In the *second* place, no chyle can be discovered in the blood after it has passed through the lungs. Therefore the *white colour* of the chyle at least, is destroyed by respiration, and it assumes a red colour. Now if the red colour of the blood be owing to iron, as many have supposed, this change of colour is a demonstration that oxygen has combined with the iron; for we have seen already, that iron, if it exists in chyle, as it probably does, is in the state of a white oxide. Consequently, when converted into a red oxide, it must absorb oxygen. Even though iron be not the colouring matter of the blood, it would still be probable that the change of colour of the chyle depends on the fixation of oxygen; for Berthollet and Fourcroy have shewn that in several instances substances acquire a red colour by that process.

We may consider it as proved, then, that oxygen enters the blood as it passes through the lungs.

In the *third* place, when arterial blood is put in contact with azotic gas, or carbonic acid gas, it gradually assumes the dark colour of veinous blood, as Dr Priestley found *. The same philosopher also observed that arterial blood acquired the colour of veinous blood when placed in vacuo †. Consequently this alteration of colour is owing to some change which takes place in the blood itself, independent of any external agent.

* *Priestley*, iii. 363.

† *Ibid*, and *Ann. de Chim.* ix. 219.

The arterial blood becomes much more rapidly and deeply dark coloured when it is left in contact with hydrogen gas placed above it ‡. We must suppose therefore that the presence of this gas accelerates and increases the change, which would have taken place upon the blood without any external agent.

‡ *Fourcroy*, *Ann. de Chim.* vii. 149.

If arterial blood be left in contact with oxygen gas, it gradually assumes the same dark colour which it would have acquired in vacuo, or in contact with hydrogen; and after this change oxygen can no longer restore its scarlet colour §. Therefore it is only upon a part of the blood that the oxygen acts; and after this part has undergone the change which occasions the dark colour, the blood loses the power of being affected by oxygen.

§ *Ibid.* ix. 268.

Mr Hassenfratz poured into veinous blood a quantity of oxy-muriatic acid; the blood was instantly decomposed, and assumed a deep and almost black colour. When he poured common muriatic acid into blood, the colour was not altered ‖. Now oxy-muriatic acid has the property of giving out its oxygen readily; consequently the black colour was owing to the instant combination of a part of the blood with oxygen.

‖ *Ibid.*

The facts therefore lead us to conclude, with La Grange and Hassenfratz, that during respiration the oxygen, which disappears, enters the blood; that during the circulation this oxygen combines with a certain part of the blood; and that the veinous colour is owing to this new combination. We must conclude, too, that the substance which causes this dark colour leaves the blood during its circulation thro' the lungs, otherwise it could not be capable of assuming the florid colour. Now we know what the substances are which are emitted during respiration; they are water and carbonic acid gas. It must be to the gradual combination of oxygen, then, during the circulation, with hydrogen and carbon, that the colour of veinous blood is owing. And since the same combination takes place every time that the blood passes through the lungs, we must conclude, that it is only a part of the hydrogen and carbon which is acted upon each time. Let us now attempt, with these data, to form some notion of the decomposition which goes on during the circulation of the blood.

351 Contributes to the formation of blood.

It is probable that, during a considerable part of the day, there is a constant influx of chyle into the blood; and we are certain that lymph is constantly flowing into to it. Now it appears, from the most accurate observations hitherto made, that neither chyle nor lymph contain fibrina, which forms a very conspicuous part of the blood. This fibrina is employed to supply the waste of the muscles, the most active parts of the body, and therefore, in all probability, requiring the most frequent supply. Nor can it be doubted that it is employed for other useful purposes. The quantity of fibrina in the blood, then, must be constantly diminishing, and therefore new fibrina must be constantly formed. But the only substances out of which it can be formed are the chyle and lymph, neither of which contain it. There must therefore be a continual decomposition of the chyle and lymph going on in the blood-vessels, and a continual new formation of fibrina. Other substances also may be formed; but we are certain that this *must* be formed there, because it does not exist previously. Now, one great end of respiration must undoubtedly be to assist this decomposition of chyle and complete formation of blood.

It follows, from the experiments of Fourcroy formerly enumerated, that fibrina contains more azot, and less hydrogen and carbon, than any of the other ingredients of the blood, and consequently also than any of the ingredients of the chyle. In what manner the chyle, or a part of it, is converted into fibrina, it is impossible to say: we are not sufficiently acquainted with the subject to be able to explain the process. But we can see at least, that carbon and hydrogen must be abstracted from that part of the chyle which is to be converted into fibrina: And we know, that these substances are actually thrown out by respiration. We may conclude, then, that *one* use of the oxygen absorbed is, to abstract a quantity of carbon and hydrogen from a part of the chyle by compound affinity, in such proportions, that the remainder becomes fibrina; therefore one end of respiration is to form fibrina. Doubtless the other ingredients of the blood are also new modified, though we know too little of the subject to throw any light upon it.

