, after they had usurped the supreme power, lost no time in securing it to themselves, by placing it on the basis of a wise and well-regulated government; and they employed, in quelling the troubles that had favoured their usurpation, those very legions, that same army, which they had used to excite them.

"This was not the case in France: there, the revolution, or rather the first of those it experienced, and of which the others were the inevitable consequence, was not, whatever be supposed, the result of a conspiracy, or preconcerted plan, to overturn the throne, or to place an usurper upon it. It was unexpectedly engendered by a commixture of weakness, ignorance, negligence, and numberless errors in the government. The States General, however imprudent their convocation may have been, would have produced only useful reforms, if they had found the limits of their power marked out by a hand sufficiently firm to have kept them within that extent. It was, however, but too evident that, even before their opening, they were dreaded, and that consequently they might attempt whatever they pleased. From that time, under the name of *Clubs*, various associations and factions sprang up; some more violent than others, but all tending to the subversion of the existing government, without agreeing upon the form of that which was to be substituted: and at that juncture also the projects of the faction, whose views were to have the Duke of Orleans appointed lieutenant-general of the kingdom, began to appear.

"This faction, or more properly this conspiracy, was indeed of the same nature as those that had produced all former revolutions, and might have been attended with the same consequences, had the Duke of Orleans been possessed of that energy of character, that bravery and daring spirit, requisite in the leader of a party. The people had already declared in his favour, and he might very easily have corrupted and brought over a great part of the army, had he been equal to the command of it: but, on the very first occasion of personal risk, he discovered such cowardice and meanness, that he defeated his own conspiracy, and convinced all those who had entered into it, that it was impossible to continue the revolution, either in his favour or in conjunction with him. The enthusiasm the people had felt for him ended with the efforts of those who had excited it.

"Mr Necker, whom the multitude had associated with him in their homage, still preserved for some time his adorers, and that little cabal which was for ever exalting him to the skies. But as he was inferior even to the Duke of Orleans in military talents and dispositions, he was as little calculated to be the leader of a revolution, or of a great conspiracy: for which reason his panegyrists then confined themselves in their pamphlets and placards, with which the capital was overrun, to insinuating that the only means of saving the state was to declare Mr Necker *Dictator;* or at least to confer upon him, under some title more consistent with the monarchy, the authority and powers attached to that republican office. In fact, if after his dismission, in the month of July 1789, he had dared to make this a condition of his return to the ministry, it is more than probable that the king would have been under the necessity of agreeing to it, and perhaps of re-establishing in his person the office of mayor of the palace. At that moment he might have demanded any thing: eight days later, he might have been refused every thing; and

French Revolution.

and very ſoon after, he was reduced to ſneak out of the kingdom, in order to eſcape the effects of the general contempt and cenſure which he had brought upon himſelf.

" General La Fayette, who then commanded the Pariſian National Guard, gathered the wrecks of all this popularity, and might have turned them to the greateſt advantage, if he had poſſeſſed ' that reſolute character and heroic judgment' of which Cardinal de Retz ſpeaks, and ' which ſerves to diſtinguiſh what is truly honourable and uſeful from what is only extraordinary, and what is extraordinary from what is impoſſible.' With the genius, talents, and ambition of Cromwell, he might have gone as great a length; with a leſs criminal ambition, he might at leaſt have made himſelf maſter of the revolution, and have directed it at his pleaſure: in a word, he might have ſecured the triumph of whatever party he ſhould have declared himſelf the leader. But as unfit for ſupporting the character of Monk as that of Cromwell, he ſoon betrayed the ſecret of his incapacity to all the world, and was diſtinguiſhed in the crowd of conſtitutional ringleaders only by his three-coloured plume, his epaulets, white horſe, and famous ſaying— ' Inſurrection is the moſt ſacred of duties when oppreſſion is at its height.'

" The revolution, at the period when the faction that had begun it for the Duke of Orleans became ſenſible that he was too much a coward to be the leader of it, and when La Fayette diſcovered his inability to conduct it, was too far advanced to recede or to ſtop; and it continued its progreſs, but in a line that no other revolution had taken, viz. without a military chief, without the intervention of the army, and to gain triumphs, not for any ambitious conſpirator, but for political and moral innovations of the moſt dangerous nature; the moſt ſuited to miſlead the multitude, incapable of comprehending them, and to let looſe all the paſſions. The more violent combined to deſtroy every thing; and their fatal coalition gave birth to Jacobiniſm, that terrible monſter till then unknown, and till now not ſufficiently unmaſked. This monſter took upon itſelf alone to carry on the revolution; it directed, it executed, all the operations of it, all the exploſions, all the outrages: it every where appointed the moſt active leaders, and, as inſtruments, employed the profligates of every country. Its power far ſurpaſſed that which has been attributed to the inquiſition, and other fiery tribunals, by thoſe who have ſpoken of them with the greateſt exaggeration. Its centre was at Paris; and its rays, formed by particular clubs in every town, in every little borough, overſpread the whole ſurface of the kingdom. The conſtant correſpondence kept up between thoſe clubs and that of the capital; or, to uſe their own expreſſion, *des Sociétés populaires affiliées avec la Société mere*—' between the affiliated popular Societies and the parent Society,' was as ſecret and as ſpeedy as that of free-maſons. In a word, the Jacobin clubs had prevailed in cauſing themſelves to be looked up to as the real national repreſentation. Under that pretence they cenſured all the authorities in the moſt imperious manner; and whenever their denunciations, petitions, or addreſſes, failed to produce an immediate effect, they gained their point by having recourſe to inſurrection, aſſaſſination, and fire. While Jacobiniſm thus ſubjected all France to its controul, an immenſe number of emiſſaries propagated its doctrines among foreign nations, and prepared new conqueſts for it.

French Revolution.

" The National Aſſembly, the capital, indeed we may ſay all France, was divided into three very diſtinct parties. The moſt conſiderable in number, but unhappily the weakeſt through a deficiency of plan and reſolution, was the party purely Royal: it was adverſe to every kind of Revolution, and was ſolely deſirous of ſome improvements, with the reform of abuſes and pecuniary privileges:—the moſt able, and moſt intriguing, was the Conſtitutional party, or that which was deſirous of giving France a new monarchical conſtitution, but modified after the manner of the Engliſh, or even the American, by a houſe of repreſentatives. The third party was the moſt dangerous of all, by its daring ſpirit, by its power, and by the number of proſelytes it daily acquired in all quarters of the kingdom: it compriſed the Democrats of every deſcription, from the Jacobin clubs, calling themſelves *Friends of the Conſtitution*, to the anarchs and robbers.

" The Democratic party, which at firſt was only auxiliary to the Conſtitutional one, in the end annihilated it, and became itſelf ſubdivided into ſeveral other parties, whoſe fatal ſtruggles produced the ſubſequent revolutions, and may ſtill produce many more. But in principle, the Conſtitutionaliſts and the Democrats formed two diſtinct, though confederate, factions; both were deſirous of a revolution, and employed all the uſual means of accompliſhing it, except troops, which could be of no uſe to them, for neither of them had a leader to put at the head of the army. But as it was equally of importance to both that the king ſhould be deprived of the power of making uſe of it againſt them, they laboured in concert to diſorganiſe it; and the complete ſucceſs of that manœuvre was but too fully proved by the fatal iſſue of the departure of the royal family for Montmedi. The revolution then took a more 469
daring and rapid ſtride, which was concluded by the pretended conſtitution act of 1791. The incoherence of its principles, and the defects of its inſtitutions, preſent a faithful picture of the diſunion of its authors, and of the oppoſite intereſts by which they were ſwayed. It was, properly ſpeaking, a compact between the faction of the Conſtitutionaliſts and that of the Democrats, in which they mutually made conceſſions and ſacrifices.

Conſtitution of 1791 completes the firſt revolution.

" Be that as it may, this abſurd conſtitution, the everlaſting ſource of remorſe or ſorrow to all who bore part in it, might have been got over without a ſhock, and led back to the old principles of monarchical government, if the Aſſembly who framed it had not ſeparated before they witneſſed the execution of it; if, in impoſing on the king the obligation to maintain it, they had not deprived him of the power and the means; and above all, if the certain conſequence of the new mode of proceeding at the elections had not been to ſecure, in the ſecond Aſſembly, a conſiderable majority of the Democratic againſt the Conſtitutional party.

" The ſecond Aſſembly was alſo divided by three factions, the weakeſt of which was the one that wiſhed to maintain the conſtitution. The other two were for a new revolution and a republic; but they differed in this, that the former, compoſed of the Briſſotins and Girondiſts, was for effecting it gradually, by beginning with diveſting the king of popularity, and allowing the public

French Revolution.

public mind time to wean itfelf from its natural attachment to monarchy; and the latter, which was the leaft numerous, was eager to have the republic eftablifhed as foon as poffible. Thefe two factions, having the fame object in view, though taking different roads, were neceffarily auxiliaries to each other; and the pamphlets, excitations to commotion, and revolutionary meafures of both, equally tended to overthrow the conftitution of 1791.

"Thofe different factions, almoft entirely compofed of advocates, folicitors, apoftate priefts, doctors, and a few literary men, having no military chief capable of taking the command of the army, dreaded the troops, who had fworn allegiance to the conftitution, and obedience to the king, and who moreover might be influenced by their officers, among whom there ftill remained fome royalifts. The fureft way to get rid of all uneafinefs on this fubject, was to employ the army in defending the frontiers. For this purpofe a foreign war was neceffary, to which it was known that the king and his council were equally averfe. No more was wanting to determine the attack which was directed, almoft at the fame time, againft all the minifters, in order to compel them to retire, and to put the king under the neceffity of appointing others more difpofed to fecond the views of the parties. Unhappily this attempt was attended with all the fuccefs they had promifed themfelves; and one of the firft acts of the new miniftry was to declare war againft the Emperor. At the fame time, the emigration that had been provoked, and which was almoft everywhere applauded, even by the loweft clafs of people, robbed France of the flower of the royal party, and left the king, deprived of his beft defenders, expofed to the fufpicions and infults that fprang from innumerable calumnies, for which the difafters at the beginning of the war furnifhed but too many opportunities.

470 The fecond revolution.

"In this manner was prepared and accelerated the new revolution, which was accomplifhed on the 10th of Auguft 1792, by the depofition and imprifonment of the king, and by the moft flagrant violation of the conftitution of 1791. The latter, however, was not entirely abandoned on that day; for the project of the Girondifts, who had laid the plot of that horrible confpiracy, was then only to declare the king's depofition, in order to place the prince royal upon the throne, under the guidance of a regency compofed of their own creatures; but they were hurried away much farther than they meant to go, by the violence with which the moft furious of the Jacobins, who took the lead in the infurrection, conducted all their enterprifes. The prince royal, inftead of being crowned, was fhut up in the Temple; and if France at that moment was not declared a republic, it was lefs owing to any remaining refpect for the conftitution, than to the fear the legiflative body was in of raifing the army againft it, and alfo the majority of the nation, who would naturally be angry to fee a conftitution which feemed to be rendered fecure and ftable by fo many oaths, thus precipitately overthrown, without their having been confulted.

"It was on thefe confiderations that the opinion was adopted, that a National Convention fhould be convoked, to determine the fate of royalty. Prompt in feizing all the means that might enfure the fuccefs of this fecond revolution, the Affembly, under pretence of giving every poffible latitude to the freedom of elections, decreed, that all its members fhould be eligible for the National Convention.

"From that moment the Girondifts daily loft ground, and the moft flaming members of the Democratic party, fupported by the club of Jacobins, by the new Commune of Paris, and by the Tribunes, made themfelves mafters of every debate. It was of the utmoft importance to them to rule the enfuing elections; and this was fecured to them by the horrible conflernation which the maffacres of the 2d of September ftruck throughout the kingdom. The terror of being affaffinated, or at leaft cruelly treated, drove from all the Primary Affemblies, not only the royalifts and conftitutionalifts, but moderate men of all parties. Of courfe, thofe affemblies became entirely compofed of the weakeft men and the greateft villains exifting in France; and from among the moft frantic of them were chofen thofe members of the Convention who were not taken from the legiflative body. Accordingly, this third Affembly, in the firft quarter of an hour of their firft fitting, were heard fhouting their votes for the abolition of royalty, and proclaiming the republic, upon the motion of a member who had formerly been a player.

"Such an opening but too plainly fhewed what was to be expected from that horde of plunderers which compofed the majority of the National Convention, and of whom Robefpierre, Danton, Marat, and the other ringleaders, formed their party. That of the Briffotins and Girondifts ftill exifted, and was the only one really republican. Thefe femi-wretches, glutted with the horrors already committed, feemed defirous of arrefting the torrent of them, and laboured to introduce into the Affembly the calm and moderation that were neceffary to give the new republic a wife and folid organization. But the fuperiority of their knowledge, talents, and eloquence, which their opponents could not difpute, had no power over tigers thirfting for blood, who neither attended to nor fuffered motions but of the blackeft tendency. No doubt they had occafion for atrocities upon atrocities to prepare the terror-ftruck nation to allow them to commit, in its name, the moft execrable of all, the murder of the unfortunate Louis XVI.: and that martyrdom was neceffary to bring about a third revolution, already brewing in the brain of Robefpierre. Fear had greatly contributed to the two former: but this was effected by terror alone, without popular tumults, or the intervention of the armies; which, now drawn by their conquefts beyond the frontiers, never heard any thing of the revolutions at home, till they were accomplifhed, and always obeyed the prevailing faction, by whom they were paid. 471 The third revolution.

"By the decree of ferocity difcovered by the members of the Convention in paffing fentence upon the king, and in the debates relative to the conftitution of 1793, Robefpierre was enabled to mark which of the deputies were likely to fecond his views, and which of them it was his part to facrifice.

"The people could not but with tranfport receive a conftitution which feemed to realife the chimera of its fovereignty, but which would only have given a kind of conftruction to anarchy, if the execution of this new code had not been fufpended under the pretext, belonging in common to all acts of defpotifm and tyranny, of *the fupreme law of the fafety of the ftate.* This fufpen-

French Revolution.

sion was effected, by establishing the Provisionary Government, which, under the title of Revolutionary Government, concentrated all the powers in the National Convention until there should be an end to the war and all intestine troubles.

" Although the faction, at the head of which Robespierre was, had a decided majority in the assembly, and might consequently have considered themselves as really and exclusively exercising the sovereign power, he was a demagogue of too despotic a nature to stomach even the appearance of sharing the empire with so many co-sovereigns. He greatly reduced their number, by causing all the powers invested in the National Assembly by the decrees that had established the revolutionary government, to be transferred to a committee, to which he got himself appointed, and where he was sure of the sole rule, by obtaining for colleagues men less daring than himself, though equally wicked; such as Couthon, St Just, Barrere, and others like them. This committee, who had the assurance to style themselves the *Committee of Public Safety*, very soon seized upon both the legislative and executive powers, and exercised them with the most sanguinary tyranny ever yet heard of. The ministers were merely their clerks; and the subjugated Assembly, without murmur or objection, passed all the revolutionary laws which were proposed, or rather dictated, by them. One of their most horrible and decisive conceptions was that of those Revolutionary tribunals which covered France with scaffolds, where thousands of victims of every rank, age, and sex, were daily sacrificed; so that no class of men could be free from that stupifying and general terror which Robespierre found it necessary to spread, in order to establish and make his power known. He soon himself dragged some members of his own party, such as Danton, Camille des Moulins, and others, whose energy and popularity had offended him, before one of those tribunals, where he had them condemned to death. By the same means he got rid of the chief leaders among the Brissotines and Girondists; while he caused all the moderate republican party, who were still members of the Assembly, except those who had time and address to escape, to be sent to prison, in order to be sentenced and executed on the first occasion.

472 The fourth revolution produces

" In this manner ended the third revolution, in which the people, frozen with terror, did not dare to take a part. Instead of an army of soldiers, Robespierre employed an army of executioners and assassins, set up as revolutionary judges; and the guillotine, striking or menacing all heads indiscriminately, made France, from one end to the other, submit to him, by the means of terror or of death. Thus was this nation, formerly so proud, even to idolatry, of its kings, seen to expiate, by rivers of blood, the crime of having suffered his to be spilt who was the most virtuous of all their monarchs.

" In the room of that famous Bastile, whose celebrated capture and demolition had set only seven prisoners at liberty, two of whom had been long in a state of lunacy, the colleges, the seminaries, and all the religious houses of the kingdom, were converted into so many state prisons, into which were incessantly crowded, from time to time, the victims devoted to feed the ever-working guillotines, which were never suffered to stand still for a day, because they were at once the chief resource of supplies for the government, and the instrument of its ferocity. ' The guillotine coins money for the republic,' was said in the tribune by one of Robespierre's vilest agents *. In fact, according to the jurisprudence of the Revolutionary Tribunals, the rich of every class, being declared suspected persons, received sentence of death, for no other reason than that of giving the confiscation of their property a show of judicial form.

* *Barrere.*

" Still blood flowed too slowly to satisfy Robespierre; his aim was but partly attained by the proscription of the nobles, the priests, and the wealthy. He fancied, not only an aristocracy of talents and knowledge, but of the virtues, none of which would his trusty orators and journalists admit, save that horrid *patriotism* which was estimated according to the enormity of the crimes committed in favour of the revolution. His plan was to reduce the French people to a mere plantation of slaves, too ignorant, too stupid, or too pusillanimous, to conceive the idea of breaking the chains with which he would have loaded them in the name of liberty; and he might have succeeded in it, had not his ambition, as impatient as it was jealous, too soon unveiled the intention of resorting to the guillotine to strike off the shackles with which an assembly of representatives of the nation fettered, or might fetter, his power. He was about to give this decisive blow, which he had concerted with the Commune of Paris, the Revolutionary Tribunal, the Club of Jacobins, and the principal officers of the National Guard, when the members of the Convention, who were marked out to be the first sacrificed, anticipated him at a moment when he least expected it, by attacking himself in the Assembly, with energy sufficient to rouse all the sections of the capital against him and against the Jacobins. The parties came to blows, and victory remained uncertain for several hours; but at length declared against Robespierre. In the space of a day, that execrable monster was dragged from the highest pitch of power ever attained by any tyrant, to the very scaffold that was still reeking with the blood of his last victims. His principal accomplices in the Committee of Public Safety, in the Commune, in the National Guard, in the Revolutionary Tribunal, and many of his agents in the provinces, met the same fate. The Revolutionary Tribunals were suppressed, and the prisons thrown open to all whom they had cast into them.

473 The constitution of 1795.

" This fourth revolution, in which the faction then esteemed the moderate party overthrew the terrorists, and seized the supreme power, was no less complete than those which had preceded it, and produced the constitution of 1795. All France received as a great blessing a constitution that delivered them from the revolutionary government and its infernal policy. Besides, it had, in spite of great defects, the merit of coming nearer than the two preceding ones, to the principles of order, of justice, and real liberty; the violation of which had, for five years before, been the source of so many disasters and so many crimes. The royalists, considering it as a step towards monarchy, were unfortunately so imprudent as to triumph in it; and their joy, as premature as indiscreet, alarmed the Assembly to such a degree, that they passed the famous law, ordaining the Primary Assemblies to return two-thirds of the members of the Convention to the legislative body, which

was

French Revolution.

was to succeed that assembly. It was thus that the spirit of the Convention continued, for the first year, to be displayed in the two councils.

"In the year following, the bias of the public mind, perhaps too hastily turned towards royalty, shewed itself in the elections of the members for the new third, so clearly as to alarm the regicides who composed the Directory, and the Conventionalists, who still made a third of the legislative body; nor did they lose a moment in devising means for their defence. That which appeared the surest to them was, to publish notices of plots among the royalists, and annex one or more denunciations, in terms so vague as to leave room for implicating, when necessary, all their adversaries; while by the help of this imposture they procured some secret information, artfully fabricated, and ever easily obtained through threats or rewards by those who have at command the guillotine and the public treasure.

"This masked battery was ready to be opened before the members of the new third took their seats. These at first confined themselves to the securing of a constant majority in the two councils in favour of the moderate opinions; but in a little time every sitting was marked by the repeal of some revolutionary law, or by some decree tending to restrain the executive authority within the limits fixed by the constitution.

473 The fifth revolution.

"The Directory, alarmed at the abridgment of their power, and dreading still more serious attacks upon it, came to a resolution of no longer postponing the blow they had been meditating against the legislative assembly: and they accomplished, in the manner related in n° 309. a fifth revolution, as complete as any of those by which it was preceded. It differed indeed from them essentially in the facility and promptness with which it was effected, although the party which prevailed, that is to say, the majority of the Directory, and the minority of the Legislative Body, had to combat not only against the constitution, but against the opinion, and even against the indignation, of the public. That moral force, on which the majority of the two councils had unluckily placed all their reliance, vanished in an instant before the physical force of a detachment of troops consisting of six or seven hundred men; so true is it that the power of the public opinion, ridiculously exaggerated in these days, is and can be no more, under a firm and well ordered government, than a mere fancy. Men accustom themselves too easily to take for public opinion the private opinions made public by certain writers, whose caution or audaciousness depends always upon the energy or feebleness of the supreme authority. It is the same thing with popular commotions: they are easily excited under a weak government, which does not possess the wisdom to prevent or the spirit to suppress them; but a vigorous, just, and strict government has nothing to fear from them. The Directory, compelled to withdraw the larger body of troops, which they had thought necessary to ensure the revolution they were meditating, discovered, no doubt, great ability in securing the two councils, by appearing to dread them: but it was chiefly to the energy of their measures, and to the concentration and promptness with which they were executed, that they owed their success. Two days before, the legislative body might, without obstruction, have impeached, arrested, and even outlawed, the majority of the Directory, who were execrated by the public under the title of Triumvirate; and, if requisite, they would have been supported by more than 30,000 armed citizens, who, with Pichegru and Villot at their head, would soon have dispersed, and perhaps brought over, the feeble detachments of troops of the line which the Directory had at their command. The legislative body, relying too much upon its popularity, did not sufficiently consider, that the people, whose impetuosity is commonly decisive when allowed to take advantage in attack, are always feeble on the defensive, and totally unable to withstand every assault made previous to an insurrection, for it is always easy to prevent their assembling. It was on this principle that the Directory founded their operations, and the 5th of September too well proves how justly. That day reduced the legislative body, by the most degrading subjugation, to a mere disgusting caricature of national representation; it invested the Directory with the most arbitrary and tyrannic power, and restored the system of Robespierre, under a form less bloody, but not less pernicious; for the Revolutionary Tribunals which that monster had established, were scarcely more expeditious than the military ones of the Directory. The power of arbitrary and unlimited transportation is, in time, as destructive as the guillotine, without possessing, like that, the advantage of exciting a salutary horror, which, by recovering the people from the state of stupor and apathy, the constant effects of terror, gives them both recollection and force to break their chains. Though, in violating the most essential regulations of the constitution, the Directory obtained a temporary confirmation of their power, their example pointed out to Bonaparte and Sieyes the path which they pursued with infinite address, and in which they accomplished a sixth revolution." 474 The sixth revolution, and consular government.

How long the consular government will continue, it is impossible to conjecture; but Bonaparte has laboured successfully to reconcile to it a great part of the nation. Soon after his succession, he relaxed the severity of the existing laws against the emigrants; and he has, from time to time, struck off such numbers from the black roll of Robespierre and the Directory, that many persons, known to be royalists, as well as members of the constituent assembly, have returned to France, and enjoyed offices of trust under his government. To some he has even restored such parts of their estates as were not, by a deed of the nation, in the possession of other individuals; and he gives no countenance at his court to the Jacobinical appellation of *Citizen*, or the rest of the slang of liberty and equality.

The Cardinals had, at Venice, proceeded to the election of a Pope, while Rome was in the possession of the troops of the Directory; but the Emperor, having restored that city, together with the wreck of the ecclesiastical state, to the new Pontiff, the Chief Consul, after the battle of Marengo, not only acquiesced in the measure, but, as soon as he was firmly seated on his throne, made overtures to his Holiness for the readmission of France into the bosom of the church. This was the most judicious step that he could have taken, and the best calculated to support his authority. Having no religion himself, he was induced to establish the Catholic in preference to the Reformed, only because he found it most agreeable to the majority of the French people; but he granted to the Protestants the most li- 475 The restoration of Christianity in France.

beral

French Revolution. beral toleration, and ſeems, by his concordate with the Pope, to have retained to himſelf an authority over the church little ſhort of that which was aſſumed by Henry VIII. of England, when he broke off all correſpondence with the court of Rome.

Theſe meaſures were ſo popular, that when he reſtored peace to the republic, he was ſuddenly choſen Conſul for life; and it was even propoſed by ſome of his creatures to convert the republic into an *empire*, and create him the *firſt Emperor of the Gauls*. This propoſal, however, was ſupported by no party. The royaliſts could not give their vote for elevating a foreigner to a higher rank than was ever held by that auguſt family, for the ſupport of which they had hazarded their lives and fortunes. The genuine democrat ſubmitted with reluctance to the power of a Conſul, and abhorred the very ſound of the words *Emperor* and *empire*. Even the moderate conſtitutionaliſt, who thinks it his duty to ſupport every government which happens to be eſtabliſhed, was aſhamed to relinquiſh ſo openly the principles which had induced him to rebel againſt Louis
477 Bonaparte Conſul for life. XVI. Bonaparte was therefore not made an Emperor, but a *Conſul for life*, with more than Imperial power; and was authoriſed to nominate his ſucceſſor, in the event of his dying without male iſſue.

If this laſt revolution operate not as a warning to all the nations of Europe, ſhewing them the extreme danger of ſudden and violent innovations in the government of a great ſtate; if it convince them not that the ſovereignty of the people is, in ſuch a ſtate, the parent of individual deſpotiſm; and that the principles of democracy, however plauſible they may appear in a political eſſay, cannot be carried into practice—we muſt conclude that theſe nations are incapable of learning wiſdom from experience. In the 17th century the conſtitution of Great Britain was overturned, and a virtuous monarch murdered, to make way for a republic, which ſoon gave place to the military deſpotiſm of a private Engliſh gentleman. In the ſucceeding century a crew of lawyers and philoſophiſts, who, under the denomination of the ſtates general, had been called together to deviſe ſome remedy for the diſorder into which the finances of France had fallen, ſnatched the ſceptre from the hands of their mild ſovereign, who was ſoon afterwards brought to the block. In France, as in England, the monarchy was ſucceeded by a democratical government, exceeding in tyranny and cruelty all the deſpotiſms of ſingle men, whether called Kings or
478 Conſequences of violent innovations. Emperors, that the world has yet ſeen. There, too, the democracy gave place to the military deſpotiſm of a private gentleman; but that gentleman is not a native, but a foreign adventurer, of a family never heard of beyond the limits of the little iſle of Corſica till after the commencement of the revolution, which involved all Europe in its vortex. If the conſular government continue, the reign of equality is indeed at an end; but the ſurrounding nations have more to dread from conſular ambition, than they had to dread from the ambition of Louis XIV. when he was at the ſummit of his glory and his arrogance. Many circumſtances conſpired to reſtrain his Majeſty's ambition within certain limits; but the ambition of him who has no ſon to ſucceed him, and who is placed in ſuch a ſituation, that events may fall out which will preſent to him no perſonal ſafety but in foreign war, is obviouſly under no reſtraint. All this might have been prevented had the coaleſced powers, at the beginning of the conteſt, acted conſcientiouſly on the principles ſo ably enforced by that illuſtrious ſtateſman Mr Burke; but the King of Pruſſia's jealouſy of the Houſe of Auſtria made him abandon the cauſe, and, for the ſake of humbling his rival, ſacrifice Europe to the ambition of France.

Rhabdology || Rice.

RHABDOLOGY, or RABDOLOGY, in arithmetic, a name given by Napier to a method of performing ſome of the more difficult operations of numbers by means of certain ſquare little rods. Upon theſe are inſcribed the ſimple numbers; then by ſhifting them according to certain rules, thoſe operations are performed by ſimply adding or ſubtracting the numbers as they ſtand upon the rods. See Napier's *Rabdologia*, printed in 1617. See alſo the article *NAPIER's Bones*.

RHOMB SOLID, conſiſts of two equal and right cones joined together at their baſes.

RICE (ſee that article, and ORYZA, *Encycl.*) is ſtrongly recommended, in a late publication, as the beſt corrective of *ſprit* flour, of which there is a great quantity in Scotland every year, and of courſe a great deal of unpleaſant and unwholeſome bread. The gentleman, who writes the ſhort paper alluded to, directs ten pounds of flour and one pound of ground rice, with the uſual quantity of yeſt, to be placed, for about two hours, before a fire, and then formed into bread in the common way. This addition of rice, beſides correcting the bad qualities of the damaged flour, adds, he ſays, much to its nutriment: and he is undoubtedly right; for the flour of rice, though very nutritious, is ſo dry, that it is difficult to make bread of it by itſelf. See *BREAD of Rice* in this *Suppl.*

As rice is a favourite ſubſtitute for bread in years of ſcarcity, it may not be diſagreeable to our readers to know the method of cultivating the plant in thoſe countries where it is the principal food of the inhabitants. We have the following full and perſpicuous account of the Chineſe practice by Sir George Staunton.

"Much of the low grounds in the middle and ſouthern provinces of the empire are appropriated to the culture of that grain. It conſtitutes, in fact, the principal part of the food of all thoſe inhabitants, who are not ſo indigent as to be forced to ſubſiſt on other and cheaper kinds of grain. A great proportion of the ſurface of the country is well adapted for the production of rice, which, from the time the ſeed is committed to the ſoil till the plant approaches to maturity, requires to be immerſed in a ſheet of water. Many and great rivers run through the ſeveral provinces of China, the low grounds bordering on thoſe rivers are annually inundated, by which means is brought upon their ſurface a rich mud or mucilage that fertilizes the ſoil, in the ſame manner as Egypt receives its fecundative quality from the overflowing of the Nile. The periodical rains which fall near the ſources of the Yellow and the Kiang rivers, not very far diſtant from thoſe of the Ganges and the Burampooter, among the mountains bounding India to the north, and China to the weſt, often ſwell thoſe rivers to a prodigious height, though not a drop of rain ſhould have fallen on the plains through which they afterwards flow.

"After the mud has lain ſome days upon the plains in China, preparations are made for planting them with rice. For this purpoſe, a ſmall ſpot of ground is incloſed

Rice.

closed by a bank of clay; the earth is ploughed up; and an upright harrow, with a row of wooden pins in the lower end, is drawn lightly over it by a buffalo. The grain, which had previously been steeped in dung diluted with animal water, is then sown very thickly on it. A thin sheet of water is immediately brought over it, either by channels leading to the spot from a source above it, or when below it by means of a chain pump, of which the use is as familiar as that of a hoe to every Chinese husbandman. In a few days the shoots appear above the water. In that interval, the remainder of the ground intended for cultivation, if stiff, is ploughed, the lumps broken by hoes, and the surface levelled by the harrow. As soon as the shoots have attained the height of six or seven inches, they are plucked up by the roots, the tops of the blades cut off, and each root is planted separately, sometimes in small furrows turned with the plough, and sometimes in holes made in rows by a drilling stick for that purpose. The roots are about half a foot asunder. Water is brought over them a second time. For the convenience of irrigation, and to regulate its proportion, the rice fields are subdivided by narrow ridges of clay, into small inclosures. Through a channel, in each ridge, the water is conveyed at will to every subdivision of the field. As the rice approaches to maturity, the water, by evaporation and absorption, disappears entirely; and the crop, when ripe, covers dry ground. The first crop or harvest, in the southern provinces particularly, happens towards the end of May or beginning of June. The instrument for reaping is a small sickle, dentated like a saw, and crooked. Neither carts nor cattle are used to carry the sheaves off from the spot where they were reaped; but they are placed regularly in frames, two of which, suspended at the extremities of a bamboo pole, are carried across the shoulders of a man, to the place intended for disengaging the grain from the stems which had supported it. This operation is performed, not only by a flail, as is customary in Europe, or by cattle treading the corn in the manner of other Orientalists, but sometimes also by striking it against a plank set upon its edge, or beating it against the side of a large tub scolloped for that purpose; the back and sides being much higher than the front, to prevent the grain from being dispersed. After being winnowed, it is carried to the granary.

"To remove the skin or husk of rice, a large strong earthen vessel, or hollow stone, in form somewhat like that which is used elsewhere for filtering water, is fixed firmly in the ground; and the grain, placed in it, is struck with a conical stone fixed to the extremity of a lever, and cleared, sometimes indeed imperfectly, from the husk. The stone is worked frequently by a person treading upon the end of the lever. The same object is attained also by passing the grain between two flat stones of a circular form, the upper of which turns round upon the other, but at such a distance from it as not to break the intermediate grain. The operation is performed on a large scale in mills turned by water; the axis of the wheel carrying several arms, which, by striking upon the ends of levers, raise them in the same manner as is done by trading on them.. Sometimes twenty of these levers are worked at once. The straw from which the grain has been disengaged is cut chiefly into chaff, to serve as provender for the very few cattle employed in Chinese husbandry.

Rideau, Ridley.

"The labour of the first crop being finished, the ground is immediately prepared for the reception of fresh seeds. The first operation undertaken is that of pulling up the stubble, collecting it into small heaps, which are burnt, and the ashes scattered upon the field. The former processes are afterwards renewed. The second crop is generally ripe late in October or early in November. The grain is treated as before; but the stubble is no longer burnt. It is turned under with the plough, and left to putrefy in the earth. This, with the slime brought upon the ground by inundation, are the only manures usually employed in the culture of rice."

RIDEAU, in fortification, a small elevation of earth, extending itself lengthwise on a plain; serving to cover a camp, or give an advantage to a post.

RIDEAU is sometimes also used for a trench, the earth of which is thrown up on its side, to serve as a parapet for covering the men.

RIDLEY (Dr Gloster), was of the same family with D. Nicolas Ridley, Bishop of London, and martyr to the Reformation. (See RIDLEY, *Encycl.*) He was born at sea, in 1702, on board the Gloucester East Indiaman; to which circumstance he was indebted for his Christian name. He received his education at Winchester school, and thence was elected to a fellowship at New college, Oxford, where he proceeded B. C. L. April 29. 1729. In those two seminaries he cultivated an early acquaintance with the muses, and laid the foundation of those elegant and solid acquirements for which he was afterwards so eminently distinguished as a poet, an historian, and a divine. During a vacancy in 1728, he joined with four friends. viz. Mr Thomas Fletcher (afterwards Bishop of Kildare), Mr (afterwards Dr) Eyre, Mr Murrison, and Mr Jennens, in writing a tragedy called "The Fruitless Redress," each undertaking an act on a plan previously concerted.. When they delivered in their several proportions at their meeting in the winter, few readers would have known that the whole was not the production of a single hand. This tragedy, which was offered to Mr Wilks, but never acted, is still in MS. with another called "Jugurtha." Dr Ridley in his youth was much addicted to theatrical performances. Midhurst, in Sussex, was the place where they were exhibited; and the company of gentlemen actors to which he belonged consisted chiefly of his coadjutors in the tragedy already mentioned. He is said to have performed the characters of Marc Antony, Jaffier, Horatio, and Moneses, with distinguished applause; a circumstance that will be readily believed by those who are no strangers to his judicious and graceful manner of speaking in the pulpit.

For great part of his life he had no other preferment than the small college living of Westow in Norfolk, and the donative of Poplar in Middlesex, where he resided. To these his college added, some years after, the donative of Romford in Essex. "Between these two places the curricle of his life had (as he expressed it) rolled for some time almost perpetually upon postchaise wheels, and left him not time for even the proper studies of economy, or the necessary ones of his profession." Yet in this obscure situation he remained in possession of, and

Rienzi.

and content with domestic happiness; and was honoured with the intimate friendship of some who were not less distinguished for learning than for worth.

In 1740 and 1741 he preached "Eight Sermons at Lady Moyer's Lecture," which were published in 1742, 8vo. In 1756 he declined an offer of going to Ireland as first chaplain to the Duke of Bedford; in return for which he was to have had the choice of promotion, either at Christ-church, Canterbury, Westminster, or Windsor. His modesty inducing him to leave the choice of these to his patron, the consequence was, that he obtained none of them. In 1763, he published the "Life of Bishop Ridley," in 4to, by subscription, and cleared by it as much as brought him 800l. in the public funds. In the latter part of his life he had the misfortune to lose both his sons, each of them a youth of abilities. The elder, James, was author of "The Tales of the Genii," and some other literary performances. Thomas, the younger, was sent by the East India Company as a writer to Madras, where he was no sooner settled than he died of the small-pox. In 1765, Dr Ridley published his "Review of Philips's Life of Cardinal Pole; and in 1768, in reward for his labours in this controversy, and in another which "The Confessional" produced, he was presented by Archbishop Secker to a golden prebend in the cathedral church of Salisbury (an option), the only reward he received from the great during a long, useful, and laborious life, devoted to the duties of his function. At length, worn out with infirmities, he departed this life in 1774, leaving a widow and four daughters. His epitaph, which was written by Bishop Lowth with his usual elegance, informs us, that for his merits the university of Oxford conferred upon him the degree of D. D. by diploma, which is the highest literary honour which that learned body has to bestow.

RIENZI (Nicolas Gabrini de), one of the most extraordinary men of the 14th century, was born at Rome, we know not in what year. His father, Lawrence Gabrini, was a mean vintner, or, as others say, a miller, and his mother a laundress. These persons, however, found the means of giving their son a liberal education; and to a good natural understanding he joined an uncommon assiduity, and made great proficiency in ancient literature. Every thing which he read he compared with similar passages that occurred within his own observation; whence he made reflections, by which he regulated his conduct. To this he added a great knowledge in the laws and customs of nations. He had a vast memory: he retained much of Cicero, Valerius Maximus, Livy, the two Senecas, and Cæsar's Commentaries especially, which he read continually, and often quoted by application to the events of his own times. This fund of learning proved the basis and foundation of his rise. The desire he had to distinguish himself in the knowledge of monumental history, drew him to another sort of science, in which few men at that time exerted themselves. He passed whole days among the inscriptions which are to be found at Rome, and acquired soon the reputation of a great antiquary. Having hence formed within himself the most exalted notions of the justice, liberty, and ancient grandeur of the old Romans, words he was perpetually repeating to the people, he at length persuaded not only himself, but the giddy mob his followers, that he should one day become the restorer of the Roman republic. His advantageous stature, his countenance, and that air of importance which he well knew how to assume, deeply imprinted all that he said in the minds of his audience.

Rienzi.

Nor was it only by the populace that he was admired; he also found means to insinuate himself into the favour of those who partook of the administration. Rienzi's talents procured him to be nominated one of the deputies sent by the Romans to Pope Clement VI. who resided at Avignon. The intention of this deputation was to make his Holiness sensible, how prejudicial his absence was, as well to himself as to the interest of Rome. At his first audience, our hero charmed the court of Avignon by his eloquence and the sprightliness of his conversation. Encouraged by success, he one day took the liberty to tell the Pope, that the grandees of Rome were avowed robbers, public thieves, infamous adulterers, and illustrious profligates; who, by their example, authorised the most horrid crimes. To them he attributed the desolation of Rome; of which he drew so lively a picture, that the Holy Father was moved, and exceedingly incensed against the Roman nobility. Cardinal Colonna, in other respects a lover of real merit, could not help considering these reproaches as reflecting upon some of his family; and therefore found means of disgracing Rienzi, so that he fell into extreme misery, vexation, and sickness, which, joined with indigence, brought him to an hospital. Nevertheless, the same hand that threw him down, raised him up again. The cardinal, who was all compassion, caused him to appear before the Pope, in assurance of his being a good man, and a great partizan for justice and equity. The Pope approved of him more than ever; and to give him proofs of his esteem and confidence, made him apostolic notary, and sent him back loaded with favours.

Being returned to Rome, he began to execute the functions of his office; and by affability, candour, assiduity, and impartiality, in the administration of justice, he arrived at a superior degree of popularity; which he still improved by continued invectives against the vices of the great, whom he took care to render as odious as possible; till at last, for some ill timed freedoms of speech, he was not only severely reprimanded, but displaced. From this time it was his constant endeavour to inspire the people with a fondness for their ancient liberties; to which purpose he caused to be hung up in the most public places emblematic pictures, expressive of the former splendour and present decline of Rome. To these he added frequent harangues and predictions upon the same subject. In this manner he proceeded till one party looked on him only as a madman, while others caressed him as their protector. At length he ventured to open himself to such as he believed mal-contents. At first he took them separately; afterwards, when he thought he had firmly attached a sufficient number to his interest, he assembled them together, and represented to them the deplorable state of the city, over-run with debaucheries, and the incapacities of their governors to correct or amend them. As a necessary foundation for the enterprise, he gave them an insight into the immense revenues of the apostolic chamber: He demonstrated, that the Pope could, only at the rate of fourpence, raise a hundred thousand florins

Rienzi. rins by firing, as much by falt, and as much more by the cuftoms and other duties. As for the reft, faid he, I would not have you imagine that it is without the Pope's confent I lay hands on the revenues. Alas! how many others in this city plunder the effects of the church contrary to his will!

By this artful lie, he fo animated his auditors, that they declared they would make no fcruple of fecuring thefe treafures for whatever end might be moft convenient; and that they were devoted to the will of him their chief. Having obtained fo much, to fecure his adherents from a revolt, he tendered them a paper, fuperfcribed, "an *oath* to procure the good eftablifhment;" and made them fubfcribe and fwear to it before he difmiffed them. By what means he prevailed on the Pope's vicar to give a tacit fanction to his project, is not certainly known; that he did procure that fanction, and that it was looked on as a mafterpiece of policy, is generally admitted. "The 20th of May, being Whitfunday, he fixed upon to fanctify in fome fort his enterprife; and pretended, that all he acted was by particular infpiration of the Holy Ghoft. About nine, he came out of the church bare-headed, accompanied by the Pope's vicar, furrounded by an hundren armed men. A vaft crowd followed him with fhouts and acclamations." The gentlemen confpirators carried three ftandards before him, on which were wrought devices, infinuating, that his defign was to re-eftablifh liberty, juftice, and peace. In this manner he proceeded directly to the Capitol, where he mounted the roftrum; and, with more boldnefs and energy than ever, expatiated on the miferies to which the Romans were reduced: at the fame time telling them, without hefitation, "that the happy hour of their deliverence was at length come, and that he was to be their deliverer, regardlefs of the dangers he was expofed to for the fervice of the Holy Father and the people's fafety." After which, he ordered the laws of what he called the good eftablifhment to be read: "affured that the Romans would refolve to obferve thefe laws, he engaged in a fhort time to re-eftablifh them in their ancient grandeur."

The laws of the good eftablifhment promifed plenty and fecurity, which were greatly wanted; and the humiliation of the nobility, who were deemed common oppreffors. Such laws could not fail of being agreeable to a people who found in them thefe double advantages; wherefore, "enraptured with the pleafing ideas of a liberty to which they were at prefent ftrangers, and the hope of gain, they came moft zealoufly into the fanaticifm of Rienzi. They refumed the pretended authority of the Romans; they declared him fovereign of Rome; and granted him the power of life and death, of rewards and punifhments, of enacting and repealing the laws, of treating with foreign powers; in a word, they gave him the full and fupreme authority over all the extenfive territories of the Romans.

Rienzi, arrived at the fummit of his wifhes, kept at a great diftance his artifice: he pretended to be very unwilling to accept of their offers, but upon two conditions; the firft, that they fhould nominate the Pope's vicar (the Bifhop of Orvieto) his copartner; the fecond, that the Pope's confent fhould be granted him, which (he told them) he flattered himfelf he fhould obtain. "On the other hand, he hazarded nothing in thus making his court to the Holy Father; and, on the other, he well knew, that the Bifhop of Orvieto would carry a title only, and no authority. The people granted his requeft, but paid all the honours to him: he poffeffed the authority without reftriction; the good Bifhop appeared a mere fhadow and veil to his enterprifes. Rienzi was feated in his triumphal chariot, like an idol, to triumph with the greater fplendour. He difmiffed the people replete with joy and hope. He feized upon the palace, where he continued after he had turned out the fenate; and, the fame day, he began to dictate his laws in the Capitol." This election, though not very pleafing to the Pope, was ratified by him; neverthelefs, Rienzi meditated the obtaining of a title, exclufive of the papal prerogative. Well verfed in the Roman hiftory, he was no ftranger to the extent of the tribunitial authority; and as he owed his elevation to the people, he chofe to have the title of their magiftrate. He afked it, and it was conferred on him and his copartner, with the addition of deliverers of their country. Our adventurer's behaviour in his elevation was at firft fuch as commanded efteem and refpect, not only from the Romans, but from all the neighbouring ftates. But it is difficult for a perfon of mean birth, elevated at once, by the caprice of fortune, to the moft exalted ftation, to move rightly in a fphere wherein he muft breathe an air he has been unaccuftomed to. Rienzi afcended by degrees the fummit of his fortune. Riches foftened, power dazzled, the pomp of his cavalcades animated, and formed in his mind ideas adequate to thofe of princes born to empire. Hence luxury invaded his table, and tyranny took poffeffion of his heart. The Pope conceived his defigns to be contrary to the interefts of the holy fee; and the nobles, whofe power it had been his conftant endeavours to deprefs, confpired againft him: they fucceeded; and Rienzi was forced to quit an authority he had poffeffed little more than fix months. It was to a precipitate flight that he was indebted, at this juncture, for his life; and to different difguifes for his fubfequent prefervation.

Having made an ineffectual effort at Rome, and "not knowing where to find a new refource to carry on his defigns he took a moft bold ftep, conformable to that rafhnefs which had fo often affifted him in his former exploits. He determined to go to Prague, to Charles king of the Romans, whom the year before he had fummoned to his tribunal," and who, he forefaw, would deliver him up to a Pope highly incenfed againft him. He was accordingly foon after fent to Avignon, and there thrown into a prifon, where he continued three years. The divifions and difturbances in Italy, occafioned by the number of petty tyrants that had eftablifhed themfelves in the ecclefiaftical territories, and even at Rome, occafioned his enlargement. Innocent VI. who fucceeded Clement in the papacy, fenfible that the Romans ftill entertained an affection for our hero, and believing that his chaftifement would teach him to act with more moderation than he had formerly done, as well as that "gratitude would oblige him, for the remainder of his life, to preferve an inviolable attachment to the holy fee (by whofe favour he fhould be re-eftablifhed)," thought him a proper inftrument to affift his defign of reducing thofe other tyrants; and therefore, not only gave him his liberty, but alfo appointed him governor and fenator of Rome. He met with many obftacles to the affumption of this newly-granted authority; all which, by cunning and refolution, he at length overcame. But giving way to his paffions, which were immoderately warm, and inclined him to cruelty, he excited fo general a refentment againft him that he was murdered October 8. 1354.

"Such was the end of Nicolas Rienzi, one of the moft renowned men of the age; who, after forming a confpiracy full of extravagance, and executing it in the fight of almoft the whole world, with fuch fuccefs that he became fovereign of Rome; after caufing plenty, juftice, and liberty, to flourifh among the Romans; after protecting potentates, and terrifying fovereign princes; after being arbiter of crowned heads; after re-eftablifhing the ancient majefty and power of the Roman republic, and filling all Europe with his fame during the feven months of his firft reign; after having compelled his mafters themfelves to confirm him in the authority he had ufurped againft their interefts—fell at length at the end of his fecond, which lafted not four months, a facrifice to the nobility whofe ruin he had vowed, and to thofe vaft projects which his death prevented him from putting into execution *."

* Biog. Dict. new edit.

If the reader perceive any thing fimilar at prefent to the rife of this wonderful man to fovereign authority, he may perhaps confole himfelf with the hope that the modern conful will in all probability fall like the modern tribune. Both rofe by difplays of the moft daring courage; the affociates of both were priefts, who in the actual exercife of government were cyphers; both promifed liberty and plenty to the people whom they ruled with abfolute fway; and both have trampled upon the order of nobility.

RING, in aftronomy and navigation, an inftrument ufed for taking the fun's altitude, &c. It is ufually of brafs, about nine inches diameter, fufpended by a little fwivel, at the diftance of 45°, from the point of which is a perforation, which is the centre of a quadrant of 90° divided in the inner concave furface. To ufe it, let it be held up by the fwivel, and turned round to the fun, till his rays, falling through the hole, make a fpot among the degrees, which marks the altitude required. This inftrument is preferred before the aftrolabe, becaufe the divifions are here larger than on that inftrument.

ROBERVALLIAN LINES, a name given to certain lines ufed for the transformation of figures; thus called from their inventor Roberval, an eminent French mathematician, who died in 1675, aged 76 years. Thefe lines bound fpaces that are infinitely extended in length, which are neverthelefs equal to other fpaces that are terminated on all fides.

The Abbot Gallois, in the Memoirs of the Royal Academy, anno 1693, obferves, that the method of transforming figures, explained at the latter end of Roberval's Treatife of Indivifibles, was the fame with that afterwards publifhed by James Gregory, in his *Geometria Univerfalis*, and alfo by Barrow in his *Lectiones Geometricæ;* and that, by a letter of Torricelli, it appears that Roberval was the inventor of this manner of transforming figures, by means of certain lines, which Torricelli therefore called *Robervallian lines*. He adds, that it is highly probable that J. Gregory firft learned the method in the journey he made to Padua in 1668, the method itfelf having been known in Italy from the year 1646, though the book was not publifhed till the year 1692.

This account has been, we think, completely refuted by David Gregory in his vindication of his uncle, publifhed in the Philofophical Tranfactions of 1694. The Abbot, however, rejoined in the Memoirs of the French Academy of 1703; and it is but fair to obferve, that Dr Hutton, fpeaking of the controverfy, expreffes himfelf as if he thought it undecided.

ROCKET (fee *Encycl.* vol. xvi. p. 316.) is alfo a weapon of war much employed in the countries of Hindoftan, combining with the miffile power of the javelin the impulfe of gun-powder. From the force and irregularity of its motion, the rocket is not eafily avoided, and, when thrown in numbers, it often makes very confiderable havock in an army. It confifts of a tube of iron, about eight inches long, and an inch and a half in diameter, clofed at one end: it is filled in the fame way as an ordinary fky-rocket, and fixed to a piece of ftout bamboo, from three to five feet long, the head of which is armed with a heavy iron fpike. At the extremity of the tube, which points towards the fhaft of the weapon, is the match; and the man who ufes it, placing the butt end of the bamboo upon his foot, points the fpiked end in the direction of the object to which he means to throw it, and fetting fire to the fuze, pitches it from him, when it flies with great velocity; and, on ftriking the ground by a bounding horizontal motion, acts with an almoft certain effect in fracturing the legs of the enemy. When a fhower of rockets falls among a body of cavalry, it feldom fails to throw them into confufion.

RODNEY (Lord). In our fhort fketch of the life of that gallant officer (*Encycl.*), we mentioned with regret our not having heard of any monument being erected to his honour in his native conntry. We have fince learned that there is a pillar upon the Brythen in Shropfhire, which was erected to his memory long before the publication of our article.

Having this great man again under our notice, we infert with pleafure the following extract of a letter, which we received from an obliging correfpondent foon after the publication of the volume which contains our biographical fketch of the Admiral: "Whatever were Rodney's merits as a naval commander (fays our correfpondent), there is a more brilliant part of his character which you have entirely neglected. Prior to his fuccefs againft the Spanifh Admiral Don Langara, the Englifh, who had the misfortune to become prifoners of war to the Spaniards, were treated with the greateft inhumanity, and it required more than a common ftrength of conftitution to exift for any length of time in a Spanifh prifon. When the Spanifh admiral fell into the hands of Rodney, he, his officers and feamen, expected to meet with the fame treatment they had always inflicted, and which they would have inflicted on Rodney, his officers, and feamen, had the Spaniards been the victors; but, to their furprife, they found in Admiral Rodney (and, of courfe, in all that were under his command) a man who fympathifed in their misfortune, who minifted to their neceffities, and by a humane and polite behaviour to his prifoners, made an impreffion on the minds of the Spaniards, which could not but have its effect in mitigating the fufferings of the

the Engliſh in Spaniſh priſons: but he did not ſtop here: he took an opportunity, when their minds were expanded by gratitude (and in a ſtate to receive the full force of ſuch a repreſentation), to repreſent to them the miſerable condition of his countrymen who were priſoners in Spain, and obtained a promiſe (which, I believe, was punctually performed), that Engliſhmen, when priſoners in Spain, ſhould be made as comfortable as their ſituation would admit of. This was a piece of ſervice to his country which ſurely merits to be recorded, and which will exalt him as much in the opinion of good men as the moſt brilliant diſplay of *courage*, which is a quality as frequently diſcovered in the ſavage as in the cultivated mind."

ROEBUCK (John, M. D.), was born at Sheffield in Yorkſhire in the year 1718. His father was a conſiderable manufacturer and exporter of Sheffield goods, who by his abilities and induſtry had acquired a competent fortune. John, his eldeſt ſon, the ſubject of this memoir, was intended by his father for carrying on his own lucrative buſineſs at Sheffield; but was, from his early youth, irreſiſtibly attached to other purſuits, more calculated to gratify his ambition, and give fuller play to his powers. Notwithſtanding this diſappointment in his favourite object, his father had liberality enough to encourage his riſing genius, and to give him all the advantages of a regular education.

After he had gone through the uſual courſe of the grammar ſchool at Sheffield, both his father and mother being ſtrict diſſenters, they placed their ſon for ſome years under the tuition of the late Dr Doddridge, who was at that time maſter of an academy at Northampton, and had juſtly acquired high reputation among the diſſenters, both as a divine and as an inſtructor of youth. Under the Doctor's care Mr Roebuck made great proficiency, and laid the foundation of that claſſical taſte and knowledge for which he was afterwards eminently diſtinguiſhed. It would appear that Dr Doddridge had been much pleaſed with the ardour and enthuſiaſm, in the purſuit of knowledge, diſcovered by his pupil; for Mr Roebuck, in an after period of his life, uſed frequently to mention the ſubjects of converſation and inquiries of various kinds, in which the Doctor had engaged him. It was during his reſidence at this academy that he contracted an intimate acquaintance with his fellow-ſtudents, Mr Jeremiah Dyſon, afterwards much known in the political world, and Mr Mark Akenſide, afterwards Dr Akenſide, which terminated only with their lives.

From the academy at Northampton he was ſent to the univerſity of Edinburgh, where he applied to the ſtudy of medicine, and particularly to that of chemiſtry, which about that time began to attract ſome attention in Scotland. While he reſided there he diſtinguiſhed himſelf much among his fellow-ſtudents, in their literary ſocieties and converſations, by great logical and metaphyſical acuteneſs, and by great ingenuity and reſource in argumentation. The late ſagacious Dr Potterfield, to whom he had been introduced, obſerved and encouraged his riſing genius, and was greatly inſtrumental in promoting his improvement. There, too, he formed an intimate acquaintance with Mr Hume, Mr Robertſon, afterwards Dr Robertſon, Mr Pringle, afterwards Lord Alemoor, and ſeveral other perſons of literary eminence; a circumſtance which produced in his mind a partiality ever afterwards in favour of Scotland, and contributed not a little to his making choice of it for the chief field of his future exertions and induſtry.

After Mr Roebuck had gone through a regular courſe of medical education at Edinburgh, being now determined to follow the practice of phyſic, he next ſpent ſome time at the univerſity of Leyden, then in high reputation as the firſt ſchool of medicine in Europe. There, after the uſual reſidence and courſe of trials, he obtained a degree in medicine; and his diploma, dated 21ſt February 1743, has affixed to it the reſpectable names of Muſchenbroek, Oſterdyk, Van Royen, Albinus, Gaubius, &c. He left Leyden, after having viſited ſome part of the north of Germany, about the end of the year.

Soon after his return from the continent, ſome circumſtances induced Dr Roebuck to ſettle as a phyſician at Birmingham. Before that time, Birmingham had begun to make a rapid progreſs in arts, manufactures, and population; and by the death of an aged phyſician, an opening was preſented to him, which afforded an immediate proſpect of encouragement in that line. His education, talents, and intereſting manners, were well calculated to promote his ſucceſs as a phyſician. He accordingly met there, at a period more early than he expected, with great encouragement; and was ſoon diſtinguiſhed, in that town and the country adjacent, for his ſkill, integrity, and charitable compaſſion, in the diſcharge of the duties of his profeſſion.

It appeared, however, ſoon after his reſidence was fixed at Birmingham, that his ſtudies and induſtry were turned to various objects beſides thoſe of his profeſſion. Strongly attached to the riſing ſcience of chemiſtry, he conceived high views of extending its uſefulneſs, and of rendering it ſubſervient to the improvement of arts and manufactures. With this view he fitted up a ſmall laboratory in his own houſe, in which he ſpent every moment of his time which he could ſpare from the duties of his profeſſion. There, in the true ſpirit of his great maſter Lord Bacon, of whoſe philoſophy he was an ardent admirer, he carried on various chemical proceſſes of great importance, and laid the foundation of his future projects on well-tried and well-digeſted experiments.

The firſt efforts of his genius and induſtry, thus directed, led him to the diſcovery of certain improved methods of refining gold and ſilver, and particularly to an ingenious method of collecting the ſmaller particles of theſe precious metals, which had been formerly loſt in the practical operations of many of the manufacturers. By other chemical proceſſes, carried on about the ſame time in his little laboratory, he diſcovered alſo improved methods of making ſublimate hartſhorn, and ſundry other articles of equal importance. After having received full ſatisfaction from the experiments upon which ſuch diſcoveries and improvement were founded, he next digeſted a plan for rendering them beneficial to himſelf, and uſeful to the public. A great part of his time being ſtill employed in the duties of his profeſſion, he found it neceſſary to connect himſelf with ſome perſon in whom he could repoſe confidence, and who might be, in other reſpects, qualified to give him ſupport and aſſiſtance in carrying on his intended eſtabliſhments. With this view, he choſe as his aſſociate Mr Samuel Garbet of Birmingham; a gentleman well qualified, by his abilities, activity, and enterpriſing ſpirit,

rit, for bearing his part in their future undertakings. The firſt project was the eſtabliſhment of an extenſive laboratory at Birmingham, for the purpoſes above mentioned; which, conducted by Dr Roebuck's chemical knowledge, and Mr Garbet's able and judicious management, was productive of many advantages to the manufacturers of that place, and of ſuch emolument to themſelves, as contributed greatly to the boldneſs of their future projects. That laboratory has, ever ſince that time, continued at Birmingham, and is ſtill conducted by Mr Garbet. Dr Roebuck, long before his death, had given up his intereſt in it.

About this time, in 1747, the Doctor married Miſs Ann Roe of Sheffield, a lady of a great and generous ſpirit, whoſe temper and diſpoſition equally fitted her for enjoying the proſperous circumſtances of their early life, and for bearing her equal ſhare of thoſe anxieties and diſappointments in buſineſs which ſhaded, but did not obſcure, the later period of their lives.

Dr Roebuck's unremitted perſeverance in his chemical ſtudies, together with the ſucceſs that attended them, led him, ſtep by ſtep, to other reſearches of great public and private benefit.

The extenſive uſe of the vitriolic (ſulphuric) acid in chemiſtry, and the proſpect of its application to ſome of the mechanic arts, had produced a great demand for that article, and turned the attention of chemiſts to various methods of obtaining it. The late Dr Ward had obtained a patent for making it; and though the ſubſtances from which it might be obtained, as well as certain methods of obtaining it, had been known to others, and particularly pointed out by Lemery the Elder, and by Glauber, yet Dr Ward was the firſt, it is believed, who eſtabliſhed a profitable manufacture upon the diſcovery. Much, however, was wanting to render the acid of univerſal uſe in chemiſtry, and of extenſive utility in the arts, where great quantities of it were required. The price of it was high, ariſing from the great expence of the glaſs veſſels, which were made uſe of by Dr Ward in procuring it, and the frequent accidents to which they were liable in the proceſs.

Dr Roebuck had been for ſome time engaged in making experiments with a view to reduce the price, and at length diſcovered a method of preparing it, by ſubſtituting, in place of the glaſs veſſels formerly uſed, lead ones of a great ſize; which ſubſtitution, together with ſundry other improvements in different parts of the proceſs, completely effected his end.

After the neceſſary preparations had been made, Meſſrs Roebuck and Garbet eſtabliſhed a manufacture of the oil of vitriol at Preſtonpans, in Scotland, in the year 1749. This eſtabliſhment not a little alarmed Dr Ward, who attempted to defeat their plan, by taking out a patent for Scotland, in addition to the one he had formerly obtained. In this attempt he failed. Dr Roebuck's diſcovery was found not to come within the ſpecification of Dr Ward's patent.

The Preſtonpans company, convinced that patents are of little avail in preſerving the property of new inventions or diſcoveries, in conducting their vitriol works reſolved to have recourſe to the more effectual methods of concealment and ſecrecy. By that method they were enabled to preſerve the advantages of their ingenuity and induſtry for a long period of years, and not only ſerved the public at a much cheaper rate than had ever been done formerly, but, it is believed, they realized, in that manufacture, a greater annual profit from a ſmaller capital than had been done in any ſimilar undertaking. The vitriol work is ſtill carried on at Preſtonpans; but long before Dr Roebuck's death, he was obliged to withdraw his capital from it.

About this time Dr Roebuck was urged, by ſome of his friends, to leave Birmingham, and to ſettle as a phyſician in London, where his abilities might have had a more extenſive field of exertion. He had been early honoured with the acquaintance of the late Marquis of Rockingham, who, as a lover of arts, had frequently engaged him in chemical experiments at Rockingham-houſe. It was there, alſo, he became acquainted with the late Sir George Saville, and with ſeveral other perſons of rank and influence. His old friend and ſchool-fellow Mr Dyſon, too, by this time, had acquired conſiderable name and influence, and preſſed him much to take that ſtep. Under ſuch patronage, and with the energy of ſuch talents as Dr Roebuck poſſeſſed, there could be little doubt of his ſoon arriving at an eminent rank as a phyſician in London. But the chemical concerns, with which he was at that time deeply occupied, holding out to him a proſpect of a richer harveſt, determined him to give up the practice of medicine altogether, and to fix his reſidence for the greateſt part of the year in Scotland.

The ſucceſs of the eſtabliſhment at Preſtonpans, which had far exceeded their expectation, enabled the Doctor and his partner Mr Garbet to plan and execute other works of ſtill greater benefit and public utility. In the proſecution of his chemical ſtudies and experiments, Dr Roebuck had been led to beſtow great attention on the proceſſes of ſmelting iron-ſtone, and had made ſome diſcoveries, by which that operation might be greatly facilitated, particularly by uſing pit-coal in place of charcoal. Mr William Caddell of Cockenzie, in the neighbourhood of Preſtonpans, a gentleman earneſtly intent upon promoting manufactures in Scotland, had, for ſeveral years, laboured, without much ſucceſs, in eſtabliſhing a manufacture of iron; a circumſtance which may have probably contributed to turn Dr Roebuck's attention more particularly to that ſubject. As the capital which he and his partner Mr Garbet could appropriate for carrying on the iron manufacture was not equal to ſuch an undertaking, and chiefly depended upon the profits of their other works, their firſt intention was to attempt a ſmall eſtabliſhment of that kind in the vicinity of their vitriol works at Preſtonpans. But the flattering proſpects of ſucceſs, ariſing from a courſe of experiments which Dr Roebuck had lately made, encouraged them to extend their plan, and to project a very extenſive manufactory of iron. A ſufficient capital was ſoon procured, through the confidence which many of their friends repoſed in their abilities and integrity. In fact, the eſtabliſhment which they made, or rather the capital which gave it exiſtence, was the united capital of a band of relations and friends, who truſted to Dr Roebuck and Mr Garbet the management of a great part of their fortune. When all previous matters had been concerted reſpecting their intended eſtabliſhment, the chief exertions of chemical and mechanical ſkill, neceſſary in the execution, were expected from Dr Roebuck. It fell to his ſhare alſo to fix upon the beſt and moſt favourite ſituation for erecting their intended works. With that view Dr Roebuck examined many different places in Scotland, particularly thofe on both fides of the Frith of Forth; and after a careful and minute comparifon of their advantages and difadvantages, he at length made choice of a fpot on the banks of the river *Carron* as the moft advantageous fituation for the eftablifhment of the iron manufacture. There he found they could eafily command abundance of water for the neceffary machinery; and in the neighbourhood of it, as well as everywhere both along the north and fouth coafts of the Frith, were to be found inexhauftible quarries of ironftone, limeftone, and coal. From Carron, alfo, they could eafily tranfport their manufactures to different countries by fea. The communication with Glafgow at that time by land carriage, which opened up to them a ready way to the American market, was fhort and eafy.

Many other things, that need not be here enumerated, fell to Dr Roebuck's fhare in preparing and providing for the introduction of this new manufacture into Scotland, particularly with refpect to the planning and erection of the furnaces and machinery. To infure fuccefs in that department, nothing was omitted which ability, induftry, and experience could fuggeft. With this view, he called to his affiftance Mr Smeaton, then by far the firft engineer in England. It was from him he received plans and drawings of the water-wheels and blowing apparatus, which, notwithftanding all the mechanical improvements which have been made fince, remain unrivalled in any of the other iron-works erected in Britain. This was the firft introduction of Mr Smeaton into Scotland, and was the occafion of various other difplays of the fkill and experience of that celebrated engineer in that part of the ifland. With the fame view, and to the fame effect, in a future period of his operations, he employed Mr James Watt, then of Glafgow, and had the merit of rendering that inventive genius, in the mechanical arts, better known both in this country and in England.

The neceffary preparations for the eftablifhment of the iron works at Carron were finifhed in the end of the year 1759; and on the 1ft January 1760 the firft furnace was blown; and in a fhort time afterwards a fecond was erected.

No period of Dr Roebuck's life required from him more vigorous and laborious exertions than that of the eftablifhment of the Carron works, and the firft trials of the furnaces and machinery. His family and friends remember well the ardour and intereft which he difcovered; the inceffant labour and watchfulnefs which he exerted on that occafion. Every thing was untried, the furnaces, the machinery, the materials, the workmen; the novelty of the undertaking in that country, its extent and difficulty, and the great ftake at iffue, were circumftances that muft have occafioned much ferious thought and anxiety to the partner, upon the credit of whofe knowledge and experience the work had been undertaken. But the Doctor had great powers and great refources; and the firft trial gave fufficient indications of future fuccefs.

For fome time after the eftablifhment of the Carron works, Dr Roebuck continued to give his attention and affiftance in the general management and fuperintendance of them, and with him all meafures of future operations were concerted. During this period, fome alterations of great importance were fuggefted by him, and carried into effect. By carefully obferving the progrefs of fmelting in the furnaces, at firft worked by bellows, befides their being fubject to various accidents, the Doctor difcovered the neceffity of rendering the blaft both ftronger and more equable; and propofing, as a problem to Mr Smeaton, the beft method of effecting that end, that celebrated engineer foon gave the plan of a blaft by three or four cylinders, which was afterwards tried, and fucceeded even beyond expectation.

When the bufinefs at Carron funk by degrees into a matter of ordinary detail, and afforded lefs fcope for the Doctor's peculiar talents, he was unfortunately tempted to engage in a new and different undertaking; from the failure of which he fuffered a reverfe of fortune, was deprived of the advantages refulting from his other works, and during the remainder of his life became fubjected to much anxiety and difappointment.

The eftablifhment of the Carron works, and the intereft Dr Roebuck had in their fuccefs, had naturally turned his attention to the ftate of coal in the neighbourhood of that place, and to the means of procuring the extraordinary fupplies of it which the iron-works might in future require. With the view, therefore, of increafing the quantity of coal worked in that neighbourhood, by an adventure which he thought would alfo turn out to his own emolument, he was induced to become leffee of the Duke of Hamilton's extenfive coal and falt works at Borrowftounnefs. The coal there was reprefented to exift in great abundance, and underftood to be of fuperior quality; and as Dr Roebuck had made himfelf acquainted with the moft improved methods of working coal in England, and then not practifed in Scotland, he had little doubt of this adventure turning out beneficial and highly lucrative. In this, however, he was cruelly difappointed. The opening of the principal ftratum of coal required much longer time, and much greater expence, than had been calculated; and, after it was opened, the perpetual fucceffion of difficulties and obftacles which occurred in the working and raifing of the coal, was fuch as has been feldom experienced in any work of that kind. The refult was, that after many years of labour and induftry, there were funk in the coal and falt works at Borrowftounnefs, not only his own, and the confiderable fortune brought him by his wife, but the regular profits of his more fuccefsful works; and along therewith, what diftreffed him above every thing, great fums of money borrowed from his relations and friends, which he was never able to repay; not to mention that, from the fame caufe, he was, during the laft twenty years of his life, fubjected to a conftant fucceffion of hopes and difappointments, to a courfe of labour and drudgery ill fuited to his tafte and turn of mind, to the irkfome and teafing bufinefs of managing and ftudying the humours of working colliers. But all thefe difficulties his unconquerable and perfevering fpirit would have overcome, if the never-ceafing demands of his coal works, after having exhaufted the profits, had not alfo compelled him to withdraw his capital from all his different works in fucceffion; from the refining work at Birmingham, the vitriol work at Preftonpans, the iron-works at Carron, as well as to part with his intereft in the project of improving the fteam-engine, in which he had

Roebuck. had become a partner with Mr Watt, the original inventor, and from which he had reafon to hope for future emolument.

It would be painful to mention the unhappy confequences of this ruinous adventure to his family and to himfelf. It cut off for ever the flattering profpect which they had of an independent fortune, fuited to their education and rank in life. It made many cruel encroachments upon the time and occupations of a man whofe mind was equally fitted to enjoy the high attainments of fcience, and the elegant amufements of tafte. As the price of fo many facrifices, he was only enabled to draw from his colliery, and that by the indulgence of his creditors, a moderate annual maintenance for himfelf and family during his life. At his death, his widow was left without any provifion whatever for her immediate or future fupport, and without the fmalleft advantage from the extraordinary exertions and meritorious induftry of her hufband.

Dr Roebuck had, fome years before his death, been attacked by a complaint that required a dangerous chirurgical operation. That operation he fupported with his ufual fpirit and refolution. In a fhort time he was reftored to a confiderable fhare of his former health and activity; but the effects of it never entirely left him, and feveral flighter returns of the complaint gradually impaired his conftitution. He ftill, however, continued, till within a few weeks of his death, to vifit his works, and to give direction to his clerks and overfeers. He was confined to his bed only a few days; and died on the 17th July 1794, retaining to the laft all his faculties, his fpirit and good humour, as well as the great intereft which he took, as a man of fcience and reflection, in the uncommon events which the prefent age has exhibited.

From a man fo deeply and fo conftantly engaged in the detail of active bufinefs, many literary compofitions were not to be expected. Dr Roebuck left behind him many *works*, but few *writings*. The great object which he kept invariably in view was to promote arts and manufactures, rather than to eftablifh theories or hypothefes. The few effays which he left, enable us to judge of what might have been expected from his talents, knowledge, and boldnefs of invention, had not the active undertakings in which, from an early period of life, he was engaged, and the fatiguing details of bufinefs, occupied the time for ftudy and inveftigation. A comparifon of the heat of London and Edinburgh, read in the Royal Society of London June 29, 1775; experiments on ignited bodies, read there 16th Feb. 1776; obfervations on the ripening and filling of corn, read in the Royal Society of Edinburgh 5th June 1784—are all the writings of his, two political pamphlets excepted, which have been publifhed. The publication of the effay on ignited bodies was occafioned by a report of fome experiments made by the Comte de Buffon, from which the Comte had inferred, that *matter* is heavier when hot than when cold. Dr Roebuck's experiments, made with great accuracy before a committee of the Royal Society at London, feem to refute that notion.

It is the works and eftablifhments projected and executed by Dr Roebuck, with the immediate and more remote effects of them upon the induftry, arts, and manufacturers of Scotland, which urge a juft claim to the refpect and gratitude of his country. This tribute is more due from the difcerning part of mankind, as this Roebuck. fpecies of merit is apt to be overlooked by the bufy or the fuperficial, and to fail in obtaining its due reward. The circumftances of Dr Roebuck were, in this refpect, peculiarly hard: for though, moft certainly, the projector and author of new eftablifhments highly ufeful to his country, and every day becoming more fo, he was, by a train of unfortunate events, obliged to break off his connection with them, at an unfeafonable time, when much was yet wanting to their complete fuccefs: and thus he left others in the poffeffion, not only of the lucrative advantages now derived from them, but even in fome meafure of the general merit of the undertaking, to a confiderable part of which he had the moft undoubted claim.

The eftablifhment of the laboratory at Birmingham in the year 1747, the firft public exhibition of Dr Roebuck's chemical talents, was, at that particular period, and in the ftate of the arts and manufactures at that time, highly beneficial, and fubfervient to their future progrefs: and the continuance and fuccefs of it, in that place, is a proof of the advantages which many of the manufacturers receive from it. Much had already been done, and many improvements made in arts and manufactures, chiefly by the fuggeftions of that ingenuity and experience which, in the detail of bufinefs, might be expected from the practical artift. Dr Roebuck was qualified to proceed a ftep farther; to direct experience by principles, and to regulate the mechanical operation of the artift by the lights of fcience. The effects of that eftablifhment extended, in a particular manner, to all that variety of manufactures in which gold and filver were required, to the preparing of materials, the fimplifying of the firft fteps, to the faving of expence and labour, and to the turning to fome account what had been formerly loft to the manufacturer. It is well known that, while Dr Roebuck refided at Birmingham, fuch was the opinion formed of his chemical knowledge and experience by the principal manufacturers, that they ufually confulted him on any new trial or effort to improve their feveral manufactures; and when he left that place, they fincerely regretted the lofs of that eafy and unreferved communication they had with him on the fubjects of their feveral departments.

On account of fimilar circumftances, the benefit to the public, from the eftablifhment of the vitriol works at Preftonpans, in the extention and improvement of many of the arts, cannot now be exactly afcertained. The vitriolic acid is one of the moft active agents in chemiftry, and every difcovery which renders it cheap and acceffible to the chemift muft be greatly fubfervient to the progrefs of that fcience. By the eftablifhment at Preftonpans, the price of that valuable acid was reduced from fixteen to four pence *per* pound. It is to Dr Roebuck, therefore, that chemifts are indebted for being in poffeffion of a cheap acid, to which they can have recourfe in fo many proceffes.

But Dr Roebuck's object in the profecution of that fcheme, was not fo much to facilitate the chemift's labour, as to render that acid, in a much higher degree than it had formerly been, fubfervient to many of the practical arts. By rendering the vitriolic acid cheap, great ufe came to be made of it in preparing the muriatic acid, and Glauber's falts from common falts. Its ufe

Roebuck. use has been farther extended to many metallic processes; and it has lately been employed in separating silver from the clippings of plated copper, the use of which is very extensive.

The project and establishment, however, of the iron-works at Carron, the most extensive establishment of that kind hitherto in Britain, must be considered as Dr Roebuck's principal work. The great and increasing demand for iron in the progressive state of arts, manufactures, and commerce in Britain, and the great sums of money sent every year to the north of Europe for that article, turned the attention of chemists and artists to the means of promoting the manufacture of iron, with the view of reducing the importation of it. No person has a better founded claim to merit, in this particular, than Dr Roebuck. The smelting of iron by pitcoal, it is indeed believed, had been attempted in Britain in the beginning of the last century. In the reign of James I. several patents seem to have been granted for making hammered iron by pitcoal, particularly to the Hon. Dud Dudley and Simon Starlevant. It does not appear, however, that any progress had been made in the manufacture in consequence of these patents. In later times trials have been made by so many different persons, and in so many different places in England, nearly about the same time, that it may be difficult to say where and by whom the first attempt was made, particularly as the discoverers of such processes wished to conceal the knowledge they had gained as long as they could. But Dr Roebuck was certainly among the first who, by means of pitcoal, attempted to refine crude or pig iron, and to make bar iron of it, instead of doing it by charcoal, according to the former practice: And he was, without all question, the person who introduced that method into Scotland, and first established an extensive manufacture of it. It is not meant to ascribe to him the sole merit of the establishment at Carron. No man was ever more ready than he was to do justice to the abilities and spirit of his friends and partners Messrs Garbet, Caddell, &c. who first embarked with him in that great undertaking. But still it may be said with truth, that the original project of the iron-works at Carron, the chemical knowledge and experience on which they were founded, the complicated calculations which were previously required, the choice of the situation, the general conduct and direction of the buildings and machinery, the suggestion of many occasional improvements, together with the removal of many unforeseen obstacles and difficulties, which occurred in the infant state of that establishment, were, in a great measure, the work and labour of Dr Roebuck, Nor can it, with the least shadow of justice, detract from his merit, that a larger capital, and greater expence than was at first calculated, have been found necessary to bring the works at Carron to their present state of perfection; or, that great alterations and improvements have taken place, during the course of forty years, in a great and progressive establishment. In all works of that kind, the expence exceeds the calculation. The undertakers even of the latest iron-works which have been erected, notwithstanding all the advantages obtained from recent experience, will be ready to acknowledge, that, in these respects, there is little room to blame the original projector of the first establishment of that kind in Scotland. But the best, and most infallible proof of Dr Roebuck's merit, and of the sound principles on which these works were established, is the present prosperous state of that establishment, the great perfection of many branches of their manufactures, and particularly the many extensive and flourishing iron-works which have since been erected upon the model of Carron in different parts of Scotland, at Cleugh, Clyde, Muirkirk, and Devon. It cannot be denied that all these works have sprung from the establishment at Carron, and are ultimately founded upon the knowledge and experience which have been obtained from them; for some of the partners, or overseers of these new works, and many of the workmen, have been, at one time or another, connected with that of Carron. Hence, then, it is owing to the projector and promoter of the establishment at Carron, that Scotland is, at this moment, benefited to the amount of many hundred thousand pounds, in working up the raw materials of that manufacture found in the country itself, and which, previous to that establishment, was of no value whatever. Such are the *present*, but scarcely any idea can be formed of the *future*, advantages to this country, which may be derived from the extension of the iron manufacture. About 60,000 tons of iron have been annually imported into Great Britain for more than twenty years past; and though there has been for some time about 20,000 tons of bar iron made in Britain by pitcoal, yet the foreign imported iron has suffered little or no diminution in quantity. This great consumption of iron, no doubt, is owing to the various improvements of late years, and the general extension throughout all Europe of commerce and the arts. The manufacture of iron must therefore continue to increase; and Scotland, abounding everywhere in ironstone, pitcoal, and in command of water for machinery, has the prospect of obtaining the largest share of it.

To the establishment of the Carron works, and to the consequences of that establishment, may be ascribed also the existence of other public works in Scotland of great importance and utility. The opening of a communication by water betwixt the Forth and the Clyde had long been projected, and frequently the subject of conversation in Scotland, but nothing in fact had been attempted. The establishment of the iron-works at Carron soon called forth sufficient interest and enterprise to bring about the execution of this grand design. Some of the partners of the Carron company, foreseeing the advantages they would derive from such a communication, proposed, at their own expence, to execute a small canal; and, after taking the preparatory steps, actually applied to Parliament to obtain authority for that purpose. But the project of the small canal not meeting with the approbation of some noblemen and gentlemen in that part of Scotland, they opposed the bill, and obliged themselves to execute a greater canal, which has now been many years finished, and is found to be of the greatest advantage to the trade and commerce of Scotland. The merit of this undertaking is not meant to be ascribed to Dr Roebuck, excepting in so far as it necessarily arose from the establishment of the Carron company, of which he was the original projector; and it may reasonably be doubted whether, without that establishment, it would have yet taken place.

place. Several other canals have since that time been executed in different parts of Scotland, and other very important ones are at present projected.

The different establishments which Dr Roebuck made at Borrowstounness in carrying on the coal and salt works there, though ultimately of no advantage to himself, were attended, during the course of thirty years, with the most beneficial effects upon the trade, population, and industry of that part of Scotland. They were the means also of adding very considerably to the public revenue. Previous to the time these works fell under Dr Roebuck's management, they produced no advantage either to the proprietor, to the adventurers, or to the public. But by his mode of conducting them upon a more extensive plan, by opening up new seams of coal, and of better quality, he was enabled to export a very considerable quantity, to increase the quantity of salt, and of course the revenue arising from these articles. In these works, and in the management of a large farm, Dr Roebuck gave employment to near a thousand persons at Borrowstounness and in the neighbourhood.

Nor was it solely by the different establishments which he projected and executed, but by many other things necessarily connected with them, that Dr Roebuck's labours were beneficial to Scotland. Along with them he may be said to have introduced a spirit of enterprise and industry, before that time little known in Scotland, which soon pervaded many other departments of labour, and gave birth to many other useful projects. He brought from England, then much farther advanced in arts and industry, many ingenious and industrious workmen, at great expence, who, by their instructions and example, communicated and diffused skill and knowledge to others. At all times Dr Roebuck held out liberal encouragement to rising genius and industrious merit; and spared no expence in making trials of improvements and discoveries which were connected with the different projects and works which he was carrying on.

Such was the active and useful life of Dr Roebuck, a man of no common cast, who united, in a very high degree, a great number of solid and brilliant talents, which, even separately, fall to the lot of but few individuals. Distinguished by an ardent and inventive mind, delighting in pursuit and investigation, always aspiring at something beyond the present state of science and art, and eagerly pressing forward to something better or more perfect, he thus united energies the most powerful with the most unwearied and persevering industry. To that peculiarity of imagination, so fitted for scientific pursuit, which readily combines and unites, which steadily preserves its combinations before the eye of the mind, and quickly discovers relations, results, and consequences, was added, in his character, great promptitude and firmness in decision. Strongly and early impressed with the great importance of applying chemical and physical knowledge to the useful arts, to the melioration of civil life, he never lost sight of that favourite view, and discovered great boldness and resource in the means and expedients which he adopted to promote it. He was certainly master of the best philosophy of chemistry known in the earlier parts of his life; and though in every stage of that science he marked and understood the progress of the discoveries, yet his numerous avocations did not permit him to follow them out by experimental processes of his own. Upon that, and indeed almost upon every subject, his mind readily grasped the most useful and substantial points, and enabled him to throw out such hints and hypotheses as marked him the man of genius.

During the course of a regular education, both at Edinburgh and at Leyden, Dr Roebuck studied the classic authors with great attention, particularly the historical and political parts of their works. Upon these subjects he had read much, selected with judgment, and was well acquainted with the facts and philosophy of ancient governments. This taste he carried with him, and improved in every period of his life, and in every situation. It abundantly rewarded him for the earnestness and diligence with which it had been acquired. It became his favourite resource, and indeed one of the chief enjoyments of his life. Possessing the happy talent of turning his mind from serious and fatiguing, to elegant and recreating pursuits, it was no uncommon thing with him to return from the laboratory or the coalpit, and draw relaxation or relief from some one or other of the various stores of classical learning.

No man was better acquainted with the history of his country than Dr Roebuck, or more admired and revered the constitution of its government. By temper and education he was a Whig, and at all times entered with great warmth into the political disputes and controversies which agitated parties in the different periods of his life. If the natural warmth of his temper, and his enthusiasm on these subjects, led him, on some occasions, beyond the bounds of candid argumentation, his quick sense of decorum, and his perfect habits of good manners, produced an immediate atonement, and restored the rights of elegant and polished conversation.

The general acquaintance which Dr Roebuck had acquired with natural and experimental philosophy, together with his classical and political knowledge, rendered him an agreeable companion to the learned almost of every department, and procured him the attachment and friendship of many of the first literary characters in Britain. With his friend Dr Black he lived till his death in close habits of intimacy; and he often acknowledged, with much frankness, the advantages which he derived in his various pursuits, from a free and unreserved communication with that eminent chemist.

The amiable dispositions of sensibility, humanity, and generosity, which strongly marked his character in the general intercourse of society, were peculiarly preserved and exercised in the bosom of his family, and in the circle of his friends. In the various relations of husband, father, friend, or master, and in the discharge of the respective duties arising from them, it would not be easy to do justice to his character, or to determine in which of them he most excelled; nor must it be forgot, for it reflected much honour on his benevolent heart, that his workmen not only found him at all times a kind and indulgent master; but many of them, when their circumstances required it, a skilful and compassionate physician, who cheerfully visited the humblest recesses of poverty, and who attached them to his service by multiplied acts of generosity and kindness.

ROEMER (Olaus), a noted Danish astronomer and mathematician, was born at Arhusan in Jutland, 1644; and at 18 years of age was sent to the university of

Roemer, Rollock.

of Copenhagen. He applied assiduously to the study of the mathematics and astronomy, and became so expert in those sciences, that when Picard was sent by Louis the XIV. in 1671, to make observations in the north, he was greatly surprised and pleased with him. He engaged him to return with him to France, and had him presented to the king, who honoured him with the dauphin as a pupil in mathematics, and settled a pension upon him. He was joined with Picard and Cassini, in making astronomical observations; and in 1672 he was admitted a member of the Academy of Sciences.

During the ten years he resided at Paris, he gained great reputation by his discoveries; yet it is said he complained afterwards, that his coadjutors ran away with the honour of many things which belonged to him. Here it was that Roemer, first of any one, found out the velocity with which light moves, by means of the eclipses of Jupiter's satellites. He had observed for many years, that when Jupiter was at his greatest distance from the earth where he could be observed, the emersions of his first satellite happened constantly 15 or 16 minutes later than the calculation gave them. Hence he concluded, that the light reflected by Jupiter took up this time in running over the excess of distance; and consequently that it took up 16 or 18 minutes in running over the diameter of the earth's orbit, and 8 or 9 in coming from the sun to us, provided its velocity was nearly uniform. This discovery had at first many opposers; but it was afterwards confirmed by Dr Bradley in the most ingenious and beautiful manner.

In 1681 Roemer was recalled to his native country by Christian the Vth King of Denmark, who made him professor of astronomy at Copenhagen. The king employed him also in reforming the coin and the architecture, in regulating the weights and measures, and in measuring and laying out the high roads throughout the kingdom; offices which he discharged with the greatest credit and satisfaction. In consequence he was honoured by the king with the appointment of chancellor of the exchequer and other dignities. Finally, he became counsellor of state, and burgomaster of Copenhagen, under Frederic the IV. the successor of Christian. Roemer was preparing to publish the result of his observations, when he died the 19th of September 1710, at 66 years of age: but this loss was supplied by Hurrebow, his disciple, then professor of astronomy at Copenhagen, who published, in 4to, 1753, various observations of Roemer, with his method of observing, under the title of *Basis Astronomiæ*.—He had also printed various astronomical observations and pieces, in several volumes of the Memoirs of the Royal Academy of Sciences at Paris, of the institution of 1666, particularly vol. 1. and 10. of that collection.

ROLLOCK (Robert), the first principal of the college of Edinburgh, was the son of David Rollock of *Pouhouse*, or, as it is now written, *Powis*, in the neighbourhood of Stirling. He was born in 1555; and learned the rudiments of the Latin tongue under one Mr Thomas Buchanan, who kept, says Archbishop Spottiswood, a famous school at that time, and was, according to Dr Mackenzie, one of the most eminent grammarians in Scotland. Where Mr Buchanan kept his school, neither of these authors has informed us.

From school Mr Rollock was sent, we know not in what year, to the university of St Andrews, and admitted a student in St Salvator's college. His progress in the sciences, which were then taught, was so great and so rapid, that he had no sooner taken his degree of M. A. than he was chosen a professor of philosophy, and immediately began to read lectures in St Salvator's college. This must have been at a very early period of life; for he quitted St Andrews in the year 1583, when, according to Mackenzie, he had taught philosophy for some time in that university.

Rollock.

Not long before this period, the magistrates of Edinburgh having petitioned the king to erect a university in that city, he granted them a charter under the great seal, allowing them all the privileges of a university; and the college being built in 1582, they made choice of Mr Rollock to be their principal and professor of divinity.

At what time he was admitted into holy orders, by whom he was ordained, or indeed whether he ever was ordained, has been the subject of some acrimonious controversy; but it is a controversy which we shall not revive; for, considering the manner in which orders were then conferred in Scotland, the question in debate is of very little importance. It is certain that he became famous in the university, and among his countrymen in general, for his lectures in theology, and for the persuasive power of his preaching; for Calderwood assures us, that, in 1589, he and Mr Robert Bruce, another popular orator, made the Earl of Bothwel so sensible of his sinful and vitious courses, that, upon the 9th of November, his lordship humbled himself upon his knees in the east church in the forenoon, and in the high church in the afternoon, confessing before the people, with tears in his eyes, his dissolute and licentious life, and promising to prove, for the future, another man.

In the year 1593, Principal Rollock and others were appointed by the states of parliament to confer with the popish lords; and in the next year he was one of those who, by the appointment of the general assembly of the church, met at Edinburgh in the month of May, and presented to his majesty a paper, entitled, *The dangers which, through the impunity of* EXCOMMUNICATED PAPISTS, TRAFFICKERS WITH THE SPANIARDS, *and other enemies of the religion and estate, are imminent to the true religion professed within this realm, his Majesty's person, crown, and liberty of this our native country.* His zeal against Papists was indeed ardent; and he seems to have adopted that judaical doctrine, which was embraced in some degree by all the reformers, that it is the duty of the civil magistrate to punish idolatry with death.

In the year 1595 he was nominated one of the commissioners for the visitation of colleges. These commissioners were empowered to visit all the colleges in the kingdom, to inquire into the doctrine and life of the several masters, the discipline used by them, the state of their rents and living, and to make their report to the next assembly.

In 1596, the factious behaviour of some of the ministers having drawn upon them the just resentment of the king, our principal was employed, on account of his moderation, to soften that resentment, and to turn his majesty's wrath against the *Papists!* In the year 1597, he was chosen moderator of the General Assem-

Rollock.

bly—the higheft dignity in the Scottifh church; and he had the influence to get fome great abufes redreffed. Being one of fourteen minifters appointed by this affembly to take care of the affairs of the church, the firft thing which he did was to procure an act of the legiflature, reftoring to the prelates their feats in parliament. He had here occafion for all his addrefs; for he had to reconcile to this meafure, not only fuch of the minifters as abhorred all kinds of fubordination in the church, but likewife many of the lay lords, who were not delighted with the profpect of fuch affociates in parliament as the Scotch prelates were at that period (A).

Though he fpent the greater part of his life in conducting the affairs of the church, we have the authority of Spottifwood for faying, that he would have preferred retirement and ftudy. To the buftle of public life, efpecially at that period of faction and fanaticifm, his feeble conftitution was not equal; and his inclination would have confined him to his college and his library. He was dreadfully afflicted with the ftone; the torments of which he long bore with the fortitude and refignation of a Chriftian. He died at Edinburgh on the 28th of February 1598, in the 43d year of his age; having exhorted his brethren, with his dying-breath, to carry themfelves more dutifully to their gracious fovereign.

His works are, 1. A Commentary on the Firft Book of Theodore Beza's Queftions. 2. A Commentary on St Paul's Epiftle to the Ephefians, 4to, Edinburgh, 1590. 3. A Commentary on the Prophet Daniel, 4to, Edinburgh, 1591. 4. A Logical Analyfis of St Paul's Epiftle to the Romans, 8vo, Edinburgh, 1594. 5. Some Queftions and Anfwers concerning the Covenant of Grace and the Sacraments, 8vo, Edinburgh, 1596. 6. A Treatife of Effectual Calling, 8vo, Edinburgh, 1597. 7. A Commentary on the Epiftles of St Paul to the Theffalonians and Philemon, 8vo, Geneva, 1597. 8. A Commentary upon Fifteen Select Pfalms, 8vo, Geneva, 1598. 9. A Commentary on the Gofpel of St John, with a harmony of the Four Evangelifts upon the Death, Refurrection, and Afcenfion of Jefus Chrift, 8vo, Geneva, 1599. 10. Certain Sermons on Several Places of St Paul's Epiftles, 8vo, Edinburgh, 1598. 11. A Commentary upon the Epiftle to the Coloffians, 8vo, publifhed at Geneva, 1602. 12. A Logical Analyfis of the Epiftle to the Hebrews, 8vo, Edinburgh, 1605. 13. A Logical Analyfis of the Epiftle to the Galatians, 8vo, London, 1602. 14. A Commentary upon the Two Firft Chapters of the Firft Epiftle of St Peter, 8vo, London, 1603. 15 and 16. A Treatife of Juftification, and another of Excommunication, both in 8vo, London, 1604. All thefe works, except the fermons, are in Latin. That Principal Rollock was held in high eftimation in the college over which he prefided, is made at leaft probable by the following epitaph:

Rofes, Rota.

Te Rolloce, extincto, Urbs mœfta, Academia mœfta eft;
Et tota exequiis Scotia mœfta tuis.
Uno in te nobis dederat Deus omnia, in uno
Te Deus eripuit omnia quæ dederit.

ROSES OTTER (or effential oil) OF. In the *Encyclopædia*, under the word ROSES, we have given one receipt for making this very high-priced perfume; and we fhall here give another; which, whether it be as effectual or not, is at leaft fimpler and lefs expenfive. It is by an officer who was in the country where the *Otter* is prepared, and who affifted in making it himfelf; and is as follows:

"Take a very large glazed earthen or ftone jar, or a large clean wooden cafk; fill it with the leaves of the flowers of rofes, very well picked, and freed from all feeds and ftalks; pour on them as much pure fpring water as will cover them, and fet the veffel in the fun, in the morning at fun-rife, and let it ftand till the evening, then take it into the houfe for the night; expofe it, in this manner, for fix or feven fucceffive days, and, at the end of the third or fourth day, a number of particles, of a fine yellow oily matter, will float on the furface, which, in two or three days more, will gather into a fcum, which is the otter of rofes. This is taken up by fome cotton, tied to the end of a piece of ftick, and fqueezed with the finger and thumb into a fmall phial, which is immediately well ftopped; and this is repeated for fome fucceffive evenings, or while any of this fine effential oil rifes to the furface of the water."

Dr Donald Monro, who communicated this receipt to the Royal Society of Edinburgh, fays, that he has been informed, that fome few drops of this effential oil have more than once been collected by diftillation in London, in the fame manner as the effential oils of other plants.

ROTA ARISTOTELICA, or *Ariftotle's Wheel*, denotes a celebrated problem in mechanics, concerning the motion or rotation of a wheel about its axis; fo called becaufe firft noticed by Ariftotle.

The difficulty is this. While a circle makes a revolution on its centre, advancing at the fame time in a right line along a plane, it defcribes, on that plane, a right line which is equal to its circumference. Now if this circle, which may be called the deferent, carry with it another fmaller circle, concentric with it, like the nave of a coach wheel; then this little circle, or nave, will defcribe a line in the time of the revolution, which fhall be equal to that of the large wheel or circumference

(A) The conftitution of the Scotch church was, at this period, a ftrange fyftem of inconfiftency and contradiction. It was, in fact, prefbyterian; for ecclefiaftical difcipline was adminiftered then, as at prefent, by kirkfeffions, prefbyteries, and general affemblies; and there was not a reformed bifhop in the kingdom. Whether provincial fynods were then in ufe, the writer of this note does not at prefent recollect. The king, however, who was meditating the reftoration of epifcopacy, conferred the eftates, or part of the eftates, belonging to the different fees, upon the moft eminent parochial minifters, and dignified them with the title of bifhops; though it does not appear that they had any jurifdiction over their brethren; and though they were certainly not *ex officio* fo much as moderators of the prefbyteries within the bounds of which their churches were fituated. Thefe were the men for whom Mr Rollock exerted himfelf to obtain feats in the parliament.

cumference itfelf; becaufe its centre advances in a right line as faft as that of the wheel does, being in reality the fame with it.

The folution given by Ariftotle, is no more than a good explication of the difficulty.

Galileo, who next attempted it, has recourfe to an infinite number of infinitely little vacuities in the right line defcribed by the two circles; and imagines that the little circles never applies its circumference to thofe vacuities; but in reality only applies it to a line equal to its own circumference; though it appears to have applied it to a much larger. But all this is nothing to the purpofe.

Tacquet will have it, that the little circle, making its rotation more flowly than the great one, does on that account defcribe a line longer than its own circumference; yet without applying any point of its circumference to more than one point of its bafe. But this is no more fatisfactory than the former.

After the fruitlefs attempts of fo many great men, M Dortous de Meyran, a French gentleman, had the good fortune to hit upon a folution, which he fent to the Academy of Sciences; where, being examined by Meffrs de Louville and Soulman, appointed for that purpofe, they made their report that it was fatisfactory. The folution is to this effect:

The wheel of a coach is only acted on, or drawn in a right line; its rotation or circular motion arifes purely from the refiftance of the ground upon which it is applied. Now this refiftance is equal to the force which draws the wheel in the right line, inafmuch as it defeats that direction; of confequence the caufes of the two motions, the one right and the other circular, are equal. And hence the wheel defcribes a right line on the ground equal to its circumference.

As for the nave of the wheel, the cafe is otherwife. It is drawn in a right line by the fame force as the wheel; but it only turns round becaufe the wheel does fo, and can only turn in the fame time with it. Hence it follows, that its circular velocity is lefs than that of the wheel, in the ratio of the two circumferences; and therefore its circular motion is lefs than the rectilinear one. Since then it neceffarily defcribes a right line equal to that of the wheel, it can only do it partly by fliding and partly by revolving, the fliding part being more or lefs as the nave itfelf is fmaller or larger.—*Hutton's Dictionary*.

ROWNING (John), an ingenious Englifh mathematician and philofopher, was fellow of Magdalen College, Cambridge, and afterwards Rector of Anderby in Lincolnfhire, in the gift of that Society. He was a conftant attendant at the meetings of the Spalding Society, and was a man of a great philofophical habit and turn of mind, though of a cheerful and companionable difpofition. He had a good genius for mechanical contrivances in particular. In 1738 he printed at Cambridge, A Compendious Syftem of Natural Philofophy, in 2 vols 8vo; a very ingenious work, which has gone through feveral editions. He had alfo two pieces inferted in the Philofophical Tranfactions, viz. 1. A Defcription of a Barometer, wherein the Scale of Variation may be increafed at pleafure; vol. xxxviii. p. 39. And, 2. Directions for making a Machine for finding the Roots of Equations univerfally, with the Manner of ufing it; vol. lx. p. 240.—Mr Rowning died at his lodgings in Carey ftreet, near Lincoln's-Inn Fields, the latter end of November 1771, at 72 years of age.

Though a very ingenious and pleafant man, he had but an unpromifing and forbidding appearance: he was tall, ftooping in the fhoulders, and of a fallow, downlooking countenance.

ROY ROYAN, in Bengal, the chief officer in the revenue department, next to the Dewan under the native government.

RUTHERFORD (John, M. D.), one of the illuftrious founders of the medical fchool in the univerfity of Edinburgh, was the fon of the Rev. Mr Rutherford minifter of Yarrow, in the county of Selkirk, North Britain. He was born on the 1ft Auguft 1695, and received the rudiments of his education at the parifh fchool of Selkirk. where, from his future proficiency, there is every reafon to believe that he made a rapid progrefs in the knowledge of the Latin and Greek languages.

After the death of his father, he went to Edinburgh in 1708 or 1710, where, in the univerfity, he applied himfelf to the ftudy of claffical literature, mathematics, and natural philofophy. The celebrated Dr Pitcairn was then fo highly refpected for his medical fkill, that it is not improbable but that a laudable defire of obtaining a portion of fimilar fame may have turned the attention of young Rutherford to the ftudy of medicine. Be that as it may, he engaged himfelf apprentice to Mr Alexander Nefbit, at that time an eminent furgeon in Edinburgh, with whom he remained till 1716, when he went to London. There he attended fome hofpitals, and the lectures read on anatomy by Dr Douglas, on furgery by André, and on materia medica by Strother.

After a year's refidence in London, he returned to Edinburgh; and having fettled his affairs in that city, he went to Leyden, which, from the lectures of Boerhaave, was then the moft celebrated medical fchool in Europe. In 1719 he went into France, and was at the end of July in that year admitted to the degree of M. D. in the univerfity of Rheims. He paffed the following winter in Paris, chiefly for the fake of Winflow's private demonftrations in anatomy; and in 1720 he returned to Britain.

In 1721 he fettled as a phyfician in Edinburgh; and foon afterwards Drs Rutherford, Sinclair, Plummer, and Innes, purchafed a laboratory, where they prepared compound medicines. This was an art then but little known in Scotland; and as a commercial fpeculation, the laboratory muft therefore have proved very advantageous to the partners. But they had higher objects in view than commerce. They demonftrated, as far as they were then known, the operations of chemiftry to a numerous audience; and foon afterwards, by the advice of their old mafter Boerhaave, they extended their lectures to the other branches of phyfic. In 1725 they were appointed joint profeffors in the univerfity; where, we believe, each, for fome time, read lectures in every department of medical fcience, anatomy excepted, and carried forward their claffes in rotation. The anatomical lectures were read by the elder Monro, who had been fettled a year or two before them in Edinburgh, and whofe eminence in that department is known to all Europe.

On the death of Dr Innes, a particular branch of medical ſcience was allotted to each of the other three profeſſors. Dr Plummer was appointed profeſſor of chemiſtry and materia medica, Dr Sinclair of the inſtitutes of phyſic, and Dr Rutherford of the practice; and thus was a regular medical ſchool eſtabliſhed in Edinburgh by Monro, Plummer, Sinclair, and Rutherford. The lectures on the inſtitutes and practice of phyſic were then, and for many years afterwards, delivered in Latin; and ſuch was Dr Rutherford's command of that language, that on every thing connected with medicine, he talked in it more fluently than in the language of his country.

Whether it was any improvement in the mode of medical education in Edinburgh to change the language of the lectures from Latin to Engliſh, is perhaps more than queſtionable. We have now diſperſed over the country a number of illiterate men, practiſing as ſurgeons, and even as phyſicians, who never could have boaſted of having gone through a regular courſe of medical inſtruction, had the lectures continued to be delivered in the language in which they were begun. Foreigners, too, would not have been under the neceſſity of learning a new language, before they could enter on the ſtudies, for the cultivation of which they came to Scotland; and though the medical claſſes might not have been ſo crowded perhaps as at preſent, the individuals compoſing them would have been at leaſt as reſpectable. Whether Dr Rutherford reaſoned in this way we know not; but he continued to lecture in Latin as long as he filled the practical chair.

About the year 1748 he introduced a very great improvement in the courſe of medical education. Senſible that abſtract lectures on the ſymptoms and the mode of treating various diſeaſes, of which the ſtudents know little but the names, could ſcarcely be of any benefit, he had for ſome time encouraged his pupils to bring patients to him on Saturday, when he inquired into the nature of their diſeaſes, and preſcribed for them in the preſence of the claſs. This gave riſe to the courſe of *clinical* lectures; the utility of which was ſo obvious, that it was enacted, by a decree of the ſenate of the univerſity, that no man ſhould be admitted to an examination for his doctor's degree, who had not attended thoſe lectures; to which an excellent hoſpital, then lately erected (ſee EDINBURGH, in the *Encyclopædia*), gave the profeſſors every opportunity of doing ample juſtice. To men who mean to live by the practice of phyſic, and have no inordinate ambition to raiſe their fame by fanciful theories, this is perhaps the moſt valuable courſe of lectures that is given in Edinburgh; and if ſo, Dr Rutherford muſt be conſidered as one of the greateſt benefactors of the medical ſchool.

To untried theories in phyſic he was indeed no friend; and we have heard a favourite and very able pupil of his, who knew him well, and reſpected him highly, affirm that, to his knowledge, Dr Rutherford retained his profeſſorſhip longer than he otherwiſe would have choſen to do; merely that he might keep out a ſpeculatiſt, whom he knew to be aſpiring to the practical chair. Finding at laſt in the late Dr John Gregory (ſee GREGORY, *Encycl.*) a ſucceſſor entirely to his mind, he reſigned to him in 1765, after having taught medicine in its different departments for upwards of forty years. He lived, after this period, loved by his friends, and revered by many eminent phyſicians, who had been his pupils, till 1779, when he died in Edinburgh, where he had ſpent the greater part of his life, in the 84th year of his age.

S.

SACCHAROMETER, the name given, by Mr Richardſon of Hull, to an inſtrument invented by him for aſcertaining the value of worts, and the ſtrength of different kinds of malt liquors. In plain Engliſh, the name ſignifies a *meaſurer of ſweetneſs*; and therefore, if etymology were to be attended to, the inſtrument ſhould be employed merely as a meaſurer of the ſweetneſs of worts. It is in fact beſt adapted for this purpoſe, being merely an hydrometer contrived to aſcertain the ſpecific gravity of worts, or rather to compare the weight of worts with that of equal quantities of the water employed in the brewery where the inſtrument is uſed.

The principle which ſuggeſted the invention of the inſtrument to Mr Richardſon is as follows: The menſtruum or water, employed by the brewer, becomes heavier or more denſe by the addition of ſuch parts of the materials as have been diſſolved or extracted by, and thence incorporated with it: the operation of boiling, and its ſubſequent cooling, ſtill adds to the denſity of it by evaporation; ſo that when it is ſubmitted to the action of fermentation, it is more denſe than at any other period.

In paſſing through this operation of nature, a remarkable alteration takes place. The fluid no ſooner begins to ferment than its denſity begins to diminiſh; and as the fermentation is more or leſs perfect, the fermentable matter, whoſe acceſſion has been traced by the increaſe of denſity, becomes more or leſs attenuated; and in lieu of every particle thus attenuated, a ſpirituous particle, of leſs denſity than water, is produced: ſo that when the liquor is again in a ſtate of quietude, it is ſo much ſpecifically lighter than it was before, as the action of fermentation has been capable of attenuating the component parts of its acquired denſity; and, indeed, were it practicable to attenuate the whole, the liquor

liquor would become lighter or lefs denfe than water; becaufe the quantity of fpirit produced from, and occupying the place of the fermentable matter, would diminifh the denfity of the water in a degree bearing fome proportion to that in which the latter had increafed it.

From thefe facts, the reader, who is acquainted with hydroftatical principles, will be able to conftruct a faccharometer for himfelf. Brewers who are ftrangers to thefe principles, we muft refer to Mr Richardfon's book for details, which our limits permit us not to give.

SAGITTA, in aftronomy, the *Arrow* or *Dart*; a conftellation of the northern hemifphere near the eagle, and one of the 48 old afterifms.

SAHARA, or, as it is fometimes written, ZAARA, the Great Defert, is a vaft ocean of fand in the interior parts of Africa, which, with the leffer deferts of Bornou, Bilma, Barca, Sort, &c. is equal in extent to about one half of Europe. If the fand be confidered as the ocean, the Sahara has its gulphs and bays, as alfo its iflands, or OASES, fertile in groves and paftures, and in many inftances containing a great population, fubject to order and regular government.

The great body, or weftern divifion of this ocean, comprized between Fezzan and the Atlantic, is no lefs than 50 caravan journeys acrofs, from north to fouth; or from 750 to 800 G. miles; and double that extent in length: without doubt the largeft defert in the world. This divifion contains but a fcanty portion of iflands (or oafes), and thofe alfo of fmall extent: but the eaftern divifion has many, and fome of them very large. Fezzan, Gadamis, Taboo, Ghanat, Agadez, Augela, Berdoa, are amongft the principal ones: befides which, there are a vaft number of fmall ones. In effect, this is the part of Africa alluded to by Strabo, when he fays from *Cneius Pifo*, that Africa may be compared to a leopard's fkin.

From the beft inquiries that Mr Park could make when a kind of captive among the Moors at Ludamar, the Weftern Defert, he fays, may be pronounced almoft deftitute of inhabitants; except where the fcanty vegetation, which appears in certain fpots, affords pafturage for the flocks of a few miferable Arabs, who wander from one well to another. In other places, where the fupply of water and pafturage is more abundant, fmall parties of the Moors have taken up their refidence. Here they live, in independent poverty, fecure from the tyrannical government of Barbary. But the greater part of the defert, being totally deftitute of water, is feldom vifited by any human being; unlefs where the trading caravans trace out their toilfome and dangerous route acrofs it. In fome parts of this extenfive wafte, the ground is covered with low ftunted fhrubs, which ferve as land-marks for the caravans, and furnifh the camels with a fcanty forage. In other parts, the difconfolate wanderer, wherever he turns, fees nothing around him but a vaft interminable expanfe of fand and fky; a gloomy and barren void, where the eye finds no particular object to reft upon, and the mind is filled with painful apprehenfions of perifhing with thirft. Surrounded by this dreary folitude, the traveller fees the dead bodies of birds, that the violence of the wind has brought from happier regions; and, as he ruminates on the fearful length of his remaining paffage, liftens with horror to the voice of the driving blaft; the only found that interrupts the awful repofe of the defert.

The few wild animals which inhabit thefe melancholy regions, are the antelope and the oftrich; their fwiftnefs of foot enabling them to reach the diftant wateringplaces. On the fkirts of the defert, where the water is more plentiful, are found lions, panthers, elephants, and wild boars.

Of domeftic animals, the only one that can endure the fatigue of croffing the defert is the camel. It is therefore the only beaft of burden employed by the trading caravans which traverfe, in different directions, from Barbary to Nigritia. The flefh of this ufeful and docile creature, though to our author's tafte it was dry and unfavoury, is preferred by the Moors to all others. The milk of the female, he fays, is in univerfal efteem, and is indeed pleafant and nutritive.

That the defert has a dip towards the eaft as well as the fouth, feems to be proved by the courfe of the Niger. Moreover, the higheft points of North Africa, that is to fay, the mountains of Mandinga and Atlas, are fituated very far to the weft. The defert, for the moft part, abounds with falt. But we hear of falt mines only in the part contiguous to Nigritia, from whence falt is drawn for the ufe of thofe countries, as well as of the Moorifh ftates adjoining; there being no falt in the Negro countries fouth of the Niger. There are falt lakes alfo in the eaftern part of the defert.

SAI, a large town on the banks of the Niger, or at leaft very near to that river, which Mr Park fays ftrongly excited his curiofity. It is completely furrounded by two very deep trenches, at about two hundred yards diftant from the walls. On the top of the trenches are a number of fquare towers; and the whole has the appearance of a regular fortification. Inquiring into the origin of this extraordinary entrenchment, our author learned from two of the town's people the following particulars; which, if true, furnifh a mournful picture of the enormities of African wars:

About fifteen years before our traveller vifited Sai, when the King of Bambarra defolated Maniana, the Dooty of Sai had two fons flain in battle, fighting in the king's caufe. He had a third fon living; and when the king demanded a further reinforcement of men, and this youth among the reft, the Dooty refufed to fend him. This conduct fo enraged the king, that when he returned from Maniana, about the beginning of the rainy feafon, and found the Dooty protected by the inhabitants, he fat down before Sai with his army, and furrounded the town with the trenches which had attracted our author's notice. After a fiege of two months, the town's people became involved in all the horrors of famine; and whilft the king's army were feafting in their trenches, they faw with pleafure the miferable inhabitants of Sai devour the leaves and bark of the Bentang tree that ftood in the middle of the town. Finding, however, that the befieged would fooner perifh than furrender, the king had recourfe to treachery. He promifed, that if they would open the gates, no perfon fhould be put to death, nor fuffer any injury, but the Dooty alone. The poor old man determined to facrifice himfelf, for the fake of his fellow-citizens, and immediately walked over to the king's army, where he was put to death. His fon, in attempting to efcape, was caught and maffacred in the trenches; and the reft of the town's people were carried away captives, and fold as flaves to the different Negro-traders.

traders. Sai is placed by Major Rennel in 14° N. Lat. and 3° 7′ W. Long.

SAINT CATHERINE, a Portuguese island in the South Sea, not far distant from the coast of Brazil. It was visited by La Perouse, who ascertained it to lie between 27° 19′ 10″, and 27° 49′ N. Lat. and its most northerly point to be in 49° 49′ longitude west from Paris. Its breadth from east to west is only two leagues; and it is separated from the main land by a channel only 200 toises broad. On the point which stretches furthest into this channel is situated the city of Nostra Senora del Destero, the capital of the government, and the place of residence of the governor. It contains at most 3000 souls, and about 400 houses. Its appearance is exceedingly pleasant. According to Frezier's account, this island served, in 1712, as a retreat to vagabonds, who made their escape from different parts of the Brazils; who were only nominal subjects of Portugal, and who acknowledged no authority whatever. The country is so fertile, that they were able to subsist without any succour from the neighbouring colonies: and they were so destitute of money, that they could neither tempt the cupidity of the governor-general of the Brazils, nor inspire him with any desire of subduing them. The ships that touched at the island gave them in exchange for their provisions nothing but clothes and shirts, of which they were in the utmost want. It was not till about 1740 that the court of Lisbon established a regular government in the island of St Catherine, and the parts of the continent adjacent. This government extends sixty leagues north and south from the river San Francisco to Rio Grande; its population being about 20,000 souls; but there are so great a number of children in the different families, that probably it will soon be much more considerable. The soil is exceedingly fertile, and produces all sorts of fruit, vegetables, and corn, almost spontaneously. It is covered with trees of everlasting green; but they are so interwoven with briars and creeping plants, that it is impossible to get through the forests otherwise than by opening a path with a hatchet. Danger is besides to be apprehended from snakes, whose bite is mortal. The habitations, both on the island and continent, are all close to the sea side. The woods that surround them are delightfully fragrant, owing to the great number of orange trees and other odoriferous trees and shrubs that they contain. But, notwithstanding all these advantages, the country is very poor, and totally destitute of manufactured commodities, so that the peasants are almost naked, or else covered with rags. Their soil, which is very fit for the cultivation of sugar, remains unproductive for the want of slaves, whom they are not rich enough to purchase. The whale fishery is very successful; but it is the property of the crown, and is farmed by a company at Lisbon, which has three considerable establishments upon the coast. Every year they kill about 400 whales; the produce of which, as well oil as spermaceti, is sent to Lisbon by the way of Rio Janeiro. The inhabitants are idle spectators of this fishery, from which they derive not the smallest advantage. La Perouse gives a very amiable picture, however, of their hospitality to strangers.

SALT. See CHEMISTRY-*Index*, in this *Suppl.*

SALT-Mines of Vielicza, near Cracow in Poland, are very extraordinary caverns; for a description of which we referred, in the article SALT (*Encycl.*) to M. Barniard in the *Journal de Physique* for the year 1786. Some of our readers have complained of this, and requested an account of them in the *Supplement*. With this request we shall comply, by giving them Mr Wraxall's description of these caverns*.

"After being let down (says he) by a rope to the depth of 230 feet, our conductors led us through galleries, which, for loftiness and breadth, seemed rather to resemble the avenues to some subterranean palace, than passages cut in a mine. They were perfectly dry in every part, and terminated in two chapels composed entirely of salt, hewn out of the solid mass. The images which adorn the altars, as well as the pillars and ornaments, were all of the same transparent materials; the points and spars of which, reflecting the rays of light from the lamps which the guides held in their hands, produced an effect equally novel and beautiful. Descending lower into the earth by means of ladders, I found myself in an immense hall or cavern of salt, many hundred feet in height, length, and dimensions, the floor and sides of which were cut with exact regularity. A thousand persons might dine in it without inconvenience, and the eye in vain attempted to trace or define its limits. Nothing could be more sublime than this vast subterranean apartment, illuminated by flambeaux, which faintly discover its prodigious magnitude, and leave the imagination at liberty to enlarge it indefinitely. After remaining about two hours and a half under ground, I was drawn up again in three minutes with the greatest facility."

* *Memoirs of the Courts of Berlin, Dresden, Warsaw, and Vienna.*

SALTPETRE (see *Nitre*, CHEMISTRY-*Index*, in this *Suppl.*) is an article of so much importance, and sometimes so difficult to be had, that it is wonderful more attention is not bestowed in endeavouring to discover some easy method to increase the quantity. Such a method has been long practised by the farmers of Appenzell in Switzerland. In so hilly a country, most houses and stables are built on slopes, one side of the edifice resting on the hill, and the other being supported by two strong posts, elevated two or three feet above the ground; so that the air has a free current under the building. Immediately under the stable a pit is dug, usually occupying both in breadth and length the whole space of ground covered by the building; and instead of the clayey earth which is dug out, the pit is filled up with sandy soil. This is the whole process, and all the rest is done by Nature. The animal water, which is continually oozing through the planks of the floor, having drenched the earth contained in the pit for the space of two or three years, the latter is emptied, and the saltpetre is refined and prepared in the usual manner.

That manner, however, is not the best; and the French chemists, during the incessant wars occasioned by the revolution, have, for the sake of supplying their armies with gunpowder, turned their attention to the best method of refining saltpetre. The following are directions given for this purpose by Chaptal, Champy, and Bonjour.

The crude saltpetre is to be beaten small with mallets, in order that the water may more easily attack every part of the mass. The saltpetre is then to be put into tubs, five or six hundred pounds in each tub. Twenty *per cent.* of water is to be poured into each tub, and

and the mixture well ftirred. It muft be left to macerate or digeft until the fpecific gravity of the fluid ceafes to augment. Six or feven hours are fufficient for this firft operation, and the water acquires the denfity of between 25 and 35 degrees. Sp. gr. 1.21, and 1.306, afcertained by Baumé's hydrometer. See HYDROMETER, *Suppl.*

The firft water muft then be poured off, and a fecond portion of water muft be poured on the fame faltpetre, amounting to 10 *per cent.*; after which the mixture muft be ftirred up, fuffered to macerate for one hour, and the fluid drawn or poured off.

Five *per cent.* of water muft then be poured on the faltpetre; and after ftirring the whole, the fluid muft be immediately drawn off.

When the water is drained from the faltpetre, the falt muft be thrown into a boiler containing 50 *per cent.* of boiling water. When the folution is made, it will mark between 66 and 68 degrees of the hydrometer. (Sp. gr. 1.848, and 1.898.)

The folution is to be poured into a proper veffel, where it depofits by cooling about two-thirds of the faltpetre originally taken. The precipitation begins in about half an hour, and terminates in between four and fix hours. But as it is of importance to obtain the faltpetre in fmall needles, becaufe in this form it is more eafily dried, it is neceffary to agitate the fluid during the whole time of the cryftallization. A flight motion is communicated to this liquid mafs by a kind of rake; in confequence of which the cryftals are depofited in very flender needles.

In proportion as the cryftals fall down, they are fcraped to the borders of the veffel, whence they are taken with a fkimmer, and thrown to drain in bafkets placed on treffels, in fuch a manner that the water which paffes through may either fall into the cryftallizing veffel, or be received in bafons placed underneath.

The faltpetre is afterwards put into wooden veffels in the form of a mill-hopper or inverted pyramid with a double bottom. The upper bottom is placed two inches above the lower on wooden ledges, and has many fmall perforations through which water may pafs to the lower bottom, which likewife affords a paffage by one fingle aperture. A refervoir is placed beneath. The cryftallized faltpetre is wafhed in thefe veffels with 5 *per cent.* of water; which water is afterwards employed in the folution of faltpetre in fubfequent operations.

The faltpetre, after fufficient draining, and being dried by expofure to the air upon tables for feveral hours, may then be employed in the manufacture of gunpowder.

But when it is required to ufe the faltpetre in the fpeedy and immediate manufacture of gunpowder, it muft be dried much more ftrongly. This may be effected in a ftove, or more fimply by heating it in a flat metallic veffel. For this purpofe the faltpetre is to be put into the veffel to the depth of five or fix inches, and heated to 40 or 50 degrees of the thermometer (or about 135° of Fahrenheit). The faltpetre is to be ftirred for two or three hours, and dried fo much that, when ftrongly preffed in the hand, it fhall acquire no confiftence, nor adhere together, but refemble a very fine dry fand. This degree of drynefs is not required when the powder is made by pounding.

From thefe circumftances, we find that two faline liquids remain after the operations; (1) the water from the wafhing; and (2) that from the cryftallizing veffels.

We have already remarked, that the wafhing of the faltpetre is performed in three fucceffive operations, in which, upon the whole, the quantity of fluid made ufe of amounts to 35 *per cent.* of the weight of the crude faltpetre. Thefe wafhings are eftablifhed on the principle, that cold water diffolves the muriats of foda, and the earthy nitrats and muriats, together with the colouring principle, but fcarcely attacks the nitrat of potafh.

The water of thefe three wafhings therefore contains the muriat of foda, the earthy falts, the colouring principle, and a fmall quantity of nitrat of potafh; the amount of which is in proportion to that of the muriat of foda, which determines its folution.

The water of the cryftallizing veffels contains a portion of the muriats of foda, and of the earthy falts which efcaped the operation of wafhing, and a quantity of nitrat of potafh, which is more confiderable than that of the former folution.

The waters made ufe of at the end of the operation, to whiten and wafh the cryftals depofited in the pyramidal veffel, contain nothing but a fmall quantity of nitrat of potafh.

Thefe waters are therefore very different in their nature. The water of the wafhings is really a mother water. It muft be collected in veffels, and treated with potafh by the known proceffes. It muft be evaporated to 66 degrees (or 1.848 fp. gr.), taking out the muriat of foda as it falls. This folution is to be faturated with 2 or 3 *per cent.* of potafh, then fuffered to fettle, decanted, and poured into cryftallizing veffels, where 20 *per cent.* of water is to be added to keep the whole of the muriat of foda fufpended.

The waters which are thus obtained by treatment of the mother water may be mixed with the water of the firft cryftallization. From thefe the marine falt may be feparated by fimple evaporation; and the nitrat of potafh, which they hold in folution, may be afterwards obtained by cooling.

The fmall quantity of water made ufe of to wafh and whiten the refined faltpetre, contains nothing but the nitrat of potafh: it may therefore be ufed in the folution of the falpetre when taken from the tubs.

From this defcription it follows, that a manufactory for the fpeedy refining of faltpetre ought to be provided with (1) mallets or rammers for pounding the faltpetre; (2) tubs for wafhing; (3) a boiler for folution; (4) a cryftallizing veffel of copper or lead, in which the faltpetre is to be obtained by cooling; (5) bafkets to drain the cryftals; (6) a wooden cafe or hopper for the laft wafhing and draining the faltpetre; (7) fcales and weights for weighing; (8) hydrometers and thermometers, to afcertain denfities and temperatures; (9) rakes to agitate the liquor in the cryftallizing veffel; (10) fkimmers to take out the cryftals, and to convey them to the bafkets; (11) fyphons or hand-pumps to empty the boilers.

The number and dimenfions of thefe feveral articles muft vary according to the quantity of faltpetre intended to be refined.

GUM-SANDARAC, is faid, in the *Encyclopædia*, to

Sandarac, Sanders.

to be produced from a ſpecies of juniper. This was long the common opinion; but M. Schouſboe has lately proved (A) it to be a miſtake. The *juniperus communis*, from which many have derived this gum, does not grow in Africa; and Sandarac ſeems to belong excluſively to that part of the world. The gum ſandarac of our ſhops is brought from the ſouthern provinces of the kingdom of Morocco. About ſix or ſeven hundred quintals of it are exported every year from Santa Cruz, Mogador, and Saſſy. In the language of the country it is called *el graſſa*. The tree which produces it is a *Thuia*, found alſo by M. Vahl in the kingdom of Tunis. It was made known ſeveral years ago by Dr Shaw, who named it *Cypreſſus fructu quadrivalvi, Equiſeti inſtar articulatis*; but neither of theſe learned men was acquainted with the economical uſe of this tree; probably becauſe, being not common in the northern part of Barbary, the inhabitants find little advantage in collecting the reſin which exudes from it.

M. Schouſboe, who ſaw the ſpecies of *thuia* in queſtion, ſays that it does not riſe to more than the height of twenty or thirty feet at moſt, and that the diameter of its trunk does not exceed ten or twelve inches. It diſtinguiſhes itſelf, on the firſt view, from the two other ſpecies of the ſame genus, cultivated in gardens, by having a very diſtinct trunk, and the figure of a real tree; whereas in the latter the branches riſe from the root, which gives them the appearance rather of buſhes. Its branches alſo are more articulated and brittle. Its flowers, which are not very apparent, ſhew themſelves in April; and the fruit, which are of a ſpherical form, ripen in September. When a branch of this tree is held to the light, it appears to be interſperſed with a multitude of tranſparent veſicles which contain the reſin. When theſe veſicles burſt in the ſummer months, a reſinous juice exudes from the trunk and branches, as is the caſe in other coniferous trees. This reſin is the ſandarac, which is collected by the inhabitants of the country, and carried to the ports, from which it is tranſported to Europe. It is employed in making ſome kinds of ſealing-wax, and in different ſorts of varniſh. In 1793 a hundred weight of it coſt in Morocco from 13 to 13½ piaſtres, which make from about L. 3, 5s. to L. 3, 7s. 6d. ſterling. The duty on exportation was about 7s. 6d. ſterling per quintal.

Sandarac, to be good, muſt be of a bright-yellow colour, pure and tranſparent. It is an article very difficult to be adulterated. Care, however, muſt be taken, that the Moors do not mix with it too much ſand. It is probable that a tree of the ſame kind produces the gum ſandarac of Senegal, which is exported in pretty conſiderable quantities.

SANDERS-RED (ſee PTEROCARPUS, *Encycl.*) is uſed as a dye-ſtuff, but generally in a manner which is very diſadvantageous. In Crell's Chemical Annals are given, by Mr Vogler, the following directions for dyeing with this wood.

1. Into a ſolution of tin made with aquafortis (nitric acid), and mixed with three times as much ſalt water, put clean waſhed wool, ſilk, linen, and cotton. After ſix hours, take them out, and waſh them carefully in three different quantities of clean cold water, wringing them well each time. Let them dry, and then put half the quantity of each article into the ſpirituous tincture of red ſanders, hereafter deſcribed in nº 6. letting them ſoak therein, without heat, from half an hour to an hour. To aſcertain the ſuperiority of his different proceſſes, the other half of each article muſt be boiled in the tincture of ſanders mixed with water, deſcribed in nº 7. a bare quarter of an hour. After being taken out, wrung, and dried in the ſhade, all of them will be dyed throughout of a fine rich poppy-colour.

2. Take three drams of powdered alum, and diſſolve it in twelve ounces of clean hot water. Into this ſolution, while yet warm, put ſome well-waſhed wool, ſilk, linen, and cotton. After ſuffering them to remain therein for the ſpace of twelve hours, take them out, waſh them well in three quantities of clean cold water (wringing them each time), and dry them. Then ſteep the half of each article in the cold ſpirituous tincture of ſanders (nº 6.), from half an hour to an hour; and boil the other half of each in the diluted tincture of ſanders (nº 7.) for the ſpace of ſix or ſeven minutes. After being taken out, wrung, and dried in the ſhade, they will be found to have acquired a very beautiful and rich ſcarlet colour.

3. Diſſolve three drams of blue vitriol, or vitriol of copper, in twelve ounces of hot water. Steep in this ſolution, for twelve hours, wool, ſilk, linen, or cotton; and having ſufficiently waſhed the ſtuff in clean cold water, immerſe the one half of it in the ſpirituous tincture of ſanders (nº 6.), from half an hour to an hour; and boil the other half of each for ſix or ſeven minutes in the diluted tincture, nº 7. Being then taken out, wrung, and dried in the ſhade, as before, they will have acquired a beautiful, rich, bright, crimſon colour.

4. Steep wool, ſilk, linen, and cotton, which has been well waſhed, during twelve hours, in a ſolution of three drams of white vitriol, or vitriol of zinc, in twelve ounces of hot water. After being taken out, well waſhed in clean cold water, and dried, immerſe one half of each in the cold ſpirituous tincture of ſanders (nº 6.) and boil the other half in the diluted tincture (nº 7.) as before. When taken out, wrung, and dried, they will be of a fine, rich, deep crimſon colour.

5. Diſſolve three drams of common green vitriol, or vitriol of iron, in twelve ounces of hot water: ſteep well-waſhed wool, ſilk, linen, and cotton, in the ſolution, for the ſpace of twelve hours. When taken out, waſhed ſeveral times in clean cold water, and dried, treat them, as in nº 4. and they will be generally found to be of a fine, rich, deep violet colour; though, on repeating his experiments, our author ſometimes found the colour a dark browniſh red.

The tincture in which the ſtuffs are to be died muſt be prepared in the following manner.

6. Take half an ounce of red ſanders wood, beat or ground to powder, as it is ſold at the colour ſhops or druggiſts. Having put it into a large glaſs bottle, pour upon it twelve ounces of malt ſpirit or common brandy; then cork the bottle, and ſet it in a moderately-warm place. In the ſpace of 48 hours, the ſpirit will have extracted all the colouring matter from the red ſanders, and thereby acquired a bright red colour. The bottle ſhould

(A) In a Daniſh Journal, intitled, *The Phyſical, Medical, and Economical Library*, Part III. 1799.

should be often shaken during the digestion; and the tincture, thus prepared, may be used for dyeing without heat, and without separating the powdered sanders from the liquor. The articles to be dyed (after the application of the proper mordants, n° 1, 2, 3, 4, 5) are to be steeped in the tincture for half an hour, or a whole hour: they are then to be taken out wrung, and dried in the shade. This tincture does not lose its dyeing quality by age; but dyes substances, after being kept a long time, almost as well as when it is just made. Its colouring power is indeed weakened by the frequent immersion and dyeing of different articles in it; and when that is the case, it must be again digested with some fresh sanders-wood.

7. Mix the spirituous tincture of sanders, just described, with from six to ten times as much clean cold water. The mixture was made by our author without any separation of the colouring particles worth noticing; and in this diluted tincture, the various articles (having their proper mordants first applied, n° 1, 2, 3, 4, 5) were boiled, as before mentioned. Linen and cotton, by being dipped in glue-water, after the application of the mordants, acquire, in this diluted tincture, a much deeper and richer colour.

If a very fine and bright colour be desired, the above spirituous tincture of sanders should not be too old, nor should the digestion be protracted beyond 48 hours; for after that period, the spirit appears to extract brown and yellow colouring particles from the wood. The powder of sanders need not be separated from the diluted tincture which is made use of by boiling; nor is it absolutely necessary to wash the articles in cold water after they are dyed; as the powder which adheres to them may easily be taken off by rubbing and shaking. M. Vogler, however, found it advantageous, after the articles were taken out of the dye, and wrung, to steep them for a few minutes in a cold solution of half an ounce of common salt, and a quarter of an ounce of alumn, in 12 ounces of pure water. In this case, they should afterwards be washed several times in clean cold water, then wrung and dried in the shade. By this method the colours are not only more beautiful, but are also more permanent. All the articles of wool, silk, linen, and cotton, which were dyed as is above mentioned, bore perfectly well the test of alkaline ley, soap, and acids; but, by exposure to the open air and the sun, the colours were more easily discharged, especially from linen and cotton.

N. B. Red sanders, by being ground to a fine powder, answers much better for dyeing by this process, than when it is merely cut into small pieces; but it must be remarked, that the powder of red sanders which is sold at the shops is sometimes adulterated, by being mixed with other substances, and moistened with acids. The best kind is not light, but rather heavy; and is not of a dark red colour, but clear and bright.

Goodwin SANDS, famous sand banks off the coast of Kent, lying between the north and south Foreland; and as they run parallel with the coast for three leagues together, at about two leagues and a half distant from it, they add to the security of that capacious road the Downs; for while the land shelters ships with the wind from south-west to north-west only, these sands break all the force of the sea when the wind is at east south-east. The most dangerous wind, when blowing hard on the Downs, is the south-south west. These sands occupy the space that was formerly a large tract of low ground belonging to Godwyn Earl of Kent, father of King Harold; and which being afterward given to the monastery of St Augustin at Canterbury, the abbot neglecting to keep in repair the wall that defended it from the sea, the whole tract was drowned, according to Salmon, in the year 1100, leaving these sands, upon which so many ships have since been wrecked.

SANSANDING, a town in Africa, situated near the banks of the Niger, in Lat. 14° 24′ N. and 2° 23′ W. Long. It is inhabited by Moors and Negroes to the number of from eight to ten thousand. The Negroes are kind, hospitable, and credulous; the Moors are at Sansanding, as every where else in the interior parts of Africa, fanatical, bigotted, and cruel.

SAP, or Sapp, in building, as to sap a wall, &c. is to dig out the ground from beneath it, so as to bring it down all at once for want of support.

SAPHAN, in zoology. See Mus, *Encycl.* p. 467.

SAPHIES, a kind of charms, consisting of some scrap of writing, which the credulous Negroes believe capable of protecting them from all evil. The writers of saphies are generally Moors, who sell scraps of the Koran for this purpose to a people who believe not either in the Koran or the prophet. Accordingly, any piece of writing may be sold as a saphie; and Mr Park found the Negroes disposed to place greater confidence in the saphies of a Christian than in those of a Moor. The manner in which these charms are supposed to operate, will be learned from the following story:

Mr Park being at Koolikorro, a considerable town near the Niger, and a great market of salt, his landlord, hearing that he was a Christian, immediately thought of procuring a saphie. For this purpose he brought out his *walha*, or writing board, assuring me (says our author) that he would dress me a supper of rice if I would write him a saphie to protect him from wicked men. The proposal was of too great consequence to me to be refused; I therefore wrote the board full, from top to bottom, on both sides; and my landlord, to be certain of having the whole force of the charm, washed the writing from the board into a calabash with a little water; and having said a few prayers over it, drank this powerful draught; after which, lest a single word should escape, he licked the board until it was quite dry. A saphie writer was a man of too great consequence to be long concealed: the important information was carried to the Dooty, who sent his son with half a sheet of writing-paper, desiring me to write him a *naphula saphie* (a charm to procure wealth). He brought me, as a present, some meal and milk; and when I had finished the saphie, and read it to him with an audible voice, he seemed highly satisfied with his bargain, and promised to bring me in the morning some milk for my breakfast. Our author contrived to turn this absurd superstition to his own advantage, by writing saphies for his subsistence when his money was exhausted.

SARACOLETS, a negro nation occupying the lands situated between the rivers of Senegal and Gambia. They are a laborious people, cultivate their lands with care, are plentifully supplied with all the necessaries of life, and inhabit handsome and well-built villages; their houses, of a circular form, are for the most part terraced;

ced; the others are covered with reeds as at Senegal; they are inclosed with a mud wall a foot thick, and the villages are surrounded with one of stone and earth of double that solidity. There are several gates, which are guarded at night for fear of a surprise. This nation is remarkably brave, and it is very uncommon to find a Saracolet slave. They always defend themselves with advantage against their assailants. Such Saracolets as are exposed to sale may be safely purchased, for (excepting when they are at war with the Poules) none are to be met with but such as have been condemned by the laws for some misdemeanour; in such case, these wretches could not escape slavery even by taking refuge in their own country; for they would be restored to their masters, or would be put to death, if the convey should have failed. The religious principles of this people are nearly allied to Mahometanism, and still more to natural religion. They acknowledge one God; and believe that those who steal, or are guilty of any crime, are eternally punished. They admit a plurality of wives, and believe their souls to be immortal like their own. They think lightly of adultery; for as they allow themselves several wives, they are not so unjust as to punish women who distribute their favours among several gallants; a mutual exchange is then permitted, one woman may be bartered for another, unless she be free, or a native of the country. In this last case, the French custom prevails; it is winked at, although the laws are particularly severe against the violation of the most sacred of all property. This nation lies near that of the Poules. (See that article, *Suppl.*) Its extent into the country is unknown; all that we know is, that it is governed by four powerful princes, all bearing the name of Fouquet. The least considerable, according to the testimony of the Saracolets, is that of Tuago, who can assemble thirty thousand horse, and whose subjects occupy a territory two hundred leagues in extent, as well on the Senegal as on the track that reaches beyond the Felou; a rock which, according to the same report, forms cataracts, from whence proceed the Senegal and the river Gambia, equally considerable.

SAROS, in chronology, a period of 223 lunar months. The etymology of the word is said to be Chaldean, signifying restitution, or return of eclipses; that is, conjunctions of the sun and moon in nearly the same place of the ecliptic. The Saros was a cycle like to that of Meto.

SARRASIN or SARRAZIN, in fortification, a kind of port-cullis, otherwise called a herse, which is hung with ropes over the gate of a town or fortress, to be let fall in case of a surprise.

SAVILLE (Sir Henry), a very learned Englishman, the second son of Henry Saville, Esq; was born at Bradley, near Halifax, in Yorkshire, November the 30th, 1549. He was entered of Merton college, Oxford, in 1561, where he took the degrees in arts, and was chosen fellow. When he proceeded master of arts in 1570, he read for that degree on the Almagest of Ptolemy, which procured him the reputation of a man eminently skilled in mathematics and the Greek language; in the former of which he voluntarily read a public lecture in the university for some time.

In 1578 he travelled into France and other countries; where, diligently improving himself in all useful learning, in languages, and the knowledge of the world, he became a most accomplished gentleman. At his return, he was made tutor in the Greek tongue to Queen Elizabeth, who had a great esteem and liking for him.

In 1585 he was made warden of Merton College, which he governed six-and-thirty years with great honour, and improved it by all the means in his power.—In 1596 he was chosen provost of Eton College; which he filled with many learned men.—James I. upon his accession to the crown of England, expressed a great regard for him, and would have preferred him either in church or state; but Saville declined it, and only accepted the ceremony of knighthood from the king at Windsor in 1604. His only son Henry dying about that time, he thenceforth devoted his fortune to the promoting of learning. Among other things, in 1619, he founded, in the University of Oxford, two lectures, or professorships, one in geometry, the other in astronomy; which he endowed with a salary of 160 l. a-year each, besides a legacy of 600 l. to purchase more lands for the same use. He also furnished a library with mathematical books, near the mathematical school, for the use of his professors; and gave 100 l. to the mathematical chest of his own appointing: adding afterwards a legacy of 40 l. a-year to the same chest, to the university, and to his professors jointly. He likewise gave 120 l. towards the new building of the schools, besides several rare manuscripts and printed books to the Bodleian library; and a good quantity of Greek types to the printing press at Oxford.

After a life thus spent in the encouragement and promotion of science and literature in general, he died at Eton College the 19th of February 1622, in the 73d year of his age, and was buried in the chapel there. On this occasion, the university of Oxford paid him the greatest honours, by having a public speech and verses made in his praise, which were published soon after in 4to, under the title of *Ultima Linea Savilii*.

As to the character of Saville, the highest encomiums are bestowed on him by all the learned of his time: by Casaubon, Mercerus, Meibomius, Joseph Scaliger, and especially the learned Bishop Montague; who, in his *Diatribæ* upon Selden's History of Tythes, styles him, "that magazine of learning, whose memory shall be honourable amongst, not only the learned, but the righteous for ever."

Several noble instances of his munificence to the republic of letters have already been mentioned; in the account of his publications many more, and even greater, will appear. These are,

1. Four Books of the Histories of Cornelius Tacitus, and the Life of Agricola; with Notes upon them, in folio, dedicated to Queen Elizabeth, 1581.—2. A View of certain Military Matters, or Commentaries concerning Roman Warfare, 1596.—3. *Rerum Anglicarum Scriptores post Bedam*, &c. 1598. This is a collection of the best writers of our English history; to which he added chronological tables at the end, from Julius Cæsar to William the Conqueror.—4. The Works of St Chrysostom, in Greek, in 8 vols folio, 1613. This is a very fine edition, and composed with great cost and labour. In the preface he says, "that having himself visited, about 12 years before, all the public and private libraries in Britain, and copied out thence whatever he thought useful to this design, he then sent some learned men into France, Germany, Italy,

Saville, Saussure.

Italy, and the East, to transcribe such parts as he had not already, and to collate the others with the best manuscripts." At the same time, he makes his acknowledgments to several eminent men for their assistance; as Thuanus, Valserus, Schottus, Casaubon, Ducæus, Gruter, Hoeschelius, &c. In the 8th volume are inserted Sir Henry Saville's own notes, with those of other learned men. The whole charge of this edition, including the several sums paid to learned men, at home and abroad, employed in finding out, transcribing, and collating the best manuscripts, is said to have amounted to no less than L. 8000. Several editions of this work were afterwards published at Paris.—5. In 1618 he published a Latin work, written by Thomas Bradwardin, archbishop of Canterbury, against Pelagius, intitled, *De Causa Dei contra Pelagium, et de virtute causarum;* to which he prefixed the life of Bradwardin.—6. In 1621 he published a collection of his own Mathematical Lectures on Euclid's Elements, in 4to.—7. *Oratio coram Elizabetha Regina Oxoniæ habita*, anno 1592. Printed at Oxford in 1458, in 4to. 8. He translated into Latin King James's Apology for the Oath of Allegiance. He also left several manuscripts behind him, written by order of King James; all which are in the Bodleian library. He wrote notes likewise upon the margin of many books in his library, particularly Eusebius's Ecclesiastical History; which were afterwards used by Valesius, in his edition of that work in 1659.—Four of his letters to Camden are published by Smith, among Camden's Letters, 1691, 4to.

SAUSSURE (Horace Benedict de) was born at Geneva in 1740. His father, an intelligent farmer, to whom we are indebted for some memoirs relating to rural economy, resided at Conches, a place situated on the banks of the Arve, at the distance of half a league from Geneva; and this country life, added to an active education, expanded no doubt in young De Saussure that physical strength so necessary to the naturalist who devotes himself to travel. He repaired daily to town to enjoy the advantage of public instruction; and as he lived at the bottom of Saleve, a mountain which he has since rendered celebrated, he amused himself frequently with ascending its steep and rugged sides. Being thus surrounded by the phenomena of nature, and at the same time aided by study, he conceived a taste for natural history, and avoided the error both of the learned, who form theories without having been out of their closets, and of those farmers who, living too near to Nature, are incapable of admiring her beauties.

His earliest passion was botany: a variegated soil, abundant in plants of different kinds, invites the inhabitant of the banks of the Leman to cultivate that agreeable science. This taste produced an intimacy between De Saussure and the great Haller. He paid him a visit in the year 1764, during his retreat to Bex; and he relates in his travels how much he admired that astonishing man, who excelled in every part of the natural sciences. De Saussure was induced also to study the vegetable kingdom, by his connection with Ch. Bonnet, who had married his aunt, and who soon set a just value on the rising talents of his nephew. Bonnet (See his life in this *Suppl.*) was then employed on the leaves of plants. De Saussure studied these organs of vegetables also, and he published the result of his researches, under the title of Observations on the Bark of Leaves. This small work, which appeared soon after the year 1760, contains new observations on the epidermis of leaves, and in particular on the miliary glands by which they are covered.

About that period, the place of professor of philosophy falling vacant, it was conferred upon De Saussure, who was then only twenty-one years of age. Experience proves, that if premature rewards extinguish the zeal of those who labour merely for themselves, they, on the contrary, strengthen it in those who labour only for truth. At that time the two professors of philosophy at Geneva taught physics and logic alternately. De Saussure discharged this double task with equal success. He gave to his course of logic a practical, and, as one may say, experimental turn; and his method of teaching, which began by studying the senses to arrive at the general laws of the understanding, announced already an able observer of nature.

Physics, however, were the part for which he had the greatest taste, and which conducted him to the study of chemistry and mineralogy. He then began his travels through the mountains; not now to examine their vegetable productions, but to study the mountains themselves, either in the stones of which they are composed, or the disposition of their masses. Geology, a science which was then scarcely in existence, added charms to his numerous excursions through the Alps; and it was then that the talents of the great philosopher were really displayed. During the first fifteen or twenty years of his professorship, he employed himself by turns in discharging the duties of his office, and in traversing the different mountains in the neighbourhood of Geneva. He even extended his excursions on one side as far as the banks of the Rhine, and on the other to Piedmont. At the same time he undertook a journey to Auvergne to examine there the extinguished volcanoes, and another to Paris, England, and Holland. After that he visited Italy, and even Sicily. These were not mere journeys for the purpose of reaching any particular place; he undertook them only with a view of studying nature; never travelled but surrounded by every instrument that could be of use to him, and never set out until he had drawn up a plan of the experiments and observations he intended to make. He often says in his works that he had found this method exceedingly useful.

In the year 1779 he published the first volume of his Travels through the Alps; which contains a minute description of the environs of Geneva, and an excursion as far as Chamouni, a village at the bottom of Mont Blanc. Philosophers will read there with pleasure the description of his Magnetometer. The more he examined mountains, the more was he sensible of the importance of mineralogy. To study it with advantage, he learned the German language; and it may be seen, in the last volumes of his Travels, how much new mineralogical knowledge he had acquired.

Amidst his numerous excursions through the Alps, and at the time of the political troubles of Geneva in 1782, he found means to make his beautiful experiments on hygrometry, which he published in 1783, under the title of *Essays on Hygrometry*. This work, the best that ever came from his pen, established fully his reputation as a philosopher. We are indebted to him also for the invention of a new hygrometer. Deluc had

Sauffure.

had already invented his whalebone hygrometer; and on that account there arofe between him and De Sauffure a fort of conteft, which degenerated into a pretty violent difpute.

In the year 1786 De Sauffure refigned the profeffor's chair, which he had filled for about twenty-five years, to his pupil and fellow-labourer Pictet, who difcharged with reputation the duties of an office rendered more difficult by fucceeding fo eminent a philofopher.

When De Sauffure was invited by the ftate to take a fhare in the public education, he made it one of the fubjects of his meditations, and prefented the plan of a reform in the education of Geneva: the tendency of which was, to make young people early acquainted with the natural fciences and mathematics. He even wifhed that their phyfical education fhould not be neglected, and with that view propofed gymnaftic exercifes. This plan, which excited much attention in a city where every one is convinced of the importance of education, found admirers and partifans; but the poverty of its pecuniary refources was an obftacle to every important innovation. It was befides feared that, by altering eftablifhed forms, they might lofe the fubftance, and that things might be changed for the worfe. The Genevefe were attached to their old fyftem of education; and they had reafon to be fo, becaufe it had not only proved the means of diffufing knowledge generally amongft them, but had called forth the talents of feveral eminent mathematicians (A) and philofophers (B).

But De Sauffure's attention was not confined to public education alone. He fuperintended himfelf the education of his two fons and a daughter, who have fhewn themfelves worthy of fuch an inftructor. His daughter to the charms of her fex unites an extenfive knowledge of the natural fciences; and his eldeft fon has already made himfelf known by his phyfical and chemical labours.

The fecond volume of his Travels was publifhed in 1786. It contains a defcription of the Alps around Mont Blanc, which the author confiders as a mineralogift, a geologift, and a philofopher. He gives alfo fome interefting experiments on electricity, and a defcription of his electrometer, one of the moft perfect that we have. We are indebted to him alfo for feveral inftruments of meafurement, fuch as his *cyanometer*, deftined to meafure the degree of the bluenefs of the heavens, which varies according to the elevation of the obferver; his *diaphanometer* (fee PHOTOMETER in this *Supplement*), and his *anemometer*, which, by means of a kind of balance, meafures the force of the wind.

Some years after the publication of the fecond volume of his Travels, De Sauffure was admitted as a foreign affociate of the Academy of Sciences of Paris; and Geneva could then boaft of having two of its citizens in that clafs, which confifted only of feven members. De Sauffure not only did honour to his country; he loved and ferved it. He was the founder of the Society of Arts, to which Geneva is indebted for the high ftate of profperity it has attained within the laft thirty years. He prefided over that fociety till the laft moment of his life; and one of his fondeft wifhes was the prefervation of this ufeful eftablifhment.

In confequence of M. de Sauffure's fatiguing labours in the Council of Two Hundred, of which he was a member, and afterwards in the National Affembly, his health began to be deranged, and in 1794 he was almoft deprived of the total ufe of his limbs by a ftroke of the palfy. However painful his condition then might be, his mind ftill preferved its activity; and after that accident he revifed the two laft volumes of his Travels, which appeared in 1796. They contain an account of his excurfions to the mountains of Piedmont and Switzerland, and in particular of his journey to the fummit of Mont Blanc. Thefe volumes, inftead of exhibiting any marks of his malady, prefent an enormous mafs of new facts and obfervations of the utmoft importance to phyfics.

He rendered alfo an important fervice to that fcience by publifhing the *Agenda*, which terminate his fourth volume, and in which that great man, furviving himfelf, conducts the young naturalift through the middle of mountains, and teaches him the method of obferving them with advantage. Thefe *Agenda* are a proof of his genius, and of the ftrength of mind which he retained amidft his fufferings. It was alfo during his illnefs that he directed the experiments made on the height of the bed of the Arve, and that he publifhed Obfervations on the Fufibility of Stones by the Blow-pipe, which were inferted in the *Journal de Phyfique*.

Having gone for the fake of his health to the baths of Plombiers, he ftill obferved the mountains at a diftance, and caufed to be brought to him fpecimens of the ftrata which he perceived in the fteepeft rocks. He had announced that he would conclude his travels with fome ideas on the primitive ftate of the earth; but the more he acquired new facts, and the more he meditated on the fubject, the more uncertain did his opinions become in regard to thofe grand revolutions which preceded the prefent epoch. In general he was a Neptunian; that is to fay, afcribed all the revolutions of our globe to water. He admitted the poffibility of the mountains having been thrown up by elaftic fluids difengaged from the cavities of the earth.

Though the ftate of his health began gradually to become worfe, he ftill entertained hopes of recovery; and the French government having appointed him profeffor of philofophy at the Special School of Paris, he did not defpair of being one day able to fill that office: but his ftrength was exhaufted, a general languor fucceeded the vigour he had always enjoyed, his flow and embarraffed pronunciation no longer correfponded with the vivacity of his mind, and formed a melancholy contraft with the pleafantnefs by which he had been formerly diftinguifhed. It was a painful fpectacle to fee this great man reduced thus to imbecility at an age when meditation is beneficial, and when he might have enjoyed the fruits of his reputation and labours.

In vain did he try, for the re-eftablifhment of his health, all the remedies which medicine, enlightened by the

(A) Abauzit, Cramer, Lhuilier, J. Trembley, &c.

(B) Jalabert, A. Trembley, Bonnet, Lefage, Deluc, Senebier, Prévoft, Pictet, and De Sauffure himfelf.

the phyfical fciences, could afford—all affiftance was ufelefs. The vital power quitted him with flow and painful fteps. Towards the beginning of autumn 1798 his decay became more vifible, his mind loft all its activity, and on the 22d of March 1799 he terminated his brilliant career, at the age of 59, lamented by a family to whom he was dear—by a country to which he had done honour—and by Europe, the knowledge of which he had extended.

SCALE, in architecture and geography, a line divided into equal parts, placed at the bottom of a map or draught, to ferve as a common meafure to all the parts of the building, or all the diftances and places of the map.

SCALES, in mathematics, fee SCALES *(Encycl.)*, and likewife *LOGARITHMIC Lines*, under which title are mentioned fome improvements by Mr Nicholfon on Gunter's fcale. Thefe improvements are valuable; and the reader will find a fuller account of them in the firft volume of the author's *Philofophical Journal*.

SCANTLING, a meafure, fize, or ftandard, by which the dimenfions, &c. of things are to be determined. The term is particularly applied to the dimenfions of any piece of timber, with regard to its breadth and thicknefs.

SCAPEMENT, in clock work, a general term for the manner of communicating the impulfe of the wheels to the pendulum. The ordinary fcapements confift of the fwing-wheel and pallets only; but modern improvements have added other levers or detents, chiefly for the purpofes of diminifhing friction, or for detaching the pendulum from the preffure of the wheels during part of the time of its vibration. See *WATCH Making*, in this *Suppl.*

SCARFING, a term in carpentry; by which is meant the joining of two beams of wood together to increafe the length: the beams in the joint are indented into one another, as in figures 19, 24, and 25, Plate X. *Supplement.*

SCARLET, a beautiful bright red colour given to cloth, either by a preparation of kermes (See that article in *Suppl.*), or more completely by the American cochineal. Profeffor Beckmann, in the fecond volume of his Hiftory of Inventions, feems to have eftablifhed the following conclufions:

1ft, Scarlet, or the kermes dye, was known in the Eaft in the earlieft ages, before Mofes, and was a difcovery of the Phœnicians in Paleftine, but certainly not of the fmall wandering Hebrew tribes. *2d*, *Tola* was the ancient Phœnician name ufed by the Hebrews, and even by the Syrians; for it is employed by the Syrian tranflator, Ifaiah, chap. 1. ver. 18. Among the Jews, after their captivity, the Aramæan word *zehori* was more common. *3d*, This dye was known alfo to the Egyptians in the time of Mofes; for the Ifraelites muft have carried it along with them from Egypt. *4th*, The Arabs received the name kermes, with the dye, from Armenia and Perfia, where it was indiginous, and had been long known; and that name banifhed the old name in the Eaft, as the name fcarlet has in the Weft. For the firft part of this affertion we muft believe the Arabs. *5th*, Kermes were perhaps not known in Arabia; at leaft they were not indiginous, as the Arabs appear to have had no name for them. *6th*, Kermes fignifies always *red dye*; and when pronounced fhort, it becomes *deep red*.

Concerning the origin of the name fcarlet, which was in ufe fo early as the 11th century, our author has many conjectures, which we need not tranfcribe, as he feems not quite fatisfied with any of them himfelf. The following reflections upon the comparative excellence of the ancient and modern fcarlet, together with the progrefs of the art of dyeing that colour, are worthy of notice:

"Of the preparation and goodnefs of the ancient fcarlet we certainly know nothing; but as we find in many old pieces of tapeftry of the 11th century, and perhaps earlier, a red which has continued remarkably beautiful even to the prefent time, it cannot at any rate be denied, that our anceftors extolled their fcarlet not without reafon. We can, however, venture to affert, that the fcarlet prepared at prefent is far fuperior, owing principally to the effects of a folution of tin.—This invention may be reckoned amongft the moft important improvements of the art of dyeing, and deferves a particular relation.

"The tincture of cochineal alone yields a purple colour, not very pleafant, which may be heightened to the moft beautiful fcarlet by a folution of tin in aqua-regia (nitro muriatic acid). This difcovery was made as follows: Cornelius Drebbel, who was born at Alkmaar, and died at London in 1634, having placed in his window an extract of cochineal, made with boiling water, for the purpofe of filling a thermometer, fome aqua-regia dropped into it from a phial, broken by accident, which ftood above it, and converted the purple dye into a moft beautiful dark red. After fome conjectures and experiments, he difcovered that the tin by which the window-frame was divided into fquares had been diffolved by the aqua-regia, and was the caufe of this change. He communicated his obfervation to Kuffelar, that excellent dyer at Leyden, who was afterwards his fon in-law. The latter brought the difcovery to perfection, and employed it fome years alone in his dye-houfe, which gave rife to the name of Kuffelar's colour. In the courfe of time the fecret became known to an inhabitant of Menin, called Gulich, and alfo to another perfon of the name of Van der Vecht, who taught it to the brothers Gobelins in France. Giles Gobelin, a dyer at Paris, in the time of Francis I. had found out an improvement of the then ufual fcarlet-dye; and as he had remarked that the water of the rivulet Bievre, in the fuburbs St Marceau, was excellent for his art, he erected on it a large dye-houfe; which, out of ridicule, was called *Folie Gobelins*, Gobelin's Folly. About this period, a Flemifh painter, whom fome name Peter Koek, and others Kloek, and who had travelled a long time in the Eaft, eftablifhed, and continued to his death in 1650, a manufactory for dyeing fcarlet cloth by an improved method. Through the means of Colbert, one of the Gobelins learned the procefs ufed for preparing the German fcarlet dye from one Gluck, whom fome confider as the above-mentioned Gulich, and others as Kloek; and the Parifian fcarlet dye foon rofe into fo great repute, that the populace imagined that Gobelin had acquired his art from the devil. It is well known that Louis XIV. by the advice of Colbert, purchafed Gobelin's building from his

his succeffors in the year 1667, and transformed it into a palace, to which he gave the name of *Hôtel royal des Gobelins*, and which he affigned for the ufe of firft rate artifts, particularly painters, jewellers, weavers of tapeftry, and others. After that time the rivulet was no longer called Bievre, but Gobelins. About the year 1643, a Fleming, named Kepler, eftablifhed the firft dye-houfe for fcarlet in England, at the village of Bow, not far from London; and on that account the colour was called, at firft, by the Englifh, the *Bow-dye*. In the year 1667, another Fleming, named Brewer, invited to England by King Charles II. with the promife of a large falary, brought this art there to great perfection."

SCHEME, a draught or reprefentation of any geometrical or aftronomical figure, or problem by lines fenfible to the eye; or of the celeftial bodies in their proper places for any moment; otherwife called a diagram.

SCIAGRAPHY, or Sciography, the profile or vertical fection of a building; ufed to fhew the infide of it.

Sciagraphy, in aftronomy, &c. is a term ufed by fome authors for the art of finding the hour of the day or night, by the fhadow of the fun, moon, ftars, &c.

SCIOPTIC, or *Scioptric Ball*, a fphere or globe of wood, with a circular hole or perforation, where a lens is placed. It is fo fitted, that, like the eye of an animal, it may be turned round every way, to be ufed in making experiments of the darkened room.

SCOLYMUS (fee that article *Encycl.*) is, by Pliny and Theophraftus, reckoned to belong to the genus of the thiftles. The former fays, that like moft others of the fame kind, the feeds were covered by a fort of wool *(pappus)*. It had a high ftem, furrounded with leaves which were prickly, but which ceafed to fting when the plant withered. It flowered the whole fummer through, and had often flowers and ripe feed at the fame time; which is the cafe alfo with our artichoke plants. The calyx of the *fcolymus* was not prickly; the root was thick, black, and fweet, and contained a milky juice. It was eaten both raw and cooked; and Theophraftus obferves, as fomething very remarkable, that when the plant was in flower, or, as others explain the words, when it had finifhed blowing, it was moft palatable. What renders this circumftance fingular is, that moft milky roots ufed for food lofe their milk, and become unfit to be eaten as foon as they have blown. This is the cafe with the goat's beard, which is eatable only the firft year.

Profeffor Beckmann has, with much labour and erudition, endeavoured to afcertain what is really the plant which was known to the ancients by the name of *fcolymus*. He feems to have proved fufficiently, that it was not the *cactus*, the *carduus*, or the *cinara*; but he has not been able to come to any other conclufion. "Were I appointed or condemned (fays he) to form a new Latin dictionary, I fhould explain the article *fcolymus* in the following manner: *Planta compofita, capitata. Caulis longus, obfitus foliis fpinofis. Radix carnofa, lactefcens, nigra, dulcis, edulis. Calix fquamis inermibus, difco carnofo, ante efflorefcentiam eduli. Semina pappofa. Turiones edules.* This defcription, fhort as it is, contains every thing that the ancients have faid in order to characterife that plant."

SCONCES, fmall forts, built for the defence of fome pafs, river, or other place. Some fconces are made regular, of four, five, or fix baftions; others are of fmaller dimenfions, fit for paffes or rivers; and others for the field.

SCOTALES, were meetings held formerly in England for the purpofe of drinking ale, of which the expence was defrayed by joint contribution. Thus the tenants of South Malling in Suffex, which belonged to the Archbifhop of Canterbury, were, at the keeping of a court, to entertain the Lord or his bailiff with a drinking, or an *ale;* and the ftated quotas towards the charge were, that a man fhould pay three-pence halfpenny for himfelf and his wife, and a widow and a cottager three half pence. In the manor of Ferring, in the fame county, and under the fame jurifdiction, it was the cuftom for the tenants named to make a *fcotale* of fixteen pence halfpenny, and to allow out of each fixpence three halfpence for the bailiff.

Common fcotales in taverns, at which the clergy were not to be prefent, are noticed in feveral ecclefiaftical canons. They were not to be publifhed in the church by the clergy or the laity; and a meeting of more than ten perfons of the fame parifh or vicinage was a fcotale that was generally prohibited. There were alfo common drinkings, which were denominated *leet-ale*, *bride-ale*, *clerk-ale*, and *church-ale*. To a *leet-ale* probably all the refidents in a manorial diftrict were contributors; and the expence of a *bride-ale* was defrayed by the relations and friends of a happy pair, who were not in circumftances to bear the charges of a wedding dinner. This cuftom prevails occafionally in fome diftricts of Scotland even at this day, under the denomination of a *penny bride-ale*, and was very common fifty or fixty years ago. The *clerk's*-ale was in the Eafter holidays, and was the method taken to enable clerks of parifhes to collect more readily their dues.

Mr Warton, in his Hiftory of Englifh Poetry, has inferted the following extract from an old indenture, which fhews clearly the defign of a *church*-ale. "The parifhioners of Elveftone and Okebrook, in Derbyfhire, agree jointly to brew four ales, and every ale of one quarter of malt, betwixt this and the feaft of St John the Baptift next coming; and that every inhabitant of the faid town of Okebrook fhall be at the feveral ales. And every hufband and his wife fhall pay two pence, every cottager one-penny; and all the inhabitants of Elvefton fhall have and receive all the profits and advantages coming of the faid ales, to *the ufe and behoof of the faid church of Elvefton.*"

The *give-ales* were the legacies of individuals; and from that circumftance entirely gratuitous. They feem to have been very numerous, and were generally left to the poor; though, from the largenefs of the quantity of ale enjoined to be brewed, it muft have been fometimes intended that others were to partake of them. Thefe bequefts were likewife, not unfrequently, made to the light or altar of a faint, with directions for finging maffes at the obit, trenthal, or anniverfary of the teftator. Hence, though fcotales were generally kept in houfes of public refort, the give-ales were fometimes difpenfed in the church, and often in the churchyard; by which means "Godde's houfe (as Sumner fays in his Treatife on Gavelkind) was made a tavern of gluttons." Such certainly would be Chalk church, if in it was

was kept the give-ale of William May of that parifh; for he ordered his wife to "make in bread fix bufhels of wheat, and in drink ten bufhels of mault, and in cheefe twenty-pence, to give to poor people for the health of his foul; and he ordered that, after the deceafe of his wife, his executors and feoffees fhould continue the cuftom for evermore."

SCOWRING OF STUFFS, is an art much more generally practifed than underftood. It fuppofes, fays Chaptal, 1ft, a knowledge of the different fubftances capable of ftaining any kind of cloth; 2d, of the fubftances to which recourfe muft be had, in order to make thofe depofited on the ftuff to difappear; 3d, a knowledge of the effects produced on colours by thofe re-agents, which it may be neceffary to employ to deftroy ftains; 4th, a knowledge of the manner in which the cloth is effected by thofe re agents; 5th, of the art of reftoring a colour changed or faded. Of thofe bodies which occafion fpots on different kinds of cloth, fome are eafily diftinguifhed by their appearance, fuch as greafy fubftances; but others have more complex effects, fuch as acids, alkalies, perfpired matter, fruits, urine, &c. Acids redden black, fawn, violet, and puce-colour, and every fhade communicated with orchilla-weed, iron, aftringents, and every blue except indigo and pruffian blue. They render the yellows paler, except that of arnatto, which they change into orange.

Alkalies change to violet the reds produced by Brazil-wood, logwood, and cochineal. They render the greens on woollen cloth yellowifh, make yellow brownifh, and change the yellow produced by arnatto to aurora. Perfpired matter produces the fame effects as alkalies.

When the fpots are produced by fimple bodies on ftuffs, it is eafy to remove them by the means already known. Greafy fubftances are removed by alkalies, foaps, the yolk of eggs, fat earths; oxides of iron, by the nitric and oxalic acids; acids by alkalies, and reciprocally. Stains of fruit on white ftuffs may be removed by the fulphureous acid, and ftill better by the oxigenated muriatic acid. But when the fpots are of a complex kind, it will be neceffary to employ feveral means in fucceffion. Thus, to deftroy the ftain of coom from carriage-wheels, after the greafe has been diffolved, the oxide of iron may be removed by the oxalic acid.

As colours are often changed by re-agents, it will be neceffary, in order to reftore them, that the fcowrer fhould poffefs a thorough knowledge of the art of dyeing, and how to modify the means according to circumftances. This becomes the more difficult, when it is neceffary to reproduce a colour fimilar to that of the reft of the ftuff, to apply that colour only in one place, and often to reftore the mordant by which it was fixed, and which has been deftroyed, or even the firft tint which gave the colour its intenfity. It may be readily conceived that the means to be employed muft depend on the nature of the colour and the ingredients by which it was produced; for it is known that the fame colour may be obtained from very different bodies. Thus, after an alkali has been employed to deftroy an acid fpot on browns, violets, blues, poppies, &c. the yellow fpot which remains may be made to difappear by a folution of tin; a folution of fulphat of iron reftores the colour to brown ftuffs which have been galled; acids reftore to their former fplendour yellows which have been rendered dufky or brown by alkalies; blacks produced by logwood become red by acids; alkalies change thefe red fpots to yellow, and a little of the aftringent principle makes them again become black. A folution of one part of indigo in four parts of fulphuric acid, diluted with a fufficient quantity of water, may be employed with fuccefs to revive the blue colour of cotton or wool which has been changed. Scarlet may be revived by means of cochineal and a folution of the muriat of tin, &c.

The choice of re-agents is not a matter of indifference. Vegetable acids are preferable; the fulphureous acid, however, may be employed for ftains occafioned by fruit; it does not change the blue of filk nor colours produced by aftringents; it does not degrade the yellow of cotton. Ammonia fucceeds better than fixed alkalies in removing fpots produced by acids. It is employed in vapour; its action is fpeedy, and feldom alters the colour.

The means of removing greafy fpots are well known. This effect is produced by alkalies, fullers earth, volatile oils diffolved in alcohol, a heat proper for volatilizing greafe, &c. Spots occafioned by ink, ruft, or iron-mould of any kind, and all thofe produced by the yellow oxide of iron, are removed by the oxalic acid: the colour may be reftored by alkalies, or a folution of the muriat of tin. Thefe fpots may be removed alfo by the oxygenated muriatic acid, when they are on white ftuffs or paper.

The action of alkalies, and that of perfpired matter, are the fame: their fpots may be effaced by acids, or even by a weak folution of the muriat of tin. When thefe fpots arife from feveral unknown caufes, in order to deftroy them, recourfe muft be had to polychreft compofitions. The following may be confidered as one of the moft efficacious: Diffolve white foap in alcohol, and mix this folution with the yolks of from four to fix eggs; add gradually effence of turpentine; and incorporate with the whole fome fullers earth, in fuch a manner as to form balls of a fuitable confiftence. Moiften the fpot; and having rubbed it with thefe balls, the fpot will be removed by wafhing the ftuff. All fpots, except iron-mould and ink, may be removed in this manner.

Wafhing deftroys the luftre, and leaves a tarnifhed place difagreeable to the eye; but the luftre may be reftored by drawing over the wafhed place, and in the direction of the pile, a brufh moiftened in water, impregnated with a little gum. You may then apply a fheet of paper, or a piece of cloth, and a confiderable weight, under which the cloth muft be left to dry.

SCYLLA. Under this title we gave, in the *Encyclopædia*, an account of Scylla and Charybdis, which, though taken from a work which we thought good authority, appears to be far from correct. Thefe places, fo famous in the poems of Homer and Virgil, were examined with minute attention by that accurate obferver of nature the Abbé Spallanzani; who thus defcribes Scylla.

"It is a lofty rock, diftant twelve miles from Meffina, which rifes almoft perpendicularly from the fea on the fhore of Calabria, and beyond which is the fmall city of the fame name. Though there was fcarcely any wind, I began to hear, two miles before I came to the rock,

rock, a murmur and noiſe like a confuſed barking of dogs, and on a nearer approach readily diſcovered the cauſe. This rock, in its lower parts, contains a number of caverns, one of the largeſt of which is called by the people there *Dragara*. The waves, when in the leaſt agitated, ruſhing into theſe caverns, break, daſh, throw up frothy bubbles, and thus occaſion theſe various and multiplied ſounds. I then perceived with how much truth and reſemblance of nature Homer and Virgil, in their perſonifications of Scylla, had pourtrayed this ſcene, by deſcribing the monſter they drew as lurking in the darkneſs of a vaſt cavern, ſurrounded by ravenous barking maſtiffs, together with wolves, to increaſe the horror.

"Such is the ſituation and appearance of Scylla; let us now conſider the danger it occaſions to mariners. Though the tide is almoſt imperceptible in the open parts of the Mediterranean, it is very ſtrong in the ſtrait of Meſſina, in conſequence of the narrowneſs of the channel, and is regulated, as in other places, by the periodical elevations and depreſſion of the water. Where the flow or current is accompanied by a wind blowing the ſame way, veſſels have nothing to fear, ſince they either do not enter the ſtrait, both the wind and the ſtream oppoſing them, but caſt anchor at the entrance; or, if both are favourable, enter on full ſail, and paſs through with ſuch rapidity that they ſeem to fly over the water. But when the current runs from ſouth to north, and the north wind blows hard at the ſame time, the ſhip which expected eaſily to paſs the ſtrait with the wind in its ſtern, on its entering the channel is reſiſted by the oppoſite current, and, impelled by two forces in contrary directions, is at length daſhed on the rock of Scylla, or driven on the neighbouring ſands; unleſs the pilot ſhall apply for the ſuccour neceſſary for his preſervation. For, to give aſſiſtance in caſe of ſuch accidents, 24 of the ſtrongeſt, boldeſt, and moſt experienced ſailors, well acquainted with the place, are ſtationed night and day along the ſhore of Meſſina; who, at the report of guns fired as ſignals of diſtreſs from any veſſel, haſten to its aſſiſtance, and tow it with one of their light boats. The current, where it is ſtrongeſt, does not extend over the whole ſtrait, but winds thro' it in intricate meanders, with the courſe of which theſe men are perfectly acquainted, and are thus able to guide the ſhip in ſuch a manner as to avoid it. Should the pilot, however, confiding in his own ſkill, contemn or neglect this aſſiſtance, however great his ability or experience, he would run the moſt imminent riſk of being ſhipwrecked. In this agitation and conflict of the waters, forced one way by the current, and driven in a contrary direction by the wind, it is uſeleſs to throw the line to diſcover the depth of the bottom, the violence of the current frequently carrying the lead almoſt on the ſurface of the water. The ſtrongeſt cables, though ſome feet in circumference, break like ſmall cords. Should two or three anchors be thrown out, the bottom is ſo rocky that they either take no hold; or, if they ſhould, are ſoon looſened by the violence of the waves. Every expedient afforded by the art of navigation, though it might ſucceed in ſaving a ſhip in other parts of the Mediterranean, or even the tremendous ocean, is uſeleſs here. The only means of avoiding being daſhed againſt the rocks, or driven upon the ſands in the midſt of this furious conteſt of the winds and waves, is to have recourſe to the ſkill and courage of theſe Meſſineſe ſeamen."

Charybdis is ſituated within the ſtrait, in that part of the ſea which lies between a projection of land named *Punta Secca*, and another projection on which ſtands the tower called *Lanterno*, or the light-houſe, a light being placed at its top to guide veſſels which may enter the harbour by night. Every writer, who has hitherto deſcribed Charybdis, has ſuppoſed it to be a whirlpool; but this is a miſtake, as Spallanzani has completely proved, by aſcertaining what it really is.

"Charybdis is diſtant from the ſhore of Meſſina about 750 feet, and is called by the people of the country *Calofaro*, not from the agitation of the waves, as ſome have ſuppoſed, but from καλος and φαρος; that is, *the beautiful tower*, from the light-houſe erected near it for the guidance of veſſels. The phenomenon of the Calofaro is obſervable when the current is deſcending; for when the current ſets in from the north, the pilots call it the *deſcending rema*, or current; and when it runs from the ſouth, the *aſcending rema*. The current aſcends or deſcends at the riſing or ſetting of the moon, and continues for ſix hours. In the interval between each aſcent or deſcent, there is a calm which laſts at leaſt a quarter of an hour, but not longer than an hour. Afterwards, at the riſing or ſetting of the moon, the current enters from the north, making various angles of incidence with the ſhore, and at length reaches the Calofaro. This delay ſometimes continues two hours; ſometimes it immediately falls into the Calofaro; and then experience has taught that it is a certain token of bad weather."

When our author obſerved Charybdis from the ſhore, it appeared like a group of tumultous waters; which group, as he approached, became more extenſive and more agitated. He was carried to the edge, where he ſtopped ſome time to make the requiſite obſervations; and was then convinced, beyond the ſhadow of a doubt, that what he ſaw was by no means a vortex or whirlpool.

Hydrologiſts teach us, that by a whirlpool in a running water we are to underſtand that circular courſe which it takes in certain circumſtances; and that this courſe or revolution generates in the middle of a hollow inverted cone, of a greater or leſs depth, the internal ſides of which have a ſpiral motion. But Spallanzani perceived nothing of this kind in the Calofaro. Its revolving motion was circumſcribed to a circle of at moſt 100 feet in diameter; within which limits there was no incurvation of any kind, nor vertiginous motion, but an inceſſant undulation of agitated waters, which roſe, fell, beat, and daſhed on each other. Yet theſe irregular motions were ſo far placid, that nothing was to be feared in paſſing over the ſpot, which he did; though their little bark rocked very much from the continual agitation, ſo that they were obliged conſtantly to make uſe of their oars to prevent its being driven out of the Calofaro. Our author threw ſubſtances of different kinds into the ſtream. Such as were ſpecifically heavier than the water ſunk, and appeared no more; thoſe which were lighter remained on the ſurface, but were ſoon driven out of the revolving circle by the agitation of the water.

Though from theſe obſervations he was convinced that there was no gulph under the Calofaro, as otherwiſe

Scylla, Sea fickness.

wife there would have been a whirlpool, which would have carried down into it the floating fubftances ; he determined to found the bottom with the plummet, and found its greateft depth did not exceed 500 feet. He was likewife informed, to his no fmall furprife, that beyond the Calofaro, towards the middle of the ftrait, the depth was double.

When the current and the wind are contrary to each other, and both in their greateft violence, efpecially when the fcilocco, or fouth wind, blows, the fwelling and dafhing of the waves within the Calofaro is much ftronger, more impetuous, and more extenfive. It then contains three or four fmall whirlpools, or even more, according to the greatnefs of its extent and violence. If at this time fmall veffels are driven into the Calofaro by the current or the wind, they are feen to whirl round, rock, and plunge, but are never drawn down into the vortex. They only fink when filled with water, by the waves beating over them. When veffels of a larger fize are forced into it, whatever wind they have they cannot extricate themfelves; their fails are ufelefs; and after having been for fome time toffed about by the waves, if they are not affifted by the pilots of the country, who know how to bring them out of the courfe of the current, they are furioufly driven upon the neighbouring fhore of the Lanterna, where they are wrecked, and the greater part of their crews perifh in the waves.

From thefe facts, the claffical reader will perceive that the ancient defcriptions of Charybdis are by no means fo accurate as thofe of Scylla. The faying, however, which became proverbial among the ancients, viz. that "he who endeavours to avoid Charybdis, dafhes upon Scylla," is, in a great meafure, true. If a fhip be extricated from the fury of Charybdis, and carried by a ftrong foutherly wind along the ftrait towards the northern entrance, it will indeed pafs out fafely ; but fhould it meet with a wind in a nearly oppofite direction, it would become the fport of both thefe winds, and, unable to advance or recede, be driven in a middle courfe between their two directions, that is to fay, full upon the rock of Scylla, if it be not immediately affifted by the pilots. It is likewife obferved, that in thefe hurricanes a land wind frequently rifes, which defcends from a narrow pafs in Calabria, and increafes the force with which the fhip is impelled towards the rock.

SEA-SICKNESS is a diforder which has been but little treated of, notwithftanding the frequency of its occurrence, and the irkfomenefs and diftrefs to which the patient is fubjected during its continuance. It has been found to be very beneficial in feveral difeafes, among which the principal are afthmatic and pulmonary complaints ; and there are very few inftances of its being attended with fatal confequences. The fea-ficknefs feems to be a fpafmodic affection of the ftomach, produced by the alternate preffure and recefs of the contents of that vifcus againft its lower internal furface, according as the rife and fall of the fhip oppofes or recedes from the action of gravity.

The feas in which this diforder attacks the paffenger with the greateft violence, are thofe where the waves have long uninterrupted freedom of action ; of courfe, bay, gulphs, and channels, may be navigated with lefs inconvenience, as the waves, meeting with more frequent refiftance, and the repercuffion being confiderably ftronger, the veffel does not experience that gentle uniform vacillation which fickens the ftomach, and renders the head giddy. By the fame argument, a perfon feels lefs inconvenience from the diforder on the wide ocean in a fmall veffel, on which the flighteft motion of the waves makes a ftrong impreffion. He is likewife lefs expofed to it in a very large veffel, as in a fhip of the line, or a large merchantman deeply laden ; as the waves, in this cafe, fcarcely affect the veffel. It is in fhips of the middling fize, and which carry but a light cargo, that the paffenger fuffers moft from the fea ficknefs. It has been obferved, that this diforder affects people in years lefs than young perfons ; thofe of a dark lefs than thofe of a fair complection, and that it feldom attacks infants. The duration is not limited to any fixed period of time; with fome it lafts only a few days, with others weeks, months, and even during the whole courfe of the voyage. The fooner it takes place after embarkation, the greater probability is there of its continuance. It does not always ceafe immediately on landing, but has been known, in fome cafes, to continue for a confiderable time. Even the oldeft and moft fkilful feamen have experienced a relapfe, efpecially if they have quitted the fea-fervice for a long term of years.

There have been many modes recommended for mitigating, if not entirely preventing, this diforder; among which the following feem the moft efficacious :

1. Not to go on board immediately after eating ; and, when on board, not to eat in any great quantity at any one meal.

2. To take ftrong exercife, with as little intermiffion as conveniently can be done ; for inftance, to affift at the pumps, or any other active employment, as indolent and flothful paffengers always fuffer moft from the diforder.

3. To keep much upon deck, even in ftormy and rainy weather, as the fea breeze is lefs liable to affect the ftomach than the ftagnated air of the cabin, which is frequently rendered infectious for want of fufficient circulation.

4. Not to watch the motion of the waves, efpecially when ftrongly agitated with tempeft.

5. To avoid carefully all employments which harafs the mind, as reading, ftudy, meditation, and gaming : and, on the other hand, to feek every opportunity of mirth and mental relaxation.

6. To drink occafionally carbonic acids, as the froth of ftrong fermented beer, or wine mixed with Seltzer water, and fermented with pounded fugar, or a glafs of Champaign.

7. It will be found of great fervice to take the acid of fulphur dulcified, dropped upon lump fugar, or in peppermint water ; or ten drops of fulphureous ether.

With regard to eating, it is advifable to be very fparing, at leaft not to eat much at one meal. The proper diet is bread and frefh meat, which fhould be eaten cold with pepper. All fweet favoured food fhould be carfully avoided ; and the paffenger fhould refrain from fat, but efpecially from all meat that is in the leaft degree tainted. Even the odour of flowers is very pernicious ; for which reafon it is not expedient to examine marine productions, as thefe generally have a naufeating fmell. The fumes of vinegar may be inhaled with great benefit. The drink fhould confift of

tart

tart wines, lemonade, or Seltzer water, but never of common water. The paſſenger would do well to drink little and often. As experience has proved, than an accidental diarrhœa has frequently relieved the patient from the ſea-ſickneſs, it will be prudent to follow the clue of nature, and take a gentle laxative, or, if circumſtances will permit, a clyſter of ſalt-water and Venice ſoap, which is the more neceſſary, as ſea-faring people are liable to obſtructions. It will further be found uſeful to apply to the pit of the ſtomach a tonic anodyne antiſpaſmodic emplaſtrum, ſpread upon leather, and covered with linen.

Where the above preventives have not been employed, or have not ſucceeded in ſecuring the paſſenger from the ſea-ſickneſs, he may, however, experience conſiderable relief from the following remedies:

If ſymptoms of vomiting appear, they may frequently be remedied by the patient proſtrating himſelf in a horizontal poſition, upon the back or belly, and lying perfectly ſtill. We would recommend likewiſe a gentle compreſſion of the abdomen. But if the fits of vomiting are too violent to be repreſſed, in that caſe, it is beſt to promote them by a ſtrong doſe of ſalt water; an expedient, however, which muſt not be too often repeated, as it tends ſtill more to weaken the ſtomach. When the emetic takes effect, let the patient bend his body, advancing his knees towards his breaſt, and ſupport his head againſt a firm and ſolid reſting-place. He muſt be particularly careful to untie his garters and cravat, as this precaution will ſecure him from the riſk of a rupture, and from the ill effects of the blood ruſhing violently towards the head and breaſt.

After the vomiting has ſubſided, its return may be guarded againſt by preſerving a ſtate of repoſe, and even keeping the eyes ſhut for a conſiderable time. Let the patient chooſe a cool, ventilated place, remembering to keep himſelf warm and well clothed, as perſpiration is highly ſalutary. But he muſt not indulge in too long ſleep during the day-time, as this induces torpidneſs. In the morning he ſhould conſtantly take a gargle of ſugar diſſolved in vinegar. Let him eat often, but ſparingly; and if he can content himſelf with a diſh of chocolate, coffee, or ſtrong tea, he will reap ſtill greater benefit. He ſhould never drink water in its pure elementary ſtate, but mix it with brandy, vinegar, or wine. In the morning, inſtead of brandy, he may take a glaſs of wine, with an infuſion of orange peel, gentian root, or peruvian bark (*quinquina*). A glaſs of punch taken occaſionally will prove of very eſſential ſervice, as it promotes perſpiration.

Perſons in the habit of ſmoking, will find a pleaſant and ſalutary companion in the pipe; but thoſe who are not accuſtomed to it will be ſufferers by taking to the practice.

In concluſion, it is proper to add, that warm clothing, flannel ſhirts, trowſers, caps, &c. are efficacious remedies againſt exceſſive expectoration, and all other ſymptoms of this terrible diſorder.

SECTOR OF A SPHERE, is the ſolid generated by the revolution of the ſector of a circle about one of its radii; the other radius deſcribing the ſurface of a cone, and the circular arc a circular portion of the ſurface of the ſphere of the ſame radius. So that the ſpherical ſector conſiſts of a right cone, and of a ſegment of the ſphere having the ſame common baſe with the cone. And hence the ſolid content of it will be found by multiplying the baſe or ſpherical ſurface by the radius of the ſphere, and taking a third part of the product.

SECTOR *of an ellipſe*, or *of an hyperbola*, &c. is a part reſembling the circular ſector, being contained by three lines, two of which are radii, or lines drawn from the centre of the figure to the curve, and the intercepted arc or part of that curve.

SEEDS, PRESERVATION OF, in a ſtate fit for vegetation, is a matter of great and general importance, becauſe, if it can be accompliſhed, it will enable us to rear many uſeful plants in one country which are there unknown, being indigenous only in others at a great diſtance from it. There is a letter on this ſubject in the 16th volume of the *Tranſaction of the Society of Arts*, &c. from which we ſhall extract what is fit for our purpoſe.

"Many years ago (ſays the author), having obſerved ſome ſeeds which had got accidentally amongſt raiſins, and that they were ſuch as are generally attended with difficulty to raiſe in England after coming in the uſual way from abroad, I ſowed them in pots, within a framing; and as all of them grew, I commiſſioned my ſons, who were then abroad, to pack up all ſorts of ſeeds they could procure in abſorbent paper, and ſend ſome of them ſurrounded by raiſins, and others by brown moiſt ſugar; concluding that the former ſeeds had been preſerved by a peculiarly favourable ſtate of moiſture thus afforded them. It occurred, likewiſe, that as many of our common ſeeds, ſuch as clover, charlock, &c. would lie dormant for ages within the earth, well preſerved for vegetation whenever they might happen to be thrown to the ſurface, and expoſed to the atmoſphere, ſo theſe foreign ſeeds might be equally preſerved, for many months at leaſt, by the kindly covering and genial moiſture that either raiſins or ſugar afforded them: and this conjecture was really fulfilled, as not one in twenty of them failed to vegetate, when thoſe of the ſame kinds, that I ordered to be ſent lapped in common parcels, and forwarded with them, would not grow at all. I obſerved, upon examining them all before they were committed to the earth, that there was a prevailing dryneſs in the latter, and that the former looked freſh and healthy, and were not in the leaſt infeſted by inſects, as was the caſe with the others. It has been tried repeatedly to convey ſeeds (of many plants difficult to raiſe) cloſed up in bottles, but without ſucceſs; ſome greater proportion of air, as well as a proper ſtate of moiſture, perhaps, being neceſſary. I ſhould alſo obſerve, that no difference was made in the package of the ſeeds, reſpecting their being kept in huſks, pods, &c. ſo as to give thoſe in raiſins or ſugar any advantage over the others, all being ſent equally guarded by their natural teguments."

SEGALIEN, the name given by Europeans to a large iſland, ſeparated by a narrow channel from the coaſt of Chineſe Tartary, and called by the natives *Tchoka*, and by the Chineſe *Oku-Jeſſu*. It lies between the 46th and 54th degrees of north latitude, but its breadth from eaſt to weſt is not known. Indeed hardly any thing about it was known till the year 1787, that M. La Perouſe penetrated almoſt to the bottom of the channel which ſeparates it from the continent, and which grew ſo very ſhallow as he advanced northward that, Segalien. that, in all probability, the island will soon become a peninsula. The French frigates came to anchor in different bays on the coast of Segalien; and the finest of these bays, to which the Commodore gave the name of *Baie d'Estaing*, is situated in 48° 59′ N. Lat. and 140° 32′ Lon. East from Paris.

La Perouse, and M. Rollin the surgeon of his ship, both describe the natives of this island as a worthy and intelligent people. Of the presents which were made to them, they seemed to set a value only on such as were useful. Iron and stuffs prevailed over every thing; they understood metals as well as their guests, and for ornament preferred silver to copper, and copper to iron. They make use of looms, which, though small, are very complete instruments; and by means of spindles they prepare thread of the hair of animals, of the bark of the willow, and the great nettle, from which they make their stuffs. They are of a moderate size, squat, and strong built, with the muscles of their bodies very exactly defined: their common height is five feet, and the greatest does not exceed five feet four inches; but men of this size are very uncommon among them. They have all a large head, and a broad and more rounded face than Europeans; their countenance is animated and agreeable, though, upon the whole, it is destitute of that regularity and grace which we esteem so essential to beauty: they have large cheeks, a short nose rounded at its extremity, with very broad nostrils: their eyes are lively, of a moderate size, for the most part black, though some have blue ones among them: their eyebrows are bushy, their mouth of the common size, their voice is strong, their lips are rather thick, and of a dull red: M. Rollin remarked, that in several the upper lip was tattoed, and tinged of a blue colour: these, as well as their eyes, are capable of every variety of expression: their teeth are white, even, and of the usual number; their chin is rounded and a little advancing: their ears are small; they bore and wear in them glass ornaments or silver rings.

The women are not so large as the men, and are of a more rounded and delicate figure, though there is but little difference between the features of their faces. Their upper lip is tattoed all over of a blue colour, and they wear their hair long and flowing: their dress hardly differs from that of the men; the colour of the skin in both sexes is tawny, and that of their nails, which they suffer to grow to a great length, is a shade darker than that of Europeans. These islanders are very hairy, and have long beards, which gives, especially to the old men, a grave and venerable air: these last appear to be held in much respect by the younger part of the inhabitants. The hair of their head is black, smooth, and moderately strong; in some it is of a chesnut colour: they all wear it round, about six inches long behind, and cut into a brush on the top of their head and over the temples.

Their clothing consists of a kind of surtout which wraps over before, where it is fastened by little buttons, strings, and a girdle placed above the haunches. This surtout is made of skin or quilted nankeen, a kind of stuff that they make of willow bark; it generally reaches to the calf of the leg, and sometimes even lower, which for the most part renders the use of drawers unnecessary: some of them wear seal skin boots, the feet of which, in form and workmanship, resembles the Chinese shoe; but the greater number of them go bare-footed and bare-headed: a few indeed wear a bandage of bear-skin round the head; but this is rather as an ornament than a defence against the weather.

Segalien. Like the lower classes of the Chinese, they all wear a girdle, to which they hang their knife as a defence against the bears, and several little pockets, into which they put their flint and steel, their pipe, and their box of tobacco; for they make a general practice of smoking.

Their huts are sufficient to defend them against the rain and other inclemencies of the air, but are very small in proportion to the number of the inhabitants which they contain. The roof is formed of two inclined planes, which are from ten to twelve feet high at their junction, and three or four on the sides: the breadth of the roof is about fifteen feet, and its length eighteen: these cabins are constructed of frame work, strongly put together, the sides being filled up with the bark of trees, and the top thatched with dry grass in the same manner as our cottages are.

On the inside of these houses is a square of earth raised about six inches above the ground, and supported on the sides by strong planking; on this they make the fire: along the sides of the apartment are benches twelve or fifteen inches high, which they cover with mats, on which they sleep.

The utensils that they employ in cooking their food consist of an iron pot, shells, vessels made of wood and birch bark, of various shapes and workmanship; and, like the Chinese, they take up their food with little sticks: they have generally two meals in the day, one at noon, and the other in the evening.

The habitations in the south part of the island are much better built and furnished, having for the most part planked floors: our author saw in them some vessels of Japan porcelain, on which the owners appeared to set great value, probably because they are not to be procured but with great trouble and at considerable expence. They cultivate no kind of vegetable, living only on dried and smoked fish, and what little game they take by hunting.

Each family has its own canoe, and implements for fishing and hunting. Their arms are bows, javelins, and a kind of spontoon, which they use principally in bear-hunting. By the side of their houses are the magazines, in which they lay up the provision which they have prepared and collected during summer for their winter subsistence. It consists of dried fish, and a considerable quantity of garlic and wild celery, angelica, a bulbous root which they call *apè*, better known under the name of the yellow lily of Kamtschatka, and fish oil, which they preserve in the stomachs of bears, and other large animals. These magazines are made of planks, strongly and closely put together, raised above the ground on stakes about four feet high.

Dogs are the only domestic animals belonging to the natives of Tchoka; they are of a middling size, with shaggy hair, pricked ears, and a sharp long muzzle; their cry is loud and not savage.

These people, who are of a very mild and unsuspecting disposition, appear to have commercial intercourse with the Chinese by means of the Mantchou Tartars, with the Russians to the north of their island, and the Japanese to the south: but the articles of trade are of

 no

no great confequence, confifting only of a few furs and whale oil. This fifh is caught only on the fouthern coaft of the ifland. Their mode of extracting the oil is by no means economical; they drag the whale on fhore on a floping ground, and fuffering it to putrify, receive in a trench, at the foot of the flope, the oil, which feparates fpontaneoufly.

The ifland is well wooded, and mountainous towards the centre, but is flat and level along the coaft, the foil of which appears admirably adapted to agriculture: vegetation is extremely vigorous here: forefts of pine, willow, oak, and birch, cover nearly the whole furface. The fea abounds with fifh, as well as the rivers and brooks, which fwarm with falmon and trout of an excellent quality. The weather is, in general, foggy and mild. All the inhabitants have an air of health and ftrength, which they retain even to extreme old age; nor did our author obferve among them any inftance of defective organization, or the leaft trace of contagious or eruptive diforders.

SEGMENTS, LINE OF, are two particular lines, fo called on Gunter's fector. They lie between the lines of fines and fuperficies, and are numbered with 5, 6, 7, 8, 9, 10. They reprefent the diameter of a circle, fo divided into 100 parts, as that a right line drawn through thofe parts, and perpendicular to the diameter, fhall cut the circle into two fegments, the greater of which fhall have the fame proportion to the whole circle, as the parts cut off have to 100.

SEGO, the capital of the kingdom of Bambarra in Africa, is fituated on the banks of the Niger, in 14° 4′ N. Lat. and 2° 1′ W. Long. It confifts, properly fpeaking, of four diftinct towns; two on the northern bank of the Niger, called Sego Korro, and Sego Boo; and two on the fouthern bank, called Sego Soo Korro, and Sego See Korro. They are all furrounded with high mud-walls; the houfes are built of clay, of a fquare form, with flat roofs; fome of them have two ftories, and many of them are white-wafhed. Befides thefe buildings, Moorifh mofques are feen in every quarter; and the ftreets, though narrow, are broad enough for every ufeful purpofe in a country where wheel-carriages are entirely unknown. Mr Park informs us, that from the beft inquiries that he could make, he has reafon to believe that Sego contains altogether about thirty thoufand inhabitants. The King of Bambarra conftantly refides at Sego. See Korro. He employs a great many flaves in conveying people over the river; and the money they receive (though the fare is only ten kowrie fhells for each individual) furnifhes a confiderable revenue to the king in the courfe of a year. The canoes are of a fingular conftruction, each of them being formed of the trunks of two large trees, rendered concave, and joined together, not fide by fide, but endwife; the junction being exactly acrofs the middle of the canoe: they are therefore very long, and difproportionably narrow, and have neither decks nor mafts; they are, however, very roomy; for our author obferved in one of them four horfes, and feveral people, croffing over the river. The view of this extenfive city; the numerous canoes upon the river; the crowded population, and the cultivated ftate of the furrounding country, formed altogether a profpect of civilization and magnificence which he little expected to find in the bofom of Africa.

He met not, however, in Sego with that hofpitality which he had experienced in fome other African towns. The Moors, who abound in it, and whofe bigotry renders them the implacable enemies of every white man fufpected of being a Chriftian, contrived to perfuade the king that it was for no good purpofe he had come into the territories of Bambarra. He was therefore ordered to take up his refidence at a village a little diftant, without being admitted into the royal prefence. Even there, fo ftrong was the prejudice that had been excited againft him, no perfon would admit him into his houfe. About funfet, however, as he was preparing to pafs the night in the top of a tree, that he might not be in danger of being torn to pieces by wild beafts, a poor Negro woman conducted him to her hut, dreffed a fine fifh for his fupper, and furnifhed him with a mat to fleep on. She then called to the female part of her family, who had ftood gazing on him all the while with fixed aftonifhment, to refume their tafk of fpinning cotton; in which they continued to employ themfelves great part of the night. They lightened their labour by fongs; one of which was compofed extempore, for our author was himfelf the fubject of it. It was fung by one of the young women, the reft joining in a fort of chorus. The air was fweet and plaintive, and the words, literally tranflated, were thefe: "The winds roared, and the rains fell.—The poor white man, faint and weary, came and fat under our tree.—He has no mother to bring him milk; no wife to grind his corn.—*Chorus.* Let us pity the white man; no mother has he, &c. &c. "Trifling (fays Mr Park) as this recital may appear to the reader, to a perfon in my fituation the circumftance was affecting in the higheft degree."

Having remained three days in this village, he was difmiffed on the fourth, after receiving from the king 5000 kowries, to enable him to purchafe provifions in the courfe of his journey. Though this fum amounted only to one pound fterling, fo cheap are the neceffaries of life in Bambarra, that it was fufficient to purchafe provifions for himfelf, and corn for his horfe, for fifty days.

SELL, in building, is of two kinds, viz. *Ground Sell*, which denotes the loweft piece of timber in a wooden building, and that upon which the whole fuperftructure is raifed; and *Sell of a Window*, or *of a Door*, which is the bottom piece in the frame of them, upon which they reft.

SENN, a kind of itinerant cowkeeper in Switzerland, particularly in the canton of Appenzell. Thefe men do not grow fo much hay themfelves as they require for their cattle during the winter feafon, and fome of them have no grafs lands at all. To fupply this deficiency, they employ agents throughout the canton, who are to inform them where good hay may be obtained, which farmers made it in favourable weather, &c. and then the Senn, or the great cowkeeper, who is in want of fodder, makes his agreements for the winter with the wealthier farmers, to whom he fucceffively drives his cattle as foon as they return from grafs. Thus the itinerant Senn, with his cows, often vifits five different places during the winter feafon. He who fells the hay, furnifhes the Senn not only with ftabling for his beafts, but boards and lodges him as well as his whole family. In return, the Senn, befides paying the ftipulated price for the hay, allows to his hoft as much milk, whey, and *zieger* (a kind of lean cheefe) as may be be ufed in the houfe, and leaves him alfo the manure of his cows. In the middle of April, when Nature revives, the Senn again iffues forth with his herd to the meadows and fertile Alps, which he rents for the fummer. Thus the life of thefe men is a conftant migration, affording the moft pleafing variety, and bleffing them with health, content, and cheerfulnefs; but they had not been then curfed with French fraternity.