352 Produces animal heat;

13. But the complete formation of blood is not the only advantage gained by respiration: the *temperature* of all animals depends upon it. It has been long known, that those animals which do not breathe have a temperature but very little superior to the medium in which they live. This is the case with fishes and many insects. Man, on the contrary, and quadrupeds which breathe, have a temperature considerably higher than the atmosphere: that of man is 98°. Birds, who breathe in proportion a still greater quantity of air than man, have a temperature equal to 103° or 104°. It has been proved, that the temperature of all animals is proportional to the quantity of air which they breathe in a given time.

These facts are sufficient to demonstrate, that the heat of animals depends upon respiration. But it was not till Dr Black's doctrine of latent heat became known to the world, that any explanation of the cause of the temperature of breathing animals was attempted. That illustrious philosopher, whose discoveries form the basis upon which all the scientific part of chemistry has been reared, saw at once the light which his doctrine of latent heat threw upon this part of physiology, and he applied it very early to explain the temperature of animals.

According to him, part of the latent heat of the air inspired becomes sensible; and of course, the temperature of the lungs, and the blood that passes through them, must be raised; and the blood, thus heated, communicates its heat to the whole body. This opinion was ingenious, but it was liable to an unanswerable objection: for if it were true, the temperature of the body ought to be greatest in the lungs, and to diminish gradually as the distance from the lungs increases; which is not true. The theory, in consequence, was abandoned even by Dr Black himself; at least he made no attempt to support it.

Lavoisier and Crawford, who considered all the changes operated by respiration as taking place in the lungs, accounted for the origin of the animal heat almost precisely in the same manner with Dr Black. According to them, the oxygen gas of the air combines in the lungs with the hydrogen and carbon emitted by the blood. During this combination, the oxygen gives out a great quantity of caloric, with which it had been combined; and this caloric is not only sufficient to support the temperature of the body, but also to carry off the new formed water in the state of vapour, and to raise considerably the temperature of the air inspired. According to these philosophers, then, the whole of the caloric which supports the temperature of the body is evolved in the lungs. Their theory accordingly was liable to the same objection with Dr Black's; but they obviated it in the following manner: Dr Crawford found, that the specific caloric of arterial blood was 1.0300, while that of veinous blood was only 0.8928. Hence he concluded, that the instant veinous blood is changed into arterial blood, its specific caloric increases; consequently it requires an additional quantity of caloric to keep its temperature as high as it had been while veinous blood. This addition is so great, that the whole new caloric evolved is employed: therefore the temperature of the lungs must necessarily remain the same as that of the rest of the body. During the circulation, arterial blood is gradually converted into veinous; consequently its specific caloric diminishes, and it must give out heat. This is the reason that the temperature of the extreme parts of the body does not diminish.

This explanation is certainly ingenious; but it is not quite satisfactory; for the difference in the specific caloric, granting it to be accurate, is too small to account for the great quantity of heat which must be evolved. It is evident that it must fall to the ground altogether, provided, as we have seen reason to suppose, the carbonic acid gas and water be not formed in the lungs, but during the circulation.

Since the oxygen enters the blood, and combines with it in the state of gas, it is evident that it will only part at first with some of its caloric; and this portion is chiefly employed in carrying off the carbonic acid gas and the water. For the reason that the carbonic acid leaves the blood at the instant that the oxygen gas enters it, seems to be this: The oxygen gas combines with the blood, and part of its caloric unites at the same instant to the carbonic acid, and converts it into gas: another portion converts the water into vapour. The rest of the caloric is evolved during the circulation when the oxygen combines with hydrogen and carbon, and forms water and carbonic acid gas. The quantity of caloric evolved in the lungs seems not only sufficient to carry off the carbonic acid and water, which the diminution

...ution of the ſpecific caloric (if it really take place) muſt facilitate; but it ſeems alſo to raiſe the temperature of the blood a little higher than it was before. For Mr John Hunter conſtantly found, that the heat of the heart in animals was a degree higher than any other part of the body which he examined. Now this could ſcarcely happen unleſs the temperature of the blood were ſomewhat raiſed during reſpiration.