Fine cattle are the pride of the cowkeeper who inhabits the Alps:—but, not fatisfied with their natural beauty, he will likewife pleafe his vanity. He adorns his beft cows with large bells fufpended from broad thongs; and the expence in fuch bells is carried even to a luxurious excefs. Every Senn has an harmonious fet of at leaft two or three bells, chiming in with the famous *ranz des vaches* (A). The inhabitants of the Tyrol bring a number of fuch bells, of all fizes, to every fair kept in the canton of Appenzell. They are fixed to a broad ftrap, neatly pinked, cut out, and embroidered; which is faftened round the cow's neck by means of a large buckle. A bell of the largeft fize meafures upwards of a foot in diameter, is of an uniform width at top, fwells out in the middle, and tapers towards the end. It cofts from forty to fifty gilders; and the whole peal of bells, including the thongs, will fometimes be worth between 140 and 150 gilders, while the whole apparel of the Senn himfelf, when beft attired, does not amount to the price of twenty gilders. The fineft black cow is adorned with the largeft bell, and thofe next in appearance have two fmaller. Thefe ornaments, however, are not worn on every day, but only on folemn occafions, viz. when, in the fpring, they are driven up the Alps, or removed from one pafture to another; or when they defcend in the autumn, or travel in the winter to the different farms, where their owner has contracted for hay. On fuch days, the Senn, even in the depth of winter, appears dreffed in a fine white fhirt, of which the fleeves are rolled up above the elbow; neatly embroidered red braces keep up his yellow linen trowfers, which reach down to the fhoes; a fmall leather cap, or hat, covers his head; and a new milk bowl, of wood fkilfully carved, hangs acrofs the left fhoulder. Thus arrayed, the Senn precedes finging the *ranz des vaches*, and followed by three or four fine goats; next comes the handfomeft cow with the great bell; then the two other cows with fmaller bells; and thefe are fucceeded by the reft of the cattle walking one after another, and having in their rear the bull with a one-legged milking ftool hanging on his horns; the proceffion is clofed by a *traineau*, or fledge, on which are placed the implements for the dairy. It is furprifing to fee how proud and pleafed the cows ftalk forth when ornamented with their bells. Who would imagine that even thefe animals are fenfible of their rank, nay, touched with vanity and jealoufy! If the leading cow, who hitherto bore the largeft bell, be deprived of her honours, fhe very plainly manifefts her grief at the difgrace, by lowing inceffantly, abftaining from food, and growing lean. The happy rival, on whom the diftinguifhing badge of fuperiority has devolved, experiences her marked vengeance, and is butted, wounded, and perfecuted by her in the moft furious manner; until the former either recovers her bell, or is entirely removed from the herd. However fingular this phenomenon may appear, it is placed beyond all doubt by the concurring teftimony of centuries.

The cows, when difperfed on the Alps, are brought together by the voice of the Senn, who is then faid to *allure* them (*locken*). How well the cattle diftinguifh the note of their keeper appears from the circumftance of their haftening to him, though at a great diftance, whenever he begins to hum the *ranz des vaches*. He furnifhes that cow which is wont to ftray fartheft with a fmall bell, and knows by her arrival that all the reft are affembled.

SERRISHTEHDAR, in Bengal, keeper of records or accounts.

SEVEN STARS, a common denomination given to the clufter of ftars in the neck of the fign Taurus, the bull, properly called the *Pleiades*. They are fo called from their number Seven which appear to the naked eye, though fome eyes can difcover only fix of them; but by the help of telefcopes there appears to be a great multitude of them.

SESAWUL, in Bengal, an officer deputed occafionally to enforce the due payment of the revenue.

SHADOWS (COLOURED), a curious optical phenomenon, which was obferved, a confiderable number of years ago, by Profeffor Scherffer of Vienna, and more lately by Count Rumford. The Count made the difcovery when profecuting his experiments upon light; of which the reader will find fome account under the titles LAMP and PHOTOMETER in this *Suppl.* "Defirous (fays he) of comparing the intenfity of the light of a clear blue fky by day with that of a common wax-candle, I darkened my room, and letting the day light from the north, coming through a hole near the top of the window fhutter, fall at an angle of about 70° upon a fheet of very fine white paper, I placed a burning wax candle in fuch a pofition that its rays fell upon the fame paper, and, as near as I could guefs, in the line of reflection of the rays of day-light from without; when, interpofing a cylinder of wood, about half an inch in diameter, before the centre of the paper, and at the diftance of about two inches from its furface, I was much furprifed to find that the two fhadows projected by the cylinder upon the paper, inftead of being merely fhades without colour, as I expected; the one of them, that which, correfponding with the beam of day-light, was illuminated by the candle, was yellow; while the other, correfponding to the light of the candle, and confequently illuminated by the light of the heavens, was of the moft beautiful blue that it is poffible to imagine. This appearance, which was not only unexpected, but was really in itfelf in the higheft degree ftriking and beautiful,

(A) This famous paftoral fong is never fung by the cowherds with words to it: all the tones of it are fimple, and moftly formed within the throat. Hence the tune produces very little or no motion of the jawbones, and its founds do not refemble thofe which commonly iffue from the human throat, but rather feem to be the tones of fome wind inftrument: particularly as fcarcely any breathing is perceived, and as the cowherds fometimes fing for minutes together without fetching breath.

Shadows, Shagreen. beautiful, I found upon repeated trials, and after varying the experiment in every way I could think of, to be so perfectly permanent, that it is absolutely impossible to produce two shadows at the same time, from the same body, the one answering to a beam of day light, and the other to the light of a candle or lamp, without these shadows being coloured, the one yellow, and the other blue.

"If the candle be brought nearer to the paper, the blue shadow will become of a deeper hue, and the yellow shadow will gradually grow fainter; but if it be removed farther off, the yellow shadow will become of a deeper colour, and the blue shadow will become fainter; and the candle remaining stationary in the same place, the same varieties in the strength of the tints of the coloured shadows may be produced merely by opening the window-shutter a little more or less, and rendering the illumination of the paper, by the light from without, stronger or weaker. By either of these means, the coloured shadows may be made to pass through all the gradations of shade, from the deepest to the lightest, and *vice versa*; and it is not a little amusing to see shadows thus glowing with all the brilliancy of the purest and most intense prismatic colours, then passing suddenly through all the varieties of shade, preserving in all the most perfect purity of tint, growing stronger and fainter, and vanishing and returning, at command."

With respect to the causes of the colours of these shadows, there is no doubt (says the Count) but they arise from the different qualities of the light by which they are illuminated: but how they are produced, does not appear to him so evident. With the utmost deference to this amiable and very ingenious philosopher, we think all the phenomena of coloured shadows which he enumerates *, have been, or may be accounted for by Professor Scherffers theory; of which the reader will find, we hope, a perspicuous view under *Accidental* COLOURS in this *Supplement*.

* *Phil. Transf.* 1794, p. 107.

SHAGREEN, or CHAGRIN, in commerce, a kind of grained leather; of the process of preparing which, we gave the best account that we could then find in the *Encyclopædia*. That account, however, as we learn from Professor Pallas, is very defective. He says, indeed, that no accurate account of it has ever been published in Europe previous to his own; of which we shall now lay an abridgment before our readers.

"All kinds of horses or asses skin, which have been dressed in such a manner as to appear grained, are, by the Tartars, called *sauwer*, by the Persians *sogre*, and by the Turks *sagri*, from which the Europeans have made *shagreen* or *chagrin*. The Tartars who reside at Astracan, with a few of the Armenians of that city, are the only people in the Russian empire acquainted with the art of making shagreen. Those who follow this occupation not only gain considerable profit by the sale of their production to the Tartars of Cuban, Astracan, and Casan, who ornament with it their Turkey leather boots, slippers, and other articles made of leather, but they derive considerable advantage from the great sale of horses hides, which have undergone no other process than that of being scraped clean, and of which several thousands are annually exported, at the rate of from 75 to 85 roubles per hundred to Persia, where there is a scarcity of such hides, and from which the greater part of the shagreen manufactured in that country is prepared. The hind part only of the hide, however, which is cut out in the form of a crescent about a Russian ell and a half in length across the loins, and a short ell in breadth along the back, can properly be employed for shagreen. The remaining part, as is proved by experience, is improper for that purpose, and is therefore rejected.

Shagreen.

"The preparation of the skins, after being cut into the above form, is as follows:—They are deposited in a tub filled with pure water, and suffered to remain there for several days, till they are thoroughly soaked, and the hair has dropped off. They are then taken from the tub, one by one, extended on boards placed in an oblique direction against a wall, the corners of them, which reach beyond the edges of the board, being made fast, and the hair with the epidermis is then scraped off with a blunt iron scraper called *urak*. The skins thus cleaned are again put in pure water to soak. When all the skins have undergone this part of the process, they are taken from the water a second time, spread out one after the other as before, and the flesh side is scraped with the same kind of instrument. They are carefully cleaned also on the hair side, so that nothing remains but the pure fibrous tissue, which serves for making parchment, consisting of coats of white medullary fibres, and which has a resemblance to a swine's bladder softened in water.

"After this preparation, the workmen take a certain kind of frames called *pälzi*, made of a straight and a semicircular piece of wood, having nearly the same form as the skins. On these the skins are extended in as smooth and even a manner as possible by means of cords; and during the operation of extending them, they are several times besprinkled with water, that no part of them may be dry, and occasion an unequal tension. After they have been all extended on the frames, they are again moistened, and carried into the house, where the frames are deposited close to each other on the floor with the flesh side of the skin next the ground. The upper side is then thickly bestrewed with the black exceedingly smooth and hard seeds of a kind of goose foot (*chenopodium album*), which the Tartars call *alabuta*, and which grows in abundance, to about the height of a man, near the gardens and farms on the south side of the Volga; and that they may make a strong impression on the skins, a piece of felt is spread over them, and the seeds are trod down with the feet, by which means they are deeply imprinted into the soft skins. The frames, without shaking the seeds, are then carried out into the open air, and placed in a reclining position against a wall to dry, the side covered with the seeds being next the wall, in order that it may be sheltered from the sun. In this state the skins must be left several days to dry in the sun, until no appearance of moisture is observed in them, when they are fit to be taken from the frames. When the impressed seeds are beat off from the hair side, it appears full of indentations or inequalities, and has acquired that impression which is to produce the grain of the shagreen, after the skins have been subjected to the last smoothing or scraping, and have been dipped in a ley, which will be mentioned hereafter, before they receive the dye.

"The operation of smoothing is performed on an inclined bench or board, which is furnished with an iron hook, and is covered with thick felt of sheep's wool, on

Shagreen. on which the dry ſkin may gently reſt. The ſkin is ſuſpended in the middle of the bench or board to its iron hook, by means of one of the holes made in the edge of the ſkin for extending it in its frame as before mentioned; and a cord, having at its extremity a ſtone or a weight, is attached to each end of the ſkin, to keep it in its poſition while under the hands of the workman. It is then ſubjected to the operation of ſmoothing and ſcraping by means of two different inſtruments. The firſt uſed for this purpoſe, called by the Tartars *tokar*, is a piece of ſharp iron bent like a hook, with which the ſurface of the ſhagreen is pretty cloſely ſcraped to remove all the projecting inequalities. This operation, on account of the corneous hardneſs of the dry ſkin, is attended with ſome difficulty; and great caution is at the ſame time required that too much of the impreſſion of the *alabuta* ſeed be not deſtroyed, which might be the caſe if the iron were kept too ſharp. As the iron, however, is pretty blunt, which occaſions inequalities on the ſhagreen, this inconvenience muſt afterwards be remedied by means of a ſharp ſcraping iron or *urak*, by which the ſurface acquires a perfect uniformity, and only faint impreſſions of the *alabuta* ſeed then remain, and ſuch as the workman wiſhes. After all theſe operations, the ſhagreen is again put into water, partly to make it pliable, and partly to raiſe the grain. As the ſeeds occaſion indentations in the ſurface of the ſkin, the intermediate ſpaces, by the operations of ſmoothing and ſcraping, loſe ſome part of their projecting ſubſtance; but the points which have been depreſſed, and which have loſt none of their ſubſtance, now ſwell up above the ſcraped parts, and thus form the grain of the ſhagreen. To produce this effect, the ſkins are left to ſoak in water for 24 hours; after which they are immerſed ſeveral times in a ſtrong warm ley, obtained, by boiling, from a ſtrong alkaline earth named *ſchora*, which is found in great abundance in the neighbourhood of Aſtracan. When the ſkins have been taken from this ley, they are piled up, while warm, on each other, and ſuffered to remain in that ſtate ſeveral hours; by which means they ſwell, and become ſoft. They are then left 24 hours in a moderately ſtrong pickle of common ſalt, which renders them exceedingly white and beautiful, and fit for receiving any colour. The colour moſt uſual for theſe ſkins is a ſea-green; but old experienced workmen can dye them blue, red, or black, and even make white ſhagreen.

"For the green colour nothing is neceſſary but filings of copper and ſal ammoniac. Sal ammoniac is diſſolved in water till the water is completely ſaturated; and the ſhagreen ſkins, ſtill moiſt, after being taken from the pickle, are waſhed over with the ſolution on the ungrained fleſh ſide, and when well moiſtened a thick layer of copper filings is ſtrewed over them: the ſkins are then folded double, ſo that the ſide covered with the filings is innermoſt. Each ſkin is then rolled up in a piece of felt; the rolls are all ranged together in proper order, and they are preſſed down in an uniform manner by ſome heavy bodies placed over them, under which they remain 24 hours. During that period, the ſolution of ſal ammoniac diſſolves a quantity of the cupreous particles ſufficient to penetrate the ſkin, and to give it a ſea-green colour. If the firſt application be not ſufficient, the proceſs is repeated in the ſame manner; after which the ſkins are ſpread out and dried.

"For the blue dye, indigo is uſed. About two pounds of it, reduced to a fine powder, are put into a kettle; cold water is poured over it, and the mixture is ſtirred round till the colour begins to be diſſolved. Five pounds of pounded *alakar*, which is a kind of barilla or crude ſoda, prepared by the Armenians and Calmucs, is then diſſolved in it, with two pounds of lime and a pound of pure honey, and the whole is kept ſeveral days in the ſun, and during that time frequently ſtirred round. The ſkins intended to be dyed blue muſt be moiſtened only in the natrous ley *ſchora*, but not in the ſalt brine. When ſtill moiſt, they are folded up and ſhewed together at the edge, the fleſh ſide being innermoſt, and the ſhagreened hair ſide outwards; after which they are dipped three times in the remains of an exhauſted kettle of the ſame dye, the ſuperfluous dye being each time expreſſed; and after this proceſs they are dipped in the freſh dye prepared as above, which muſt not be expreſſed. The ſkins are then hung up in the ſhade to dry; after which they are cleaned and paired at the edges.

"For black ſhagreen, gall-nuts and vitriol are employed in the following manner:—The ſkins, moiſt from the pickle, are thickly beſtrewed with finely pulveriſed gall-nuts. They are then folded together, and laid over each other for 24 hours. A new ley, of bitter ſaline earth or *ſchora*, is in the mean time prepared, and poured hot into ſmall troughs. In this ley each ſkin is ſeveral times dipped; after which they are again beſtrewed with pounded gall-nuts, and placed in heaps for a certain period, that the galls may thoroughly penetrate them, and they are dried and beat, to free them from the duſt of the galls. When this is done, they are rubbed over, on the ſhagreen ſide, with melted ſheep's tallow, and expoſed a little in the ſun, that they may imbibe the greaſe. The ſhagreen-makers are accuſtomed alſo to roll up each ſkin ſeparately, and to preſs or ſqueeze it with their hands againſt ſome hard ſubſtance, in order to promote the abſorption of the tallow. The ſuperfluous particles are removed by means of a blunt wooden ſcraper (*urac*): and when this proceſs is finiſhed, and the ſkins have lain ſome time, a ſufficient quantity of vitriol of iron is diſſolved in water, with which the ſhagreen is moiſtened on both ſides, and by this operation it acquires a beautiful black dye. It is then dreſſed at the edges, and in other places where there are any blemiſhes.

"To obtain white ſhagreen, the ſkins muſt firſt be moiſtened on the ſhagreen ſide with a ſtrong ſolution of alum. When the ſkin has imbibed this liquor, it is daubed over on both ſides with a paſte made of flour, which is ſuffered to dry. The paſte is then waſhed off with alum-water, and the ſkin is placed in the ſun till it is completely dry. As ſoon as it is dry, it is gently beſmeared with pure melted ſheep's tallow, which it is ſuffered to imbibe in the ſun; and to promote the effect, it is preſſed and worked with the hands. The ſkins are then faſtened in ſucceſſion to the before mentioned bench, where warm water is poured over them, and the ſuperfluous fat is ſcraped off with a blunt wooden inſtrument. In the laſt operation the warm water is of great ſervice. In this manner ſhagreen perfectly white is obtained, and nothing remains but to pare the edges and dreſs it.

"But this white ſhagreen is not intended ſo much for

for remaining in that ſtate, as for receiving a dark red dye; becauſe, by the above previous proceſs, the colour becomes much more perfect. The ſkins deſtined for a red colour muſt not be immerſed firſt in ley of bitter ſalt earth (*ſchora*), and then in pickle, but after they have been whitened, muſt be left to ſoak in the pickle for 24 hours. The dye is prepared from cochineal, which the Tartars call *kirmitz*. About a pound of the dried herb *tſchagann*, which grows in great abundance in the neighbourhood of Aſtracan, and is a kind of ſoda plant or kali (*ſalſola ericoides* (A), is boiled a full hour in a kettle containing about four common pailfuls of water; by which means the water acquires a greeniſh colour. The herb is then taken out, and about half a pound of pounded cochineal is put into the kettle, and the liquor is left to boil a full hour, care being taken to ſtir it that it may not run over. About 15 or 20 drams of a ſubſtance which the dyers call *lüter* (orchilla) is added, and when the liquor has been boiled for ſome time longer, the kettle is removed from the fire. The ſkins taken from the pickle are then placed over each other in troughs, and the dye-liquor is poured over them four different times, and rubbed into them with the hands, that the colour may be equally imbibed and diffuſed. The liquor each time is expreſſed; after which they are fit for being dried. Skins prepared in this manner are ſold at a much dearer rate than any of the other kinds."

SHARP (Abraham), an eminent mathematician, mechaniſt, and aſtronomer, was deſcended from an ancient family at Little Horton, near Bradford, in the Weſt Riding of Yorkſhire, where he was born about the year 1651. At a proper age he was put apprentice to a merchant at Mancheſter; but his genius led him ſo ſtrongly to the ſtudy of mathematics, both theoretical and practical, that he ſoon became uneaſy in that ſituation of life. By the mutual conſent, therefore, of his maſter and himſelf, though not altogether with that of his father, he quitted the buſineſs of a merchant. Upon this he removed to Liverpool, where he gave himſelf up wholly to the ſtudy of mathematics, aſtronomy, &c.; and where, for a ſubſiſtence, he opened a ſchool, and taught writing and accounts, &c.

He had not been long at Liverpool when he accidentally fell in company with a merchant or tradeſman viſiting that town from London, in whoſe houſe it ſeems the aſtronomer Mr Flamſteed then lodged. With the view therefore of becoming acquainted with this eminent man, Mr Sharp engaged himſelf with the merchant as a book-keeper. In conſequence he ſoon contracted an intimate acquaintance and friendſhip with Mr Flamſteed, by whoſe intereſt and recommendation he obtained a more profitable employment in the dock-yard at Chatham; where he continued till his friend and patron, knowing his great merit in aſtronomy and mechanics, called him to his aſſiſtance, in contriving, adapting, and fitting up the aſtronomical apparatus in the Royal Obſervatory at Greenwich, which had been lately built, namely, about the year 1676. He was principally employed in the conſtruction of the mural arch; which in the compaſs of 14 months he finiſhed ſo greatly to the ſatisfaction of Mr Flamſteed, that he ſpeaks of him in terms of the higheſt praiſe. According to Mr Smeaton, this was the firſt good and valid inſtrument of the kind; and Mr Sharp the firſt artiſt who cut accurate and delicate diviſions upon aſtronomical inſtruments. At the time this inſtrument was conſtructed, Mr Flamſteed was 30 and Mr Sharp 25 years of age.

Theſe two friends continued together for ſome time, making obſervations on the meridional zenith diſtances of the fixed ſtars, ſun, moon, and planets, with the times of their tranſits over the meridian; alſo the diameters of the ſun and moon, and their eclipſes, with thoſe of Jupiter's ſatellites, the variation of the compaſs, &c.

Mr Sharp aſſiſted Mr Flamſteed alſo in making a catalogue of near 3000 fixed ſtars, with their longitudes and magnitudes, their right aſcenſions and polar diſtances, with the variations of the ſame while they change their longitude by one degree.

But from the fatigue of continually obſerving the ſtars at night, in a cold thin air, joined to a weakly conſtitution, he was reduced to a bad ſtate of health; for the recovery of which he deſired leave to retire to his houſe at Horton; where, as ſoon as he found himſelf on the recovery, he began to fit up an obſervatory of his own; having firſt made an elegant and curious engine for turning all kinds of work in wood or braſs, with a maundril for turning irregular figures, as ovals, roſes, wreathed pillars, &c. Beſide theſe, he made himſelf moſt of the tools uſed by joiners, clockmakers, opticians, mathematical inſtrument makers, &c. The limbs or arcs of his large equatorial inſtrument, ſextant, quadrant, &c. he graduated with the niceſt accuracy, by diagonal diviſions into degrees and minutes. The teleſcopes he made uſe of were all of his own making, and the lenſes ground, figured, and adjuſted with his own hands.

It was at this time that he aſſiſted Mr Flamſteed in calculating moſt of the tables in the ſecond volume of his *Hiſtoria Cœleſtis*, as appears by their letters, to be ſeen in the hands of Mr Sharp's friends at Horton. Likewiſe the curious drawings of the charts of all the conſtellations viſible in our hemiſphere, with the ſtill more excellent drawings of the planiſpheres both of the northern and ſouthern conſtellations. And though theſe drawings of the conſtellations were ſent to be engraved at Amſterdam by a maſterly hand, yet the originals far exceeded the engravings in point of beauty and elegance: theſe were publiſhed by Mr Flamſteed, and both copies may be ſeen at Horton.

The mathematician, ſays Dr Hutton, meets with ſomething extraordinary in Sharp's elaborate treatiſe of *Geometry Improved* (in 4to, 1717, ſigned A. S. Philomath): 1ſt, by a large and accurate table of ſegments of circles, its conſtruction and various uſes in the ſolution of ſeveral difficult problems, with compendious tables for

(A) The beautiful red Turkey leather is dyed with cochineal prepared in the ſame manner. Profeſſor Gmelin junior, in the ſecond part of his Travels through Ruſſia, explains the herb *tſchagann* by *artemiſia annua*, having doubtleſs been deceived by the appearance the plant acquires after it has been dried. Beſides, this *artemiſia* is found only in the middle of Siberia, and never on the weſt ſide of the Irtiſch.

for finding a true proportional part; and their ufe in thefe or any other tables exemplified in making logarithms, or their natural numbers, to 60 places of figures; there being a table of them for all primes to 1100, true to 61 figures. 2d, His concife treatife of Polyedra, or folid bodies of many bafes, both the regular ones and others: to which are added twelve new ones, with various methods of forming them, and their exact dimenfions in furds, or fpecies, and in numbers; illuftrated with a variety of copperplates, neatly engraved by his own hands. Alfo the models of thefe polyedra he cut out in boxwood with amazing neatnefs and accuracy. Indeed few or none of the mathematical inftrument makers could exceed him in exactly graduating or neatly engraving any mathematical or aftronomical inftrument, as may be feen in the equatorial inftrument above mentioned, or in his fextant, quadrants, and dials of various forts; alfo in a curious armillary fphere, which, befide the common properties, has moveable circles, &c. for exhibiting and refolving all fpherical triangles; alfo his double fector, with many other inftruments, all contrived, graduated, and finifhed, in a moft elegant manner, by himfelf. In fhort, he poffeffed at once a remarkably clear head for contriving, and an extraordinary hand for executing, any thing, not only in mechanics, but likewife in drawing, writing, and making the moft exact and beautiful fchemes or figures in all his calculations and geometrical conftructions.

The quadrature of the circle was undertaken by him for his own private amufement in the year 1699, deduced from two different feries, by which the truth of it was proved to 72 places of figures; as may be feen in the introduction to Sherwin's Tables of Logarithms; that is, if the diameter of a circle be 1, the circumference will be found equal to 3·141592653589793238 46264338327950288419716939937510582097494459230781640 5, &c. In the fame book of Sherwin's may alfo be feen his ingenious improvements on the making of logarithms, and the conftructing of the natural fines, tangents, and fecants.

He alfo calculated the natural and logarithmic fines, tangents, and fecants, to every fecond in the firft minute of the quadrant; the laborious inveftigation of which may probably be feen in the archives of the Royal Society, as they were prefented to Mr Patrick Murdoch for that purpofe; exhibiting his very neat and accurate manner of writing and arranging his figures, not to be equalled perhaps by the beft penman now living.

Mr Sharp kept up a correfpondence by letters with moft of the eminent mathematicians and aftronomers of his time, as Mr Flamfteed, Sir Ifaac Newton, Dr Halley, Dr Wallis, Mr Hodgfon, Mr Sherwin, &c. the anfwers to which letters are all written upon the backs, or empty fpaces, of the letters he received, in a fhorthand of his own contrivance. From a great variety of letters (of which a large cheftful remain with his friends) from thefe and many other celebrated mathematicians, it is evident that Mr Sharp fpared neither pains nor time to promote real fcience. Indeed, being one of the moft accurate and indefatigable computers that ever exifted, he was for many years the common refource for Mr Flamfteed, Sir Jonas Moore, Dr Halley, and others, in all forts of troublefome and delicate calculations.

Mr Sharp continued all his life a bachelor, and fpent his time as reclufe as a hermit. He was of a middle ftature, but very thin, being of a weakly conftitution. He was remarkably feeble the laft three or four years before he died, which was on the 18th of July 1742, in the 91ft year of his age.

In his retirement at Little Horton, he employed four or five rooms or apartments in his houfe for different purpofes, into which none of his family could poffibly enter at any time without his permiffion. He was feldom vifited by any perfons, except two gentlemen of Bradford, the one a mathematician, and the other an ingenious apothecary; thefe were admitted, when he chofe to be feen by them, by the fignal of rubbing a ftone againft a certain part of the outfide wall of the houfe. He duly attended the diffenting chapel at Bradford, of which he was a member, every Sunday; at which time he took care to be provided with plenty of halfpence, which he very charitably fuffered to be taken fingly out of his hand, held behind him during his walk to the chapel, by a number of poor people who followed him, without his ever looking back, or afking a fingle queftion.

Mr Sharp was very irregular as to his meals, and remarkably fparing in his diet; which he frequently took in the following manner. A little fquare hole, fomething like a window, made a communication between the room where he was ufually employed in calculations, and another chamber or room in the houfe where a fervant could enter; and before this hole he had contrived a fliding board: the fervant always placed his victuals in this hole, without fpeaking or making any the leaft noife; and when he had a little leifure, he vifited his cupboard to fee what it afforded to fatisfy his hunger or thirft. But it often happened, that the breakfaft, dinner, and fupper, have remained untouched by him, when the fervant has gone to remove what was left—fo deeply engaged had he been in calculations.

SHARPS in flour, the finer part of what we have denominated Pollards. See that article, *Suppl.*

SHASTAH, the fame as Shaster; which fee, *Encycl.*

SHEA, the name of a tree, from the fruit of which the Negroes, in the interior parts of Africa between the tropics, prepare a kind of vegetable butter. Thefe trees are not planted by the natives, but are found growing naturally in the woods; and in clearing wood land for cultivation, every tree is cut down but the Shea. The tree itfelf very much refembles the American oak; and the fruit, from the kernel of which being firft dried in the fun the butter is prepared, by boiling the kernel in water, has fomewhat the appearance of a Spanifh olive. The kernel is enveloped in a fweet pulp, under a thin green rind; and the butter produced from it, befides the advantage of its keeping the whole year without falt, is whiter, firmer, and, Mr Park fays, to his palate, of a richer flavour than the beft butter which he ever tafted made from cows milk. The growth and preparation of this commodity, feem to be among the firft objects of African induftry in this and the neighbouring ftates; and it conftitutes a main article of their inland commerce. In fome places they dry the fruit in kilns, containing each about half a cart load of fruit, under which is kept up a clear wood fire. Our author, who faw the fruit in one of thefe kilns, was informed, that in three days the fruit would

would be ready for pounding and boiling; and that the butter thus manufactured is preferable to that which is prepared from fruit dried in the sun; especially in the rainy season, when the process by insolation is always tedious, and oftentimes ineffectual. Might it not be worth while, if practicable, to cultivate Shea-trees in some of our West India islands?

SHEAVE, in mechanics, a solid cylindrical wheel, fixed in a channel, and moveable about an axis, as being used to raise or increase the mechanical powers applied to remove any body.

SHEBBEARE (John) was born at Bideford, a considerable sea port and corporation town in Devonshire, in the year 1709. His father was an attorney; but having small practice and little fortune, he carried on also the business of a corn-factor. He had four children, two sons and two daughters. Of the sons, John, the subject of our present memoir, was the eldest. The other son was called Richard, and entirely the reverse of his brother in disposition; he was bred to the sea, and died young.

John received the rudiments of his education at the free grammar school of Exeter, then conducted by the learned Mr Zachary Mudge (author of an Essay for a new Version of the Psalms, and a volume of excellent Sermons), afterwards Rector of St Andrew in Plymouth. It has oftentimes been remarked, that the future life of a man may be nearly guessed at from his puerile character. Thus Shebbeare, while a schoolboy, gave the strongest indications of his future eminence in misanthropy and literature, by the remarkable tenaciousness of his memory, and the readiness of his wit, and no less so by the malignity of his disposition; being universally considered as a lad of surprising genius, while at the same time he was as generally despised for his malicious and ungrateful temper. This may easily be believed, when it is said, that he formed not one connection, either at school or afterwards, with any person in the way of friendship, except with a young barber of an abandoned character, but whose soul was perfectly congenial to that of Shebbeare's.

Such is the account of Shebbeare's boyish years which we have in the 14th volume of the *European Magazine*. It is probably much exaggerated; for Shebbeare continued through life a staunch Tory, if not a Jacobite; and it is well known that many of our journalists consider themselves as at liberty to give what characters they please of such men.

In the fifteenth or sixteenth year of his age, young Shebbeare was bound apprentice to a very eminent and worthy surgeon in his native town; in which situation he acquired a considerable share of medical knowledge. His genius for lampoon appeared at this early period, and he could nor forbear from exercising it on his master. No one indeed could give him the slightest offence with impunity; for which reason almost every person avoided his acquaintance, as we would avoid the caressing of an adder. The chief marks, however, of the arrows of his wit were the gentlemen of the corporation: one or other, and sometimes all of them, were almost constantly exposed in a libel upon the public posts and corners of the streets. But though the wiser part of them only laughed at these harmless trifles, yet some were more irritable, and many a prosecution was commenced against, but not one could fix itself upon him, so artfully had he contrived to conceal himself. He was also several times summoned to appear at the sessions, for daring to speak and write irreverently of the worshipful magistrates; but the laugh was always on the side of Shebbeare, nor could they ever come at his back, so closely had he fitted on his armour, with the whip of authority.

When he was out of his time he set up trade for himself, and then shewed a taste for chemistry; and soon after he married a very agreeable and amiable young woman, of no fortune, but of a genteel family. Whether his insuperable propensity to satire deprived him of friends and of business, or that he spent too much in chemical experiments, we know not; but failing at Bideford, he removed, about the year 1736, to Bristol, where he entered into partnership with a chemist, and never afterwards set his foot in his native town.

In the year 1739 he attracted the attention of the public, by an epitaph to the memory of Thomas Coster, Esq. member for Bristol; in which, it has been truly observed, that he has contrived to raise emotions of pity, grief, and indignation, to a very high degree. The next year he published a pamphlet on the Bristol waters; from which period there is a chasm in our author's life we are unable to fill up. In this interval may probably be placed his failure in business, and his effort to obtain a higher situation in his profession. It is certain that in the year 1752 he was at Paris, and there he obtained the degree, if he obtained it at all, which gave him the addition to his name which accompanied him during the rest of his life, that of Doctor. Until this time he appears to have lived in obscurity; but at an age when vigorous exertion usually subsides, he seems to have resolved to place himself in a conspicuous situation, whatever hazard might attend it, and commenced a public writer with a degree of celerity and virulence for which it would be difficult to find a parallel even in the most temperate times. To read over his works now, when the passions they then raised have subsided, we feel surprise at the effect they produced; and it is within the memory of many yet living, that their influence was very considerable. In the year 1754, he began his career with The Marriage Act, a political novel; in which he treated the legislature with such freedom, that it occasioned his being taken into custody, from whence, however, he was soon released.

The performances, however, most celebrated, were a series of Letters to the People of England, which were written in a style vigorous and energetic, though slovenly and careless, well calculated to make an impression on common readers; and were accordingly read with avidity, and circulated with diligence. They had a very considerable effect on the minds of the people, and galled the ministry, who seem to have been at first too eager to punish the author. On the publication of the Third Letter, we find warrants, dated 4th and 8th of March, 1756, issued by Lord Holdernesse, to take up both Scott the publisher and the author. This prosecution, however, seems to have been dropt, and the culprit proceeded for some time unmolested, "having declared (says one of his answerers) that he would write himself into a post or into the pillory; in the last of which he at length succeeded." On the 12th of January 1758, a general warrant was signed by Lord Holdernesse, to search for the author, printer, Shebbeare. printer, and publishers of a wicked, audacious, and treasonable libel, entitled, "A Sixth Letter to the People of England, on the progress of national ruin; in which is shewn that the present grandeur of France and calamities of this nation are owing to the influence of Hanover on the councils of England;" and them having found, to seize and apprehend, together with their books and papers.

At this juncture government seem to have been effectually roused; for having received information that a seventh letter was printing, by virtue of another warrant, dated January 23, all the copies were seized and entirely suppressed. In Easter Term an information was filed against him by Mr Pratt, then attorney general, afterwards Lord Camden; in which it is now worthy of remark, that the crown officer, in his application to the court, in express terms admitted a point, since much disputed, that of the jury's right to determine both the law and the fact in matters of libel. "What I urge (says the advocate) to the court, is only to shew there is reasonable ground for considering this publication as a libel, and for putting it in a way of trial, and therefore it is I pray to have the rule made absolute; for I admit, and your lordship well knows, that the jury in matter of libel are judges of the law as well as the fact, and have an undoubted right to consider whether, upon the whole, the pamphlet in question be, or be not, a false, malicious, and scandalous libel." On the 17th of June, the information was tried, when our author was found guilty; and on the 28th November he received sentence, by which he was fined five pounds, ordered to stand in the pillory December 5, at Charing Cross, to be confined three years, and to give security for his good behaviour for seven years, himself in 500l. and two others in 250l. each.

On the day appointed, that part of the sentence which doomed him to the pillory was put in execution, amidst a prodigious concourse of people assembled on the occasion. The under sheriff, at that time, happened to be Mr Beardmore, who had sometimes been assisted by the Doctor in writing the Monitor, a paper in its principles of the same tendency with the writings of the culprit, who consequently might expect every indulgence from the officer to whom the execution of his sentence was committed. The manner in which it was conducted may be learned from the affidavits on which afterwards the under sheriff's conduct became the subject of animadversion in the court of King's Bench, and which assert, "that the defendant only stood upon the platform of the pillory, unconfined, and at his ease, attended by a servant in livery (which servant and livery were hired for the occasion only) holding an umbrella over head all the time: but his head, hands, neck, and arms, were not at all confined, or put into the holes of the pillory; only that he sometimes put his hands upon the holes of the pillory in order to rest himself." For this neglect of duty, Beardmore was fined 50l. and suffered two months imprisonment.

Some time before he was tried for the obnoxious publication already mentioned, the Duchess of Queensbury, as heir of Lord Clarendon, obtained an injunction in the Court of Chancery to stop the publication of the continuation of that nobleman's history; a copy of which had got into the hands of Francis Gwyn, Esq. between whom and the Doctor there had been an agreement to publish it and equally divide the profits. The care and expences attending the ushering this work into the world were to be wholly Dr Shebbeare's, who performed his part of the agreement, and caused it to be handsomely printed in quarto, with a Tory preface, containing frequent reflections on, and allusions to recent events, and to living characters, which gave it the appearance rather of a temporary pamphlet than of a work calculated for posterity. On the injunction being obtained, Dr Shebbeare was under the necessity of applying to the aid of law to recover the money expended by him in printing, amounting to more than 500l. Of that sum more than half had been wasted on his side in the courts of law and equity. And some years afterwards, speaking of the situation of his affairs, he says, "It may be easily imagined, that my circumstances were not improved by three years imprisonment. I had no club of partizans to maintain me during that time, to discharge my debts, nor even the fine, which I was obliged to pay after a three years confinement for a single offence. Notwithstanding the difficulties which inevitably arose from these particulars, and although an insolvent act was passed soon after his Majesty's accession to the throne, and my circumstances might have apologised for my taking that opportunity which it offered; I nevertheless declined from availing myself of that occasion to evade the payment of my debts. I preferred the labour of endeavouring to pay them, and the risk of being again imprisoned if I did not succeed. But, thank Heaven, I am in no danger of a second imprisonment on that account." During his confinement, he declares he never received as presents more than twenty guines from all the world.

While he was confined in the King's Bench, he solicited subscriptions for the first volume of a History of England, from the Revolution to the then present time. But at the persuasion of his friends he was induced to alter his design, and receipts were issued for a first volume of the History of England, and of the Constitution thereof from its origin. That volume he wrote, and had transcribed. "But as it was impracticable (to use his own words), whilst I was in confinement, to procure that variety of books, or to apply to manuscript authorities, for all that was requisite to the completing of this first volume, I found on being released from my imprisonment, and on application to the former only, that the volume which I had written was incorrect, insufficient, and erroneous, in too many particulars, to admit of its being published, without injustice to my subscribers, and reprehensions on myself. Into this displeasing situation I had been misled by relying on the authorities of modern historians, who pretend to cite the authors from whence their materials are taken, many of whom appear never to have seen them, but implicitly to have copied one another, and all of them manifestly defective; not only in the authorities they should have sought, but in their omissions and misrepresentations of those whom they had consulted: more especially respecting those parts of the old German codes, on which our constitution is erected, and without which it cannot be properly explained or understood. Such being the real situation of things, I perceived that more time than I could expect to live would be necessarily required for so extensive a work as the

Shebbeare.

the whole hiftory I had propofed; and that a fingle volume, or even a few volumes of an hiftory incomplete, would by no means anfwer either the intention of my fubfcribers, or my own: I determined therefore to change my plan, and to include in one volume that which might require no others to complete this new defign.

"In confequence of this alteration, I refolved to exert my beft abilities, not only to trace the conftitution of England from its origin in the woods of Germany, as M. de Montefquieu expreffes it, but from the firft principles of human nature, from which the formation of all kinds of government is derived. With this view, I have attempted an analyzation of the mental and corporeal faculties, in order to fhew in what manner they reciprocally influence each other in the various actions of man, not only as an individual, but as a gregarious being, impelled by nature to affociate in communities. From hence I have attempted to delineate in what manner legiflature fprang and proceeded from its fource, through that variety of meanders which it hath formed in its current, both before and fince the introduction of one common fign, whereby to exprefs the intrinfic value, not only of all the productions of nature and of art, but even of the human faculties, as they are now eftimated; to compare the conftitutions of thofe different ftates which have been, and are the moft celebrated in ancient and modern hiftory, with each other, and with that of England; and then to derive fome reafonable grounds for the determination of that which feems to be the moft confentaneous with the primogenial inftitutes of nature, and the happinefs of human kind. In confequence of this intent, the manners that fucceffively arofe and prevailed in fuch ftates, the benefits and mifchiefs which enfued from them, are delineated, in order to explain on what foundation the welfare of national communities may moft probably be eftablifhed."

This plan, thus delineated, he at times employed himfelf in filling up; but on being rudely attacked for not performing his promife with his fubfcribers, he, in 1774, obferved—"From the inevitable obligations, not only of fupporting my own family, but thofe alfo whom as fon and brother it was my duty to fuftain for forty years, and which, refpecting the claims of the latter, ftill continues; it will be eafily difcerned that many an avocation muft have proceeded from thefe circumftances, as well as from a fenfe of gratitude to his majefty, in defence of whofe government I have thought it my duty occafionally to exert my beft abilities." He adds, however, that he did not intend to die until what he had propofed was finifhed; a promife which the event has fhewn he was unable to perform.

In prifon he was detained during the whole time of the fentence, and with fome degree of rigour; for when his life was in danger from an ill ftate of health, and he applied to the court of King's Bench for permiffion to be carried into the rules a few hours in a day, tho' Lord Mansfield acceded to the petition, yet the prayer of it was denied and defeated by Judge Fofter. At the expiration of the time of his fentence, a new reign had commenced; and fhortly afterwards, during the adminiftration of Mr Grenville, a penfion was granted him by the crown. This he obtained by the perfonal application of Sir John Philips to the King, who, on that occafion, was pleafed to fpeak of him in very favourable terms, which he promifed undeviatingly to endeavour to deferve by allegiance and gratitude.

Shebbeare.

From the time of that event we find Dr Shebbeare a uniform defender of the meafures of Government, and the mark againft whom every oppofer of adminiftration confidered himfelf at liberty to throw out the groffeft abufe. Even the friends of power were often adverfe to him. Dr Smollet introduced him in no very refpectful light, under the name of Ferret, in the novel of Sir Launcelot Greaves, and Mr Hogarth made him one of the group in the third election print.

Scarce a periodical publication was without fome abufe of him, which he feems to have in general had the good fenfe to neglect. In the year 1774, however, he departed from his general practice, and defended himfelf from fome attacks at that time made upon him. In this pamphlet he reprefented the conduct and character of King William in fuch a light as to excite the indignation of every Whig in the kingdom: he treated him in print with as great feverity as Johnfon ufed to do in converfation.

Early in life he appears to have written a comedy, which in 1766 he made an effort to get reprefented at Covent Garden. In 1768 he wrote the Review of Books in the Political Regifter for three months, and was often engaged to write for particular perfons, with whom he frequently quarrelled when he came to be paid. This was the cafe with Sir Robert Fletcher, and we think of others. His pen feems to have been conftantly employed, and he wrote with great rapidity, what certainly can now be read with little fatisfaction, and muft foon be forgotten. Though penfioned by government, he can fcarce be faid to have renounced his opinions; for in the pamphlet already mentioned, his abufe of the Revolution is as grofs as in that for which he fuffered the pillory. His violence defeated his own purpofe, and made thofe who agreed in party with him revolt from the virulence with which he treated his adverfaries. During the latter years of his life he feems to have written but little. He was a ftrenuous fupporter of the miniftry during the American war, having publifhed, in 1775, An Anfwer to the printed Speech of Edmund Burke, Efq; fpoken in the Houfe of Commons, April 19, 1774. In which his knowledge in polity, legiflature, human kind, hiftory, commerce, and finance, is candidly examined; his arguments re fairly refuted; the conduct of adminiftration is fully defended; and his oratoric talents are clearly expofed to view.—And An Effay on the Origin, Progrefs, and Eftablifhment of National Society; in which the principles of Government, the definitions of phyfical, moral, civil, and religious Liberty contained in Dr Price's Obfervations, &c. are fairly examined, and fully refuted; together with a juftification of the Legiflature in reducing America to obedience by force. To which is added, an Appendix on the Excellent and Admirable in Mr Burke's fecond printed Speech of the 22d of March 1775, both 8vo.

His publications, fatirical, political, and medical, amount to thirty-four, befides a novel, entitled Lydia, or Filial Piety; in which religious hypocrify and bluftering courage are very properly chaftifed. He died on the 1ft of Auguft 1788, leaving, among thofe who knew him beft, the character of a benevolent man; a character

character which, from the manner in which he ſpeaks of his connections, he probably deſerved.

SHEERS, aboard a ſhip, an engine uſed to hoiſt or diſplace the lower maſts of a ſhip.

SHEIBON, a diſtrict in Africa, lying to the ſouth-eaſt of the kingdom of Dar-Fur (See SOUDAN in this volume), where much gold is found both in duſt and in ſmall pieces. The natives, who are idolaters and ſavages, collect the duſt in quills of the oſtrich and vulture, and in that condition ſell it to the merchants. They have a ceremony on diſcovering a large piece of gold, of killing a ſheep on it before they remove it. The people, who are all black, have ſome form of marriage, *i. e.* of an agreement between man and woman to cohabit. Women of full age wear a piece of plaited graſs on their parts. The younger and unmarried are quite naked. The ſlaves, which are brought in great numbers from this quarter, are ſome priſoners of war among themſelves (for their wars are frequent), and ſome ſeduced by treachery, and ſold. But it is ſaid to be a common practice for a father in time of ſcarcity to ſell his children.

At Sheibon are ſome Mahommedans, who live among the idolaters, and wear clothing: it is not ſaid whether Arabs or not. Mr Browne, from whoſe travels we have taken this account of Sheibon, does not give its latitude or longitude.

SHILLUK, a town in Africa on the banks of the Bahr-el-abiad, or true Nile. The houſes are built of clay, and the inhabitants, who are idolaters, have no other clothing than bands of long graſs, which they paſs round the waiſt and between the thighs. They are all black; both ſexes are accuſtomed to ſhave their heads. The people of Shilluk have the dominion of the river, and take toll of all paſſengers, in ſuch articles of traffick as paſs among them. The name Shilluk is not Arabic, and its meaning is unknown.—When aſked concerning their name or country, the people reply Shilluk. When employed in tranſporting Mahommedans acroſs the ferry, they occaſionally exhibit the importance which their ſituation gives them. After the Muſlim has placed himſelf in the boat, they will aſk him, "Who is the maſter of that river?" The other replies, as is uſual, "Ullah or Rubbani"—God is the maſter of it. "No (anſwers the Shilluk), you muſt ſay that ſuch a one (naming his chief) is the maſter of it, or you ſhall not paſs." They are repreſented as ſhewing hoſpitality to ſuch as come among them in a peaceable manner, and as never betraying thoſe to whom they have once accorded protection. The particulars of their worſhip have not been deſcribed. In Mr Browne's map, Shilluck is placed in about 13° N. Lat. and 32° 26′ E. Long.

SHIP. See that article, and SHIPBUILDING (*Encycl.*), and likewiſe FLOATING *Bodies* (*Suppl.*) In the *Tranſactions of the Royal Society of London* for 1798, Mr Atwood has completed his diſquiſition on the *Stability* of Ships; but as the memoir cannot be abridged, we muſt refer the ſcientific naval architect to the original for much uſeful information.

A ſmall work has lately been publiſhed by Charles Gore, Eſq: of Weimar in Saxony, upon *the reſpective Velocity of Floating Bodies varying in Form.* It contains merely the reſults of two ſeries of experiments: from the firſt of which ſeries, it ſeems to appear that the form beſt calculated for velocity is a long parallel body, terminating at each end in a parabolic cuneus, and having the extreme breadth in the centre. Alſo, that making the cuneus more obtuſe than is neceſſary to break with fairneſs the curve line into the ſtraight, creates a conſiderable degree of impediment. And Mr Gore is inclined to think, that the length of ſhips, which has already been extended with ſucceſs, to four times the breadth, is capable, with advantage, of ſtill further extenſion, perhaps to five, and, in ſome caſes, even to ſix times.

The ſecond ſet of experiments was inſtituted to aſcertain the reſpective degrees of ſtability, or power of reſiſting the preſſure of the wind, in carrying ſail, on bodies of different forms. The bodies uſed in the experiments had their ſpecific capacities and weights preciſely equal, but their forms different; and from the reſults, it appears that the form of a midſhip body, beſt adapted for ſtability only, is a flat bottom, with perpendicular ſides; and that the next beſt adapted is a ſemicircle. But as there exiſts much difficulty in conſtructing the former with ſufficient ſtrength, beſides its being ill adapted to heavy ſeas, as, by the ſudden deſcent in pitching, the bottom will ſtrike the water nearly at right angles, and ſuſtain thereby a tremendous ſhock. And as the latter ſeems to be too inclinable to tranſverſe oſcillation, or rolling, and alſo to be deficient in capacity for many ſervices, our author is of opinion, that a midſhip body, of a compounded form, is moſt applicable to general purpoſes.

On account of the few documents before us, we are unable to ſpeak critically concerning this tract. To benefit naval architecture, we are of opinion, that the method of experiment is more ſure and expeditious than that of calculation: yet concluſions from experiments muſt be drawn with great caution. It is by no means certain that a reſult obtained for a body of a given bulk will obtain for ſimilar bodies which differ in dimenſions.

We ſhall conclude this ſhort article with a ſtatement of the principles upon which Patrick Miller, Eſq; of Dalſwinton (Scotland), propoſes to conſtruct ſhips and veſſels which cannot founder.

The veſſel is to be kept afloat, without the aid of its ſides, ſolely by the buoyancy of its bottom, which is flat; the bottom never being ſo deeply immerſed as to bring the upper ſurface thereof on a level with the water; ſuch veſſels not being conſtructed for the purpoſe of carrying cargoes, but for that of carrying paſſengers, with the neceſſary ſtores and proviſions; and as theſe veſſels are not kept afloat by the aid of their ſides, but by the buoyancy of their bottom, as above deſcribed, they cannot ſink, and therefore pumps are not required, nor are they in any reſpect neceſſary for the preſervation of ſuch veſſels. The ſaid veſſel is put in motion, during calms, and againſt light winds, by means of wheels. Theſe wheels project beyond the ſides of the veſſel, and are wrought by means of capſtans: the number and the dimenſions of the wheels depend upon the length of the veſſel. Theſe wheels are built with eight arms, which conſiſt entirely of plank. Sliders are uſed to work and to keep the veſſel to windward when under ſail. Theſe ſliders are placed in the centre of the veſſel, from ſtem to ſtern; they are made of plank, and the number and dimenſions muſt depend on the length of the veſſel; and they are raiſed and let

down,

down, either by the hand, or by means of a purchase, according to the size of the vessel. Vessels of this construction draw water, in proportion to their dimensions, as follows: a vessel of forty feet in length, and from thirteen to nineteen feet in breadth, will draw from thirteen to sixteen inches of water. One of fifty feet in length, and from seventeen to twenty-four feet in breadth, will draw from fifteen to eighteen inches of water. One sixty feet long, and from twenty to twenty-eight feet broad, will draw from eighteen to twenty-one inches of water. One seventy feet long, and from twenty-three to thirty two feet broad, will draw from twenty one to twenty-four inches of water. One eighty feet long, and from twenty-seven to thirty-seven feet broad, will draw from twenty-four to twenty seven inches of water. One ninety feet long, and from thirty to forty two feet broad, will draw from twenty seven to thirty inches of water. One of one hundred feet in length, and from thirty-three to forty-seven feet in breadth, will draw from thirty to thirty-three inches of water.

As, from the principle upon which this vessel is constructed, she cannot sink, the invention must prove a means of saving many lives; and as it will give more room and height between the decks than any vessel of the same dimensions of another construction, it must add greatly to the comfort and accommodation of persons at sea of all descriptions. It is expected that, from these advantages, a more general and friendly intercourse amongst nations will take place, which will have the effect to diffuse knowledge, and to remove national prejudices, thereby promoting the general welfare of mankind. At present (says Mr Miller), it would be altogether improper to give any description of ships of greater dimensions, left it should be converted to a purpose very different from that intended by the inventor.

SHIPWRECK, a well-known disaster, by which numbers of lives are yearly lost. In that valuable miscellany entitled, *The Philosophical Magazine*, we have an account of means for preventing that loss, when the ship is in danger within two or three hundred fathoms of the shore; and as the anonymous author (a Frenchman) says that he has by experiment ascertained the efficacy of these means, we shall state them to our readers.

The only certain means of saving the crew of a vessel in such a state is, to establish a rope of communication from the shore to the ship. But how is this to be done? The author says, by fixing the end of the rope to a bomb or cannon ball, and extending the rope afterwards, in a zig-zag direction, before the mortar or cannon, or suspending it on a piece of wood raised several feet. A rope, so placed, will not break (he says) by the greatest velocity which can be given to the bomb or ball; and thus the end of it can be sent ashore by a discharge of artillery. He prefers the bomb to the cannon ball, for reasons which he does not assign. He proposes, however, other means to effect his benevolent purpose.

"It ought to be remembered (says he), that a vessel is never cast away, or perishes on the coast, but because it is driven thither against the will of the captain, and by the violence of the waves and the wind, which almost always blows from the sea towards the shore, without which there would be no danger to be apprehended: consequently, in these circumstances, the wind comes always from the sea, either directly or obliquely, and blows towards the shore.

"1*st*, A common paper kite, therefore, launched from the vessel and driven by the wind to the shore, would be sufficient to save a crew consisting of 1500 seamen, if such were the number of a ship of war. This kite would convey to the shore a strong packthread, to the end of which might be affixed a cord, to be drawn on board by means of the string of the kite; and with this cord a rope, or as many as should be necessary, might be conveyed to the ship.

"2*d*, A small balloon, of six or seven feet in diameter, and raised by rarefied air, would be also an excellent means for the like purpose: being driven by the wind from the vessel to the shore, it would carry thither a string capable of drawing a cord with which several ropes might be afterwards conveyed to the vessel. Had not the discovery of Montgolfier produced any other benefit, it would be entitled on this account to be considered as of great importance.

"3*d*, A sky-rocket, of a large diameter, would be of equal service. It would also carry, from the vessel to the shore, a string capable of drawing a rope after it.

"*Lastly*, A fourth plan for saving the crew of a shipwrecked vessel, is that of throwing from the vessel into the sea an empty cask with a cord attached to it. The wind and the waves would drive the cask to the shore, and afford the means of establishing that rope of communication already mentioned."

SILLA, a large town on the Niger, which bounded Mr Park's travels eastward. He gives no description of the place, which he had not spirits or health to survey; but fills a page of his work with the reasons which determined him to proceed no farther. "When I arrived (says he), I was suffered to remain till it was quite dark, under a tree, surrounded by hundreds of people. But their language was very different from the other parts of Bambarra; and I was informed that, in my progress eastward, the Bambarra tongue was but little understood, and that when I reached Jenné, I should find that the majority of the inhabitants spoke a different language, called *Jenné Kummo* by the Negroes, and *Kalam Soudan* by the Moors.

"With a great deal of entreaty, the Dooty allowed me to come into his balloon, to avoid the rain; but the place was very damp, and I had a smart paroxysm of fever during the night. Worn down by sickness, exhausted with hunger and fatigue, half naked, and without any article of value, by which I might procure provisions, clothes, or lodging, I began to reflect seriously on my situation. I was now convinced, by painful experience, that the obstacles to my farther progress were insurmountable. The tropical rains were already set in with all their violence; the rice grounds and swamps were everywhere overflowed; and in a few days more, travelling of every kind, unless by water, would be completely obstructed. The kowries which remained of the king of Bambarra's present were not sufficient to enable me to hire a canoe for any great distance; and I had but little hopes of subsisting by charity, in a country where the Moors have such influence. But above all, I perceived that I was advancing more and more within the power of those merciless fanatics; and from my reception both at SEGO and SANSANDING (see these articles, *Suppl.*), I was apprehensive that, in attempting to reach even Jenné (unless under the protection of some man of consequence amongst them, which I had no no means of obtaining), I should sacrifice my life to no purpose; for my discoveries would perish with me. The prospect either way was gloomy. In returning to the Gambia, a journey on foot of many hundred miles presented itself to my contemplation, through regions and countries unknown. Nevertheless, this seemed to be the only alternative; for I saw inevitable destruction in attempting to proceed to the eastward. With this conviction on my mind, I hope my readers will acknowledge that I did right in going no farther. I had made every effort to execute my mission in its fullest extent which prudence could justify. Had there been the most distant prospect of a successful termination, neither the unavoidable hardships of the journey, nor the dangers of a second captivity, should have forced me to desist. This, however, necessity compelled me to do: and whatever may be the opinion of my general readers on this point, it affords me inexpressible satisfaction, that my honourable employers have been pleased, since my return, to express their full approbation of my conduct." He would be a very unreasonable man, indeed, who could on this point think differently from Mr Park's employers. Silla is placed in the new map of Africa in about 14° 48′ N. Lat. and 1° 24′ W. Long.

SILLON, in fortification, an elevation of earth, made in the middle of the moat, to fortify it, when too broad. It is more usually called the *envelope*.

SIMANCAS, a village on the eastern limit of the kingdom of Leon in Spain, two leagues below Valladolid, on the river Gisnerga. It is mentioned by Dr Robertson in the introduction to his History of America, and is remarkable for the archives or register office of the kingdoms of Leon and Castile, kept in the castle there. This collection was begun when the kings resided often at Valladolid; in which city to this day is the chancery or civil and military tribunal for almost all Spain to the north of the Tagus. It was thought convenient to have those papers kept in the neighbourhood of that court; and this castle was particularly fit for that purpose, as it is all built of stone. Some years ago there were two large halls in this office filled with papers relating to the first settlement of the Spaniards in South America. There was also in the room called the *ancient royal patronage* a box containing treaties with England, in which are many letters and treaties between the kings of England and Spain from about the year 1400 down to 1600. There was also in the same archives a strong box, with five locks, which, it is said, has not been opened since the time of Philip II. and it is conjectured that it contains the process against Philip's son Prince Charles. But it seems some of the state papers have been removed to Madrid.

SITUS, in algebra and geometry, denotes the situation of lines, surfaces, &c. Wolfius delivers some things in geometry, which are not deduced from the common analysis, particularly matters depending on the *situs* of lines and figures. Leibnitz has even founded a particular kind of analysis upon it, called *calculus situs*.

SIWA, a town in Egypt, to the westward of Alexandria, built on a small fertile spot or Oasis, which is surrounded on all sides by desert land. A large proportion of this space is filled with date trees; but there are also pomegranates, figs, and olives, apricots, and plantains; and the gardens are remarkably flourishing. They cultivate a considerable quantity of rice, which, however, is of a reddish hue, and different from that of the Delta. The remainder of the cultivable land furnishes wheat enough for the consumption of the inhabitants. Water, both salt and fresh, abounds: but the springs which furnish the latter are most of them tepid; and such is the nature of the water, air, and other circumstances, that strangers are often affected with agues and malignant fevers.

The greatest curiosity about Siwa is a ruin of undoubted antiquity, which, according to Mr Browne, resembles too exactly those of the Upper Egypt, to leave a doubt that it was erected and adorned by the same intelligent race of men. The figures of Isis and Anubis are conspicuous among the sculptures; and the proportions are those of the Egyptian temples, though in miniature. What of it remains is a single apartment, built of massy stones, of the same kind as those of which the pyramids consist; and covered originally with six large and solid blocks, that reach from one wall to the other. The length is 32 feet in the clear, the height about 18, the width 15. A gate, situated at one extremity, forms the principal entrance; and two doors, also near that extremity, open opposite to each other. The other end is quit ruinous; but, judging from circumstances, it may be imagined that the building has never been much larger than it now is. There is no appearance of any other edifice having been attached to it, and the less so as there are remains of sculpture on the exterior of the walls. In the interior are three rows of emblematical figures, apparently designed to represent a procession; and the space between them is filled with hieroglyphic characters, properly so called. The people of Siwa have no tradition concerning this edifice, nor attribute to it any quality, but that of concealing treasures, and being the haunt of demons. It has, however, been supposed, with some degree of probability, that Siwa is the *Siropum* of Pliny, and that this building was coeval with the famous temple of Jupiter Ammon, and a dependency on it. This may be so; but neither the natives of Siwa, nor the various tribes of Arabs who frequent that place, know any thing of the ruins of that temple, about which Mr Browne made every possible enquiry. "It may (as he observes) still survive the lapse of ages, yet remain unknown to the Arabs, who traverse the wide expanse of the desert; but such a circumstance is scarcely probable. It may be completely overwhelmed in the sand; but this is hardly within the compass of belief."

The complexion of the people of Siwa is generally darker than that of the Egyptians. Their dialect is also different. They are not in the habitual use either of coffee or tobacco. Their sect is that of Malik. The dress of the lower class is very simple, they being almost naked: among those whose costume was discernible, it approaches nearer to that of the Arabs of the desert than of the Egyptians or Moors. Their clothing consists of a shirt of white cotton, with large sleeves, and reaching to the feet; a red Tunisine cap, without a turban; and shoes of the same colour. In warm weather they commonly cast on the shoulder a blue and white cloth, called in Egypt *melayé*; and in winter they are defended from the cold by an *ihhram* or blanket. The list of their household furniture is very short; some earthen ware made by themselves, and a few mats, form the chief part of it, none but the richer order being

being possessed of copper utensils. They occasionally purchase a few slaves from the Murzouk caravan. The remainder of their wants is supplied from Cairo or Alexandria, whether their dates are transported, both in a dry state and beaten into mash, which, when good, in some degree resembles a sweet meat. They eat no large quantity of animal food; and bread of the kind known to us is uncommon. Flat cakes, without leaven, kneaded, and then half baked, form part of their nourishment. The remainder consists of thin sheets of paste, fried in the oil of the palm tree, rice, milk, dates, &c. They drink in great quantities the liquor extracted from the date-tree, which they term *date-tree water*, though it have often, in the state they drink it, the power of inebriating. Their domestic animals are, the hairy sheep and goat of Egypt, the ass, and a very small number of oxen and camels. The women are veiled, as in Egypt. After the rains, the ground in the neighbourhood of Siwa is covered with salt for many weeks. Siwa is situated in 29° 12′ N. Lat. and 44° 54′ E. Long.

SKIRMISH Bay, the name given by Lieutenant Broughton to a bay in an island, which was discovered by him in latitude 43° 48′ south, and in longitude 183° east. The Chatham armed tender, which Mr Broughton commanded, under Captain Vancouver in his voyage of discovery, worked up into the bay, and came to anchor about a mile from the shore. The Lieutenant, the master, and one of the mates, landed, and found the people so extremely inhospitable, that they were obliged to fire upon them in their own defence. The land, whether island or continent, is of considerable magnitude; the part which they saw extended nearly 40 miles from east to west; and the appearance of the country, according to the description given, is very promising. In many respects, the natives resemble those of New Zealand; from which country they are distant about 100 leagues: but their skins were destitute of any marks, and they had the appearance of being cleanly in their persons. Their dresses were of seal, or sea-bear skin, and some had fine woven mats fastened round the waist. "They seemed a cheerful race, our conversation (says Mr Broughton) frequently exciting violent bursts of laughter amongst them. On our first landing their surprise and exclamations can hardly be imagined; they pointed to the sun, and then to us, as if to ask, whether we had come from thence?" Their arms were spears, clubs, and a small weapon resembling the New Zealand patoo.

SLIDING-rule (see that article, as likewise *Gauging-Rod*, Geometry, and *Logarithmic Lines*, Encycl.) is introduced here, for the sake of a new, and (except in working direct proportions) a more commodious method than the common, of applying the slider. This method, which is proposed by the Rev. W. Pearson of Lincoln, is as follows:

Invert the slider B on any common sliding rule, whereby the numerical figures will ascend on it, and on the fixed line A, in contrary directions: now, as the distance from unity to any multiplier, on Gunter's line, will invariably extend from any multiplicand to their product, it follows, that if any particular number on the inverted slider B be placed opposite to any other given number on A, the product of those numbers will stand on the slider B, against unity on A; for, in any position of the inverted slider, the distance from unity to the multiplier on A, instead of being carried forward on B, as when the slider is in a direct position, is brought back thereby to unity again; so that unity (or *ten* on single lines where the slider is too short for the operation) is invariably the index for the product of any two coincident numbers throughout the lines.

In division, by the same process, if the dividend on B be put to the index, or unity on A, the division and quotient will coincide on the two opposite lines; so that when one is given, and sought for on either line, the other is seen on its opposite line at the same time.

The next operation which offers itself here is reciprocal proportion, which can be effected by no other method than by inverting the slider, but which is rendered as easy by this application, as direct proportion is in the common way; for if any antecedent number on B inverted be set to its consequent on A, any other antecedent on B, in the same position, will stand against its consequent on A, so as that the terms may be in a reciprocal ratio. In squaring any number, it will appear from what has been already said, that if the number to be squared be placed on B, inverted against the same on A, the square will stand on B, against unity on A. Therefore, to extract the square root of any number, let that number on B stand against unity on A; and then wherever the coincident numbers are both of the same value, that point indicates the root. If two dividing lines of the same value do not exactly coincide, the coincident point will be at the middle of the space contained between those two which are nearest a coincidence; and as there is only one such point, there can be no mistake in readily ascertaining it. The finding of a mean proportional between any two numbers is extremely easy at one operation; for if one of the numbers on B inverted be set on the other on A, the coincident point of two similar numbers shews either of those to be the mean, or square root of their product, according to the preceding process. Thus have we a short and easy method of multiplying, dividing, working reciprocal proportion, squaring and extracting the square root, at one position of the inverted slider, whereby the eye is directed to only one point of view for the result, after the slider is fixed: whereas, by the common method of extracting the square root by A and B direct, the slider requires to be moved backwards and forwards by adjustment, the eye moving alternately to two points, till similar numbers stand, one on B against unity on A, and the other on A against the square number on B; which square number, in the case of finding a mean proportional, must be found by a previous operation. Hence, for more convenience in the extraction of roots, and measuring of solids, an additional line called D has been added to the rule, which renders it more complex, and consequently seldom understood by an artificer.

SNOW. See that article (*Encycl.*), where we have endeavoured to account for snow's contributing to the preservation and growth of vegetables. It must be confessed, however, that if snow possessed only the property of preserving vegetables, and of preventing them from perishing by the severity of the cold, it is not at all probable that the ancient philosophers would have considered it as depositing on the earth nitrous salts, as they might have ascertained, by a very simple experiment, Snow.

ment, that it contains none of that salt; for they did not ascribe the same property to rain-water, but they remarked that snow burnt the skin in the manner of acids, as well as other bodies immersed in it. Being induced to conclude that there was nitre in the air, it was natural that they should ascribe to this nitre the burning qualities of snow, and consequently its influence on vegetation.

Such reflections induced Morveau, *alias* Citizen Guyton, to employ J. H. Hassenfratz to inquire into the cause of the difference of the effects of snow and rain-water on various substances. Hassenfratz found that these differences are occasioned by the oxygenation of the snow; and that these effects are to be ascribed to a particular combination of oxygen in this congealed water. He put 1000 grammes of snow in a jar, and 1000 grammes of distilled water in another. He poured into each of the jars an equal quantity of the same solution of turnsole. He placed both the jars in a warm temperature; and after the snow melted, he remarked that the dye was redder in the snow water than in the distilled water. He repeated this experiment, and with the same result. He put into a jar 1000 grammes of distilled water, and into another 1000 grammes of snow. Into each of the jars he put 6·5 grammes of very pure and clean sulphat of iron. In the first, there was precipitated 0·150 grammes of the oxide of iron, and 0.010 grammes in the other. As the oxide of iron was precipitated from a solution of the sulphat by oxygen, it thence follows, that the snow contained more oxygen than the distilled water; and it follows, from the first experiment, that this quantity of oxygen was considerable enough to redden the tincture of turnsole.

It is fully demonstrated by these two experiments, that snow is oxygenated water, and that it must consequently have on vegetation an action different from that of common ice. The experiments of Dr Ingenhousz on the germination of seeds have taught us, that the presence and contact of oxygen are absolutely necessary for the plant to expand. They have shewn also, that the more abundant the oxygen is, the more rapidly will the seeds grow. Most plants suffered to attain to their perfect maturity shed on the earth a part of their seed. These seeds, thus abandoned and exposed to the action of cold, are preserved by the snow which covers them, at the same time that they find in the water it produces by melting, a portion of oxygen that has a powerful action on the principle of germination, and determines the seeds that would have perished to grow, to expand, and to augment the number of the plants that cover the surface of the earth.

A very considerable number of the plants which are employed in Europe for the nourishment of men, are sown in the months of September, October, and November. The seeds of several of these germinate before the cold commences its action upon them, and changes the principle of their life. The snow which covers the rest, acting on the germ by its oxygenation, obliges them to expand, and to increase the number of useful plants which the farmer and gardener commit to the earth, and consequently to multiply their productions.

Here, then, we have three effects of snow upon vegetation, all very different, which contribute each separately to increase, every year, the number of our plants; to give them more vigour, and consequently to multiply our crops. These effects are: 1. To prevent the plants from being attacked by the cold, and from being changed or perishing by its force. 2. To furnish vegetables with continual moisture, which helps them to procure those substances necessary for their nutrition, and to preserve them in a strong healthy state. 3. To cause a greater number of seeds to germinate, and consequently to increase the number of our plants.

Soap. Soldering.

SOAP. See CHEMISTRY-*Index*, Suppl.

SOLDERING. Under this title, in the *Encyclopædia*, we have given directions for soldering silver, brass, and iron: but there are other metals which must sometimes be soldered; and the following account of different solders, taken from the *Philosophical Magazine*, may be useful to many of our readers.

" When lead, tin, and bismuth, are mixed in a certain proportion, they produce a metal exceedingly fusible, which is known by the name of *soft solder*; but which, from its singular properties, may be applied with advantage to many other useful purposes. Newton, and after him Kraft and Muschenbroek, observed, that five parts of bismuth, three of tin, and two of lead, also five parts of bismuth, four of tin, and one part of lead, melted with a heat of 220 degrees of Fahrenheit; and they found that various mixtures of this kind were fusible by a heat not much greater than that of boiling water. At a later period, V. Rose, a German naturalist, discovered, that a mixture of four parts of bismuth, two of tin, and two of lead, as Kunkel recommended for soldering tin; and D'Arcet, among the French, that a mixture of eight parts of bismuth, three of tin, and five of lead; or eight of bismuth, four of tin, and four of lead; or eight of bismuth, two of tin, and six of lead; also sixteen of bismuth, seven of tin, and nine of lead—all melted, or at least became soft, in boiling water.

" According to the experiments made by Professor Gmelin, respecting the fusion of these three metals, a mixture, consisting of two parts of bismuth, one part of tin, and one of lead, which is the same as Rose proposed, gave a metal that was fused in boiling water. A mixture of six or more parts of bismuth, six of tin, and three of lead, or one part of bismuth, two parts of tin, and two of lead, gave, according to Klein, the solder used by the tin button-makers. The same workmen use also for soldering, according to Klein, a mixture of four parts of bismuth, three parts of tin, and five parts of lead. Among the many soft solders employed by the tin-men, a mixture of one part of bismuth, two parts of tin, and one part of lead, is, according to Klein, very much employed. Respecting this kind of solder, the experiments of Professor Gmelin give the following result: One part of bismuth, two parts of tin, and one part of lead, melt in boiling water. According to Klein, the tin-men employ for soldering a mixture of one part of bismuth, twenty-four parts of tin, and four parts of lead. Eight parts of bismuth, three of tin, and five of lead, gave a metal exceedingly like tin in its colour and brightness, but very brittle; in water beginning to boil, it became not only soft, but was completely fused. This imitation, however, may be better accomplished by the mixture of Professor Lightenberg, which consists of five parts of bismuth, Soldering, Soudan.

three of tin, and two of lead. This metal is very like the former, though not so brittle; but it seemed to melt in hot water even before it came to boil."

As this subject has again come under our notice, it may be proper to lay before our readers what M. Van Braam says of the Chinese method of soldering frying-pans and other vessels of cast-iron, when cracked and full of holes. As the author admits that it *must* appear *impossible* to those who have not *witnessed* the process, such of our artists as have not been in China will give to the tale what credit they think it deserves.

"All the apparatus of the workman consists in a little box, 16 inches long and 6 wide, and 18 inches in depth, divided into two parts. The upper contains three drawers with the necessary ingredients; in the lower is a bellows, which when a fire is wanted is adapted to a furnace eight inches long and four inches wide. The crucibles for melting the small pieces of iron intended to serve as solder are a little larger than the bowl of a common tobacco pipe, and of the same earth of which they are made in Europe: thus the whole business of soldering is executed.

"The workman receives the melted matter out of the crucible upon a piece of *wet paper*, approaches it to one of the holes or cracks in the frying-pan, and applies it there, while his assistant smooths it over by scraping the surface, and afterwards rubs it with a bit of *wet linen*. The number of crucibles which have been deemed necessary are thus successively emptied, in order to stop up all the holes with the melted iron, which consolidates and incorporates itself with the broken utensil, and which becomes as good as new. The furnace which our author saw was calculated to contain eight crucibles at a time; and while the fusion was going on, was covered with a stone, by way of increasing the intensity of the heat."—M. Van Braam affects frequently to correct the mistakes of Sir George Staunton!

SOUDAN, literally signifies the country of the negroes; but it is likewise used as one of the names of an African kingdom, otherwise called DAR-FUR. We know not that this kingdom has been visited by any European besides Mr Browne, who places it between the 11th and 16th degrees of north latitude, and between the 26th and 30th degrees of east longitude. These numbers are not exact: it does not reach so far east as the 30th degree, nor so far north as the 16th; but on his map minutes are not marked. On the north, it is bounded by a desart which separates it from Egypt; on the east, by Kordofan, which is now subject to Soudan, and lies between it and Sennaar; and on the south and east, by countries of which the names are hardly known. Mr Browne was induced to visit Soudan in hopes of being able to trace the Bahr-el-abiad, or true Nile, to its source: but he was disappointed, for that river rises in mountains considerably farther south than the limits of this kingdom; and the Sultan, a cruel and capricious tyrant, detained him a prisoner at large almost three years.

Soudan, or Dar-Fur, abounds with towns or villages, ill-built, of clay, and none of them very large. Of these it is not worth while to give an account. Its seasons are divided into rainy and dry. The perennial rains, which fall in Dar-Fur from the middle of June till the middle of September in greater or less quantity, but generally both frequent and violent, suddenly invest the face of the country, till then dry and steril, with a delightful verdure. Except where the rocky nature of the soil absolutely impedes vegetation, wood is found in great quantity; nor are the natives assiduous completely to clear the ground, even where it is designed for the cultivation of grain. As soon as the rains begin, the proprietor, and all the assistants that he can collect, go out to the field; and having made holes at about two feet distance from each other, with a kind of hoe, over all the ground he occupies, the *dokn*, a kind of millet, is thrown into them, and covered with the foot, for their husbandry requires not many instruments. The time for sowing the wheat is nearly the same. The *dokn* remains scarcely two months before it is ripe; the wheat about three.

The animals in Soudan, both wild and tame, are the same as in other parts of Africa in the same latitude. Though the Furians breed horses, and purchase very fine ones in Dongola, and from the Arabs to the east of the Nile, the ass is more used for riding; and an Egyptian ass (for the asses of Dar-Fur are diminutive and indocile like those of Britain) fetches from the value of one to that of three slaves. The villages of this country, like those of Abyssinia, are infested with hyenas; and in the unfrequented parts of the country are the elephant, the rhinoceros, the lion, the leopard, and all the other quadrupeds of Africa. The Arabs often eat the flesh of the lion and the leopard; and sometimes they so completely tame those animals, as to carry them loose into the market place. Our author tamed two lions, of which one acquired most of the habits of a dog. He satiated himself twice a week with the offal of the butchers, and then commonly slept for several hours successively. When food was given them, they both grew ferocious towards each other, and towards any one who approached them. Except at that time, though both were males, he never saw them disagree, nor shew any sign of ferocity towards the human race. Even lambs passed them unmolested.

Among the birds, the *vulture perenopterus*, or white-headed vulture, is most worthy of notice. It is of surprising strength, and is said by the natives to be very long-lived, *sed fides penes auctores*. "I have lodged (says Mr Browne) a complete charge of large shot, at about 50 yards distance, in the body of this bird: it seemed to have no effect on him, as he flew to a considerable distance, and continued walking afterwards. I then discharged the second barrel, which was loaded with ball: this broke his wing; but on my advancing to seize him, he fought with great fury with the other. There are many thousands of them in the inhabited district. They divide the field with the hyena: what carrion the latter leaves at night, the former come in crowds to feed on in the day. Near the extremity of each wing is a horny substance, not unlike the spur of an old cock. It is strong and sharp, and a formidable instrument of attack. Some fluid exudes from this bird that smells like musk; but from what part of him I am uncertain." The serpents found in Soudan are the same as in Egypt; but the natives have not the art of charming them like the Egyptians. The locust of Arabia is very common, and is frequently roasted and eaten, particularly by the slaves.

In Dar-Fur there seems to be a scarcity of metals; but

Soudan.

but in its neighbourhood to the fouth and weft all kinds are to be found. The copper brought by the merchants from the territories of certain idolatrous tribes bordering on Fur, is of the fineft quality, in colour refembling that of China, and appears to contain a portion of zinc, being of the fame pale hue. Iron is found in abundance; but they have not yet learned the art of converting it into fteel. Silver, lead, and tin, our author never heard mentioned in Soudan, but as coming from Egypt; but of gold, in the countries to the eaft and weft, the fupply is abundant. Alabafter, and various kinds of marble, are found within the limits of Fur, as is foffil falt within a certain diftrict; and there is a fufficient fupply of nitre, of which, however, no ufe is made.

The reftraint under which Mr Browne was kept in this inhofpitable country, prevented him from making a full catalogue of its vegetable productions. Of the trees which fhade our forefts or adorn our gardens in Europe, very few exift in Dar-Fur. The characteriftic marks of thofe fpecies which moft abound there, are their fharp thorns, and the folid and unperifhable quality of their fubftance. They feem to be much the fame as thofe which Bruce found in Abyffinia. There is a fmall tree called *enneb*, to the fruit of which they have given the name of grapes. It bears leaves of light green hue; and the fruit, which is of a purple colour, is attached, not in bunches, but fingly to the fmaller branches, and interfperfed among the leaves. The internal ftructure of the fruit is not very unlike the grape, which it alfo refembles in fize: but the pulp is of a red hue, and the tafte is ftrongly aftringent. The water-melon *(cucurbita citrullus)* grows wild over almoft all the cultivable lands, and ripens as the corn is removed. In this ftate it does not attain a large fize. The infide is of a pale hue, and has little flavour. As it ripens, the camels, affes, &c. are turned to feed on it, and it is faid to fatten them. The feeds, as they grow blackifh, are collected to make a kind of tar, *kutran*. Thofe plants of the melon which receive artificial culture grow to a large fize, and are of exquifite flavour. Tobacco is produced in abundance; and our author fpeaks of cochineal as found in Dar-Fur, or fome of the neighbouring countries.

The harveft is conducted in a very fimple manner. The women and flaves of the proprietor are employed to break off the ears with their hands, leaving the ftraw ftanding, which is afterwards applied to buildings and various other ufeful purpofes. They then accumulate them in bafkets, and carry them away on their heads. When thrafhed, which is aukwardly and incompletely performed, they expofe the grain to the fun till it become quite dry; after this a hole in the earth is prepared, the bottom and fides of which are covered with chaff to exclude the vermin. This cavity or magazine is filled with grain, which is then covered with chaff, and afterwards with earth. In this way the maize is preferved tolerably well. In ufing it for food, they grind it, and boil it in the form of polenta, which is eaten either with frefh or four milk, or ftill more frequently with a fauce made of dried meat pounded in a mortar, and boiled with onions, &c. The Furians ufe little butter; with the Egyptians and Arabs it is an article in great requeft. There is alfo another fauce which the poorer people ufe and highly relifh; it is compofed of an herb called *cowel* or *cawel*, of a tafte in part acefcent and in part bitter, and generally difagreeable to ftrangers.

Soudan.

The magiftracy of one, which feems tacitly, if it be not exprefsly favoured by the difpenfation of Mohammed, as in moft other countries profeffing that religion, prevails in Dar-Fur. The monarch indeed can do nothing contrary to the Koran, but he may do more than the laws eftablifhed thereon will authorife; and as there is no council to controul or even to affift him, his power may well be termed defpotic. He fpeaks in public of the foil and its productions as his perfonal property, and of the people as little elfe than his flaves.

His power in the provinces is delegated to officers, who poffefs an authority equally arbitrary. In thofe diftricts, which have always, or for a long time, formed an integral part of the empire, thefe officers are generally called *Meleks*. In fuch as have been lately conquered, or, perhaps more properly, have been annexed to the dominion of the Sultan under certain ftipulations, the chief is fuffered to retain the title of Sultan, yet is tributary to and receives his appointment from the Sultan of Fur.

Defpotic and arbitrary as he is, the Sultan here does not feem wholly inattentive to that important object, agriculture. Neverthelefs, it may be efteemed rather a blind compliance with ancient cuftom, than individual public fpirit, in which has originated a practice adopted by him, in itfelf fufficiently laudable, fince other of his regulations by no means conduce to the fame end. At the beginning of the *Harif*, or wet feafon, which is alfo the moment for fowing the corn, the king goes out with his Melecks and the reft of his train; and while the people are employed in turning up the ground and fowing the feed, he alfo makes feveral holes with his own hand. The fame cuftom, it is faid, obtains in Bornou and other countries in this part of Africa. It calls to the mind a practice of the Egyptian kings mentioned by Herodotus.

The population of Dar-Fur is not large. An army of 2000 men was fpoken of, when Mr Browne was in the country, as a great one; and he does not think that the number of fouls within the empire can much exceed 200,000. The troops of this country are not famed for fkill, courage, or perfeverance. In their campaigns, much reliance is placed on the Arabs who accompany them, and who are properly tributaries rather than fubjects of the fultan. One energy of barbarifm they indeed poffefs in common with other favages, that of being able to endure hunger and thirft; but in this particular they have no advantage over their neighbours. In their perfons the Furians are not remarkable for cleanlinefs. Though obferving as Mahommedans all the fuperftitious formalities of prayer, their hair is rarely combed, or their bodies completely wafhed. The hair of the pubes and axillæ it is ufual to exterminate; but they know not the ufe of foap; fo that with them polifhing the fkin with unguents holds the place of perfect ablutions and real purity. A kind of farinaceous pafte is however prepared, which being applied with butter to the fkin, and rubbed continually till it become dry, not only improves its appearance, but removes from it accidental furdes, and ftill more the effect of continued tranfpiration, which, as there are no baths in the country, is a confideration of fome import-

ance.

Soudan.

ance. The female flaves are dextcrous in the application of it; and to undergo this operation is one of the refinements of African fenfuality.

Nothing refembling current coin is found in Soudan, unlefs it be certain fmall tin rings, the value of which is in fome degree arbitrary. The Auftrian dollars, and other filver coins brought from Egypt, are all fold as ornaments for the women.

The difpofition of the Furians is cheerful; and that gravity and referve which the precepts of Mahommedifm infpire, and the practice of the greater number of its profeffors countenances and even requires, feems by no means as yet to fit eafy on them. A government perfectly defpotic, and not ill adminiftered, as far as relates to the manners of the people, yet forms no adequate reftraint to their violent paffions. Prone to inebriation, but unprovided with materials or ingenuity to prepare any other fermented liquor than *buza*, with this alone their convivial exceffes are committed. But though the Sultan publifhed an ordnance (March 1795), forbidding the ufe of that liquor under pain of death, the plurality, though lefs publicly than before, ftill indulge themfelves in it. A company often fits from funrife to fun-fet, drinking and converfing, till a fingle man fometimes carries off near two gallons of that liquor. The buza has, however, a diuretic and diaphoretic tendency, which precludes any danger from thefe exceffes. In this country dancing is practifed by the men as well as the women, and they often dance promifcuoufly.

The vices of thieving, lying, and cheating, in bargains, with all others nearly or remotely allied to them, as often happen among a people under the fame circumftances, are here almoft univerfal. No property, whether confiderable or trifling, is fafe out of the fight of the owner, nor indeed fcarcely in it, unlefs he be ftronger than the thief. In buying and felling, the parent glories in deceiving the fon, and the fon the parent; and God and the Prophet are hourly invocated, to give colour to the moft palpable frauds and falfehoods.

The privilege of polygamy, which, as is well known, belongs to their religion, the people of Soudan pufh to the extreme. By their law, they are allowed four free women, and as many flaves as they can maintain; but the Furians take both free women and flaves without limitation. The Sultan has more than a hundred free women, and many of the Meleks have from twenty to thirty. In their indulgence with women, they pay little regard to reftraint or decency. The form of the houfes fecures no great fecrecy to what is carried on within them; yet even the concealment which is thus offered is not always fought. The fhade of a tree, or long grafs, is the fole temple required for the facrifices to the Cyprian goddefs. In the courfe of licentious indulgence, father and daughter, fon and mother, are fometimes mingled; and the relations of brother and fifter are exchanged for clofer intercourfe.

Previoufly to the eftablifhment of Iflamifm * and kingfhip, the people of Fur feem to have formed wandering tribes; in which ftate many of the neighbouring nations to this day remain. In their perfons they differ from the negroes of the coaft of Guinea. Their hair is generally fhort and woolly, though fome are feen with it of the length of eight or ten inches, which they efteem a beauty. Their complexion is for the moft part perfectly black. The Arabs, who are numerous within the empire, retain their diftinction of feature, colour, and language. They moft commonly intermarry with each other. The flaves, which are brought from the country they call *Fertit* (land of idolaters), perfectly refemble thofe of Guinea, and their language is peculiar to themfelves.

* About a century and a half ago.

Soudan, Souffriere.

The revenues of the crown confift of a duty on all merchandife imported, which, in many inftances, amounts to near a tenth; of a tax on all flaves exported to Egypt; of all forfeitures for mifdemeanors; of a tenth on all merchandife, efpecially flaves, brought from every quarter but Egypt, and when flaves are procured by force, this tenth is raifed to a fifth; of a tribute paid by the Arabs, who breed oxen, horfes, camels, fheep; of a certain quantity of corn paid annually by every village; befides many valuable prefents, which muft be paid by the principal people, both at ftated times and on particular occafions. Add to all this, that the king is chief merchant in the country; and not only difpatches with every caravan to Egypt a great quantity of his own merchandife, but alfo employs his flaves and dependents to trade with the goods of Egypt on his own account, in the countries adjacent to Soudan.

The commodities brought by the caravans from Egypt are, 1. Amber beads. 2. Tin, in fmall bars. 3. Coral beads. 4. Cornelian beads. 5. Falfe cornelian beads. 6. Beads of Venice. 7. Agate. 8. Rings, filver and brafs, for the ancles and wrifts. 9. Carpets, fmall. 10. Blue cotton cloths of Egyptian fabric. 11. White cotton ditto. 12. Indian muflins and cottons. 13. Blue and white cloths of Egypt, called *Melayes*. 14. Sword-blades, ftrait (German), from Cairo. 15. Small looking-glaffes. 16. Copper face-pieces, or defenfive armour for the horfes heads. 17. Fire arms. 18. Kohhel for the eyes. 19. Rhea, a kind of mofs from European Turkey, for food and a fcent. 20. *She*, a fpecies of abfynthium, for its odour, and as a remedy: both the laft fell to advantage. 21. Coffee. 22. *Mahleb*, *Krumphille*, *Symbille*, *Sandal*, nutmegs, 23. *Dufr*, the fhell of a kind of fifh in the Red Sea, ufed for a perfume. 24. Silk unwrought. 25. Wire, brafs, and iron. 26. Coarfe glafs beads, made at Jerufalem, called *herfh* and *munjur*. 27. Copper culinary utenfils, for which the demand is fmall. 28. Old copper for melting and reworking. 29. Small red caps of Barbary. 30. Thread linens of Egypt—fmall confumption. 31. Light French cloths, made into benifhes. 32. Silks of Scio, made up. 33. Silk and cotton pieces of Aleppo, Damafcus, &c. 34. Shoes of red leather. 35. Black pepper. 36. Writing paper *(papier des trois lunes)*, a confiderable article. 37. Soap of Syria.

The goods tranfported to Egypt are, 1. Slaves, male and female. 2. Camels. 3. Ivory. 4. Horns of the rhinoceros. 5. Teeth of the hippopotamus. 6. Oftrich feathers. 7. Whips of the hippopotamus's hide. 8. Gum. 9. Pimento. 10. Tamarinds, made into round cakes. 11. Leather facks for water (*ray*) and dry articles (*geraub*). 12. Peroquets in abundance, and fome monkeys and Guinea fowls. 13. Copper, white, in fmall quantity.

SOUFFRIERE, a fmall town, fituated at the bottom of a bay, towards the leeward extremity of the ifland of St Lucia. There is nothing in the town itfelf which could

could have entitled it to notice in this work; but the ground about it is very remarkable. It has been defcribed by different authors; and our readers will probably not be ill pleafed with the following defcription of this wonderful fpot by Dr Rollo.

"Souffriere (fays he) is furrounded by hills covered with trees, the declivities of which, and every part capable of produce, are cultivated, and afford good fugar-cane. This place has its marfhes, but not fo extenfive, or fo much to windward as thofe about Carenage.

"The extremity of the fouth fide of Souffriere Bay runs into two fteep hills of a conical figure, which are nearly perpendicular: they are reckoned the higheft on the ifland, and are known by the name of the *Sugar Loaf Hills*. From their height and ftraitnefs it is impoffible to afcend them: we were told it was once attempted by two negroes, but they never returned. They are covered with trees and fhrubs, and are the fhelter of goats, feveral of which fometimes defcend, and are fhot by the natives.

"After you pafs the hills to windward of Souffriere, a fine clear and level country prefents itfelf. From the back of the Sugar Loaf Hills, and all along the fea-coaft, to the diftance, we fuppofe, of from fifteen to twenty miles, this flat or level extends: it is all cultivated and divided into rich eftates, affording fugar-cane equal to any in our iflands. This beautiful fpot is interfected by many rivers of very clear water, and thefe are conducted by art to the purpofe of fugar making. The rains in this part are lefs frequent than on any other part of the ifland; however, they have often a proportion more than fufficient. The wind here blows from the fea, or nearly fo.

"We cannot finifh this defcription without taking notice of a volcano in the neighbourhood of Souffriere. You pafs over one or two fmall hills to the fouthward of the town, and before any mark of the place is perceived you are fenfible of the fmell of fulphur. The firft thing you difcern is a rivulet of black running water, fending forth ftreams as if nearly boiling. From the profpect of this you foon open on the volcano, which appears in a hollow, furrounded clofe on every fide by hills. There are only two openings; the one we entered, and another almoft oppofite to it on the north fide. In the hollow there are many pits of a black and thick boiling matter, which feems to work with great force. Lava is flowly thrown out; and in the centre of the hollow there is a large mafs of it, forming a kind of hill. This we afcended; but were foon obliged to return from the exceffive heat. The lava is a fulphur mixed with a calcareous earth and fome faline body. We found fmall quantities of alum in a perfect ftate. In the opening, at the north fide of the hollow, there is a rivulet of very good water. On ftirring the bottom, over which this water runs, we were furprifed with feeling it very hot; and on placing a tumbler filled with fome of the water clofe to the bottom of the rivulet, it foon became fo hot as not to be touched. The liquid which runs from the pits is ftrongly impregnated with fulphur, and refembles a good deal the preparation fold in the fhops, known by the name of *aqua fulphurata*, or *gas fulphuris*."

SOUND-BOARD, the principal part of an organ, and that which makes the whole machine play. This found-board, or fummer, is a refervoir into which the wind, drawn in by the bellows, is conducted by a port-vent, and thence diftributed into the pipes placed over the holes of its upper part. The wind enters them by valves, which open by preffing upon the ftops or keys, after drawing the regifters, which prevent the air from going into any of the other pipes befides thofe it is required in.

Sound-Board denotes alfo a thin broad board placed over the head of a public fpeaker, to enlarge and extend or ftrengthen his voice.

Sound-boards, in theatres, are found by experience to be of no fervice; their diftance from the fpeaker being too great to be impreffed with fufficient force. But found-boards immediately over a pulpit have often a good effect, when the cafe is made of a juft thicknefs, and according to certain principles.

Sound-Poft, is a poft placed withinfide of a violin, &c. as a prop between the back and the belly of the inftrument, and nearly under the bridge.

SOWAL, in the language of Bengal, a queftion or requeft.

SPALLANZANI (Lazarus), was born at Scandiano, in the duchy of Modena, on the 10th of January 1729. He was fon of Jean Nicholas Spallanzani, an efteemed jurifconfult, and of Lucia Zugliani. He commenced his ftudies in his own country, and at the age of fifteen years went to Reggio de Modena in order to continue them. The Jefuits, who inftructed him in the belles lettres, and the Dominicans, who heard of his progrefs, were each defirous of attaching him to them; but his paffion for extending his knowledge led him to Bologna, where his relation Laura Baffi, a woman juftly celebrated for her genius, her eloquence, and her fkill in natural philofophy and the mathematics, was one of the moft illuftrious profeffors of the Inftitute and of Italy. Under the direction of this enlightened guide, he learned to prefer the ftudy of Nature to that of her commentators, and to judge of the value of the commentary by its refemblance to the original. He inftantly availed himfelf of the wifdom of that lady's counfels, and was not long before he experienced the happy effects of it. How agreeable it is to fee him in 1765 painting his gratitude for his inftructor, to whom he dedicated a Latin differtation at that time, in which he mentions the applaufes that Laura Baffi received at Modena, when fhe entered the auditory of her pupil, then become profeffor. The tafte of Spallanzani for philofophy was not exclufive; he already thought, like all great men, that the ftudy of antiquity and the belles lettres was requifite to give to ideas that clearnefs, to expreffions that accuracy, and to reafonings that connection, without which the fineft thoughts become barren. He ftudied his own language with care, and perfected himfelf in the Latin tongue; but above all, he attached himfelf to the Greek and the French. Homer, Demofthenes, St Bafil, were his favourite authors. Spallanzani applied himfelf to jurifprudence at the inftance of a father whom he tenderly loved: he was upon the point of receiving the degree of doctor of civil law, when Anthony Vallifneri, profeffor of natural hiftory at Padua, perfuaded him to renounce this vocation, by promifing to obtain the confent of his father, who was fenfibly touched by his fon's devotion to his will, and who thereby left him at liberty to follow his own inclinations. From that moment he gave himfelf up with more ardour than ever to the ſtudy of mathematics, continuing that alſo of the living and dead languages.

Spallanzani was preſently known all over Italy, and his own country was the firſt to do homage to his talents. The univerſity of Reggio, in 1754, choſe him to be profeſſor in logic, metaphyſics, and Greek. He taught there for ten years; and during that period conſecrated all the time he could ſpare from his leſſons to the obſervation of Nature. Now and then an accidental diſcovery would increaſe his paſſion for natural hiſtory, which always augmented by new ſucceſſes. His obſervations upon the animalculæ of infuſions fixed the attention of Haller and of Bonnet; the latter of whom aſſiſted him in his glorious career, and thenceforth diſtinguiſhed him as one of the learned interpreters of Nature.

In 1760 Spallanzani was called to the univerſity of Modena; and although his intereſt would have made him accept the advantageous offers of the univerſity of Coimbra, of Parma, and of Ceſena; yet his patriotiſm and his attachment to his family confined his ſervices to his own country. The ſame conſiderations engaged him to refuſe the propoſitions made him by the academy of Peterſburg ſome years after. He remained at Modena till the year 1768, and he ſaw raiſed by his care a generation of men conſtituting at this time the glory of Italy. Among them may be counted *Venturi*, profeſſor of natural philoſophy at Modena; *Belloni*, biſhop of Carpi; *Luccheſini*, ambaſſador of the late king of Pruſſia; and the poet *Angelo Mazzo* of Parma.

During his reſidence at Modena, Spallanzani publiſhed, in 1765, *Saggio di Oſſervazioni Microſcopiche concernente il Syſtema di Needham e Buffon.* He therein eſtabliſhes the *animality* of what had been called, but not generally aſſented to as, *microſcopic animalculæ*, by the moſt ingenious, and at the ſame time ſolid, experiments. He ſent this work to Bonnet, who formed his opinion of the author accordingly, and who lived to ſee the accompliſhment of the prophecy he drew from it. From that moment the moſt intimate acquaintance was formed between them, and it laſted during their lives, of which it conſtituted the chief happineſs. In the ſame year Spallanzani publiſhed a diſſertation truly original: *De Lapidibus ab Aqua reſilientibus.* In that work he proves, by ſatisfactory experiments, contrary to the commonly received opinion, that the ducks and drakes (as they are called) are not produced by the elaſticity of the water, but by the natural effect of the change of direction which the ſtone experiences in its movement, after the water has been ſtruck by it, and that it has been carried over the bend or hollow of the cup formed by the concuſſion.

In 1768 he prepared the philoſophers for the ſurpriſing diſcoveries he was about to offer them throughout his life, in publiſhing his *Prodromo di un Opera da Imprimerſi ſopra le Riproduzioni Animali.* He therein lays down the plan of a work which he was anxious to get up on this important ſubject; but this ſimple proſpectus contains more real knowledge than all the books which had appeared, becauſe it taught the method that ought to be followed in this dark reſearch, and contained many unexpected facts; ſuch as the pre-exiſtence of tadpoles at the fecundation, in many ſpecies of toads and frogs; the reproduction of the head cut off from ſnails, which he had already communicated to Bonnet in 1766, and which was diſputed for ſome time, in ſpite of the repeated confirmation of this phenemenon by Heriſſant and Lavoiſier. He demonſtrated it again afterwards in the *Memorie della Societa Italiana;* as alſo the renewal of the tail, the limbs, and even the jaws, taken from the aquatic ſalamander. Theſe facts continue to aſtoniſh even at this day, when they are thought of, notwithſtanding every one has had the opportunity of familiariſing himſelf with them: and we hardly know which we ought moſt to admire, the expertneſs of Spallanzani in affording ſuch deciſive proofs, or his boldneſs in ſearching after them, and ſeizing them. We have to regret, that the project of his great undertaking is not realized; but various circumſtances prevented him from giving way to the ſolicitations of his friends for its accompliſhment. Perhaps he deſpaired of throwing upon every part of it all the light which at firſt he thought he might be able; and found it prudent to mature his ideas by new meditations: this may probably have been as powerful a cauſe as that other calls and occupations, perpetually accumulating, ſhould not have allowed him to purſue it as he had intended. He has always laid Nature open to full view; and the thinneſt veil darkened her till he ſucceeded in removing it altogether.

The phyſiology of Haller that Spallanzani ſtudied, fixed his attention upon the circulation of the blood, in which he diſcovered ſeveral remarkable phenomena. He publiſhed, in 1768, a ſmall tract: *Dell' Azione del Cuore ne' Vaſi Sanguigni nuovi Oſſervazioni*, and he reprinted it in 1773, with three new diſſertations, *De' Fenomeni della Circolazione oſſervata nel' Giro univerſali de' Vaſi; De' Fenomeni della Circolazione Languente; De' Moti del Sangue, independente del Azione del Cuore e del Pulſare delle Arterie* This work, but little known, contains a ſeries of obſervations and experiments, of the moſt ingenious and delicate nature, upon a ſubject of which the ſurface only is known. It merits the attention of thoſe who are intereſted in the progreſs of phyſiology.

When the univerſity of Padua was re-eſtabliſhed upon a larger ſcale, the Empreſs Maria Thereſa directed the Count de Firmian to invite him to fill a chair, as profeſſor of natural hiſtory; his great reputation rendered him eligible for this diſtinction, ſolicited by many celebrated men, and he merited it by his ſucceſs, and by the crowd of ſtudents who thronged to his leſſons. Only great men make excellent maſters, becauſe their ideas are the moſt perſpicuous, the moſt extenſive, and beſt connected.

Spallanzani united a vaſt extent of knowledge to a fine genius; a method ſimple, but rigorous in its nature; and he connected what he knew to principles firmly eſtabliſhed. His ardent love of truth made him diſcuſs, with the utmoſt care, the theories which prevailed; to found their ſolidity, and diſcover their weak ſides. The great art which he had acquired, of interpreting Nature by herſelf, diffuſed ſuch a light over his leſſons, as made every thing perſpicuous that was capable of affording inſtruction. An eloquence at once plain and lively animated his diſcourſe; the purity and elegance of his ſtyle charmed all who heard it: in ſhort, it was known that he always occupied himſelf about the

the means of rendering his lessons useful, which he prepared a year beforehand. They became always new and engaging, by his new observations, and by the enlarged views that his meditations presented to him. The learned persons who attended his lectures were pleased to become his scholars, in order to know better what they already knew, and to learn that which otherwise they would perhaps never have known.

In arriving at the university, Spallanzani took the *Contemplation de la Nature* of Bonnet for the text of his lessons: he filled up the vacancies in it, he unfolded the ideas, and confirmed the theories by his experiments. He believed, with reason, that the book which inspired him with the love of natural history by reading it, was the most proper to give birth to it in the minds of his disciples.

He translated it into Italian, and enriched it with notes; he added a preface to it, wherein he pointed out the subjects of the vegetable and animal economy, which in an especial manner deserved the attention of his pupils; and sometimes pointing out to them the means of succeeding in their researches. It was thus he at first devoted himself to the pleasing employment of instructor of his countrymen, and that he became the model of those who were desirous of instructing usefully. He published the first volume of his translation in 1769, and the second in 1770.

The connection of Spallanzani with Bonnet had an influence upon his genius, which bent to the severe method of the philosopher of Geneva. He prided himself in being his pupil, and he unceasingly meditated upon his admirable writings; and thus it was that he became desirous of seeking in Nature for the proofs of Bonnet's opinion upon the generation of organized bodies, and that this charming subject fixed his attention for a long time.

He published, in 1776, the two first volumes of his *Opuscoli di Fisica Animale e Vegetabile*: they are the explanation of a part of the microscopic observations which had already appeared.

If the art to observe be the most difficult, it is nevertheless the most necessary of all the arts; but it supposes every quality, every talent: and further, though each believes himself more or less consummate therein, yet it is obvious, that only great men have exercised it in a distinguished manner. Genius alone fixes the objects worthy of regard; that alone directs the senses to the obscurities which it is necessary to dissipate; it watches over them to prevent error; it animates them to follow by the scent, as it were, that which they have but a distant view of: it takes off the veil which covers what we are looking after; it supports the patience which waits the moment for gratifying the sight in the midst of obstacles multiplying one upon another: in short, it is genius that concentrates the attention upon an object, which communicates that energy to him for imagining, that sagacity for discovering, that promptness for perceiving, without which we see only one side of truth, when we do not happen to let it escape altogether. But this is not all; for after Nature has been read with precision, it is necessary to interpret her with fidelity; to analyse by the thought the phenomena anatomised by the senses; to consider of the species by observing the individual, and to anticipate the general propositions by considering the unconnected facts. Here prudence and circumspection will not always secure us against error, if an ardent love for the truth does not assay observations and their consequences in its crucible, and thereby reduce every thing to *scoriæ* which is not truth.

Such was Spallanzani in all his researches; such we see him in all his writings. Occupied by the great phenomenon of generation, he examined the opinion of Needham to demonstrate its want of foundation. The latter, not satisfied with the microscopic observations of Spallanzani, which weakened the imagined vegetative force to put the matter in motion, challenged the professor of Reggio to a reperusal of what he had written; but he proved to the other, that we in common practice always see that which has been *well observed*, but that we never again see that which we have been contented with *imagining we saw*.

Spallanzani has received much praise for the politeness with which he carried on this controversy, and for the severe logic with which he demonstrates to Needham the causes of his error; and proves, that the animalculæ of infusions are produced by germs; that there are some of them which defy, like certain eggs and seeds, the most excessive cold, as well as the heat of boiling water. On this occasion, he treats on the influence of cold upon animals, and proves that the lethargic numbness of some, during winter, does not depend upon the impression the blood may receive from it; since a frog, deprived of his blood, becomes lethargic when he is reduced to the same cold state by an immersion in ice, and swims as before when restored to warmth. In the same manner he shews that odours, various liquors, the vacuum, act upon animalculæ as upon other animals; that they are oviparous, viviparous, and hermaphrodite. Thus, in running over these distant regions of Nature with this illustrious traveller, we are always meeting with new facts, profound remarks, precious details, and some curious anecdotes; in short, an universal history of those beings which are the most numerous of the globe, although their existence is scarcely suspected, and whose organization is in many respects different from that of known animals.

The second volume of this work is a new voyage into the most unknown parts: a sublime pencil had already painted it, but the picture was not done after Nature. Spallanzani here gives a history of the spermatic animalculæ, which the eloquent historian above alluded to always confounds with the animalculæ of infusions. We cannot but admire the modest diffidence of this new demonstrator, struggling against his own opinion and the authority of Buffon; and he appears to admit, with repugnance, the results of his multiplied, and in a thousand ways varied, observations, which expose the feebleness of the system of organic moleculæ.

Spallanzani afterwards describes the volvox and the slow-moving animalculæ (*rotifere* and *tardigrade*), those colossuses of the microscopic world, so singular by their figure and organization, but more singular still by their faculty of resuming life, after a total suspence of all the apparent acts of it during many years.

We will not here speak of the experiments of Spallanzani on the death of animals in close vessels, because he took up the subject again, and enlarged and exemplified it by the new lights of chemistry; but this collection

Spallanzani.

lection he concludes with another on the hiftory of vegetable mould growing on the furface of liquors and moift fubftances, the feeds of which he fhews to float in the air; and he remarks, that thefe microfcopic champignons or mufhrooms diftinguifh themfelves from other plants by their tendency to grow in all directions, without conforming to the almoft univerfal law of perpendicularity of ftalk to the ground.

Spallanzani was placed at the head of the univerfity's cabinet of natural hiftory, but he was little more than titular depofitary of a treafure which no longer exifted. He laid the foundations, however, for its renewal, and by his care it is become one of the moft precious and ufeful. He enriched it through his repeated travels by land and fea, in Europe, in Afia, acrofs the Apennines, the Alps, the Krapacks, at the bottom of mines, on the top of volcanoes, at the mouth of craters: fupported by his ardent paffion in the midft of perils, he preferved the *fang froid* of the philofopher to contemplate thefe wonders, and the piercing eye of an obferver to ftudy them. It is thus that he always diftinguifhed the proper objects for improving fcience by favouring inftruction; it is thus that he filled this depofitary with treafures, that all the gold in the world could not have obtained, becaufe gold never fupplies the genius and the difcernment of the enlightened naturalift.

In 1779 Spallanzani ran over Switzerland and the Grifons; he then went to Geneva, where he fpent a month with his friends, who admired him the more in his converfations after having admired him in his writings. He then returned to Pavia, and publifhed, in 1780, two new volumes of his *Differtazione di Fifica Animale e Vegetabile.* He therein reveals the fecrets of the interpretation of two very obfcure phenomena, concerning the vegetable and animal economy.

Some experiments made by Spallanzani upon *digeftion*, for his leffons, engaged him to ftudy this dark operation: he repeated Reaumur's experiments upon the gallinaceous birds; and he obferved that the trituration, which is in this cafe an aid to digeftion, could not, however, be a very powerful means. He faw that the gizzard of thofe birds which pulverife the ftones of fruit to pieces, as if done with needles or other fharp-pointed inftruments, did not digeft the powder fo formed: that it was neceffary it fhould undergo a new operation in the ftomach, before it could become fit chyle for affording the elements of the blood and other humours. He eftablifhed the point, that the digeftion was performed in the ftomach of numerous animals by the powerful action of a juice which diffolves the aliments; and to render his demonftration the more convincing, he had the courage to make feveral experiments on himfelf which might have proved fatal, and had the addrefs to complete his proofs by artificial digeftions, made in glaffes upon the table, by mixing the chewed aliments with the gaftric juice of animals, which he knew how to extract from their ftomachs. But this book, fo original by the multitude of experiments and curious obfervations which it contains, is ftill more worthy of attention by the philofophic fpirit which detected it.

This fubject is one of the moft difficult in phyfiology: the obferver is always compelled to act and to look with darknefs around him; he is obliged to manage the animal with care, to avoid the derangement of his operations; and when he has laborioufly completed his experiments, it is neceffary that he fhould well diftinguifh the confequences, fometimes erroneous, which may be drawn from thofe of obfervation, which never deceive when they are immediate. Spallanzani, in this work, is truly a fine fpectacle; fcrupuloufly analyfing the facts in order to difcover their caufes with certainty; inventing happy refources for furmounting the obftacles which renew themfelves; comparing Nature with his experiments, to judge of them; catching hold in his obfervations of every thing that is effential in them; meafuring their folidity by the augmentation or diminution of fuppofed caufes; drawing the beft founded conclufions, and rejecting the moft plaufible hypothefes; modeftly expofing the errors of thofe who have gone before him, and employing analogy with that wife circumfpection which infpires confidence in an inftrument at once fo dangerous and fo ufeful. But let it be known, Spallanzani had a capacity in particular for difcovering the truth, while the greater part of obfervators fcarcely ever attain it; and then, after having defcribed around them a circuitous trace, he runs upon it by a ftraight line, and poffeffes himfelf of it fo as that it cannot efcape him.

This work put John Hunter out of humour; and he publifhed, in 1785, *Some Obfervations upon Digeftion*, wherein he threw out fome bitter farcafms againft Spallanzani; who took ample revenge by publifhing this work in Italian, and addreffing to *Caldani*, in 1788, *Una Lettera Apologetica in Rifpofta alle Offervazione del Signor Giovanni Hunter*. He expofes, with moderation, but with an irrefiftible logic, the overfights of the Englifh phyfiologift, and points out his errors in a manner which left him no hope of a reply.

The fecond volume treats of the generation of animals and plants. Spallanzani proves, by experiments as fatisfactory as they are furprifing, the pre-exiftence of germs to fecundation; he fhews the exiftence of tadpoles in the females of five different fpecies of frogs, in toads, and in falamanders, before their fecundation: he recounts the fuccefs of fome artificial fecundations upon the tadpoles of thofe five fpecies, and even upon a quadruped. He in the fame manner fhews the feed in the flowers, before the emiffion of their farina; and by a fubtle anatomy of which one can hardly form an idea, he exhibits to the eye in the flower of the *fpartium junceum*, the filiqua, its feeds, with their lobes, and the embryo plant; he purfues them in their expanfion before and after fecundation, and leaves not a doubt but that the feeds and the pericarpia exifted long before the bloffoming of the buds, and confequently a long time before they could have been fecundated. He has repeated thefe obfervations upon various fpecies of plants with the fame refults; in fhort, he has raifed the individuals of plants with female flowers which have borne fecundated feeds, although they were out of the reach even of fufpicion of a communication with the farina of the male flowers. Such is the feries of furprifing phenomena Spallanzani adds to the hiftory of Nature.

According to cuftom, he availed himfelf of the academical vacation of 1781, to make a journey, the object of which was to add to the cabinet of Pavia. He fet out in the month of July for Marfeilles, where he commenced a new hiftory of the fea, which had prefented him with a crowd of novel and curious facts upon

Spallanzani.

on numerous genera of the inhabitants of the ocean. He went likewise to Finale, to Genoa, to Maſſa, and to Carrara, to obſerve the quarries of marble ſo famous with the ſtatuaries; he returned to Spezzia, and thence brought to Pavia an immenſe harveſt of fiſhes, cruſtaceous and teſtaceous, which he depoſited in that cabinet of which his voyages and travels had rendered him ſo worthy to be the guardian. He viſited, in the ſame view, and with the ſame ſucceſs, the coaſts of Iſtria in 1782; the Apennine Mountains in 1783, where he noticed the terrible hurricanes, and the ſurpriſing vapours which rendered that year ſo famous in meteorology. The cabinet of Pavia thus every year ſaw its riches increaſe; and in the ſame proportion it became the object of ſtrangers admiration; but every one admired ſtill more the immenſe labour of Spallanzani, who had collected every part of it.

The Emperor Joſeph knew this when he came into Lombardy: he deſired to have a converſation with Spallanzani; and his majeſty expreſſed his approbation by preſenting him with his medal in gold.

The univerſity of Padua offered to Spallanzani, in 1785, the chair of natural hiſtory, which the death of Anthony Vallifneri had left vacant, promiſing him more conſiderable advantages than thoſe which he enjoyed at Pavia; but the archduke doubled his penſion, and allowed him to accompany to Conſtantinople the Chevalier Zuliani, who had juſt been nominated ambaſſador from the republic of Venice.

He left this city the 21ſt of Auguſt; and during his voyage made ſeveral obſervations upon the marine productions he met with in thoſe climates, as well as upon the meteorological events of every day, among which he had the advantage of beholding a ſpecies of water-ſpout. He touched at ſeveral iſlands in the Archipelago; which he examined, and went aſhore at Troy to viſit the places ſung by the poet whom he preferred to all others; and in treading upon that ground ſo anciently famous, he made ſome geological obſervations truly original. One may judge before hand of the intereſt we ſhall feel in reading the Voyage of Spallanzani, by ſome memoirs which have appeared in the *Memorie della Societa Italiana* upon the water-ſpouts at ſea, the ſtroke of the torpedo, divers marine productions, and the iſland of Cytherea, where he diſcovered a mountain compoſed of various ſpecies of foſſils. Spallanzani arrived at Conſtantinople the 11th of October, and remained there eleven months: he muſt have been greatly out of his element in that country of ignorance and ſuperſtition, if he had not had Nature to ſtudy, and Zuliani to hear him. The phyſical and moral phenomena of this country, quite new to him, fixed his attention; he ſtrayed over the borders of the two ſeas, and climbed up the neighbouring hills; he viſited the iſland of Chalki, where he made known to the Turks a mine of copper, the exiſtence of which they never ſo much as ſuſpected. He went to the Principi iſland, a few miles diſtant from Conſtantinople, where he diſcovered an iron mine equally unthought of by the Turks. He returned to Europe loaded with ſpoils from the Eaſt, compoſed of the creatures of the three kingdoms, peculiar to thoſe regions: after having been uſeful to the Orientals, who were incapable of appreciating his merit, or rather of imagining he could have any, he ſet out on his return for Italy the 16th of Auguſt, 1786.

A voyage by ſea was in every reſpect the moſt ſafe and the moſt commodious; but Spallanzani conſidered the dangers and the inconveniences of the road as nothing when employed in any beneficial purſuit; he braved all the perils of thoſe deſert regions, where there is no police, no ſecurity. When he arrived at Bucharest, he was retained there during nine days by the celebrated and unhappy Mauroceni, hoſpodar of Wallachia. This prince, the friend of ſcience, received him with diſtinction, preſented him with many of the rarities of his country, furniſhed him with horſes for travelling, and alſo gave him an eſcort of thirty troopers throughout the whole extent of his dominions. Spallanzani paſſed by Hermanſtadt in Tranſylvania, and arrived at Vienna the 7th of December, after having viewed the numerous mines of Tranſylvania, of Hungary, and of Germany, which lay in the neighbourhood of his route. Spallanzani remained five days in this capital of Auſtria; he had two very long audiences with the Emperor Joſeph II.; was well received by the higheſt nobility in that metropolis, and viſited by the men of letters. At length arrived at Pavia; the ſtudents came to meet him out of the gates of the city, and accompanied him home, manifeſting their joy all the way by repeated ſhouts. Their great deſire to hear him, drew him almoſt immediately to the auditory, where they forced him to aſcend the chair from which he had been accuſtomed to deliver his lectures to them. Spallanzani, affected by this ſcene, teſtified with eloquence his gratitude and attachment;—friendly wiſhes, cries of joy, clapping of hands, recommenced with more force, and he was obliged to requeſt them to deſiſt, and allow him to take in his houſe that repoſe which was more neceſſary than ever. He had in the courſe of this year above 500 ſtudents.

Spallanzani had acquired glory enough to merit the attacks of envy; but his diſcoveries were too new, too original, too ſolid to be diſputed; envy itſelf was therefore forced to admire him: but that unworthy paſſion, being tired out by the increaſing reputation of that great man, watched the moment to prove that it had not forgotten him. Envy and malignity then called in queſtion his uprightneſs in the adminiſtration of the cabinet of Pavia; the whole of which was the fruit of his own labours: but the darts aimed at his honour only made it ſhine with new luſtre. The integrity of Spallanzani appeared even more pure after the juridical examination of the tribunals. But let us ſtop here; Spallanzani had the fortitude to forget this event which had torn his heart to pieces; the great part of his enemies acknowledged their miſtake, abjured their hatred, and did not deſpair of regaining his friendſhip.

The cabinet of Pavia was always the object of Spallanzani's thoughts; amidſt the numerous rarities which he had placed there, he only ſaw thoſe that were wanting. Struck with its deficiency in volcanic matters, which had neither ſeries nor order, and conſequently excited little intereſt, being a mute article with reſpect to inſtruction (although Italy was the theatre where the fires of volcanoes had for ſo many ages exerciſed their deſolating powers), he took the reſolution, with which his talents, his courage, and his zeal, inſpired him.

Spallanzani.

him. He was defirous to inftruct his pupils, his nation, himfelf, concerning the phenomena fo ftriking, and yet fo little known, and to collect the documents of their hiftory in the places where they have always been the terror of thofe who furrounded them, and where they have been ufelefsly the fubject of the obfervations of the philofopher. He therefore prepared himfelf for this great enterprife by deep ftudies. He fet out for Naples, in the fummer of 1788, and afcended mount Vefuvius; he looked attentively into its crater, examined and made notes in his books, and embarked for the Lipari iflands. He diffected, as it were, the uninhabited volcanoes, with the exactnefs of a naturalift anatomifing a butterfly, and the intrepidity of a warrior defying the moft imminent dangers. It was then that he had the boldnefs to walk over that fulphurous cruft, cleft with chinks, trembling, fmoking, burning, and fometimes treacheroufly covering the hearth of the volcano. He paffed into Sicily, where he climbed up to Etna, and coafted its immenfe crater. His curiofity not being exhaufted, he would collect around him, and have in his mind, all the fingular phenomena that Sicily contained; he examined the ftones and the mountains, and difcovered many new marine animals; he approached Scylla and Charybdis, and in a boat croffed the frothy billows of thofe deadly rocks, celebrated for fo many fhipwrecks, and fo often fung by the poets; but in the very midft of their frightful waves, he difcovered the caufe of their fury (See Scylla, *Suppl.*) It was thus that, at the age of 60, he picked up thofe numberlefs anecdotes which fill his voyages in the two Sicilies; and that he compared the defcription which Homer, Pindar, Virgil, Diodorus Siculus, and Strabo, have given of thefe ever famous places, with that which he made himfelf. In this manner he fhewed the connection of ancient literature with natural hiftory.

We find in the voyages of Spallanzani a new volcanology. He therein teaches the way to meafure the intenfity of the fire of volcanoes, to glance at the caufes, to touch almoft, in the analyfis which he makes of the lava, that particular gas which, refembling a powerful lever, tears from the bowels of the earth, and raifes up to the top of Etna, thofe torrents of ftone in fufion which it difgorges; to furvey the nature of thofe pumice-ftones, which he has fince explained in his artificial pumice-ftones. He concludes this charming work with fome interefting inquiries into the nature of fwallows, their mild difpofitions, rapid flight; fuggefting that an advantage might be drawn from them in the way of aerial poft; their migrations determined by the temperature of the air, and the birth of infects it occafions: in fhort, he difcuffes the famous problem of their remaining benumbed during winter; and proves, that artificial cold, much greater than that ever naturally felt in our climates, does not render thefe birds lethargic. He next fpeaks of a fpecies of owl, hitherto very ill defcribed; and, laftly, of eels and their generation, which is a problem ftill in fome meafure to be folved; but he carries it on by his inquiries to that ftep which alone remains to be made for obtaining a complete folution; or to get over it eafily by a fmall number of obfervations in thofe times and places pointed out, but which the academical occupations of Spallanzani forced him to give up to others.

Spallanzani followed the progrefs of the French chemiftry with much fatisfaction, nor was he long before he adopted it; it was calculated for a juft conception like his, delighting to give an account of every phenomenon he obferved. The folidity of principles in this new doctrine, the precifion in its way of proceeding, the elegance of its interpretation, the generality of its confequences, prefently replaced in his mind the hefitations and the obfcurities of the ancient chemiftry; and his heart anticipated with pleafure the triumphs that it was about to obtain.

In 1791, Spallanzani publifhed a letter addreffed to Profeffor Fortis, upon the Pennet Hydrofcope. He there relates the experiments which he had directed to be made for afcertaining the degree of confidence which might be allowed to the fingular talents of this man; but he ingenuoufly confeffes, that he is not decided upon the reality of the phenomenon.

Spallanzani has often difcovered that which might have been deemed impoffible. In 1795 he made a difcovery of this nature, which he publifhed in his *Lettere fopra il fofpetto d'un nuovo fenfo nei Pippiftrelli*. We therein learn that the bats, if blinded, act in every refpect with the fame precifion as thofe which have their eyes; that they in the fame manner avoid the moft trifling obftacles, and that they know where to fix themfelves on ceafing their flight. Thefe extraordinary experiments were confirmed by feveral natural philofophers, and gave occafion to fufpect a new fenfe in thefe birds, becaufe Spallanzani thought he had evinced by the way of exclufion, that the other fenfes could not fupply the deficiency of that fight which he had deprived them of; but the anatomical details of Profeffor Jurine, upon the organ of hearing in this fingular bird, made him incline afterwards towards the idea, that the fenfe of hearing might in this cafe fupply that of fight, as in all thofe where the bats are in the dark.

Spallanzani concluded his literary career for the public, by a letter addreffed to the celebrated Giobert; *Sopra la piante chiufe ne'vafi dentro l'aqua e l'aria, efpofte a l' immediàta lume folare e a l'ombra.* It is a misfortune for this part of the fcience, that his death has deprived us of the difcoveries he was about to make in it.

Thefe numerous works, printed and applauded, did not however contain all the feries of Spallanzani's labours. He had been occupied a confiderable time upon the phenomena of refpiration; their refemblances and differences in a great number of fpecies of animals; and he was bufily employed in reducing to order his refearches upon this fubject, which will aftonifh by the multitude of unforefeen and unexpected facts. He has left a precious collection of experiments and new obfervations upon animal reproductions, upon fponges, the nature of which he determines, and upon a thoufand interefting phenomena which he knew how to draw out of obfcurity. He had almoft finifhed his voyage to Conftantinople, and had amaffed confiderable materials for a Hiftory of the Sea, when an end was put to his life and his labours.

On the 4th of February 1799, he was feized with a retention of urine, the fame night was unquiet, and in the morning he loft all powers of reafon, which he never recovered but during very fhort intervals. His intimate friends, Tourdes, a French phyfician, and the celebrated Profeffor Scarpa, did every thing which could,

could be expected from genius, experience, and friendship, to save him; but he died the 17th, after having edified those around him by his piety. This lamentable event overwhelmed all his family in sorrow, occasioned the tears to flow from all his friends, filled his disciples with a deep affliction, and excited the regret of a nation proud of having given him birth.

The reader cannot but have perceived in this sketch the strain of panegyric, rather than the calm narrative of impartial biography. It is, in fact, an abridged translation of an *eloge* by a *citizen* philosopher of Geneva, who has adopted the calendar, and probably the principles of republican France. Some abatement therefore will naturally be made by every Briton of the praises bestowed upon the piety of Spallanzani; but after proper allowance of this kind, truth will proclaim him a very great man. Accordingly, France, Germany, England, all were eager to avail themselves of his works by means of translations. He was admitted into the academies and learned societies of London, Stockholm, Gottingen, Holland, Lyons, Bologna, Turin, Padua, Mantua, and Geneva. He was a correspondent of the academy of sciences of Paris and of Montpelier: and received from the great Frederic himself the diploma of member of the academy of Berlin.

SPECIES, in algebra, are the letters, symbols, marks, or characters, which represent the quantities in any operation or equation.

Species, in optics, the image painted on the retina by the rays of light reflected from the several points of the surface of an object, received in by the pupil, and collected in their passage through the crystalline, &c.

SPECTACLES (See *Encycl.*) are certainly the most valuable of all optical instruments, thougb there is not the same science and mechanical ingenuity displayed in the making of them as in the construction of microscopes and telescopes. A man, especially if accustomed to spend his time among books, would be much to be pitied, when his sight begins to fail, could he not, in a great measure, restore it by the aid of spectacles; but there are some men whose sight cannot be aided by the use either of convex or concave glasses. The following method adopted by one of those to aid his sight is certainly worthy of notice:

When about sixty years of age, this man had almost entirely lost his sight, seeing nothing but a kind of thick mist, while little black specks which appeared to float in the air. He knew not any of his friends, he could not even distinguish a man from a woman, nor could he walk in the streets without being led. Glasses were of no use to him; the best print, seen through the best spectacles, seemed to him like a daubed paper. Wearied with this melancholy state, he thought of the following expedient.

He procured some spectacles with very large rings; and, taking out the glasses, substituted in each circle a conic tube of black Spanish copper. Looking through the large end of the cone he could read the smallest print placed at its other extremity. These tubes were of different lengths, and the openings at the end were also of different sizes; the smaller the aperture the better could he distinguish the smallest letters; the larger the aperture the more words or lines it commanded; and consequently the less occasion was there for moving the head and the hand in reading. Sometimes he used one eye, sometimes the other, alternately relieving each, for the rays of the two eys could not unite upon the same object when thus separated by two opaque tubes. The thinner these tubes, the less troublesome are they. They must be totally blackened within so as to prevent all shining, and they should be made to lengthen or contract, and enlarge or reduce the aperture at pleasure.

When he placed convex glasses in these tubes, the letters indeed appeared larger, but not so clear and distinct as through the empty tube: he also found the tubes more convenient when not fixed in the spectacle rings; for when they hung loosely they could be raised or lowered with the hand, and one or both might be used as occasion required. It is almost needless to add, that the material of the tubes is of no importance, and that they may be made of iron or tin as well as of copper, provided the insides of them be sufficiently blackened. See *La Nouvelle Bigarure* for February 1754, or *Monthly Magazine* for April 1799.

SPECTRE of the Broken, a curious phenomenon observed on the summit of the *Broken*, one of the Harz mountains in Hanover. We have the following account of it by M. Haue. "After having been here (says he) for the thirtieth time, and having procured information respecting the abovementioned atmospheric phenomenon, I was at length, on the 23d of May 1797, so fortunate as to have the pleasure of seeing it; and perhaps my description may afford satisfaction to others who visit the Broken through curiosity. The sun rose about four o'clock, and, the atmosphere being quite serene towards the east, his rays could pass without any obstruction over the Heinrichshöhe. In the south-west, however, towards Achtermannshöhe, a brisk west wind carried before it thin transparent vapours, which were not yet condensed into thick heavy clouds.

"About a quarter past four I went towards the inn, and looked round to see whether the atmosphere would permit me to have a free prospect to the south-west; when I observed, at a very great distance towards Achtermannshöhe, a human figure of a monstrous size. A violent gust of wind having almost carried away my hat, I clapped my hand to it by moving my arm towards my head, and the colossal figure did the same.

"The pleasure which I felt on this discovery can hardly be described; for I had already walked many a weary step in the hopes of seeing this shadowy image, without being able to gratify my curiosity. I immediately made another movement by bending my body, and the colossal figure before me repeated it. I was desirous of doing the same thing once more—but my colossus had vanished. I remained in the same position, waiting to see whether it would return; and in a few minutes it again made its appearance on the Achtermannshöhe. I paid my respects to it a second time, and it did the same to me. I then called the landlord of the Broken; and having both taken the same position which I had taken alone, we looked towards the Achtermannshöhe, but saw nothing. We had not, however, stood long, when two such colossal figures were formed over the above eminence, which repeated our compliments by bending their bodies as we did; after which they vanished. We retained our position; kept our eyes fixed on the same spot, and in a little the two figures again stood before us, and were joined by a third. Every movement that we made by bending our bodies these figures imitated—but with this difference, that the phenomenon was sometimes weak and faint, sometimes strong and well defined. Having thus had an opportunity of discovering the whole secret of this phenomenon, I can give the following information to such of my readers as may be desirous of seeing it themselves. When the rising sun, and according to analogy the case will be the same at the setting sun, throws his rays over the Broken upon the body of a man standing opposite to fine light clouds floating around or hovering past him, he needs only fix his eyes stedfastly upon them, and, in all probability, he will see the singular spectacle of his own shadow extending to the length of five or six hundred feet, at the distance of about two miles before him."

If our memory does not deceive us, there is in one of the volumes of the *Manchester Transactions* an account of a similar phenomenon observed by Dr Ferrier, on a hill somewhere in England.

SPECULUM for reflecting telescopes. Under this title (*Encycl.*) we have given the composition of the mixt metal of which it has been found by experience that the best speculums are made; we have likewise given, under the same title, some directions for casting speculums: but owing to a circumstance in which the public can take no interest, we neglected to give directions for grinding and polishing them, and omitted some other circumstances, which, though not so important as these, are certainly worthy of notice. These omissions it is the object of this article to supply.

When the metal is taken out of the flasks (See n° 3. of the article referred to), which it should be as soon as it has become solid, and while it is yet red-hot, care must be taken to keep the face downwards to prevent it from sinking. Holding it in that position by the git, force out the sand from the hole in the middle of the mirror with a piece of wood or iron, and place the speculum in an iron pot, with a large quantity of hot ashes or small coals, so as to bury the speculum in them a sufficient depth. If the sand is not forced out of the hole in the manner above directed, the metal, by sinking as it cools, will embrace the sand in the middle of the speculum so tight, as to cause it to crack before it becomes entirely cold. And if the metal is not taken out of the sand, and put in a pot with hot ashes or coals to anneal it, the moisture from the sand will always break the metal. Let the speculum remain in the ashes till the whole is become quite cold. The git may be easily taken off by marking it round with a common fine half round file, and giving it then a gentle blow. The metal is then to be rough ground and figured.

It may be proper, however, before we proceed to describe that process, to give an account of another composition for the speculum of a reflecting telescope, which has been employed with great success, by Rochon director of the marine observatory at Brest. Of this composition the principal ingredient is platinum; which, in grains, must be purified in a strong fire by means of nitre and the salt of glass, or that flux which in the English glass-houses is called by the workmen *sandifer*. To the platinum, when purified, add the eighth part of the metal employed in the composition of common specula; for tin without red copper would not produce a good effect. This mixture is then to be exposed to the most violent heat, which must be still excited by the oxygen gas that disengages itself from nitre when thrown into the fire. One melting would be insufficient: five or six are requisite to bring the mixture to perfection. It is necessary that the metal should be in a state of complete fusion at the moment when it is poured into the mould. By this process I have been enabled (says our author) to construct a telescope with platinum, which magnifies the diameters of objects five hundred times, with a degree of clearness and distinctness requisite for the nicest observations. The large speculum of platinum weighs fourteen pounds: it is eight inches in diameter, and its focus is six feet. Though the high price of platinum will, in all probability, for ever prevent it from coming into general use for the speculums of telescopes, we thought it proper to notice this discovery, and shall now proceed to the grinding of the speculum.

For the accomplishing of this object, a very complicated process is recommended in Smith's Optics, and one not much more simpler by Mr Mudge in the 67th volume of the *Philosophical Transactions*; but according to Mr Edwards, whose speculums are confessedly the best, neither of these is necessary. Besides a common grindstone, all the tools that he made use of are a rough grinder, which serves also as a polisher, and a bed of hones. When the speculum was cold, he ground its surface bright on a common grindstone, previously brought to the form of the gage; and then took it to the rough grinder.

This tool is composed of a mixture of lead and tin, or of pewter, and is made of an elliptical form, of such dimensions, that the shortest diameter of the ellipse is equal to the diameter of the mirror or speculum, and the longest diameter is to the shortest in the proportion of ten to nine. This rough grinder may be fixed upon a block of wood, in order to raise it higher from the bench; and as the metal is ground upon it with fine emery, Mr Mudge, with whom, in this particular, Mr Edwards agrees, directs a hole or pit to be made in the middle of it as a lodgement for the emery, and deep grooves to be cut out across its surface with a graver for the same purpose. By means of a handle, fixed on the back of the metal with soft cement, the speculum can be whirled round upon this grinder so rapidly, that a common labourer has been known to give a piece of metal, four inches in diameter, so good a face and figure as to fit it for the hones in the space of two hours. The emery, however fine, will break up the metal very much; but that is remedied by the subsequent processes of honing and polishing.

When the metal is brought to a true figure, it must be taken to a convex tool, formed of some stones from a place called Edgedon in Shropshire, situated between Ludlow and Bishop's castle. The common blue hones, used by many opticians for this purpose, will scarcely touch the metal of Mr Edwards's speculums; but where they must be employed for want of the others, as little water should be used as possible when the metal is put upon them; because it is found by experience that they cut better when but barely wet, than when drenched with water. The stones, however, from Edgedon are greatly preferable; for they cut the metal more easily, and having a very fine grain, they bring it to a smooth face. These stones are directed by Mr Mudge to be cemented in small pieces upon a thick round piece of marble,

marble, or of metal made of tin and lead like the former compofitions, in fuch a manner, that the lines between the ftones may run ftraight from one fide to the other; fo that placing the teeth of a very fine faw in each of thefe divifions, they may be cleared from one end to the other of the cement which rifes between the ftones. As foon as the hones are cemented down, this tool muft be fixed in the lathe, and turned as exactly true to the gage as poffible. It fhould be of a circular figure, and but very little larger than the metal intended to be figured upon it. If it be made confiderably larger, it will grind the metal into a larger fphere and a bad figure; and if it be made exactly of the fame fize, it will work the metal indeed into a figure truly fpherical, but will be apt to fhorten its focus, unlefs the metal and tool be worked alternately upwards. On thefe accounts, Mr Edwards recommends it to be made about one twentieth part longer in diameter than the fpeculum, becaufe he has found that it does not then alter its focus; and he earneftly diffuades the ufe of much water on the hone pavement at the time of ufing it, otherwife, he fays, that the metal in different parts of it will be of different degrees of brightnefs.

When the metal is brought to a very fine face and figure by the bed of ftones, it is ready to receive a polifh, which is given to it by the elliptical rough grinder covered with pitch. With refpect to the confiftency of this pitch, Mr Mudge and Mr Edwards give very different directions. Whilft the former fays that it fhould be neither too hard nor too foft, the latter affirms that the harder the pitch is, the better figure it will give to the metal. Pitch may be eafily made of a fufficient hardnefs by adding a proper quantity of rofin; and when it is hardened in this way, it is not fo brittle as pitch alone, which is hardened by boiling. Mr Edwards advifes to make the mixture juft fo hard as to receive, when cold, an impreffion from a moderate preffure of the nail of one's finger. When the elliptical tool is to be covered with this mixture, it muft be made pretty warm, and in that ftate have the mixture poured upon it when beginning to cool in the crucible. Our author recommends this coating to be made everywhere of about the thicknefs of half-a-crown; and to give it the proper form, it muft, when fomewhat cool, be preffed upon the face of the mirror, which has firft been dipped in cold water, or covered over with very fine writing paper. If it be not found to have taken the exact figure from the firft preffure, the furface of the pitch muft be gently warmed, and the operation repeated as before. All the fuperfluous pitch is now to be taken away from the edge of the polifher with a penknife, and a hole to be made in the middle, accurately round, with a conical piece of wood. This hole fhould go quite through the tool, and fhould be made of the fame fize, or fomewhat lefs than the hole in the middle of the fpeculum. Mr Edwards fays, that he has always found that fmall mirrors, though without any hole in the middle, polifh much better, and take a more correct figure, for the polifher's having a hole in the middle of it.

The polifher being thus formed, it muft be very gently warmed at the fire, and divided into feveral fquares by the edge of a knife. Thefe, by receiving the fmall portion of metal that works off in polifhing, will caufe the figure of the fpeculum to be more correct than if no fuch fquares had been made. Mr Mudge directs the polifher to be ftrewed over with very fine *putty*; but Mr Edwards prefers Colcothar of vitriol. (See that article, *Encycl.*) Putty (fays he) gives metals a white luftre, or, as workmen call it, a filver hue; but good colcothar of vitriol will polifh with a very fine and high black luftre, fo as to give the metal finifhed with it the complection of polifhed fteel. To know if the colcothar of vitriol is good, put fome of it into your mouth, and if you find it diffolves away it is good; but if you find it hard, and crunch between your teeth, then it is bad, and not well burned. Good colcothar of vitriol is of a deep red, or of a deep purple colour; and is foft and oily when rubbed between the fingers; bad colcothar of vitriol is of a light red colour, and feels harfh and gritty. The colcothar of vitriol fhould be levigated between two furfaces of polifhed fteel, and wrought with a little water; when it is worked dry, you may add a little more water, to carry it lower down to what degree you pleafe. When the colcothar of vitriol has been wrought dry three or four times, it will acquire a black colour, and will be low enough, or fufficiently fine, to give an exquifite luftre. This levigated colcothar of vitriol muft be put into a fmall phial, and kept with fome water upon it. When it is to be ufed, every part of the pitch-polifher muft be firft brufhed over with a fine camel's hair brufh, which has been dipped in pure water, and rubbed gently over a piece of dry clean foap. The wafhed colcothar of vitriol is then to be put upon the polifher; and Mr Edwards directs a large quantity of it to be put on at once, fo as to faturate the pitch, and form a fine coating. If a fecond or third application of this powder be found neceffary, it muft be ufed very fparingly, or the polifh will be deftroyed which has been already attained. When the metal is nearly polifhed, there will always appear fome black mud upon its furface, as well as upon the tool. Part of this muft be wiped away with fome very foft wafh leather: but if the whole of it be taken away, the polifhing will not be fo well completed.

With refpect to the *parabolic figure* to be given to the mirror, Mr Edwards affures us, that a very little experience in thefe matters will enable any one to give it with certainty, by polifhing the fpeculum in the common manner, only with crofs ftrokes in every direction, upon an elliptical tool of the proper dimenfions.

SPINDLE, in geometry, a folid body generated by the revolution of fome curve line about its bafe or double ordinate; in oppofition to a conoid, which is generated by the rotation of the curve about its axis or abfcifs, perpendicular to its ordinate. The fpindle is denominated circular, elliptic, hyperbolic, or parabolic, &c. according to the figure of its generating curve.

Spindle, in mechanics, fometimes denotes the axis of a wheel, or roller, &c. and its ends are the pivots.

SPINNING machine. The ancient Greeks were not, like the modern philofophers, unwilling to acknowledge their obligations to Providence for all the comfort and enjoyments of life, nor felt pride in deriving every thing from their own talents. They were even difpofed to think that thofe very talents were infpired. Their firft inftructors, the poets, gave to Apollo the honour of that power of invention and imagination by which they inftructed and charmed their admiring hearers. The prophetefs dictated her oracles, the

Spinning-Machine.

the poet sung his enraptured strain only when inspired. The happy thought of twining a thread, and working it into a blanket, when viewed by that ingenious and acutely sensible people in all its importance, as the protector of the human race from the severity of the weather, seemed a present from heaven, as the inspiration of a divinity; and the distaff and the loom were Minerva's first title to a seat among the great gods on Olympus.

We are much inclined to be of the same opinion. When we observe, that in all the countries which have been discovered by the navigators of the three last centuries, the distaff and spindle, and the needle, have been found, we own ourselves much disposed to think that they are the results of instinct. Our instincts are not all simple and blind, like that which directs the new-born animal to the breast of its mother without knowing why. We have instincts of intellect as well as of appetite; and the logic of common conversation is an example of many such. We doubt not but that the noble-minded inhabitants of Pelew would have worshipped as a divinity an English maiden with her spinning wheel and fly. Surely he who should carry them this homely but ingenious machine, and a potter's wheel, would do them more service than if he taught them all the science of a Newton, with all the philosophy of the 18th century into the bargain. We do not know, except perhaps the steam engine, any mechanical invention that has made such amazing addition to the activity and industry and opulence of this highly favoured island, as the invention of Mr Arkwright for spinning by water, where dead matter is made to perform all that the nicest finger can do when directed by the never-ceasing attention of the intelligent eye. Minerva has the undisputed honours of the distaff and spindle. We know not to what benefactor we owe the fly-wheel. Mr Arkwright has the honour of combining them both, and inspiring them with his own spirit: for we may truly say of the contrivance which pervades the wonderful machinery of a cotton mill,

Totosque infusa per artus
Mens agitat molem et magno se corpore miscet.

To give an intelligible and accurate description of a cotton mill would be abundant employment for a volume. Our limits admit of nothing like this; but as we are certain that many of our readers have viewed a cotton mill with wonder, but not with intelligence, nor with leisure to trace the steps by which the wool from the bag ultimately assumes the form of a very fine thread. Bewildered by such a complication of machinery, all in rapid motion, very few, we imagine, are able to recollect with distinctness and intelligence the essential part of the process by which the form of the cotton is so wonderfully changed. Such readers will not think a page or two misemployed, if they are thereby able to understand this particular, to which all the rest of the process is subservient.

We pass over the operation of carding, by which all the clots and inequalities of the cotton wool are removed, and the whole is reduced to an uniform thin fleece, about 20 inches broad. This is gradually detached from the finishing card, and, if allowed to hang down from it, would pile up on the floor as long as the mill continues to work; but it is guided off from the card, very tenderly, in a horizontal direction, by laying its detached end over a roller, which is slowly turned round by the machine. Another roller lies above the fleece, pressing it down by its weight. By this pressure, a gentle hold is taken of the fleece, and therefore the slow motion of the rollers draws it gently from the card at the same rate as it is disengaged by the comb; but between the card and the rollers a set of smooth pins are placed in two rows, leading from the card to the rollers, and gradually approaching each other as we approach the rollers. By these pins the broad fleece is hemmed in on both sides, and gradually contracted to a thick roll: and in this state passes between the rollers, and is compressed into a pretty firm flat riband about two inches broad, which falls off from the rollers, and piles up in deep tinplate cans set below to receive it.

It is upon this stripe or riband of cotton wool that the operation of spinning begins. The general effect of the spinning process is to draw out this massive roll, and to twist it as it is drawn out. But this is not to be done by the fingers, pulling out as many cotton fibres at once as are necessary for composing a thread of the intended fineness, and continuing this manipulation regularly across the whole end of the riband, and thus, as it were, nibbling the whole of it away. The fingers must be directed, for this purpose, by an attentive eye. But in performing this by machinery, the whole riband must be drawn out together, and twisted as it is drawn. This requires great art, and very delicate management. It cannot be done at once; that is, the cotton roll cannot first be stretched or drawn out to the length that is ultimately produced from a tenth of an inch of the roll, and then be twisted. There is not cohesion enough for this purpose; we should only break off a bit of the roll, and could make no farther use of it. The fibres of cotton are very little implicated among each other in the roll, because the operation of carding has laid them almost parallel in the roll; and though compressed a little by its contraction from a fleece of 20 inches to a riband of only 2, and afterwards compressed between the discharging rollers of the carding machine, yet they cohere so slightly, that a few fibres may be drawn out without bringing many others along with them. For these reasons, the whole thickness and breadth of two or three inches of the riband is stretched to a very minute quantity, and then a very slight degree of twist is given it, viz. about three turns in the inch; so that it shall now compose an extremely soft and spongy cylinder, which cannot be called a thread or cord, because it has scarcely any firmness, and is merely rounder and much slenderer than before, being stretched to about thrice its former length. It is now called slab, or roove.

Although it be still extremely tender, and will not carry a weight of two ounces, it is much more cohesive than before, because the twist given to it makes all the longitudinal fibres bind each other together, and compress those which lie athwart; therefore it will require more force to pull a fibre from among the rest, but still not nearly enough to break it. In drawing out a single fibre, others are drawn out along with it; and if we take hold of the whole assemblage, in two places, about an inch or two inches asunder, we shall find that we may draw it to near twice its length without any risk

riſk of its ſeparating in any intermediate part, or becoming much ſmaller in one part than another. It ſeems to yield equably over all.

Such is the ſtate of the ſlab or roove of the firſt formation. It is uſually called the *preparation*; and the operation of ſpinning is conſidered as not yet begun. This preparation is the moſt tedious, and requires more attendance and hand labour than any ſubſequent part of the proceſs. For the ſtripes or ribands from which it is made are ſo light and bulky, that a few yards only can be piled up in the cans ſet to receive them. A perſon muſt therefore attend each thread of ſlab, to join freſh ſtripes as they are expended. It is alſo the moſt important in the manufacture; for as every inch of the ſlab meets with preciſely the ſame drawing and the ſame twiſting in the ſubſequent parts of the proceſs, therefore every inequality and fault in the ſlab (indeed in the fleece as it quits the finiſhing card) will continue through the whole manufacture. The ſpinning of cotton yarn now divides into two branches. The firſt, performed by what are called *jennies*, perfectly reſembles the ancient ſpinning with the diſtaff and ſpindle; the other, called *ſpinning of twiſt*, is an imitation of the ſpinning with the fly-wheel. They differ in the ſame manner as the ſpinning with the old wool or cotton-wheel differs from the ſpinning with the flax-wheel. Mr Arkwright's chief invention, the ſubſtitution of machinery for the immediate work of the human finger, is ſeen only in the manufacture of twiſt. We ſhall therefore confine our attention to this.

The reſt of the proceſs is little more than a repetition of that gone through in making the firſt ſlab or roove. It is formed on bobins. Theſe are ſet on the back part of the drawing frame; and the end of the ſlab is brought forwards toward the attending workman. As it comes forward, it is ſtretched or drawn to about $\frac{4}{5}$ of its former length, or lengthened $\frac{1}{5}$; and is then twiſted about twice as much as before, and in this ſtate wound up on another bobin. In ſome mills two rooves, after having been properly drawn, are brought together through one hole, and twiſted into one; but we believe that, in the greater number of mills, this is deferred to the ſecond drawing. It is only after the firſt drawing that the produce of the operation gets the name of *ſlab*; before this it is called *preparation*, or *roove*, or by ſome other name. The ſlab is ſtill a very feeble, ſoft, and delicate yarn, and will not carry much more weight than it did before in the form of roove. The perfection of the ultimate thread or yarn depends on this extreme ſoftneſs; for it is this only which makes it ſuſceptible of an equable ſtretching; all the fibres yielding and ſeparating alike.

The next operation is the *ſecond drawing*, which no way differs from the firſt, except in the different proportions of the lengthening, and the proportion between the lengthening and the ſubſequent twiſt. On theſe points we cannot give any very diſtinct information. It is different in different mills, and with different ſpecies of cotton wool, as may be eaſily imagined. The immediate mechaniſm or manipulation muſt be ſkilfully accommodated to the nature of that friction which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a conſiderable degree of elaſticity which it poſſeſſes. In this reſpect it greatly reſembles woollen fibres, and differs exceedingly from thoſe of flax: and it is for this reaſon that it is ſcarcely poſſible to ſpin flax in this way: its fibres become lank, and take any ſhape by the ſlighteſt compreſſion, eſpecially when damp in the ſlighteſt degree. But beſides this, the ſurface of a cotton fibre has a harſhneſs or roughneſs, which greatly augments their mutual friction. This is probably the reaſon why it is ſo unfit for tents and other dreſſings for wounds, and is refuſed by the ſurgeon even in the meaneſt hoſpitals. But this harſhneſs and its elaſticity fit it admirably for the manufacture of yarn. Even the ſhortneſs of the fibre is favourable: and the manufacture would hardly be poſſible if the fibre were thrice as long as it generally is. If it be juſt ſo long that in the finiſhed thread a fibre will rather break than come out from among the reſt, it is plain that no additional length can make the yarn any ſtronger with the ſame degree of compreſſion by twining. A longer fibre will indeed give the ſame firmneſs of adherence with a ſmaller compreſſion. This would be an advantage in any other yarn; but in cotton yarn the compreſſion is already as ſlight as can be allowed; were it leſs, it would become woolly and rough by the ſmalleſt uſage, and is already too much diſpoſed to teazle out. It can hardly be uſed as ſewing thread. Now ſuppoſe the fibres much longer; ſome of them may chance to be ſtretched along the ſlab through their whole length. If the ſlab is pulled in oppoſite directions, by pinching it at each end of ſuch fibres, it is plain that it will not ſtretch till this fibre be broken or drawn out; and that while it is in its extended ſtate, it is acting on the other fibres in a very unequable manner, according to their poſitions, and renders the whole apt to ſeparate more irregularly. This is one great obſtacle to the ſpinning of flax by ſimilar machinery; and it has hitherto prevented (we believe) the working up of any thing but the *ſhorts* or tow, which is ſeparated from the long fine flax in the operation of hatcheling.

A third, and ſometimes even a fourth, drawing is given to the ſlab formed on the bobins of this ſecond operation. The ſlab produced is now a ſlender, but ſtill extremely ſoft cord, ſuſceptible of conſiderable extenſion, without riſk of ſeparation, and without the ſmalleſt chance of breaking a ſingle fibre in the attempt. In one or more of the preparatory drawings now deſcribed, two, and ſometimes three ſlabs of a former drawing, are united before the twiſt is given them. The practice is different in different mills. It is plain, that unleſs great care be taken to preſerve the ſlab extremely ſoft and compreſſible during the whole proceſs, the ſubſequent drawing becomes more precarious, and we run a riſk of at laſt making a bad and looſe thread inſtead of a uniform and ſimple yarn. Such a thread will have very little lateral connection, and will not bear much handling without ſeparating into ſtrands. The perfection of the yarn depends on having the laſt ſlab as free of all appearance of ſtrands as poſſible.

The laſt operation is the ſpinning this ſlab. This hardly differs from the foregoing drawings in any thing but the twiſt that is given it after the laſt ſtretching in its length. This is much greater than any of the preceding, being intended to give the yarn hardneſs and firmneſs, ſo that it will now break rather than ſtretch any more.

The

The reader, moderately acquainted with mechanics, cannot but perceive that each of the operations now defcribed, by which the roove is changed into the foft flab, and each of thefe into one flenderer and fomewhat firmer, by alternately teazling out and twining the foft cord, is a fubftitute for a fingle pull of the finger and thumb of the fpinfter, which fhe accommodates precifely to the peculiar condition of the lock of wool which fhe touches at the moment. She can follow this thro' all its irregularities; and perhaps no two fucceeding plucks are alike. But when we cannot give this momentary attention to every minute portion, we muft be careful to introduce the roove in a ftate of perfect uniformity; and then every inch being treated in the fame manner, the final refult will be equable—the yarn will be uniform.

We are now to defcribe the mechanifm by which all this is effected. But we do not mean to defcribe a cotton mill; we only mean to defcribe what comes into immediate contact with the thread; and in fo doing, to confine ourfelves to what is neceffary for making the reader perceive its ability to perform the required tafk. We fee many cafes where individuals can apply this knowledge to ufeful purpofes. More than this would, we think, be improper, in a national point of view.

Plate XLIII.

Let ABC reprefent the fection of a roller, whofe pivot D does not turn in a pivot hole, but in the bottom of a long narrow notch DE, cut in an iron ftandard. *a b c* is the fection of another iron roller, whofe pivot *d* is in the fame notches at each end, while the roller itfelf lies or refts on the roller ABC below it. The furfaces of thefe rollers are fluted lengthwife like a column; only the flutings are very fmall and fharp, like deep ftrokes of engraving very clofe together. It is plain, that if the roller ABC be made to turn flowly round its axis by machinery, in the direction ABC (as expreffed by the dart), the roughnefs of the flutings will take hold of the fimilar roughnefs of the upper roller *a b c*, and carry it round alfo in the direction of the dart, while its pivots are engaged in the notches DE, which they cannot quit. If therefore we introduce the end F of the cotton ftring or riband, formed by the carding machine, it will be pulled in by this motion, and will be delivered out on the other fide at H, confiderably compreffed by the weight of the upper roller, which is of iron, and is alfo preffed down by a lever which refts on its pivots, or other proper places, and is loaded with a weight. There is nothing to hinder this motion of the riband thus compreffed between the rollers, and it will therefore be drawn thro' from the cans. The compreffed part at H would hang down, and be piled up on the floor as it is drawn thro'; but it is not permitted to hang down in this manner, but is brought to another pair of fharp fluted iron rollers K and L. Suppofing this pair of rollers to be of the fame diameter, and to turn round in the fame time, and in the fame direction with the rollers ABC, *a b c*; it is plain that K and L drag in the compreffed riband at I, and would deliver it on the other fide at M, ftill more compreffed. But the roller K is made (by the wheelwork) to turn round more fwiftly than ABC. The difference of velocity at the furface of the rollers is, however, very fmall, feldom exceeding one part in 12 or 15. But the confequence of this difference is, that the fkein of cotton HI will be lengthened in the fame proportion; for the upper rollers preffing on the under ones with a confiderable force, their fharp flutings take good hold of the cotton between them; and fince K and L take up the cotton fafter than ABC, and *a b c* deliver it out, it muft either be forcibly pulled through between the firft rollers, or it muft be ftretched a little by the fibres flipping among each other, or it muft break. When the extenfion is fo very moderate as we have juft now faid, the only effect of it is merely to begin to draw the fibres (which at prefent are lying in every poffible direction) into a more favourable pofition for the fubfequent extenfions.

The fibres being thus drawn together into a more favourable pofition, the cotton is introduced between a third pair of rollers O, P, conftructed in the fame way, but fo moved by the wheelwork that the furface of O moves nearly or fully twice as faft as the furface of K. The roller P being alfo well loaded, they take a firm hold of the cotton, and the part between K and O is nearly or fully doubled in its length, and now requires a little twining to make it roundifh, and to confolidate it a little.

It is therefore led floping downwards into a hole or eye in the upper pivot of the firft fly, called a *jack*. This turns round an upright axis or fpindle; the lower end of which has a pulley on it to give it motion by means of a band or belt, which paffes round a drum that is turned by the machinery. This jack is of a very ingenious and complicated conftruction. It is a fubftitute for the fly of the common fpinning wheel. If made precifely in the form of that fly, the thread, being fo very bulky and fpongy, and unable to bear clofe packing on the bobin, would fwag out by the whirling of the fly, and would never coil up. The bobin therefore is made to lie horizontally; and this occafions the complication, by the difficulty of giving it a motion round a horizontal axis, in order to coil up the twifted roove. Mr Arkwright has accomplifhed this in a very ingenious manner; the effential circumftances of which we fhall here briefly defcribe. A is a roller of hard wood, having its furface cut into fharp flutes longitudinally. On the axis, which projects through the fide of the general frame, there is a pulley P, connected by a band with another pulley Q, turning with the horizontal axis QR. This axis is made to turn by a contrivance which is different in every different cotton mill. The fimpleft of all is to place above the pulley C (which is turned by the great band of the machinery, and thus gives motion to the jack) a thin circular difc D, loofe upon the axis, fo as to turn round on it without obftruction. If this difc exceed the pulley in breadth about one-tenth of an inch, the broad belt which turns the pulley will alfo turn it; but as its diameter is greater than that of the pulley, it will turn fomewhat flower, and will therefore have a relative motion with refpect to the axis QR. This can be employed, in order to give that axis a very flow motion, fuch as one turn of it for 20 or 30 of the jack. This we leave to the ingenuity of the reader. The bobin B, on which the roove is to be coiled up, lies on this roller, its pivots paffing through upright flits in the fides of the general frame. It lies on A, and is moved round by it, in the fame manner as the uppermoft of a pair of drawing rollers lies on the under one, and receives motion from it. It is evident that the fluted furfaces of A, by turning flowly round, and carrying

carrying the weight of the bobin, compreffes a little the cotton that is between them; and its flutings, being fharp, take a flight hold of it, and caufe it to turn round alfo, and thus coil up the roove, pulling it in through the hole E in the upper pivot (which refembles the fore pivot or eye of a fpinning wheel fly) in fo gentle a manner as to yield whenever the motion of the bobin is too great for the fpeed with which the cotton fkein is difcharged by the rollers O and P.—*N. B.* The axis QR below, alfo gives motion to a guide within the jack, which leads the roove gradually from one end of the bobin to the other, and back again, fo as to coil it with regularity till the bobin is full. The whole of this internal mechanifm of the jack is commonly fhut up in a tin cylinder. This is particularly neceffary when the whirling motion muft be rapid, as in the fecond and third drawings. If open, the jacks would meet with much refiftance from the air, which would load the mill with a great deal of ufelefs work.

The reader is defired now to return to the beginning of the procefs, and to confider it attentively in its different ftages. We apprehend that the defcription is fufficiently perfpicuous to make him perceive the efficacy of the mechanifm to execute all that is wanted, and prepare a flab that is uniform, foft, and ftill very extenfible; in fhort, fit for undergoing the laft treatment, by which it is made a fine and firm yarn.

As this part of the procefs differs from each of the former, merely by the degree of twift that is given to the yarn, and as this is given by means of a fly not materially different from that of the fpinning wheel for flax, we do not think it at all neceffary to fay any thing more about it.

The intelligent reader is furely fenfible that the yarn produced in this way muft be exceedingly uniform. The uniformity really produced even exceeds all expectation; for even although there be fome fmall inequalities in the carded fleece, yet if thefe are not matted clots, which the card could not equalife, and only confift of a little more thicknefs of cotton in fome places than in others, when fuch a piece of the ftripe comes to the firft roller, it will be rather more ftretched by the fecond, and again by the bobin, after the firft very flight twining. That this may be done with greater certainty, the weights of the firft rooving rollers are made very fmall, fo that the middle part of the fkein can be drawn through, while the outer parts remain faft held.

We are informed that a pound of the fineft Bourbon cotton has been fpun into a yarn extending a few yards beyond 119 miles.

Elater SPRING, in phyfics, denotes a natural faculty, or endeavour, of certain bodies to return to their firft ftate, after having been violently put out of the fame by compreffing, or bending them, or the like. This faculty is ufually called by philofophers *elaftic force*, or *elafticity*.

T. SQUARE, or *Tee Square*, an inftrument ufed in drawing, fo called from its refemblance to the capital letter T.

STAPELIA, a genus of plants belonging to the clafs pentandria, in the Linnæan arrangement, and to the order digynia. The generic characters are the following: The *calyx* is monophyllous, quinquefid, acute, fmall, and permanent. The *corolla* is monopetalous, flat, large, and divided, deeper than the middle, into five parts, with broad, flat, pointed *laciniæ*. The *nectarium* is fmall, ftar-fhaped, flat, quinquefid, with linear *laciniæ*; and embracing with its ragged points the feed-forming parts. Another fmall ftar, which is alfo flat and quinquefid, covers the feminiferous parts with its entire acute *laciniæ*. The *ftamina* are five in number; the *filaments* are erect, flat, and broad; and the *antheræ* are linear, on each fide united to the fide of the filament. The *piftillum* has two *germina*, which are oval and flat on the infide. There are no *ftyles*; and the *ftigmata* are obfolete. The *feed-veffel* confifts of two oblong, awl-fhaped, unilocular and univalved follicles. The *feeds* are numerous, imbricated, compreffed, and crowned with a *pappus* or down.

This fingular tribe of plants is peculiar to the fandy deferts of Africa and Arabia. They are extremely fucculent. From this peculiarity of ftructure, the power of retaining water to fupport and nourifh them, they are enabled to live during the prevalent droughts of thofe arid regions. On this account the ftapelia has been compared to the camel; and we are told that, by a very apt fimilitude, it has been denominated "the *camel* of the vegetable kingdom." We muft confefs ourfelves quite at a lofs to fee the propriety or aptitude of this comparifon. In many parts of the animal and vegetable economy there is doubtlefs a very obvious and ftriking analogy: but this analogy has been often carried too far; much farther than fair experiment and accurate obfervation will in any degree fupport. It is perhaps owing to this inaccuracy in obferving the peculiarity of ftructure and diverfity of functions, that a refemblance is fuppofed to exift, as in the prefent cafe, where in reality there is none. The camel is provided with a bag or fifth ftomach, in addition to the four with which ruminant animals are furnifhed. This fifth ftomach is deftined as a refervoir to contain water; and it is fufficiently capacious to receive a quantity of that neceffary fluid, equal to the wants of the animal, for many days; and this water, as long as it remains in the fifth ftomach, is faid to be perfectly pure and unchanged. The *ftapelia*, and other fucculent plants, have no fuch refervoir. The water is equally, or nearly fo, diffufed through the whole plant. Every veffel and every cell is fully diftended. But befides, this water, whether it be received by the roots, or abforbed from the atmofphere, has probably undergone a complete change, and become, after it has been a fhort time within the plant, a fluid poffeffed of very different qualities.

The peculiar economy in the ftapelia, and other fucculent plants, feems to exift in the abforbent and exhalant fyftems. The power of abforption is as much increafed as the power of the exhalant or perfpiratory veffels is diminifhed. In thefe plants, a fmall quantity of nourifhment is required. There is no folid part to be formed, no large fruit to be produced. They generally have very fmall leaves, often are entirely naked; fo that taking the whole plant, a fmall furface only is expofed to the action of light and heat, and confequently a much fmaller proportion of water is decompofed than in plants which are much branched and furnifhed with leaves.

Two fpecies of ftapelia only were known at the beginning of the century. The unfortunate Forfkål, the companion

Star, Starch.

companion of Niebhur, who was fent out by the king of Denmark to explore the interior of Arabia, and who fell a facrifice to the peftilential difeafes of thofe inhofpitable regions, difcovered two new fpecies. Thunberg, in his *Prodromus*, has mentioned five more. Forty new fpecies have been difcovered by Mr Maffon of Kew Gardens, who was fent out by his prefent Majefty for the purpofe of collecting plants round the Cape of Good Hope. Defcriptions of thefe, with elegant and highly finifhed coloured engravings, have lately been publifhed. They are chiefly natives of the extenfive deferts called *Karro*, on the weftern fide of the Cape.

STAR, in fortification, denotes a fmall fort, having five or more points, or faliant and re-entering angles, flanking one another, and their faces 90 or 100 feet long.

STARCH (fee *Encycl.*) is commonly made of wheat, and the very beft ftarch can poffibly be made of nothing elfe. Wheat, however, is too valuable an article of food to be employed as the material of ftarch, when any thing elfe will anfwer the purpofe; and it has long been known that an inferior kind of ftarch may be made of potatoes. Potatoes, however, are themfelves a valuable article of food: and it is therefore an object of importance to try if ftarch may not be made of fomething ftill lefs ufeful.

On the 8th of March 1796, a patent was granted to Lord William Murray for his difcovery of a method by which ftarch may be extracted from horfe-chefnuts. That method is as follows:

Take the horfe-chefnuts out of the outward green prickly hufks; and then, either by hand, with a knife or other tool, or elfe with a mill adapted for that purpofe, very carefully pare off the brown rind, being particular not to leave the fmalleft fpeck, and to entirely eradicate the fprout or growth. Next take the nuts, and rafp, grate, or grind them fine into water, either by hand, or by a mill adapted for that purpofe. Wafh the pulp, which is thereby formed in this water, as clean as poffible, through a coarfe horfe hair fieve; this again wafh through a finer fieve, and then again through a ftill finer, conftantly adding clean water, to prevent any ftarch from adhering to the pulp. The laft procefs is, to put it with a large quantity of water (about four gallons to a pound of ftarch) through a fine gauze, muflin, or lawn, fo as entirely to clear it of all bran or other impurities. As foon as it fettles, pour off the water; then mix it up with clean water, repeating this operation till it no longer imparts any green, yellow, or other colour to the water. Then drain it off till nearly dry, and fet it to bake, either in the ufual mode of baking ftarch, or elfe fpread out before a brifk fire; being very attentive to ftir it frequently to prevent its horning, that is to fay, turning to a pafte or jelly, which, on being dried, turns hard like horn. The whole procefs fhould be conducted as quickly as poffible.

Mention is here made of a mill which may be employed to grind the horfe-chefnuts; but none is defcribed as proper for that purpofe. Perhaps the following mill, which was invented by M. Beaumé for grinding potatoes, with a view to extract ftarch from them, may anfwer for grinding horfe-chefnuts.

Plate XLII.

He had a grater made of plate iron, in a cylindrical form (fig. 1.) about feven inches in diameter, and about eight inches high: the burs made by ftamping the holes are on the infide. This grater is fupported upon three feet AAA, made of flat iron bars, feven feet high, ftrongly rivetted to the grater; the bottom of each foot is bent horizontally, and has a hole in it which receives a fcrew, as at A, fig. 4. A little below the upper end of the three feet is fixed a crofs piece B (fig. 1. and 4.), divided into three branches, and rivetted to the feet. This crofs piece not only ferves to keep the feet at a proper diftance from each other, and to prevent their bending; but the centre of it having a hole cut in it, ferves to fupport an axis or fpindle of iron, to be prefently defcribed.

The upper end of this cylindrical grater has a diverging border of iron C (fig. 1. 4. and 7.), about ten inches in diameter at the top, and five inches in height.

Within this cylindrical grater is placed a fecond grater (fig. 2. and 3.), in the form of a cone, the point of which is cut off. The latter is made of thick plate iron, and the burs of the holes are on the outfide; it is fixed, with the broad end at the bottom, as in fig. 4. At the upper end of the cone is rivetted a fmall triangle, or crofs piece of iron, confifting of three branches D (fig. 2.), in the middle of which is made a fquare hole, to receive an axis or fpindle; to give more refiftance to this part of the cone, it is ftrengthened by means of a cap of iron E, which is fixed to the grater by means of rivets, and has alfo a fquare hole made in it, to let the axis pafs through.

Fig. 3. reprefents the fame cone feen in front; the bafe F has alfo a crofs piece of three branches, rivetted to a hoop of iron, which is fixed to the inner furface of the cone; the centre of this crofs piece has alfo a fquare hole for the paffage of the axis.

Fig. 5. is a fpindle or axis itfelf; it is a fquare bar of iron about 16 inches long, and more than half an inch thick; round at the bottom, and alfo towards the top, where it fits into the crofs piece I, fig. 7. and B, fig. 1. and 4.; in thefe pieces it turns round, and by them it is kept in its place. It muft be fquare at its upper extremity, that it may have a handle, about nine inches long, fixed to it, by means of which the conical grater is turned round. At G. (fig. 5.), a fmall hole is made through the axis, to receive a pin H, by means of which the conical grater is kept at its proper height within the cylindrical one.

Fig. 6. is a bird's eye view, in which the mill is reprefented placed in an oval tub, like a bathing tub. I is the fore-mentioned triangular iron crofs, fixed with fcrews to the fide of the tub; the centre of it has a round hole, for the axis of the mill to move in when it is ufed.

Fig. 7. reprefents the mill in the oval tub; it is placed at one end of it, that the other end may be left free for any operation to be performed in it which may be neceffary. A part of the tub is cut off, that the infide of it, and the manner of fixing the mill, may be feen. That the bottom of the tub may not be worn by the fcrews which pafs through the feet of the mill, a deal board, about an inch thick, and properly fhaped, is placed under the mill.

When we wifh to make ufe of this mill, it is to be fixed by the feet, in the manner already defcribed; it is alfo fixed at the top, by means of the crofs piece I, fig. 6. and 7. The tub is then to have water poured into

into it as high as K, and the top of the mill is to be filled with potatoes, properly washed and cut; the handle L is to be turned round, and the potatoes, after being ground between the two graters, go out gradually at the lower part, being assisted by the motion produced in the water by the action of the mill.

It is not necessary, in the construction of such a mill, to be very particular with respect to its proportions; but, in order to make known those which experience has proved to be good ones, a scale is given with the figures, to which recourse may be had. With a mill of this size, 100 pounds of potatoes may be ground in the space of two hours.

We are persuaded that this mill will answer perfectly well for grinding horse-chesnuts; and we hope, that where they can be had they will be used in preference to potatoes. We shall, however, give M. Beaumé's method of extracting starch from the ground potatoes, not only because it will be acceptable to those who have not horse-chesnuts, but also because those who have may, by following it, be able, perhaps, to make starch of them, without encroaching upon Lord William Murray's patent.

In order to prepare starch from potatoes, says M. Beaumé, any quantity of these roots may be taken, and soaked in a tub of water for about an hour; they are afterwards to have their fibres and shoots taken off, and then to be rubbed with a pretty strong brush, that the earth, which is apt to lodge in the inequalities of their surface, may be entirely removed; as this is done, they are to be washed, and thrown into another tub full of clean water. When the quantity which we mean to make use of has been thus treated, those which are too large are to be cut into pieces about the size of eggs, and thrown into the mill; that being already fixed in the oval tub, with the proper quantity of water; the handle is then turned round, and as the potatoes are grated they pass out at the bottom of the mill The pulp which collects about the mill must be taken off from time to time with a wooden spoon, and put aside in water.

When all the potatoes are ground, the whole of the pulp is to be collected in a tub, and mixed up with a great quantity of clean water. At the same time, another tub, very clean, is to be prepared, on the brim of which are to be placed too wooden rails, to support a hair sieve, which must not be too fine. The pulp and water are to be thrown into the sieve; the flour passes through with the water, and fresh quantities of water are successively to be poured on the remaining pulp, till the water runs through as clear as it is poured in. In this way we are to proceed till all the potatoes that were ground are used.

The pulp is commonly thrown away as useless; but it should be boiled in water, and used as food for animals; for it is very nourishing, and is about $\frac{7}{8}$ths of the whole quantity of potatoes used.

To return from this short digression, The liquor which has passed through the sieve is turbid, and of a brownish colour, on account of the extractive matter which is dissolved in it; it deposits, in the space of five or six hours, the flour which was suspended in it. When all the flour is settled to the bottom, the liquor is to be poured off and thrown away, being useless; a great quantity of very clan water is then to be poured upon the flour remaining at the bottom of the tub, which is to be stirred up in the water, that it may be washed, and the whole is to stand quiet till the day following. The flour will then be found to have settled at the bottom of the tub; the water is again to be poured off as useless, the flour washed in a fresh quantity of pure water, and the mixture passed through a silk sieve pretty fine, which will retain any small quantity of pulp which may have passed through the hair sieve. The whole must once more be suffered to stand quiet till the flour is entirely settled; if the water above it is perfectly clear and colourless, the flour has been sufficiently washed; but if the water has any sensible appearance either of colour or of taste, the flour must be again washed, as it is absolutely necessary that none of the extractive matter be suffered to remain.

When the flour is sufficiently washed, it may be taken out of the tub with a wooden spoon; it is to be placed upon wicker frames covered with paper, and dried, properly defended from dust. When it is thoroughly dry, it is to be passed through a silk sieve, that if any clotted lumps should have been formed they may be divided. It is to be kept in glass vessels stopped with paper only. See *Vegetable* SUBSTANCES, Suppl.

N. B. Almost all the flour of potatoes that is to be bought contains a small quantity of sand, which is perceived between the teeth; it is owing to the potatoes not having been properly washed; for the sand which lodges in the knobs and wrinkles of these roots, is not always easy to get out.

STARLINGS, or STERLINGS, the name given to the strong pieces of timber which were driven into the bed of the river to protect the piles, on the top of which were laid the flat beams upon which were built the bases of the stone piers that support the arches of London bridge. In general, starlings are large piles placed on the outside of the foundation of the piers of bridges, to break the force of the water, and to protect the stone work from injury by floating ice. They are otherwise called JETTES, which see in this *Supplement*; and their place is often supplied by large stones thrown at random round the piers of bridges, as may be seen at Stirling bridge when the river is low; and as was done by Mr Smeaton's direction round the piers of the centre arch of London bridge, when it was thought in danger of being undermined by the current. See SMEATON, *Encycl.*

STATIONARY, in astronomy, the state of a planet when, to an observer on the earth, it appears for some time to stand still, or remain immoveable in the same place in the heavens. For as the planets, to such an observer, have sometimes a progressive motion, and sometimes a retrograde one, there must be some point between the two where they must appear stationary.

STEAM, STEAM-ENGINE. The few following corrections of these articles in the *Encycl.* were communicated by the author.

Page 745. col. 1.—It was not at the York Building waterworks in London that the boiler burst, but in the country in an engine erected by Dr Desaguilliers. See his *Experimental Philosophy*, Vol. II. p. 489.

Page 746. col 2.—The condensation requires more cold water than is here allowed, as will appear by and bye; and we also suspect that the rapidity is overrated with which a great volume of steam is condensed by the cold furface of a veffel. We are well informed that Mr Watt was much difappointed in his expectations from a conftruction in which this mode of condenfation was adopted. The condenfer employed by Mr Cartwright (fee *Phil. Mag.*) was one of the very firft thought of and tried for this purpofe, and was given up, as well as all others on the fame principle ; and the immediate contact of cold water was preferred as incomparably more effective. The great fuperiority of the capacity of water for heat is now well known. It is true, that when we employ an extenfive cold furface of the condenfer, this furface is kept cold by the water round it ; and therefore we ftill avail ourfelves of this great avidity of water for heat. But this water muft act through the intervention of the veffel ; and the fubftance of the veffel does not convey heat to the furrounding water in an inftant.

Page 749. col. 2.—No diftinct experiment fhews fo great an expanfion of water, when converted into fteam at the temperature 212° ; and under the preffure of the air Mr Watt never found it more than 1800 times rarer than water.

Page 753. col. 1.—The heat expended in boiling off a cubic foot of water is about fix times as much as would bring it to a boiling heat from the medium temperature (55°) in this climate.

Page 758. col. 2.—The quantity of water neceffary for injection may be determined on principle, at leaft for an engine having a feparate condenfer. Every cubic foot of common fteam produces about an inch of water when condenfed, and contains about as much latent heat as would raife 1100 inches of water one degree. This fteam muft not only be condenfed, but muft be cooled to the temperature of the hot well ; therefore as many inches of cold water muft be employed as will require all this heat to raife it to the temperature of the hot well. Therefore let x be the cubic feet of fteam, or capacity of the cylinder, and let y be the inches of cold water expended in condenfing it. Let a be the difference between 212° and the temperature of the hot well, and b the difference between the temperature of the well and the injection ciftern. We have $y\,b = x \times \overline{1100 + a}$, or $y = \dfrac{\overline{1100 + a} \times x}{b}$.

Thus, if the temperature of the hot well be 100° (and it fhould never be higher, if we would have a tolerable vacuum in the cylinder), and that of the injection ciftern be 50°, we have $a = 112$, and $b = 50$, and $y = \dfrac{1212}{50}\,x, = 24{,}24\,x$, or $24\frac{1}{4}\,x$; that is, every foot of the capacity of the cylinder, or every inch of water evaporated from the boiler, requires more than 24 inches of water to condenfe the fteam. A wine pint for every inch of water boiled off, or every cubic foot of capacity of the cylinder, may be kept in mind, as a large allowance. Or, more exactly, if the engine be in good order, and the injection water as low as 50°, and the hot well not above 100°, we may allow 25 gallons of injection for one gallon of water boiled off. This greatly exceeds the quantity mentioned in the cafe of a good Newcomen's engine, the cylinder of which contained almoft 30 cubic feet of fteam. And this circumftance fhews the fuperiority of the engine with a feparate condenfer. The injection of Newcomen's engine had been adjufted by experience, fo as to make the beft compenfation for the unavoidable wafte in the cylinder. We prefume that this machine was not loaded above eight pounds per inch, more likely with feven ; whereas Watt's engine, working in the condition now defcribed, bears a load not much below twelve, making at leaft twelve ftrokes per minute.

This is not a matter of mere curiofity ; it affords a very exact rule for judging of the good working order of the engine. We can meafure with accuracy the water admitted into the boiler during an hour, without allowing its furface to rife or fall, and the water employed for injection. If the laft be below the proportion now given (adapted to the temperatures 50° and 100°), we are certain that fteam is wafted by leaks, or by condenfation in fome improper place. The rule is not ftrictly conformable to the latent heat of fteam which balances the atmofphere, 1100° being fomewhat too great a value. It is accommodated to the actual performance of Watt's engines, when in their beft working condition.

It is evident that it is of great importance to have the temperature of the hot well as low as poffible ; becaufe there always remains a fteam in the cylinder, of the fame, or rather higher temperature, poffeffing an elafticity which balances part of the preffure on the other fide of the pifton, and thus diminifhes the power of the engine. This is clearly feen by the barometer, which Mr Watt applies to many of his beft engines, and is a moft ufeful addition for the proprietor. It fhews him, in every moment, the ftate of the vacuum, and the real power of his engine, and tells him when there are leaks by which air gets in.

Page 762 cols. 1. 2.—Mr Watt's firft experiment was not exactly as here related, but much more analogous to the prefent form of his engine. The condenfer was a cylinder of tinplate, fitted with a pifton, which was drawn up from the bottom to the top, before the eduction cock was opened. Without this previous rarefaction in the condenfer, there was no inducement for the fteam to take this courfe, unlefs it were made much ftronger than that of ordinary boiling water.

The defcription of the firft form of the engine is alfo faulty, by the omiffion of a valve immediately below the eduction pipe. This valve is fhut along with the valve I, to prevent the fteam, which fhould then go into the lower part of the cylinder, from alfo going down into the condenfer. This is not abfolutely neceffary, but its advantage is evident.

Page 766. col. 1.—This form of the engine was very early put in practice by Mr Watt—about the year 1775. The fmall engine at Mr Boulton's works at Soho was erected in 1776 ; and the engine at Shadwell waterworks, one of the beft yet erected, had been working fome time when we faw it in 1778. We mention this, becaufe we have been told that Mr Hornblower puts in fome claim to priority in this invention. We do not think that Mr Hornblower erected any of his engines before 1782 ; and as Mr Hornblower was, we believe, working with Boulton and Watt before that time, we think it fully more probable that he has in this refpect profited by the inftruction of fuch intelligent employers. We may alfo obferve, that Mr Watt employed the fame contrivance which we have defcribed with much approbation in p. 772. *Encycl.* for keeping the

the collar round the piston rods steam and air tight. He found them effectual, but that they required more attention for keeping them in fit condition than the usual mode of packing. He made a similar packing for the piston, and with a similar result.

Page 769. cols. 1. 2.—Mr Boulton estimates the performance of the engines in the following manner. Seeing that the great expence of the engine is the consumption of fuel, he makes this the standard of computation, and estimates the performanee by the work which he *engages* to perform by the consumption of one bushel of good Newcastle coal, London measure, or containing 84 lbs. without regard to the time in which this bushel is expended. This depends on the size of the engine.

The burning one bushel of coal will,

1. Raise 30 million pounds one foot high.
2. It will grind and dress 11 bushels of wheat.
3. It will slit and draw into nail rods 5 cwt. of iron.
4. It will drive 1000 cotton spindles, with all the preparation machinery, with the proper velocity.
5. It is equivalent to the work of ten horses.

The general performance of the double stroke expansive engines is somewhat beyond this; and their performance in cotton spinning, or as compared with horse work, is much under-rated. The first estimation is without ambiguity. Suppose the engine of such a size as to consume a bushel of coals per hour. This will be found equivalent to raising 97 wine hogsheads of water ten feet high in a minute, which ten stout draught horses cannot do for a quarter of an hour together. They can raise 60 in that time, and work at this rate eight or perhaps ten hours from day to day.

Mr Watt finds that, with the most judiciously constructed furnaces, it requires eight feet of surface of the boiler to be exposed to the action of fire and flame to boil off a cubic foot of water in an hour, and that a bushel of coals so applied will boil off from eight to twelve cubic feet.

Boulton and Watt now make steam-engines equivalent in power to one or two horses. The cylinder and whole machinery does not occupy more room than a fine lady's working table, standing in a square of about $2\frac{1}{2}$ feet, and about 5 feet high.

STEEL (see that article *Encycl.* and CHEMISTRY, n° 114. *Suppl.*) is composed of iron and carbon. In addition to the old proofs which we had of this fact, it occurred to *Morveau*, alias *Guyton*, to attempt to convert soft iron into steel, by using the diamond instead of charcoal in the process of cementation. This expensive experiment, which was suggested by M. Clouet, was made, by inclosing within a small crucible of very soft iron a diamond, and shutting up the crucible by a stopper well adjusted. This crucible of iron, with its contents, was placed, without the addition of any surrounding matter, in a very small Hessian crucible, and the latter in a second crucible of the same earth; but the space between the two latter crucibles was filled with siliceous sand, free from all ferruginous particles. In the last place, the large crucible was luted with earth arising from pounded crucibles and unbaked clay, and the whole was exposed about an hour to a three blast forge fire. When the whole was cooled, the iron was found in the interior Hessian crucible converted into a solid ingot of cast steel. Thus the diamond disappeared by the affinity which iron exercised on it by the help of the high temperature to which they were both exposed, in the same manner as a metal disappears in the alloy of another metal. The diamond therefore furnished here the same principle as carbon, since the product of the union has the same properties.

The conversion into steel could not be doubted. The ingot having been polished on a lapidary's wheel, a drop of weak nitrous acid immediately produced a dark-grey spot, absolutely like that exhibited on English cast steel, and on cast steel produced by the process of M. Clouet. Those who have often tried steel by this kind of proof, long ago pointed out by Rinmann, had occasion to remark, that the spot of cast steel, tho' very sensible, is, however, less black than that of steel made by cementation, which depends perhaps on the different degree of oxydation of the carbon which they have taken in.

The process of M. Clouet here mentioned, for producing cast steel, consists in nothing more than throwing a quantity of glass into the mass of iron and charcoal during the formation of the former into steel. The same chemist has ascertained that iron, during its conversion into steel, absorbs 0.2013 of its weight of carbon; and that the affinity of iron for carbon is so strong, that, at a white heat, it is capable of decomposing carbonic acid gas. This he proved by the following experiment.

If six parts of iron be mixed with four parts of a mixture composed of equal quantities of carbonat of lime and clay, and kept in a crucible at a white heat for an hour or longer, according to the quantity, the iron will be converted into steel. The decomposition of carbonic acid is evidently the consequence of a compound affinity; part of the iron combining with the carbon, and another part with the oxygen of the carbonic acid gas. Accordingly the commissioners, who were appointed to examine the process, remark, that a quantity of oxide of iron was always mixed with the melted earthy substance, which was separated from the steel.

STEEVENS (George), the most successful of all the editors and commentators of Shakespeare, was born 1735. Of his parents we know nothing, but that they seem to have been in circumstances which may be deemed affluent. George received the rudiments of his classical education at Kingston-upon-Thames, under the tuition of Dr Woodeson and his assistants; and had for a companion at that school Gibbon the historian. From Kingston he went to Eton, whence, after some years, he was admitted a fellow-commoner of King's College, Cambridge; but with the course of his studies in the university we are not acquainted. If we might hazard a conjecture, from the manner in which he employed his riper years, we should suppose that he had little relish for those mathematical speculations which in Cambridge lead to academical honours. After he left the university, he accepted a commission in the Essex militia on its first establishment; and he spent the latter years of his life at Hampstead in almost total seclusion from the world; seldom mixing with society but in the shops of booksellers, in the Shakespeare Gallery, or in the morning *conversations* of Sir Joseph Banks. He died January 1800.

This

Steevens.

This is a very meagre account of the incidents which muſt have taken place in the life of a man ſo conſpicuous in the republic of letters; but we have had no opportunity of improving it. His character, as drawn in the Monthly Magazine, believing it to be juſt, we ſhall adopt, as it will ſupply in ſome degree the defects of our narrative.

Though Mr Steevens is known rather as a commentator than as an original writer; yet, when the works which he illuſtrated, the learning, ſagacity, taſte, and general knowledge which he brought to the taſk, and the ſucceſs which crowned his labours, are conſidered, it would be an act of injuſtice to refuſe him a place among the firſt literary characters of the age. Adorned by a verſatility of talents, he was indeed eminent both by his pen and his pencil. With the one there was nothing which he could not compoſe, and with the other there was nothing which he could not imitate ſo cloſely, as to leave a doubt which was the original and which the copy. But his chief excellence lay in his critical knowledge of an author's text; and the beſt ſpecimen of his great abilities is his edition of Shakeſpeare, in which he has left every competitor far behind him. He had, in ſhort, ſtudied the age of Shakeſpeare, and had employed his perſevering induſtry in becoming acquainted with the writings, manners, and laws of that period, as well as the provincial peculiarities, whether of language or cuſtom, which prevailed in different parts of the kingdom, but more particularly in thoſe where Shakeſpeare paſſed the early years of his life. This ſtore of knowledge he was continually increaſing, by the acquiſition of the rare and obſolete publications of a former age, which he ſpared no expence to obtain; while his critical ſagacity and acute obſervation were employed inceſſantly in calling forth the hidden meanings of the great dramatic bard, from their covert, and conſequently enlarging the diſplay of his beauties. This advantage is evident from his laſt edition of Shakeſpeare, which contains ſo large a portion of new, intereſting, and accumulated illuſtration. In the preparation of it for the preſs, he gave an inſtance of editorial activity and perſeverance which is without example. To this work he devoted ſolely, and excluſively of all other attentions, a period of 18 months; and during that time he left his houſe every morning at one o'clock with the Hampſtead patrole, and proceeded, without any conſideration of the weather or the ſeaſon, to his friend Mr Iſaac Read's chambers, in Barnard's Inn, where he was allowed to admit himſelf, and found a room prepared to receive him, with a ſheet of the Shakeſpeare letter preſs ready for correction. There was every book which he might wiſh to conſult; and to Mr Read he could apply, on any doubt or ſudden ſuggeſtion, as to a man whoſe knowledge of Engliſh literature was perhaps equal to his own. This nocturnal toil greatly accelerated the printing of the work; as while the printers ſlept the editor was awake; and thus, in leſs than twenty months, he completed his laſt ſplendid edition of Shakeſpeare, in fifteen large octavo volumes; an almoſt incredible labour, which proved the aſtoniſhing energy and perſevering powers of his mind.

That Mr Steevens contented himſelf with being a commentator, aroſe probably from the habits of his life, and his devotion to the name, with which his own will deſcend to the lateſt poſterity. It is probable that many of his *jeux d'eſprit* might be collected: there is a poem of his in Dodſley's Annual Regiſter, under the title of *The Frantic Lover*, which is ſuperior to any ſimilar production in the Engliſh language. Mr Steevens was a claſſical ſcholar of the firſt order. He was equally acquainted with the belles lettres of Europe. He had ſtudied hiſtory, ancient and modern, but particularly that of his own country. He poſſeſſed a ſtrong original genius, and an abundant wit; his imagination was of every colour, and his ſentiments were enlivened with the moſt brilliant expreſſions. His colloquial powers ſurpaſſed thoſe of other men. In argument he was uncommonly eloquent: and his eloquence was equally logical and animated. His deſcriptions were ſo true to nature, his figures were ſo finely ſketched, of ſuch curious ſelection, and ſo happily grouped, that he might be conſidered as a ſpeaking Hogarth. He would frequently, in his ſportive and almoſt boyiſh humours, condeſcend to a degree of ribaldry but little above O'Keefe—with him, however, it loſt all its coarſeneſs, and aſſumed the air of claſſical vivacity. He was indeed too apt to catch the ridiculous, both in characters and things, and indulge an indiſcreet animation wherever he found it. He ſcattered his wit and his humour, his gibes and his jeers, too freely around him, and they were not loſt for want of gathering.

Mr Steevens poſſeſſed a very handſome fortune, which he managed with diſcretion, and was enabled by it to gratify his wiſhes, which he did without any regard to expence, in forming his diſtinguiſhed collections of claſſical learning, literary antiquity, and the arts connected with it. His generoſity alſo was equal to his fortune; and though he was not ſeen to give eleemoſynary ſixpences to ſturdy beggars or ſweepers of the croſſings, few perſons diſtributed bank-notes with more liberality; and ſome of his acts of pecuniary kindneſs might be named, which could only proceed from a mind adorned with the nobleſt ſentiments of humanity. He poſſeſſed all the grace of exterior accompliſhment, acquired at a period when civility and politeneſs were characteriſtics of a gentleman.

He has bequeathed his valuable Shakeſpeare, illuſtrated with near 1500 prints, to Lord Spencer; his Hogarth perfect, with the exception of one or two pieces, to Mr Windham; and his corrected copy of Shakeſpeare, with 200 guineas, to his friend Mr Read.

Steevens, Stereometer.

STEREOMETER, an inſtrument lately invented in France for meaſuring the volume of a body, however irregular, without plunging it in any liquid. If the capacity of a veſſel, or, which is the ſame thing, the volume of air contained in that veſſel, be meaſured, when the veſſel contains air only, and alſo when the veſſel contains a body whoſe volume is required to be known, the volume of air aſcertained by the firſt meaſurement, deducting the volume aſcertained by the ſecond, will be the volume of the body itſelf. Again, if it be admitted as a law, that the volume of any maſs of air be inverſely as the preſſure to which it is ſubjected, the temperature being ſuppoſed conſtant, it will be eaſy to deduce, from the mathematical relations of quantity, the whole bulk, provided the difference between the two bulks under two known preſſures be obtained by experiment.

Let it be ſuppoſed, for example, that the firſt preſſure is double the ſecond, or, which follows as a conſequence,

quence, that the ſecond volume of the air be double the firſt, and that the difference be fifty cubic inches, it is evident that the firſt volume of the air will likewiſe be fifty cubic inches. The ſtereometer is intended to aſcertain this difference at two known preſſuers.

Plate XLIII.

The inſtrument is a kind of funnel AB (fig. 1.), compoſed of a capſule A, in which the body is placed, and a tub B as uniform in the bore as can be procured. The upper edge of the capſule is ground with emery, in order that it may be hermetically cloſed with a glaſs cover M ſlightly greaſed. A double ſcale is paſted on the tube, having two ſets of graduations; one to indicate the length, and the other the capacities, as determined by experiment.

When this inſtrument is uſed, it muſt be plunged in a veſſel of mercury with the tube very upright, until the mercury riſes within and without to a point C of the ſcale. See fig. 2.

The capſule is then cloſed with the cover, which being greaſed will prevent all communication between the external air and that contained within the capſule and tube.

In this ſituation of the inſtrument, in which the mercury ſtands at the ſame height within and without the tube, the internal air is compreſſed by the weight of the atmoſphere, which is known and expreſſed by the length of the mercury in the tube of the common barometer.

The inſtrument is then to be elevated, taking care to keep the tube conſtantly in the vertical poſition. It is repreſented in this ſituation, fig. 2. ſecond poſition. The mercury deſcends in the tube, but not to the level of the external ſurface, and a column DE of mercury remains ſuſpended in the tube, the height of which is known by the ſcale. The interior air is therefore leſs compreſſed than before, the increaſe of its volume being equal to the whole capacity of the tube from C to D, which is indicated by the ſecond ſcale.

It is known therefore that the preſſures are in proportion to the barometrical column, and to the ſame column diminiſhed by the ſubtraction of DE. And the bulks of the air in theſe two ſtates are inverſely in the ſame proportion; and again the difference between theſe bulks is the abſolute quantity left void in the tube by the fall of the mercury; from which data, by an eaſy analytical proceſs, the following rule is deduced: Multiply the number which expreſſes the leſs preſſure by that which denotes the augmentation of capacity, and divide the product by the number which denotes the difference of the preſſures. The quotient will be the bulk of the air when ſubject to the greater preſſure.

To render this more eaſy by an example, ſuppoſe the height of the mercury in the barometer to be 78 centimetres, and the inſtrument being empty to be plunged in the mercury to the point C. It is then covered, and raiſed until the ſmall colum of mercury DE is ſuſpended, for example, at the height of ſix centimetres. The internal air, which was the firſt compreſſed by a force repreſented hy 78 centimetres, is now compreſſed only by a force repreſented by 78 − 6, or 72 centimetres.

Suppoſe it to be obſerved, at the ſame time, by means of the graduations of the ſecond ſcale, that the capacity of the part CD of the tube which the mercury has quitted is two cubic centimetres. Then by the rule $\frac{72}{6} \times 2$ give 24 cubical centimetres, which is the volume of the air included in the inſtrument when the mercury roſe as high as C in the tube.

The body of which the volume is to be aſcertained muſt then be placed in the capſule, and the operation repeated. Suppoſe, in this caſe, the column of mercury ſuſpended to be eight centimetres, when the capacity of the part CD of the tube is equal to two centimetres cube. Then the greateſt preſſure being denoted by 78 centimetres, as before, the leaſt will be 70 centimetres, the difference of the preſſures being 8, and the difference of the volumes two cubical centimetres. Hence $\frac{70}{8} \times 2$ gives the bulk of the included air under the greateſt preſſure 17,5 cubic centimetres. If therefore 17,5 centimetres be taken from 24 centimetres, or the capacity of the inſtrument when empty, the difference 6,5 cubic centimetres will expreſs the volume of the body which was introduced. And if the abſolute weight of the body be multiplied by its bulk in centimetres, and divided by the abſolute weight of one cubic centimetre of diſtilled water, the quotient will expreſs the ſpecific gravity of the body in the common form of the tables where diſtilled water is taken as unity, or the term of compariſon.

After this deſcription and explanation of the uſe of his inſtrument, the author proceeds with the candour and acuteneſs of a philoſopher to aſcertain the limits of error in the reſults; an object ſeldom ſufficiently attended to in the inveſtigation of natural phenomena. From his reſults it appears, that with the dimenſions he has aſſumed, and the method preſcribed for operating, the errors may affect the ſecond figure. He likewiſe gives the formulæ by means of which the inſtrument itſelf may be made to ſupply the want of a barometer in aſcertaining the greateſt preſſure. He likewiſe adverts to the errors which may be produced by change of temperature. To prevent theſe as much as poſſible, the actual form of the inſtrument and arrangements of its auxiliary parts are ſettled, as in fig. 3. by which means the approach of the hand near the veſſel and its tube is avoided. In this figure the vertical poſition of the tube is ſecured by the ſuſpenſion of the veſſel, and a perforation in the table through which the tube paſſes. The table itſelf ſupports the capſule in its firſt poſition, namely, that at which the cover is required to be put on.

Mr Nicholſon, from whoſe Journal this abſtract is immediately taken, ſuppoſes, with great probability, that the author of the invention had not finiſhed his meditations on the ſubject, when the memoir giving an account of it was publiſhed. If he had, ſays the ingenious journaliſt, it is likely that he would have determined his preſſures, as well as the meaſures of bulks by weight. For it may be eaſily underſtood, that if the whole inſtrument were ſet to its poſitions by ſuſpending it to one arm of a balance at H (fig. 3.), the quantity of counterpoiſe, when in equilibrio, might be applied to determine the preſſures to a degree of accuracy much greater than can be obtained by linear meaſurement.

STEWART-Denham (Sir James) was born at Edinburgh on the 10th of October, O. S. in the year 1713. His father was Sir James Stewart of Goodtrees, Bart. Solicitor-general for Scotland; and his mother

ther was Anne, daughter of Sir Hugh Dalrymple of North Berwick, Bart. prefident of the college of juftice.

The firft rudiments of his education he received at the grammer-fchool of North-Berwick, which at the time of his father's death he quitted at the age of fourteen, with the reputation of being a good fcholar, but without any extraordinary advancement in knowledge.

It is remarkable, that many men who have been fingularly ufeful to fociety have not fhewn early fymptoms of the greatnefs of their intellectual powers. A great underftanding muft be the offspring of happy organization in a healthy body, with co-operation of time, of circumftance, and of inftitution, without being forced into prematurity by exceffive cultivation. This holds with refpect to the growth and perfection of every creature; and the truth appears remarkable with refpect to our own fpecies, becaufe we are apt to miftake the flimfy attainments of artificial education for the fteady and permanent foundations of progreffive knowledge.

From the fchool of North-Berwick Sir James was fent to the univerfity of Edinburgh, where he continued until the year 1735, when he paffed advocate before the court of Seffion, and immediately afterwards went abroad to vifit foreign countries. He was then in the 23d year of his age, had made himfelf well acquainted with the Roman law and hiftory, and the municipal law of Scotland. He had likewife maturely ftudied the elements of jurifprudence; was verfed in the general, as well as the particular, politics of Europe; and was bent upon applying his knowledge to the inveftigation of the ftate of men and of manners in other nations, with a view to promote the benefit of his own, and to confirm himfelf in the love of a free conftitution of government, by contemplating the baneful effects of unlimited monarchy in Germany, Italy, and Spain, and of extravagant attachment to a king and nobility, to war, and to pernicious fplendour in France.

He travelled firft, however, into Holland, with a view to ftudy the conftitution of the empire before he fhould vifit Germany, and to attend fome of the lectures of the moft eminent profeffors at Utrecht and Leyden, on public law and politics. From thence he paffed into Germany, refided about a year in France, travelled thro' fome part of Spain, where he had a fever, that obliged him, for his perfect recovery from its effects, to go by the advice of his friends to the fea-coaft of the lovely province of Valentia; thence returning, he croffed the Alps, and by Turin made the tour of Italy, where chiefly at Rome and Florence he refided till the beginning of the year 1740; when, having fpent five years on his travels, he returned to Scotland, and married the Lady Frances Wemyfs, eldeft daughter of the Earl of Wemyfs, about two years after his return.

A few months after his marriage the reprefentation of the county of Mid-Lothian became vacant, by the member being made a Lord of trade and plantation. The candidates were the late member and Sir John Baird of Newbyth. On the day of election Mr Dundas of Arnifton, one of the fenators of the college of juftice, was chofen prefes of the meeting; and fome how or other omitted to caufe the name of Sir James Stewart to be called on the roll of freeholders. For this illegal ufe of his temporary power, Sir James commenced a fuit againft the prefident; and refuming the gown as an advocate, pleaded his own caufe with great energy and eloquence, and with the applaufe of the bench, the bar, and the public. This called Lord Arnifton from the bench to plead in his own defence at the bar; and Sir James could not have been oppofed to an antagonift better qualified to call forth all his powers; for that judge is talked of at this day in Edinburgh as the profoundeft lawyer and the ableft pleader that ever graced the Scottifh bench or the Scottifh bar.

With the iffue of this conteft we are not acquainted; but it drew upon Sir James Stewart very general attention, and convinced the public, that had he continued at the bar, he muft have rifen rapidly to the head of his profeffion. On his travels, however, he had contracted friendfhips with Lord Marifchal, and other eminent men, attached to the pretenfions of the royal family of Stuart, and had received flattering attentions from the Pretender to the Britifh throne; the impreffion arifing from which, added to the irritations of his controverfy with the powerful party in Scotland attached to the court, led him, unadvifedly, into connections with the movers of the rebellion in 1745.

As he was by far the ableft man of their party, the Jacobites engaged him to write the Prince Regent's manifefto, and to affift in his councils. Information having been given of his participation in thefe affairs, he thought it prudent, on the abortion of this unhappy attempt, to leave Britain; and by the zeal, it is faid, of Arnifton, he was excepted afterwards from the bill of indemnity, and rendered an exile from his country.

He chofe France for his refidence during the ten firft years of his banifhment, and was chiefly at Angoulefme, where he fuperintended the education of his fon; from thence he went to Tubingen in Swabia, for the benefit of its univerfity, in profecution of the fame dutiful and laudable defign; but in the end of the war 1756, having been fufpected by the court of Verfailles of communicating intelligence to the court of London, he was feized at Spa, and kept fome time in confinement; from which being liberated, after the acceffion of the prefent king of Great Britain, he came, by toleration, to England, and refided at London, where he put the laft hand to his Syftem of Political Economy, the copy-right of which he fold to Andrew Millar; and being permitted to dedicate this work to the king, he applied for a *noli profequi*, which, after fome malicious objections, he obtained, and had the comfort of returning to his family eftate in Scotland.

Having nothing profeffional to do during his long refidence in France, the active mind of Sir James was occupied in ftudy. His book on the Principles of Political Economy contains moft of the fruits of it. He turned himfelf, in the intervals of leifure, to confider the refources of France, that he might the better compile that part of his great work which was to treat of revenue and expenditure. It was by ftudying the language of the finances, without which nobody can afk a proper queftion concerning them, fo as to be underftood, that he attained his great purpofe.

As foon as he could afk queftions properly, he applied in familiar converfation to the intendants and their fubftitutes in the provinces where he refided, whom he found extremely defirous to learn the ftate of the Britifh finances, under the branches of the land-tax, cuftoms, excife, and other inland duties. This led him to

compare

Stewart-Denham.

compare the ftate of the two nations. The information he gave was an equivalent for the information he received; curiofity balanced curiofity, each was fatisfied and inftructed. The department of the intendants in France was confined to the taxes which compofed the *recettes generales*, namely, the *taille*, the *capitation*, and the *twentieths*, or *vigntiemes*. All the intendants had been *Maitres des Requetes*, bred at Paris, and could not fail to have much knowledge of the general *fermes* and other branches of the revenue. He carefully noted down at all times the anfwers he got; and when he came to refide at Paris, he obtained more ample information, both from the gentlemen of the revenue, and from perfons of the parliament of Paris, who to the number of 25 had been for 15 months exiled in the province where he had fo long refided at Angoulefme.

With thefe advantages, with much ftudy and attention to arrangement, he was enabled to compofe the fixth chapter of the fourth part of the fourth book of his Syftem of Political Economy; a portion of that great work well worthy the attention of thofe who wifh to know the ftate of France in refpect of revenue under the old government.

Although Sir James Stewart's leifure, during the firft ten years of his exile, was chiefly employed in focial intercourfe with the moft learned, elegant, and polifhed characters in France, who delighted in the converfation and friendfhip of a man who poffeffed at once immenfe information, on almoft every fubject, important or agreeable to fociety, and the talent of clearly and beautifully expreffing his fentiments in flowing and animated converfation; yet he did not allow the pleafures of the circle and of the table to blunt the fine feelings of a man of genius and fcience. The labour of collecting materials for his great political work was oppreffive, and he relieved himfelf with various enquiries, fuited to the exalted ambition of his cultivated underftanding, while he turned the charms of converfation to the permanent delight of his affociates and of pofterity. The motto of Apelles, "*Nulla dies fine linea*," was the emblem of his employment; and it is amazing what may be done by daily attention for improvement, without appearing to abftract any extraordinary time from the common offices and rational pleafures of fociety.

In the beginning of the year 1755, Sir James wrote his Apology, or Defence of Sir Ifaac Newton's Chronology, which at that time he intended to publifh, but was prevented by other engagements. It was communicated to feveral perfons of eminence in France and Germany in MS. and produced, in the month of December that year in the "*Mercure de France*," an anfwer from M. Defhoulieres, to which Sir James foon after replied.

The great Newton, applying aftronomical and ftatiftical principles to the ancient chronology of Greece, had chaftifed the vanity of nations, and arrefted the progrefs of infidelity in delineating the hiftory of the world. Loft in the confufion of exceffive pretenfions to an antiquity beyond all meafure, and difgufted by the fuperftitious aids that were affumed to fupport thefe pretenfions among ancient nations, the revivers of learning in Europe, during the laft and the preceding century, turmoiled themfelves with controverfies between the comparative merits of the ancients and moderns; and the abettors of the latter, entrenching themfelves behind the falfehoods of the ancients, on the fcope of their remote hiftory, gave the lie to all antiquity, and in defpair plunged themfelves into the ocean of fcepticifm.

Happy had it been for fociety if this fcepticifm had confined itfelf to the hiftory of ancient nations in general; but the fame fpirit, taking difguft at the horrors of Chriftian ambition and bigotry, and contemplating with derifion the ridiculous legends of modern miracles, gave the lie to all religious fcripture of the Jews and Chriftians, and attempted to banifh divine intelligence, the fuperintending providence of Deity, and the true dignity of the human fpecies, from the face of the earth!

It was a noble undertaking, therefore, in Sir James, to attempt to difperfe this mift of error, by difpaffionately and fcientifically explaining and fupporting the chronology of Sir Ifaac Newton. He has done it with great precifion and effect; and it is a book well worth the perufal of thofe who wifh to read ancient hiftory with improvement, or to prevent themfelves from being bewildered in the mazes of modern conjecture. It was printed in 4to at Franckfort on the Maine, for John Bernard Eichemberg the Elder, in 1757.

In the year 1758, and the following, the Britifh Houfe of Commons took up the confideration of a ftatute to regulate a general uniformity of weights and meafures throughout the united kingdoms, which had been fo often unfuccefsfully attempted.

This called the attention of Sir James, not only to the inveftigation of the particular fubject that engaged that of the Houfe of Commons, but to devife a method of rendering an uniformity of weights and meafures univerfal. He thought the caufe of former difappointments in this ufeful purfuit had been the miftaken notion that one or other of our prefent meafures fhould be adopted for the new ftandard. After the plan had been relinquifhed by the parliament of England, he digefted his notes and obfervations on this important difquifition into the form of an epiftolary differtation, which he tranfmitted to his friend Lord Barrington, and refolved, if there had been a congrefs affembled, as was once propofed, to adjuft the preliminaries of the general peace in 1763, to have laid his plan before the minifters of the different nations, who were to prepare that falutary pacification of the contending powers.

This epiftolary differtation Sir James afterwards reduced at Coltnefs, in the year 1777, into a form more proper for the public eye, and fent a corrected copy to a friend, referving another for the prefs, which was printed 1790 for Stockdale in Piccadilly.

In this tract the author fhews, from the ineffectual attempts that have been made to alter partially, by innovation, the ftandards of meafures or weights, that the effectual plan to be adopted, is to depart entirely from every meafure whatfoever now known, and to take, *ad libitum*, fome new mafs inftead of our pound, fome new length inftead of our ell, fome new fpace inftead of our acre, and fome new folid inftead of our gallon and bufhel.

For this purpofe Sir James propofes as the unit a mafs to be verified with the greateft poffible accuracy, equal in weight to ten thoufand Troy grains. The pendulum, as it fwings at London, to beat feconds of time,

time, he propofes to be the meafure of length; and after having laid down his fundamental principles, he propofes an ingenious plan for rendering their adoption univerfal through the whole world.

Having obtained his pardon, Sir James Stewart retired to Coltnefs, in the county of Lanark, the paternal eftate of his family, where he turned his attention to the improvement of his neighbourhood by public works and police, and drew the firft good plan for a turnpike bill, fuited to the circumftances of Scotland, which has been fince generally adopted. He repaired his houfe, planted, improved, and decorated his eftate, and in focial intercourfe rendered himfelf the delight of his neighbourhood and country.

Never was there a man who, with fo much knowledge, and fo much energy of expreffion in converfation, rendered himfelf more delightful to his company, or was more regretted by his acquaintance when he died. Nor was the active mind of Sir James unemployed for the general benefit of his country during his retreat. He was engaged by the directors of the Eaft India Company of England to digeft a cod for the regulation of the current coin of Bengal; the plan for which important regulation he printed, and received from the court of directors a handfome diamond ring, as a mark of their approbation.

He prepared for the prefs, but never publifhed, an antidote to the *Syfteme de law Nature* by Mirabeau, wherein the parallelogifms and foolifh reafoning of that infidel work are examined, detected, and confuted. It is written in French; and were the work of Mirabeau worth refutation, might be printed with much advantage to Sir James's reputation as a controverfial writer.

This great and good man died in November 1780, and was buried at Cambufnethan, in Lanarkfhire, on the 28th of the fame month; the Duke of Hamilton and his neighbours performing the laft offices to the remains of their highly valued friend, and bedewing his afhes with their tears.

For this fhort fketch of the principle events in the life of Sir James Stewart-Denham, we are indebted to his nephew the Earl of Buchan, who, juftly proud of his relation to fuch a man, cannot be fuppofed to view all his projects, or even all his reafonings, with the cool impartiality of ftrangers. His plan, for inftance, of a univerfal ftandard of weights and meafures for the *whole world*, though certainly a grand conception, we cannot help confidering as romantic and impracticable. The author indeed was fenfible, that time would be requifite for its execution; and fo large a portion of time, that, compared with it, a thoufand years are but as one day, when compared with the ordinary life of man: but fchemes of this magnitude are not for creatures fo blind and weak as we are, who, when we wander to a diftance beyond the limits of our narrow fphere, with the ambitious view of benefiting pofterity, are almoft certain to injure ourfelves, without a probability of ferving thofe for whom we dream that we are exerting our abilities. Sir James's Political Economy, however, is a very great work, which has not received half the praifes to which it is entitled, and which, we fufpect, provoked the envy of another great writer on fimilar fubjects, who exerted himfelf privately to leffen its fame. The defence of Newton's chronology is likewife very valuable, though we certainly do not think that part of the fyftem invulnerable, in which the great aftronomer attempts to prove, that *Ofiris*, *Sefoftris*, and *Sefac*, are three names of the fame Egyptain king. This, however, is a very trifling miftake; and the modern fciolift, who can lay hold of it to reject the whole, has certainly never read, or, if he has read, does not underftand the defence of the fyftem by Sir James Stewart.

SUBCONTRARY POSITION, in geometry, is when two equiangular triangles are fo placed, as to have one common angle at the vertex, and yet their bafes not parallel; confequently the angles at the bafes are equal, but on the contrary fides.

SUBDUCTION, in arithmetic, the fame as *Subtraction*.

ANIMAL AND VEGETABLE SUBSTANCES.

THE reader will recollect, that the article CHEMISTRY, in this *Supplement*, was divided into four parts; of which only the firft three, comprehending the elements of the fcience, were given under the word CHEMISTRY. The *fourth part*, which was entitled an examination of bodies as they are prefented to us by nature in the mineral, vegetable, and animal kingdoms, naturally fubdivides itfelf into three parts, comprehending refpectively, 1. Minerals; 2. Vegetables; 3. Animals.

1 Nature of the article.

The firft of thefe fubdivifions, which has been deftinguifhed by the name of MINERALOGY, we have treated of already in a former part of this volume. As the other two fubdivifions have not hitherto received any appropriate name, we have fatisfied ourfelves with the word SUBSTANCE, by which chemifts have agreed to denote the objects which belong to thefe dubdivifions. This name, it muft be acknowledged, is not unexceptionable; but we did not confider ourfelves as at liberty to invent a new one.

2 Divifion of it.

The prefent article, then, feems to divide itfelf into two parts: the firft part comprehending *vegetable*; the fecond *animal* fubftances. But there are certain animal and vegetable fubftances diftinguifhed from all others by being ufed as articles of clothing. It is ufual to tinge thefe of various colours, by combining with them different colouring matters for which they have an affinity. This procefs, well known by the name of DYEING, is purely chemical; and as it belongs exclufively to animal and vegetable fubftances, it comes naturally to be examined here. We fhall therefore add a *third part*, in which we fhall give a view of the prefent ftate of DYEING, as far, at leaft, as is confiftent with the nature of a fupplementary article.

PART

PART I. OF VEGETABLE SUBSTANCES.

Sugar.

VEGETABLES, or plants, as they are alfo called, are too well known to require any definition. Their number is prodigious, and their variety, regularity, and beauty, are wonderful. But it is not our intention in this place either to enumerate, to defcribe, or to claffify plants. Thefe tafks belong to the botanift, and have been fuccefsfully accomplifhed by the zeal, the fingular addrefs, and the indefatigable labour of Linnæus and his followers.

3 Chemical examination of vegetables. It is the bufinefs of the chemift to analyfe vegetables, to difcover the fubftances of which they are compofed, to examine the nature of thefe fubftances, to inveftigate the manner in which they are combined, to detect the proceffes by which they are formed, and to afcertain the chemical changes to which plants, after they have ceafed to vegetate, are fubject. Hence it is evident, that a chemical inveftigation of plants comprehends three particulars:

1. An account of the *fubftances* of which plants are compofed.

2. An account of the *vegetation* of plants, as far as it can be illuftrated by chemiftry.

3. An account of the *changes* which plants undergo after they ceafe to vegetate.

We therefore divide this part into three chapters, affigning a chapter to each of thefe particulars.

CHAP. I. OF THE INGREDIENTS OF PLANTS.

THE fubftances hitherto found in the vegetable kingdom, all of them at leaft which have been examined with any degree of accuracy, may be reduced to the following heads:

1. Sugar,	10. Camphor,
2. Starch,	11. Refins,
3. Gluten,	12. Caoutchouc,
4. Albumen,	13. Wax,
5. Gum,	14. Wood,
6. Jelly,	15. Acids,
7. Extract,	16. Alkalies,
8. Tan,	17. Earths,
9. Oils,	18. Metals.

Thefe fhall form the fubject of the following fections:

SECT. I. *Of SUGAR.*

SUGAR, which at prefent forms fo important an article in our food, feems to have been known at a very early period to the inhabitants of India and China.

4 Difcovery of fugar. But Europe probably owes it acquaintance with it to the conquefts of Alexander the Great. For ages after its introduction into the weft, it was ufed only as a medicine; but its confumption gradually increafed, and during the time of the Crufades the Venetians, who brought it from the eaft, and diftributed it to the northern parts of Europe, carried on a lucrative commerce with fugar. It was not till after the difcovery of America, and the extenfive cultivation of fugar in the Weft Indies, that its ufe in Europe, as an article of food, became general *.

* See *Falconer's Hiftory of Sugar. Manchefter Memoirs*, iv. 291. and *Mozeley's Hiftory of Sugar.*

Sugar is obtained from the *arundo faccharifera*, or *fugar cane*. The juice of this plant is preffed out and boiled in as low a temperature as poffible, till the fugar precipitates in the form of confufed cryftals. Thefe

5 How obtained. cryftals, known by the name of *raw fugar*, are again diffolved in water, the folution is clarified, and purer cryftals are obtained by a fubfequent evaporation. But for the particulars of the art of manufacturing fugar, we refer the reader to the article SUGAR in the *Encyclopædia*.

6 Its properties. Sugar, after it has been purified, or *refined* as the manufacturers term it, is ufually fold in Europe in the form of a white opake mafs, well known by the name of *loaf fugar*. Sometimes alfo it is cryftallized, and then it is called *fugar candy*.

Sugar has a very ftrong fweet tafte; when pure it has no fmell; its colour is white, and when cryftallized it is fomewhat tranfparent. It has often a confiderable degree of hardnefs; but it is always fo brittle that it can be reduced without difficulty to a very fine powder. It is not altered by expofure to the atmofphere.

7 Solubility in water. It is exceedingly foluble in water. At the temperature of 48°, water, according to Mr Wenzel, diffolves its own weight of fugar. The folvent power of water increafes with its temperature; when nearly at the boiling point, it is capable of diffolving any quantity of fugar whatever. Water thus faturated with fugar is known by the name of *fyrup*.

Syrup is thick, ropy, and very adhefive; when fpread thin upon paper, it foon dries, and forms a kind of varnifh, which is eafily removed by water. Its fpecific caloric, according to the experiments of Dr Crawford, is 1.086.

8 Its cryftals. When fyrup is fufficiently concentrated, the fugar which it contains precipitates in cryftals. The primitive form of thefe cryftals is a four-fided prifm, whofe bafe is a rhomb, the length of which is to its breadth as 10 to 7; and whofe height is a mean proportion between the length and breadth of the bafe. The cryftals are ufually four or fix-fided prifms, terminated by two-fided, and fometimes by three-fided fummits †.

† *Gillot, Ann. de Chim.* xviii. 317.

9 Solubility in alcohol. Sugar is foluble in alcohol, but not in fo large a proportion as in water. According to Wenzel, four parts of boiling alcohol diffolve one of fugar §. It unites readily with oils, and renders them mifcible with water. A moderate quantity of it prevents, or at leaft retards, the coagulation of milk; but Scheele difcovered that a very large quantity of fugar caufes milk to coagulate ‖.

§ *Enc. Meth. Chim.* i. 271.

‖ *Scheele* ii. 52. Dijon tranflation.

Sugar abforbs muriatic acid gas flowly, and affumes a brown colour and very ftrong fmell ‡.

‡ *Prieftley*, ii. 291.

10 Action of acids. Sulphuric acid, when concentrated, readily decompofes fugar; water is formed and perhaps alfo acetous acid; while charcoal is evolved in great abundance, and gives the mixture a black colour, and a confiderable degree of confiftency. The charcoal may be eafily feparated by dilution and filtration. When heat is applied, the fulphuric acid is rapidly converted into fulphurous acid.

11 Of potafs. When fugar is mixed with potafs, the mixture acquires a bitter and aftringent tafte, and is infoluble in alcohol, though each of the ingredients is very foluble in that liquid. When the alkali is faturated with fulphuric

Sugar. ric acid, and precipitated by means of alcohol, the fweet tafte of the fugar is reftored; a proof that it had undergone no decompofition from the action of the potafs, but had combined with it in the ftate of fugar*.

* Cruickfhank, Rollo on Diabetes, p. 442.

12 Of lime. Lime boiled with fugar produces nearly the fame effect as potafs; when an alkali is added to the compound, a fubftance precipitates in white flakes. This fubftance is fugar combined with lime†. Sugar and chalk compofe, as Leonardi informs us, a kind of cement‡.

† Ibid.

‡ Encyc. Meth. Chim. i. 271.

13 Of heat. Sugar, when thrown upon a hot iron, melts, fwells, becomes brownifh black, emits air bubbles, and exhales a peculiar fmell, known in French by the name of *caromel*. At a red heat it inftantly burfts into flames with a kind of explofion. The colour of the flame is white with blue edges.

14 Diftillation of it. When fugar is diftilled in a retort, there comes over a fluid which, at firft, fcarcely differs from pure water; by and bye it is mixed with pyromucous acid, afterwards fome empyreumatic oil makes its appearance; and a bulky charcoal remains in the retort. This charcoal very frequently contains lime, becaufe lime is ufed in refining fugar; but if the fugar, before being fubmitted to diftillation, be diffolved in water, and made to cryftallize by evaporation in a temperature fcarcely higher than that of the atmofphere, no lime whatever, nor any thing elfe, except pure charcoal, will be found in the retort. During the diftillation, there comes over a confiderable quantity of carbonic acid, and carbonated hydrogen gas*. Sugar therefore is decompofed by the action of heat; and the following compounds are formed from it: Water, pyromucous acid, oil, charcoal, carbonic acid, carbonated hydrogen gas. The quantity of oil is inconfiderable; by far the moft abundant product is pyromucous acid. Sugar indeed is very readily converted into pyromucous acid; for it makes its appearance always whenever fyrup is raifed to the boiling temperature. Hence the fmell of caromel, which fyrup at that temperature emits. Hence alfo the reafon that, when we attempt to cryftallize fyrup by heat, there always remains behind a quantity of incryftallizible matter, known by the name of *molaffes*; whereas if the fyrup be cryftallized without artificial heat, every particle of fugar may be obtained from it in a cryftalline form †. Hence we fee the importance of properly regulating the fire during the cryftallization of fugar, and the immenfe faving that would refult from conducting the operation at a low heat.

* Scopoli and Morveau, Enc. Meth. Chim. i. 269.

† Morveau. Enc. Meth. Chim. i. 266.

15 Its compofition. It follows from thefe facts, and from various other methods of decompofing fugar, that it is compofed of oxygen, hydrogen, and carbon; for all the fubftances obtained from fugar by diftillation may be refolved into thefe elements. Lavoifier has made it probable, by a feries of very delicate experiments, that thefe fubftances enter into the compofition of fugar in the following proportions:

64	oxygen,
28	carbon,
8	hydrogen.
100	

Of the way in which thefe ingredients are combined in fugar, we are ftill entirely ignorant. Lavoifier's conclufions can only be confidered as approximations to the truth.

Sugar is confidered as a very nourifhing article of food. It is found moft abundantly in the juice of the fugar cane, but many other plants alfo contain it. The juice of the acer faccharinum, or *fugar maple*, contains fo much of it, that in North America fugar is often extracted from that tree*. Sugar is alfo found in the roots of carrot, parfnip, beet, &c. Mr Achard has lately pointed out a method of increafing the quantity of fugar in beet fo much, that, according to his own account, it is at prefent cultivated in large quantities in Pruffia, and fugar extracted from it with advantage†. Parmentier has alfo afcertained that the grains of wheat, barley, &c. and all the other fimilar feeds which are ufed as food, contain at firft a large quantity of fugar, which gradually difappears as they approach to a ftate of maturity. This is the cafe alfo with peas and beans, and all leguminous feeds, and is one reafon why the flavour of young peas is fo much fuperior to that of old ones.

Starch. 16 Plants containing it.

* Rufh. Tranf. Phil. ad. iii. 64.

† Ann. de Chim. xxxii. 163.

SECT. II. *Of STARCH.*

17 Method of obtaining ftarch. WHEN a quantity of wheat flour is formed into a pafte, and water poured upon it till it runs off colourlefs, this water foon depofits a very fine whitifh powder; which, when properly wafhed and dried, is known by the name of *ftarch*. When firft prepared, it is of a grey colour; but the ftarchmakers render it white by fteeping it in water flightly acidulated. The acid feems to diffolve and carry off the impurities.

Starch was well known to the ancients. Pliny informs us, that the method of obtaining it was firft invented by the inhabitants of the ifland of Chio†.

† Lib. xviii. c. 7.

18 Its properties. Starch has a fine white colour, and is ufually concreted in longifh maffes; it has fcarcely any fmell, and very little tafte. When kept dry, it continues for a long time uninjured though expofed to the air.

19 How acted on by water. Starch does not diffolve in cold water, but very foon falls to powder. It combines with boiling water, and forms with it a thick pafte. Linen dipt into this pafte, and afterwards dried fuddenly, acquires, as is well known, a great degree of ftiffnefs. When this pafte is left expofed to damp air it foon lofes its confiftency, acquires an acid tafte, and its furface is covered with mould.

20 Alcohol. Starch is fo far from diffolving in alcohol, even when affifted by heat, that it does not even fall to powder.

21 Acids. When ftarch is thrown into any of the mineral acids, at firft no apparent change is vifible. But if an attempt is made to break the larger pieces while in acids to powder, they refift it, and feel exceedingly tough and adhefive. Sulphuric acid diffolves it flowly, and at the fame time a fmell of fulphurous acid is emitted, and fuch a quantity of charcoal is evolved, that the difh containing the mixture may be inverted without fpilling any of it. Indeed if the quantity of ftarch be fufficient, the mixture becomes perfectly folid. The charcoal may be feparated by dilution and filtration. In muriatic acid ftarch diffolves ftill more flowly. The folution refembles mucilage of gum arabic, and ftill retains the peculiar odour of muriatic acid. When allowed to ftand for fome time, the folution gradually feparates into two parts; a perfectly tranfparent ftraw-coloured liquid below, and a thick, muddy, oily, or rather mucilaginous fubftance, above. When water is poured in, the muriatic fmell inftantly difappears, and a ftrong fmell is exhaled, precifely fimilar to that which is felt in cornmills.

Gluten.

mills. Ammonia occasions a slight precipitate, but too small to be examined.

Nitric acid dissolves starch more rapidly than the other two acids; it acquires a green colour, and emits nitrous gas. The solution is never complete, nor do any crystals of oxalic acid appear unless heat be applied. In this respect starch differs from sugar, which yields oxalic acid with nitric acid, even at the temperature of the atmosphere. When heat is applied to the solution of starch in nitric acid, both oxalic and malic acid is formed, but the undissolved substance still remains. When separated by filtration, and afterwards edulcorated, this substance has the appearance of a thick oil, not unlike tallow; but it dissolves readily in alcohol. When distilled, it yields acetous acid, and an oil having the smell and the consistence of tallow*.

* *Scheele*, Crell's Jour. ii. 14. English translation.

22 Heat.

When starch is thrown upon a hot iron, it melts, blackens, froths, swells, and burns with a bright flame like sugar, emitting, at the same time, a great deal of smoke; but it does not explode, nor has it the caromel smell which distinguishes burning sugar. When distilled, it yields water impregnated with an acid, supposed to be the pyromucous, and mixed with a little empyreumatic oil. The charcoal which remains is easily dissipated when set on fire in the open air; a proof that it contains very little earth.

23 Its composition.

Barley grain consists almost entirely of starch, not however in a state of perfect purity. In the process of malting, which is nothing else than causing the barley to begin to vegetate, a great part of the starch is converted into sugar. During this process oxygen gas is absorbed, and carbonic acid gas is emitted. Water, too, is absolutely necessary; hence it is probable, that it is decomposed, and its hydrogen retained†. Starch, then, seems to be converted into sugar by diminishing the proportion of its carbon, and encreasing that of its hydrogen and oxygen. Its distillation shews us that it contains no other ingredients than these three.

† *Cruikshank, Rollo on Diabetes.*

24 Substances containing it.

Starch is contained in a great variety of vegetable substances; most commonly in their seeds or bulbous roots; but sometimes also in other parts. Mr Parmentier, whose experiments have greatly contributed towards an accurate knowledge of starch, has given us the following list of the plants from the roots of which it may be extracted.

Arctium lappa,	Imperatoria ostrutheum,
Atropa belladonna,	Hyoscyamus niger,
Polygonum bistorta,	Rumex obtusifolius,
Bryonia alba,	——— acutus,
Colchicum autumnale,	——— aquaticus,
Spiræa filipendula,	Arum maculatum,
Ranunculus bulbosus,	Orchis mascula,
Scrophularia nodosa,	Iris pseudacorus,
Sambucus ebulus,	— fœtidissima,
——— nigra,	Orobus tuberosus,
Orchis morio,	Bunium bulbocastanum.

It is found also nearly pure in the following seeds:

Oats,	Chesnut,	Acorn,
Rice,	Horsechesnut,	And also in
Maiz,	Peas,	Salop,
Millet,	Beans,	Sago.

SECT. III. *Of Gluten.*

WHEN wheat flour is washed in the manner described in the last section, in order to obtain starch from it, the substance which remains, after every thing has been washed away which cold water can separate, is called *gluten*. It was discovered by Beccaria an Italian philosopher, to whom we are indebted for the first analysis of wheat flour†.

25 Gluten, how obtained.

† *Collect. Acad.* x. 1.

26 Its properties.

Gluten, when thus obtained, is of a grey colour, exceedingly tenacious, ductile, and elastic, and may be extended to twenty times its original length. When very thin, it is of a whitish colour, and has a good deal of resemblance to animal tendon or membrane. In this state it adheres very tenaciously to other bodies, and has often been used to cement together broken pieces of porcelain. Its smell is agreeable. It has scarce any taste, and does not lose its tenacity in the mouth.

27 Action of air,

When exposed to the air, it gradually dries; and, when completely dry, it is pretty hard, brittle, slightly transparent, of a dark brown colour, and has some resemblance to *glue*. It breaks like a piece of glass, and the edges of the fracture resemble in smoothness those of broken glass; that is to say, it breaks with a *vitreous* fracture.

28 Water,

When exposed to the air, and kept moist, it soon putrifies; but when dry, it may be kept any length of time without alteration. It is insoluble in water; tho' it imbibes and retains a certain quantity of it with great obstinacy. To this water it owes its elasticity and tenacity. When boiled in water, it loses both these properties. It is soluble in alcohol, as Mr Vauquelin informs us‡; and precipitated again, as Mr Fourcroy has observed, by pouring into the alcohol two parts of water§.

‡ *Ann de Chim.* vi. 278.

§ *Ibid.* viii. 135.

29 Acids,

Gluten is soluble in the three mineral acids. When nitric acid is poured on it, and heat applied, there is a quantity of azotic gas emitted, as Berthollet discovered; and, by continuing the heat, a quantity of oxalic acid is formed||.

|| *Vauquelin, Ibid.* vi. 278.

30 Alkalies,

Alkalies dissolve gluten when they are assisted by heat. The solution is never perfectly transparent. Acids precipitate the gluten from alkalies, but it is destitute of its elasticity¶.

¶ *Fourcroy.*

31 Heat.

When moist gluten is suddenly dried, its swells amazingly. Dry gluten, when exposed to heat, cracks, swells, melts, blackens, exhales a fetid odour, and burns precisely like feathers or horn. When distilled, there comes over water impregnated with ammonia and an empyreumatic oil; the charcoal which remains is with difficulty reduced to ashes. From these phenumena, it is evident that gluten is composed of carbon, hydrogen, azot, and oxygen: perhaps also it contains a little lime. In what manner these substances are combined is unknown.

32 Its composition.

33 Substances containing it.

The only vegetable substance which has been hitherto found to contain it abundantly, is wheat flour. Vauquelin also found it in the fruit of the *cassia fistuloris**, and Fourcroy in the bark of a species of quinquina from St Domingo†. It probably exists in many other plants.

* *Ibid.*

† *Ibid.* viii. 135.

SECT. IV. *Of Albumen.*

Albumen.

IF the water in which wheat flour has been washed in order to obtain starch and gluten, according to the directions laid down in the two last sections, be filtrated, and afterwards boiled, a substance precipitates in white flakes; to which Mr Fourcroy, who first pointed it

Jelly. it out, has given the name of *albumen* (A), on account of its resemblance to the *white* of an egg ‡.

‡ Ann. de Chim. iii. 259.

34 Properties of albumen. It is evident, from the method of obtaining it, that albumen, in its natural state, is soluble in water, and that heat precipitates it from that fluid in a concrete state. While dissolved in water, it has scarcely any taste; but it has the property of changing vegetable blues, especially that which is obtained from the flowers of the mallow (*malva sylvestris*), into a green §. When allowed to remain dissolved in water, it putrifies without becoming previously acid ‖.

§ Fourcroy, Ibid. 257.

‖ Ibid.

After it has been precipitated from water in a concrete state by boiling, it is no longer soluble in water as before. Alcohol also precipitates it from water precisely in the same state as when it is precipitated by heat.

When concrete albumen is dried it becomes somewhat transparent, and very like glue. In that state it is soluble in alkalies, especially ammonia *.

* Ibid.

35 Its composition. When distilled it gives out carbonat of ammonia, a red fetid oil, and carbonated hydrogen gas; and a spongy charcoal remains behind †. From this, it is evident that albumen, like gluten, is composed of carbon, azot, hydrogen, and oxygen; but the proportions and combinations of these substances are altogether unknown.

† Ibid.

Mr Fourcroy found albumen in the expressed juice of scurvy grass, cresses, cabbage, and almost all cruciform plants. He found it, too, in a great many young and succulent plants; but never a particle in those parts of vegetables which contain an acid. He observed also that the quantity decreased constantly with the age of the plant.

SECT. V. *Of Jelly.*

If we press out the juice of ripe blackberries, currants, and many other fruits, and allow it to remain for some time in a state of rest, it partly coagulates into a tremulous soft substance, well known by the name of *jelly*. If we pour off the uncoagulated part, and wash the coagulum with a small quantity of water, we obtain *jelly* approaching to a state of purity.

36 Properties of jelly. In this state it is nearly colourless, unless tinged by the peculiar colouring matter of the fruit; it has a pleasant taste, and a tremulous consistency. It is scarcely soluble in cold water, but very soluble in hot water; and, when the solution cools, it again coagulates into the form of a jelly †. When long boiled, it loses the property of gelatinising by cooling, and becomes analagous to mucilage ‡. This is the reason that in making currant jelly, or any other jelly, when the quantity of sugar added is not sufficient to absorb all the watery parts of the fruit, and consequently it is necessary to concentrate the liquid by long boiling, the mixture often loses the property of coagulating, and the jelly, of course, is spoiled. §.

† Vauquelin, Ann. de Chim. vi. 282.

‡ Id. Ibid. v. 100.

Gum.

§ Ann. de Chim. v. 102.

Jelly combines readily with alkalies; nitric acid converts it into oxalic acid, without separating any azotic gas ‖. When dried it becomes transparent ¶. When distilled it affords a great deal of pyromucous acid, a small quantity of oil, and scarcely any ammonia †.

‖ Ibid. vi. 282.

¶ Ibid. v. 100.

† Ibid. vi. 286.

Jelly exists in all acid fruits, as oranges, lemons, gooseberries, &c. and no albumen is ever found in those parts of vegetables which contain an acid. This circumstance has induced Fourcroy to suppose that jelly is albumen combined with an acid *: but this conjecture has not been verified by experiment; nor indeed is it probable that it ever shall; as albumen evidently contains a quantity of azot, and jelly scarcely any. The products of jelly by distillation shew that it approaches nearer than any other vegetable substance to the nature of sugar.

* Ibid. iii. 261.

SECT. VI. *Of Gum.*

37 Gum how obtained. There is a thick transparent tastelefs fluid which sometimes exsudes from certain species of trees. It is very adhesive, and gradually hardens without losing its transparency; but easily softens again when moistened with water. This exsudation is known by the name of *gum*. The gum most commonly used is that which exsudes from different species of the *mimosa*, particularly the *nilotica* †. It is known by the name of *gum arabic*. Gum likewise exsudes abundantly from the *prunus avium* or common wild cherry tree of this country.

† Shousbar, Phil. Mag. v. 241.

Gum is usually obtained in small pieces like tears, moderately hard, and somewhat brittle while cold, so that it can be reduced by pounding to a fine powder. Its colour is usually yellowish, and it is not destitute of lustre. It has no smell; its taste is insipid.

38 Action of water. Gum undergoes no change from being exposed to the atmosphere; but the light of the sun makes it assume a white colour. Water dissolves it in large quantities. The solution which is known by the name of *mucilage* (B), is thick and adhesive: it is often used as a paste, and to give stiffness and lustre to linen. When spread out thin it soon dries, and has the appearance of a varnish; but it readily attracts moisture, and becomes glutinous. Water washes it away entirely. When mucilage is evaporated the gum is obtained unaltered.

39 Alcohol. Gum is insoluble in alcohol. When alcohol is poured into mucilage, the gum immediately precipitates; because the affinity between water and alcohol is greater than that between water and gum.

The action of alkalies and earths upon gum has not been

(A) The existence of albumen in vegetables was known to Scheele. He mentions it particularly in his paper on Milk, first published in the year 1780. See *Scheele's Works*, II. 55. Dijon edition.

(B) Hermstadt uses this word in a different sense. He makes a distinction between *gum* and *mucilage*. The solution of *gum* in water is transparent and glutinous, and can be drawn out into threads; whereas that of *mucilage* is opake, does not feel glutinous, but slippery, and cannot be drawn into threads. Gum may be separated from mucilage by the following process:

Let the gum which is supposed to be mixed with mucilage, previously reduced to a dry mass, be dissolved in as small a quantity of water as possible, and into the solution drop at intervals diluted sulphuric acid. The mucilage coagulates while the gum remains dissolved. When no more coagulation takes place, let the mixture remain at rest for some time, and the mucilage will precipitate to the bottom, and assume the consistence of jelly. Decant off the liquid part, and evaporate the mucilage to dryness by a gentle heat till it acquires the consistence of horn. *Med. and Phys. Jour.* iii. 370.

Extract. been examined. Acids do not precipitate it from mucilage ‡. The concentrated mineral acids destroy it. Concentrated sulphuric acid decomposes it; water is formed, and perhaps also acetous acid; while charcoal is precipitated. Nitric acid converts it into oxalic acid; oxy-muriatic acid, on the contrary, into citric acid *.

‡ Vauquelin.

* Id. Ann. de Chim. vi. 78.

40 Of heat. When gum is exposed to heat it softens and swells, but does not melt; it emits air bubbles, blackens, and at last, when nearly reduced to charcoal, emits a low blue flame. This flame appears sooner if a flaming substance be held just above the gum. After the gum is consumed, there remains a small quantity of white ashes, composed chiefly of the carbonats of lime and potash.

When gum is distilled in a retort, the products are water impregnated with a considerable quantity of pyromucous acid, a little empyreumatic oil, carbonic acid gas, and carbonated hydrogen gas. When the pyromucous acid obtained by this process is saturated with lime, a quantity of ammonia is disengaged with which that acid had been combined. The charcoal which remained in the retort leaves behind it, after incineration, a little lime, and phosphat of lime §.

§ Cruikshank, Rollo on Diabetes.

41 Its composition. These experiments shew us that gum is composed of hydrogen, carbon, oxygen, azot, lime, and phosphorus; but the proportions and combinations of these substances are unknown to us. Mr Cruickshank has rendered it probable that the quantity of carbon is greater, and the quantity of oxyen less, in gum than in sugar ||.

|| Ibid.

Gum, or mucilage, exists most abundantly in young plants, and gradually disappears as they arrive at perfection. It forms a great proportion of the leaves and roots of many eatable plants.

SECT. VII. *Of Extract*.

THE word *extract* was at first applied to all those substances which were extracted from plants by means of water, and consequently included gum, jelly, and several other bodies. But of late it has been confined, by those chemists who have paid attention to the use of language, to a substance which exists in many plants, and which may be obtained by infusing *saffron* in water for some time, filtrating the infusion, and evaporating it to dryness. The residuum, after evaporation, is *extract* nearly pure ¶. It possesses the following properties:

42 Extract, how obtained.

¶ Hermstadt.

43 Its properties. Water dissolves it in considerable quantities, especially hot water. Alcohol also dissolves it with facility. This property of being soluble both in water and alcohol has induced some chemists to give *extract* the name of *soap*. It is insoluble in sulphuric ether. These three properties are sufficient to distinguish it from every other vegetable substance *.

* Hermstadt.

When the solution of extract in water is exposed for some time in the open air, the extract precipitates, and is now no longer soluble in water. This change is supposed to proceed from the addition of a quantity of oxygen which it imbibes from the atmosphere †.

† Fourcroy.

When oxy-muriatic acid is poured into a watery solution of extract, that substance precipitates in yellow flakes. These flakes are insoluble in water; they are insoluble also in alcohol at the temperature of 97°; but that liquid dissolves them at the temperature of 120°. They are soluble also in alkalies, and in boiling-hot water they melt into a yellow mass ‡.

‡ Fourcroy.

Extract is soluble in acids. Heat softens but does not melt it §.

Tan.

§ Id. Ann. de Chim. viii.

It is found in a great variety of plants; but as no method of obtaining it perfectly pure has hitherto been discovered, the extracts of different plants differ somewhat from each other both in their colour and smell.

SECT. VIII. *Of Tan*.

44 Preparation of tan. IF a quantity of nut galls, coarsely powdered, be kept for some time infused in cold water, if the water be filtered, and a solution of muriat of tin be dropt into it, a copious white precipitate falls to the bottom. This precipitate is to be carefully washed and diffused (for it will not dissolve) thro' a large quantity of water, and this water is to be saturated with sulphurated hydrogen gas so completely that it will not absorb any more. By this treatment the white precipitate will gradually disappear, and a brown precipitate will take its place. This brown precipitate must be separated by filtration; and the water, which has now acquired the colour and the taste of the infusion of nut galls, must be evaporated to dryness. A substance remains behind, known by the name of *tan* or *tannine*.

It was first discovered by Seguin, who pointed out some of its properties, and the method of detecting it in plants ||. The above method of obtaining it in a state of purity was contrived by Mr Proust. Tan exists in the solution of nut galls combined with gallic acid. The oxyd of tin has a strong affinity for it. When muriat of tin is poured in, the tan combines with the oxide, and the compound, being insoluble, falls to the bottom. Sulphur has a stronger affinity for the oxide than tan has. Hence when sulphurated hydrogen gas is thrown upon this compound, the sulphur leaves the gas and combines with the tin; and the compound, being insoluble, falls to the bottom: The hydrogen gas escapes, and nothing remains in the water except the tan.

|| Nicholson's Jour. i. 271.

45 Its properties. Tan is a brittle substance, of a brown colour. It breaks with a vitreous fracture, and does not attract moisture from the air. Its taste is exceedingly astringent. It is very soluble in water. The solution is of a deep brown colour, a very astringent and bitter taste, and has the odour which distinguishes a solution of nut galls. It froths, when agitated, like a solution of soap; but does not feel unctuous. Acids precipitate the tan from this solution.

Tan is still more soluble in alcohol than in water.

When the solution of tan is poured into a solution of the brown sulphat of iron, a deep blue coloured precipitate immediately appears, consisting of the tan combined with the oxide. This precipitate, when dried, assumes a black colour. It is decomposed by acids. The green sulphat of iron is not altered by tan.

When too great a proportion of brown sulphat of iron is poured into a solution of tan, the sulphuric acid, set at liberty by the combination of the iron and tan, is sufficient to redissolve the precipitate as it appears; but the precipitate may easily be obtained by cautiously saturating this excess of acid with potash. When the experiment is performed in this manner, all the red sulphat of iron which remains in the solution undecomposed is converted into green sulphat. Mr Proust, to whom we are indebted for almost every thing yet known concerning the properties of tan, supposes that this change is produced

Camphor.

produced by the tan absorbing oxygen from the iron. This may very possibly be the case; but his experiments are insufficient to prove that it is. The same change takes place if red oxide be mixed with a considerable excess of sulphuric acid, and diluted with water.

Tan combines readily with oxygen. When oxy-muriatic acid is poured upon it, its colour deepens, and it loses all its peculiar characters *.

* Proust, Ann. de Chim. xxv. 225.

46 Plants containing it.

Tan exists in almost all those vegetable substances which have an astringent taste. It is almost constantly combined with gallic acid. The following table, drawn up by Mr Biggin †, though the rule which the author followed in making his experiments precluded rigid accuracy, will serve to give some idea of the proportions of tan which exist in different plants:

† Phil. Trans. 1799.

	Prop. of Tan.		Prop. of Tan.
Elm - -	2,1	Sallow - -	4,6
Oak cut in winter -	2,1	Mountain ash -	4,7
Horse chesnut -	2,2	Poplar - -	6,0

Birch - -	4,1		
Cherry tree - -	4,2	Sumach - -	16,2

Sect. IX. *Of Oils.*

There are two species of oils; namely, *fixed* and *volatile*: both of which are found abundantly in plants.

1. Fixed oil is found in the seeds of many plants, especially of the oil, beech, flax, almond, rape, &c.

2. Volatile oil is obtained by distillation from the leaves, flowers, or roots of aromatic plants, as lavender, roses, rosemary, &c.

As an account of the properties of oils has been given already in the article Chemistry, *Suppl.* it would be superfluous to repeat it here.

Sect. X. *Of Camphor.*

The laurus camphorata is a tree which grows in China, Japan, and several parts of India. When the roots of this tree are put into an iron pot furnished with a capital, and a sufficient heat is applied, a particular substance sublimes into the capital, which is known by the name of *camphor*. The Dutch afterwards purify this camphor by a second sublimation.

Camphor is a white brittle substance, having a peculiar aromatic odour and a strong taste.

47 Properties of camphor.

It is not altered by atmospheric air; but it is so volatile, that if it be exposed during warm weather in an open vessel, it evaporates completely. When sublimed in close vessels it crystallises in hexagonal plates or pyramids *.

* Romieu.

It is insoluble in water; but it communicates to that liquid a certain portion of its peculiar odour.

It dissolves readily in alcohol, and is precipitated again by water. If the alcohol be diluted with water as much as possible, without causing the camphor to precipitate, small crystals of camphor resembling feathers gradually form †.

† Romieu, Mem. Par. 1756, p. 41.

Camphor is soluble also in hot oils, both fixed and volatile; but as the solution cools the camphor precipitates, and assumes the form of plumose, or feather-like crystals ‡.

‡ Romieu, Mem. Par. 1756, p. 41.

Camphor is not acted on by alkalies, either pure or in the state of carbonats. Pure alkalies indeed seem to dissolve a little camphor; but the quantity is too small to be perceptible by any other quality than its odour §. Neither is it acted upon by any of the neutral salts which have hitherto been tried.

§ Bouillon, la Grange, Ann. de Chim. xxiii. 154.

Acids dissolve camphor, but it is precipitated again, unaltered, by alkalies, and even by water. The solution of camphor in sulphuric acid is red; that in the nitric acid is yellow. This last solution has obtained the absurd name of *oil of camphor*. When nitric acid is distilled repeatedly off camphor, it converts it into camphoric acid.

Muriatic, sulphurous, and fluoric acids, in the state of gas, dissolve camphor. When water is added, the camphor appears unaltered in flakes, which swim on the surface of the water §.

§ Fourcroy.

When heat is applied to camphor it is volatilized. If the heat be sudden and strong, the camphor melts before it evaporates. It catches flame very readily, and emits a great deal of smoke as it burns, but it leaves no residuum. It is so inflammable that it continues to burn even on the surface of water. When camphor is set on fire in a large glass globe filled with oxygen gas, and containing a little water, it burns with a very bright flame, and produces a great deal of heat. The inner surface of the glass is soon covered with a black powder, which has all the properties of charcoal, a quantity of carbonic acid gas is evolved, the water in the globe acquires a strong smell, and is impregnated with carbonic acid and camphoric acid ‖.

‖ Bouillon la Grange, ibid. p. 168.

48 Its analysis.

If two parts of alumina and one of camphor be formed into a paste with water, and distilled in a glass retort, there comes over into the receiver (which should contain a little water, and communicate with a pneumatic apparatus) a volatile oil of a golden yellow colour, a little camphoric acid which dissolves in the water, and a quantity of carbonic acid gas, and carbonated hydrogen gas, which may be collected by means of a pneumatic apparatus. There remains in the retort a substance of a deep black colour, composed of alumina and charcoal. By this process, from 122.284 parts of camphor, Mr Bouillon la Grange, to whom we are indebted for the whole of the analysis of camphor, obtained 45.856 parts of volatile oil, and 30.571 parts of charcoal. The proportion of the other products was not ascertained *.

* Ibid. p. 157.

From this analysis, Mr Bouillon la Grange concludes that camphor is composed of volatile oil, and charcoal or carbon, combined together. We learn from his experiments, that the ultimate ingredients of camphor are carbon and hydrogen; and that the proportion of carbon is much greater than in oils.

49 Plants containing it.

Camphor exists in a great many plants. Neumann, Geoffroy, and Cartheuser, extracted it from the roots of zedoary, thyme, sage, &c. and rendered it probable that it is contained in almost all the labiated plants. It has been supposed to exist in these plants combined with volatile oil. Proust has shewn how it may be extracted, in considerable quantity, from many volatile oils †.

† Ann. de Chim. iv. 179.

Camphor, which was unknown to the ancient Greeks and Romans, was introduced into Europe by the Arabians.

Resins. bians. Ætius is the first person who mentions it. It seems, however, to have been very early known to the eastern nations.

It is much used in medicine. It is a powerful stimulant; it is considered as peculiarly efficacious in diseases of the urinary organs; it is often serviceable in mania, and procures sleep when every other medicine fails.

SECT. XI. *Of Resins.*

THERE is a yellowish white coloured substance which often exsudes from the *Abies Montana*, or *common Scotch fir*, and likewise from other fir trees. It is somewhat transparent, is hard and brittle, of a disagreeable taste, and may be collected in considerable quantities. This substance is known by the name of *resin*; and the same name is also applied to all substances which possess nearly the same properties with it. Resin may be distinguished from every other substance by the following properties:

50 Properties of resin. It is more or less concrete, and has an acrid and hot taste.

It is totally insoluble in water. By this property it may easily be separated from gum, if they happen to be mixed together.

It is soluble in alcohol, and in sulphuric ether *. By the first of these properties we may separate it from gum, and by the last from extract; for extract is insoluble in sulphuric ether. When these solutions are evaporated the resin is obtained unaltered. If the solution be spread thin upon any body, it soon dries by the evaporation of the alcohol; the resin remains behind, and covers the body with a smooth shining transparent coat, which cannot be washed off by water. This process is called *varnishing*.

Resin is soluble also in volatile oils; and these solutions are often used likewise in varnishing.

Resin is scarcely acted upon by acids. Alkalies combine with it, but the combination is not easily effected.

When resin is heated it readily melts; and if the heat be increased it is volatilized, and burns with a white flame and strong smell. When distilled it yields much volatile oil, but scarcely any acid.

When volatile oils are exposed for some time to the action of the atmosphere they acquire consistency, and assume the properties of resins. During this change they absorb a quantity of oxygen from the air. Westrum put 30 grains of oil of turpentine into 40 cubic inches of oxy-muriatic acid gas. Heat was evolved, the oil gradually evaporated, and assumed the form of yellow resin †. These facts render it probable that resin is merely volatile oil combined with a quantity of oxygen.

To know whether any vegetable substance contains resin, we have only to pour some sulphuric ether upon it in powder, and expose the infusion to the light. If any resin be present the ether will assume a brown colour ‡.

51 Number of resins. The number of resins is considerable. They differ from each other chiefly in colour, taste, smell, and consistency. Whether these resins be really different combinations, or, as is most likely, owe these differences to foreign ingredients, either combined with the resin, or mechanically mixed with it, is not at present known. To describe each resin separately would be to little purpose, as scarcely any thing is known of them except their general properties as resins. The following is a list of the principal. The reader will find an account of the manner of obtaining them, and of their uses, by consulting the name of each in the *Encyclopædia*.

1. Common resin,	7. Sandarac,
2. Turpentine,	8. Guiacum,
3. Pitch,	9. Labdanum,
4. Galipot,	10. Dragon's blood,
5. Elemi,	11. Copaiba.
6. Mastic,	

52 Balsams. There are three vegetable substances which have been denominated *balsams* by some of the later French writers. They appear to consist of resin, or volatile oil combined with benzoic acid. These substances are, benzoin, balsam of Tolu, and storax. For an account of them we refer to the *Encyclopædia*.

53 Gum resins. Many vegetable substances occur in medicine which consist chiefly of a mixture of gum and resin. These substances, of course, have a number of the properties both of gums and resins. For this reason they have been denominated *gum resins*. The following are the most important of these substances:

Olibanum,	Aloes,
Galbanum,	Myrrh,
Scammony,	Ammoniac,
Asafœtida,	Opium.

For an account of them we refer to the *Encyclopædia*.

SECT. XII. *Of Caoutchouc.*

54 Discovery of caoutchouc. ABOUT the beginning of the 18th century a substance, called *caoutchouc*, was brought as a curiosity from America. It was soft, wonderfully elastic, and very combustible. The pieces of it that came to Europe were usually in the shape of bottles, birds, &c. This substance is very much used in rubbing out the marks made upon paper by a black lead pencil; and therefore in this country it is often called *Indian rubber*. Nothing was known of its production, except that it was obtained from a tree, till the French academicians went to South America in 1735 to measure a degree of the meridian. Mr de la Condamine sent an account of it to the French Academy in the year 1736. He told them, that there grew in the province of Esmeraldas, in Brazil, a tree, called by the natives *Hhevé*; that from this tree there flowed a milky juice, which, when inspissated, was *caoutchouc*. Don Pedro Maldonado, who accompanied the French academicians, found the same tree on the banks of the Maragnon; but he died soon after, and his papers were never published. Mr Fresnau, after a very laborious search, discovered the same tree in Cayenne. His account of it was read to the French Academy in 1751.

55 Plants containing it. It is now known that there are at least two trees in South America from which caoutchouc may be obtained, the Hævea Caoutchouc and the Jatropha Elastica; and it is exceedingly probable that it is extracted also from other species of Hævea and Jatropha. Several trees likewise which grow in the East Indies yield caoutchouc; the principal of these are, the Ficus Indica, the Artocarpus Integrifolia, and the Urceola Elastica; a plant discovered by Mr Howison, and first described and named by Dr Roxburgh *.

* Hermstadt.
† Crell's Annals, i. 90.
‡ Hermstadt.
* Asiatic Researches, v. 167. London edition.

Caoutchouc.

When any of theſe plants is punctured, there exſudes from it a milky juice, which, when expoſed to the air, gradually lets fall a concrete ſubſtance, which is caoutchouc.

If oxy-muriatic acid be poured into the milky juice, the caoutchouc precipitates immediately, and, at the ſame time, the acid loſes its peculiar odour. This renders it probable that the formation of the caoutchouc is owing to its baſis abſorbing oxygen *. If the milky juice be confined in a glaſs veſſel containing common air, it gradually abſorbs oxgen, and a pellicle of caoutchouc appears on its ſurface †.

* Fourcroy, Ann. de Chim. xi. 229.
† Ibid.

56
Properties of caoutchouc.

Caoutchouc was no ſooner known than it drew the attention of philoſophers. Its ſingular properties promiſed that it would be exceedingly uſeful in the arts, provided any method could be fallen upon to mould it into the various inſtruments for which it ſeemed peculiarly adapted. Meſſrs de la Coudimine and Freſnau had mentioned ſome of its properties; but Macquer was the firſt perſon who undertook to examine it with attention. His experiments were publiſhed in the memoirs of the French Academy for the year 1768. They threw a good deal of light on the ſubject; but Macquer fell into ſome miſtakes, which were pointed out by Mr Berniard, who publiſhed an admirable paper on caoutchouc in the 17th volume of the *Journal de Phyſique*. To this paper we are indebted for the greater number of facts at preſent known reſpecting caoutchouc. Mr Groſſart and Mr Fourcroy have likewiſe added conſiderably to our knowledge of this ſingular ſubſtance; both of their treatiſes have been publiſhed in the 11th volume of the *Annales de Chemie*.

Caoutchouc, when pure, is of a white colour (c), and without either taſte or ſmell ‡. The blackiſh colour of the caoutchouc of commerce is owing to the method employed in drying it after it has been ſpread upon moulds. The uſual way is to ſpread a thin coat of the milky juice upon the mould, and then to dry it by expoſing it to ſmoke; afterwards another coat is ſpread on, which is dried in the ſame way. Thus the caoutchouc of commerce conſiſts of numerous layers of pure caoutchouc alternating with as many layers of ſoot.

‡ Fourcroy, ibid. 232.

Caoutchouc is ſoft and pliable like leather. It is exceedingly elaſtic and adheſive; ſo that it may be forcibly ſtretched out much beyond its uſual length, and inſtantly recover its former bulk when the force is withdrawn. It cannot be broken without very conſiderable force.

57
Action of water,

It is not altered by expoſure to the air; it is perfectly inſoluble in water: but if boiled for ſome time its edges become ſomewhat tranſparent, owing undoubtedly to the water carrying off the ſoot; and ſo ſoft, that when two of them are preſſed and kept together for ſome time, they adhere as cloſely as if they formed one piece. By this contrivance pieces of caoutchouc may be ſoldered together, and thus made to aſſume whatever ſhape we pleaſe §.

§ Groſſart, Ann. de Chim. xi. 133.

58
Alcohol,

Caoutchouc is inſoluble in alcohol. This property was diſcovered very early, and fully confirmed by the experiments of Mr Macquer. The alcohol, however, renders it colourleſs.

59
Ether,

Caoutchouc is ſoluble in ether. This property was firſt pointed out by Macquer. Berniard, on the contrary, found that caoutchouc was ſcarcely ſoluble at all in ſulphuric ether, which was the ether uſed by Macquer, and that even nitric ether was but an imperfect ſolvent. The difference in the reſults of theſe two chemiſts was very ſingular; both were remarkable for their accuracy, and both were too well acquainted with the ſubject to be eaſily miſled. The matter was firſt cleared up by Mr Cavallo. He found that ether, when newly prepared, ſeldom or never diſſolved caoutchouc completely; but if the precaution was taken to waſh the ether previouſly in water, it afterwards diſſolved caoutchouc with facility. Mr Groſſart tried this experiment, and found it accurate *. It is evident from this that theſe chemiſts had employed ether in different ſtates. The waſhing of ether has two effects. It deprives it of a little acid with which it is often impregnated, and it adds to it about one-tenth of water, which remains combined with it.

* Ann. de Chim. xi. 147.

When the ether is evaporated, the caoutchouc is obtained unaltered. Caoutchouc, therefore, diſſolved in ether, may be employed to make inſtruments of different kinds, juſt as the milky juice of the hævea; but this method would be a great deal too expenſive for common uſe.

60
Oils,

Caoutchouc is ſoluble in volatile oils †; but, in general, when theſe oils are evaporated, it remains ſomewhat glutinous, and therefore is ſcarcely proper for thoſe uſes to which, before its ſolution, it was ſo admirably adapted.

† Berniard.

61
Acids and alkalies,

It is inſoluble in alkalies ‡. The acids act upon it with more or leſs violence according to their nature. Sulphuric acid decompoſes it completely, charcoal precipitates, and part of the acid is converted into ſulphurous acid. Nitric acid converts it into a yellow ſubſtance, analogous to ſuberic acid. Muriatic acid does not affect it §. The other acids have not been tried.

‡ Id.
§ Id.

Fabroni has diſcovered, that rectified petroleum diſſolves it, and leaves it unaltered when evaporated ‖.

‖ Ibid. 195. and xii. 156

62
Heat.

When expoſed to heat it readily melts; but it never afterwards recovers its properties, but continues always of the conſiſtence of tar. It burns very readily with a bright white flame, and diffuſes a fetid odour. In thoſe countries where it is produced, it is often uſed by way of candle.

When diſtilled, it gives out ammonia ¶. It is evident from this, and from the effect of ſulphuric and nitric acid upon it, that it is compoſed of carbon, hydrogen, azot, and oxygen; but the manner in which they are combined is unknown.

¶ Fourcroy, Ann. de Chim. xi. 232.

When treated with nitric acid, there came over azotic gas, carbonic acid gas, pruſſic acid gas; and oxalic acid was formed *.

* Ibid.

63
How to ſeparate it from plants

It ſeems to exiſt in a great variety of plants; but is uſually confounded with the other ingredients. It may be ſeparated from reſins by means of alcohol. It may be extracted from the different ſpecies of *miſletoe* by water, with which, in the fluid ſtate in which it exiſts in theſe plants, it readily combines. When mixed with gum or extract, it may be ſeparated by the following proceſs: Digeſt a part of the plant containing it firſt in water and then in alcohol, till all the ſubſtances ſoluble

(c) Mr De Fourcroy ſays, that blackiſh brown is the natural colour of caoutchouc. But we have ſeen ſome pieces of it from the Eaſt Indies, which had been allowed to inſpiſſate in the open air: They were white, with a ſlight caſt of yellow, and had very much the appearance and feel of white ſoap.

Wax.

luble in these liquids be extracted. Dry the residuum, and digest it in five times its weight of rectified petroleum. Express the liquid part by squeezing the substance in a linen cloth. Let this liquid remain several days to settle, then decant off the clear liquid part, mix it with a third part of water and distil, the caoutchouc remains behind *.

* Hermstadt, Med. and Phys Jour. ii. 372.

SECT. XIII. *Of Wax.*

THE upper surface of the leaves of many trees is covered with a varnish of wax. This varnish may be separated and obtained in a state of purity by the following process.

64 Wax a vegetable production.

Digest the bruised leaves, first in water and then in alcohol, till every part of them which is soluble in these liquids be extracted. Then mix the residuum with six times its weight of a solution of pure ammonia, and, after sufficient maceration, decant off the solution, filter it, and drop into it, while it is incessantly stirred, diluted sulphuric acid, till more be added than is sufficient to saturate the alkali. The wax precipitates in the form of a yellow powder. It should be carefully washed with water, and then melted over a gentle fire †.

Mr Tingry first discovered that this varnish possessed all the properties of *bees wax* ‡. Wax then is a vegetable product. The bees extract it unaltered from the leaves of trees and other vegetable substances which contain it. They seem, however, to mix it with some of the pollen of flowers.

† Id. ibid. 373.

‡ Enc. Meth. Forets et Bois, i. 100.

65 Its properties.

Wax, when pure, is of a whitish colour, it is destitute of taste, and has scarcely any smell. Bees wax indeed has a pretty strong aromatic smell; but this seems chiefly owing to some substance with which it is mixed; for it disappears almost completely by exposing the wax, drawn out into thin ribands, for some time to the atmosphere. By this process also, which is called *bleaching*, the yellow colour of the wax disappears, and it becomes very white. Bleached wax is not affected by the air §.

Wax is insoluble in water and in alcohol. It combines readily with alkalies, and forms with them a soap which is soluble in water ||.

Punic wax, which the ancients employed in painting in encausto, is a soap composed of twenty parts of wax and one of soda *. Its composition was ascertained by Mr Lorgna †.

§ Senebier, Ann. de Chim xii. 60. and Jour. de Phys. xxxviii. 56.

|| Chaptal, iii. 164.

* Plin. l. 21. c. 14.

† Jour de Phys. Nov. 1785.

Sulphuric and nitric acids decompose wax completely; oxy-muriatic acid bleaches it instantaneously.

Wax combines readily with oils, and forms with them a substance of greater or less consistency according to the quantity of oil. This composition, which is known by the name of *cerate*, is much employed by surgeons.

When heat is applied to wax it becomes soft; and at the temperature of 142°, if unbleached, or of 155° if bleached ‡, it melts into a colourless transparent fluid, which concretes again, and resumes its former appearance as the temperature diminishes. If the heat be still farther increased, the wax boils and evaporates; and if a red heat be applied to the vapour, it takes fire and burns with a bright flame. It is this property which renders wax so useful for making candles.

‡ Nicholson's Journal, i. 71.

66 Analysis.

Mr Lavoisier, by means of the apparatus described in the article CHEMISTRY, *Suppl.* nº 353. contrived to burn wax in oxygen gas. The quantity of wax consumed was 21.9 grains. The oxygen gas employed in consuming that quantity amounted to 66.55 grains. Consequently the substances consumed amounted to 88.45 grains. After the combustion there were found in the glass vessel 62.58 grains of carbonic acid, and a quantity of water, which was supposed to amount to 25.87 grains. These were the only products.

Now 62.58 grains of carbonic acid gas contain

44.56 of oxy. and 18.02 of carb; and 25.87 gr. of water contain
21.99 of oxy. and 3.88 of hydro.

66.55	21.90

Consequently 21.9 parts of wax are composed of 18.02 of carbon, and 3.88 of hydrogen. And 100 parts of wax are composed of

82.28 carbon,
17.72 hydrogen,

100.00 *

* Lavoisier, Jour. de Phys. xxxi. 59.

If wax be distilled with a heat greater than 212°, there comes over a little water, some sebacic acid, a little very fluid and odorous oil: the oil, as the distillation advances, becomes thicker and thicker, till at last it is of the consistency of butter, and for this reason has been called *butter of wax*. There remains in the retort a small quantity of coal, which is not easily reduced to ashes. When the butter of wax is repeatedly distilled it becomes very fluid, and assumes the properties of volatile oil †.

† Lemery, Mem. Par. 1708. p. 53.

Woody Fibre.

SECT. XIV. *Of the WOODY FIBRE.*

ALL trees, and most other plants, contain a particular substance, well known by the name of *wood*. If a piece of wood be well dried, and digested, first in a sufficient quantity of water, and then of alcohol, to extract from it all the substances soluble in these liquids, there remains behind only the *woody fibre*.

67 Properties of wood.

This substance, which constitutes the basis of wood, is composed of longitudinal fibres, easily subdivided into a number of smaller fibres. It is somewhat transparent; is perfectly tasteless; has no smell; and is not altered by exposure to the atmosphere.

It is insoluble in water and in alcohol; but soluble in alkalies. The mineral acids decompose it. When distilled it yields, in all probability, pyrolignous acid. When burnt with a smothered fire it leaves behind it a considerable quantity of charcoal.

It is precipitated from alkalies unaltered by acids ‡.

‡ Fourcroy, Ann. de Chim. viii. 149.

68 Its analysis.

By nitric acid Fourcroy converted the residuum of quinquina, which does not seem to differ from the woody fibre, into oxalic acid; at the same time there was a little citric acid formed, and a very small quantity of malic and acetous acids. Some azotic gas also was disengaged. By this process he obtained from 100 parts of woody fibre

56.250 oxalic acid,
3.905 citric acid,
0.388 malic acid,
0.486 acetous acid,
0.867 azotic gas,
8.330 carbonat of lime.

70.226
32.031 residuum.

102.257

There was likewise a quantity of carbonic acid gas disengaged, the weight of which was unknown. This

increase

Acids.

increaſe of weight in the product was evidently owing to the oxygen derived from the nitric acid*.

* Ann. de Chim. viii. 153.

When diſtilled in a retort, 100 parts yield the following products:

26.62 of a yellow liquid, containing alcohol, and acid which had the ſmell of pyromucous.

6.977 of concrete oil, moſtly ſoluble in alcohol.

22.995 charcoal } in the retort.
3.567 carbonat of lime }

60.159

39.841 gas, half carbonic acid, half carbonated hydrogen.

100.000*.

* Ibid. 151.

Theſe facts ſhew us, that the woody fibre is compoſed of oxygen, carbon, hydrogen, azot, and lime. Mr Chaptal ſuppoſes that mucilage differs from woody fibre merely in containing leſs oxygen. We are certain at leaſt that mucilage or gum is compoſed of the ſame ingredients; and Mr Chaptal has ſhewn, that the juices of plants are partly converted into woody fibre by oxy-muriatic acid, which imparts to them oxygen†. Theſe juices contain both gum and reſin: after the formation of the woody fibre the reſin is ſtill unaltered. This gives a good deal of probability to his opinion.

† Ibid. xxi. 285.

SECT. XV. *Of Acids.*

THE acids found ready formed in vegetables are the following:

1. Oxalic,	5. Gallic,
2. Tartarous,	6. Benzoic,
3. Citric,	7. Phoſphoric.
4. Malic,	

Sometimes alſo the ſulphuric, nitric, and muriatic acids occur in vegetables, combined with alkalies or earths, but never except in very minute quantities.

69
Plants containing oxalic acid.

1. Oxalic acid is eaſily detected and diſtinguiſhed by the following properties: It decompoſes all calcareous ſalts, and forms with lime a ſalt inſoluble in water. It readily cryſtallizes. Its cryſtals are quadrilateral priſms. It is totally deſtroyed by heat.

Oxalic acid was firſt detected in vegetables by Mr Scheele. It has been diſcovered in the following plants:

The leaves of the oxalis acetoſella†.
oxalis corniculata.
The root of rhubarb‡.
The leaves of the geranium acidum§.

† Scheele, Crell's Jour. i. 107. Engl. Tranſl.
‡ Ibid. 34.
§ Hermſtadt.

70
Tartarous acid,

2. Tartarous acid is known by the following properties: When a little potaſs is cautiouſly dropt into a ſolution containing it, common tartar is formed, and precipitates to the bottom. Tartarous acid does not decompoſe the ſulphat, nitrat, or muriat of lime. Tartrite of lime is ſoluble in water. Tartarous acid cryſtallizes. Its cryſtals are long ſlender priſms. It is deſtroyed by heat.

Tartarous acid has been found in the following vegetable ſubſtances:

The pulp of the tamarind*.
The juice of grapes.
Mulberries†.
Rumex acetoſa, *ſorrel*†.
Rhus coriaria, *ſumach*†.
Rheum rhaponticum||.
Agave Americana¶.
The roots of triticum repens†.
Leontodon taraxicum†.

* Vauquelin, Ann. de Chim. v. 92.
† Hermſtadt on Veget. Acids.
|| Bindheim, Crell, 1788, St. 7. s. 42.
¶ Hoffman of Weimar.
† Hermſtadt on Veget. Acids.

71
Citric acid,

3. Citric acid is diſtinguiſhed by the following properties: It does not form tartar when potaſs is added to it. With lime it forms a ſalt inſoluble in water, which is decompoſed by ſulphuric, nitric, and muriatic acids. It readily cryſtallizes. It is deſtroyed by heat.

Citric acid has been found unmixed with other acids in the following vegetable ſubſtances*:

The juice of oranges and lemons.
The berries of vaccinium oxycoccos, *cranberry*.
—— —vitis idæa, *red whortle berry*.
Prunus padus, *birdcherry*.
Solanum dulcamara, *nightſhade*.
Roſa canina, *hip*.

* Scheele, Crell's Jour. ii. 8. Eng. Tranſl.

It occurs mixed with other acids in many other fruits.

72
Malic acid,

4. Malic acid is known by the following properties: It forms with lime a ſalt ſoluble in water, which is decompoſed by citric acid. It does not form tartar with potaſs. It is incryſtallizable. Heat deſtroys it.

Malic acid has been found, by Scheele†, in the fruits of the following plants, which contain no other acid:

Apples.
Berberis vulgaris, *barberry*.
Prunus domeſtica, *plum*.
—— ſpinoſa, *ſloe*.
Sambucus nigra, *elder*.
Sorbus aucuparia, *roan* or *ſervice*.

† Ibid.

73
Malic and citric.

In the following fruits he found nearly an equal quantity of malic and citric acids‡.

Ribes groſſularia, *gooſeberry*.
—— rubrum, *currants*.
Vaccinium myrtillus, *bleaberry*.
Crategus aria, *beam*.
Prunus ceraſus, *cherry*.
Fragaria veſca, *ſtrawberry*.
Rubus chamæmorus, *cloudberries*, *evrochs*.
—— idæus, *raſpberry*.

‡ Ibid.

Malic acid has alſo been found in the agave americana§, and in the pulp of tamarinds||. In the firſt of theſe it is mixed with tartarous acid; in the ſecond with tartarous and citric acids.

§ Hoffman of Weimar.
|| Vauquelin, Ann. de Chim. v. 92.

74
Gallic acid,

5. Gallic acid is known by the following properties: With the brown oxide of iron it produces a black colour. It is cryſtallizable. Heat deſtroys it. It has been found in a great number of plants, chiefly in the bark.—The following table, drawn up by Mr Biggin*, will ſerve to ſhew the relative proportions of this acid in different plants:

* Nicholſon's Journal, iii. 394.

Elm	7	Sallow	8
Oak cut in winter	8	Mountain aſh	8
Horſe cheſnut	6	Poplar	8
Beech	7	Hazel	9
Willow (boughs)	8	Aſh	10
Elder	4	Spaniſh cheſnut	10
Plum tree	8	Smooth oak	10
Willow (trunk)	9	Oak cut in ſpring	10
Sycamore	6	Huntingdon or Leiceſter willow	10
Birch	4		
Cherry tree	8	Sumach	14

75
Benzoic acid,

6. Benzoic acid is diſtinguiſhed by its aromatic odour, and its votality on the application of a very moderate heat. It has been found hitherto only in three vegetable ſubſtances, to which the French chemiſts have confined the term *balſam*. Theſe three are, *benzoin*, *balſam of tolu*, and *ſtorax*. In theſe ſubſtances it ſeems to be combined with a reſin, or ſomething which has nearly the properties of a reſin.

7. Phoſ-

Alkalies.

76 Phoſphoric acid.

7. Phoſphoric acid is eaſily diſtinguiſhed from the former ſix, for it is very fixed, and a violent heat does not deſtroy it as it does the others.

Phoſphoric acid has been found in different plants, but only in very ſmall quantities; it is almoſt conſtantly combined with lime. Meyer found it in the leaves of many trees*; Thuren found phoſphat of lime in the Aconitus Napellus†; and Bergmann found it in all kinds of grain‡.

* Enc. Meth. Phyſiol. Veg. i. 100. † Ann. de Chim. ii. 8. ‡ Bergmann, 96.

SECT. XVI. *Of Alkalies.*

THE only alkalies found in plants are potaſs and ſoda. Ammonia may indeed be obtained by diſtilling many vegetable ſubſtances, but it is produced during the operation. One or other of theſe alkalies is found in every plant which has hitherto been examined. The quantity indeed is uſually very ſmall.

77 Proportion of potaſs in plants.

1. Potaſs is found in almoſt all plants which grow at a diſtance from the ſea. It may be extracted by burning the vegetable, waſhing the aſhes in water, filtrating the water, and evaporating it to dryneſs. It is in this manner that all the potaſh of commerce is procured.

The following table exhibits the quantity of aſhes and potaſs which may be extracted from 100 parts of various plants:

	Aſhes.	*Potaſs.*
Sallow	2.8	0.285*(c)
Elm	2.36727	0.39*
Oak	1.35185	0.15343
Poplar	1.23476	0.07481

In general, three times as much aſhes are obtained from ſhrubs, and five times as much from herbs, as from trees. Equal weights of the branches of trees produce more aſhes than the trunk, and the leaves more than the branches. Herbs arrived at maturity produce more aſhes than at any other time. Green vegetables produce more aſhes than dry†.

† Ann. de Chim. xix. 4.

The ſalt which is obtained from plants does not conſiſt wholly of potaſs, there are other ſalts mixed with it; theſe uſually are ſulphat of potaſs, muriat of potaſs, ſulphat of lime, phoſphat of lime, &c.; but theſe bear, in general, but a ſmall proportion to the potaſs. The aſhes conſiſt of potaſs mixed with earths.

Some judgment may be formed of the quantity of potaſs which a plant contains from the quantity of aſhes which it yields: but the above table is ſufficient to ſhew us, that were we to truſt to that we would often be miſled.

Earths.

78 Soda.

2. Soda is found in almoſt all the plants which grow in the ſea, and in many of thoſe which grow on the ſhore. In general, the quantity of ſoda which plants contain bears a much greater proportion to their weight than the potaſs does which is found in inland vegetables. 100 parts of the *ſalſola ſoda*, for inſtance, yield 19.921 of aſhes; and theſe contain 1.992 parts of ſoda, ſome of which, however, is combined with muriatic acid*. The plants from which the greater part of the ſoda, or *barilha*, as it is called, which is imported from Spain, is extracted, are the *ſalſola ſativa*, and *vermiculata*.

* Vauquelin, Ann. de Chim. xviii. 77.

SECT. XVII. *Of Earths.*

THE only earths hitherto found in plants are the four following; *lime, ſilica, magneſia, alumina.*

79 Lime.

1. Lime is uſually the moſt abundant of the earths of plants, and the moſt generally diffuſed over the vegetable kingdom. Indeed, it is a very uncommon thing to find a plant entirely deſtitute of lime: ſalſola ſoda is almoſt the only one in which we know for certain that this earth does not exiſt*.

* Id. ibid.

80 Silica.

2. Silica exiſts alſo in many plants, particularly graſſes and equiſetums. Mr Davy has aſcertained, that it forms a part of the epidermis, or outermoſt bark of theſe plants; and that in ſome of them almoſt the whole epidermis is ſilica.

		Parts Silica.
100 parts of the epid. of	bonnet-cane yielded	90
	bamboo	71.4
(arundo phragm.)	common reed	48.1
	ſtalks of corn	6.5

The concretions which are ſometimes found in the bamboo cane have been aſcertained by Mr Macie to be compoſed of pure ſilica.

81 Magneſia.

3. Magneſia does not exiſt ſo generally in the vegetable kingdom as the two preceding earths. It has been found, however, in conſiderable quantities in ſeveral ſea plants, eſpecially fuci†. But the ſalſola ſoda contains a greater proportion of magneſia than any plant hitherto examined. Mr Vauquelin found that 100 parts of it contained 17.929 of that earth‡.

† Id. ibid. 80. and ix. 94. ‡ Ibid. 78.

82 Alumina.

4. Alumina has only been found in very ſmall quantities in plants.

83 Proportion of earths in plants.

The following table will ſhew the quantity of theſe four earths which exiſt in ſeveral vegetables.

100 parts of oak contain of earths	1.03*
Beech	0.453†
Fir	0.003†

Metals.

This table ſhews us, that the quantity of earth is greater in herbs than in trees.

Bergman found all the four earths in every kind of grain which he analyſed *.

* Opuſc. v. 94.

Vauquelin found, that 100 parts of oat grain left 3 1591 of reſiduum. This reſiduum is compoſed of

60.7 ſilica,
39.3 phoſphat.

———

100.0 †.

† Ann. de Chim. xxix. 17.

When the whole of the avena ſativa, however, ſtalk and ſeed together, are burnt, they leave a reſiduum compoſed of

55 ſilica,
15 phoſphat of lime,
20 potaſs,
5 carbonat of lime.

———

95, and a little oxide of iron ‡.

‡ Ibid. 19.

This ſhews us that the ſtalk contains ſeveral ſubſtances not to be found in the grain.

SECT. XVIII. *Of Metals.*

SEVERAL metallic ſubſtances have alſo been found in vegetables, but their quantity is exceedingly ſmall; ſo ſmall, indeed, that without very delicate experiments their preſence cannot even be detected.

84 Three metals found in plants.

The metals hitherto diſcovered are iron, which is by far the moſt common, mangane$ſ$e, and gold.

Scheele firſt detected mangane$ſ$e in vegetables *. Prouſt found it in the aſhes of the pine, calendula, vine, green oak, and fig-tree †. M. Sage has ſhewn, that gold exiſts in many plants. Iron exiſts in moſt plants. The aſhes of ſome ſpecies of ſalſola contain a conſiderable quantity of it.

* Opuſc. i. 106.
† Phil. Mag. v. 99.

WE have now taken a ſurvey of all the ſubſtances which have hitherto been obtained from vegetables; by analyſing each of theſe, we come at laſt to thoſe bodies which we are at preſent obliged to conſider as ſimple, becauſe they have not yet been decompoſed, and of which accordingly we muſt ſuppoſe that vegetables are ultimately compoſed. Theſe bodies amount to 16, namely,

85 Simple ſubſtances contained in plants.

1. Oxygen,	9. Gold,
2. Sulphur,	10. Lime,
3. Phoſphorus	11. Magneſia,
4. Carbon,	12. Silica,
5. Hydrogen,	13. Alumina,
6. Azot,	14. Potaſs,
7. Iron,	15. Soda,
8. Mangane$ſ$e,	16. Muriatic acid.

But of theſe ſubſtances there are twelve which compoſe but a very ſmall proportion indeed of vegetables. Almoſt the whole of vegetable ſubſtances are compoſed of four ingredients, namely,

Carbon, Oxygen,
Hydrogen, Azot.

Of theſe the laſt, namely azot, forms but a ſmall proportion even of thoſe vegetable ſubſtances of which it is a conſtituent part, while into many it does not enter at all: So that, upon the whole, by far the greater part of vegetable ſubſtances is compoſed of carbon, hydrogen, and oxygen. We do not mention caloric and light, concerning the nature of which too little is known to enable us to determine with certainty into what ſubſtances they enter.

Vegetation.

The ſubſtances at preſent known to chemiſts, which they have not been hitherto able to decompoſe, amount (omitting caloric and light) to 40. Sixteen of theſe exiſt in plants; the other 24 belong excluſively to the mineral kingdom: for it is a fact, that no ſubſtance (we mean ſimple ſubſtance) has been hitherto found in the animal kingdom which does not exiſt alſo in vegetables.

On the contrary, all the ſimple ſubſtances at preſent known may be found in minerals. This indeed ought not to ſurpriſe us, if we recollect, that the ſpoils of animals and vegetables, after they have undergone decompoſition, are ultimately confounded with minerals, and conſequently arranged under the mineral kingdom. Beſides, as vegetables draw all their food from the mineral kingdom, it would be abſurd to ſuppoſe that they contain ſubſtances which they could not have procured from minerals. It muſt follow, therefore, of neceſſity, that minerals contain all the ſimple ſubſtances which exiſt in this globe of our's; and that plants owe their diverſity merely to different modifications of thoſe principles which they imbibe from the ſoil. But it is impoſſible to have any preciſe notions about a ſubject ſo intricate, without conſidering with ſome attention the ſtructure of vegetables, the food which they imbibe, and the changes which they produce on that food. Theſe enquiries ſhall form the ſubject of the next chapter; in which we propoſe to take a view of thoſe phenomena of vegetation which are connected with chemiſtry, or which may be elucidated by the application of the principles of that ſcience.

CHAP. II. OF VEGETATION.

WE have now ſeen the different ſubſtances which are contained in plants; but we have ſtill to examine the manner in which theſe ſubſtances are produced, and to endeavour to trace the different proceſſes which conſtitute vegetation. We muſt warn our readers not to expect complete information in this chapter. The wonders of the vegetable kingdom are ſtill but very imperfectly explored; many of the organs of plants are too minute for our ſenſes; and ſcarcely a ſingle proceſs can be completely traced.

86 Phenomena of vegetation very numerous.

The multiplicity of operations continually going on in vegetables at the ſame time, and the variety of different, and even oppoſite ſubſtances, formed out of the ſame ingredients, and almoſt in the ſame place, aſtoniſh and confound us. The order, too, and the ſkill with which every thing is conducted, are no leſs ſurpriſing. No two operations claſh; there is no diſcord, no irregularity, no diſturbance; every object is gained, and every thing is ready for its intended purpoſe. This is too wonderful to eſcape our obſervation, and of too much importance not to claim our attention. Many philoſophers, accordingly, diſtinguiſhed equally by their induſtry and ſegacity, have dedicated a great part of their lives to the ſtudy of *vegetation*. But hitherto their ſucceſs has not been equal to their exertions. No perſon has been able to detect this *agent*, always ſo buſy, and performing ſuch wonders, or to diſcover him at his work; nor have philoſophers been much more fortunate

Vegetation.

nate in their attempts to aſcertain the inſtruments which he employs in his operations. A great variety, however, of curious and intereſting facts, have been diſcovered. Theſe we ſhall attempt in this chapter to collect and arrange, to point out their dependence on each other, and perhaps to deduce ſuch conſequences as obviouſly reſult from their mutual dependence.

87 Plants ariſe from ſeed.

1. Natural hiſtorians have proved, by a very complete induction of facts, that all plants ariſe from *ſeeds*. The pretended exceptions have diſappeared, one after another, as our knowledge of vegetables increaſed: and now there remains ſcarcely a ſingle objection entitled to the ſmalleſt regard. The late attempt of Girtanner * to revive the doctrine of equivocal generation, deſerves no attention whatever; becauſe his concluſions are abſolutely incompatible with the *experiments* of Mr Senebier upon the very ſubſtance on which his theory is founded.

* Ann. de Chim. xxxiv. 5.

88 Seeds compoſed of three parts.

A SEED conſiſts of three parts; namely, the *cotyledons*, the *radicle*, and the *plumula*, which are uſually incloſed in a cover.

If we take a garden bean, we may perceive each of theſe three parts with great eaſe; for this ſeed is of ſo large a ſize, that all its organs are exceedingly diſtinct.

When we ſtrip off the external coats of the bean, which are two, and of different degrees of thickneſs in different parts, we find that it eaſily divides into two lobes, pretty nearly of the ſame ſize and figure. Each of theſe lobes is called a *cotyledon* (fig. 1. *a*). The cotyledons of the bean, then, are two in number.

Plate XLIII.

Near that part of the lobes which is contiguous to what is called the *eye* of the bean, there is a ſmall round white body (*b*), which comes out between the two lobes. This body is called the *radicle*.

Attached to the radicle, there is another ſmall round body (*c*), which lies between the cotyledons and wholly within them, ſo that it cannot be ſeen till they are ſeparated from each other. This body is called the *plumula*.

The appearance and ſhape of theſe three parts differ very much in different ſeeds, but there is no ſeed which wants them. The figure and ſize of the ſeed depend chiefly upon the cotyledons. This is evidently the caſe with the bean, and it is ſo with all other ſeeds. The number of cotyledons is different in different ſeeds. Some ſeeds have only one cotyledon, as the ſeeds of wheat, oats, barley, and the whole tribe of graſſes: ſome have three; others ſix, as the ſeeds of the garden graſs; but moſt ſeeds, like the bean, have two cotyledons.

89 Germination of ſeeds.

2. When a ſeed is placed in a ſituation favourable to vegetation, it very ſoon changes its appearance. The radicle is converted into a root, and ſinks into the earth; the plumula, on the other hand, riſes above the earth, and becomes the trunk or ſtem. When theſe changes take place, the ſeed is ſaid to *germinate*: the proceſs itſelf has been called *germination*. Seeds do not germinate equally and indifferently in all places and ſeaſons. Germination, therefore, is a proceſs which does not depend upon the ſeed alone; ſomething external muſt alſo affect it.

90 Requires moiſture,

3. It is a well known fact, that ſeeds will not germinate unleſs *moiſture* have acceſs to them; for ſeeds, if they are kept perfectly dry, never vegetate at all, and yet their power of vegetating is not deſtroyed. There are indeed ſome apparent objections to this; potatoes, for inſtance, and other bulbous bodies, germinate, tho' kept ever ſo dry. But the reaſon of this is, that theſe bodies (which are not ſeeds, though they reſemble them in ſome particulars) have a ſufficient quantity of water within themſelves to give a beginning to germination. We may conclude, then, that no ſeed will germinate unleſs water has acceſs to it. *Water*, then, is eſſential to germination. Too much water, however, is no leſs prejudicial to moſt ſeeds than none at all. The ſeeds of water plants, indeed, germinate and vegetate extremely well in water; but moſt other ſeeds, if they are kept in water beyond a certain time, are rotted and deſtroyed altogether.

91 Heat,

4. It is well known alſo, that ſeeds will not germinate, even though ſupplied with water, provided the temperature be below a certain degree. No ſeed, for inſtance, on which the experiment has been tried, can be made to vegetate at or below the freezing point: yet this degree of cold does not injure the vegetating power of ſeeds; for many ſeeds will vegetate, as well as ever, after having been frozen, or after having been kept in frozen water. We may conclude, then, that a certain degree of heat is neceſſary for the germination of ſeeds. And every ſpecies of plants ſeems to have a degree peculiar to itſelf, at which its ſeeds begin to germinate; for we find that almoſt every ſeed has a peculiar ſeaſon at which it begins to germinate, and this ſeaſon varies always according to the temperature of the air. Mr Adanſon found that ſeeds, when ſown at the ſame time in France and in Senegal, always appeared ſooner above ground in the latter country, where the climate is hotter, than in France §.

§ Enc. Meth. Phyſiol. Veget. 124.

92 And oxygen gas.

5. Seeds, although ſupplied with moiſture, and placed in a proper temperature, will not germinate, provided atmoſpherical air be completely excluded from them. Mr Ray found that grains of lettuce did not germinate in the vacuum of an air-pump, but they began to grow as ſoon as air was admitted to them †. Homberg made a number of experiments on the ſame ſubject, which were publiſhed in the Memoirs of the French Academy for the year 1693. He found, that the greater number of ſeeds which he tried refuſed to vegetate in the vacuum of an air-pump. Some, however, did germinate; but Boyle, Muſchenbroek, and Boerhaave, who made experiments on the ſame ſubject in ſucceſſion, proved beyond a doubt that no plant vegetates in the vacuum of an air-pump; and that in thoſe caſes in which Homberg's ſeeds germinated, the vacuum was far from perfect, a quantity of air ſtill remaining in the receiver. It follows, therefore, that no ſeed will germinate unleſs atmoſpherical air, or ſome air having the ſame properties, have acceſs to it. It is for this reaſon that ſeeds will not germinate at a certain depth below the ſurface of the earth.

† Phil. Tranſ. No 53.

Mr Scheele found that beans would not germinate except oxygen gas were preſent; Mr Achard afterwards proved, that oxygen gas is abſolutely neceſſary for the germination of all ſeeds, and that no ſeed will germinate in azotic gas, or hydrogen gas, or carbonic acid gas, unleſs theſe gaſes contain a mixture of oxygen gas. Theſe experiments have been confirmed by Mr

Vegetation.

Mr Gough, Mr Cruickſhank, and many other philoſophers. It follows, therefore, that it is not the whole atmoſpheric air, but merely the oxygen gas which it contains, that is neceſſary for the germination of ſeeds.

93 Injured by the preſence of light.

6. Seeds do not germinate equally well when they are expoſed to the light, and when they are kept in a dark place; light therefore has ſome effect on germination.

Mr Ingenhouſz found, that ſeeds always germinate faſter in the dark than when expoſed to the light *. His experiments were repeated by Mr Senebier with equal ſucceſs †; and it was concluded, in conſequence of their experiments, that light is injurious to germination. But the Abbé Bertholin, who diſtinguiſhed himſelf ſo much by his labours to demonſtrate the effect of electricity on vegetation, objected to the concluſions of theſe philoſophers, and affirmed that the difference in the germination of ſeeds in the ſhade and in the light was owing, not to the light itſelf, but to the difference of the moiſture in the two ſituations; the moiſture evaporating much faſter from the ſeeds in the light than from thoſe in the ſhade; and he affirmed, that when precautions were taken to keep the ſeeds equally moiſt, thoſe in the ſun germinated ſooner than thoſe in the ſhade ‡. But when Mr Senebier repeated his former experiments, and employed every poſſible precaution to enſure the equality of moiſture in both ſituations, he conſtantly found the ſeeds in the ſhade germinate ſooner than thoſe in the light §. We may conclude, therefore, that light is injurious to germination; and hence one reaſon for covering ſeeds with the ſoil in which they are to grow.

* *Experience ſur les Vegetaux*, ii

† *Mem. Phyſico-chimique*, iii. 341.

‡ *Jour. de Phyſ.* 1789, Decemb.

§ *Enc. Meth. Phyſiol. Veget.* 126.

7. Thus we have ſeen that ſeeds will not germinate unleſs *moiſture*, *heat*, and *oxygen gas*, be preſent; and that they do not germinate well if they are expoſed to the action of *light*. Now, in what manner do theſe ſubſtances affect the ſeed? What are the changes which they produce?

94 Phenomena of germination.

We obſerved before, that all ſeeds have one or more cotyledons. Theſe cotyledons contain a quantity of farinaceous matter, laid up on purpoſe to ſupply the embryo plant with food as ſoon as it begins to require it. This food, however, muſt undergo ſome previous preparation, before it can be applied by the plant to the formation or completion of its organs. Now all the phenomena of germination, which we can perceive, conſiſt in the chemical changes which are produced in that food, and the conſequent developement of the organs of the plant.

95 The cotyledons prepare food,

When a ſeed is placed in favourable circumſtances, it gradually imbibes moiſture, and very ſoon after emits a quantity of carbonic acid gas, even though no oxygen gas be preſent *. This ſeems to prove, as Mr Cruickſhank has ſuppoſed, that ſome of the water imbibed by the ſeed is decompoſed, that its oxygen combines with part of the carbon of the farina, and goes off in the form of carbonic acid gas, while the hydrogen remains behind, and combines with the ingredients contained in the cotyledon. The firſt part of germination, then, conſiſts in diminiſhing the quantity of carbon, and increaſing the hydrogen of the farina. If no oxygen gas be preſent, the proceſs ſtops here, and no germination takes place.

* *Gough, Manch. Mem.* iv. 315. *Cruickſhank, Rollo on Diabetes*, p. 452.

But if oxygen gas be preſent, it is gradually abſorbed and retained by the ſeed; and at the ſame time, the farina of the cotyledons aſſumes a ſweet taſte reſembling ſugar: it is therefore converted into ſugar, or ſome ſubſtance analogous to it *. Farina, then, is changed into ſugar, by diminiſhing its carbon, and augmenting the proportion of its hydrogen and oxygen. This is preciſely the proceſs of malting, or of converting grain into malt; during which it is well known that there is a conſiderable heat evolved; ſo much indeed, that in certain circumſtances grain improperly kept has even taken fire. We may conclude from this, that during the germination of ſeeds in the earth there is alſo an evolution of a conſiderable portion of heat. This indeed might have been expected, as it uſually happens when oxygen gas is abſorbed.

* *Ibid.*

So far ſeems to be the work of chemiſtry alone; at leaſt we have no right to conclude that any other agent interferes; ſince *hay*, when it happens to imbibe moiſture, exhibits nearly the ſame proceſſes. Carbonic acid gas is evolved, oxygen gas is abſorbed, heat is produced ſo abundantly, that the hay often takes fire: at the ſame time a quantity of ſugar is formed. It is owing to a partial change of the ſame kind that old hay generally taſtes much ſweeter than new hay. Now we have no reaſon to ſuppoſe that any agents peculiar to the vegetable kingdom reſide in hay; as all vegetation, and all power of vegetating, are evidently deſtroyed.

96 Which paſſes into the radicle,

But when the farina in the ſeeds of vegetables is converted into ſugar, a number of veſſels make their appearance in the cotyledon. The reader will have a pretty diſtinct notion of their diſtribution, by inſpecting fig. 2. Theſe veſſels may indeed be detected in many ſeeds before germination commences, but they become much more diſtinct after it has made ſome progreſs. Branches from them have been demonſtrated by Grew, Malpighi, and Hedwig, paſſing into the radicle, and diſtributed through every part of it. Theſe evidently carry the nouriſhment prepared in the cotyledons to the radicle; for if the cotyledons be cut off even after the proceſſes above deſcribed are completed, germination, as Bonnet and Senebier aſcertained by experiment, immediately ſtops. The food therefore is conveyed from the cotyledons into the radicle, the radicle increaſes in ſize, aſſumes the form of a *root*, ſinks down into the earth, and ſoon becomes capable of extracting the nouriſhment neceſſary for the future growth of the plant. Even at this period, after the radicle has become a perfect root, the plant, as Senebier aſcertained by experiment, ceaſes to vegetate if the *cotyledons* be cut off. They are ſtill then abſolutely neceſſary for the vegetation of the plant.

97 And converts it into a root.

98 Cotyledons become ſeminal leaves.

The cotyledons now aſſume the appearance of leaves, and appear above the ground, forming what are called the *ſeminal leaves* of the plant. After this the *plumula* gradually increaſes in ſize, riſes out of the earth, and expands itſelf into branches and leaves. The ſeminal leaves, ſoon after this, decay and drop off, and the plant carries on all the proceſſes of vegetation without their aſſiſtance.

Mr Eller attempted to ſhew, that there is a veſſel in ſeeds which paſſes from the cotyledons to the plumula; but later anatomiſts have not been able to perceive any ſuch veſſel. Even Mr Hedwig, one of the moſt patient, acute, and ſucceſsful philoſophers that ever turned their attention to the ſtructure of vegetables, could never

Vegetation.

never discover any such vessel, although he traced the vessels of the cotyledons even through the radicle. As it does not appear, then, that there is any communication between the cotyledons and the plumula, it must follow that the nourishment passes into the plumula from the radicle: and accordingly we see, that the plumula does not begin to vegetate till the radicle has made some progress. Since the plant ceases to vegetate, even after the radicle has been converted into a root, if the cotyledons be removed before the plumula is developed, it follows, that the radicle is insufficient of itself to carry on the processes of vegetation, and that the cotyledons still continue to perform a part. Now we have seen already what that part is: they prepare *food* for the nourishment of the plant. The root, then, is of itself insufficient for this purpose. When the cotyledons assume the form of seminal leaves, it is evident that the nourishment which was originally laid up in them for the support of the embryo plant is exhausted, yet they still continue as necessary as ever. They must therefore receive the nourishment which is imbibed by the root; they must produce some changes on it, render it suitable for the purposes of vegetation, and then send it back again to be transmitted to the plumula.

99 Which prepare the food sent from the root.

After the plumula has acquired a certain size, which must be at least a *line*, if the cotyledons be cut off, the plant, as Mr Bonnet ascertained by a number of experiments, afterwards repeated with equal success by Mr Senebier, does not cease to vegetate, but it continues always a mere pigmy: its size, when compared with that of a plant whose cotyledons are allowed to remain, being only as 2 to 7 *.

* *Enc. Meth. Physiol. Veget.* 41

When the plumula has expanded completely into leaves, the cotyledons may be removed without injuring the plant, and they very soon decay of themselves. It appears, then, that this new office of the cotyledons is afterwards performed by that part of the plant which is above ground.

100 Plumula forms the stem and leaves.

Thus we have traced the phenomena of germination as far as they have been detected. The facts are obvious; but the *manner* in which they are produced is a profound secret. We can neither explain how the food enters into the vessels, how it is conveyed to the different parts of the plant, how it is deposited in every organ, nor how it is employed to increase the size of the old parts, or to form new parts. These phenomena are analogous to nothing in mechanics or chemistry. He that attempts to explain them on the principles of these sciences, merely substitutes new meanings of words instead of old ones, and gives us no assistance whatever in conceiving the processes themselves. As the substances employed in vegetation are all material, it is evident that they possess the properties of matter, and that they are arranged in the plant according to these laws. It follows, therefore, that all the changes which take place in the plant are produced according to the known laws of mechanics and chemistry. This cannot be disputed: but it explains nothing; for what we want to know is the *agent* that brings every particle of matter to its proper place, and enables the laws of chemistry and mechanics to act only in order to accomplish a certain end. Who is the agent that acts according to this end? To say that it is chemistry or mechanics, is to pervert the use of words. For what are the laws of chemistry and mechanics? Are they not certain fixed and unalterable properties of matter? Now, to say that a property of matter has an end in view, or that it acts in order to accomplish some design, is a downright absurdity. There must therefore be some agent in all cases of germination, which regulates and directs the mechanical and chemical processes, and which therefore is neither a mechanical nor chemical property.

8. When the process of germination is accomplished, the plant is complete in all its parts, and capable of vegetating in a proper soil, for a time and with a vigour proportional to its nature. 101

Plants composed of bark, wood, and pith.

Plants, as every body knows, are very various, and of course the structure of each species must have many peculiarities. Trees have principally engaged the attention of anatomists, on account of their size and the distinctness which they expected to find in their parts. We shall therefore take a tree as an instance of the structure of plants; and we shall do it the more readily, as the greater number of vegetables are provided with analogous organs, dedicated to similar uses.

A TREE is composed of a *root*, a *trunk*, and *branches*; the structure of each of which is so similar, that a general description of their component parts will be sufficient. Each of them consists of three parts, the *bark*, the *wood*, and the *pith*. 102

Bark.

The BARK is the outermost part of the tree. It covers the whole plant from the extremity of the roots to the extremity of the branches. It is usually of a green colour: if a branch of a tree be cut across, the bark is easily distinguished from the rest of the branch by this colour. If we inspect such a horizontal section with attention, we shall perceive that the bark itself is composed of three distinct bodies, which, with a little care, may be separated from each other. The outermost of these bodies is called the *epidermis*, the middlemost is called the *parenchyma*, and the innermost, or that next the wood, is called the *cortical layers*. 103

Composed of epidermis,

The *epidermis* is a thin transparent membrane, which covers all the outside of the bark. It is pretty tough. When inspected with a microscope, it appears to be composed of a number of slender fibres crossing each other, and forming a kind of network. It seems even to consist of different thin retiform membranes, adhering closely together. This, at least, is the case with the epidermis of the birch, which Mr Duhamel separated into six layers. The epidermis, when rubbed off, is reproduced. In old trees it cracks and decays, and new epidermes are successively formed. This is the reason that the trunks of many old trees have a rough surface. 104

Parenchyma,

The *parenchyma* lies immediately below the epidermis; it is of a deep green colour, very tender, and succulent. When viewed with a microscope, it seems to be composed of fibres which cross each other in every direction, like the fibres which compose a hat. Both in it and the epidermis there are numberless interstices, which have been compared to so many small bladders. 105

And cortical layers.

The *cortical layers* form the innermost part of the bark, or that which is next to the wood. They consist of several thin membranes, lying the one above the other; and their number appears to increase with the age of the plant. Each of these layers is composed of longitudinal fibres, which separate and approach each other alternately, so as to form a kind of network. The meshes of this network correspond in each of the layers;

Vegetation.

ers; and they become smaller and smaller in every layer as it approaches the wood. These meshes are filled with a green coloured cellular substance, which has been compared by anatomists to a number of bladders adhering together, and communicating with each other.

106 Wood composed of

The WOOD lies immediately under the bark, and forms by far the greatest part of the trunk and large branches of trees. It consists of concentric layers, the number of which increases with the age of the part. Each of these layers, as Mr Du Hamel ascertained, may be separated into several thinner layers, and these are composed chiefly of longitudinal fibres. Hence the reason that wood may be much more easily split asunder than cut across.

The *wood*, when we inspect it with attention, is not, through its whole extent, the same; the part of it next the bark is much softer and whiter, and more juicy than the rest, and has for that reason obtained a particular name: it has been called the *alburnum* or *aubier*.

107 Alburnum and perfect wood,

The *perfect wood* is browner, and harder, and denser, than the alburnum, and the layers increase in density the nearer they are to the centre. Sir John Hill gave to the innermost layer of wood the name of *corona*, or rather he gave this name to a thin zone which, according to him, lies between the wood and the pith.

108 Pith,

The PITH occupies the centre of the wood. It is a very spongy body, containing a prodigious number of cells, which anatomists have compared to bladders. In young shoots it is very succulent; but it becomes dry as the plant advances, and at last in the large trunks of many trees disappears altogether.

109 Leaves.

The LEAVES are attached to the branches of plants by short footstalks. From these footstalks a number of fibres issue, which ramify and communicate with each other in every part of the leaf, and form a very curious network. These fibres may be obtained separately, by keeping the leaf long in moisture. Every other part of it putrefies and falls off, or may easily be rubbed off, and only the fibres remain, constituting a skeleton of the leaf. In every leaf there are two layers of these fibres, forming two distinct skeletons, which had constituted the upper and under surface of the leaf.

The whole leaf is covered with the epidermis of the plant; and this epidermis, as Saussure has shewn, contains in it a great number of glands. The other parts of the bark may also be traced on many leaves; at least Saussure has shewn, that the *bark* of leaves is composed of two different layers. The interstices between the fibres of the leaf are filled up by a pulpy-like substance, to which the green colour of the leaf is owing.

Such is a short description of the most conspicuous parts of plants. A more minute account would have been foreign to the subject of the present article.

110 Plants increase in size.

9. Plants, after they have germinated, do not remain stationary, but are continually increasing in size. A tree, for instance, every season, adds considerably to its former bulk. The root sends forth new shoots, and the old ones become larger and thicker. The same increment takes place in the branches and the trunk. When we examine this increase more minutely, we find that a new layer of wood, or rather of alburnum, has been added to the tree in every part, and this addition has been made just under the bark. We find, too, that a layer of alburnum has assumed the appearance of perfect wood. Besides this addition of vegetable fibre, a great number of leaves have been produced; and the tree puts forth flowers, and forms seeds.

111 Therefore require food.

It is evident from all this, that a great deal of new matter is continually making its appearance in plants. Hence, since it would be absurd to suppose that they *create* new matter, it must follow that they receive it by some channel or other. Plants, then, require food as well as animals. Now, what is this food, and whence do they derive it? These questions can only be answered by an attentive survey of the substances which are contained in vegetables, and an examination of those substances which are necessary for their vegetation. If we could succeed completely, it would throw a great deal of light upon the nature of soils and of manures, and on some of the most important questions on agriculture. But we are far indeed at present from being able to examine the subject to the bottom.

112 Water necessary.

10. In the first place, it is certain that plants will not vegetate without water; for whenever they are deprived of it, they wither and die. Hence the well-known use of rains and dews, and the artificial watering of ground. We may conclude, then, that water is at least an essential part of the food of plants.

But many plants grow in pure water; and therefore it may be questioned whether water is not the only food of plants. This opinion was adopted very long ago, and numerous experiments have been made in order to demonstrate it. Indeed, it was the general opinion of the 17th century; and some of the most successful improvers of the physiology of plants, in the 18th century, have embraced it. The most zealous advocates for it were, Van Helmont, Boyle, Bonnet, Duhamel, and Tillet.

113 Supposed the whole food of plants;

Van Helmont planted a willow which weighed five pounds, in an earthen vessel filled with soil previously dried in an oven, and moistened with rain water. This vessel he sunk into the earth, and he watered his willow sometimes with rain, and sometimes with distilled water. After five years it weighed $169\frac{1}{4}$ lbs. and the earth in which it was planted, when again dried, was found to have lost only two ounces of its original weight. Here, it has been said, was an increase of 164 lb. and yet the only food of the willow was pure water; therefore it follows that pure water is sufficient to afford nourishment to plants. The insufficiency of this experiment to decide the question was first pointed out by Bergman in 1773 *. He shewed, from the experiments of Margraff, that the rain water employed by Van Helmont contained in it as much earth as could exist in the willow at the end of five years. For, according to the experiments of Margraff, 1 lb. of rain water contains 1 gr. of earth †. The growth of the willow, therefore, by no means proves that the earth which plants contain has been formed out of water. Besides, as Mr Kirwan has remarked ‡, the earthen vessel must have often absorbed moisture, from the surrounding earth, impregnated with whatever substance that earth contained; for unglazed earthen vessels, as Hales * and Tillet † have shewn, readily transmit moisture.

* *Opusc.* v. 92.

† *Opusc.* ii. 15. and 19.

‡ *Irish Transf.* v. 150.

* *Veget. Stat.* i. 5.

† *Mem. Par.* 1772. 298.

114 But without reason

Hence it is evident that no conclusion whatever can be drawn from this experiment; for all the substances which the willow contained, except water, may have been derived from the rain water, the earth in the pot, and the moisture imbibed from the surrounding soil.

The

Vegetation.

The experiments of Duhamel and Tillet are equally inconclusive; so that it is impossible from them to decide the question, Whether water be the sole nourishment of plants or not? We owe the solution of this difficulty to the experiments of Mr Hassenfratz, who pointed out the fallacy of those just mentioned.

He analysed the bulbous roots of hyacinths, in order to discover the quantity of water, carbon, and hydrogen, which they contained; and by repeating the analysis on a number of bulbs, he discovered how much of these ingredients was contained in a given weight of the bulb. He analysed also kidney beans and cress seeds in the same manner. Then he made a number of each of these vegetate in pure water, taking the precaution to weigh them beforehand, in order to ascertain the precise quantity of carbon which they contained. The plants being then placed, some within doors, and others in the open air, grew and flowered, but produced no seed. He afterwards dried them, collecting with care all their leaves and every other part which had dropt off during the course of the vegetation. On submitting each plant to a chemical analysis, he found that the quantity of carbon, which it contained, was somewhat less than the quantity which existed in the bulb or the seed from which the plant had sprung *.

* *Ann. de Chim.* xiii. 188.

Hence it follows irresistibly, that plants growing in pure water do not receive any increase of *carbon;* that the water merely serves as a vehicle for the carbonaceous matter already present, and diffuses it thro' the plant. Water, then, is not the sole food of plants; for all plants during vegetation receive an increase of carbonaceous matter, without which they cannot produce perfect seeds, nor even continue to vegetate beyond a certain time; and that time seems to be limited by the quantity of carbonaceous matter contained in the bulb or the seed from which they grow. For Duhamel found, that an oak which he had raised by water from an acorn, made less and less progress every year. We see, too, that those bulbous roots, such as hyacinths, tulips, &c. which are made to grow in water, unless they be planted in the earth every other year, refuse at last to flower, and even to vegetate; especially if they produce new bulbous roots annually, and the old ones decay.

115
A certain portion only proper.

So far, indeed, is water from being the sole food of plants, that in general only a certain proportion of it is serviceable, too much being equally prejudicial to them as too little. Some plants, it is true, grow constantly in water, and will not vegetate in any other situation; but the rest are entirely destroyed when kept immersed in that fluid beyond a certain time. Most plants require a certain degree of moisture, in order to vegetate well. This is one reason why different soils are required for different plants. Rice, for instance, requires a very wet soil: were we to sow it in the ground on which wheat grows luxuriously, it would not succeed; and wheat, on the contrary, would rot in the rice ground.

We should, therefore, in choosing a soil proper for the plants which we mean to raise, consider the quantity of moisture which is best adapted for them, and choose our soil accordingly. Now, the dryness or moisture of a soil depends upon two things; the nature and proportions of the earths which compose it, and the quantity of rain which falls upon it. Every soil contains at least three earths, silica, lime, and alumina, and sometimes also magnesia. The silica is always in the state of sand. Now soils retain moisture longer or shorter according to the proportions of these earths. Those which contain the greatest quantity of sand retain it the shortest, and those which contain the greatest quantity of alumina retain it longest. The first is a dry, the second a wet soil. Lime and magnesia are intermediate between these two extremes: they render a sandy soil more retentive of moisture, and diminish the wetness of a clayey soil. It is evident, therefore, that, by mixing together proper proportions of these four earths, we may form a soil of any degree of dryness and moisture that we please.

But whatever be the nature of the soil, its moisture must depend in general upon the quantity of rain which falls. If no rain at all fell, a soil, however retentive of moisture it be, must remain dry; and if rain were very frequently falling, the soil must be open indeed, if it be not constantly wet. The proportion of the different earths in a soil, therefore, must depend upon the quantity of rain which falls. In a rainy country, the soil ought to be open; in a dry country, it ought to be retentive of moisture. In the first, there ought to be a greater proportion of sand; in the second, of clay. 116

11. Almost all plants grow in the earth, and every soil contains at least silica, lime, alumina, and often magnesia. We have seen already, that one use of these earths is to administer the proper quantity of water to the vegetables which grow in the soil. But as all plants contain earths as a part of their ingredients, is it not probable that earths also serve as a food for plants? It has not yet indeed been shewn, that those plants which vegetate in pure water do not contain the usual quantity of earth; but as earths are absolutely necessary for the perfect vegetation of plants, as they are contained in all plants, and are even found in their juices, we can scarcely doubt that they are actually imbibed, though only in small quantities (D). 117

Earth necessary;

12. We have seen in the last chapter, that all plants contain various saline substances; and if we analyse the most fertile soils, and the richest manures, we never find them destitute of these substances. Hence it is probable that different salts enter as ingredients into the food of plants. It is probable also, that every plant absorbs particular kinds of salts. Thus sea plants yield soda by analysis, while inland plants furnish potass. The potass contained in plants has indeed been supposed to be the produce of vegetation; but this has not been proved in a satisfactory manner. We find potass in the very juices of plants, even more abundantly than in the vegetable fibres themselves. But this subject is still buried in obscurity; and indeed it is extremely difficult

And salts;

(D) Mr Tennant has ascertained, that magnesia, when uncombined with carbonic acid gas, is injurious to corn when employed as a manure; and that lime, which contains a mixture of magnesia, likewise injures corn.—See *Phil. Transf.* 1799, p. 2. This important fact demonstrates, that earths are not mere vehicles for conveying water to plants.

Vegetation.

ficult to make deciſive experiments, on account of the very ſmall quantity of potaſs which moſt plants contain.

The phoſphorus, too, and the iron, and other metals which are found in plants, are no doubt abſorbed by them as a part of their food. We may ſuppoſe alſo, that the ſulphuric and muriatic acids, and perhaps even the nitric acid, when found in plants, are imbibed by them along with the reſt of their aliment.

Nothing is at preſent known concerning thoſe ſaline ſubſtances which form an eſſential part of the food of plants; though it has been long remarked that certain ſalts are uſeful as manures.

118 And carbon,

13. Water, then, and earths, and perhaps alſo ſalts, form a part of the food of plants. But plants contain carbon, which cannot be derived from any of theſe ſubſtances; conſequently ſome ſubſtance or other beſides, which contains carbon, muſt conſtitute a part of the food of plants.

Mr Giobert mixed together the four earths, ſilica, alumina, lime, magneſia, in the proper proportions, to conſtitute a fertile ſoil; and after moiſtening them with water, planted ſeveral vegetables in them; but none of his plants grew well, till he moiſtened his artificial ſoil with water from a dunghill *. Now it is certain, from the experiments of Haſſenfratz, that this water contains carbon; for when evaporated, it conſtantly left behind it a reſiduum of charcoal †. We know likewiſe, from a great variety of experiments, that all fertile ſoils contain a conſiderable quantity of carbonaceous matter; for all of them, when expoſed to heat, are ſuſceptible of partial combuſtion, during which a quantity of carbonic acid gas eſcapes. Thus Fourcroy and Haſſenfratz found, that 9216 parts of fertile ſoil contained 305 parts of carbon, beſides 279 parts of oil; which, from the analyſis of Lavoiſier, we may ſuppoſe to contain about 220 parts of carbon. It follows, therefore, from the experiments of theſe chemiſts ‡, that 9216 parts of ſoil contain 525 parts of carbon. But theſe 9216 parts of ſoil contained 806 parts of roots of vegetables which were excluded from the analyſis; conſequently a fertile ſoil contains (excluſive of the roots of vegetables (about one-ſixteenth of its weight of carbon.

* *Encyc. Meth. Phyſ. Veget.* p. 275.

† *Ann. de Chim.* xiv. 56.

‡ *Encyc. Meth. Phyſ. Veget.* p. 277.

119 Which muſt be in a particular ſtate;

But the carbon muſt exiſt in the ſoil in a particular ſtate of combination, otherwiſe it does not anſwer as food for plants: For inſtance, powdered pitcoal, mixed with earths, is not found to act, at leaſt immediately, as a manure; yet pitcoal contains a very great quantity of carbon. Farther, it appears, from the experiments of Mr Haſſenfratz, that ſubſtances employed as manures produce effects in times proportioned to their degree of putrefaction; thoſe ſubſtances which are moſt putrid producing the moſt ſpeedy effects, and of courſe ſooneſt loſing their efficacy. Having manured two pieces of the ſame kind of ſoil, the one with a mixture of dung and ſtraw highly putrefied, the other with the ſame mixture newly made, and the ſtraw almoſt freſh, he obſerved that, during the firſt year, the plants which grew on the land manured with the putrefied dung produced a much better crop than the other; but the ſecond year (no new dung being added), the ground which had been manured with the unputrefied dung produced the beſt crop; the ſame thing took place the third year; after which, both ſeemed to be equally exhauſted *. Here it is evident that the putrefied dung acted ſooneſt, and was ſooneſt exhauſted. It follows from this, that carbon only acts as a manure when in a particular ſtate of combination; and this ſtate, whatever it may be, is evidently produced by putrefaction. Another experiment of the ſame chemiſt renders this truth ſtill more evident. He allowed ſhavings of wood to remain for about ten months in a moiſt place till they began to putrefy, and then ſpread them over a piece of ground by way of manure. The firſt two years this piece of ground produced nothing more than others which had not been manured at all; the third year is was better, the fourth year ſtill better, the fifth year it reached its maximum of fertility; after which it declined conſtantly till the ninth, when it was quite exhauſted †. Here the effect of the manure evidently depended upon its progreſs in putrefaction.

* *Ann. de Chim.* xiv. 57.

† *Ibid.* p. 58.

120 And ſoluble in water.

Now what is the particular ſtate into which carbon muſt be reduced before it be fit for the food of plants? This ſubject has never been examined with attention; the different combinations of carbon having been in a great meaſure overlooked. And yet it is evident, that it is only by an accurate examination of theſe combinations, and a thorough analyſis of manures, in order to diſcover what particular combinations of carbon exiſt in them, and in what the moſt efficacious manures differ from the reſt, that we can expect to throw complete light upon the nature and uſe of manures, one of the moſt important ſubjects to which the farmer can direct his attention. We know, from the experiments of Mr Haſſenfratz, that all thoſe manures which act with efficacy and celerity contain carbon in ſuch a ſtate of combination, that it is ſoluble in water, and that the efficacy of the manure is proportional to the quantity of carbon ſo ſoluble. He found that all efficacious manures gave a brown colour to water, and that the water ſo coloured, when evaporated, left a reſiduum, which conſiſted in a great meaſure of carbon *. He obſerved, too, that the ſoil which gives the deepeſt colour to water, or which contains the greateſt quantity of carbon ſoluble in water, is, other things being the ſame, the moſt fertile.

* *Ibid.* p. 56.

This is not, however, to be underſtood without limitation; for it is well known that if we employ exceſſive quantities of manure, we injure vegetation inſtead of promoting it. This is the reaſon that plants will not, as Mr Duhamel found by experiment, vegetate in ſaturated ſolutions of dung †.

† *Mem. Par.* 1748.

121 This ſtate not carbonic acid gas;

One of the combinations of carbon which is ſoluble in water, and with which we are beſt acquainted, is carbonic acid gas. It has been ſuppoſed by many philoſophers, particularly by Mr Senebier, that this gas, diſſolved in water, ſupplies plants with a great part of their carbon. But Mr Haſſenfratz, on making the experiment, found that the plants which he raiſed in water, impregnated with carbonic acid gas, differed in no reſpect from thoſe which grew in pure water, and did not contain a particle of carbon which had not exiſted in the ſeeds from which they ſprung ‡. This experiment proves, that carbonic acid gas, diſſolved in water, does not ſerve as food for plants. It appears, however, from the experiments of Ruckert, that when plants growing in ſoil are watered daily with water impregnated with carbonic acid gas, they vegetate faſter than when this watering is omitted. He planted two beans in

‡ *Ann. de Chim.* xiii. 320.

122 Though that gas is uſeful.

Vegetation.

in pots of equal dimenſions, filled with garden mould. One of theſe was watered almoſt daily with diſtilled water, the other with water, every ounce of which was impregnated with half a cubic inch of carbonic acid gas. Both were placed in the open air, but in a ſituation where they were ſecure from rain. The bean treated with the water impregnated with carbonic acid gas appeared above ground nine days before the other, and produced 25 beans; whereas the other produced only 15. The ſame experiment was tried on other plants with equal ſucceſs †. This ſhews us that carbonic acid gas is ſomehow or other uſeful to plants when they vegetate in mould; but it gives us no information about its mode of acting. Some ſoils, we know, are capable of decompoſing it; for ſome ſoils contain the green oxide of iron: and Gadolin has proved, that ſuch ſoils have the property of decompoſing carbonic acid gas *. Indeed almoſt all ſoils contain iron, either in the ſtate of the brown or the green oxide; and Beaumé has ſhewn, that oils convert the brown oxide of iron into the green †. Now dung contains a quantity of oily ſubſtance; and this is the caſe alſo with rich ſoils. One uſe of manures, therefore, may be, to reduce the brown oxide of iron to the green, that it may be capable of decompoſing carbonic acid gas; and the carbon, thus precipitated, doubtleſs enters into ſome new combination, in which ſtate it ſerves as food for plants.

Mr Humbolt has lately proved, that ſoils have the property of abſorbing oxygen. It can ſcarcely be doubted that this abſorption has an influence on vegetation, eſpecially as watering plants with weak ſolutions of oxy-muriatic acid accelerates vegetation *. But we know too little of the ſubject at preſent to be able to ſpecify preciſely what that influence is.

123 Food abſorbed by the roots.

14. Since the only part of plants which is contiguous to the ſoil is the root, and ſince the plant periſhes when the root is pulled out of the ground, it is evident that the food of plants muſt be imbibed by the roots.

When we examine the roots, we do not find them to contain any large opening. The paſſages by which the food enters are too ſmall for the naked eye. This ſhews us that the food can enter plants only in a fluid ſtate; and that conſequently every thing which can be rendered uſeful as food for plants muſt be previouſly in a ſtate of ſolution.

It ſeems moſt probable, that the whole, or the greateſt part of the food, enters at the extremities of the roots; for Duhamel obſerved, that the portion of the ſoil which is ſooneſt exhauſted, is preciſely that part in which the greateſt number of the extremities of roots lies ‡. This ſhews us the reaſon why the roots of plants are continually increaſing in length. By this means they are enabled, in ſome meaſure, to go in queſt of nouriſhment. The extremities of the roots ſeem to have a peculiar ſtructure adapted for the imbibing of moiſture. If we cut off the extremity of a root, it never increaſes any more in length: therefore its uſe as a root has been in a great meaſure deſtroyed. But it ſends out fibres from its ſides which act the part of roots, and imbibe food by their extremity. Nay, in ſome caſes, when the extremity of a root is cut off, the whole decays, and a new one is formed in its place. This, as Dr Bell informs us, is the caſe with the hyacinth †.

† Crell's Annals, 1788. ii. 399.

* Ibid. 1791, i. 53.

† Kirwan, Iriſh Tranſ. v. 156.

* Ingenhouſz.

‡ Phyſique des Arbres, ii. 239.

† Manch. Mem. ii. 112.

Since the food of plants muſt be in a fluid ſtate, and ſince no plant will live if it be deprived of moiſture, we may conclude that all its food is previouſly diſſolved in water. As for the carbon, we know, that in all active manures it is in ſuch a ſtate of combination, that it is ſoluble in water. We know, too, that all the ſalts which we can ſuppoſe to make a part of the food of plants, are more or leſs ſoluble in water. Lime alſo is ſoluble in water, whether it be pure or in the ſtate of a ſalt; magneſia and alumina may be rendered ſo by means of carbonic acid gas; and Bergman, Macie, and Klaproth, have ſhewn that even ſilica may be diſſolved in water. We can ſee, therefore, in general, though we have no preciſe notions of the very combinations which are immediately imbibed by plants, that all the ſubſtances which form eſſential parts of that food *may* be diſſolved in water.

124 Diſſolved in water.

125 Therefore fluid.

15. Since the food of plants is imbibed by their roots in a fluid ſtate, it muſt exiſt in plants in a fluid ſtate; and unleſs it undergoes alterations in its compoſition juſt when imbibed, we may expect to find it in the plant unaltered. If there were any method of obtaining this fluid food from plants before it has been altered by them, we might analyſe it, and obtain by that means a much more accurate knowledge of the food of plants than we can by any other method. This plan indeed muſt fail, provided the food undergoes alteration juſt when it is abſorbed by the roots: but if we conſider, that when one ſpecies of tree is grafted upon another, each bears its own peculiar fruit, and produces its own peculiar ſubſtances, we can ſcarcely avoid thinking that the *great* changes, at leaſt which the food undergoes after abſorption, are produced, not in the roots, but in other parts of the plant.

126 Sap of plants.

If this concluſion be juſt, the food of plants, after being imbibed by the roots, muſt go directly to thoſe organs where it is to receive new modifications, and to be rendered fit for being aſſimilated to the different parts of the plant. There ought therefore to be certain juices continually aſcending from the roots of plants; and theſe juices, if we could get them pure and unmixed with the other juices or fluids which the plant muſt contain, and which have been ſecreted and formed from theſe primary juices, would be, very nearly at leaſt, the food as it was imbibed by the plant. Now during the vegetation of plants, there actually is a *juice* continually aſcending from their roots. This juice has been called the *ſap*, the *ſuccus communis*, the *lymph* of plants. We ſhall adopt the firſt of theſe names, becauſe it has been moſt generally received.

The firſt ſtep towards an accurate knowledge of the food, and of the changes which take place during vegetation, is an analyſis of the ſap. The ſap is moſt abundant during the ſpring. At that ſeaſon, if a cut be made through the bark and part of the wood of ſome trees, the ſap flows out very profuſely. The trees are then ſaid to *bleed*. By this contrivance any quantity of ſap we think proper may be collected. It is not probable, indeed, that by this method we obtain the aſcending ſap in all its purity: it is no doubt mixed with the peculiar juices of the plant; but the leſs progreſs vegetation has made, the purer we may expect to find it; both becauſe the peculiar juices muſt be in much ſmaller quantity, and becauſe its quantity

may

Vegetation. may be fuppofed to be greater. We fhould therefore examine the fap as early in the feafon as poffible, and at all events before the leaves have expanded.

127 Analyfed. For the moft complete fet of experiments hitherto made upon the fap, we are indebted to Mr Vauquelin. An account of his experiments has been publifhed in the 31ft volume of the *Annales de Chimie*. He has neglected to inform us of the ftate of the tree when the fap which he analyfed was taken from it; fo that we are left in a ftate of uncertainty with refpect to the purity of the fap: but from the comparifon which he has put it in our power to draw between the ftate of the fap at different fucceffive periods, we may in fome meafure obviate this uncertainty.

He found that 1039 parts of the fap of the ulmus campeftris, or common elm, were compofed of

1027.567 water and volatile matter,
9.553 acetite of potafs,
1.062 vegetable matter,
0.818 carbonat of lime,

Befides fome flight traces of fulphuric and muriatic acids.

On analyfing the fame fap fomewhat later in the feafon, Mr Vauquelin found the quantity of vegetable matter a little increafed, and that of the carbonat of lime and acetite of potafs diminifhed. Still later in the feafon the vegetable matter was farther increafed, and the other two ingredients farther diminfhed. The acetite of potafs, in 1039 parts of this third fap, amounted to 8.615 parts *.

If thefe experiments warrant any confequence to be drawn from them, they would induce us to fuppofe that the carbonat of lime and acetite of potafs were contained in the pure afcending fap, and that part at leaft of the vegetable matter was derived from the peculiar juices altered by the fecreting organs of the plant; for the two falts diminifhed in quantity, and the vegetable matter increafed as the vegetation of the tree advanced. Now this is precifely what ought to have taken place, on the fuppofition that the fap became more and more mixed with the peculiar juices of the tree, as we are fuppofing it to do. If thefe conclufions have any folidity, it follows from them, that carbonat of lime and acetite of potafs are abforbed by plants as a part of their food. Now thefe falts, before they are abforbed, muft be diffolved in water. But the carbonat of lime may be diffolved in water by the help of carbonic acid. This fhews us how water faturated with carbonic acid may be ufeful to plants vegetating in a proper foil, while it is ufelefs to thofe that vegetate in pure water. In the pure water there is no carbonat of lime to be diffolved; and therefore carbonic acid gas cannot enter into a combination which renders it proper for becoming the food of plants. Part of the vegetable matter was precipitated from the fap by alcohol. This part feems to have been gummy. Now gums we know are produced by vegetation.

* *Ann. de Chim.* xxxi. 32.

The fap of the fagus fylvatica, or beech, contained the following ingredients.

Water,
Acetite of lime with excefs of acid,
Acetite of potafs,
Gallic acid,
Tan,
A mucous and extractive matter,
Acetite of alumina.

Although Mr Vauquelin made two different analyfes of this fap at different feafons, it is impoffible to draw any fatisfactory conclufions from them, as he has not given us the proportions of the ingredients. It feems clear that the gallic acid and tan were combined together; for the fap tafted like the infufion of oak bark. The quantity of each of thefe ingredients increafed as vegetation advanced; for the colour of the fecond fap collected later was much deeper than that of the firft. This fhews us that thefe ingredients were produced by vegetation, and that they did not form a part of the afcending fap. Probably they were derived from the bark of the tree. The prefence of alumina, and the abfence of carbonic acid gas, would feem to indicate that all plants do not imbibe the very fame food.

The fap of the capinus fylveftris contains water, acetite of potafs, acetite of lime, fugar, mucilage, vegetable extract. It cannot be doubted that the fugar and the mucilage are the produce of vegetation.

The fap of the betula alba, or common birch, contains water, fugar, vegetable extract, acetite of lime, acetite of alumina, and acetite of potafs.

Thefe experiments are curious, and certainly add to the precifion of our notions concerning the food of plants; but they are not decifive enough to entitle us to draw conclufions. They would feem to fhew, either that acetite of potafs and lime are a part of the food of plants, or at leaft fome fubftances which have the property of affuming thefe combinations.

16. Thefe experiments lead to the conclufion that acetous acid forms a component part of the fap. Now it is not eafy to fuppofe that this fubftance is actually abforbed by the roots in the ftate of acetous acid. The thing might be determined by examining the mould in which plants grow. This examination indeed has been performed; but no chemift has ever found acetous acid, at leaft in any fenfible quantity. Is it not probable, then, that the food, after it is imbibed, is fomewhat modified and altered by the roots? In what manner this is done we cannot fay, as we know very little about the vafcular ftructure of the roots. We may conclude, however, that this modification is nearly the fame in moft plants: for one plant may be engrafted on another, and each continue to produce its own peculiar products; which could not be, unlefs the proper fubftances were conveyed to the digeftive organs of all. There are feveral circumftances, however, which render the modifying power of the roots fomewhat probable. The ftrongeft of thefe is the nature of the ingredients found in the fap. It is even poffible that the roots may, by fome means or other, throw out again fome part of the food which they have imbibed as excrementitious. This has been fufpected by feveral phyfiologifts; and there are feveral circumftances which render it probable. It it well known that fome plants will not vegetate well after others; and that fome again vegetate unufually well when planted in ground where certain plants had been growing. Thefe facts, without doubt, may be accounted for on other principles. If there be any excrementitious matter emitted by the roots, it is much more probable that this happens in the laft ftage of vegetation. That is to fay, when the food, after digeftion, is applied to the purpofes which the root requires. But the fact ought to be fupported by experiments, otherwife it cannot be admitted.

128 Whether the food is altered by the roots.

17. The

Vegetation.

17. The ſap, as Dr Hales has ſhewn us, aſcends with a very conſiderable force. It iſſued during the bleeding ſeaſon with ſuch impetuoſity from the cut end of a vine branch, that it ſupported a column of mercury $32\frac{1}{2}$ inches high *.

* Veg. Stat. 105.

129
Sap aſcends

Now what is the particular channel through which the ſap aſcends, and what is the cauſe of the force with which it moves? Theſe are queſtions which have excited a great deal of the attention of thoſe philoſophers who have made the phyſiology of vegetables their particular ſtudy; but the examination of them is attended with ſo many difficulties that they are very far from being decided.

It is certain that the ſap flows from the roots towards the ſummit of the tree. For if in the bleeding ſeaſon a number of openings be made in the tree, the ſap begins firſt to flow from the loweſt opening, then from the loweſt but one, and ſo on ſucceſſively, till at laſt it makes its appearance at the higheſt of all. And when Duhamel and Bonnet made plants vegetate in coloured liquors, the colouring matter, which was depoſited in the wood, appeared firſt in the loweſt part of the tree, and gradually aſcended higher and higher, till at laſt it reached the top of the tree, and tinged the very leaves.

130
Through the wood.

It ſeems certain, too, that the ſap aſcends through the wood, and not through the bark of the tree: for a plant continues to grow even when ſtript of a great part of its bark; which could not happen if the ſap aſcended through the bark. When an inciſion, deep enough to penetrate the bark, and even part of the wood, is carried quite round a branch, provided the wound be covered up from the external air, the branch continues to vegetate as if nothing had happened; which could not be the caſe if the ſap aſcended between the bark and the wood. It is well known, too, that in the bleeding ſeaſon little or no ſap can be goot from a tree unleſs our inciſion penetrate deeper than the bark.

131
Not by the parenchyma;

If the ſap aſcended thro' the parenchyma of plants, as ſome phyſiologiſts have ſuppoſed, ſince there is a communication between every part of that organ, it is evident that the tree ought to bleed whenever any part of the parenchyma is wounded. But this is not the caſe. Conſequently the ſap does not aſcend through the parenchyma. Beſides, if the ſuppoſition were true, the ſap, from the very ſtructure of the parenchyma, muſt aſcend in the ſame manner as water through a ſponge; and in that caſe could not poſſibly poſſeſs the force with which we know that it aſcends. But if the ſap is not found in the parenchyma, as is now well known to be the caſe, it muſt, of neceſſity, be confined in particular veſſels; for if it were not, it would undoubtedly make its appearance there. Now what are the veſſels through which the ſap aſcends?

132
But in veſſels.

Grew and Malpighi, the firſt philoſophers who examined the ſtructure of plants, took it for granted that the woody fibres were tubes, and that the ſap aſcended through them. For this reaſon they gave theſe fibres the name of *lymphatic* veſſels. But they were unable, even when aſſiſted by the beſt microſcopes, to detect any thing in theſe fibres which had the appearance of a tube; and ſucceeding obſervers have been equally unſucceſsful. The conjecture therefore of Malpighi and Grew, about the nature and uſe of theſe fibres, remains totally unſupported by any proof. Duhamel has even gone far to overturn it altogether. For he found that theſe woody fibres are diviſible into ſmaller fibres, and theſe again into ſtill ſmaller; and even, by the aſſiſtance of the beſt microſcopes, he could find no end of this ſubdiviſion *. Now granting theſe fibres to be veſſels, it is ſcarcely poſſible, after this, to ſuppoſe that the ſap really moves through tubes, whoſe diameters are almoſt infinitely ſmall. There are, however, veſſels in plants which may eaſily be diſtinguiſhed by the help of a ſmall microſcope, and even, in many caſes, by the naked eye. Theſe were ſeen, and diſtinctly deſcribed, by Grew and Malpighi. They conſiſt of a fibre twiſted round like a corkſcrew. If we take a ſmall cylinder of wood, and wrap round it a ſlender braſs wire, ſo cloſely that all the rings of the wire touch each other, and if, after this, we pull out the wooden cylinder altogether, the braſs wire thus twiſted will give us a very good repreſentation of theſe veſſels. If we take hold of the two ends of the braſs wire thus twiſted, and pull them, we can eaſily draw out the wire to a conſiderable length. In the ſame manner, when we lay hold of the two extremities of theſe veſſels, we can draw them out to a great length. Malpighi and Grew finding them always empty, concluded that they were intended for the circulation of the air through the plant, and therefore gave them the name of *tracheæ*; which word is uſed to denote the *windpipe* of animals. Theſe *tracheæ* are not found in the bark; but Hedwig has ſhewn that they are much more numerous in the wood than was ſuppoſed; and that they are of very different diameters; and Reichel has demonſtrated that they go to the minuteſt branches, and ſpread through every leaf. He has ſhewn, too, that they contain ſap; and Hedwig has proved that the notion which generally prevailed of their containing nothing but air, aroſe from this circumſtance, that the larger tracheæ, which alone were attended to, loſe their ſap as ſoon as they are cut; and, of courſe, unleſs they are inſpected the inſtant they are divided, they appear empty †. Is it not probable, then, or rather is it not certain, from the diſcoveries of that very ingenious phyſiologiſt, that the tracheæ are, in reality, the ſap veſſels of plants? Indeed it ſeems eſtabliſhed by the experiments both of Reichel and Hedwig, that all, or almoſt all the veſſels of plants may, if we attend only to their ſtructure, be denominated *tracheæ*.

* *Phyſique des Arbres*, i. 57.

† *Fundament. Hiſt. Nat. Muſcor. Frondos.* Part i. p. 54.

133
Why it aſcends.

But by what powers is the ſap made to aſcend in theſe veſſels? And not only to aſcend, but to move with very conſiderable force; a force, as Hales has ſhewn, ſufficient to overcome the preſſure of 43 feet perpendicular of water ‡?

‡ *Veget. Stat.* i. 107.

134
Hypotheſes of Grew, Malpighi, and de la Hire.

Grew aſcribed this phenomenon to the levity of the ſap; which, according to him, entered the plant in the ſtate of a very light vapour. But this opinion will not bear the ſlighteſt examination. Malpighi ſuppoſed that the ſap was made to aſcend by the contraction and dilation of the air contained in the air veſſels. But even were we to grant that the tracheæ are air veſſels, the ſap, according to this hypotheſis, could only aſcend when a change of temperature takes place; which is contrary to fact. And even if we were to wave every objection of that kind, the hypotheſis would not account for the circulation of the ſap, unleſs the ſap veſſels be provided with valves. Now the experiments of Hales and Duhamel ſhew that no valves can poſſibly exiſt in them. For branches imbibe moiſture nearly equally

equally by either end; and conſequently the ſap moves with equal facility both upwards and downwards, which it could not do were there valves in the veſſels. Beſides, it is known, from many experiments, that we may convert the roots of a tree into the branches, and the branches into the roots, by covering the branches with earth, and expoſing the roots to the air. Now this would be impoſſible if the ſap veſſels were provided with valves. The ſame remarks overturn the hypotheſis of Mr de la Hire, which is merely that of Malpighi, expreſſed with greater preciſion, and with a greater parade of mechanical knowledge. Like Borelli, he placed the aſcending power of the ſap in the parenchyma. But his very experiments, had he attended to them with care, would have been ſufficient to ſhew the imperfection of his theory.

The greater number of philoſophers (for it is needleſs to mention thoſe who, like Perrault, had recourſe to fermentation, nor thoſe who introduced the weight of the atmoſphere) have aſcribed the motion of the ſap to *capillary attraction.*

135 Aſcribed to capillary attraction.

There exiſts a certain attraction between many ſolid bodies and liquids; in conſequence of which, if theſe ſolid bodies be formed into ſmall tubes, the liquid enters them, and riſes in them to a certain height. But this is perceptible only when the diameter of the tube is very ſmall. Hence the attraction has been denominated *capillary.* We know that there is ſuch an attraction between vegetable fibres and watery liquids. For ſuch liquids will aſcend through dead vegetable matter. It is highly probable, therefore, that the food of plants enters the roots, in conſequence of the capillary attraction which ſubſiſts between the ſap veſſels and the liquid imbibed. This ſpecies of attraction, then, will account perfectly well for the entrance of moiſture into the mouths of the ſap veſſels. But will it account alſo, as ſome have ſuppoſed, for the aſcent of the ſap, and for the great force with which it aſcends?

136 This opinion examined;

The nature and laws of capillary attraction have been very much overlooked by philoſophers. But we know enough concerning it to enable us to decide the preſent queſtion. It conſiſts in a certain attraction between the particles of the liquid and of the tube. It has been demonſtrated, that it does not extend, or at leaſt that it produces no ſenſible effect, at greater diſtances than $\frac{1}{1000}$th part of an inch. It has been demonſtrated, that the water aſcends, not by the capillary attraction of the whole tube, but of a ſlender film of it; and Clairaut has ſhewn that this film is ſituated at the lowermoſt extremity of the tube (G). This film attracts the liquid with a certain force; and if this force be greater than the coheſion between the particles of the liquid, part enters the tube, and continues to enter, till the quantity above the attracting film of the tube juſt equals, by its weight, the exceſs of the capillary attraction between the tube and the liquid, above the coheſion of the liquid. The quantity of water therefore in the tube is pretty nearly the meaſure of this exceſs; for the attracting film is probably very minute.

It has been demonſtrated, that the heights to which liquids riſe in capillary tubes, are inverſely as the diameter of the tube. Conſequently the ſmaller the diameter of the tube, the greater is the height to which the liquid will riſe. But the particles of water are not infinitely ſmall; therefore whenever the diameter of the tube is diminiſhed beyond a certain ſize, water cannot aſcend in it, becauſe its particles are now larger than the bore of the tube. Conſequently the riſe of water in capillary tubes muſt have a limit: if they exceed a certain length, how ſmall ſoever their bore may be, water will either not riſe to the top of them, or it will not enter them at all. We have no method of aſcertaining the preciſe height to which water would riſe in a capillary tube, whoſe bore is juſt large enough to admit a ſingle particle of water. Therefore we do not know the limit of the height to which water may be raiſed by capillary attraction. But whenever the bore is diminiſhed beyond a certain ſize, the quantity of water which riſes in it is too ſmall to be ſenſible. We can eaſily aſcertain the height which water cannot exceed in capillary tubes before this happens; and if any perſon calculate, he will find that this height is not nearly equal to the length of the ſap veſſels of many plants. But beſides all this, we ſee in many plants very long ſap veſſels, of a diameter too large for a liquid to riſe in them a ſingle foot by capillary attraction, and yet the ſap riſes in them to very great heights.

If any perſon ſays that the ſap veſſels of plants gradually diminiſh in diameter as they aſcend; and that, in conſequence of this contrivance, they act preciſely as an indefinite number of capillary tubes, one ſtanding upon another, the inferior ſerving as a reſervoir for the ſuperior: we anſwer, that the ſap may aſcend by that means to a conſiderable height; but certainly not in any greater quantity than if the whole ſap veſſel had been preciſely of the bore of its upper extremity. For the quantity of ſap raiſed muſt depend upon the bore of the upper extremity, becauſe it muſt all paſs through that extremity. The quantity of ſap, too, on that ſuppoſition, muſt diminiſh the farther we go from the root, becauſe the bore of the ſap veſſels is conſtantly diminiſhing; the aſcending force muſt alſo diminiſh, becauſe it is, in all caſes, proportional to the quantity of water raiſed. Now neither of theſe, as Dr Hales has demonſtrated, is true.

137 And refuted.

But farther, if the ſap moved only in the veſſels of plants by capillary attraction, it would be ſo far from flowing out at the extremity of a branch, with a force ſufficient to overcome the preſſure of a column of water 43 feet high, that it could not flow out at all. It would be impoſſible in that caſe for any ſuch thing as the bleeding of trees ever to happen.

If we take a capillary tube, of ſuch a bore that a liquid will riſe in it ſix inches, and after the liquid has riſen to its greateſt height, break it ſhort three inches from the bottom, none of the liquid in the under half flows over. The tube, thus ſhortened, continues indeed full, but not a ſingle particle of liquid ever eſcapes from it. And how is it poſſible for it to eſcape? The film,

(G) The action of all the other films, of which the tube is compoſed, on the water, as far as it is meaſured by its effect, is nothing at all. For every particle of water in the tube (except thoſe attracted by the undermoſt film) is attracted upwards and downwards by the ſame number of films: it is therefore preciſely in the ſame ſtate as if it were not attracted at all.

Vegeta-tion film, at the *upper* extremity of the tube, must certainly have as strong an attraction for the liquid as the film at the *lower* extremity. As part of the liquid is within its attracting distance, and as there is no part of the tube above to counterbalance this attraction, it must of necessity attract the liquid nearest it, and with a force sufficient to counterbalance the attraction of the undermost film, how great soever we may suppose it. Of course no liquid can be forced up, and consequently none can flow out of the tube. Since then the sap *flows out* at the upper extremity of the sap vessels of plants, we are absolutely certain that it does not ascend in them merely by its capillary attraction, but that there is some other cause.

It is impossible therefore to account for the motion of the sap in plants by any mechanical or chemical principles whatever; and he who ascribes it to these principles has not formed to himself any clear or accurate conception of the subject. We know indeed that heat is an agent; for Dr Walker found that the ascent of the sap is much promoted by heat, and that after it had begun to flow from several incisions, cold made it give over flowing from the higher orifices while it continued to flow at the lower *. But this cannot be owing to the dilating power of heat; for unless the sap vessels of plants were furnished with valves (and they have no valves), dilatation would rather retard than promote the ascent of the sap. Consequently the effect of heat can give us no assistance in explaining the ascent of the sap upon mechanical and chemical principles.

* Edin. Tranf. i.

138 The vessels must contract,

We must therefore ascribe it to some other cause: the vessels themselves must certainly act. Many philosophers have seen the necessity of this, and have accordingly ascribed the ascent of the sap to *irritability*. But the first person who gave a precise view of the manner in which the vessels probably act was Saussure. He supposes that the sap enters the open mouths of the vessels, at the extremity of the roots; that these mouths then contract, and by that contraction propel the sap upwards; that this contraction gradually follows the sap, pushing it up from the extremity of the root to the summit of the plant. In the mean time the mouths are receiving new sap, which in the same manner is pushed upwards †. Whether we suppose the contraction to take place precisely in this manner or not, we can scarcely deny that it must take place; but by what means it is impossible to say. The agents cannot precisely resemble the muscles of animals; because the whole tube, however cut or maimed, still retains its contracting power, and because the contraction is performed with equal readiness in every direction. It is evident, however, that they must be the same in kind. Perhaps the particular structure of the vessels may fit them for their office. Does ring after ring contract its diameter? The contracting agents, whatever they are, seem to be excited to act by some stimulus communicated to them by the sap. This capacity of being excited to action is known in physiology by the name of *irritability*; and there are not wanting proofs that plants are possessed of it. It is well known that different parts of plants move when certain substances act upon them. Thus the flowers of many plants open at sunrise, and close again at night. Linnæus has given us a list of these plants. Des Fontaines has shewn that the stamina and antheræ of many plants exhibit distinct motions ‡. Dr Smith has observed, that the stamina of the barberries are thrown into motions when touched §. Roth has ascertained that the leaves of the drosera longifolia and rotundifolia have the same property. Mr Coulon, too, who has adopted the opinion that the motion of the sap in plants is produced by the contraction of vessels, has even made a number of experiments in order to shew this contraction. But the fact is, that every one has it in his power to make a decisive experiment. Simply cutting a plant, the *euphorbia peplis* for instance, in two places, so as to separate a portion of the stem from the rest, is a complete demonstration that the vessels actually do contract. For whoever makes the experiment, will find that the milky juice of that plant flows out at both ends so completely, that if afterwards we cut the portion of the stem in the middle, no juice whatever appears. Now it is impossible that these phenomena could take place without a contraction of the vessels; for the vessels in that part of the stem which has been detached cannot have been *more* than full; and their diameter is so small, that if it were to continue unaltered, the capillary attraction would be more than sufficient to retain their contents, and consequently not a drop could flow out. Since, therefore, the whole liquid escapes, it must be driven out forcibly, and consequently the vessels must contract.

† Encyc. Meth. Phyf. Art. p.

‡ Mem. Par. 1787. § Phil. Tranf. lxxviii.

It seems pretty plain, too, that the vessels are excited to contract by various stimuli; the experiments of Coulon and Saussure render this probable, and an observation of Dr Smith Barton makes it pretty certain. He found that plants growing in water vegetated with much greater vigour, provided a little camphor was thrown into the water *. 139 In consequence of stimuli.

* Ann. de Chim. xxiii. 63.

18. Besides the sap which ascends upwards towards the leaves, they contain also another fluid, known by the name of *succus proprius*, or *peculiar juice*. This juice differs very considerably in different plants. It seems to be the sap altered by some process or other, and fitted for the various purposes of vegetation. That it flows from the leaves of the plant towards the roots, appears from this circumstance, that when we make an incision into a plant, into what ever position we put it, much more of the succus proprius flows from that side of the wound which is next the leaves and branches, than from the other side: and this happens even though the leaves and branches be held undermost †. When a ligature is tied about a plant, a swelling appears above, but not below the ligature. 140 Peculiar juice formed from the sap;

† Bell, Manch. Mem. ii. 402.

The vessels containing the peculiar juice are found in all the parts of the plant. Hedwig, who has examined the vessels of plants with very great care, seems to consider them as of the same structure with the tracheæ. The peculiar juice is easily known by its colour and its consistence. In some plants it is green, in some red, in many milky. It cannot be doubted that its motion in the vessels is performed in the same way as that of the sap.

19. It appears, then, that the sap ascends to the leaves, that there it undergoes certain alterations, and is converted into the peculiar juices; which, like the blood in animals, are afterwards employed in forming the various substances found in plants. Now the changes which the sap undergoes in the leaves, provided we can trace them, must throw a great deal of light upon the nature of vegetation. 141 In the leaves.

Vegetation.

142 Part of the ſap perſpires thro' the leaves.

No ſooner has the ſap arrived at the leaves, than a great part of it is thrown off by evaporation. The quantity thus perſpired bears a very great proportion to the moiſture imbibed. Mr Woodward found that a ſprig of mint in 77 days imbibed 2558 grains of water, and yet its weight was only increaſed 15 grains *: therefore it muſt have given out 2543 grains. Another branch, which weighed 127 grains, increaſed in weight 128, and it had imbibed 14190 grains. Another ſprig, weighing 76 grains, growing in water mixed with earth, increaſed in weight 168 grains, and had imbibed 10731 grains of water. Theſe experiments demonſtrate the great quantity of matter which is conſtantly leaving the plant. Dr Hales found that a cabbage tranſmitted daily a quantity of moiſture equal to about half its weight; and that a ſun-flower, three feet high, tranſmitted in a day 1 lb. 14 oz. avoirdupois †. He ſhewed, that the quantity of tranſpiration in the ſame plant was proportional to the ſurface of the leaves, and that when the leaves were taken off, the tranſpiration nearly ceaſed ‡. By theſe obſervations, he demonſtrated that the leaves are the organs of tranſpiration. He found, too, that the tranſpiration was nearly confined to the day, very little taking place during the night §; that it was much promoted by heat, and ſtopped by rain and froſt ||. And Millar ¶, Guettard *, and Senebier, have ſhewn that the tranſpiration is alſo very much promoted by ſunſhine.

* *Phil. Tranſ.* No. 253.
† *Veget. Stat.* i. 5. and 15.
‡ *Ibid.* 30.
§ *Ibid.* 5.
|| *Ibid.* 27. and 48.
¶ *Ibid.* 22.
* *Mem. Par.* 1748.

The quantity of moiſture imbibed by plants depends very much upon what they tranſpire. The reaſon is evident: when the veſſels are once filled with ſap, if none be carried off, no more can enter; and, of courſe, the quantity which enters muſt depend upon the quantity emitted.

In order to diſcover the nature of the tranſpired matter, Hales placed plants in large glaſs veſſels, and by that means collected a quantity of it †. He found that it reſembled pure water in every particular, excepting only that it ſometimes had the odour of the plant. He remarked, too, as Guettard and Du Hamel did after him, that when kept for ſome time it putrefied, or at leaſt acquired a ſtinking ſmell. Senebier ſubjected a quantity of this liquid to a chemical analyſis.

† *Ibid.* 49.

143 Its nature,

He collected 13030 grains of it from a vine during the months of May and June. After filtration he gradually evaporated the whole to dryneſs. There remained behind two grains of reſiduum. Theſe two grains conſiſted of nearly ½ grain of carbonat of lime, $\frac{1}{11}$ grain of ſulphat of lime, ½ grain of matter ſoluble in water, and having the appearance of gum, and ½ grain of matter which was ſoluble in alcohol, and apparently reſinous. He analyzed 6c768 grains of the ſame liquid, collected from the vine during the months of July and Auguſt. On evaporation he obtained $2\frac{1}{8}$ grains of reſiduum, compoſed of ¾ grain of carbonat of lime, ¼ grain of ſulphat of lime, ½ grain of mucilage, and ½ grain of reſin. The liquid tranſpired by the *aſter novæ Angliæ* afforded preciſely the ſame ingredients ‡.

‡ *Enc. Meth. Phyſ. Veget.* 287.

144 And quantity.

Senebier attempted to aſcertain the proportion which the liquid tranſpired bore to the quantity of moiſture imbibed by the plant. But it is eaſy to ſee that ſuch experiments are liable to too great uncertainties to be depended on. His method was as follows: He plunged the thick end of the branch on which he made the experiment into a bottle of water, while the other end, containing all its leaves, was thruſt into a very large glaſs globe. The apparatus was then expoſed to the ſunſhine. The quantity imbibed was known exactly by the water which diſappeared from the bottle, and the quantity tranſpired was judged of by the liquid which condenſed and trickled down the ſides of the glaſs globe. The following table exhibits the reſult of his experiments:

Plants.	*Imbibed.*	*Perſpired.*	*Time.*
Peach	100 gr.	35 gr.	
Ditto	210	90	
Ditto	220	120	
Mint	200	90	2 days.
Ditto	575	120	10
Raſp	725	560	2
Ditto	1232	765	2
Peach	710	295	1
Apricot	210	180	1

In ſome of his experiments no liquid at all was condenſed. Hence it is evident that the quantity of matter tranſpired cannot be deduced from theſe experiments. The mouth of the glaſs globe does not ſeem to have been accurately cloſed; the air within it communicated with the external air: conſequently the quantity condenſed muſt have depended entirely upon the ſtate of the external air, the heat, &c.

The firſt great change, then, which takes place upon the ſap after it arrives at the leaves, is the evaporation of a great part of it: conſequently what remains muſt be very different in its proportions from the ſap. The leaves ſeem to have particular organs adapted for throwing off part of the ſap by tranſpiration. For the experiments of Guettard *, Duhamel †, and Bonnet ‡, ſhew that it is performed chiefly by the upper ſurfaces of leaves, and may be nearly ſtopped altogether by varniſhing the upper ſurface.

* *Mem. Par.* 1749.
† *Phyſique des Arbres*, i. 158.
‡ *Traité des Feuilles*, i. *Mem.*

145 Why the leaves fall off.

The leaves of plants become gradually leſs and leſs fit for this tranſpiration; for Senebier found, that when all other things are equal, the tranſpiration is much greater in May than in September *. Hence the reaſon that the leaves are renewed annually. Their organs become gradually unfit for performing their functions, and therefore it is neceſſary to renew them. Thoſe trees which retain their leaves during the winter were found by Hales and ſucceeding phyſiologiſts to tranſpire leſs than others. It is now well known that theſe trees alſo renew their leaves.

* *Enc. Method. Veget.* 285.

20. Leaves have alſo the property of abſorbing carbonic acid gas from the atmoſphere.

146 Leaves abſorb carbonic acid gas.

We are indebted for this very ſingular diſcovery to the experiments of Dr Prieſtley, though he himſelf did not diſcover the truth, and though he even refuſed to acknowledge it when it was pointed out by others. It has been long known, that when a candle has been allowed to burn out in any quantity of air, no candle can afterwards be made to burn in it. In the year 1771 Dr Prieſtley made a ſprig of mint vegetate for ten days in contact with a quantity of ſuch air; after which he found that a candle would burn in it perfectly well ¶. This experiment he repeated frequently, and found that it was always attended with the ſame reſult. According to the opinion at that time univerſally received, that the

¶ *On Air*, iii. 251.

Vegetation. the burning of candles rendered air impure by communicating phlogiston to it, he concluded from it, that plants, while they vegetate, absorb phlogiston.

Carbonic acid gas was at that time supposed to contain phlogiston. It was natural, therefore, to suppose that it would afford nourishment to plants, since they had the property of absorbing phlogiston from the atmosphere. Dr Percival had published a set of experiments; by which he endeavoured to shew that this was actually the case.

These experiments induced Dr Priestley, in 1776, to consider the subject with more attention. But as, in all the experiments which he made, the plants confined in carbonic acid gas very soon died, he concluded that carbonic acid gas was not a food, but a poison to plants *. Mr Henry of Manchester was led, in 1784, probably by the contrariety of these results, to examine the subject. His experiments, which were published in the Manchester Transactions †, perfectly coincided with those of Dr Percival. For he found, that carbonic acid gas, so far from killing plants, constantly promoted their growth and vigour. Meanwhile Mr Senebier was occupied at Geneva with the same subject; and he published the result of his researches in his *Memoires Physico-chymique* about the year 1780. His experiments shewed, in the clearest manner, that carbonic acid gas is used by plants as food. The same thing was supported by Ingenhousz in his second volume. The experiments of Saussure the Son, published in 1797, have at last put the subject beyond the reach of dispute. From a careful comparison of the experiments of these philosophers, it will not be difficult for us to discover the various phenomena, and to reconcile all the seeming contradictions which occur in them. The facts are as follows:

* On Air, 100.

† ii. 341.

Mr Saussure has shewn, that plants will not vegetate when totally deprived of carbonic acid gas. They vegetate indeed well enough in air which has been previously deprived of carbonic acid gas; but when a quantity of lime was put into the glass vessel which contained them, they no longer continued to grow, and the leaves in a few days fell off ‡. The air, when examined, was found to contain no carbonic acid gas. The reason of this phenomenon is, that plants (as we shall see afterwards) have the power of forming and giving out carbonic acid in certain circumstances; and this quantity is sufficient to continue their vegetation for a certain time. But if this new formed gas be also withdrawn, by quicklime, for instance, which absorbs it the instant it appears, the leaves droop, and refuse to perform their functions. Carbonic acid gas, then, applied to the leaves of plants, is *essential* to vegetation.

‡ Ann. de Chim xxiv. 145. 148.

147 Decompose it, and emit the oxygen;

Dr Priestley, to whom we are indebted for many of the most important facts relative to vegetation, observed, in the year 1778, that plants, in certain circumstances, emitted oxygen gas ‖; and Ingenhousz very soon after discovered that this gas is emitted by the *leaves* of plants, and only when they are exposed to the bright light of day. His method was to plunge the leaves of different plants into vessels full of water, and then expose them to the sun, as Bonnet, who had observed the same phenomenon, though he had given a wrong explanation of it, had done before him. Bubbles of oxygen gas very soon detached themselves from the leaves, and were collected in an inverted glass vessel *. He observed, too, that it was not a matter of indifference what kind of water was used. If the water, for instance, had been previously boiled, little or no oxygen gas escaped from the leaves; river water afforded but little gas; but pump water was the most productive of all †.

‖ On Air, iii. 284.

* Ingenhousz on Veget. i. 15. &c.

† Ibid. 83.

Senebier proved, that if the water be previously deprived of all its air by boiling, the leaves do not emit a particle of air; that those kinds of water which yield most air, contain in them the greatest quantity of carbonic acid gas; that leaves do not yield any oxygen when plunged in water totally destitute of carbonic acid gas; that they emit it abundantly when the water, rendered unproductive by boiling, is impregnated with carbonic acid gas; that the quantity of oxygen emitted, and even its purity, is proportional to the quantity of carbonic acid gas which the water contains; that water impregnated with carbonic acid gas gradually loses the property of affording oxygen gas with leaves; and that whenever this happens, all the carbonic acid gas has disappeared; and on adding more carbonic acid gas the property is renewed ‡. These experiments prove, in a most satisfactory manner, that the oxygen gas which the leaves of plants emit depends upon the presence of carbonic acid gas; that the leaves absorb carbonic acid gas, decompose it, give out the oxygen, and retain the carbon.

‡ Enc. Method. Phys. Veget. 181.

148 But during the day only.

We now see why plants will not vegetate without carbonic acid gas. They absorb it and decompose it; but this process goes on only when the plants are exposed to the light of day. Therefore we may conclude, that the absorption and decomposition of carbonic acid gas is confined to the day, and that light is an essential agent in the decomposition. Probably it is by its agency, or by its entering into combination with the oxygen, that this substance is enabled to assume the gaseous form, and to separate from the carbon.

If we reason from analogy, we shall conclude, that during this process a quantity of caloric is necessary; and that therefore no increase of temperature takes place, but rather the contrary. This may be one reason why the operation takes place only during the day.

149 In this way plants may acquire much carbon.

It is extremely probable that plants by this process acquire the greatest part of the carbonaceous matter which they contain; for if we compare the quantity of carbon contained in plants vegetating in the dark, where this process cannot go on, with the quantity which those plants contain which vegetate in the usual manner, we shall perceive a very conspicuous difference. Chaptal found that a byssus, which was vegetating in the dark, contained only $\frac{1}{80}$ of its weight of carbonaceous matter; but the same plant, after being made to vegetate in the light for 30 days, contained $\frac{1}{12}$th of its weight of carbonaceous matter *. Hassenfratz ascertained, that plants growing in the dark contain much more water, and much less carbon and hydrogen, than plants growing in the light. Senebier analysed both with the same result. Plants growing in the dark yielded less hydrogen gas and oil: their resinous matter was to that of plants growing in the light as 2 to 5,5, and their moisture as 13 to 6; they contain even one-half less of fixed matters.

* Mem. Par. 1786.

It is evident, however, that this absorption and decomposition of carbonic acid gas does not depend upon the

Vegetation.

the light alone. The nature of the sap has also it's influence; for Hassenfratz found, that the quantity of carbon did not increase when plants vegetated in pure water. Here the sap seems to have wanted that part which combines with and retains the carbon; and which therefore is by far the most important part of the food of plants. Upon the discovery and mode of applying this substance, whatever it is, the improvements in agriculture must in a great measure depend.

If we consider the difference in the proportion of carbonaceous matter in plants vegetating in the dark and in the usual manner, we can scarcely avoid concluding that the quantity of carbonic acid gas absorbed by plants is considerable. To form an estimate of it, would require a set of experiments performed in a very different manner from any hitherto made. The stems and branches of plants vegetating in a rich soil should be confined within a large glass globe, the inside of which ought to have no communication with the external air. A very small stream of carbonic acid gas should be made occasionally to flow into this globe, so as to supply the quantity that may appear necessary; and there should be a contrivance to carry off and examine the air within the globe when it increases beyond a certain quantity. Experiments conducted in this manner would probably throw a great deal of light upon this part of vegetation, and enable us to calculate the quantity of carbonic acid decomposed, and the quantity of oxygen emitted by plants; to compare these with the waste of oxygen by the respiration of animals and combustion, and to see whether or not they balance each other.

150 The decomposition performed by the parenchyma.

Senebier has ascertained, that the decomposition of the carbonic acid takes place in the parenchyma. He found, that the epidermis of a leaf would, when separated, give out no air, neither would the nerves in the same circumstances; but upon trying the parenchyma, thus separated from its epidermis and part of its nerves, it continued to give out oxygen as before †. He remarked also, that every thing else being equal, the quantity of oxygen emitted, and consequently of carbonic acid decomposed, is proportional to the thickness of the leaf; and this thickness depends upon the quantity of parenchyma.

† *Enc. Method Phys. Veget.* 180.

That the decomposition is performed by peculiar organs, is evident from an experiment of Ingenhousz. Leaves cut into small pieces continued to give out oxygen as before; but leaves pounded in a mortar lost the property entirely. In the first state, the peculiar structure remained; in the other, it was destroyed. Certain experiments of Count Rumford, indeed, are totally incompatible with this conclusion; and they will naturally occur to the reader as an unsurmountable objection. He found, that dried leaves, black poplar, fibres of raw silk, and even glass, when plunged into water, gave out oxygen gas by the light of the sun. But when Senebier repeated these experiments, not one of them would succeed ‡; and we have attempted them with the same bad success. The Count must have been misled by something which he has not mentioned.

‡ *Ann. de Chim.* i. 115.

Thus we have seen, that when the sap arrives at the leaves, great part is thrown off by evaporation, and that the nature of the remainder is considerably altered by the addition of a quantity of carbon: but these are by no means all the alterations produced upon the sap in the leaves.

151 Leaves absorb oxygen,

21. Plants will not vegetate unless atmospheric air or oxygen gas have access to their leaves. This was rendered probable by those philosophers who, about the end of the 17th century, turned their attention particularly towards the physical properties of the air: But Mr Ingenhousz was perhaps the first of the modern chemists who put it beyond doubt. He found that carbonic acid gas, azot, and hydrogen gas, destroyed plants altogether, unless they were mixed with atmospheric air or oxygen gas. He found also, that plants grew very well in oxygen gas and in atmospheric air *. These experiments are sufficient to shew, that oxygen gas is necessary to vegetation. The leaves of plants seem to absorb it; and most probably this absorption takes place only in the night. We know, at least, that in germination light is injurious to the absorption of oxygen gas; and therefore it is probable that this is the case also in vegetation.

* *Ingenhousz* i. passim.

152 And water,

22. The leaves of plants not only absorb carbonic acid gas and oxygen gas, but water also. This had been suspected in all ages: the great effect which dew, slight showers, and even wetting the leaves of plants, have in recruiting their strength, and making them vegetate with vigour, are so many proofs that the leaves imbibe moisture from the atmosphere. Hales rendered this still more probable, by observing, that plants increase considerably in weight when the atmosphere is moist; and Mr Bonnet put the matter beyond doubt in his *Researches concerning the Use of the Leaves.* He shewed, that leaves continue to live for weeks when one of their surfaces is applied to water; and that they not only vegetate themselves, but even imbibe enough of water to support the vegetation of a whole branch, and the leaves belonging to it. He discovered also, that the two surfaces of leaves differ very considerably in their power of imbibing moisture; that in trees and shrubs, the under surface possesses almost the whole of the property, while the contrary holds in many of the other plants; the kidney bean for instance.

These facts prove, not only that the leaves of plants have the power of absorbing moisture, but also that the absorption is performed by very different organs from those which emit moisture; for these organs lie on different sides of the leaf. If we consider that it is only during the night that the leaves of plants are moistened with dew, we can scarcely avoid concluding, that, except in particular cases, it is during the night that plants imbibe almost all the moisture which they do imbibe.

153 And emit carbonic acid gas.

23. During the night the leaves of plants emit carbonic acid gas. This fact was first demonstrated by Mr Ingenhousz †, and it has been since confirmed by every philosopher who has attended to the subject.

† *On Vegetables,* i. 47. and ii. passim.

Thus we have seen that the leaves of plants perform very different operations at different times. During the day they are giving out moisture, absorbing carbonic acid gas, and emitting oxygen gas; during the night, on the contrary, they are absorbing moisture, giving out carbonic acid gas, and absorbing oxygen gas.

The emission of the carbonic acid gas seems to be the consequence of the decomposition of water; either of the water which is already contained in the sap, or of

Vegetation.

of that which the leaves imbibe during the night; but which of the two, it is impossible to determine, nor is it of much consequence. We may conclude that this is the case, because it takes place during the germination of the seed, where all the circumstances seem to be perfectly analogous. The water is decomposed, its oxygen is combined with part of the carbon which had been absorbed during the day, and the hydrogen enters into new combinations in the sap. It appears, also, that this decomposition of water depends in a good measure upon the quantity of oxygen gas absorbed; for Dr Ingenhousz found, that when plants are confined in oxygen gas, they emit more carbonic acid gas than when they are confined in common air †.

† Ingenhousz,

154
Sap converted by these processes into the peculiar juice.

To describe in what manner these decompositions take place, is impossible; because we neither know precisely the substances into which the sap has been converted by the operations performed during the day, nor the new substances formed by the operations of the night. We only see the elementary substances which are added and subtracted; which is far from being sufficient to give us precise notions concerning the chemical changes and the affinities by which these changes are produced. We have reason, however, to conclude, that during the day the carbon of the sap is increased, and that during the night the hydrogen and oxygen are increased; but the precise new substances formed are unknown to us. Nor let any one suppose that the increase of the hydrogen, and of the oxygen of the sap, is the same thing as the addition of a quantity of water. Far from it. The substances into which the sap is converted have been enumerated in the last chapter; almost all of them consist chiefly of carbon, hydrogen, and oxygen, and yet none of them has the smallest resemblance to water. In water, oxygen and hydrogen are already combined together in a certain proportion; and this combination must be broken before these elementary bodies can enter into those triple compounds with carbon, of which a great part of the vegetable products consist. We have not the smallest conception of the manner in which these triple combinations are formed, and as little of the manner in which the bodies which compose vegetable substances are combined together. The combination may, for any thing we know to the contrary, be very complicated, though it consists only of three ingredients; and analogy leads us to suppose, that it actually is very complicated: for in chemistry it may be considered as a truth, to which at present few or no exceptions are known, that bodies are decomposed with a facility inversely as the simplicity of their composition; that is to say, that those bodies which consist of the fewest ingredients are most difficultly decomposed, and that those which are formed of many ingredients are decomposed with the greatest facility.

Neither let any one suppose, that the absorption of carbonic acid gas, during the day, is balanced by the quantity emitted during the night, and that therefore there is no increase of carbon: for Ingenhousz has shewn, that the quantity of oxygen gas emitted during the day is much greater than the carbonic acid gas emitted during the night; and that in favourable circumstances, the quantity of oxygen gas in the air surrounding plants is very much increased, and the carbonic acid gas diminished; so much so, that both Dr Priestley and Dr Ingenhousz found, that air which had been spoiled by a lighted candle, or by animals, was rendered as good as ever by plants. Now we know, that combustion and respiration diminish the oxygen gas, and add carbonic acid gas to air; therefore vegetation, which restores the purity of air altered by these processes, must increase the oxygen, and diminish the carbonic acid gas of that air; consequently the quantity of carbonic acid gas absorbed by plants during the day is greater than the quantity emitted by them during the night, and of course the carbon of the sap is increased in the leaves.

It is true, that when plants are made to vegetate for a number of days in a given quantity of air, its ingredients are not found to be altered. Thus Hassenfratz ascertained, that the air in which young chesnuts vegetated for a number of days together, was not altered in its properties, whether the chesnuts were vegetating in water or in earth *. And Saussure the Younger proved, that pease growing for ten days in water did not alter the surrounding air †. But this is precisely what ought to be the case, and what must take place, provided the conclusions which we have drawn be just. For if plants only emit oxygen gas, by absorbing and decomposing carbonic acid gas, it is evident, that unless carbonic acid gas be present, they can emit no oxygen gas; and whenever they have decomposed all the carbonic acid gas contained in a given quantity of air, we have no longer any reason to look for their emitting any more oxygen gas; and if the quantity of carbonic acid gas emitted during the night be smaller than that absorbed during the day, it is evident, that during the day the plant will constantly decompose all the acid which had been formed during the night. By these processes, the mutual changes of day and night compensate each other; and they are prevented from more than compensating each other by the forced state of the plant. It is probable, that when only part of a plant is made to vegetate in this forced state, some *carbonated sap* (if we may be allowed the expression) is supplied by the rest of the plant; and that therefore the quantity of carbonic acid gas emitted during the night may bear a nearer proportion to that emitted in a state of nature, than that of the absorption of fixed air can possibly do. And probably, even when the whole plant is thus confined, the nightly process goes on for a certain time at the expence of the carbon already in the sap; for Hassenfratz found, that in these cases the quantity of carbon in the plant, after it had vegetated for some time in the dark, was less than it had been when it began to vegetate *. This is the reason that plants growing in the dark, when confined, absorb all the oxygen gas, and emit an equal quantity of carbonic acid gas: and whenever this has happened, they die; because then neither the daily nor nightly processes can go on.

* *Ann. de Chim.* xiii. 25.

† *Ibid.* xxiv. 139.

* *Ann. de Chim.* xiii. 168.

24. Certain changes are also produced on the sap in the leaves by the action of light; and these changes seem to be in some measure independent, or at least different from the absorption and decomposition of carbonic acid gas, in which light, as we have seen, acts an important part.

155
Green colour of plants produced by light.

The green colour of plants is owing entirely to their vegetating in the light; for when they vegetate in the dark they are white; and when exposed to the light, they acquire a green colour in a very short time, in what-

Vegetation.

whatfoever fituation they are placed, even though plunged in water, provided always that oxygen be prefent; for Mr Gough has fhewn, that light without oxygen has not the power of producing the green colour *. In what manner this change is operated, cannot, in the prefent limited ftate of our knowledge, be afcertained. We know too little about the properties of light to be able even to conjecture with any plaufibility. We know indeed, that part of the light is abforbed by green plants; but this will not account for the phenomenon. When dilated, it amounts to no more than this, that plants which have grown in the dark reflect all the rays of light; while thofe which vegetate in the light reflect the green and abforb the others. The very mention of this phenomenon is enough to fhew us, that we have not advanced far enough to be able to explain it.

* Manch. Memoirs, iv. 501.

Etiolated (E) plants want fomething, or poffefs fomething peculiar; and it is on this fomething that the phenomenon depends. But what is this fomething? The fudden appearance of the green colour is rather againft the fuppofition, that it is owing to any fpecific change in the qualities of the fap.

Senebier has obferved, that when plants are made to vegetate in the dark, their etiolation is much diminifhed by mixing a little hydrogen gas with the air that furrounds them *. Ingenhoufz had already remarked, that when a little hydrogen gas is added to the air in which plants vegetate, even in the light, it renders their verdure deeper †: and he feems to think alfo, that he has proved by experiments, that plants abforb hydrogen gas in thefe circumftances ‡. Mr Humbolt has obferved that the poa annua and compreffa, plantago lanceolata, trifolium arvenfe, cheiranthus cheiri, lichen verticillatus, and feveral other plants which grow in the galleries of mines, retain their green colour even in the dark, and that in thefe cafes the air around them contains a quantity of hydrogen gas. Thefe facts are fufficient to fhew that there is fome connection between the green colour of plants and the action of hydrogen gas on them; but what that connection is, it is impoffible at prefent to fay.

* Enc. Method. Phif. Veget. 77.
† Ann. de Chim. iii. 57.
‡ Ibid. 61.

25. By thefe different changes which go on in the leaves, the nature of the fap is altogether changed. It is now converted into what is called the *peculiar juice*, and is fit for being affimilated to the different parts of the plant, and for being employed in the formation of thofe fecretions which are neceffary for the purpofes of the vegetable economy.

156 Leaves the digefting organs of plants.

The leaves, therefore, may be confidered as the digefting organs of plants, and as equivalent in fome meafure to the ftomach and lungs of animals. The leaves confequently are not mere ornaments; they are the moft important parts of the plant. Accordingly we find, that whenever we ftrip a plant of its leaves, we ftrip it entirely of its vegetating powers till new leaves are formed. It is well known, that when the leaves of plants are deftroyed by infects they vegetate no longer, and that their fruit never make any farther progrefs in ripening, but decays and dries up. Even in germination no progrefs is made in the growth of the ftem till the feed leaves appear. As much food indeed is laid up in the cotyledons as advances the plant to a certain ftate, the root is prepared, and made ready to perform its functions; but the fap which it imbibes muft be firft carried to the feed leaves, and digefted there, before it be proper for forming the plumula into a ftem. Accordingly if the feed leaves are cut off, the plant refufes to vegetate.

157 How they are produced.

It will be very natural to afk, If this be true, how come the leaves themfelves to be produced? Even if no anfwer could be given to this queftion, it could not overturn a fingle fact which has been formerly mentioned, nor affect a fingle conclufion as far as it has been fairly deduced from thefe facts. We know that the leaves exift long before they appear; they have been traced even five years back. They are completely formed in the bud, and fairly rolled up for evolution, many months before that fpring in which they expand. We know, too, that if we take a bud, and plant it properly, it vegetates, forms to itfelf a root, and becomes a complete plant. It will not be faid, furely, that in this cafe the bud imbibes nourifhment from the earth; for it has to form a root before it can obtain nourifhment in that manner; and this root cannot be formed without nourifhment. Is not this a demonftration that the bud contains, already laid up in itfelf, a fufficient quantity of nourifhment, not only to develope its own organs, but alfo to form new ones. This we confider as a fufficient anfwer to the objection. During the fummer, the plant lays up a fufficient quantity of nourifhment in each bud, and this nourifhment is afterwards employed in developing the leaves. This is the reafon that the leaves make their appearance, and that they grow during the winter, when the plant is deprived of its organs of digeftion.

Hence we fee why the branch of a vine, if it be introduced into a hothoufe during the winter, puts forth leaves and vegetates with vigour, while every other part of the plant gives no figns of life. Hence alfo the reafon that the inoculation of plants fucceeds (F).

If a tree be deprived of its leaves, new leaves make their appearance, becaufe they are already prepared for that purpofe: but what would be the confequence if a tree were deprived of its leaves and of all its buds for five

(E) Plants of a white colour, from vegetating in the dark, are called *etiolated*, from a French word which fignifies a *ftar*, as if they grew by *ftar light*.

(F) Hence alfo the caufe of another well known phenomenon. The fap flows out of trees very readily in fpring before the leaves appear, but after that the bleeding ceafes altogether. It is evident that there can be fcarcely any circulation of fap before the leaves appear; for as there is no outlet, when the veffels are once full, they can admit no more. It appears, however, from the bleeding, that the roots are capable of imbibing, and the veffels of circulating the fap with vigour. Accordingly, whenever there is an outlet, they perform their functions as ufual, and the tree bleeds; that is, they fend up a quantity of fap to be digefted as ufual: but as there are no digefting organs, it flows out, and the tree receives no injury, becaufe the fap that flows out would not have been imbibed at all, had it not been for the artificial opening. But when the digeftive organs appear, the tree will not bleed; becaufe thefe organs require all the fap, and it is conftantly flowing to them.

Vegetation.

five years back? That plants do not vegetate without leaves, is evident from an experiment of Duhamel. He ſtript the bark off a tree in ringlets ſo as to leave five or ſix rings of it at ſome diſtance from each other, with no bark in the intervals. Some of theſe rings had buds and leaves; theſe increaſed conſiderably in ſize; but one ring which had none of theſe remained for years unaltered.

158 Nature of the peculiar juices.

26. The peculiar juice thus formed in the leaves is carried by veſſels intended for that uſe to all the parts of the plant, in order to be employed for the purpoſes of vegetation;—to increaſe the wood, the bark, the roots; to prepare the ſeeds, lay up nouriſhment for the buds, and to repair the decayed parts of the ſyſtem, or form new ones.

If we had any method of obtaining this peculiar juice in a ſtate of purity, the analyſis of it would throw a great deal of light upon vegetation; but this is ſcarce poſſible, as we cannot extract it without dividing at the ſame time the veſſels which contain the ſap. In many caſes, however, the peculiar juice may be known by its colour; and then its analyſis may be performed with an approach towards accuracy. The experiments made on ſuch juices have proved, as might have been expected, that they differ very conſiderably from each other, and that every plant has a juice peculiar to itſelf. Hence it follows, that the proceſſes which go on in the leaves of plants muſt differ at leaſt in degree, and that we have no right to transfer the concluſions deduced from experiments on one ſpecies of plants to thoſe of another ſpecies. It is even probable, that the proceſſes in different plants are not the ſame in kind; for it is not reaſonable to ſuppoſe, that the phenomena of vegetation in an agaric or a boletus are preciſely the ſame as thoſe which take place in trees and in larger vegetables, on which alone experiments have hitherto been made.

To attempt any general account of the ingredients of the peculiar juice of plants, is at preſent impoſſible. We may conclude, however, from the experiments of Chaptal, that it contains the *vegetable fibre* of wood, either ready formed, or very nearly ſo; juſt as the blood in animals contains a ſubſtance which bears a ſtrong reſemblance to the muſcular fibres.

When oxy-muriatic acid was poured into the peculiar juice of the euphorbia, which in all the ſpecies of that ſingular genus is of a milky colour and conſiſtency, a very copious white precipitate fell down. This powder, when waſhed and dried, had the appearance of fine ſtarch, and was not altered by keeping. It was neither affected by water nor alkalies. Alcohol, aſſiſted by heat, diſſolved two thirds of it; which were again precipitated by water, and had all the properties of reſin. The remaining third part poſſeſſed the properties of the *woody fibre*. Mr Chaptal tried the ſame experiment on the juices of a great number of other plants, and he conſtantly found that oxy-muriatic acid precipitated from them *woody fibre*. The ſeeds of plants exhibited exactly the ſame phenomenon; and a greater quantity of woody fibre was obtained from them than from an equal portion of the juices of plants *. Theſe experiments are ſufficient to ſhew, that the proper juices of plants contain their nouriſhment ready prepared, nearly in the ſtate in which it exiſts in the ſeed for the uſe of the young embryo.

* Ann. de Chim. xxi. 85.

The peculiar juices of plants, then, contain more carbon, hydrogen, and oxygen and leſs water, and probably lime alſo, than the ſap. They are conveyed to every part of the plant; and all the ſubſtances which we find in plants, and even the organs themſelves, by which they perform their functions, are formed from them. But the thickeſt veil covers the whole of theſe proceſſes; and ſo far have philoſophers hitherto been from removing this veil, that they have not even been able to approach it. All theſe operations, indeed, are evidently chemical decompoſitions and combinations; but we neither know what theſe decompoſitions and combinations are, nor the inſtruments in which they take place, nor the agents by which they are regulated.

159 Its uſes.

160 Plants decay and die.

27. Such, as far as we are acquainted with them, are the changes produced by vegetation. But plants do not continue to vegetate for ever; ſooner or later they decay, and wither, and rot, and are totally decompoſed. This change indeed does not happen to all plants at the end of the ſame time. Some live only for a ſingle ſeaſon, or even for a ſhorter period; others live two ſeaſons, others three, others a hundred or more; and there are ſome plants which continue to vegetate for a thouſand years. But ſooner or later they all ceaſe to live; and then thoſe very chemical and mechanical powers which had promoted vegetation combine to deſtroy the remains of the plant. Now, What is the cauſe of this change? Why do plants die?

This queſtion can only be anſwered by examining with ſome care what it is which conſtitutes the *life* of plants; for it is evident, that if we can diſcover what that is which conſtitutes the life of a plant, it cannot be difficult to diſcover what conſtitutes its death.

161 Phenomena of vegetable life.

Now the phenomena of vegetable life are in general *vegetation*. As long as a plant continues to vegetate, we ſay that it lives; when it ceaſes to vegetate, we conclude that it is dead.

The life of vegetables, however, is not ſo intimately connected with the phenomena of vegetation that they cannot be ſeparated. Many ſeeds may be kept for years without giving any ſymptom of vegetation; yet if they vegetate when put into the earth, we ſay that they poſſeſs life: and if we would ſpeak accurately, we muſt ſay alſo, that they poſſeſſed life even before they were put into the earth; for it would be abſurd to ſuppoſe that the ſeed *obtained* life merely by being put into the earth. In like manner, many plants decay, and give no ſymptoms of vegetation during winter; yet if they vegetate when the mild temperature of ſpring affects them, we conſider them as having lived all winter. The life of plants, then, and the phenomena of vegetation, are not preciſely the ſame thing; for the one may be ſeparated from the other, and we can even ſuppoſe the one to exiſt without the other. Nay, what is more, we can, in many caſes, *decide*, without heſitation, that a vegetable is not dead, even when no vegetation appears; and the proof which we have for its life is, that it *remains unaltered*; for we know that when a vegetable is dead, it ſoon changes its appearance, and falls into decay.

Thus it appears that the *life* of a vegetable conſiſts in two things. 1. In remaining unaltered, when circumſtances are unfavourable to vegetation; 2 In exhibiting

Vegetation. hibiting the phenomena of vegetation when circumftances are favourable. When neither of thefe two things happens, we fay that a vegetable is dead.

The phenomena of vegetation have been enumerated above. They confift in the formation or expanfion of the organs of the plant, in the taking in of nourifhment, in carrying it to the leaves, in digefting it, in diftributing it through the plant, in augmenting the bulk of the plant, in repairing decayed parts, in forming new organs when they are neceffary, in producing feeds capable of being converted into plants fimilar to the parent. The *caufe* of thefe phenomena, whatever it may be, is the *caufe* alfo of *vegetable life*.

All the fubftances which have been enumerated in the firft part of the article CHEMISTRY, *Suppl.* together with their compounds and component parts, poffefs certain qualities in common: in confequence of which, a term has been invented which includes them all. This term is *matter*. Now thefe common qualities may all ultimately be refolved into certain attractions and repulfions which thefe fubftances exert. Thefe qualities may be faid, without any impropriety, to be *effential to matter*; becaufe every body to which we give the name of *matter* poffeffes them; and if any body were to be deprived of thefe qualities, it could no longer be included under the denomination *matter*. In fhort, the word *matter* comprehends under it certain qualities: every fubftance which poffeffes thefe qualities is called *matter*; and no other fubftance except thefe can receive the name of *matter* without altering the meaning of the word.

162 Not reducible to the laws of matter;

The attractions and repulfions of matter have been examined with care; and the changes which they produce have been afcertained with confiderable accuracy. They have even been reduced to general principles under the name of *mechanical and chemical laws*. Whenever any change is obferved, if that change be a cafe of a mechanical or chemical law, we fay that the agent is *matter*; but if the change cannot be reduced under thefe laws, or if it be incompatible with thefe laws, we muft fay, unlefs we would pervert the meaning of words altogether, that the agent is not *matter*.

Now it cannot be difputed that feveral of the phenomena of life in vegetables are incompatible with the laws of mechanics and chemiftry. The motion of the fap, for inftance, muft be produced by the contraction of the veffels; and the contraction of veffels, on the application of ftimuli, is incompatible with the laws of chemiftry, becaufe no decompofition takes place; and of mechanics, becaufe a much greater force is generated than the generating body itfelf poffeffed. The evolution of the organs of vegetables, the reparation of decayed organs, the formation of new ones to fupply the place of the old, the production of feeds capable of producing new plants, the conftant fimilarity of individuals of the fame fpecies—thefe, and many other well known phenomena, cannot be reduced under mechanical and chemical laws. The caufe of life, then, in plants, is a *fubftance* (for we can form no conception of an agent which is not a fubftance) which does not act according to the laws of mechanics and chemiftry, and which confequently is *not matter*. We fhall therefore, till a better name be chofen, denominate it the *vegetative principle* (G).

163 Confequently owing to an immaterial caufe.

164 Nature of the vegetative principle.

The nature of the *vegetative principle* can only be deduced from the phenomena of vegetation. It evidently follows a fixed plan, and its actions are directed to promote the good of the plant. It has a power over matter, and is capable of directing its attractions and repulfions, in fuch a manner as to render them the inftruments of the formation, and improvement, and prefervation of the plant. It is capable alfo of generating fubftances endowed with powers fimilar to itfelf. The plan according to which it acts, difplays the moft confummate wifdom and forefight, and a knowledge of the properties of matter infinitely beyond what man can boaft.

165 Whether endowed with confcioufnefs.

Metaphyficians have thought proper to divide all fubftances into two claffes, *matter* and *mind*. If we follow this divifion, the vegetative principle, as it is not *material*, muft undoubtedly be ranked under *mind*. But if *confcioufnefs* and *intelligence* be confidered as effential to mind, which is the cafe according to their definition, we cannot give the vegetative principle the name of *mind*, becaufe it has not been proved that it poffeffes confcioufnefs and intelligence. It acts indeed according to a fixed plan, which difplays the higheft degree of intelligence; but this plan may belong, not to the vegetative principle itfelf, but to the Being who formed that principle. We can conceive it to have been endowed by the Author of Nature with peculiar powers, which it muft always exert according to certain fixed laws; and the phenomena of vegetation *may be* the refult of this mode of acting. This, as far as we can fee, is not impoffible. It muft be fhewn to be impoffible by every perfon who wifhes to prove that plants poffefs confcioufnefs and intelligence; for the proofs of this confcioufnefs can only be deduced from the defign which the actions of plants manifeft. Thofe philofophers who have afcribed confcioufnefs and intelligence to plants, have founded their belief principally on certain actions which plants perform on the application of ftimuli. But thefe actions prove nothing more than what cannot be denied, that there exifts a vegetative principle, which is not material, and which has certain properties in common with the living principles of animals; but whether or not this vegetative principle poffeffes confcioufnefs and intelligence, is a very different queftion, and muft be decided by very different proofs. We do not fay that the heart of an animal is confcious, becaufe it continues to beat on the application of proper ftimuli for fome time after it has been feparated from the reft of the body.

166 Death of plants.

The death of plants, if we can judge from the phenomena, is owing, not to the vegetative principle leaving them, but to the organs becoming at laft altogether unfit for performing their functions, and incapable of being repaired by any of the powers which that principle poffeffes. The changes which vegetable fubftances undergo after death come now to be examined. They fhall form the fubject of the enfuing chapter.

CHAP.

(G) Phyfiologifts have ufually given it the name of *living principle*. We would have adopted that name, if it had not been too general for our purpofe.

Bread.

CHAP. III. OF THE DECOMPOSITION OF VEGETABLE SUBSTANCES.

NOT only entire plants undergo decompofition after death, but certain vegetable fubftances alfo, whenever they are mixed together, and placed in proper circum-
167 Vegetable decompofitions, ftances, mutually decompofe each other, and new compound fubftances are produced. Thefe mutual decompofitions, indeed, are naturally to be expected: for as all vegetable fubftances are compofed of feveral ingredients, differing in the ftrength of their affinity for each other, it is to be fuppofed that, when two fuch fubftances are mixed together, the divellent affinities will, in many cafes, prove ftronger than the quiefcent; and therefore decompofition, and the formation of new compounds, muft take place: juft as happens when the acetite of lead and fulphat of potafs are mixed together.

Thefe mutual decompofitions of vegetable fubftances are by no means fo eafily traced, or fo readily explained, as the mutual decompofitions of neutral falts; partly on account of the number of fubftances, whofe affinities for each other are brought into action, and partly becaufe we are ignorant of the manner in which the ingredients of vegetable fubftances are mutually combined.

168 Called FERMENTATION. Chemifts have agreed to give thefe mutual decompofitions which take place in vegetable fubftances the name of *fermentation*; a word firft introduced into chemiftry by Van Helmont *; and the new fubftances produced they have called the *products* of fermentation. All the phenomena of fermentation lay for many years concealed in the completeft darknefs, and no chemift was bold enough to hazard even an attempt to explain them. They were employed, however, and without hefitation too, in the explanation of other phenomena; as if giving to one procefs, the name of another of which we are equally ignorant, could, in reality, add any thing to our knowledge. The darknefs which enveloped thefe phenomena has lately begun to difperfe; but they are ftill furrounded with a very thick mift; and we muft be much better acquainted with the compofition of vegetable fubftances, and the mutual affinities of their ingredients, than we are at prefent, before we can explain them in a fatisfactory manner.

* *Stahl, Fundament. Chim.* i. 124.

169 Divifion of them. The vegetable fermentations or decompofitions may be arranged under five heads; namely, that which produces *bread*, that which produces *wine*, that which produces *beer*, that which produces *acetous acid* or *vinegar*, and the *putrefactive* fermentation, or that which produces the fpontaneous decompofition of decayed vegetables. Thefe fhall be the fubject of the five following fections. In order to avoid long titles, we fhall give to the firft three fections the name of the new fubftances produced by the fermentation.

SECT. I. *Of BREAD.*

170 Difcovery of bread. SIMPLE as the manufacture of bread may appear to us who have been always accuftomed to confider it as a common procefs, its difcovery was probably the work of ages, and the refult of the united efforts of men, whofe fagacity, had they lived in a more fortunate period of fociety, would have rendered them the rivals of Ariftotle or of Newton.

The method of making bread fimilar to ours was known in the Eaft at a very early period; but neither the precife time of the difcovery, nor the name of the perfon who publifhed it to the world, has been preferved. We are certain that the Jews were acquainted with it in the time of Mofes; for in Exodus * we find a prohibition to ufe leavened bread during the celebration of the paffover. It does not appear, however, to have been known to Abraham; for we hear in his hiftory of cakes frequently, but nothing of leaven. Egypt, both from the nature of the foil and the early period at which it was civilized, bids faireft for the difcovery of making bread. It can fcarcely be doubted that the Jews learned the art from the Egyptians. The Greeks affure us that they were taught the art of making bread by the god Pan. We learn from Homer that it was known during the Trojan war †. The Romans were ignorant of the method of making bread till the year 580, after the building of Rome, or 200 years before the commencement of the Chriftian era ‡. Since that period the art has never been unknown in the fouth of Europe; but it made its way to the north very flowly, and even at prefent in many northern countries fermented bread is but very feldom ufed.

* Ch. xii. v. 15.

† *Iliad*, ix. 216.

‡ *Plin.* l. 18. cap. 11.

171 Subftances which make bread. The only fubftance well adapted for making bread, we mean *loaf bread*, is wheat flour, which is compofed of four ingredients; namely, gluten, ftarch, albumen, and a *fweet mucous matter*, which poffeffes nearly the properties of fugar, and which is probably a mixture of fugar and mucilage. It is to the gluten that wheat flour owes its fuperiority to every other as the bafis of bread. Indeed there are only two other fubftances at prefent known of which good loaf bread can be made; thefe are *rye* and *potatoes*. The rye loaf is by no means fo well raifed as the wheat loaf; and potatoes will not make bread at all without particular management. Potatoes, previoufly boiled and reduced to a very fine tough pafte by a rolling pin, muft be mixed with an equal weight of potatoe ftarch. This mixture, baked in the ufual way, makes a very white, well raifed, pleafant bread. We are indebted for the procefs to Mr Permentier. Barley-meal perhaps might be fubftituted for ftarch.

172 Baking of bread. The baking of bread confifts in mixing wheat flour with water, and forming it into a pafte. The average proportion of thefe is two parts of water to three of flour. But this proportion varies confiderably, according to the age and the quality of the flour. In general, the older and the better the flour is, the greater is the quantity of water required. If the pafte, after being thus formed, be allowed to remain for fome time, its ingredients gradually act upon each other, and the pafte acquires new properties. It gets a difagreeable four tafte, and a quantity of gas (probably carbonic acid gas) is evolved. In fhort, the pafte ferments (H). Thefe changes do not take place without water; that liquid, therefore, is a neceffary agent. Poffibly it is decompofed by the action of the ftarch upon it; for when ftarch is diluted with water, it gradually becomes four. The gluten, too, is altered, either by the action of the water on it, or of the ftarch; for if we examine the pafte after

(H) It was from this procefs that Van Helmont transferred the word *fermentation* into chemiftry.

Bread. after it has undergone fermentation, the gluten is no longer to be found. If paste, after standing for a sufficient time to ferment, be baked in the usual way, it forms a loaf full of eyes like our bread, but of a taste so sour and unpleasant that it cannot be eaten. If a small quantity of this old paste, or *leaven* as it is called, be mixed with new made paste, the whole begins to ferment in a short time; a quantity of gas is evolved; but the glutinous part of the flour renders the paste so tough, that the gas cannot escape; it therefore causes the paste to swell in every direction: and if it be now baked into loaves, the immense number of air bubbles imprisoned in every part renders the bread quite full of eyes, and very light. If the precise quantity of leaven necessary to produce the fermentation, and no more, has been used, the bread is sufficiently light, and has no unpleasant taste; but if too much leaven be employed, the bread has a bad taste; if too little, the fermentation does not come on, and the bread is too compact and heavy. To make good bread with leaven, therefore, is very difficult.

The ancient Gauls had another method of fermenting bread. They formed their paste in the usual way; and instead of leaven, mixed with it a little of the *barm* which collects on the surface of fermenting beer *. This mixture produced as complete and as speedy a fermentation as leaven; and it had the great advantage of not being apt to spoil the taste of the bread. About the end of the 17th century, the bakers in Paris began to introduce this practice into their processes. The practice was discovered, and exclaimed against; the faculty of medicine, in 1688, declared it prejudicial to health; and it was not till after a long time that the bakers succeeded in convincing the public that bread baked with *barm* is superior to bread baked with leaven. In this country the bread has for these many years been fermented with barm.

* Plin. xviii. 7.

173 Barm. What is this *barm* which produces these effects? The question is curious and important; but we are not able to answer it completely. Mr Henry of Manchester has concluded, from a number of very interesting experiments, that the only useful part of barm is carbonic acid gas, and that this gas therefore is the real fermenter of paste †.

† Manch. Mem. ii. 262.

That the barm of beer, in its usual state, contains carbonic acid gas, cannot be doubted; and that carbonic acid gas acts as a ferment, the experiments of Mr Henry prove decisively. But that the only active part of barm is carbonic acid gas, and nothing but carbonic gas, is extremely doubtful, or rather we are certain that it is not true. It has been customary with the bakers of Paris to bring their barm from Flanders and Picardy in a state of dryness. When skimmed off the beer, it is put into sacks, and the moisture allowed to drop out; then these sacks are subjected to a strong pressure, and when the barm is dry it is made up into balls †. Now, in this state, it is not to be supposed that bubbles of carbonic acid can remain entangled in the barm; they must have been squeezed out by the press, and by the subsequent formation of the barm into balls: yet this barm, when moistened with water, ferments the bread as well as new barm.

† Enc. Meth. art. i. 249.

After the bread has fermented, and is properly raised, it is put into the oven previously heated, and allowed to remain till it be baked. The mean heat of an oven, as ascertained by Mr Tillet, is 448° *. The bakers do not use a thermometer; but they judge that the oven is arrived at the proper heat when flour thrown on the floor of it becomes black very soon without taking fire. We see, from Tillet's experiment, that this happens at the heat of 448°. 174 Heat of the oven.

* Enc. Meth. art. i. 275.

When the bread is taken out of the oven, it is found to be lighter than when put in; as might naturally have been expected, from the evaporation of moisture, which must have taken place at that temperature. Mr Tillet, and the other commissioners who were appointed to examine this subject in consequence of a petition from the bakers of Paris, found that a loaf, which weighed before it was put into the oven 4.625 lbs. after being taken out baked, weighed, at an average, only 3.813 lbs. or 0.812 lb. less than the paste. Consequently 100 parts of paste, lose, at an average, 17.34 parts, or somewhat more than $\frac{1}{5}$th by baking *. They found, however, that this loss of weight was by no means uniform, even with respect to those loaves which were in the oven at the same time, of the same form, and in the same place, and which were put in and taken out at the same instant. The greatest difference in these circumstances amounted to .2889, or 7.5 parts in the hundred, which is about $\frac{1}{13}$th of the whole. This difference is very considerable, and it is not easy to say to what it is owing. It is evident, that if the paste has not all the same degree of moisture, and if the barm be not accurately mixed through the whole, if the fermentation of the whole be not precisely the same, that these differences must take place. Now it is needless to observe how difficult it is to perform all this completely. The French commissioners found, as might indeed have been expected, that, other things being equal, the loss of weight sustained is proportional to the extent of surface of the loaf, and to the length of time that it remains in the oven; that is to say, the smaller the extent of the external surface, or, which is the same thing, the nearer the loaf approaches to a globular figure, the smaller is the loss of weight which it sustains; and the longer it continues in the oven, the greater is the loss of weight which it sustains. Thus a loaf which weighed exactly 4 lbs. when newly taken out of the oven, being replaced as soon as weighed, lost, in ten minutes, .125 lb. of its weight, and in ten minutes more it again lost .0625 lb. †. 175 Loss of weight sustained in it.

* Ibid. 275.

† Ibid. p. 270.

Loaves are heaviest when just taken out of the oven; they gradually lose part of their weight, at least if not kept in a damp place, or wrapt round with a wet cloth (K). Thus Mr Tillet found that a loaf of 4 lbs. after being kept for a week, wanted .3125, or nearly $\frac{1}{13}$th of its original weight ‡.

‡ Ibid.

When bread is newly taken out of the oven, it has a peculiar, and rather pleasant smell, which it loses by keeping; as it does also the peculiar taste by which new bread is distinguished. This shews us, that the bread undergoes chemical changes; but what these changes are, or what the peculiar substance is to which the odour of bread is owing, is not known. 176 Properties of bread.

Bread

(K) This is an excellent method of preserving bread fresh, and free from mould, for a long time.

Wine. Bread differs very completely from the flour of which it is made, for none of the ingredients of the flour can now be difcovered in it. The only chemift who has attempted an analyfis of bread is Mr Geoffroy. He found that 100 parts of bread contained the following ingredients:

24.735 water.
32.030 gelatinous matter, extracted by boiling water.
39.843 refiduum infoluble in water.

96.608
3.392 lofs.

100.

But this analyfis, which was publifhed in the Memoirs of the French Academy for the year 1732, was made at a time when the infant ftate of the fcience of chemiftry did not admit of any thing like accuracy.

SECT. II. *Of Wine.*

177 Fruits affording wine. THERE is a confiderable number of ripe fruits from which a fweet liquor may be expreffed, having at the fame time a certain degree of acidity. Of fuch fruits we have in this country the apple, the cherry, the goofeberry, the currant, &c. but by far the moft valuable of thefe fruits is the *grape*, which grows luxuriantly in the fouthern parts of Europe. From grapes, fully ripe, may be expreffed a liquid of a fweet tafte, to which the name of *muft* has been given. This liquid is compofed almoft entirely of five ingredients; namely, *water*, *fugar*, *jelly*, *mucilage*, and *tartarous* acid partly faturated with potafs. The quantity of fugar which grapes fully ripe contain is very confiderable; it may be obtained in cryftals by evaporating muft to the confiftence of fyrup, feparating the tartar which precipitates during the evaporation, and then fetting the muft afide for fome months. The cryftals of fugar are gradually formed.

178 Undergo the vinous fermentation; When muft is put into the temperature of about 70°, the different ingredients begin to act upon each other, and what is called *vinous fermentation* commences. The phenomena of this fermentation are an inteftine motion in the liquid, its becoming thick and muddy, a temperature equal to 72.5°, and an evolution of carbonic acid gas. In a few days the fermentation ceafes, the thick part fubfides to the bottom, the liquid becomes clear, it has loft much of its faccharine tafte, and affumed a new one, its fpecific gravity is diminifhed; and in fhort, it has become the liquid well known under the name of *wine*.

Now what is the caufe of this fermentation; what are the fubftances which mutually decompofe each other; and what is the nature of the new fubftance formed?

Thefe changes are produced altogether by the mutual action of the fubftances contained in muft; for they take place equally well, and wine is formed equally well in clofe veffels as in the open air §.

If the *muft* be evaporated to the confiftency of a thick fyrup, or to a *rob*, as the elder chemifts termed

179 For which water, it, the fermentation will not commence, though the proper temperature, and every thing elfe neceffary to produce fermentation, be prefent ‖. But if this fyrup be again diluted with water, and placed in favourable circumftances, it will ferment. Therefore the prefence of *water* is abfolutely neceffary for the exiftence of vinous fermentation.

180 Sugar, If the juice of thofe fruits which contain but little fugar, as currants, be put into a favourable fituation, fermentation indeed takes place, but fo flowly, that the product is not *wine*, but *vinegar*: but if a fufficient quantity of fugar be added to thefe very juices, wine is readily produced. No fubftance whatever can be made to undergo vinous fermentation, and to produce wine, unlefs fugar be prefent. *Sugar* therefore is abfolutely neceffary for the exiftence of vinous fermentation; and we are certain that it is decompofed during the procefs, for no fugar can be obtained from properly fermented wine.

181 An acid, All thofe juices of fruits which undergo the vinous fermentation, either with or without the addition of fugar, contain an acid. We have feen already in the firft chapter that the vegetable acids are obtained chiefly from fruits. The apple, for inftance, contains malic acid; the lemon, citric acid; the grape, tartarous acid. The Marquis de Bullion has afcertained, that *muft* will not ferment if all the tartarous acid which it contains be feparated from it *. We may conclude from this, that the prefence of a vegetable acid is abfolutely neceffary for the commencement of the vinous fermentation. This renders it probable that the effential part of barm is a vegetable acid, or fomething equivalent; for if fugar be diffolved in four times its weight of water, mixed with the yeaft of beer, and placed in a proper temperature, it undergoes the vinous fermentation †.

182 And jelly are neceffary. All the juices of fruits which undergo the vinous fermentation contain a quantity of jelly, or mucilage, or of both. Thefe two fubftances refemble each other in fo many particulars, and it is fo difficult to feparate them, that we fhall fuppofe they have the fame effect in the mixture. The prefence of thefe fubftances renders it probable that they alfo are neceffary for the vinous fermentation. Perhaps they act chiefly by their tendency to become acid.

Thus we fee, that for the production of wine a certain temperature, a certain portion of water, fugar, a vegetable acid, and, in all probability, jelly alfo, is neceffary. Mr Lavoifier found that fugar would not ferment unlefs diffolved in at leaft four times its weight of water. This feems to indicate that the particles of fugar muft be removed to a certain diftance from each other before the other ingredients can decompofe them. The evolution and feparation of carbonic acid gas in fuch quantity, fhews us that the proportion of the carbon and the oxygen of the fugar is diminifhed. It is not certain that the mucilage of the wine is decompofed fo completely as the fugar; for it has been obferved, that when the muft abounds in mucilage, the wine is apt to become four.

183 Decompofition of wine. When wine is diftilled by means of a low heat, there comes over a quantity of *alcohol*, and the remainder is a folution of acetous acid. From this fact, it has been concluded that wine is compofed of acetous acid and alcohol. But that the diftillation occafions a chemical change in the ingredients of wine is evident from this, that if we again mix the alcohol and acetous acid, we do not reproduce the wine.

Fourcroy has attempted to fhew that alcohol exifted ready formed; but his proofs are not conclufive. Fabroni

§ *Fabroni*, *Ann. de Chim.* xxxi. 302.

‖ *Stahl*, i.

* *Chaptal.*

† *Bergman.*

Beer.

roni has ſhewn, that alcohol cannot be obtained from new made wine by any other method than diſtillation. When wine is ſatured with very dry carbonat of potaſs, no alcohol makes its appearance on the ſurface of the mixture, yet a very ſmall quantity of alcohol, artificially mixed with wine, may be detected by this method. It is certain, however, that alcohol exiſts ready formed in old wine.

Sect. III. *Of Beer.*

The method of making beer was known in the moſt remote ages; we are ignorant to whom the world is indebted for the diſcovery of it. Beer is uſually made from *barley*.

184 Method of making malt,

The barley is ſteeped in water for about ſixty hours, in order to ſaturate it with that liquid. It ought then to be removed as ſpeedily as poſſible, otherwiſe the water diſſolves, and carries off the moſt valuable part of the grain. This barley is then to be laid in a heap for twenty-four hours; heat is evolved, oxygen gas abſorbed, carbonic acid gas emitted, and germination commences with the ſhooting forth of the radicle. It is then ſpread upon a cool floor, dried ſlowly, and is afterwards known by the name of *malt* *.

* *Collier, Manch. Mem.* v. 185.

Wort,

Malt, previouſly ground to a courſe powder, is to be infuſed in a ſufficient quantity of pure water, of the temperature of 160°, for an hour. The infuſion is then to be drawn off, and more water may be added, at a higher temperature, till all the ſoluble part of the malt is extracted. This infuſion is known by the name of *wort*. It has a ſweet taſte, and contains a quantity of ſaccharine, and doubtleſs alſo of gelatinous matter.

186 And beer.

When *wort* is placed in the temperature of about 60°, fermentation gradually takes place in it, and the very ſame phenomena appear which diſtinguiſh the production of wine. The fermentation of wort, then, is nothing but a particular caſe of the vinous fermentation. But wort does not ferment ſo well, nor ſo ſoon, nor does it produce nearly ſo great a quantity of good fermented liquor, as when *yeaſt* is added to it. The reaſon of which is, probably, that the fermentation does not commence till an acid is generated in the wort, and before that happens part of the ſaccharine contents are decompoſed; whereas the yeaſt adds an acid, or, at leaſt, ſomething equivalent to it, at once.

Wort ferments in cloſe veſſels, as Mr Collier aſcertained by experiment, equally well as in the open air. Therefore the decompoſition is produced entirely by the ſubſtances contained in the wort, without the addition of any thing from the air. The quantity of beer produced in cloſe veſſels is much greater than when the proceſs takes place in the open air. The reaſon of which is, that in the open air the beer gradually evaporates during the fermentation. Thus Mr Collier found that 11 quarts, $3\frac{1}{2}$ oz. fermented in open veſſels, loſt, in 12 days, 40 oz.; whereas an equal weight, fermented in cloſe veſſels, loſt only 8 oz. in the ſame time. Yet the quality of the *beer* was the ſame in each; for equal quantities of both, when diſtilled, yielded preciſely the ſame portion of alcohol †.

† *Ibid*, p. 160.

Acetous Fermentation, Putrefaction.

During the fermentation, a quantity of carbonic acid gas is conſtantly diſengaged, not in a ſtate of purity, but containing, combined with it, a portion of the wort; and if this gas be made to paſs through water, it will depoſite wort, which may be fermented in the uſual manner *.

When beer is diſtilled, alcohol is obtained, and the reſiduum is an acid liquor †. The theory of beer is ſo obviouſly the ſame with that of wine that it requires no additional explanation.

* *Collier, Manch. Mem.*

† *Henry, Mem.* ii. 257.

Sect. IV. *Of the Acetous Fermentation.*

187 Subſtances which undergo the acetous fermentation.

If wine or beer be kept at a temperature between 70° and 90°, it gradually loſes its properties, and is converted into *acetous acid*.

During this change, a quantity of oxygen gas is abſorbed, and the whole of the ſpirituous part of the wine or beer diſappears. Conſequently its ingredients naturally decompoſed each other.

Neither pure alcohol, nor alcohol diluted with water, are capable of undergoing this change, neither do they abſorb any oxygen. This abſorption, then, is made by the mucilaginous matter which always exiſts in theſe liquids. No acetous acid is ever produced, unleſs ſome acid be preſent in the liquid. We may conclude, then, that the mucilage acquires the properties of an acid before it begins to act upon the ſpirituous part of the beer or the wine.

As the acetous acid has been already treated of in the article Chemistry, *Suppl.* it is unneceſſary to dwell any longer on this ſubject here.

Sect. V. *Of Putrefaction.*

188 Nature of putrefaction.

All vegetable ſubſtances, both complete plants and their component parts ſeparately, when left entirely to themſelves, are gradually decompoſed and deſtroyed, provided moiſture be preſent, and the temperature be not much under 45°, nor too high to evaporate ſuddenly all the moiſture, This decompoſition has obtained the name of *putrefaction*.

It proceeds with moſt rapidity in the open air; but the contact of air is not abſolutely neceſſary. Water is, in all caſes, eſſential to the proceſs, and therefore is moſt probably decompoſed.

Putrefaction is conſtantly attended with a fetid odour, owing to the emiſſion of certain gaſeous matters, which differ according to the putrefying ſubſtance. Some vegetable ſubſtances, as gluten, and cruciform plants, emit ammonia; others, as onions, ſeem to emit phoſphorated hydrogen gas. Carbonic acid gas, and hydrogen gas, impregnated with unknown vegetable matters, are almoſt conſtantly emitted in abundance. When the whole proceſs is finiſhed, ſcarcely any thing remains but the earths, the ſalts, and the metals, which formed a conſtituent part of the vegetable. But our chemical knowledge of vegetable compounds is by far too limited to enable us to follow this very complicated proceſs with any chance of ſucceſs.

PART

Part II. Of Animal SUBSTANCES.

gredients animals, Fibrina. WHEN we compare animals and vegetables together, each in their moft perfect ftate, nothing can be eafier than to diftinguifh them. The plant is
189 confined to a particular fpot, and exhibits no marks of
laffes of confcioufnefs or intelligence; the animal, on the con-
imals and trary, can remove at pleafure from one place to another,
getables. is poffeffed of confcioufnefs, and a high degree of intelligence. But on approaching the contiguous extremities of the animal and vegetable kingdom, thefe ftriking differences gradually difappear, the objects acquire a greater degree of refemblance, and at laft approach each other fo nearly, that it is fcarcely poffible to decide whether fome of thofe fituated on the very boundary belong to the animal or vegetable kingdom.

190 ifficulty diftinguifh- To draw a line of diftinction, then, between animals and vegetables, would be a very difficult tafk; but it is not neceffary for us, in this place at leaft, to attempt it; for almoft the only animals whofe bodies have been hitherto examined with any degree of chemical accuracy, belong to the moft perfect claffes, and confequently are in no danger of being confounded with plants. Indeed the greater number of facts which we have to relate, apply only to the human body, and to thofe of a few domeftic animals. The tafk of analyfing all animal bodies is immenfe, and muft be the work of ages of indefatigable induftry.

191 ivifion of is Part. We fhall divide this Part of the article into four chapters. In the firft chapter, we fhall give an account of the different ingredients hitherto found in animals, fuch of them at leaft as have been examined with any degree of accuracy: in the fecond, we fhall treat of the different members of which animal bodies are compofed; which muft confift each of various combinations of the ingredients defcribed in the firft chapter: in the third, we fhall treat of thofe animal functions which may be elucidated by chemiftry: and, in the fourth, of the changes which animal bodies undergo after death.

Chap. I. Of the Ingredients of Animals.

The fubftances which have been hitherto detected in the animal kingdom, and of which the different parts of animals, as far as thefe parts have been analyfed, are found to be compofed, may be arranged under the following heads:

1. Fibrina,	8. Sulphur,
2. Albumen,	9. Oils,

Thefe fhall form the fubject of the following fections:

Sect. I. *Of Fibrina.*

If a quantity of blood, newly drawn from an animal, be allowed to remain at reft for fome time, a thick red clot gradually forms in it, and fubfides. Separate this clot from the reft of the blood, wafh it repeatedly in water till it ceafes to give out any colour or tafte to the liquid; the fubftance which remains after this process is denominated *fibrina*. It has been long known to phyficians under the name of the *fibrous part of the blood*, but has not till lately been accurately defcribed. Albumen. 192 Fibrina how obtained.

193 Its properties. Fibrina is of a white colour, has no tafte, and is infoluble in water and in alcohol. It is foft and ductile, has a confiderable degree of elafticity, and refembles very much the gluten of vegetables.

Pure fixed alkalies do not act upon it, unlefs they be very much concentrated, and then they decompofe it. All the acids combine with it readily, and diffolve it. Water and alkalies feparate it again; but it has loft entirely its former properties. With muriatic acid it forms a green coloured jelly.

When nitric acid is poured upon fibrina, azotic gas is difengaged, as Berthollet firft difcovered. The quantity of this gas is greater than can be obtained from the fame quantity of other animal fubftances by the fame procefs *. After this, pruffic acid and carbonic acid gas are exhaled. By the affiftance of heat the fibrina is diffolved; much nitrous gas is difengaged; the liquid, when concentrated, yields oxalic and malic acids; and white flakes are depofited, confifting of an oily fubftance, and of phofpat of lime †.

When fibrina is diftilled, it yields a very large quantity of ammonia ‡.

Thefe properties are fufficient to fhew us that this fubftance is compofed of azot, hydrogen, and carbon; but neither the precife proportion of thefe ingredients, nor the manner of their combination, are at prefent known.

* Fourcroy, *Ann. de Chim.* i. 41.

† Fourcroy.

‡ Fourcroy, *Ann. de Chim.* i. 43.

Sect. II. *Of Albumen.*

194 Albumen contained in Eggs. The eggs of fowls contain two very different fubftances: a yellow oily-like matter, called the *yolk*; and a colourlefs gloffy vifcid liquid, diftinguifhed by the name of *white*. This laft is the fubftance which chemifts have agreed to denominate *albumen* (L). The white of an egg, however, is not pure albumen. It contains, mixed with it, fome carbonat of foda, and fome fulphur; but the quantity of thefe fubftances is fo fmall that they do not much influence its properties. We fhall therefore confider it as *albumen*.

195 Coagulated by heat. On the application of a heat of 165° § it *coagulates*, as is well known, into a white folid mafs; the confiftency of which, when other things are equal, depends, in fome meafure, on the time during which the heat was applied. The coagulated mafs has precifely the fame weight that it had while fluid.

§ Cullen.

The tafte of coagulated albumen is quite different from that of liquid albumen: its appearance, too, and its

(L) This is merely the Latin term for the white of an egg. It was firft introduced into chemiftry by the phyfiologifts.

Albumen.

its properties, are entirely changed; for it is no longer soluble, as before, either in hot or in cold water.

196 Phenomena of this coagulation.

The coagulation of albumen takes place even though air be completely excluded; and even when air is present there is no absorption of it, nor does albumen in coagulating change its volume *. Acids have the property of coagulating albumen, as Scheele ascertained †. Alcohol also produces, in some measure, the same effect. *Heat*, then, *acids* and *alcohol*, are the agents which may be employed to coagulate albumen.

* Carradori, Ann de Chim xxix 98.

† Scheele, ii 58.

It is remarkable, that if albumen be diluted with a sufficient quantity of water, it can no longer be coagulated by any of those agents. Scheele mixed the white of an egg with ten times its weight of water, and then, though he even *boiled* the liquid, no coagulum appeared. Acids indeed, and alcohol, even then coagulated it; but they also lose their power, if the albumen be diluted with a much greater quantity of water, as has been ascertained by many experiments. Now we know, that when water is poured into albumen, not only a mechanical mixture takes place, but a chemical combination; for the albumen is equally distributed through every part of the liquid. Consequently its integrant particles must be farther separated from each other, and their distance must increase with the quantity of water with which they are diluted. We see, therefore, that albumen ceases to coagulate whenever its particles are separated from each other beyond a certain distance. That no other change is produced, appears evident from this circumstance, that whenever the watery solution of albumen is sufficiently concentrated by evaporation, coagulation takes place, upon the application of the proper agents, precisely as formerly.

It does not appear that the distance of the particles of albumen is changed by coagulation; for coagulated albumen occupies precisely the same sensible space as liquid albumen *.

* Carradori.

197 Enquiry into its cause.

Thus two things seem certain respecting the coagulation of albumen: 1. That its particles must not be beyond a certain distance; 2. That the coagulation does not produce any sensible change in their distance. To what, then, is the coagulation of albumen owing? We can conceive no change to take place from a state of liquidity to that of solidity, without some change in the figure of the particles of the body which has undergone that change: for if the figure and the distance of the particles of bodies continue the same, it is impossible to conceive any change at all to take place. Since, then, the distance of the particles of albumen does not, as far at least as we can perceive, change, we must conclude that the figure of the particles actually does change. Now such a change may take place three ways; 1. The figure may be changed by the addition of some new molecules to each of the molecules of the body. 2. Some molecules may be abstracted from every integrant particle of the body. 3. Or the molecules, of which the integrant particles are composed, may enter into new combinations, and form new integrant particles, whose form is different from that of the old integrant particles. Some one or other of these three things must take place during the coagulation of albumen.

1. Scheele and Fourcroy have ascribed the coagulation of albumen to the first of these causes, namely, to the addition of a new substance. According to Scheele, *caloric* is the substance which is added. Fourcroy, on the contrary, affirms that it is *oxygen*.

Scheele supported his opinion with that wonderful ingenuity which shone so eminently in every thing which he did. He mixed together one part of white of egg and four parts of water, added a little pure alkali, and then dropt in as much muriatic acid as was sufficient to saturate the alkali. The albumen coagulated; but when he repeated the experiment, and used carbonat of alkali instead of pure alkali, no coagulation ensued. In the first case, says he, there was a double decomposition: the muriatic acid separated from a quantity of caloric with which it was combined, and united with the alkali: while, at the same instant, the caloric of the acid united with the albumen, and caused it to coagulate. The same combination could not take place when the alkaline carbonat was used, because the carbonic acid gas carried off the caloric, for which it has a strong affinity *.

* Scheele, ii. 58.

This explanation is plausible; but it is contrary to every other known fact in chemistry, to suppose that caloric can combine with a substance without occasioning any alteration in its bulk, and cannot therefore be admitted without the most rigid proof.

Fourcroy observes, in support of his opinion, that the white of an egg is not at first capable of forming a hard coagulum, and that it only acquires that property by exposure to the atmosphere. It is well known that the white of a new laid egg is milky after boiling; and that if the shell be covered over with grease, to exclude the external air, it continues long in that state; whereas the white of an old egg, which has not been preserved in that manner, forms a very hard tough coagulum. These facts are undoubted; and they render it exceedingly probable, that albumen acquires the property of forming a hard coagulum only by absorbing oxygen: but they by no means prove that coagulation itself is owing to such an absorption. And since coagulation takes place without the presence of air, and since no air, even when it is present, is absorbed, this opinion cannot be maintained without inconsistency.

2. The only substance which can be supposed to leave albumen during coagulation, since it does not lose weight, is *caloric*. We know that in most cases where a fluid is converted into a solid, caloric is actually disengaged. It is extremely probable, then, that the same disengagement takes place here. But the opinion has not been confirmed by any proof. Fourcroy indeed says, that in an experiment made by him, the thermometer rose a great number of degrees. But as no other person has ever been able to observe any such thing, it cannot be doubted that this philosopher has been misled by some circumstance or other to which he did not attend †. It is usual, in many cases, for bodies to lose bulk when they give out caloric; but that there are exceptions to this rule, is well known.

† Thomson's Fourcroy, iii. 271.

3. Even if the second opinion were true, it is scarcely possible to conceive the coagulation of albumen to take place without some change in its integrant particles. We can see how all the substances which coagulate albumen might produce such a change; and the insolubility of coagulated albumen in water, and its other different properties, render it more than probable that some such change actually takes place. But what that change is, cannot even be conjectured.

The

Gelatine.

198 Properties of albumen.

The coagulation of albumen is intimately connected with one of the moſt important problems in chemiſtry, namely, the cauſe of fluidity and ſolidity. But this problem can only be reſolved, with any proſpect of ſucceſs, by a geometrical inveſtigation of the phenomena of heat.

Coagulated albumen is diſſolved by the mineral acids, greatly diluted with water; and if a concentrated acid be added to the ſolution, the albumen is again precipitated *. Alkalies, however, do not precipitate it from its ſolution in acids †. But if a ſolution of tan be poured into the acid ſolution of albumen, a very copious precipitate appears ‡.

If the ſolution of tan be poured into an aqueous ſolution of uncoagulated albumen, it forms with it a very copious precipitate, which is inſoluble in water. This precipitate is a combination of tan and albumen. This property which albumen has of precipitating with tan, was diſcovered by Seguin §: it furniſhes us with a method of detecting the preſence of albumen in any liquid in which we ſuſpect it.

* Scheele, 57.
† Vauquelin, Ann. de Chim. xxix.
‡ Ibid.
§ Nicholſon's Journal, i. 271.

Pure alkalies and lime water alſo diſſolve albumen; at the ſame time ammonia is diſengaged, owing to the decompoſition of part of the albumen. Acids precipitate the albumen from alkalies, but its properties are changed *.

Nitric acid, when aſſiſted by heat, diſengages azotic gas from albumen †; but the quantity is not ſo great as may be obtained from fibrina ‡. The albumen is gradually diſſolved, nitrous gas is emitted, oxalic and malic acids are formed, and a thick oily matter makes its appearance on the ſurface §. When diſtilled, it furniſhes the ſame products as fibrina, only the quantity of ammonia is not ſo great ‖.

Hence it follows, that albumen is compoſed of azot, hydrogen, and carbon, as well as fibrina; but the proportion of azot is not ſo great in the firſt ſubſtance as in the ſecond.

* Scheele, 57.
† Scheele and Bertholet.

§ Scheele, Crell's Annals, ii. 17. Eng. Tranſl.
‖ Fourcroy, Ann. de Chim. i. 43.

SECT III. *Of Gelatine.*

199 Gelatine how obtained.

If a piece of the freſh ſkin of an animal, an ox for inſtance, after the hair and every impurity is carefully ſeparated, be waſhed repeatedly in cold water, till the liquid ceaſes to be coloured, or to abſtract any thing; if the ſkin, thus purified, be put into a quantity of pure water, and boiled for ſome time, part of it will be diſſolved. Let the decoction be ſlowly evaporated till it is reduced to a ſmall quantity, and then put aſide to cool. When cold, it will be found to have aſſumed a ſolid form, and to reſemble preciſely that tremulous ſubſtance well known to every body under the name of *jelly*. This is the ſubſtance called in chemiſtry *gelatine*. If the evaporation be ſtill farther continued, by expoſing the gelly to dry air, it becomes hard, ſemitranſparent, breaks with a glaſſy fracture, and is in ſhort the ſubſtance ſo much employed in different arts under the name of *glue*. Gelatine, then, is preciſely the ſame with glue; only that it muſt be ſuppoſed always free from thoſe impurities with which glue is ſo often contaminated.

200 Its properties.

Gelatine is tranſparent and colourleſs; when thrown into water, it very ſoon ſwells, and aſſumes a gelatinous form, and gradually diſſolves completely. By evaporating the water, it may be obtained again unaltered in the form of jelly.

Animal Mucilage.

When an infuſion of tan is dropt into a ſolution of gelatine in water, there is inſtantly formed a copious white precipitate, which has all the properties of leather. This precipitate is compoſed of tan and gelatine. Theſe two ſubſtances, therefore, when combined, form leather. Albumen and gelatine are the only animal ſubſtances known which have the property of combining with tan, and forming with it an inſoluble compound. They may be always eaſily detected, therefore, by means of tan; and they may be readily diſtinguiſhed from each other, as albumen alone coagulates by heat, and gelatine alone concretes into a jelly.

Gelatine is inſoluble in alcohol, and is even precipitated from water by it; but both acids and alkalies diſſolve it. Nitric acid diſengages from it a ſmall quantity of azotic gas; diſſolves it, when aſſiſted by heat, excepting an oily matter, which appears on the ſurface of the ſolution; and converts it, partly into oxalic and malic acids *.

When diſtilled, there comes over firſt water, containing ſome animal matter; the gelatine then ſwells, becomes black, emits a fetid odour, accompanied with acrid fumes: Some empyreumatic oil then comes over, and a very ſmall quantity of carbonat of ammonia: its coaly reſiduum remains behind. Theſe phenomena ſhew, that gelatine is compoſed of carbon, hydrogen, and azot; but the proportion of azot is evidently much ſmaller than in either fibrina or albumen †.

* Scheele, Crell's Ann. ii. 17. Eng. Tranſl.
† Fourcroy, Ann de Chim. i. 42.

SECT. IV. *Of Animal Mucilage.*

No word in chemiſtry is uſed with leſs accuracy than *mucilage*. It ſerves as a common name for almoſt every animal ſubſtance which cannot be referred to any other claſs.

None of the ſubſtances to which the name of *animal mucilage* has been given, have been examined with care; of courſe it is unknown whether theſe ſubſtances be the ſame or different.

201 Properties of mucilage.

Whether an animal ſubſtance poſſeſſes the following properties, it is at preſent denominated an animal mucilage by chemiſts.

1. Soluble in water.
2. Inſoluble in alcohol.
3. Neither coagulable by heat, nor concreting into a gelly by evaporation.
4. Not precipitated by the ſolution of tan.

Moſt of the ſubſtances called *mucilage* have alſo the property of abſorbing oxygen, and of becoming by that means inſoluble in water.

The mucilaginous ſubſtances ſhall be pointed out in the next chapter. In the preſent ſtate of our knowledge, any account of them here would merely be a repetition of the properties juſt mentioned.

SECT. V. *Of the Basis of Bile.*

202 Baſis of bile how obtained,

Into 32 parts of freſh ox bile pour one part of concentrated muriatic acid. After the mixture has ſtood for ſome hours, paſs it through a filter, in order to ſeparate a white coagulated ſubſtance. Pour the filtrated liquor, which has a fine green colour, into a glaſs veſſel, and evaporate it by a moderate heat. When it has arrived at a certain degree of concentration, a green coloured ſubſtance precipitates. Decant off the clear liquid, and waſh the precipitate in a ſmall quantity of pure

Baſis of Bile.

pure water. This precipitate is the *baſis of bile*, or the *reſin of bile*, as it is ſometimes called*.

203 Its properties.

The baſis of bile is of a black colour; but when ſpread out upon paper or on wood, it is green: its taſte is intenſely bitter†.

When heated to about 122°, it melts; and if the heat be ſtill farther increaſed, it takes fire, and burns with rapidity. It is ſoluble in water, both cold and hot, and ſtill more ſoluble in alcohol; but water precipitates it from that liquid‡.

It is ſoluble alſo in alkalies, and forms with them a compound which has been compared to a ſoap. Acids, when ſufficiently diluted, precipitate it both from water and alkalies without any change; but if they be concentrated, the precipitate is rediſſolved§.

When diſtilled, it furniſhes ſome ſebacic‖.

204 Combines with oxygen.

From theſe properties, it is clear that the baſis of bile has a conſiderable reſemblance to oils; but it differs from them entirely in ſeveral of its properties. The addition of oxygen, with which it combines readily, alters it ſomewhat, and brings it ſtill nearer to the claſs of oils.

In this altered ſtate, the baſis of bile may be obtained by the following proceſs. Pour oxy-muriatic acid cautiouſly into bile till that liquid loſes its green colour; then paſs it through a filter to ſeparate ſome albumen which coagulates. Pour more oxy-muriatic acid into the filtered liquid, and allow the mixture to repoſe for ſome time. The oxy-muriatic acid is gradually converted into common muriatic acid; and in the mean time the baſis of bile abſorbs oxygen, and acquires new properties. Pour into the liquid, after it has remained a ſufficient time, a little common muriatic acid, a white precipitate immediately appears, which may be ſeparated from the fluid. This precipitate is the baſis of bile combined with oxygen.

It has the colour and the conſiſtence of tallow, but ſtill retains its bitter taſte. It melts at the temperature of 104°. It diſſolves readily in alcohol, and even in water, provided it be aſſiſted by heat. Acids precipitate it from theſe ſolutions¶.

§ Cadet and Maclurg.
‖ Fourcroy.
¶ Fourcroy, Ann. de Chim. vii. 176.

Sect. VI. *Of Urea.*

105 Urea how obtained.

Evaporate, by a gentle heat, a quantity of human urine voided ſix or eight hours after a meal, till it be reduced to the conſiſtence of a thick ſyrup. In this ſtate, when put by to cool, it concretes into a cryſtalline maſs. Pour, at different times, upon this maſs four times its weight of alcohol, and apply a gentle heat; a great part of the maſs will be diſſolved, and there will remain only a number of ſaline ſubſtances. Pour the alcohol ſolution into a retort, and diſtil by the heat of a ſand bath till the liquid, after boiling ſome time, is reduced to the conſiſtence of a thick ſyrup. The whole of the alcohol is now ſeparated, and what remains in the retort cryſtallizes as it cools. Theſe cryſtals conſiſt of the ſubſtance known by the name of *urea**.

This ſubſtance was firſt deſcribed by Rouelle the Younger in 1773, under the name of the *ſaponaceous extract of urine*. He mentioned ſeveral of its properties; but very little was known concerning its nature till Fourcroy and Vauquelin publiſhed their experiments on it in 1799. Theſe celebrated chemiſts have given it the name of *urea*, which we have adopted.

* Fourcroy and Vauquelin, Ann. de Chim. xxxii. 86.

Urea.

206 Its properties.

Urea, obtained in this manner, has the form of cryſtalline plates croſſing each other in different directions. Its colour is yellowiſh white; it has a fetid ſmell, ſomewhat reſembling that of garlic or arſenic; its taſte is ſtrong and acrid, reſembling that of ammoniacal ſalts; it is very viſcid and difficult to cut, and has a good deal of reſemblance to thick honey†. When expoſed to the open air, it very ſoon attracts moiſture, and is converted into a thick brown liquid. It is extremely ſoluble in water; and during its ſolution, a conſiderable degree of cold is produced‡. Alcohol diſſolves it with facility, but ſcarcely in ſo large a proportion as water. The alcohol ſolution yields cryſtals much more readily on evaporation than the ſolution in water.

When nitric acid is dropt into a concentrated ſolution of urea in water, a great number of bright pearl coloured cryſtals are depoſited, compoſed of urea and nitric acid. No other acid produces this ſingular effect. The concentrated ſolution of urea in water is brown, but it becomes yellow when diluted with a large quantity of water. The infuſion of nut-galls gives it a yellowiſh brown colour, but cauſes no precipitate. Neither does the infuſion of tan produce any precipitate‖.

207 Its component parts.

When heat is applied to urea, it very ſoon melts, ſwells up, and evaporates, with an inſupportably fetid odour. When diſtilled, there comes over firſt benzoic acid, then carbonat of ammonia in cryſtals, ſome carbonated hydrogen gas, with traces of pruſſic acid and oil; and there remains behind a large reſiduum, compoſed of charcoal, muriat of ammonia, and muriat of ſoda. The diſtillation is accompanied with an almoſt inſupportably fetid alliaceous odour. Two hundred and eighty-eight parts of urea yield by diſtillation 200 parts of carbonat of ammonia, 10 parts of carbonated hydrogen gas, 7 parts of charcoal, and 68 parts of benzoic acid, muriat of ſoda, and muriat of ammonia. Theſe three laſt ingredients Fourcroy and Vauquelin conſider as foreign ſubſtances, ſeparated from the urine by the alcohol at the ſame time with the urea. Hence it follows, that 100 parts of urea, when diſtilled, yield

92.027	carbonat of ammonia,
4.608	carbonated hydrogen gas,
3.225	charcoal.
99.860	

Now 200 parts of carbonat of ammonia are compoſed of 86 ammonia, 90 carbonic acid gas, and 24 water. Hence it follows, that 100 parts of urea are compoſed of

39.5	oxygen,
32.5	azot,
14.7	carbon,
13.3	hydrogen.
100.0	

But it can ſcarcely be doubted, that the water which was found in the carbonat of ammonia exiſted ready formed in the urea before the diſtillation¶.

When the ſolution of urea in water is kept in a boiling heat, and new water is added as it evaporates, the urea is gradually decompoſed, a very great quantity of carbonat of ammonia is diſengaged, and at the ſame time acetous acid is formed, and ſome charcoal precipitates*.

208 Spontaneous decompoſition.

When a ſolution of urea in water is left to itſelf for ſome time, it is gradually decompoſed. A froth collects

† Fourcroy and Vauquelin, Ann. de Chim. xxxii. p. 87.
‡ Ibid. p. 88.
‖ Ibid.
¶ Ibid.
* Ibid. p. 96.

Urea. lects on its ſurface; air bubbles are emitted which have a ſtrong diſagreeable ſmell, in which ammonia and acetous acid are diſtinguiſhable. The liquid contains a quantity of acetous acid. The decompoſition is much more rapid if a little gelatine be added to the ſolution. In that caſe more ammonia is diſengaged, and the proportion of acetous acid is not ſo great*.

* Fourcroy and Vauquelin, Ann. de Chim. xxii. p. 96.

209 Action of acids.

When the ſolution of urea is mixed with one-fourth of its weight of diluted ſulphuric acid, no effervefcence takes place; but, on the application of heat, a quantity of oil appears on the ſurface, which concretes upon cooling; the liquid, which comes over into the receiver, contains acetous acid, and a quantity of ſulphat of ammonia remained in the retort diſſolved in the undiſtilled maſs. By repeated diſtillations, the whole of the urea is converted into acetous acid and ammonia†.

† Ibid. p. 94.

When nitric acid is poured upon cryſtallized urea, a violent effervefcence takes place, the mixture froths, aſſumes the form of a dark red liquid, great quantities of nitrous gas, azotic gas, and carbonic acid gas, are diſengaged. When the effervefcence is over, there remains only a concrete white matter, with ſome drops of reddiſh liquid. When heat is applied to this reſiduum, it detonates like nitrat of ammonia. Into a ſolution of urea, formed by its attracting moiſture from the atmoſphere, an equal quantity of nitric acid, of the ſpecific gravity 1.460, diluted with twice its weight of water, was added; a gentle effervefcence enſued: very gentle heat was applied, which ſupported the effervefcence for two days. There was diſengaged the firſt day a great quantity of azotic gas and carbonic acid gas; the ſecond day, carbonic acid gas, and at laſt nitrous gas. At the ſame time with the nitrous gas an odour was perceivable of the oxygenated pruſſic acid of Berthollet. At the end of the ſecond day, the matter in the retort, which was become thick, took fire, and burnt with a violent exploſion. The reſiduum contained traces of pruſſic acid and ammonia. The receiver contained a yellowiſh acid liquor, on the ſurface of which ſome drops of oil ſwam‡.

‡ Ibid. p. 97.

Muriatic acid diſſolves urea, but does not alter it. Oxy-muriatic acid gas is abſorbed very rapidly by a diluted ſolution of urea; ſmall whitiſh flakes appear, which ſoon become brown, and adhere to the ſides of the veſſel like a concrete oil. After a conſiderable quantity of oxy-muriatic acid had been abſorbed, the ſolution, left to itſelf, continued to effervefce exceeding ſlowly, and to emit carbonic acid and azotic gas. After this effervefcence was over, the liquid contained muriat and carbonat of ammonia.

210 Of alkalies.

Urea is diſſolved very rapidly by a ſolution of potaſs or ſoda; and at the ſame time a quantity of ammonia is diſengaged, the ſame ſubſtance is diſengaged when urea is treated with barytes, lime, or even magneſia. Hence it is evident, that this appearance muſt be aſcribed to the muriat of ammonia, with which it is conſtantly mixed. When pure ſolid potaſs is triturated with urea, heat is produced, a great quantity of ammonia is diſengaged. The mixture becomes brown, and a ſubſtance is depoſited, having the appearance of an empyreumatic oil. One part of urea and two of potaſs, diſſolved in four times its weight of water, when diſtilled give out a great quantity of ammoniacal water; the reſiduum contained acetite and carbonat of potaſs||.

|| Ibid.

When muriat of ſoda is diſſolved in a ſolution of urea in water, it is obtained by evaporation, not in cubic cryſtals, its uſual form, but in regular octohedrons. Muriat of ammonia, on the contrary, which cryſtallizes naturally in octohedrons, is converted into cubes, by diſſolving and cryſtallizing it in the ſolution of urea.

Such are the properties of this ſingular ſubſtance, as far as they have been aſcertained by the experiments of Fourcroy and Vauquelin. It differs from all animal ſubſtances hitherto examined, in the great proportion of azot which enters into its compoſition, and in the facility with which it is decompoſed, even by the heat of boiling water.

SECT. VII. *Of SUGAR.*

Sugar.

SUGAR has been already deſcribed in the former part of this article as a vegetable ſubſtance; nothing therefore is neceſſary here but to point out the different ſtates in which it is found in animals. It has never indeed been found in animals in every reſpect ſimilar to the ſugar of vegetables; but there are certain animal ſubſtances which have ſo many properties in common with ſugar, that they can ſcarcely be arranged under any other name. Theſe ſubſtances are,

1. Sugar of milk,
2. Honey,
3. Sugar of diabetic urine.

211 Sugar of milk.

1. The method of obtaining ſugar of milk has been already detailed in the article CHEMISTRY, nº. 488. to which we refer the reader. For an account of its properties, we are indebted to the obſervations of Mr Lichtenſtein.

When pure, it has a white colour, a ſweetiſh taſte, and no ſmell. Its cryſtals are ſemitranſparent regular parallelopipeds, terminated by four-ſided pyramids. Its ſpecific gravity, at the temperature of 55°, is 1.543. At that temperature, it is ſoluble in ſeven times its weight of water; but is perfectly inſoluble in alcohol. When burnt, it emits the odour of caromel, and exhibits preciſely the appearance of burning ſugar. When diſtilled, it yields the ſame products as ſugar, only the empyreumatic oil obtained has the odour of benzoic acid§.

§ Scheele, ii. 70.

212 Honey.

2. Honey is prepared by bees, and perhaps rather belongs to the vegetable than the animal kingdom. It has a white or yellowiſh colour, a ſoft and grained conſiſtence, a ſaccharine and aromatic ſmell; by means of alcohol, and even by water, with peculiar management, a true ſugar is obtained; by diſtillation it affords an acid phlegm and an oil, and its coal is light and ſpongy like that of the mucilages of plants. Nitric acid extracts the oxalic acid, which is entirely ſimilar to that of ſugar; it is very ſoluble in water, with which it forms a ſyrup, and like ſugar paſſes to the vinous fermentation*.

* Fourcroy.

3. The urine of perſons labouring under the diſeaſe known to phyſicians by the name of *diabetes*, yields, when evaporated, a conſiderable quantity of matter, which poſſeſſes the properties of ſugar.

SECT. VIII. *Of OILS.*

213 Fixed oils.

THE oily ſubſtances found in animals may be arranged under three heads: 1. Fixed oils; 2. Fat; 3. Spermaceti.

1. The fixed oils are obtained chiefly from different kinds of fiſh, as the whale, &c.; and they are diſtin-

Oils.

guished by the name of the animal from which they are obtained, as *whale oil*, &c. These oils agree in their properties with other fixed oils; which have been already described in the article CHEMISTRY, Part II. Chap. iii. *Suppl.*

2. *Fat*, or rather tallow, is a well known animal substance, much employed in the manufacture of candles and soap.

214 Properties of fat.

It has a white colour, often with a shade of yellow. When fresh, it has no smell, and but little taste. While cold, it is hard and brittle; but when exposed to the heat of 92°, it melts, and assumes the appearance of oil. The fat, however, which is extracted from flesh by boiling, does not melt till it reach the temperature of 127°*. Tallow and fat, in other respects, have the properties of fixed oils. They seem to be composed of a fixed oil combined with sebacic acid. When strongly heated, with contact of air, it emits a smoke of a penetrating smell, which excites tears and coughing, and takes fire when sufficiently heated to be volatilized: the charcoal it affords is not abundant. If fat be distilled on a water-bath, an insipid water, of a slight animal smell, is obtained, which is neither acid nor alkaline, but which soon acquires a putrid smell, and deposits filaments of a mucilaginous nature. This phenomenon, which takes place with the water obtained by distillation on the water bath from any animal substance, proves, that this fluid carries up with it a mucilaginous principle, which is the cause of its alteration. Fat, distilled in a retort, affords phlegm, at first aqueous, and afterwards strongly acid; an oil, partly liquid, and partly concrete; and a very small quantity of charcoal, exceedingly difficult to incinerate, in which Crell found a small quantity of phosphat of lime. These products have an acid and penetrating smell, as strong as that of sulphurous acid. The acid is the sebacic.

* *Nicholson's Journal*, i. 71.

215 Properties of spermaceti.

3. *Spermaceti*, is an oily, concrete, crystalline, semi-transparent matter, of a peculiar smell, which is taken out of the cavity of the cranium of the cachalot; it is purified by liquefaction, and the separation of another fluid and inconcrescible oil, with which it is mixed. This substance exhibits very singular chemical properties; for it resembles fixed oils in some respects, and volatile oils in others.

When heated to the temperature of 133°† it melts; and if the heat be increased, it evaporates without much alteration. When repeatedly distilled, however, it loses its solid form, and becomes like oil. When heated in contact with air, it takes fire, and burns uniformly without any disagreeable odour: hence its use in making candles.

† *Ibid.*

By long exposure in hot air it becomes yellow and rancid. Pure alkali combines with it, and forms a soap. Nitric and muriatic acids do not affect it, but sulphuric acid dissolves it and alters its colour.

SECT. IX. *Of Acids.*

THE acids hitherto discovered in the animal kingdom are the nine following.

Acids.

1. Sulphuric,	4. Carbonic,	7. Formic,
2. Muriatic,	5. Benzoic,	8. Bombyc,
3. Phosphoric,	6. Sebacic,	9. Uric.

The first eight of these have been already described in the article CHEMISTRY, *Suppl.* it is unnecessary therefore to describe them here.

216 Discovery of uric acid.

Few persons are ignorant that concretions sometimes form in the human urinary bladder, and produce that very formidable disease known by the names of the *stone* and the *gravel*. These concretions are often extracted by a surgical operation: they are called *urinary calculi*.

The most common of these calculi is of a brown colour, and very soluble in pure potass or soda ley.

If into an alkaline solution of one of these calculi a quantity of acetous acid be poured, a copious brown coloured precipitate immediately appears, which may be separated and edulcorated in a small quantity of water. This substance is *uric acid* *.

* Fourcroy *Ann. de Chim.* xvi. 116.

It was discovered by Scheele in 1776, and the French chemists afterwards called it *lithic acid*: but this name, in consequence chiefly of some remarks of Dr Pearson on its impropriety, has been lately given up, and that of *uric* (L) acid substituted in its place. We have adopted the new name, because we think it preferable to the old; which indeed conveyed a kind of inconsistency to those who attended to the etymological meaning of the word.

217 Its properties.

Uric acid possesses the following properties: it crystallizes in thin plates; has a brown colour, and scarcely any taste. Cold water scarcely dissolves any part of it; but it is soluble in 360 parts of boiling water. The solution reddens vegetable blues, especially the tincture of turnsol. A great part of the acid precipitates again as the water cools. It combines readily with alkalies and earths; but the compound is decomposed by every other acid. Sulphuric acid, when concentrated, decomposes it entirely*. Nitric acid dissolves it readily: the solution is of a pink colour, and has the property of tinging animal substances, the skin for instance, of the same colour†. When this solution is boiled, a quantity of azotic gas, carbonic acid gas, and of prussic acid, is disengaged ‡. Oxy-muriatic acid converts it in a few minutes into oxalic acid §.

* *Scheele*, i. 200.

† *Ibid.* and *Pearson.*

‡ *Fourcroy, Ann. de Chim.* xxvii. 267.

§ *Brugnatelli, ibid.* xxxii. 184.

When distilled, about a fourth of the acid passes over a little altered, and is found in the receiver crystallized in plates; a few drops of thick oil make their appearance; $\frac{1}{8}$th of the acid of concrete carbonat of ammonia, some prussiat of ammonia, some water, and carbonic acid; and there remains in the retort charcoal, amounting to about $\frac{1}{85}$th of the weight of the acid distilled ||.

|| *Fourcroy, ibid.* xvi. 116.

These facts are sufficient to shew us, that uric acid is composed of carbon, azot, hydrogen, and oxygen; and that the proportion of the two last ingredients is much smaller than of the other two.

The different salts which uric acid forms with alkaline and earthy bases have not been examined with attention; but urat of potass, of soda, and of lime, have been formed both by Scheele and Fourcroy; and urat of

(L) From *urine*; because this acid is always found in human urine.

Alkalies, Earths, and Metals.

of ammonia is not unfrequently found cryſtallized in urinary calculi.

The order of the affinities of the different baſes for uric acids is entirely unknown; but it has been aſcertained, that its affinity for theſe baſes is much weaker than that of any other acid. Its ſalts are decompoſed even by pruſſic and carbonic acid.

SECT. X. *Of ALKALIES, EARTHS, and METALS.*

1 ALL the three alkalies have been found in the animal kingdom, as we ſhall ſhew in the next chapter.

2. The only earths which have been found in animals are,

1. Lime,
2. Magneſia,
3. Silica.

The firſt in great abundance, almoſt in every large animal; the other two very rarely, and only as it were by accident.

3. The metals hitherto found in animals are,

1. Iron,
2. Manganeſe.

The firſt exiſts in all the larger animals in ſome conſiderable quantity; the ſecond has ſcarce ever been found in any quantity ſo great as to admit of being weighed.

218 Subſtances found in animals.

Such are the ſubſtances hitherto found in animals. The ſimple bodies of which all of them conſiſt are the following:

1. Azot,	6. Phoſphorus,	11. Magneſia,
2. Carbon,	7. Muriatic acid,	12. Silica,
3. Hydrogen,	8. Potaſs,	13. Iron,
4. Oxygen,	9. Soda,	14. Manganeſe.
5. Lime,	10. Sulphur,	

Of theſe, magneſia and ſilica may in a great meaſure be conſidered as foreign bodies; for they are only found in exceedingly minute quantities, and the laſt not unleſs in caſes of diſeaſe. The principal elementary ingredients are the firſt ſix: animal ſubſtances may be conſidered as in a great meaſure compoſed of them. The firſt four conſtitute almoſt entirely the ſoft parts, and the other two form the baſis of the hard parts. But we will be able to judge of this much better, after we have taken a view of the various parts of animals as they exiſt ready formed in the body. This ſhall be the ſubject of the next chapter.

CHAP. II. OF THE PARTS OF ANIMALS.

The different ſubſtances which compoſe the bodies of animals have been deſcribed with ſufficient minuteneſs in the article ANATOMY, *Encycl.* to which we beg leave to refer the reader. Any repetition in this place would be improper. Theſe ſubſtances are the following:

1. Bones and ſhells,	6. Cartilages,
2. Muſcles,	7. Skin,
3. Tendons,	8. Brain and nerves,
4. Ligaments,	9. Horns and nails,
5. Membranes,	10. Hair and feathers.

Beſides theſe ſubſtances which conſtitute the ſolid part of the bodies of animals, there are a number of fluids, the moſt important of which is the *blood*, which pervades every part of the ſyſtem in all the larger animals: The reſt are known by the name of *ſecretions*, becauſe they are formed or *ſecreted*, as the anatomiſts term it, from the blood. The principal animal ſecretions are the following:

1. Milk,	6. Mucus of the noſe,
2. Saliva,	7. Sinovia,
3. Pancreatic juice,	8. Semen,
4. Bile and biliary calculi,	9. Liquor of the amnios,
5. Tears,	10. Urine and urinary calculi.

Theſe ſubſtances ſhall form the ſubject of the following ſections.

Bones.

SECT I. *Of BONES.*

By *bones*, we mean thoſe hard, ſolid, well known ſubſtances, to which the firmneſs, ſhape, and ſtrength of animal bodies, are owing; which, in the larger animals, form, as it were, the ground-work upon which all the reſt is built. In man, in quadrupeds, and many other animals, the bones are ſituated below the other parts, and ſcarcely any of them are expoſed to view; but ſhell-fiſh and ſnails have a hard covering on the outſide of their bodies, evidently intended for defence. As theſe coverings, though known by the name of *ſhells*, are undoubtedly of a bony nature, we ſhall include them alſo in this ſection. For the very ſame reaſons, it would be improper to exclude *egg-ſhells*, and thoſe coverings of certain animals, the tortoiſe for inſtance, known by the name of *cruſts*.

It had been long known, that bones may be rendered ſoft and cartilaginous by keeping them in diluted acid ſolutions, and that ſome acids even diſſolve them altogether; that when expoſed to a violent heat, they become white, opaque, and brittle; and Dr Lewis had obſerved, that a ſudden and violent heat rendered them hard, ſemitranſparent, and ſonorous. But their component parts remained unknown till Scheele mentioned, in his diſſertation on Fluor Spar, publiſhed in the Stockholm Tranſactions for 1771, that the earthy part of bones is *phoſphat of lime* (M). Since that time conſiderable additions have been made to the chemical analyſis of theſe ſubſtances by Berniard, Bouillon, and Rouelle. Mr Hatchett has publiſhed a very valuable paper on the ſubject in the Philoſophical Tranſactions for 1799; and in the 34th volume of the *Annales de Chimie*, Mr Merat Guillot has given us a table of the component parts of the bones of a conſiderable number of animals.

The *bony parts* of animals may be divided into three claſſes; namely, *bones*, *cruſts*, and *ſhells*.

219 Properties of bones.

1. Bones have a conſiderable degree of hardneſs; when recent, they contain a quantity of marrow, which may be partly ſeparated from them. When the water in which bones have been for ſome time boiled is evaporated to a proper conſiſtence, it aſſumes the form of a *gelly*; bones therefore contain *gelatine*.

220 Their component parts.

If a piece of bone be kept for ſome time in diluted muriatic, or even acetous acid, it gradually loſes a conſiderable part of its weight, becomes ſoft, and acquires a

(M) The diſcoverer of this has not been completely aſcertained: Scheele does not claim it in that paper; Bergman gives it to Gahn; but Crell affirms that it was made by Scheele.

Bones.

a certain degree of tranſparency: and, in ſhort, acquires all the properties of *cartilage*. Bone therefore conſiſts of *cartilage*, combined with ſome ſubſtance which theſe acids are capable of diſſolving and carrying off.

If pure ammonia be dropt into the acid which has reduced the bone to this ſtate, a quantity of white powder precipitates, which poſſeſſes all the properties of *phoſphat of lime*. The ſubſtance, then, which was combined with the cartilage is *phoſphat of lime*.

After the phoſphat of lime has precipitated, the addition of carbonat of ammonia occaſions a farther precipitate, which conſiſts of carbonat of lime: but the quantity of this precipitate is inconſiderable*. When concentrated acids are poured on bones, whether recent or calcined, an efferveſcence is perceptible; the gas which eſcapes renders lime water turbid, and is therefore *carbonic acid*. Now ſince bones contain carbonic acid, and ſince they contain lime alſo uncombined with any acid ſtronger than carbonic—it is evident that they contain a little *carbonat of lime*. Mr Hatchett found this ſubſtance in all the bones of quadrupeds and of fiſh which he examined†.

* *Hatchett*, *Phil Tranſ.* 1799, p. 327.

† *Ibid.*

When bones are calcined, and the reſiduum is diſſolved in nitric acid, nitrat of barytes cauſes a ſmall precipitate, which is inſoluble in muriatic acid, and is therefore ſulphat of barytes‡. Conſequently bones contain ſulphuric acid. It has been aſcertained, that this acid is combined with lime. The proportion of *ſulphat of lime* in bones is very inconſiderable.

‡ *Ibid.*

Thus we have ſeen, that bones are compoſed of cartilage, which conſiſts almoſt entirely of gelatine, of phoſphat of lime, carbonat of lime, and ſulphat of lime. The following table, drawn up by Merat-Guillot ‖, exhibits a comparative view of the relative proportion of theſe ingredients in a variety of bones. The ſulphat of lime, which occurs only in a very ſmall quantity, has been confounded with phoſphat of lime.

‖ *Ann. de Chim* xxxiv. 71.

One hundred parts contain	Gelatine.	Phoſp. of lime	Carb. of lime	Loſs.
Human bones from a burying ground,	16	67	1.5	15.5
Do. dry, but not from under the earth,	23	63	2	2
Bone of ox, . . .	3	93	2	2
calf, . . .	25	54	trace	21
horſe, . . .	9	67.5	1.25	22.25
ſheep, . . .	16	70	0.5	13.5
elk, . . .	1.5	90	1	7.5
hog, . . .	17	52	1	30
hare, . . .	9	85	1	5
pullet, . .	6	72	1.5	20.5
pike, . . .	12	64	1	23
carp, . . .	6	45	0.5	48.5
Horſe tooth, . . .	12	85.5	0.25	2.25
Ivory, ...	24	64	0.1	11.15
Hartſhorn, ...	27	57.5	1	14.5

The enamel of the teeth is compoſed of the ſame earthy ingredients as other bones; but is totally deſtitute of cartilage*.

* *Hatchett*, *Phil Tranſ.* 1799, p. 328.

221 Component parts of cruſts.

2. The cruſtaceous coverings of animals, as of echini, crabs, lobſters, prawns, and cray fiſh, and alſo the ſhells of eggs, are compoſed of the ſame ingredients as bones; but in them the proportion of carbonat of lime far exceeds that of phoſphat*.

* *Hatchett*, *Phil. Tranſ.* 1799, p. 321, and 324.

Thus 100 parts of lobſter cruſt contain

60 carbonat of lime,
14 phoſphat,
26 cartilage,
———
100 †

One hundred parts of crawfiſh cruſt contain

60 carbonat of lime,
12 phoſphat of lime,
28 cartilage.
———
100 ‡.

† *Merat-Guillot*, *Ann de Chim.* xxxiv. 71.

‡ *Ibid.*

One hundred parts of hens egg-ſhells contain

89.6 carbonat of lime,
5.7 phoſphat of lime,
4.7 animal matter.
———
100.0 ‖.

‖ *Vauquelin*, *ibid.* xxix. 6.

Mr Hatchett found traces of phoſphat of lime alſo in the ſhells of ſnails.

222 Component parts of ſhells.

3. The ſhells of ſea animals may be divided into two claſſes: The firſt has the appearance of porcelain; their ſurface is enamelled, and their texture is often ſlightly fibrous. Mr Hatchett has given them the name of *porcellaneous* ſhells. The ſecond kind of ſhell is known by the name of *mother of pearl*. It is covered with a ſtrong epidermis, and below it lies the ſhelly matter in layers*. The ſhell of the freſh water muſcle, mother of pearl, heliotis iris, and turbo olearius, are inſtances of theſe ſhells.

* *Heriſſaut*, *Mem. Par.* 1766, p. 22.

Porcellaneous ſhells are compoſed of carbonat of lime cemented together by a very ſmall quantity of animal matter†.

Hatchett, *ibid.* 317.

† *Hatchett*, *ibid.*

Mother of pearl ſhells are compoſed of alternate layers of carbonat of lime and a thin membranaceous or cartilaginous ſubſtance. This cartilage ſtill retains the figure of the ſhell, after all the carbonat of lime has been ſeparated by acids‡.

‡ *Ibid.* 318.

Mother of pearl contains 66 carbonat of lime,
34 cartilage.
———
100 ‖

‖ *Merat-Guillot*, *ibid.*

Coral, which is a bony ſubſtance formed by certain ſea inſects, has a nearer relation to mother of pearl ſhells in its ſtructure than to any other bony ſubſtance, as the following table ¶ will ſhew.

¶ *Merat-Guillot*, *ibid.*

	White coral.	Red coral.	Articulated coraline.
Carbonat of lime,	50	53.5	49
Animal matter,	50	46.5	51
	100	100.0	100

SECT. II. *Of the* MUSCLES *of* ANIMALS.

The muſcular parts of animals are known in common language by the name of *fleſh*. They conſtitute a conſiderable proportion of the food of man.

Muſcular fleſh is compoſed of a great number of fibres or threads, commonly of a reddiſh or whitiſh colour; but its appearance is too well known to require any deſcription. Hitherto it has not been ſubjected to any accurate chemical analyſis. Mr Thouvenel, indeed, has publiſhed a very valuable diſſertation on the ſubject;

Muscles of Animals.

subject; but his analysis was made before the method of examining animal substances was so well understood as it is at present. It is to him, however, that we are indebted for almost all the facts known concerning the composition of muscle.

It is scarcely possible to separate the muscle from all the other substances with which it is mixed. A quantity of fat often adheres to it closely; blood pervades the whole of it; and every fibre is enveloped in a particular thin membranous matter, which anatomists distinguish by the name of *cellular substance*. The analysis of the muscle, then, cannot be supposed to exhibit an accurate view of the composition of pure muscular fibres, but only of muscular fibre not perfectly separated from other substances.

223 Analysis of muscles.

1. When a muscle is well washed in cold water, several of its parts are dissolved, and may be obtained by the usual chemical methods. When the water is evaporated slowly, it at last coagulates, and the coagulum may be separated by means of a filter. It possesses the properties of *albumen*.

2. The water is then to be evaporated gently to dryness, and alcohol poured upon the dry mass: part of it is dissolved by digestion, and there remains a saline substance, which has not been examined; but which Fourcroy conjectures to be a *phosphat*.

3. When the alcohol is evaporated to dryness, it leaves a peculiar mucous substance, soluble both in water and alcohol; and when its watery solution is very much concentrated, it assumes an acid and bitter taste. It swells upon hot coals, and melts, emitting an acid and penetrating smell. It attracts moisture from the air, and forms a saline efflorescence. In a hot atmosphere it becomes sour and putrefies. All these properties render it probable that this substance of Mr Thouvenel is that which is converted into *zoonic* acid during the roasting of meat.

4. The muscle is now to be boiled in water for some time. A quantity of fat appears on its surface in the form of oil, which may be taken off.

5. The water, when evaporated sufficiently, assumes the form of a jelly on cooling, and therefore contains a portion of *gelatine*. It contains also a little of the saline substance, and of the mucous substance mentioned above.

6. The residuum of the muscle is now white and insipid, of a fibrous structure, and insoluble in water, and has all the properties of *fibrina*.

Thus it appears that muscle is composed of

Albumen,
Mucous matter,
Gelatine,
Fibrina,
A salt.

The French chemists have discovered, that when a piece of muscle is allowed to remain a sufficient time in diluted sulphuric acid, it is converted into a substance resembling tallow: weak nitric acid, on the other hand, converts it into a substance resembling *wax* *.

* *Humbolt* Galvinism, 170.

SECT. III. *Of the SOFT and WHITE PARTS of ANIMALS.*

Those parts of animals to which anatomists have given the names of cartilage, tendon, ligament, membrane, differ altogether in their appearance from the muscles. They have never been analysed. We know only that they are composed, in a great measure, of *gelatine*; for it is partly from them that *glue* is made; which does not differ from gelatine, except in not being perfectly pure.

Skin.

Mr Hatchett has ascertained that they contain no phosphat of lime as a constituent part, and scarcely any saline ingredients; for when calcined they leave but a very inconsiderable residuum. Thus 250 grains of hog's bladder left only 0.02 grain of residuum †.

† *Phil. Transf.* 1799. p. 333.

SECT. IV. *Of the SKIN.*

THE skin is that strong thick covering which envelopes the whole external surface of animals. It is composed chiefly of two parts: a thin white elastic layer on the outside, which is called *epidermis* or *cuticle*; and a much thicker layer, composed of a great many fibres, closely interwoven, and disposed in different directions; this is called the *cutis*, or *true skin*. The *epidermis* is that part of the skin which is raised in blisters.

224 Epidermis.

1. The epidermis is easily separated from the cutis by maceration in hot water. It possesses a very great degree of elasticity.

225 Its properties.

It is totally insoluble in water and in alcohol. Pure fixed alkalies dissolve it completely, as does lime likewise, though slowly ‡. Sulphuric and muriatic acids do not dissolve it, at least they have no sensible action on it for a considerable time; but nitric acid soon deprives it of its elasticity, causes it to fall to pieces, and probably soon decomposes it §.

It is well known that the living epidermis is tinged yellow almost instantaneously by nitric acid; but this effect does not take place, at least so speedily, when the dead cuticle is plunged in nitric acid altogether ||.

‡ *Chaptal, Ann. de Chim.* xxii. 221.

§ *Cruikshank on Insensible Perspiration*, p. 32.

|| *Ibid.*

226 Cutis.

2. When a portion of cutis is macerated for some hours in water, and agitation and pressure is employed to accelerate the effect, the blood, and all the extraneous matter with which it was loaded, are separated from it, but its texture remains unaltered. On evaporating the water employed, a small quantity of gelatine may be obtained. No subsequent maceration in cold water has any farther effect; the weight of the cutis is not diminished, and its texture is not altered: but if it be boiled in a sufficient quantity of water, it may be completely dissolved, and the whole of it, by evaporating the water, obtained in the state of *gelatine* *.

* *Seguin, Nicholson's Journal*, i. 271.

227 Composed of gelatine.

Seguin informs us that he has ascertained, by a great variety of experiments, that the cutis differs from gelatine merely in containing an additional quantity of oxygen. Hot water (he says) expels this oxygen, and thus converts cutis into gelatine †. As these experiments have not been published, it is impossible to form any judgment of their weight.

† *Ibid.* 277.

228 Nature of tanning.

It is the skin or cutis of animals of which leather is formed. The process of converting skin into leather is called *tanning*. This process, though practised in the earliest ages, was merely empyrical, till the happy ingenuity of Mr Seguin led him to discover its real nature. After the epidermis and all the impurities of the skin have been separated, and its pores have been so far opened as to admit of being completely penetrated, it is steeped in an infusion of oak-bark, which consists of gallic acid and tan. The gallic acid (if we believe Seguin) deprives the skin gradually of oxygen, and thus converts it into gelatine, and the tan combines with this gelatine the instant it is formed; and this process goes

Brain and Nerves.

goes on so slowly that the texture of the skin is not altered. Leather, therefore, is merely a combination of gelatine and tan ‡.

‡ Nicholson's Journal, i. 171.

Sect. V. *Of the Brain and Nerves.*

The brain and nerves are the instruments of sensation, and even of motion; for an animal loses the power of moving a part the instant that the nerves which enter it are cut.

The brain and nerves have a strong resemblance to each other; and it is probable that they agree also in their composition. But hitherto no attempt has been made to analyse the nerves. The only chemists who have examined the nature of *brain* are Mr Thouret * and Mr Fourcroy †.

* Jour. de Phys. xxxviii. 329.
† Ann. de Chim. xvi. 282.

The brain consists of two substances, which differ from each other somewhat in colour, but which, in other respects, seem to be of the same nature. The outermost matter, having some small resemblance in colour to wood-ashes, has been called the *cineritious* part; the innermost part has been called the *medullary* part.

229 Properties of brain.

Brain has a soft feel, not unlike that of soap; its texture appears to be very close; its specific gravity is greater than that of water.

When brain is kept in close vessels so that the external air is excluded, it remains for a long time unaltered. Fourcroy filled a glass vessel almost completely with pieces of brain, and attached it to a pneumatic apparatus; a few bubbles of carbonic acid gas appeared at first, but it remained above a year without undergoing any farther change ‡.

‡ Ibid. 297.

This is very far from being the case with brain exposed to the atmosphere. In a few days (at the temperature of 60°) it exhales a most detestable odour, becomes acid, assumes a green colour, and very soon a great quantity of ammonia makes its appearance in it.

Cold water does not dissolve any part of the brain; but by trituration in a mortar, it forms with water a whitish coloured emulsion, which appears homogeneous, may be passed through a filter, and the brain does not precipitate by rest. When this emulsion is heated to 145°, a white coagulum is formed. The addition of a great quantity of water also causes a coagulum to appear, which swims on the surface, but the water still retains a milky colour. When sulphuric acid is dropt into the watery emulsion of brain, white flakes separate and swim on the surface, and the liquid becomes red. Nitric acid produces the same effects, only the liquid becomes yellow. Alcohol also separates a white coagulum from the emulsion, after it has been mixed with it for some hours. When nitric acid is added to the emulsion till it becomes slightly acid, a coagulum is also separated. This coagulum is of a white colour; it is insoluble in water and in alcohol. Heat softens, but does not melt it. When dried, it becomes transparent, and breaks with a glassy fracture. It has therefore some resemblance to *albumen* ‖.

‖ Ibid. 288.

When brain is triturated in a mortar with diluted sulphuric acid, part is dissolved, the rest may be separated, by filtration, in the form of a coagulum. The acid liquor is colourless. By evaporation, the liquid becomes black, sulphurous acid is exhaled, and crystals appear; and when evaporated to dryness, a black mass remains behind. When this mass is diluted with water, a quantity of charcoal separates, and the water remains clear. The brain is completely decomposed, a quantity of ammonia combines with the acid and forms sulphat of ammonia, while charcoal is precipitated. The water, by evaporation and treatment with alcohol, yields sulphats of ammonia and lime, phosphoric acid, and phosphats of soda and ammonia. Brain therefore contains

230 Its analysis.

Phosphat of lime,
——— soda,
——— ammonia.

Traces also of sulphat of lime can be discovered in it. The quantity of these salts is very small; altogether they do not amount to $\frac{1}{100}$th part ‖.

‖ Ann. de Chim. xvi. 288.

Diluted nitric acid, when triturated with brain, likewise dissolves a part, and coagulates the rest. The solution is transparent. When evaporated till the acid becomes concentrated, carbonic acid gas and nitrous gas are disengaged; an effervescence takes place, white fumes appear, an immense quantity of ammonia is disengaged, a bulky charcoal remains mixed with a considerable quantity of oxalic acid †.

† Ibid. 307.

When brain is gradually evaporated to dryness by the heat of a water bath, a portion of transparent liquid separates at first from the rest, and the residuum, when nearly dry, acquires a brown colour; its weight amounts to about one-fourth of the fresh brain. It may still be formed into an emulsion with water, but very soon separates again spontaneously.

When alcohol is repeatedly boiled upon this dried residuum till it ceases to have any more action, it dissolves about five-eighths of the whole. When this alcohol cools, it deposits a yellowish white substance, composed of brilliant plates. When kneaded together by the fingers, it assumes the appearance of a ductile paste: at the temperature of boiling water it becomes soft, and when the heat is increased it blackens, exhales empyreumatic and ammoniacal fumes, and leaves behind it a charry matter †. When the alcohol is evaporated, it deposits a yellowish black matter, which reddens paper tinged with turnsol, and readily diffuses itself through water ‡.

† Ibid. 313.
‡ Ibid. 317.

Pure concentrated potass dissolves brain, disengaging a great quantity of ammonia.

These facts are sufficient to shew us, that, exclusive of the small proportion of saline ingredients, brain is composed of a peculiar matter, differing in many particulars from all other animal substances, but having a considerable resemblance in many of its properties to albumen. Brain has been compared to a soap; but it is plain that the resemblance is very faint, as scarcely any oily matter could be extricated from brain by Fourcroy, though he attempted it by all the contrivances which the present state of chemistry suggested; and the alkaline proportion of it is a great deal too small to merit any attention.

Sect. VI. *Of Nails, Horns, Hair, Feathers.*

These substances have not hitherto been analysed. We know only that they have a great resemblance to each other. They give out the same smell, and exhibit the same phenomena when burnt, and they yield the same products when distilled.

Pure fixed alkali has the property of decomposing these substances, and of converting them into ammonia and oil. The ammonia is disengaged in great abundance, and the oil combines with the alkali, and forms a

Blood.

a species of soap. When muriatic acid is poured into the solution of these substances in pure soda, a quantity of sulphurated hydrogen gas is disengaged, and a black substance, doubtless charcoal, precipitates. Hence it follows that these substances contain in their composition a quantity of sulphur. Accordingly, if a bit of silver is put into the solution, it instantly assumes a black colour §.

These substances scarcely contain any earthy ingredients. One hundred grains of ox horn, after calcination, left only 0.04 grain of residuum, half of which was phosphat of lime Seventy eight grains of chamois horn left five grains of residuum ||.

§ Merat-Guillot, Ann. de Chim. xxxiv. ..

|| Hatchett, Phil. Trans. 1799. p. 2.

Such is a very imperfect account of the solids which compose animal bodies. We proceed next to the fluid which circulates through living bodies, namely *blood;* and to the various *secretions* formed from the blood, either in order to answer some important purpose to the animal, or to be evacuated as useless, that the blood thus purified may be more proper for answering the ends for which it is destined. Many of these substances have been examined with more care by chemists than the animal solids.

SECT. VII. *Of Blood.*

231 Properties of blood.

BLOOD is a well known fluid, which circulates in the veins and arteries of the more perfect animals. It is of a red colour, has a considerable degree of consistency, and an unctuous feel, as if it contained a quantity of soap. Its taste is slightly saline, and it has a peculiar smell.

The specific gravity of human blood is, at a medium, 1.0527 *. Mr Fourcroy found the specific gravity of bullock's blood, at the temperature of 60°, to be 1.056 †. The blood does not uniformly retain the same consistence in the same animal, and its consistence in different animals is very various. It is easy to see that its specific gravity must be equally various.

* Haller's Physiology, ii. ..

† Ann. de Chim. vii. ..

232 Composed of red globules,

When the blood is viewed through a microscope, a great many globules, of a red colour, are seen floating in it. It is to these globules that the red colour of the blood is owing. They were first examined with attention by Leuwenhoeck. Their form, their proportion, and the changes which they undergo from the addition of various substances, have been examined with the greatest care; but hitherto without adding much to our knowledge. We neither know the ingredients of which the red globules are composed, nor the changes to which they are subjected, nor the useful purposes which they serve; nor has any accurate method been discovered of separating them from the rest of the blood, and of obtaining them in a state of purity.

When blood, after being drawn from an animal, is allowed to remain for some time at rest, it very soon coagulates into a solid mass, of the consistence of curdled milk. This mass gradually separates into two parts: one of which is fluid, and is called *serum;* the other, the coagulum, has been called *cruor,* because it alone retains the red colour which distinguishes blood. This separation is very similar to the separation of curdled milk into curds and whey. The cruor usually sinks to the bottom of the vessel, and, of course, is covered by the serum.

233 ..

The cruor, or *clot* as it is sometimes called, is of a red colour, and possesses considerable consistence. Its mean specific gravity is about 1.245 ‡. If we wash the cruor in a sufficient quantity of water, it gradually loses its red colour, and assumes the appearance of a whitish, fibrous, elastic mass, which possesses all the properties of *fibrina.* The cruor therefore is composed chiefly of fibrina. The water in which it has been washed assumes a red colour, but continues transparent. It is evident from this that it contains, dissolved in it, the red globules; not, however, in a state of purity, for it is impossible to separate the cruor completely from the serum: consequently the water must contain both serum and red globules. We know, however, from this, that the red globules are soluble in water. The cruor of the blood, then, is composed of red globules and fibrina.

‡ Jurin, Haller's Physiology, ii. 41.

If the cruor of the blood be exposed to a gentle heat, it becomes gradually dry and brittle. If this dry mass be submitted to distillation, it yields water, ammonia, a thick empyreumatic oil, and much carbonat of ammonia: there remains a spongy coal of a brilliant appearance, from which sulphuric acid extracts *soda* and *iron;* there remains behind a mixture of phosphat of lime and charcoal ||.

|| Fourcroy, iii. 267.

When the fibrina is distilled, it yields precisely the same products; but the residuum contains neither iron nor soda. The red water, on the contrary, which had been employed to wash the cruor, contains both of these substances, especially iron; which may be obtained in the state of oxide by evaporating this water to dryness, and calcining the residuum ¶. These facts are sufficient to demonstrate that the red globules contain iron; consequently the opinion that their colour depends upon that metal is at least possible. It is probably owing to the soda which it contains, that the presence of iron cannot be ascertained in the solution of these globules by the usual test. The prussian alkali causes no precipitate; the infusion of nut galls gives it no blue or purplish tinge *.

¶ Ibid.

* Well's Phil. Trans. 1797.

234 And serum.

The serum is of a light greenish yellow colour; it has the taste, smell, and feel of the blood, but its consistence is not so great. Its mean specific gravity is about 1.0287 †. It converts syrup of violets to a green, and therefore contains an alkali. On examination, it is found that it owes this property to a portion of soda. When heated to the temperature of 156° §, the serum coagulates, as Harvey first discovered †. It coagulates also when boiling water is mixed with it; but if serum be mixed with six parts of cold water, it does not coagulate by heat ‡. When thus coagulated, it has a greyish white colour, and is not unlike the boiled white of an egg §. If the coagulum be cut into small pieces, a muddy fluid may be squeezed from it, which has been termed the *serosity.* After the separation of this fluid, if the residuum be carefully washed in boiling water and examined, it will be found to possess all the properties of *albumen.* The serum, therefore, contains a considerable proportion of albumen. Hence its coagulation by heat, and the other phenomena which albumen usually exhibits.

† Jurin, Haller's Physiology, ii. 41.

§ Cullen.

† De Gener. Anim. p. 161.

‡ Fourcroy, Ann. de Chim. vii. 157.

§ Ibid. 156.

If the serosity be gently evaporated till it becomes concentrated, and then be allowed to cool, it assumes the form of a jelly, as was first observed by De Haen ||. Consequently it contains *gelatine.*

|| Ibid. 157.

If serum be mixed with twice its weight of water, and, after coagulation by heat, the albumen be separated

Blood.

ted by filtration, and the liquid be flowly evaporated till it is confiderably concentrated, a number of cryftals are depofited when the liquid is left ftanding in a cool place. Thefe cryftals confift of muriat of foda and carbonat of foda ¶.

¶ Fourcroy, Ann. de Chim. vii. 155.

Thus it appears that the ferum of the blood contains albumen, gelatine, foda, muriat of foda, and carbonat of foda, befides a portion of water.

Gelatine may be precipitated from the ferofity by the three mineral acids. Mr Hunter obferved, that Goulard's extract, or, which is the fame thing, acetite of lead diffolved in acetous acid, produces with gelatine a copious precipitate ¶. When nitric acid is diffolved off ferum, it converts it partly into pruffic acid *. Acids, alcohol, and tan, precipitate the albumen in different ftates; but this, after what has been faid in the laft chapter, fection ii. requires no farther explanation.

¶ On the Blood, 35.
* Fourcroy, Ann. de Chim. vi. 180.

The proportion between the cruor and ferum of the blood varies much in different animals, and even in the fame animal in different circumftances. The moft common proportion is about one part of cruor to three parts of ferum ; but in many cafes the cruor exceeds and falls fhort of this quantity : the limits of the ratios of thefe fubftances to each other appear, from a comparifon of the conclufions of moft of thofe who have written accurately on the fubject, to be 1 : 1 and 1 : 4 ; but the firft cafe muft be very rare indeed *.

* Haller's Phyfiology, ii. 47.

When new-drawn blood is ftirred brifkly round with a ftick, or the hand, the whole of the fibrina collects together upon the ftick, and in this manner may be feparated altogether from the reft of the blood. The red globules, in this cafe, remain behind in the ferum. It is in this manner that the blood is prepared for the different purpofes to which it is put ; as clarifying fugar, making puddings, &c. After the fibrina is thus feparated, the blood no longer coagulates when allowed to remain at reft, but a fpongy flaky matter feparates from it and fwims on the furface †.

† Fourcroy, Ann. de Chim. vii. 146.

When blood is dried by a gentle heat, water exhales from it, retaining a very fmall quantity of animal matter in folution, and confequently having the odour of blood. Blood dried in this manner being introduced into a retort and diftilled, there comes over, firft a clear watery liquor, then carbonic acid gas, and carbonat of ammonia, which cryftallizes in the neck of the retort ; after thefe products there comes over a fluid oil, carbonated hydrogen gas, and an oily fubftance of the confiftence of butter. The watery liquor poffeffes the property of precipitating from fulphat of iron a green powder ; muriatic acid diffolves part of this powder, and there remains behind a little pruffian blue. Confequently this watery liquor contains both an alkali and pruffic acid ‡.

‡ Ibid. 153.

9216 grains of dried blood being put into a large crucible, and gradually heated, at firft became nearly fluid, and fwelled up confiderably, emitted a great many fetid fumes of a yellowifh colour, and at laft took fire and burned with a white flame, evidently owing to the prefence of oil. After the flame and the fumes had difappeared, a light fmoke was emitted, which affected the eyes and the nofe, which had the odour of pruffic acid, and reddened moift papers ftained with vegetable blues. At the end of fix hours, when the matter had loft five-fixths of its fubftance, it melted anew, exhibited a purple flame on its furface, and emitted a thick fmoke. This fmoke affected the eyes and noftrils, and reddened blue paper, but it had not the fmell of pruffic acid. When a quantity of it was collected and examined, it was found to poffefs the properties of phofphoric acid. The refiduum amounted to 181 grains ; it had a deep black colour, and a metallic brilliancy, and its particles were attracted by the magnet. It contained no uncombined foda, though the blood itfelf, before combuftion, contains it abundantly ; but water extracted from it muriat of foda, part of the reft was diffolved by muriatic acid, and, of courfe, was lime ; there was befides a little filica, which had evidently been feparated from the crucible. The iron had been reduced during the combuftion ‡.

‡ Fourcroy, Ann. de Chim. vii. 151.

Such are the properties of blood, as far as they have been hitherto afcertained by experiment. We have feen that it contains the following ingredients :

235 Component parts of blood.

1. Water,	5. Iron,
2. Fibrina,	6. Soda,
3. Albumen,	7. Muriat of foda,
4. Gelatine,	8. Phofphat of lime.

But our knowledge of this fingular fluid is by no means fo complete as it ought to be ; a more accurate analyfis would probably difcover the prefence of other fubftances, and enable us to account for many of the properties of blood which at prefent are inexplicable.

It would be of great confequence alfo to compare together the blood of different animals, and of the fame animal at different ages, and to afcertain in what particulars they differ from each other. This would probably throw light on fome of the obfcureft parts of the animal economy. Very little progrefs has hitherto been made in thefe refearches : if we except the labours of Rouelle, who obtained nearly the fame ingredients, though in different proportions, from the blood of a great variety of animals, the experiments of Fourcroy on the blood of the human fœtus are almoft the only ones of that kind with which we are acquainted.

236 Blood of the fœtus.

He found that it differs from the blood of the adult in three things: *1ft*, Its colouring matter is darker, and feems to be more abundant ; *2d*, It contains no fibrina, but probably a greater proportion of gelatine than blood of adults; *3d*, It contains no phofphoric acid §.

§ Ibid. 16[illegible]

237 Difeafed blood.

The examination of difeafed blood, too, would be of great confequence ; becaufe the difference of its properties from the blood of people in health might throw much light on the nature of the difeafe. It is well known, that when a perfon labours under inflammation, his blood is not fufceptible of coagulating fo foon as healthy blood. This longer time allows the red globules to fink to the bottom, and the coagulated fibrina appears at the top, of its natural whitifh colour. Hence the appearance of the *buffy coat*, as it is called, which characterizes blood during inflammation.

During that difeafe which is known by the name of *diabetes*, in which the urine is exceffive in quantity, and contains fugar, the ferum of blood often, as appears from the experiments of Dr Dobfon and Dr Rollo, affumes the appearance of whey ; and, like it, feems to contain fugar, or, at leaft, it has loft its ufualt falt tafte.

Fourcroy mentions a cafe of extreme feeblenefs, in which all the parts of the body were in an unufual relaxed ftate. In that patient a quantity of blood oozed out

Milk. out from the eye-lids, which tinged linen blue, as if it had been ftained with pruffian blue. Here pruffic alkali feems to have been formed in the blood.

Sect. VIII. *Of Milk.*

Milk is a fluid fecreted by the female of all thofe animals denominated *mammalia*, and intended evidently for the nourifhment of her offspring.

The milk of every animal has certain peculiarities which diftinguifh it from every other milk. But the animal whofe milk is moft made ufe of by man as an article of food, and with which, confequently, we are beft acquainted, is the *cow*. Chemifts, therefore, have made choice of cow's milk for their experiments. We fhall at firft confine ourfelves to the properties and analyfis of cow's milk, and afterwards point out in what refpect the milk of other animals differs from it, as far at leaft as thefe differences have hitherto been afcertained.

238 Properties of milk.

Milk is an opaque fluid, of a white colour, a flight peculiar fmell, and a pleafant fweetifh tafte. When newly drawn from the cow, it has a tafte very different from that which it acquires after it has been kept for fome hours.

It is liquid, and wets all thofe fubftances which can be moiftened by water; but its confiftence is greater than that of water, and it is flightly unctuous. Like water, it freezes when cooled down to about 30°; but Parmentier and Deyeux, to whom we are indebted for by far the completeft account of milk hitherto publifhed, found that its freezing point varies confiderably in the milk of different cows, and even of the fame cow at different times *. Milk boils alfo when fufficiently heated; but the fame variation takes place in the boiling point of different milks, though it never deviates very far from the boiling point of water. Milk is fpecifically heavier than water, and lighter than blood; but the precife degree cannot be afcertained, becaufe almoft every particular milk has a fpecific gravity peculiar to itfelf.

* *Jour. de Phyf.* xxxvii. 362.

When milk is allowed to remain for fome time at reft, there collects on its furface a thick unctuous yellowifh coloured fubftance, known by the name of *cream*. The cream appears fooner in milk in fummer than in winter, evidently owing to the difference of temperature. In fummer, about four days of repofe are neceffary before the whole of the cream collects on the furface of the liquid; but in winter it requires at leaft double the time †.

† Fourcroy, *Ann. de Chim.* vii. 67.

After the cream is feparated, the milk which remains is much thinner than before, and it has a bluifh white colour. If it be heated to the temperature of 100°, and a little *rennet*, which is water digefted with the inner coat of a calf's ftomach, and preferved with falt, be poured into it, coagulation enfues; and if the coagulum be broken, the milk very foon feparates into two fubftances: a folid white part, known by the name of *curd;* and a fluid part, called *whey*.

Thus we fee that milk may be eafily feparated into three parts; namely, *cream*, *curd*, and *whey*.

239 Cream.

Cream is of a yellow colour, and its confiftence increafes gradually by expofure to the atmofphere. In three or four days, it becomes fo thick that the veffel which contains it may be inverted without rifking any lofs. In eight or ten days more its furface is covered over with mucors and byffi, and it has no longer the flavour of cream, but of very fat cheefe *. This is the procefs for making what in this country is called a *cream cheefe*.

* Parmentier and Deyeux, *Ann. de Chim.* vii. 372.

Cream poffeffes many of the properties of an oil. It is fpecifically lighter than water, it has an unctuous feel, ftains clothes precifely in the manner of oil; and if it be kept fluid, it contracts at laft a tafte which is very analogous to the rancidity of oils †. When kept boiling for fome time, a little oil makes its appearance, and floats upon its furface ‡. Cream is neither foluble in alcohol nor oils §. Thefe properties are fufficient to fhew us that it contains a quantity of oil; but this oil is combined with a part of the curd, and mixed with fome ferum. Cream, then, is compofed of a peculiar oil, curd, and ferum. The oil may be eafily obtained feparate by agitating the cream for a confiderable time. This procefs, known to every body, is called *churning*. After a certain time, the cream feparates into two portions: one fluid, and refembling creamed milk; the other folid, and called *butter*.

† *Ibid.* 375.
‡ *Ibid.* 374.
§ *Ibid.*

240 Converted into butter,

Butter is of a yellow colour, poffeffes the properties of an oil, and mixes readily with other oily bodies. When heated to the temperature of 96°, it melts, and becomes tranfparent; if it be kept for fome time melted, fome curd and water or whey feparate from it, and it affumes exactly the appearance of oil ||. But this procefs deprives it in a great meafure of its peculiar flavour.

|| Fourcroy, *Ann. de Chim.* vii. 170.

When butter is kept for a certain time, it becomes rancid, owing in a good meafure to the prefence of thefe foreign ingredients; for if butter be well wafhed, and a great portion of thefe matters feparated, it does not become rancid nearly fo foon as when it is not treated in this manner. It was formerly fuppofed that this rancidity was owing to the developement of a peculiar acid: but Parmentier and Deyeux have fhewn that no acid is prefent in rancid butter *. When butter is diftilled, there comes over water, febacic acid, and oil, at firft fluid, but afterwards concrete. The carbonaceous refiduum is but fmall.

* *Ibid.* 375.

241 And how.

Butter may be obtained by agitating cream newly taken from milk, or even by agitating milk newly drawn from the cow. But it is ufual to allow cream to remain for fome time before it is churned. Now cream, by ftanding, acquires a four tafte; butter therefore is commonly made from four cream. Frefh cream requires at leaft four times as much churning before it yields its butter as four cream does †; confequently cream acquires, by being kept for fome time, new properties, in confequence of which it is more eafily converted into butter. When very four cream is churned, every one who has paid the fmalleft attention muft have perceived, that the butter-milk, after the churning, is not nearly fo four as the cream had been. The butter, in all cafes, is perfectly fweet; confequently the acid which had been evolved has in a great meafure difappeared during the procefs of churning. It has been afcertained, that cream may be churned, and butter obtained, though the contact of atmofpheric air be excluded ‡. We have no doubt, that in all cafes where fuch an experiment fucceeded, the cream on which it was made had previoufly become four. On the other hand, it has been afcertained, that when cream is churned in contact with air, it abforbs a confiderable quantity of it §; and it cannot

† Fourcroy, *ibid.* 169.
‡ Young *de Lacte*, 15.
§ *Mid-Lothian Report for* 1795.

Milk.

cannot be doubted, that the portion abſorbed is oxygen.

Theſe facts are ſufficient to afford us a key to explain what takes place during the proceſs of churning. There is a peculiar oil in milk, which has ſo ſtrong an affinity for the other ingredients, that it will not ſeparate from them ſpontaneouſly; but it has an affinity for oxygen, and when combined with it, forms the concrete body called *butter*. Agitation produces this combination of the oil with oxygen; either by cauſing it to abſorb oxygen from the air, or, if that be impoſſible, by ſeparating it from the acid which exiſts in ſour cream. Hence the abſorption of air during churning; hence alſo the increaſe of temperature of the cream, which Dr Young found to amount conſtantly to 4°; and hence the ſweetneſs of the butter-milk compared with the cream from which it was obtained.

The affinity of the oil of cream for the other ingredients is ſuch, that it never ſeparates completely from them. Not only is curd and whey always found in the cream, but ſome of this oil is conſtantly found in creamed milk and even in whey: for it has been aſcertained by actual experiment, that butter may be obtained by churning whey; 27 Scotch pints of whey yield at an average about a pound of butter‖. This accounts for a fact well known to thoſe who ſuperintend dairies, that a good deal more butter may be obtained from the ſame quantity of milk, provided it be churned as drawn from the cow, than when the cream alone is collected and churned.

‖ Mid-Lothian Report, 1795.

The butter-milk, as Parmentier and Deyeux aſcertained by experiment, poſſeſſes preciſely the properties of milk deprived of cream¶.

¶ Ann. de Chim. vii. 379.

272
Properties of curd.

Curd, which may be ſeparated from creamed milk by rennet, has all the properties of coagulated albumen. It is white and ſolid; and when all the moiſture is ſqueezed out, it has a good deal of brittleneſs. It is inſoluble in water; but pure alkalies and lime diſſolve it readily, eſpecially when aſſiſted by heat; and when fixed alkali is uſed, a great quantity of ammonia is emitted during the ſolution. The ſolution of curd in ſoda is of a red colour, at leaſt if heat be employed; owing probably to the ſeparation of charcoal from the curd by the action of the alkali*. Indeed, when a ſtrong heat has been uſed, charcoal precipitates as the ſolution cools†. The matter diſſolved by the alkali may be ſeparated from it by means of any acid; but it has loſt all the properties of curd. It is of a black colour, melts like tallow by the application of heat, leaves oily ſtains on paper, and never acquires the conſiſtence of curd‡. Hence it appears that curd, by the action of a fixed alkali, is decompoſed, and converted into two new ſubſtances, ammonia, and oil or rather fat.

* Ibid.

† Fourcroy, ibid. p. 175.

‡ Ibid.

Curd is ſoluble alſo in acids. If, over curd newly precipitated from milk, and not dried, there be poured eight parts of water, containing as much of any of the mineral acids as gives it a ſenſibly acid taſte, the whole is diſſolved after a little boiling§. Acetous acid and lactic acid do not diſſolve curd when very much diluted‖. But theſe acids, when concentrated, diſſolve it readily, and in conſiderable quantity¶. It is remarkable enough, that concentrated vegetable acids diſſolve curd readily, but have very little action on it when they are very much diluted: whereas the mineral diſſolve it when much diluted; but when concentrated, have either very little effect on it, as ſulphuric acid*; or decompoſe it, as nitric acid. By means of this laſt acid, as Berthollet diſcovered, a quantity of azotic gas may be obtained from curd.

§ Scheele, ii. 53.

‖ Ibid.

¶ Parmentier and Deyeux, ibid. 417. Fourcroy, ibid. p. 173.

* Parmentier, ibid.

Curd, as is well known, is uſed in making *cheeſe*; and the cheeſe is the better the more it contains of cream, or of that oily matter which conſtitutes cream. It is well known to cheeſemakers, that the goodneſs of it depends in a great meaſure on the manner of ſeparating the whey from the curd. If the milk be much heated, the coagulum broken in pieces, and the whey forcibly ſeparated, as is the practice in many parts of Scotland, the cheeſe is ſcarce good for any thing; but the whey is delicious, eſpecially the laſt ſqueezed out whey, and butter may be obtained from it in conſiderable quantity. A full proof that nearly the whole creamy part of the milk has been ſeparated with the whey. Whereas if the milk be not too much heated (about 100° is ſufficient), if the coagulum be allowed to remain unbroken, and the whey be ſeparated by very ſlow and gentle preſſure, the cheeſe is excellent; but the whey is almoſt tranſparent, and nearly colourleſs. 273 Of cheeſe.

Good cheeſe melts at a moderate heat; but bad cheeſe, when heated, dries, curls, and exhibits all the phenomena of burning horn. Hence it is evident, that all the properties in which curd differs from albumen are owing to its containing combined with it a quantity of the peculiar oil which conſtitutes the diſtinguiſhing characteriſtic of cream; hence its flavour and ſmell; and hence alſo the white colour of milk.

274
Coagulation of milk.

This ſameneſs of curd and albumen ſhews us, that the coagulation of milk and of albumen depend upon the ſame cauſe. Heat, indeed, does not coagulate milk, becauſe the albumen in it is diluted with too large a quantity of water. But if milk be boiled in contact with air, a pellicle ſoon forms on its ſurface, which has the properties of coagulated albumen: if this pellicle be removed, another ſucceeds; and by continuing the boiling, the whole of the albuminous or curdy matter may be ſeparated from milk*. When this pellicle is allowed to remain, it falls at laſt to the bottom of the veſſel, where, being expoſed to a greater heat, it becomes brown, and communicates to milk that diſagreeable taſte which, in this country, is called a *ſinged* taſte. It happens more readily when milk is boiled along with rice, flour, &c.

* Parmentier, ibid. p. 415.

If to boiling milk there be added as much of any neutral ſalt as it is capable of diſſolving, or of ſugar, or of gum arabic, the milk coagulates, and the curd ſeparates†. Alcohol alſo coagulates milk‡; as do all acids, rennet, and the infuſion of the flowers of artichoke, and of the thiſtle‖. If milk be diluted with ten times its weight of water, it cannot be made to coagulate at all¶.

† Scheele, ii. 52.

‡ Parmentier, ibid. p. 416.

‖ Ibid.

¶ Scheele, ii. 54.

275
Properties of whey.

Whey, after being filtered, to ſeparate a quantity of curd which ſtill continues to float through it, is a thin pellucid fluid, of a yellowiſh green colour and pleaſant ſweetiſh taſte, in which the flavour of milk may be diſtinguiſhed. It always contains ſome curd; but nearly the whole may be ſeparated by keeping the whey for ſome time boiling; a thick white ſcum gathers on the ſurface, which in Scotland is known by the name of *float whey*. When this ſcum, which conſiſts of the curdy part, is carefully ſeparated, the whey, after being allowed to remain at reſt for ſome hours, to give the

remainder

Milk.

remainder of the curd time to precipitate, is decanted off, almost as colourless as water, and scarcely any of the peculiar taste of milk can be distinguished in it. If it be now slowly evaporated, it deposites at last a number of white coloured crystals, which are *sugar of milk*. Towards the end of the evaporation, some crystals of muriat of potash and of muriat of lime make their appearance*. According to Scheele, it contains also a little phosphat of lime†.

After the salts have been obtained from whey, what remains concretes into a jelly on cooling‡. Hence it follows, that whey also contains *gelatine*. Whey, then, is composed of water, sugar of milk, gelatine, muriat of potash, and muriat of lime. The other salts, which are sometimes found in it, are only accidentally present.

If whey be allowed to remain for some time, it becomes sour, owing to the formation of a peculiar acid known by the name of *lactic acid*. It is to this property of whey that we are to ascribe the acidity which milk contracts; for neither curd nor cream, perfectly freed from serum, seem susceptible of acquiring acid properties. Hence the reason, also, that milk, after it becomes sour, always coagulates. Boiled milk has the property of continuing longer sweet; but it is singular enough, that it runs sooner to putrefaction than ordinary milk*.

* Parmentier, p. 417.
† Scheele, ii. 1.
‡ Rouelle.
* Parmentier, ibid. p. 43.

276 Vinegar obtained from milk.

The acid of milk differs considerably from the acetous; yet vinegar may be obtained from milk by a very simple process. If to somewhat more than 8 lbs. troy of milk, six spoonfuls of alcohol be added, and the mixture well corked be exposed to a heat sufficient to support fermentation (provided attention be paid to allow the carbonic acid gas to escape from time to time), the whey, in about a month, will be found converted into vinegar†.

† Scheele. ii. 8.

297 Milk undergoes fermentation.

Milk is almost the only animal substance which may be made to undergo the vinous fermentation, and to afford a liquor resembling wine or beer, from which alcohol may be separated by distillation. This singular fact seems to have been first discovered by the Tartars; they obtain all their spirituous liquors from mares milk. It has been ascertained, that milk is incapable of being converted into wine till it has become sour; after this, nothing is necessary but to place it in the proper temperature, the fermentation begins of its own accord, and continues till the formation of wine be completed‡. Scheele had observed, that milk was capable of fermenting, and that a great quantity of carbonic acid gas was extricated from it during this fermentation||. But he did not suspect, that the result of this fermentation was the formation of an intoxicating liquor similar to wine.

‡ Parmentier, ibid. p. 55.
|| Scheele, ii. 5.

When milk is distilled by the heat of a water bath, there comes over water, having the peculiar odour of milk; which putrifies, and consequently contains, besides mere water, some of the other constituent parts of milk. After some time, the milk coagulates¶, as always happens when hot albumen acquires a certain degree of concentration. There remains behind a thick unctuous yellowish white substance, to which Hoffman gave the name of *franchipann*. This substance, when the fire is increased, yields at first a transparent liquid, which becomes gradually more coloured; some very fluid oil comes over, then ammonia, an acid, and at last a very thick black oil. Towards the end of the process carbonated hydrogen gas is disengaged*. There remains in the retort a coal which contains carbonat of potash, muriat of potash, and phosphat of lime, and sometimes magnesia, iron, and muriat of soda†.

¶ Bouquet.
* Parmentier, ibid. p. 368.
† Mem. Med. Par. 1787 p. 606.

278 Its component parts.

Thus we see, that cow's milk is composed of the following ingredients.

1. Water,	5. Sugar of milk,
2. Oil,	6. Muriat of lime,
3. Albumen,	7. Muriat of potash,
4. Gelatine,	8. Sulphur.

The milk of all other animals, as far as it has hitherto been examined, consists nearly of the same ingredients; but there is a very great difference in their proportion.

279 Woman's milk.

WOMAN'S MILK has a much sweeter taste than cow's milk. When allowed to remain at rest for a sufficient time, a cream gathers on its surface. This cream is more abundant than in cow's milk, and its colour is usually much whiter. After it is separated, the milk is exceedingly thin, and has the appearance rather of whey, with a bluish white colour, than of creamed milk. None of the methods by which cow's milk is coagulated succeed in producing the coagulation of woman's milk*. It is certain, however, that it contains curd; for if it be boiled, pellicles form on its surface, which have all the properties of curd†. Its not coagulating, therefore, must be attributed to the great quantity of water with which the curd is diluted.

* Clark, Irish Trans. ii. 175.
† Parmentier, ibid. p. 419.

Though the cream be churned ever so long, no butter can be obtained from it; but if, after being agitated for some hours, it be allowed to remain at rest for a day or two, it separates into two parts; a fluid which occupies the inferior part of the vessel, pellucid, and colourless, like water, and a thick white unctuous fluid, which swims on the surface. The lowermost fluid contains sugar of milk and some curd; the uppermost does not differ from cream except in consistence. The oily part of the cream, then, cannot be separated by agitation from the curd‡. This cream contains a greater portion of curd than the cream of cow's milk*:

‡ Ibid.
* Ibid.

When this milk, after the curd is separated from it, is slowly evaporated, it yields crystals of sugar of milk, and of muriat of soda. The quantity of sugar is rather greater than in cow's milk. According to Haller, the sugar obtained from cow's milk is to that obtained from an equal quantity of woman's milk as 35 : 58, and sometimes as 37 : 67, and in all the intermediate ratios.

280 Its peculiarities.

Thus it appears, that woman's milk differs from that of cow's in three particulars.

1. It contains a much smaller quantity of curd.
2. Its oil is so intimately combined with its curd, that it does not yield butter.
3. It contains rather more sugar of milk.

Parmentier and Deyeux ascertained, that the quantity of curd in woman's milk increases in proportion to the time after delivery||. Nearly the same thing has been observed with respect to cow's milk.

|| Ibid. p. 42c.

281 Ass's milk.

ASS'S MILK has a very strong resemblance to human milk: it has nearly the same colour, smell, and consistence. When left at rest for a sufficient time, a cream forms upon its surface, but by no means in such abundance as in woman's milk. This cream, by very long agitation, yields a butter, which is always soft, white, and tasteless; and, what is singular, very readily mixes again with the butter-milk; but it may be again separated

Milk, Saliva.

rated by agitation, while the vessel, which contains it, is plunged in cold water. Creamed ass's milk is thin, and has an agreeable sweetish taste. Alcohol and acids separate from it a little curd, which has but a small degree of consistence. The serum yields sugar of milk and muriat of lime *.

* *Parmentier*, p. 423.

282 Its peculiarities.

Ass's milk therefore differs from cow's milk in three particulars.

1. Its cream is less abundant and more insipid.
2. It contains less curd.
3. It contains more sugar of milk: the proportion is 35 : 80.

283 Goat's milk.

Goat's milk, if we except its consistence, which is greater, does not differ much from cow's milk. Like that milk, it throws up abundance of cream, from which butter is easily obtained. The creamed milk coagulates just as cow's milk, and yields a greater quanity of curd. Its whey contains sugar of milk, muriat of lime, and muriat of soda †.

† *Ibid.* p. 425.

284 Ewes milk.

Ewe's milk resembles almost precisely that of the cow. Its cream is rather more abundant, and yields a butter which never acquires the consistence of butter from cow's milk. Its curd has a fat and viscid appearance, and is not without difficulty made to assume the consistence of the curd of cow's milk. It makes excellent cheese ‡.

‡ *Ibid.* p. 428.

285 Mares milk.

Mare's milk is thinner than that of the cow, but scarcely so thin as human milk. Its cream cannot be converted into butter by agitation. The creamed milk coagulates precisely as cow's milk, but the curd is not so abundant. The serum contains sugar of milk, sulphat of lime, and muriat of lime ‖.

‖ *Ibid.* p. 431.

Sect. IX. *Of Saliva.*

The fluid secreted in the mouth, which flows in considerable quantity during a repast, is known by the name of *saliva*. No accurate analysis has hitherto been made of it, though it possesses some very singular properties.

286 Properties of saliva.

It is a limpid fluid like water, but much more viscid: it has neither smell nor taste.

Its specific gravity, according to Hamberger, is 1.0167 *. When agitated, it froths like all other adhesive liquids; indeed it is usually mixed with air, and has the appearance of froth.

* *Haller's Phys.* vi. 52.

It neither mixes readily with water nor oil †; but by trituration in a mortar, it may be mixed so with water as to pass through a filter ‡. It has a great affinity for oxygen, absorbs it readily from the air, and gives it out again to other bodies §. Hence the reason why gold or silver, triturated with saliva in a mortar, is oxydated, as Dutenner has observed; and why the killing of mercury by oils is much facilitated by spitting into the mixture ¶. Hence also, in all probability, the reason that saliva is a useful application to sores of the skin. Dogs, and several other animals, have constantly recourse to this remedy, and with much advantage.

† *Narcessus. Haller, ibid.* p. 54.
‡ *Fordyce on Digest.* p. 51.
§ *Fourcroy, Ann. de Chim.* xxviii 262.
¶ *Ibid.*

Saliva is coagulated by oxy muriat of mercury, by alcohol, and by nitre *. Therefore, in all probability, it contains albumen and gelatine, or some analogous substances.

* *Haller's Phys.* vi. 54.

When 100 parts of saliva are distilled, there came over 80 parts of water nearly pure, then a little carbonat of ammonia, some oil, and an acid, which perhaps is the prussic. The residuum amounts to about 1.56 parts, and is composed of muriat of soda and phosphat of lime †.

Bile.

287 Tartar of the teeth.

The *tartar* of the teeth, which is a crust deposited from saliva, consists, as Fourcroy has ascertained, of phosphat of lime.

288 Pancreatic juice.

The pancreatic juice has never been examined with much attention; but it does not appear, from the experiments that have been made, to differ much from saliva.

† *Verheyen, Textor, Nuck*, &c. as quoted by Haller, *Physiol.* vi. 55.

Sect. X. *Of Bile.*

Bile is a liquid of a yellowish green colour, an unctuous feel, and bitter taste, is secreted by the liver; and in most animals considerable quantities of it are usually found collected in the gall-bladder.

Great attention has been paid to this liquid by physicians; because the ancients were accustomed to ascribe a very great number of diseases, and even affections of the mind, to its agency. The most accurate chemical analysis of it which has hitherto appeared, is that of Mr Cadet, which was published in the Memoirs of the French Academy of Sciences for the year 1767. Several important observations had been previously made on it by Boyle, Boerhaave, Verheyen, Ramsay, and Baglivi; and some facts have since been added to our chemical knowledge of bile by Maclurg and Fourcroy. The experiments have chiefly been confined to the bile of oxen, known in this country by the name of *gall*; because it is most easily procured in large quantities.

289 Properties of bile.

The specific gravity of bile seems to vary, like that of all other animal fluids. According to Hartmann, it is 1.027 *. When strongly agitated, it lathers like soap; and for this reason, as well as from a medical theory concerning its use, it has been often called an *animal soap*.

* *Haller's Phys.* vi. 546.

It mixes readily with water in any proportion, and assumes a yellow colour: but it refuses to unite with oil when the two fluids are agitated together; the instant that they are left at rest, the oil separates and swims on the surface †.

† *Ramsay, Thesaur. Med. Edin.* ii. 459.

When muriatic acid is poured upon bile, let it be ever so fresh, an odour of sulphurated hydrogen gas is constantly exhaled ‡. When on 100 parts of ox-bile four parts of strong muriatic acid are poured, the whole instantly coagulates; but in some hours the greater part becomes again fluid; and when passed through the filter it leaves 0.26 of a white matter, which has all the properties of albumen §. This matter was detected by Ramsay; who found that it could be precipitated from bile by alcohol, acetous acid, sulphat of potass, and muriat of soda *. Cadet ascertained, that 100 parts of ox-bile contain about 0.52 of albumen. It is precipitated in a state of purity by oxy muriatic acid, provided that acid be not employed in excess †.

‡ *Maclurg*, p. 10.

290 Its component parts.

§ *Cadet, Mem. Par.* 1707. p. 340.
§ *Ibid.*
* *Thesaur. Edin.* ii. 460.
† *Fourcroy, Ann. de Chim.* vii. 170.

The muriatic acid solution, after the separation of the albumen, has a fine grass-green colour. When concentrated by some hours evaporation in a glass cucurbit on hot coals, it deposites a very copious precipitate, and loses almost the whole of its green colour. By longer evaporation, a new precipitate, similar to the first, appears, and the remaining liquid assumes the colour of beer. The precipitate possesses all the properties of the *resin of bile*. In its moist state it amounts to 10.8 parts ‡. The same substances may be obtained from bile by nitric acid; but the resin in that

‡ *Cadet, ib.*

case

Bile, biliary Calculi.

cafe has a yellow colour, and its properties are fomewhat altered *.

If 100 parts of bile be gently evaporated to drynefs by a very moderate heat, the dry mafs only weighs 10 parts, and has a brownifh black colour. When expofed to a ftrong heat in a crucible, this matter fwells up, takes fire, and emits very thick fumes. The refiduum amounts to 1.09. By lixivation with water, 1.87 of cryftallized foda may be obtained †; confequently 100 parts of bile contain, according to Mr Kirwan's table, 0.403546 of pure foda. But it is evident that, by this method, part of the foda muft have been evaporated; therefore 100 parts of bile contain more than 0.403546 of foda. Befides the foda, there is found alfo a fmall portion of muriat of foda ‡.

Cadet found the refiduum, after the feparation of the falts, of a black colour: it gave fome traces of iron. He alfo obtained a calcareous falt from bile, which he confidered as a fulphat; but it is more than probable that it was phofphat of lime.

Cadet alfo obtained from bile, by evaporating the muriatic acid folution after the feparation of the refin, a falt which cryftallized in trapeziums; it had a fweetifh tafte, and was confidered by him as analogous to fugar of milk *.

Thus we fee that bile contains the following ingredients:

1. Water,	5. A fweetifh falt,
2. Refin,	6. Muriat of foda,
3. Albumen,	7. Phofphat of lime,
4. Soda,	8. Iron.

The proportion of thefe ingredients has by no means been afcertained. The prefence of iron has been denied in bile, becaufe it gives no blue precipitate with pruffic alkali, and becaufe tincture of nut-galls does not give it a black colour †. But thefe reafons are infufficient to overturn the experiment of Cadet, who actually found it in bile.

When four parts of vinegar and five of bile are mixed together, the mixture has a fweet tafte, and does not coagulate milk. The lactic acid has precifely the fame effect as vinegar ‡.

When bile is diftilled in a water bath, it affords a tranfparent watery liquor, which contracts a pretty ftrong odour, not unlike that of mufk or amber, efpecially if the bile has been kept for fome days before it is fubmitted to diftillation §. The refiduum is of a deep brownifh green; it attracts moifture from the air, and diffolves readily in water. When diftilled in a retort, it affords a watery liquor of a yellowifh colour, and impregnated with alkali, oil, carbonat of ammonia, carbonic acid, and hydrogen gas. The coaly refiduum is eafily incinerated *. Bile, expofed to a temperature between 65° and 85° foon lofes its colour and vifcidity, acquires a naufeous fmell, and depofites whitifh mucilaginous flakes After the putrefaction has made confiderable progrefs, its fmell becomes fweet, and refembles amber †. If bile be heated, and flightly concentrated by evaporation, it may be kept for many months without alteration ‡.

SECT. XI. *Of Biliary Calculi.*

HARD bodies fometimes form in the gall bladder, or in the duct through which the bile paffes into the inteftinal canal, and ftop up the paffage altogether. Thefe concretions have got the name of *biliary calculi* or *gall-ftones*. As they are formed in the midft of bile, and as the fubftances of which they are compofed muft be derived from the bile, it is proper to give an account of them here, becaufe their properties cannot fail to throw fome additional light on the nature of bile itfelf.

Biliary Calculi.

291 Biliary calculi of three kinds.

Biliary calculi, all of them at leaft which have been hitherto examined with attention, may be divided into three claffes.

1. The firft kind comprehends thofe which have a white colour, and a cryftallized, fhining, lamellated ftructure.

2. The fecond is dark coloured, and has precifely the appearance of infpiffated bile. Both thefe kinds are combuftible.

3. The third kind comprehends thofe gall-ftones which do not flame, but gradually wafte away at a red heat.

We fhall take a view of each of thefe kinds of biliary calculi in their order. For the greater part of the chemical knowledge which has been hitherto acquired of them, the world is chiefly indebted to Mr Fourcroy.

292 Properties of the firft.

1. The firft fpecies of biliary calculi was pointed out for the firft time by Haller, in a differtation publifhed in 1749. Walther afterwards added feveral new facts; and at laft it was accurately defcribed by Vicq d'Azyr. It is almoft always of an oval fhape, fometimes as large as a pigeon's egg, but commonly about the fize of a fparrow's; and for the moft part only one calculus (when of this fpecies) is found in the gall bladder at a time. It has a white colour; and when broken, prefents cryftalline plates or ftriæ, brilliant and white like mica, and having a foft greafy feel. Sometimes its colour is yellow or greenifh; and it has conftantly a nucleus of infpiffated bile †.

Its fpecific gravity is lower than that of water: Gren found he fpecific gravity of one 0.803 ‡.

When expofed to a heat confiderably greater than that of boiling water, this cryftallized calculus foftens and melts, and cryftallizes again when the temperature is lowered §. It is altogether infoluble in water; but hot alcohol diffolves it with facility. Alcohol, of the temperature of 167°, diffolves $\frac{1}{20}$ of its weight of this fubftance; but alcohol, at the temperature of 60°, fcarcely diffolves any of it *. As the alcohol cools, the matter is depofited in brilliant plates refembling talc or boracic acid †. It is foluble in oil of turpentine ‡. When melted, it has the appearance of oil, and exhales the odour of melted wax: when fuddenly heated, it evaporates altogether in a thick fmoke. It is foluble in pure alkalies, and the folution has all the properties of a foap. Nitric acid alfo diffolves it; but it is precipitated unaltered by water ‡.

This matter, which is evidently the fame with the cryftals which Cadet obtained from bile, and which he confidered as analogous to fugar of milk, has a ftrong refemblance to fpermaceti. Like that fubftance, it is of an oily nature, and inflammable; but it differs from it in a variety of particulars.

Since it is contained in bile, it is not difficult to fee how it may cryftallize in the gall-bladder if it happens to be more abundant than ufual; and the confequence muft

‡ Gren, ibid. v. 187.
‡ Fourcroy, ibid. iii. 247.

Biliary calculi, Tears. must be a gall-stone of this species. Fourcroy found a quantity of the same substance in the dried human liver *.

* Fourcroy, ibid. p. 126.

293 Of the second. 2. The second species of biliary calculus is of a round or polygonal shape, of a grey colour exteriorly, and brown within. It is formed of concentric layers of a matter which seems to be inspissated bile; and there is usually a nucleus of the white crystalline matter at the centre. For the most part there are many of this species of calculus in the gall-bladder together: indeed it is frequently filled with them. Their size is usually much smaller than that of the last species.

This is the most common kind of gall-stone. It may be considered as a mixture of inspissated bile, and of the crystalline matter which forms the first species: and the appearance of calculi of this kind must vary considerably, according to the proportion of these ingredients.

294 Of the third. 3. Concerning the third species of gall-stone, very little is known with accuracy. Dr Saunders tells us, that he has met with some gall-stones insoluble both in alcohol and oil of turpentine; some which do not flame, but become red, and consume to an ash like a charcoal †. Haller quotes several examples of similar calculi ‡.

† On the Liver, p. 112

‡ Physiol. vi. 567.

Gall-stones often occur in the inferior animals, particularly in cows and hogs; but the biliary concretions of these animals have not hitherto been examined with attention.

Sect. XII. *Of Tears.*

That peculiar fluid which is employed in lubricating the eye, and which is emitted in considerable quantities when we express grief by weeping, is known by the name of *tears*. For an accurate analysis of this fluid, chemistry is indebted to Messrs Fourcroy and Vauquelin. Before their dissertation, which was published in 1791, appeared, scarcely any thing was known about the nature of tears.

295 Properties of tears. The liquid called tears is transparent and colourless like water; it has scarcely any smell, but its taste is always perceptibly salt. Its specific gravity is somewhat greater than that of distilled water. It gives to paper, stained with the juice of the petals of mallows or violet, a permanently green colour, and therefore contains a fixed alkali *. It unites with water, whether cold or hot, in all proportions. Alkalies unite with it readily, and render it more fluid. The mineral acids produce no apparent change upon it †. Exposed to the air, this liquid gradually evaporates, and becomes thicker. When nearly reduced to a state of dryness, a number of cubic crystals form in the midst of a kind of mucilage. These crystals possess the properties of muriat of soda; only they tinge vegetable blues green, and therefore contain an excess of soda. The mucilaginous matter acquires a yellowish colour as it dries ‡.

* Fourcroy, and Vauquelin, Jour. de Phys. xxxix. 256.

† Ibid. p. 257.

‡ Ibid. p. 256.

This liquid boils like water, excepting that a considerable froth collects on its surface. If it be kept a sufficient time at the boiling temperature, $\frac{96}{100}$ parts of it evaporate in water; and there remain about .04 parts of a yellowish matter, which by distillation in a strong heat yield water and a little oil: the residuum consists of different saline matters §.

§ Ibid.

When alcohol is poured into this liquid, a mucilaginous matter is precipitated in the form of large white flakes. The alcohol leaves behind it, when evaporated, traces of muriat of soda and soda. The residuum which remains behind, when inspissated tears are burnt in the open air, exhibits some traces of phosphat of lime and phosphat of soda ‖.

‖ Fourcroy and Vauquelin, Jour. de Phys. p. 259.

296 Component parts. Thus it appears that tears are composed of the following ingredients:

1. Water,	4. Soda,
2. Mucilage,	5. Phosphat of lime,
3. Muriat of soda,	6. Phosphat of soda.

The saline parts amount only to about 0.01 of the whole, or probably not so much.

The *mucilage* contained in the tears has the property of absorbing oxygen gradually from the atmosphere, and of becoming thick and viscid, and of a yellow colour. It is then insoluble in water, and remains long suspended in it without alteration. When a sufficient quantity of oxy-muriatic acid is poured into tears, a yellow flaky precipitate appears absolutely similar to this inspissated mucilage. The oxy-muriatic acid loses its peculiar odour; hence it is evident that it has given out oxygen to the mucilage. The property which this mucilage has of absorbing oxygen, and of acquiring new qualities, explains the changes which take place in tears which are exposed for a long time to the action of the atmosphere, as is the case in those persons who labour under a fistula lachrymalis *.

* Ibid. p. 257.

297 Mucus of the nose. The mucus of the nose has also been examined by Fourcroy and Vauquelin. They found it composed of precisely the same ingredients with the tears. As this fluid is more exposed to the action of the air than the tears, in most cases its mucilage has undergone less or more of that change which is the consequence of the absorption of oxygen. Hence the reason of the greater viscidity and consistence of the mucus of the nose; hence also the great consistence which it acquires during colds, where the action of the atmosphere is assisted by the increased action of the parts †.

† Ibid. p. 259.

Sect. XIII. *Of Sinovia.*

Within the capsular ligament of the different joints of the body, there is contained a peculiar liquid, intended evidently to lubricate the parts, and to facilitate their motion. This liquid is known among anatomists by the name of *sinovia*.

Whether it be the same in different animals, or even in all the different joints of the same animal, has not been determined; as no accurate analysis of the sinovia of different animals has been attempted. The only analysis of sinovia which has hitherto appeared is that by Mr Margueron, which was published in the 14th volume of the *Annales de Chimie*. He made use of sinovia obtained from the joints of the lower extremities of oxen.

298 Sinovia of the ox. The sinovia of the ox, when it has just flowed from the joint, is a viscid semitransparent fluid, of a greenish white colour, and a smell not unlike frog spawn. It very soon acquires the consistence of jelly; and this happens equally whether it be kept in a cold or a hot temperature, whether it be exposed to the air or excluded from it. This consistence does not continue long; the sinovia soon recovers again its fluidity, and at the same time deposites a thready-like matter *.

* Margueron, Ann. de Chim. xiv. 124.

299 Its properties. Sinovia mixes readily with water, and imparts to that liquid a great deal of viscidity. The mixture froths when agitated; becomes milky when boiled, and deposites

sinovia, semen. fites some pellicles on the sides of the dish; but its viscidity is not diminished †.

Margueron, Ann. Chim. p. 106. When alcohol is poured into sinovia, a white substance precipitates, which has all the properties of albumen. One hundred parts of sinovia contain 4.52 of albumen. The liquid still continues as viscid as ever;
300 component parts. but if acetous acid be poured into it, the viscidity disappears altogether, the liquid becomes transparent, and deposites a quantity of matter in white threads, which possesses the following properties:

1. It has the colour, smell, taste, and elasticity of vegetable gluten.

2. It is soluble in concentrated acids and pure alkalies.

3. It is soluble in cold water, the solution frothes; acids and alcohol precipitate the fibrous matter in flakes. One hundred parts of sinovia contain 11.86 of this matter ‡.

Ibid. p. —130. When the liquid, after these substances have been separated from it, is concentrated by evaporation, it deposites crystals of acetite of soda. Sinovia, therefore, contains *soda*. Margueron found that 100 parts of sinovia contained about 0.71 of soda.

When strong sulphuric, muriatic, nitric, acetic, or sulphurous acid is poured into sinovia, a number of white flakes precipitate at first, but they are soon redissolved, and the viscidity of the liquid continues. When these acids are diluted with five times their weight of water, they diminish the transparency of sinovia, but not its viscidity; but when they are so much diluted that their acid taste is just perceptible, they precipitate the peculiar thready matter, and the viscidity of the sinovia disappears §.

When sinovia is exposed to a dry atmosphere it gradually evaporates, and a scaly residuum remains, in which cubic crystals, and a white saline efflorescence, are apparent. The cubic crystals are muriat of soda. One hundred parts of sinovia contain about 1.75 of this salt. The saline efflorescence is carbonat of soda ||.

Sinovia soon putrefies in a moist atmosphere, and during the putrefaction ammonia is exhaled. When sinovia is distilled in a retort there comes over, first water, which soon putrefies; then water containing ammonia; then empyreumatic oil and carbonat of ammonia. From the residuum muriat and carbonat of soda may be extracted by lixiviation. The coal contains some phosphat of lime ¶.

From the analysis of Mr Margueron it appears that sinovia is composed of the following ingredients:

11.86	fibrous matter,
4.52	albumen,
1.75	muriat of soda,
.71	soda,
.70	phosphat of lime (N),
80.57	water,
100.00.	

Sect. XIV. *Of Semen.*

The peculiar liquid secreted in the testes of males, and destined for the impregnation of females, is known by the name of *semen*. The human semen alone has hitherto been subjected to chemical analysis. Nothing is known concerning the seminal fluid of other animals. Vauquelin published an analysis of the human semen in 1791.

301 Properties of semen. Semen, when newly ejected, is evidently a mixture of two different substances: the one, fluid and milky, which is supposed to be secreted by the prostate gland; the other, which is considered as the true secretion of the testes, is a thick mucilaginous substance, in which numerous white shining filaments may be discovered *. It has a slight disagreeable odour, an acrid irritating taste, and its specific gravity is greater than that of water. When rubbed in a mortar it becomes frothy, and of the consistence of pomatum, in consequence of its enveloping a great number of air bubbles. It converts paper stained with the blossoms of mallows or violets to a green colour, and consequently contains an alkali †.

As the liquid cools, the mucilaginous part becomes transparent, and acquires greater consistency; but in about twenty minutes after its emission, the whole becomes perfectly liquid. This liquefaction is not owing to the absorption of moisture from the air, for it loses instead of acquiring weight during its exposure to the atmosphere; nor is it owing to the action of the air, for it takes place equally in close vessels ‡.

Semen is insoluble in water before this spontaneous liquefaction, but afterwards it dissolves readily in it. When alcohol or oxy-muriatic acid is poured into this solution, a number of white flakes are precipitated §. Concentrated alkalies facilitate its combination with water. Acids readily dissolve the semen, and the solution is not decomposed by alkalies; neither indeed is the alkaline solution decomposed by acids ||.

Lime disengages no ammonia from fresh semen; but after that fluid has remained for some time in a moist and warm atmosphere, lime separates a great quantity from it. Consequently ammonia is formed during the exposure of semen to air ¶.

302 Its component parts. When oxy-muriatic acid is poured into semen, a number of white flakes precipitate, and the acid loses its peculiar odour. These flakes are insoluble in water, and even in acids. If the quantity of acid be sufficient, the semen acquires a yellow colour. Thus it appears that semen contains a mucilaginous substance, analogous to that of the tears, which coagulates by absorbing oxygen. Mr Vauquelin obtained from 100 parts of semen six parts of this mucilage.

When semen is exposed to the air about the temperature of 60°, it becomes gradually covered with a transparent pellicle, and in three or four days deposites small transparent crystals, often crossing each other in such a manner as to represent the spokes of a wheel. These crystals, when viewed through a microscope, appear to be four-sided prisms, terminated by very long four-sided pyramids. They may be separated by diluting the liquid with water, and decanting it off. They have all the properties of phosphat of lime *. If, after the appearance of these crystals, the semen be still allowed to remain exposed to the atmosphere, the pellicle on

(N) Mr Hatchett found only 0.208 of phosphat of lime in the sinovia which he examined. He found, however, traces of some other phosphat; probably phosphat of soda. *Phil. Trans.* 1799, p. 246.

Semen, Liquor of the Amnios.

on its furface gradually thickens, and a number of white round bodies appear on different parts of it. Thefe bodies alfo are phofphat of lime, prevented from cryftallizing regularly by the too rapid abftraction of moifture. Mr Vauquelin found that 100 parts of femen contain three parts of phofphat of lime †. If at this period of the evaporation the air becomes moift, other cryftals appear in the femen, which have the properties of carbonat of foda. The evaporation does not go on to complete exficcation, unlefs at the temperature of 77°, and when the air is very dry. When all the moifture is evaporated, the femen has loft 0.9 of its weight, the refiduum is femi-tranfparent like horn, and brittle ‡.

† Vauquelin, Ann. de Chim. p. 68.

‡ Ibid.

When femen is kept in very moift air, at the temperature of about 7-°, it acquires a yellow colour, like that of the yolk of an egg: its tafte becomes acid, it exhales the odour of putrid fifh, and its furface is covered with abundance of the byffus feptica §.

§ Ibid.

When dried femen is expofed to heat in a crucible, it melts, acquires a brown colour, and exhales a yellow fume, having the odour of burnt horn. When the heat is raifed, the matter fwells, becomes black, and gives out a ftrong odour of ammonia. When the odour of ammonia difappears, if the matter be lixiviated with water, an alkaline folution may be obtained, which, by evaporation, yields cryftals of carbonat of foda. Mr Vauquelin found that 100 parts of femen contain one part of foda ¶. If the refiduum be incinerated, there will remain only a quantity of white afhes, confifting of phofphat of lime.

¶ Ibid. p. 75.

Thus it appears that femen is compofed of the following ingredients:

90	water,
6	mucilage,
3	phofphat of lime,
1	foda,
100	

Sect. XV. *Liquor of the Amnios.*

The fœtus in the uterus is enveloped in a peculiar membranous covering, to which anatomifts have given the name of *amnios*. Within this amnios there is a liquid, diftinguifhed by the name of the *liquor of the amnios*, which furrounds the fœtus on every part. This liquid, as might have been expected, is very different in different animals, at leaft the liquor amnii in women and in cows, which alone have hitherto been analyfed, have not the fmalleft refemblance to each other. Thefe two liquids have been lately analyfed by Vauquelin and Buniva, and the refult of their analyfis has been publifhed in the 33d volume of the *Annales de Chimie*.

303 Liquor of the human amnios.

1. The liquor of the amnios of women is a fluid of a flightly milky colour, a weak but pleafant odour, and a faltifh tafte. The white colour is owing to a curdy matter fufpended in it, for it may be obtained quite tranfparent by filtration *.

* Ann. de Chim. xxxiii. 270.

Its fpecific gravity is 1.005. It gives a green colour to the tincture of violets, and yet it reddens very decidedly the tincture of turnfol. Thefe two properties would indicate at once the prefence of an acid and of an alkali. It frothes confiderably when agitated. On the application of heat it becomes opaque, and has then a great refemblance to milk diluted with a large quantity of water. At the fame time it exhales the odour of boiled white of egg *.

* Ann. de Chim. xxx 271.

Acids render it more tranfparent. Alkalies precipitate an animal matter in fmall flakes. Alcohol likewife produces a flaky precipitate, which, when collected and dried, becomes tranfparent, and very like glue. The infufion of nut-galls produces a very copious brown coloured precipitate. Nitrat of filver occafions a white precipitate, which is infoluble in nitric acid, and confequently is muriat of filver †.

† Ibid.

When flowly evaporated it becomes flightly milky, a tranfparent pellicle forms on its furface, and it leaves a refiduum which does not exceed 0.012 of the whole. By lixiviating this refiduum, and evaporating the ley, cryftals of muriat and carbonat of foda may be obtained. The remainder, when incinerated, exhales a fetid and ammoniacal odour, refembling that of burning horn; the afhes confift of a fmall quantity of carbonat of foda, and of phofphat and carbonat of lime ‡.

‡ Ibid. p. 272.

Thus we fee that the liquor of the human amnios is compofed of about

$$\begin{array}{l} 98.8 \text{ water,} \\ 1.2 \left\{ \begin{array}{l} \text{albumen,} \\ \text{muriat of foda, foda,} \\ \text{phofphat of lime, lime,} \end{array} \right. \\ \hline 100.0 \end{array}$$

304 Curdy matter depofited on the fœtus.

While the fœtus is in the uterus, a curdy-like matter is depofited on the furface of its fkin, and in particular parts of its body. This matter is often found collected in confiderable quantities. It is evidently depofited from the liquor of the amnios; and confequently the knowledge of its peculiar nature muft throw confiderable light upon the properties and ufe of that liquor. For an analyfis of this fubftance we are alfo indebted to Vauquelin and Buniva.

Its colour is white and brilliant; it has a foft feel, and very much refembles newly prepared foap. It is infoluble in water, alcohol, and oils. Pure alkalies diffolve part of it, and form with it a kind of foap. On burning coals it decrepitates like a falt, becomes dry and black, exhales vapours which have the odour of empyreumatic oil, and leaves a refiduum, which is very difficultly reduced to afhes. When heated in a platinum crucible it decrepitates, lets an oil exfude, curls up like horn, and leaves a refiduum confifting chiefly of carbonat of lime ‡.

‡ Ibid. p. 274.

Thefe properties fhew that this matter is different from every one of the component parts of the liquor of the amnios, and that it has a great refemblance to the *fat*. It is probable, as Vauquelin and Buniva have conjectured, that it is formed from the albumen of that liquid, which has undergone fome unknown changes. It has been long known, that the parts of a fœtus which has lain for fome time after it has been deprived of life in the uterus, are fometimes converted into a kind of fatty matter. It is evident that this fubftance, after it is depofited upon the fkin of the fœtus, muft preferve it in a great meafure from being acted upon by the liquor of the amnios.

30[5] Liquor of the amnios of the cow.

2. The liquor of the amnios of the cow has a vifcidity fimilar to mucilage of gum arabic, a brownifh red colour, an acid and bitter tafte, and a peculiar odour, not unlike that of fome vegetable extracts. Its fpecific gravity is 1.028. It reddens the tincture of turnfol, and

Liquor of the Amnios. and therefore contains an acid. Muriat of barytes causes a very abundant precipitate, which renders it probable that it contains sulphuric acid. Alcohol separates from it a great quantity of a reddish coloured matter *.

* Ann. de Chim xxxiii. 275

306 Its component parts. When this liquid is evaporated, a thick frothy scum gathers on the surface, which is easily separated, and in which some white acid-tasted crystals may be discovered. By continuing the evaporation, the matter becomes thick, and viscid, and has very much the look of honey. Alcohol boiled upon this thick matter, and filtered off, deposites upon cooling brilliant needle-formed crystals nearly an inch in length. These crystals may be obtained in abundance by evaporating the liquor of the amnios to a fourth part of its bulk, and then allowing it to cool. The crystals soon make their appearance. They may be separated and purified by washing them in a small quantity of cold water. These crystals have the properties of an acid §.

§ Ibid. p.

If after the separation of this acid the liquor of the amnios be evaporated to the consistence of a syrup, large transparent crystals appear in it, which have all the properties of sulphat of soda. The liquid of the amnios of cows contains a considerable quantity of this salt.

Thus it appears that the liquor of the amnios of cows contains the following ingredients:

1. Water,
2. A peculiar animal matter,
3. A peculiar acid,
4. Sulphat of soda.

307 Nature of the animal matter. The animal matter possesses the following properties: It has a reddish brown colour, and a peculiar taste; it is very soluble in water, but insoluble in alcohol, which has the property of separating it from water. When exposed to a strong heat it swells, exhales first the odour of burning gum, then of empyreumatic oil and of ammonia, and at last the peculiar odour of prussic acid becomes very conspicuous. It differs from gelatine in the viscidity which it communicates to water, in not forming a jelly when concentrated, and in not being precipitated by tan. It must be therefore ranked among the very undefined and inaccurate class of *animal mucilages*.

When burnt, it leaves a very large coal, which is readily incinerated, and leaves a little white ashes, composed of phosphat of magnesia, and a very small proportion of phosphat of lime ‖.

‖ Ibid. p.

308 Amniotic acid. The acid substance is of a white and brilliant colour; its taste has a very slight degree of sourness; it reddens the tincture of turnsol; it is scarcely soluble in cold water, but very readily in hot water, from which it separates in long needles as the solution cools. It is soluble also in alcohol, especially when assisted by heat. It combines readily with pure alkalies, and forms a substance which is very soluble in water. The other acids decompose this compound; and the acid of the liquor of the amnios is precipitated in a white crystalline powder. This acid does not decompose the alkaline carbonats at the temperature of the atmosphere, but it does so when assisted by heat. It does not alter solutions of silver, lead, or mercury, in nitric acid. When exposed to a strong heat, it frothes and exhales an odour of ammonia and of prussic acid. The properties are sufficient to shew that it is different from every other acid. Vauquelin and Boniva have given it the name of *amniotic acid*. It approaches nearest to the saccholactic and the *uric* acids; but the sachlactic acid does not furnish ammonia by distillation like the amniotic. The uric acid is not so soluble in hot water as the amniotic, it does not crystallize in white brilliant needles, and it is insoluble in boiling alcohol; in both which respects it differs completely from amniotic acid *.

* Ann. de Chim. xxxiii. p. 279.

Sect. XVI. *Of Urine*.

309 Urine. No animal substance has attracted more attention than urine, both on account of its supposed connection with various diseases, and on account of the very singular products which have been obtained from it. Mr Boyle, and the other chemists who were his contemporaries, were induced to attend particularly to this liquid, by the discovery of a method of obtaining phosphorus from it. Boerhaave, Haller, Haupt, Margraf, Pott, Rouelle, Proust, and Klaproth, successively improved the method of obtaining the phosphoric salts from urine, or added something to our knowledge of the component parts of these salts. Scheele added greatly to our knowledge of urine by detecting several new substances in it which had not been suspected. Cruickshank has given us a very valuable paper on urine in the second edition of *Rollo's Diabetes*; and Fourcroy and Vauquelin have lately published the most complete analysis of it which has hitherto appeared.

Fresh urine is a liquid of a peculiar aromatic odour, an orange colour, of greater or less intensity, and an acrid saline taste.

Its specific gravity varies from 1.005 to 1.033 *.

* Cruickshank, Phil. Mag. ii. 240.

1. It reddens paper stained with turnsol and with the juice of radishes, and therefore contains an acid.

310 Contains phosphat of lime. 2. If a solution of ammonia be poured into fresh urine, a white powder precipitates, which has the properties of phosphat of lime. The presence of this substance in urine was first discovered by Scheele †. If lime water be poured into urine, phosphat of lime precipitates in greater abundance than when ammonia is used; consequently the acid which urine contains is the phosphoric. Thus we see that the phosphat of lime is kept dissolved in urine by an excess of acid. This also was first discovered by Scheele ‡. This substance is most abundant in the urine of the sick. Berthollet has observed that the urine of gouty people is less acid than that of people in perfect health. The average quantity of phosphat of lime in healthy urine is, as Cruickshank has ascertained, about $\frac{1}{900}$ of the weight of the urine §.

† Scheele, i. 208.

‡ Ibid.

§ Phil. Mag. ii. 241.

311 Phosphat of magnesia. 3. If the phosphat of lime precipitated from urine be examined, a little magnesia will be found mixed with it. Fourcroy and Vauquelin have ascertained that this is owing to a little phosphat of magnesia which urine contains, and which is decomposed by the alkali or lime employed to precipitate the phospat of lime ¶.

¶ Ann. de Chim. xxxi. 66.

312 Uric acid. 4. When fresh urine cools, it often lets fall a brick coloured precipitate, which Scheele first ascertained to be crystals of uric acid. All urine contains this acid, even when no sensible precipitate appears when it cools. For if a sufficient quantity of clear and fresh urine be evaporated to $\frac{1}{118}$ of its weight, a subtle powder precipitates to the bottom, and attaches itself in part very firmly to the vessel. This part may be dissolved in pure alkali, and precipitated again by acetous acid. It exhibits all the properties of uric acid *. The quantity of uric acid in urine is very various. During intermittent

* Scheele, i. 207.

Urine.

termittent fevers it is depofited very copioufly, and has been long known to phyficians under the name of *lateritious fediment*. This fediment always makes its appearance at the crifis of fevers. In gouty people, the fame fediment appears in equal abundance towards the end of a paroxyfm of the difeafe (P). And if this fediment fuddenly difappears after it has begun to be depofited, a frefh attack may be expected*.

* *Cruikfhank, Phil. Mag.* ii. 249.

313 Benzoic acid,

5. If frefh urine be evaporated to the confiftence of a fyrup, and muriatic acid be then poured into it, a precipitate appears which poffeffes the properties of benzoic acid. Scheele firft difcovered the prefence of benzoic acid in urine. He evaporated it to drynefs, feparated the faline part, and applied heat to the refiduum. The benzoic acid was fublimed, and found cryftallized in the receiver. The method which we have given is much eafier; it was firft propofed by Fourcroy and Vauquelin†. By it very confiderable quantities of benzoic acid may be obtained from the urine of horfes and cows, where it is much more abundant than in human urine. In human urine it varies from $\frac{1}{1000}$ to $\frac{1}{1055}$ of the whole§.

† *Ann. de Chim.* xxxi. 62.

§ *Ibid.* p. 63.

314 Albumen and gelatine,

6. When an infufion of tan is dropt into urine, a white precipitate appears, having the properties of the combination of tan and albumen, or gelatine. Urine, therefore, contains albumen and gelatine. Thefe fubftances had been fufpected to be in urine, but their prefence was firft demonftrated by Seguin, who difcovered the above method of detecting them. Their quantity in healthy urine is very fmall. Cruikfhank found that the precipitate afforded by tan in healthy urine amounted to $\frac{1}{240}$th part of the weight of the urine‡. It is to thefe fubftances that the appearance of the *cloud*, as it is called, or the mucilaginous matter, which is fometimes depofited as the urine cools, is owing. It is probable that healthy urine contains only gelatine and not albumen, though the quantity is too fmall to admit of accurate examination; but in many difeafes the quantity of thefe matters is very much increafed. The urine of dropfical people often contains fo much albumen, that it coagulates not only on the addition of acids, but even on the application of heat§. In all cafes of impaired digeftion, the albuminous and gelatinous part of urine is much increafed. This forms one of the moft confpicuous and important diftinctions between the urine of thofe who enjoy good and bad health‖.

‡ *Phil. Mag.* ii. 243.

§ *Cruikfhank, ibid.* 248.

‖ *Fourcroy and Vauquelin, Ann. de Chim.* xxxi. 61.

315 Urea,

7. If urine be evaporated by a flow fire to the confiftence of a thick fyrup, it affumes a deep brown colour, and exhales a fetid ammoniacal odour. When allowed to cool, it concretes into a mafs of cryftals, compofed of all the component parts of urine. If four times its weight of alcohol be poured upon this mafs, at intervals, and a flight heat be applied, the greateft part of it is diffolved. The alcohol, which has acquired a brown colour, is to be decanted off, and diftilled in a crucible in a fand heat, till the mixture has boiled for fome time, and acquired the confiftence of a fyrup. By this time the whole of the alcohol has paffed off, and the matter, on cooling, cryftallizes in quadrangular plates which interfect each other. This fubftance is *urea*, which compofes $\frac{19}{20}$ of the urine, provided the watery part be excluded. To this fubftance the tafte, fmell, and colour of urine are owing. It is a fubftance which characterizes urine, and conftitutes it what it is, and to which the greater part of the very fingular phenomena of urine are to be afcribed.

The colour of urine depends upon the urea; the greater the quantity, the deeper is the colour. It may be detected by evaporating urine to the confiftence of a fyrup, and pouring into it concentrated nitric acid. Immediately a great number of white fhining cryftals appear in the form of plates, very much refembling cryftallized boracic acid. Thefe cryftals are urea combined with nitric acid.

The quantity of urea varies exceedingly in different urines. In the urine voided foon after a meal, very little of it is to be found, and fcarcely any at all in that which hyfterical patients void during a paroxyfm.

316 Muriat of foda,

8. If urine be flowly evaporated to the confiftence of a fyrup, a number of cryftals make their appearance in it. Two of thefe are remarkable by their form: one of them confifts of fmall regular octahedrons; which, when examined, are found to poffefs the properties of muriat of foda. Urine, therefore, contains muriat of foda. It is well known that muriat of foda cryftallizes in cubes; the fingular modification of its form in urine is owing to the action of urea. It has been long known that urine faturated with muriat of foda depofites that falt in regular octahedrons.

317 Muriat of ammonia,

9. Another of the falts which appear during the evaporation of urine has the form of regular cubes. This falt has the properties of muriat of ammonia. Now the ufual form of the cryftals of muriat of ammonia is the octahedron. The change of its form in urine is produced alfo by urea.

318 Phofphats of ammonia and of foda,

10. The faline refiduum which remains after the feparation of urea from cryftallized urine by means of alcohol, has been long known under the names of fufible falt of urine and microcofmic falt. Various methods of obtaining it have been given by chemifts from Boerhaave, who firft publifhed a procefs, to Rouelle and Chaulnes, who gave the method juft mentioned. If this faline mafs be diffolved in a fufficient quantity of hot water, and allowed to cryftallize fpontaneoufly in a clofe veffel, two fets of cryftals are gradually depofited. The lowermoft fet has the figure of flat rhomboidal prifms; the uppermoft, on the contrary, has the form of rectangular tables. Thefe two may be eafily feparated by expofing them for fome time to a dry atmofphere. The rectangular tables efflorefce and fall to powder, but the rhomboidal prifms remain unaltered.

When thefe falts are examined, they are found to have the properties of phofphats. The rhomboidal prifms confift of phofphat of ammonia united to a little phofphat of foda; the rectangular tables, on the contrary,

(P) The concretions which fometimes make their appearance in gouty joints have been found to confift chiefly of uric acid. This fingular coincidence deferves the attention of phyfiologifts: it cannot fail, fooner or later, to throw light, not only upon gout, but upon fome of the animal functions.

Urine.

trary, are phosphat of soda united to a small quantity of phosphat of ammonia. Urine, then, contains phosphat of soda and phosphat of ammonia.

Thus we have found that urine contains the twelve following substances:

1. Water,	7. Gelatine and albumen,
2. Phosphoric acid,	8. Urea,
3. Phosphat of lime,	9. Muriat of soda,
4. Phosphat of magnesia,	10. Muriat of ammonia,
5. Uric acid,	11. Phosphat of soda,
6. Benzoic acid,	12. Phosphat of ammonia.

319
[So]metimes [ot]her salts.

These are the only substances which are constantly found in healthy urine *; but it contains also occasionally other substances. Very often muriat of potash may be distinguished among the crystals which form during its evaporation. The presence of this salt may always be detected by dropping cautiously some tartarous acid into urine. If it contains muriat of potash there will precipitate a little tartar, which may easily be recognised by its properties *.

Urine sometimes also contains sulphat of soda, and even sulphat of lime. The presence of these salts may be ascertained by pouring into urine a solution of muriat of barytes, a copious white precipitate appears, consisting of the barytes combined with phosphoric acid, and with sulphuric acid, if any be present. This precipitate must be treated with a sufficient quantity of muriatic acid. The phosphat of barytes is dissolved, but the sulphat of barytes remains unaltered †.

320
[P]utrefaction of u[ri]ne.

No substance putrefies sooner, or exhales a more detestable odour during its spontaneous decomposition, than urine; but there is a very great difference in this respect in different urines. In some, putrefaction takes place almost instantaneously as soon as it is voided; in others, scarcely any change appears for a number of days. Fourcroy and Vauquelin have ascertained that this difference depends on the quantity of gelatine and albumen which urine contains. When there is very little of these substances present, urine remains long unchanged; on the contrary, the greater the quantity of gelatine or albumen, the sooner does putrefaction commence. The putrefaction of urine, therefore, is, in some degree, the test of the health of the person who has voided it; for a superabundance of gelatine in urine always indicates some defect in the power of digestion *.

The rapid putrefaction of urine, then, is owing to the action of gelatine on urea. We have seen already the facility with which that singular substance is decomposed, and that the new products into which it is changed are, ammonia, carbonic acid, and acetous acid. Accordingly, the putrefaction of urine is announced by an ammoniacal smell. Mucilaginous flakes are deposited, consisting of part of the gelatinous matter. The phosphoric acid is saturated with ammonia, and the phosphat of lime, in consequence, is precipitated. Ammonia combines with the phosphat of magnesia, forms with it a triple salt, which crystallizes upon the sides of the vessel in the form of white crystals, composed of six-sided prisms, terminated by six-sided pyramids. The uric and benzoic acids are saturated with ammonia; the acetous acid, and the carbonic acid, which are the products of the decomposition of the urea, are also saturated with ammonia, and notwithstanding the quantity which exhales, the production of this substance is so abundant, that there is a quantity of unsaturated alkali in the liquid. Putrefied urine, therefore, contains chiefly the following substances, most of which are the products of putrefaction:

Ammonia,
Carbonat of ammonia,
Phosphat of ammonia,
Phosphat of magnesia and ammonia,
Urat of ammonia,
Acetite of ammonia,
Benzoat of ammonia,
Muriat of soda,
Muriat of ammonia;

Besides the precipitated gelatine and phosphat of lime *.

The distillation of urine produces almost the same changes; for the heat of boiling water is sufficient to decompose urea, and to convert it into ammonia, carbonic and acetous acids. Accordingly, when urine is distilled, there comes over water, containing ammonia dissolved in it, and carbonat of ammonia in crystals. The acids contained in urine are saturated with ammonia, and the gelatine and phosphat of lime precipitate †.

Such are the properties of the human urine. The urine of other animals has not hitherto been examined with equal care; but it is certain that it differs very considerably from that of men. The urine of cows and horses, and of all ruminating animals, for instance, contains carbonat of lime, without any mixture of phosphat of lime ‡. It contains also a much greater proportion of benzoic acid than that of man.

SECT. XVII. *Of the URINARY CALCULUS.*

Urinary Calculus.

It is well known that concretions not unfrequently form in the bladder, or the other urinary organs, and occasion one of the most dismal diseases to which the human species is liable.

321
Urinary calculi

These concretions were distinguished by the name of *calculi*, from a supposition that they are of a stony nature. They have long attracted the attention of physicians. Chemistry had no sooner made its way into medicine than it began to exercise its ingenuity upon the urinary calculus; and various theories were given of their nature and origin. According to Paracelsus, who gave them the ridiculous name of *duelech*, urinary calculi were intermediate between tartar and stone, and composed of an *animal resin*. Van Helmont pronounced them anomalous coagulations, the offspring of the salts of urine, and of a volatile earthy spirit, produced at once, and destitute of any viscid matter §. Boyle extracted from them, by distillation, oil, and a great quantity of volatile salt. Boerhaave supposed them compounds of oil and volatile salts. Hales extracted from them a prodigious quantity of air. He gave them the name of *animal tartar*, pointed out several circumstances in which they resemble common tartar, and made many experiments to find a solvent of them *. Dr Whytt and Alston pointed out alkalies as solvents of calculi. It was an attempt to discover a more perfect solvent that induced Dr Black to make those experiments which terminated in the discovery of the nature of the alkaline carbonats.

§ De Lithiasi, c. 3.
* Veget. Stat. ii. 189.

322
Analysed by Scheele.

Such was the state of the chemical analysis of calculus, when, in 1776, Scheele published a dissertation on the subject in the *Stockholm Transactions*; which was succeeded by some remarks of Mr Bergman. These

Urinary Calculus.

illustrious chemists completely removed the uncertainty which had hitherto hung over the subject, and ascertained the nature of the calculi which they examined. Since that time considerable additional light has been thrown upon the nature of these concretions by the labours of Austin, Pearson, and, above all, of Fourcroy and Vauquelin, who have lately analysed above 300 calculi, and ascertained the presence of several new substances which had not been suspected. The substances hitherto discovered in urinary calculi are the following:

323 Their component parts.

1. Uric acid,
2. Urat of ammonia,
3. Phosphat of lime (q),
4. Phosphat of magnesia-and-ammonia,
5. Oxalat of lime,
6. Silica,
7. An animal matter.

324 Uric acid.

1. The greater number of calculi consist of uric acid. All those analysed by Scheele were composed of it entirely. Of 300 calculi analysed by Dr Pearson, scarcely one was found which did not contain a considerable quantity of it, and the greater number manifestly were formed chiefly of it. Fourcroy and Vauquelin found it also in the greater number of the 300 calculi which they analysed.

The presence of this acid may easily be ascertained by the following properties: A solution of potass or soda dissolves it readily, and it is precipitated by the weakest acids. The precipitate is soluble in nitric acid, the solution is of a pink colour, and tinges the skin red *.

* *Fourcroy, Ann. de Chim.* xxxii. 216.

325 Urat of ammonia.

2. Urat of ammonia is easily detected by its rapid solubility in fixed alkaline leys, and the odour of ammonia which is perceived during the solution. It is not so often present in urinary calculi as the last mentioned substance. No calculus has hitherto been found composed of it alone, except the very small polygonal calculi, several of which sometimes exist in the bladder together.

It is most usually in thin layers, alternating with some other substance, very easily reduced to powder, and of the colour of ground coffee †.

† *Ibid.* 218.

326 Phosphat of lime.

3. Phosphat of lime is white, without lustre, fiery, friable, stains the hands, paper and cloth. It has very much the appearance of chalk, breaks under the forceps, is insipid, and insoluble in water. It is soluble in nitric, muriatic, and acetous acids, and is again precipitated by ammonia, fixed alkalies, and oxalic acid.

It is never alone in calculi. It is intimately mixed with a gelatinous matter, which remains under the form of a membrane when the earthy part is dissolved by very diluted acids ‡.

‡ *Ibid.*

327 Phosphat of magnesia-and-ammonia.

4. Phosphat of magnesia-and-ammonia occurs in white semitransparent, lameller layers; sometimes it is crystallized on the surface of the calculi in prisms, or what are called *dog-tooth* crystals. It has a weak sweetish taste, it is somewhat soluble in water, and very soluble in acids, though greatly diluted. Fixed alkalies decompose it.

It never forms entire calculi. Sometimes it is mixed with phosphat of lime, and sometimes layers of it cover uric acid or oxalat of lime. It is mixed with the same gelatinous matter as phosphat of lime ‡.

‡ *Fourcroy, Ann de Chim.* xxxii. 219.

328 Oxalat of lime.

5. Oxalat of lime is found in certain calculi, which, from the inequality of their surface, have got the name of *moriform* or *mulberry-shaped* calculi. It is never alone, but combined with a peculiar animal matter, and forming with it a very hard calculus, of a grey colour, difficult to saw asunder, admitting a polish like ivory, exhaling, when sawed, an odour like that of semen. Insoluble and indecomposible by alkalies; soluble in very diluted nitric acid, but slowly, and with difficulty. It may be decomposed by the carbonats of potass and soda. When burnt, it leaves behind a quantity of pure lime, which may be easily recognised by its properties *.

* *Ibid.* 220.

329 Silica.

6. Silica has only been found in two instances by Fourcroy and Vauquelin, though they analysed 300 calculi. No other chemist has observed it. It must therefore be considered as a very uncommon ingredient of these concretions. In the two instances in which it occurred, it was mixed with uric acid and the two phosphats above mentioned †.

† *Ibid.* 221.

330 Animal matters.

7. *Animal matter* appears to compose the cement which binds the different particles of the calculus together, and in all probability it is the cause which influences its formation. It is different in different calculi. Sometimes it has the appearance of gelatine or albumen, at other times it resembles urea. It deserves a more accurate investigation ‡.

‡ *Ibid.*

No general description of the different calculi has hitherto appeared; but Fourcroy and Vauquelin are at present occupied with that subject. They propose to classify them according to their composition; to point out their different species and varieties; to give a method of detecting them by their appearance; to analyse the animal matter by which they are cemented; and to apply all the present chemical knowledge of the subject in the investigation of the cause, the symptoms, and the cure, of that dreadful disease which the urinary calculi produce. As their labour is already very far advanced, it would be unnecessary for us to attempt any classification of calculi. Indeed every attempt of that kind, by any person who has not had an opportunity of analysing a very great number of calculi, must be so exceedingly imperfect as scarcely to be of any use.

We shall satisfy ourselves with the following remarks, deduced almost entirely from the observations which these celebrated chemists have already published.

331 Method of dissolving the calculi.

Many calculi consist entirely, or almost entirely, of uric acid. The animal matter, which serves as a cement to these calculi, appears to be urea. Calculi of this kind may be dissolved by injecting into the bladder solutions of pure potass or soda, so much diluted as not to act upon the bladder itself. The gritty substance, which many persons threatened with the stone discharge along with their urine, which has been called *gravel*, consists almost constantly of uric acid. It may therefore serve as an indication that the subsequent stone, if any such form, is probably composed of uric acid.

The two phosphats, mixed together, sometimes compose calculi. These calculi are very brittle, and generally

(q) Brugnatelli found also phosphat of lime, with excess of acid, in calculi. See *Ann. de Chim.* xxxii. 183.

rally break in pieces during the extraction. Such calculi may be diſſolved by injecting into the bladder muriatic acid, ſo much diluted as ſcarcely to have any taſte of acid.

The phoſphats never form the nucleus of a calculus. They have never been found covered with a layer of uric acid, but they often cover that acid. Hence it would ſeem that the exiſtence of any extraneous matter in the bladder diſpoſes theſe phoſphats to cryſtallize. When extraneous bodies are accidentally introduced into the bladder, and allowed to lodge there, they are conſtantly covered with a coat of phoſphat of ammonia and magneſia, or of the two phoſphats mixed.

As the phoſphat of ammonia and magneſia is not an ingredient of freſh urine, but formed during its putrefaction, when it exiſts in calculi, it would ſeem to indicate a commencement of putrefaction during the time that the urine lodges in the bladder. But putrefaction does not take place ſpeedily in urine, unleſs where there is an exceſs of albumen and gelatine; conſequently we have reaſon to ſuppoſe, that theſe ſubſtances are morbidly abundant in the urine of thoſe patients who are afflicted with calculi conſiſting of the phoſphats: hence alſo we may conclude, that their digeſtion is imperfect. It will no doubt be objected, that dropſical people are not peculiarly ſubject to calculi; but their urine is only morbidly albuminous when the diſeaſe is beginning to diſappear, and then there ſeems to be a deficiency of urea; at leaſt their urine has not been obſerved to putrefy with uncommon rapidity. Beſides, there ſeems to be ſome animal matter preſent, which ſerves as a cement to the phoſphat in all caſes where calculi form.

Urat of ammonia is only found alone in the very ſmall polygonous calculi which exiſt, ſeveral together, in the bladder. In other caſes it is mixed with uric acid. It ſometimes alternates with uric acid or with the phoſphats. It is diſſolved by the ſame ſubſtance that acts as a ſolvent of uric acid.

Oxalat of lime often forms the nucleus of calculi compoſed of layers of uric acid or of the phoſphats. It forms thoſe irregular calculi which are called *moriform*. Theſe calculi are the hardeſt and the moſt difficult of ſolution. A very much diluted nitric acid diſſolves them but very ſlowly. As oxalic acid does not exiſt in urine, ſome morbid change muſt take place in the urine when ſuch calculi are depoſited. Brugnatelli's diſcovery of the inſtantaneous converſion of uric acid into oxalic acid by oxy-muriatic acid, which has been confirmed by the experiments of Fourcroy and Vauquelin, throws conſiderable light upon the formation of oxalic acid in urine, by ſhewing us that uric acid is probably the baſis of it; but in what manner the change is actually produced, it is not ſo eaſy to ſay.

The calculi found in the bladder of other animals have not been examined with the ſame care. Some of them, however, have been ſubjected to an accurate analyſis. No uric acid has ever been found in any of them. Fourcroy found a calculus extracted from the kidney of a horſe compoſed of three parts of carbonat of lime, and one part of phoſphat of lime *. Dr Pearſon examined a urinary calculus of a horſe; it was compoſed of phoſphat of lime and phoſphat of ammonia. Brugnatelli found a calculus extracted from the bladder of a ſow, which was exceedingly hard, compoſed of pure carbonat of lime, including a ſoft nucleus of a fœtid and urinous odour †. Bartholdi examined another calculus of a pig, the ſpecific gravity of which was 1.9300. It conſiſted of phoſphat of lime ‡. Dr Pearſon found a calculus taken from the bladder of a dog compoſed of phoſphat of lime, phoſphat of ammonia, and an animal matter. He found the urinary calculus of a rabbit, of the ſpecific gravity 2, compoſed of carbonat of lime and ſome animal matter ||.

We have now given an account of all thoſe ſecretions which have been attentively examined by chemiſts. The remainder have been hitherto neglected; partly owing to the difficulty of procuring them, and partly on account of the multiplicity of other objects which occupied the attention of chemical philoſophers (R). It remains for us now to examine by what proceſſes theſe different ſecretions are formed, how the conſtant waſte of living bodies is repaired, and how the organs themſelves are nouriſhed and preſerved. This ſhall form the ſubject of the following chapter.

Chap. III. Of the Functions of Animals.

The intention of the two laſt chapters was to exhibit a view of the different ſubſtances which enter into the compoſition of animals, as far as the preſent limited ſtate of our knowledge puts it in our power. But were our enquiries concerning animals confined to the mere ingredients of which their bodies are compoſed, even ſuppoſing the analyſis as complete as poſſible, our knowledge of the nature and properties of animals would be imperfect indeed.

How are theſe ſubſtances arranged? How are they produced?

(R) The chief of theſe ſecretions are the following:

1. Cerumen, or ear-wax, is at firſt nearly liquid, and of a whitiſh colour. It gradually acquires conſiſtence. Its taſte is very bitter. Said to be inſoluble in alcohol; but ſoluble in hot water. Does not become rancid by keeping.
2. The humours of the eye.
3. The milky liquor, ſecreted by the thyroid gland.
4. Mucus of the lungs, inteſtinal canal, &c.
5. Smegma of the areola of the breaſts, glans penis, vagina, ſubcutaneous glands, &c.
6. Marrow.

 produced? What purpoſes do they ſerve? What are the diſtinguiſhing properties of animals, and the laws by which they are regulated?

333 Animals reſemble vegetables. Animals reſemble vegetables in the complexneſs of their ſtructure. Like them, they are machines nicely adapted for particular purpoſes, conſtituting one whole, and continually performing an infinite number of the moſt delicate proceſſes. But neither an account of the ſtructure of animals, nor of the properties which diſtinguiſh them from other beings, will be expected here. Theſe have been already treated of ſufficiently in the articles ANATOMY and PHYSIOLOGY *(Encycl.)*, to which we beg leave to refer the reader. We mean only, in the preſent chapter, to take a view of thoſe proceſſes which are concerned in the *production* of animal ſubſtances, which alone properly belong to chemiſtry. The other functions are regulated by laws of a very different nature, which have no reſemblance or analogy to the laws of chemiſtry or mechanics.

334 Require food. 1. Every body knows that animals require food, and that they die ſooner or later if food be withheld from them. There is indeed a very great difference in different animals, with regard to the quantity of food which they require, and the time which they can paſs without it. In general, this difference depends upon the activity of the animal. Thoſe which are moſt active require moſt, and thoſe which move leaſt require leaſt food.

The cauſe of this is alſo well known; the bodies of animals do not remain ſtationary, they are conſtantly waſting; and the waſte is generally proportional to the activity of the animal. It is evident, then, that the body muſt receive, from time to time, new ſupplies, in place of what has been carried off. Hence the uſe of food, which anſwers this purpoſe.

335 Its nature. 2. We are much better acquainted with the food of animals than of vegetables. It conſiſts of almoſt all the animal and vegetable ſubſtances which have been treated of in the former part of this article; for there are but very few of them which ſome animal or other does not uſe as food. Man uſes as food chiefly the muſcles of animals, the ſeeds of certain graſſes, and a variety of vegetable fruits. Almoſt all the inferior animals have particular ſubſtances on which they feed excluſively. Some of them feed on animals, others on vegetables. Man has a greater range; he can feed on a very great number of ſubſtances. To enumerate theſe ſubſtances would be uſeleſs; as we are not able to point out with accuracy what it is which renders one ſubſtance more nouriſhing than another.

Many ſubſtances do not ſerve as nouriſhment at all; and not a few, inſtead of nouriſhing, deſtroy life. Theſe laſt are called *poiſons*. Some poiſons act chemically, by decompoſing the animal body. The action of others is not ſo well underſtood.

336 Converted into chyme. 3. The food is introduced into the body by the mouth, and almoſt all animals reduce it to a kind of pulpy conſiſtence. In man and many other animals this is done in the mouth by means of teeth, and the ſaliva with which it is there mixed; but many other animals grind their food in a different manner. See PHYSIOLOGY, *(Encycl.)* After the food has been thus ground, it is introduced into the ſtomach, where it is ſubjected to new changes. The ſtomach is a ſtrong ſoft bag, of different forms in different animals: in man it has ſome reſemblance to the bag of a *bag-pipe*. In this organ the food is converted into a ſoft pap, which has no reſemblance to the food when firſt introduced. This pap has been called *chyme*. Functions of Animals.

4. Since chyme poſſeſſes new properties, it is evident that the food has undergone ſome changes in the ſtomach, and that the ingredients of which it was compoſed have entered into new combinations. Now, in what manner have theſe changes been produced?

At firſt they were aſcribed to the mechanical action of the ſtomach. The food, it was ſaid, was ſtill farther triturated in that organ; and being long agitated backwards and forwards in it, was at laſt reduced to a pulp. But this opinion, upon examination, was found not to be true. The experiments of Stevens, Reumur, and Spallanzani, demonſtrated, that the formation of chyme is not owing to trituration; for on incloſing different kinds of food in metallic tubes and balls full of holes, in ſuch a manner as to ſcreen them from the mechanical action of the ſtomach, they found, that theſe ſubſtances, after having remained a ſufficient time in the ſtomach, were converted into chyme, juſt as if they had not been incloſed in ſuch tubes. Indeed, the opinion was untenable, even independent of theſe deciſive experiments, the moment it was perceived that chyme differed entirely from the food which had been taken; that is to ſay, that if the ſame food were triturated mechanically out of the body, and reduced to pap of preciſely the ſame conſiſtence with chyme, it would not poſſeſs the ſame properties with chyme; for whenever this fact was known, it could not but be evident that the food had undergone changes in its compoſition.

The change of food into chyme, therefore, was aſcribed by many to *fermentation*. This opinion is indeed very ancient, and it has had many zealous ſupporters among the moderns. When the word *fermentation* was applied to the change produced on the food in the ſtomach, the nature of the proceſs called fermentation was altogether unknown. The appearances, indeed, which take place during that proceſs, had been deſcribed, and the progreſs and the reſult of it were known. Chemiſts had even divided fermentations into different claſſes; but no attempt had been made to explain the cauſe of fermentation, or to trace the changes which take place during its continuance. All that could be meant, then, by ſaying that the converſion of food into chyme in the ſtomach was owing to fermentation, was merely, that the unknown cauſe which acted during the converſion of vegetable ſubſtances into wine or acid, or during their putrefaction, acted alſo during the converſion of the food into chyme, and that the reſult in both caſes was preciſely the ſame. Accordingly, the advocates for this opinion attempted to prove, that air was conſtantly generated in the ſtomach, and that an acid was conſtantly produced: for it was the vinous and acetous fermentations which were aſſigned by the greater number of phyſiologiſts as the cauſe of the formation of chyme. Some indeed attempted to prove, that it was produced by the putrefactive fermentation; but their number was inconſiderable, compared with thoſe who adopted the other opinion.

Our ideas reſpecting fermentation are now ſomewhat more preciſe. It ſignifies a ſlow decompoſition, which takes place when certain animal or vegetable ſubſtances are mixed together at a given temperature; and the

conſequent

Functions of Animals.

consequent production of particular compounds. If therefore the conversion of the food into chyme be owing to fermentation, it is evident that it is totally independent of the stomach any farther than as it supplies temperature; and that the food would be converted into chyme exactly in the same manner, if it were reduced to the same consistence, and placed in the same temperature out of the body. But this is by no means the case; substances are reduced to the state of chyme in a short time in the stomach, which would remain unaltered for weeks in the same temperature out of the body. This is the case with bones; which the experiments of Stevens and Spallanzani have shewn to be soon digested in the stomach of the dog. Further, if the conversion of food into chyme were owing to fermentation, it ought to go on equally well in the stomach and œsophagus. Now, it was observed long ago by Ray and Boyle, that when voracious fish had swallowed animals too large to be contained in the stomach, that part only which was in the stomach was converted into chyme, while what was in the œsophagus remained entire; and this has been fully confirmed by subsequent observations.

Still farther, if the conversion were owing to fermentation, it ought always to take place equally well, provided the temperature be the same, whether the stomach be in a healthy state or not. But it is well known, that this is not the case. The formation of chyme depends very much on the state of the stomach. When that organ is diseased, digestion is constantly ill performed. In these cases, indeed, fermentation sometimes appears, and produces flatulence, acid eructations, &c. which are the well-known symptoms of indegestion. These facts have been long known; they are totally incompatible with the supposition, that the formation of chyme is owing to fermentation. Accordingly that opinion has been for some time abandoned, by all those at least who have taken the trouble to examine the subject.

337 ...e ac... f the ...c

The formation of chyme, then, is owing to the stomach; and it has been concluded, from the experiments of Stevens, Reaumur, Spallanzani, Scopoli, Brugnatelli, Carimini, &c. that its formation is brought about by the action of a particular liquid secreted by the stomach, and for that reason called *gastric juice*.

That it is owing to the action of a liquid, is evident; because if pieces of food be inclosed in close tubes, they pass through the stomach without any farther alteration than would have taken place at the same temperature out of the body: but if the tubes be perforated with small holes, the food is converted into chyme.

This liquid does not act indiscriminately upon all substances: For if grains of corn be put into a perforated tube, and a granivorous bird be made to swallow it, the corn will remain the usual time in the stomach without alteration; whereas if the husk of the grain be previously taken off, the whole of it will be converted into chyme. It is well known, too, that many substances pass unaltered through the intestines of animals, and consequently are not acted upon by the gastric juice. This is the case frequently with grains of oats when they have been swallowed by horses entire with their husks on. This is the case also with the seeds of apples, &c. when swallowed entire by man; yet these very substances, if they have been previously ground sufficiently by the teeth, are digested. It appears, therefore, that it is chiefly the husk or outside of these substances which resists the action of the gastric juice. We see also, that trituration greatly facilitates the conversion of food into chyme.

338 Nature of gastric juice.

The gastric juice is not the same in all animals; for many animals cannot digest the food on which others live. The *conium maculatum* (hemlock), for instance, is a poison to man instead of food, yet the goat often feeds upon it. Many animals, as sheep, live wholly upon vegetables; and if they are made to feed on animals, their stomachs will not digest them: others, again, as the eagle, feed wholly on animal substances, and cannot digest vegetables.

The gastric juice does not continue always of the same nature, even in the same animal: it changes gradually, according to circumstances. Graminivorous animals may be brought to live on animal food; and after they have been accustomed to this for some time, their stomachs become incapable of digesting vegetables. On the other hand, those anamals which naturally digest nothing but animal food may be brought to digest vegetables.

What is the nature of the gastric juice, which possesses these singular properties? It is evidently different in different animals; but it is a very difficult task, if not an impossible one, to obtain it in a state of purity. Various attempts have indeed been made by very ingenious philosophers to procure it; but their analysis of it is sufficient to shew us, that they have never obtained it in a state of purity.

The methods which have been used to procure gastric juice are, *first*, to kill the animal whose gastric juice is to be examined after it has fasted for some time. By this method, Spallanzani collected 37 spoonfuls from the two first stomachs of a sheep. It was of a green colour, undoubtedly owing to the grass which the animal had eaten. He found also half a spoonful in the stomach of some young crows which he killed before they had left their nest.

Small tubes of metal, pierced with holes, and containing a dry sponge, have been swallowed by animals; and when vomited up, the liquid imbibed by the sponge is squezzed out. By this method, Spallanzani collected 481 grains of gastric juice from the stomachs of five crows.

A *third* method consists in exciting vomiting in the morning, when the stomach is without food. Spallanzani tried this method twice upon himself, and collected one of the times 1 oz. 32 gr. of liquid; but the pain was so great, that he did not think proper to try the experiment a third time. Mr Gosse, however, who could excite vomiting whenever he thought proper by swallowing air, has employed that method to collect gastric juice.

Spallanzani has observed, that eagles throw up every morning a quantity of liquid, which he considers as gastric juice; and he has availed himself of this to collect it in considerable quantities.

It is almost unnecessary to remark how imperfect these different methods are, and how far every conclusion drawn from the examination of such juices must deviate from the truth. It is impossible that the gastric juice, obtained by any one of these processes, can be pure; because in the stomach it must be constantly mixed

Functions of Animals

mixed with large quantities of faliva, mucus, bile, food, &c. It may be queftioned, indeed, whether any gaftric juice at all can be obtained by thefe methods: for as the intention of the gaftric juice is to convert the food into chyme, in all probability it is only fecreted, or at leaft thrown into the ftomach when food is prefent.

We need not be furprifed, then, at the contradictory accounts concerning its nature, given us by thofe philofophers who have attempted to examine it; as thefe relate not fo much to the gaftric juice, as to the different fubftances found in the ftomach. The idea that the gaftric juice can be obtained by vomiting, or that it is thrown up fpontaneoufly by fome animals, is, to fay the leaft of it, very far from being probable.

According to Brugnatelli, the gaftric juice of carnivorous animals, as hawks, kites, &c. has an acid and refinous odour, is very bitter, and not at all watery; and is compofed of an uncombined acid, a refin, an animal fubftance, and a fmall quantity of muriat of foda *. The gaftric juice of herbivorous animals, on the contrary, as goats, fheep, &c. is very watery, a little muddy, has a bitter faltifh tafte, and contains ammonia, an animal extract, and a pretty large quantity of muriat of foda †. Mr Carminati found the fame ingredients; but he fuppofes that the ammonia had been formed by the putrefaction of a part of their food, and that in reality the gaftric juice of thefe animals is of an acid nature ‡.

* *Scopoli's Macquer's Dict.*

† *Ibid.*

‡ *Senebier's Obfervat. on Gaftric Juice.*

The accounts which have been given of the gaftric juice of man are fo various, that it is not worth while to tranfcribe them. Sometimes it has been found of an acid nature, at other times not. The experiments of Spallanzani are fufficient to fhew, that this acidity is not owing to the gaftric juice, but to the food. He never found any acidity in the gaftric juice of birds of prey, nor of ferpents, frogs, and fifhes. Crows gave an acidulous gaftric juice only when fed on grain; and he found that the fame obfervation holds with refpect to dogs, herbiferous animals, and domeftic fowls. Carnivorous birds threw up pieces of fhells and coral without alteration; but thefe fubftances were fenfibly diminifhed in the ftomachs of hens, even when inclofed in perforated tubes. Spallanzani himfelf fwallowed calcareous fubftances enclofed in tubes; and when he fed on vegetables and fruits, they were fometimes altered and a little diminifhed in weight, juft as if they had been put into weak vinegar; but when he ufed only animal food, they came out untouched. According to this philofopher, whofe experiments have been by far the moft numerous, the gaftric juice is naturally neither acid nor alkaline. When poured on the carbonat of potafs, it caufes no effervefcence.

Such are the refults of the experiments on the juices taken from the ftomach of animals. No conclufion can be drawn from them refpecting the nature of the gaftric juice. But from the experiments which have been made on the digeftion of the ftomach, efpecially by Spallanzani, the following facts are eftablifhed.

The gaftric juice attacks the furface of bodies, unites to the particles of them which it carries off, and cannot be feparated from them by filtration. It operates with more energy and rapidity the more the food is divided, and its action is increafed by a warm temperature. The food is not merely reduced to very minute parts; its tafte and fmell are quite changed; its fenfible properties are deftroyed, and it acquires new and very different ones. This juice does not act as a ferment; fo far from it, that it is a powerful antifeptic, and even reftores flefh already putrefied. There is not the fmalleft appearance of fuch a procefs; indeed, when the juice is renewed frequently, as in the ftomach, fubftances diffolve in it with a rapidity which excludes all idea of fermentation. Only a few air bubbles make their efcape, which adhere to the alimentary matter, and buoy it up to the top, and which are probably extricated by the heat of the folution.

Functions of Animals

With refpect to the fubftances contained in the ftomach, only two facts have been perfectly afcertained; The firft is, that the juice contained in the ftomach of oxen, calves, fheep, invariably contains uncombined phofphoric acid, as Macquart and Vauquelin have demonftrated: The fecond, that the juice contained in the ftomach, and even the inner coat of the ftomach itfelf, has the property of coagulating milk and the ferum of blood. Dr Young found that feven grains of the inner coat of a calf's ftomach, infufed in water, gave a liquid which coagulated more than 100 ounces of milk; that is to fay, more than 6857 times its own weight; and yet, in all probability, its weight was not much diminifhed.

What the fubftance is which poffeffes this coagulating property, has not yet been afcertained; but it is evidently not very foluble in water; for the infide of a calf's ftomach, after being fteeped in water for fix hours, and then well wafhed with water, ftill furnifhes a liquor on infufion which coagulates milk *: And Dr Young found, that a piece of the inner coat of the ftomach, after being previoufly wafhed with water, and then with a diluted folution of carbonat of potafs, ftill afforded a liquid which coagulated milk and ferum

* *Young.*

It is evident, from thefe facts, that this coagulating fubftance, whatever it is, acts very powerfully; and that it is fcarcely poffible to feparate it completely from the ftomach. But we know at prefent too little of the nature of coagulation to be able to draw any inference from thefe facts. An almoft imperceptible quantity of fome fubftances feems to be fufficient to coagulate milk. For Mr Vaillant mentions in his Travels in Africa, that a porcelain difh which he procured, and which had lain for fome years at the bottom of the fea, poffeffed, in confequence, the property of coagulating milk when put into it; yet it communicated no tafte to the milk, and did not differ in appearance from other cups.

It is probable that the faliva is of fervice in the converfion of food into chyme as well as the gaftric juice. It evidently ferves to dilute the food; and probably it may be ferviceable alfo, by communicating oxygen.

339 Chyme converted into chyle and excrement.

5. The chyme, thus formed, paffes from the ftomach into the inteftines, where it is fubjected to new changes, and at laft converted into two very different fubftances, chyle and excrementitious matter.

6. The *chyle* is a white coloured liquid, very much refembling milk. It is exceedingly difficult to collect it in any confiderable quantity, and for that reafon it has never been accurately analyfed. We know only in general that it refembles milk; containing, like it, an albuminous part capable of being coagulated, a ferum, and globules which have a refemblance to cream †. It contains alfo different falts; and, according to fome, a fubftance fcarcely differing from the fugar of milk. It is probable alfo that it contains iron; but if fo, it muft be

† *Ford on Digeftion,* 121.

Functions of Animals.

be in the ſtate of a white oxide; for an infuſion of nut galls does not alter the colour of chyle ‡.

Fordyce on Digeſtion,

6. Concerning the proceſs by which chyle is formed from chyme, ſcarcely any thing is known. It does not appear that the chyme is preciſely the ſame in all animals; for thoſe which are herbivorous have a greater length of inteſtine than thoſe which are carnivorous. It is certain that the formation of the chyle is brought about by a chemical change, although we cannot ſay preciſely what that change is, or what the agents are by which it is produced. But that the change is chemical, is evident, becauſe the chyle is entirely different, both in its properties and appearance, from the chyme. The chyme, by the action of the inteſtines, is ſeparated into two parts, chyle and excrement: the firſt of which is abſorbed by a number of ſmall veſſels called *lacteals*; the ſecond is puſhed along the inteſtinal canal, and at laſt thrown out of the body altogether.

After the chyme has been converted into chyle and excrement, although theſe two ſubſtances remain mixed together, it does not appear that they are able to decompoſe each other; for perſons have been known ſeldom or never to emit any excrementitious matter *per anum* for years. In theſe, not only the chyle, but the excrementitious matter alſo, was abſorbed by the lacteals; and the excrement was afterwards thrown out of the body by other outlets, particularly by the ſkin: in conſequence of which, thoſe perſons have conſtantly that particular odour about them which diſtinguiſhes excrement. Now in theſe perſons, it is evident that the chyle and excrement, though mixed together, and even abſorbed together, did not act on each other; becauſe theſe perſons have been known to enjoy good health for years, which could not have been the caſe had the chyle been deſtroyed.

340 ... of

7. It has been ſuppoſed by ſome that the decompoſition of the chyme, and the formation of chyle, is produced by the agency of the bile, which is poured out abundantly, and mixed with the chyme, ſoon after its entrance into the inteſtines. If this theory were true, no chyle could be formed whenever any accident prevented the bile from paſſing into the inteſtinal canal; but this is obviouſly not true; for frequent inſtances have occurred of perſons labouring under jaundice from the bile ducts being ſtopped, either by gall-ſtones or ſome other cauſe, ſo completely, that no bile could paſs into the inteſtines; yet theſe perſons have lived for a conſiderable time in that ſtate. Conſequently digeſtion, and therefore the formation of chyle, muſt be poſſible, independent of bile.

The principal uſe of the bile ſeems to be to ſeparate the excrement from the chyle, after both have been formed, and to produce the evacuation of the excrement out of the body. It is probable that theſe ſubſtances would remain mixed together, and that they would perhaps even be partly abſorbed together, were it not for the bile, which ſeems to combine with the excrement, and by this combination to facilitate its ſeparation from the chyle, and thus to prevent its abſorption. It alſo ſtimulates the inteſtinal canal, and cauſes it to evacuate its contents ſooner than it otherwiſe would do; for when there is a deficiency of bile, the body is conſtantly coſtive.

1 ... excrementitious matter.

8. The excrement, then, which is evacuated *per anum*, conſiſts of all that part of the food and chyme which was not converted into chyle, entirely altered however from its original ſtate, partly by the decompoſition which it underwent in the ſtomach and inteſtines, and partly by its combination with bile. Accordingly we find in it many ſubſtances which did not exiſt at all in the food. Thus in the dung of cows and horſes there is found a very conſiderable quantity of benzoic acid. The excrements of animals have not yet been ſubjected to an accurate analyſis, though ſuch an analyſis would throw much light upon the nature of digeſtion. For if we knew accurately the ſubſtances which were taken into the body as food, and all the new ſubſtances which were formed by digeſtion; that is to ſay, the component parts of chyle and of excrement, and the variation which different kinds of food produce in the excrement, it would be a very conſiderable ſtep towards aſcertaining preciſely the changes produced on food by digeſtion, or, which is the ſame thing, towards aſcertaining exactly the phenomena of digeſtion. The only analyſis which has hitherto been made on human excrement is that of Homberg; and as it conſiſted merely in ſubjecting it to diſtillation, it is needleſs to give an account of it. Of late, as Mr Fourcroy informs us, the ſubject has been reſumed in France, and we may ſoon expect ſome very curious and important additions to our knowledge.

342 Excrements of fowls.

Mr Vauquelin has already publiſhed an analyſis of the fixed parts of the excrements of fowls, and a compariſon of them with the fixed parts of the food; from which ſome very curious conſequences may be deduced.

He found that a hen devoured in ten days 11111.843 grains troy of oats. Theſe contained

136.509 gr.	of phoſphat of lime,
219.548	ſilica,
356.057.	

During theſe ten days ſhe layed four eggs; the ſhells of which contained 98.776 gr. phoſphat of lime, and 453.417 gr. carbonat of lime. The excrements emitted during theſe ten days contained 175.529 gr. phoſphat of lime, 58.494 gr. of carbonat of lime, and 185.266 gr. of ſilica. Conſequently the fixed parts thrown out of the ſyſtem during theſe ten days amounted to

	Grains.	
	274.305	phoſphat of lime,
	511.911	carbonat of lime,
	185.266	ſilica,
Given out	971.482	
Taken in	356.057	
	615.425	

Conſequently the quantity of fixed matter given out of the ſyſtem in ten days exceeded the quantity taken in by 615.425 grains.

The ſilica taken in amounted to	219.548 gr.
That given out was only	185.266 gr.
Remains	34.282

Conſequently there diſappeared 34.282 grains of ſilica.

The phoſphat of lime taken in was	136.509 gr.
That given out was	274.305 gr.
	137.796

Conſequently

Functions of Animals.

Conſequently there muſt have been formed, by digeſtion in this fowl, no leſs than 137.796 grains of phoſphat of lime, beſides 511.911 grains of carbonat. Conſequently lime (and perhaps alſo phoſphorus) is not a ſimple ſubſtance, but a compound, and formed of ingredients which exiſt in oat-ſeed, water or air, the only ſuſtance to which the fowl had acceſs. Silica may enter into its compoſition, as a part of the ſilica had diſappeared; but if ſo, it muſt be combined with a great quantity of ſome other ſubſtance *.

These conſequences are too important to be admitted without a very rigorous examination. The experiment muſt be repeated frequently, and we muſt be abſolutely certain that the hen has no acceſs to any calcareous earth, and that ſhe has not diminiſhed in weight; becauſe in that caſe ſome of the calcareous earth, of which part of her body is compoſed, may have been employed. This rigour is the more neceſſary, as it ſeems pretty evident, from experiments made long ago, that *ſome* birds at leaſt, cannot produce eggs unleſs they have acceſs to calcareous earth. Dr Fordyce found, that if the canary bird was not ſupplied with lime at the time of her laying, ſhe frequently died, from her eggs not coming forward properly †. He divided a number of theſe birds at the time of their laying eggs into two parties: to the one he gave a piece of old mortar, which the little animals ſwallowed greedily; they laid their eggs as uſual, and all of them lived: whereas many of the other party, which were ſupplied with no lime, died ‡.

[342] Gaſes contained in the inteſtines.

9. The inteſtines ſeldom or never are deſtitute of gaſes, which ſeem to be evolved during the proceſs of digeſtion; and may therefore, in part, be conſidered as excrementitious matter. The only perſon who has examined theſe gaſes with care, is Mr Jurine of Geneva. The reſult of his analyſis is as follows. He found in the ſtomach and inteſtines of a man who had been frozen to death, carbonic acid gas, oxygen gas, hydrogen gas, and azotic gas. The quantity of carbonic acid was greateſt in the ſtomach, and it diminiſhed gradually as the canal receded from the ſtomach; the proportion of oxygen gas was conſiderable in the ſtomach, ſmaller in the ſmall inteſtines, and ſtill ſmaller in the great inteſtines; the hydrogen and azotic gaſes, on the contrary, were leaſt abundant in the ſtomach, more abundant in the ſmall inteſtines, and moſt abundant in the larger inteſtines; the hydrogen gas was moſt abundant in the ſmall inteſtines. It is well known that the flatus diſcharged *per anum* is commonly carbonated hydrogen gas; ſometimes alſo it ſeems to hold ſulphur, or even phoſphorus in ſolution §.

§ *Encyc. Metb. Med.* i. 516.

343 Chyle in the thoracic duct.

10. The chyle, after it has been abſorbed by the lacteals, is carried by them into a pretty large veſſel, known by the name of *thoracic duct*. Into the ſame veſſel likewiſe is diſcharged a tranſparent fluid, conveyed by a ſet of veſſels which ariſe from all the cavities of the body. Theſe veſſels are called *lymphatics*, and the fluid which they convey is called *lymph*. In the thoracic duct, then, the chyle and the lymph are mixed together.

344 Mixed with the lymph,

Very little is known concerning the nature of the *lymph*, as it is ſcarcely poſſible to collect it in any quantity. It is colourleſs, has ſome viſcidity, and is ſaid to be ſpecifically heavier than water. It is ſaid to be coagulable by heat; if ſo, it contains albumen; and, from its appearance, it probably contains gelatine. Its quantity is certainly conſiderable, for the lymphatics are very numerous.

345 And conveyed to the heart and lungs.

11. The chyle and lymph being thus mixed together, are conveyed directly into the blood veſſels. The effect produced by their union in the thoracic duct is not known, but neither the colour nor external properties of the chyle is altered. In man, and many other animals, the thoracic duct enters at the junction of the left ſubclavian and carotid veins, and the chyle is conveyed directly to the heart, mixed with the blood, which already exiſts in the blood veſſels. From the heart, the blood and chyle thus mixed together are propelled into the lungs, where they undergo farther changes.

346 Reſpiration

12. The abſolute neceſſity of *reſpiration*, or of ſomething analogous, is known to every one; and few are ignorant that in man, and hot blooded animals, the organ by which reſpiration is performed is the lungs. For a deſcription of the reſpiratory organs, we refer to the article ANATOMY, *Encycl.* and the reader will find an account of the manner in which that function is performed in the article PHYSIOLOGY, *Encycl.* But what are the changes produced upon the blood and the chyle by reſpiration? What purpoſes does it ſerve to the animal? How comes it to be ſo indiſpenſably neceſſary for its exiſtence? Theſe are queſtions which can only be anſwered by a careful examination of the phenomena of reſpiration.

347 Requires oxygen gas

It has been long known that an animal can only breathe a certain quantity of air for a limited time, after which it becomes the moſt deadly poiſon, and produces ſuffocation as effectually as the moſt noxious gas, or a total abſence of air. It was ſuſpected long ago that this change is owing to the abſorption of a part of the air; and Mayow made a number of very ingenious experiments in order to prove the fact. Dr Prieſtley and Mr Scheele demonſtrated, that the quantity of oxygen gas in atmoſpheric air is diminiſhed; and Lavoiſier demonſtrated, in 1776, that a quantity of carbonic acid gas, which did not previouſly exiſt in it, was found in air after it had been for ſome time reſpired. It was afterwards proved by Lavoiſier, and many other philoſophers, who confirmed and extended his facts, that no animal can live in air totally deſtitute of oxygen. Even fiſh, which do not ſenſibly reſpire, die very ſoon, if the water in which they live be deprived of oxygen gas. Frogs which can ſuſpend their reſpiration at pleaſure, die in about forty minutes, if the water in which they have been confined be covered over with oil *. Inſects and worms, as Vauquelin has proved, exhibit preciſely the ſame phenomena. They require oxygen gas as well as other animals, and die like them if they be deprived of it. They diminiſh the quantity of the oxygen gas in which they live, and give out, by reſpiration, the very ſame products as other animals. Worms, which are more retentive of life than moſt other animals, or at leaſt not ſo much affected by poiſonous gaſes, abſorb every particle of the oxygen gas contained in the air in which they are confined before they die. Mr Vauquelin's experiments were made on the gryllus viridiſſimus, the limax flavus, and helix pomatia †.

† *Ann. de Chim.* xii. 278.

348 Changes produced by it.

The changes which take place during reſpiration are the following:

1. Part of the oxygen gas reſpired diſappears.

2. Carbonic

Functions of Animals.

2. Carbonic acid gas is emitted.

3. Water is emitted in the state of vapour.

The first point is to ascertain exactly the amount of these changes. Though a great many experiments have been made on this subject by different philosophers, the greatest confidence ought to be put in those of Lavoisier, both on account of his uncommon accuracy, and on account of the very complete apparatus which he always employed.

He put a guinea-pig into 708 989 grains troy of oxygen, and after the animal had breathed the gas for an hour, he took it out. He found that the oxygen

gas now amounted only to	592.253 gr.
Consequently there had disappeared	116.736
The carbonic acid gas formed was	130.472
This was composed of about	94.234
oxygen, and	36.238

of carbon. Consequently supposing, as Mr Lavoisier did, that the oxygen absorbed had been employed in the formation of the carbonic acid gas, there still remained to be accounted for 22.502 grains of oxygen which had disappeared. He supposed that this had been employed in the formation of water, a quantity of which had appeared. If so, the water formed must have amounted to 26.429 grains; which was composed of 3.927 hydrogen, the rest oxygen *.

* Ann de Chim. v. 261.

Since the water emitted was not actually ascertained, this experiment can only be considered as an approximation to the truth. Accordingly that very ingenious philosopher contrived an apparatus to ascertain the quantity of oxygen gas absorbed by man, and the quantity of carbonic acid gas and water emitted by him during respiration. This apparatus he had constructed at an expence at least equal to L. 500 sterling. The experiments were completed, and he was preparing them for publication, when, on the 8th of May 1794, he was beheaded by order of Robespierre, after having in vain requested a fortnight's delay to put his papers in order for the press. Thus perished, in the 51st year of his age, the man who, if he had lived a few years longer, promised fair to become the rival of Newton himself. Chemistry, as a science, is deeply indebted to him. He saved it from that confusion into which the thoughtless ardour of many of his contemporaries were plunging it headlong: he arranged and connected and simplified and explained the multitude of insulated facts, which had been accumulating with unexampled celerity; and which, had it not been for his happy arranging genius, might have retarded, instead of advanced, the progress of the science. He reduced all the facts under a few simple heads, and thus made them easily remembered and easily classified. In a few years more, perhaps, he would have traced these general principles to their sources, established the science on the completest induction, and paved for his successors a road as unerring as that which Sir Isaac Newton formed in mechanical philosophy.

Mr Lavoisier's experiments have never been published, but fortunately Mr de la Place has given us the result of them †. He informs us that it was as follows: A man, at an average, consumes, in twenty-four hours, by respiration, 32.48437 ounces troy of oxygen gas; that is to say, that a quantity of oxygen gas, equal to that weight, disappears from the air which he respires in twenty-four hours; that he gives out by respiration, in the same time, 15.73 oz. troy of carbonic acid gas, and 28.55 of water in the state of vapour.

† La Place's Eloge.

Total	44.28	*Oxygen.*
The carbonic acid gas is composed of and 5.243 carbon.		10.486
The water of and 4.2825 hydrogen.		24.2675
Total of the oxygen emitted		34.75416
Total absorbed		32.48437
So that there is		2.2697916

ounces of oxygen emitted more than is absorbed by respiration. Thus it appears that, by respiration, the absolute quantity of oxygen in the blood is diminished.

Dr Menzies found that a man, at a medium, draws in at every respiration 43.77 cubic inches of air, and that $\frac{1}{20}$th of that quantity disappears. Consequently, according to him, at every respiration 2.1885 cubic inches of oxygen gas are consumed. Now 2.1885 cubic inches of that gas amount to 0.68669 gr. troy. Supposing, with Hales, that a man makes 1200 respirations in an hour, the quantity of oxygen gas consumed in an hour will amount to 824.028 grains, and in 24 hours, to 19776.672 grains, or 41.2014 ounces troy. This quantity exceeds that found by Lavoisier considerably; but the allowance of oxygen for every respiration is rather too great. Indeed, from the nature of Dr Menzies's apparatus, it was scarce possible to measure it accurately.

The quantity of water given out by respiration, as determined by Hales, amounts in a day to 20.4 oz. *; but his method was not susceptible of great accuracy. We may therefore, on the whole, consider Lavoisier's determination as by far the nearest to the truth of any that has been given.

* Veget. Stat. ii. 327.

There is, however, a very singular anomaly, which becomes apparent when we compare his experiments on the respiration of the guinea-pig with those on the respiration of man.

The guinea-pig consumed in 24 hours 5.8368 oz. troy of oxygen gas, and emitted 6.5236 oz. of carbonic acid gas. Man, on the other hand, consumes in the same time 32.48437 oz. of oxygen gas, and emits only 15.73 oz. of carbonic acid gas. The oxygen gas consumed by the pig is to the carbonic gas emitted as 1.00 : 1.12; whereas in man it is as 1.000 : 0.484. If we could depend upoon the accuracy of each of these experiments, they would prove, beyond a doubt, that the changes produced by the respiration of the pig are different, at least in degree, from those produced in man; but it is more than probable that some mistake has crept into one or other of the experiments. We have more reason to suspect the first, as it was made before 1778, at a time when a great many circumstances, necessary to insure accuracy, were unknown to Lavoisier.

Such are the substances imbibed and emitted during respiration. It still remains for us to determine what are the changes which it produces on the blood.

It has been long known that the blood which flows in the veins is of a dark reddish purple colour, whereas the arterial blood is of a florid scarlet colour. Lower observed that the colour of the veinous blood was converted into that of arterial during its passage through

Functions of Animals. the lungs. No chyle can be distinguished by its white colour in the blood after it has passed through the lungs. The changes, then, which take place upon the appearance of the blood are two: 1*st*, It acquires a florid red colour; 2*d*, The chyle totally disappears. Now to what are these changes owing?

Lower himself knew that the change was produced by the air, and Mayow attempted to prove that it was by absorbing a part of the air. But it was not till Dr Priestley discovered that veinous blood acquires a scar-

349 Two hypotheses to explain these changes.

let colour when put in contact with oxygen gas, and arterial blood a dark red colour when put in contact with hydrogen gas, or, which is the same thing, that oxygen gas instantly gives veinous blood the colour of arterial; and hydrogen, on the contrary, gives arterial blood the colour of veinous blood: it was not till then that philosophers began to attempt any thing like an explanation of the phenomena of respiration. Two explanations have been given; one or other of which must be true.

The first is, that the oxygen of the air, which disappears, combines with a quantity of carbon and hydrogen given out by the blood in the lungs, and forms with it carbonic acid gas and water in vapour, which are thrown out along with the air expired.

The second is, that the oxygen gas, which disappears, combines with the blood as it passes thro' the lungs; and that, at the instant of this combination, there is set free from the blood a quantity of carbonic acid gas and of water, which are thrown out along with the air expired.

The first of these theories was originally formed by Lavoisier, and it was embraced by La Place, Crawford, Gren, and Girtanner, with a small variation. Indeed it does not differ, except in detail, from the original hypothesis of Dr Priestley, that the use of respiration is to rid the blood of phlogiston; for if we substitute carbon and hydrogen for phlogiston, the two theories precisely agree. Mr Lavoisier attempted not to prove its truth; he only tried to shew that the oxygen absorbed corresponds exactly with the quantity of oxygen contained in the carbonic acid and the water emitted. This coincidence his own experiments have shewn not to hold; consequently the theory is entirely destitute of proof, as far as the proof depends upon this coincidence.

The other hypothesis was proposed by Mr de la Grange, and afterwards supported and illustrated by Mr Hassenfratz.

350 Effects of respiration examined.

In order to discover what the real effects of respiration are, let us endeavour to state accurately the phenomena as far as possible.

In the *first* place, we are certain, from the experiments of Priestley, Girtanner, and Hassenfratz, that when veinous blood is exposed to oxygen gas confined over it, the blood instantly assumes a scarlet colour, and the gas is diminished in bulk; therefore part of the gas has been absorbed. We may consider it as certain, then, that when the colour of veinous blood is changed into arterial, some oxygen gas is absorbed †.

† *Ann. de Chim.* vii. 248.