353 And ſupports the circulation.

Thus we have ſeen two uſes which reſpiration ſeems to ſerve. The firſt is the completion of blood by the formation of fibrina; the ſecond is the maintaining of the temperature of the body at a particular ſtandard, notwithſtanding the heat which it is continually giving out to the colder ſurrounding bodies. But there is a third purpoſe, which explains why the animal is killed ſo ſuddenly when reſpiration is ſtopped. The circulation of the blood is abſolutely neceſſary for the continuance of life. Now the blood is circulated in a great meaſure by the alternate contractions of the heart. It is neceſſary that the heart ſhould contract regularly, otherwiſe the circulation could not go on. But the heart is ſtimulated to contract by the blood: and unleſs blood be made to undergo the change produced by reſpiration, it ceaſes almoſt inſtantaneouſly to ſtimulate. As the blood receives oxygen in the lungs, we may conclude that the preſence of oxygen is neceſſary to its ſtimulating power *.

* *Girtanner, Jour. de Phyſ.* xxxix.

354 Kidneys employed in the formation of blood.

14. Thus we have reaſon to ſuppoſe, that chyle and lymph are converted into blood during the circulation; and that the oxygen gas ſupplied by reſpiration is one of the principal agents in this change. But beſides the lungs and arteries, there is another organ, the ſole uſe of which is alſo to produce ſome change or other in the blood, which renders it more complete, and more proper for the various purpoſes to which it is applied. This organ is the *kidney*.

For the ſtructure of the kidneys, which in man and quadrupeds are two in number, we refer to ANATOMY, *Encycl.* A very great proportion of blood paſſes thro' them; indeed, we have every reaſon to conclude, that the whole of the blood paſſes through them very frequently.

Theſe organs ſeparate the urine from the blood, to be afterwards evacuated without being applied to any purpoſe uſeful to the animal.

The kidneys are abſolutely neceſſary for the continuance of the life of the animal; for it dies very ſpeedily when they become by diſeaſe unfit to perform their functions: therefore the change which they produce in the blood is a change neceſſary for qualifying it to anſwer the purpoſes for which it is intended.

As the urine is immediately excreted, it is evident that the change which the kidneys perform is intended ſolely for the ſake of the blood. It is not merely the abſtraction of a quantity of water and of ſalts, accumulated in the blood, which the kidney performs. A chemical change is certainly produced, either upon the whole blood, or at leaſt on ſome important part of it; for there are two ſubſtances found in the urine which do not exiſt in the blood. Theſe two ſubſtances are urea and uric acid. They are formed, therefore, in the kidneys; and as they are thrown out, after being formed, without being applied to any uſeful purpoſe, they are certainly not formed in the kidneys for their own ſake. Some part of the blood, then, muſt be decompoſed in the kidney, and a new ſubſtance, or new ſubſtances, muſt be formed; and the urea and uric acid muſt be formed at the ſame time, in conſequence of the combined action of the affinities which produce the change on the blood; and being uſeleſs, they are thrown out, together with a quantity of water and ſalts, which, in all probability, were uſeful in bringing about the changes which take place in the arteries and in the kidneys, but which are no longer of any ſervice after theſe changes are brought about.

The changes operated upon the blood in the kidneys are hitherto altogether unknown; but they muſt be important.

355 Cutaneous veſſels

Provided the method of analyſing animal ſubſtances were ſo far perfected as to admit of accurate concluſions, conſiderable light might be thrown upon this ſubject, by analyſing with care a portion of blood from the emulgent vein and artery ſeparately, and aſcertaining preciſely in what particulars they differ from each other.

15. Thus we have ſeen that the principal changes which the blood undergoes, as far at leaſt as we are at preſent acquainted with them, take place in the lungs, in the kidneys, and in the arteries. In the lungs, a quantity of water and carbonic acid gas is emitted from the blood, and in the kidney the urine is formed and ſeparated from it. There ſeems alſo to be ſomething thrown out from the blood during its circulation in the arteries, at leaſt through thoſe veſſels which are near the ſurface of the body: For it is a fact, that certain ſubſtances are conſtantly emitted from the ſkins of animals. Theſe ſubſtances are known in general by the name of *perſpirable matter* or *perſpiration*. They have a great reſemblance to what is emitted in the lungs; which renders it probable, that they are both owing to the ſame cauſe; namely, to the decompoſition produced in the blood by the effects of reſpiration. They conſiſt chiefly of water in a ſtate of vapour, carbon, and oil.

356 Emit aqueous vapour

The quantity of aqueous vapour differs very conſiderably, according to circumſtances. It has been ſhewn to be greateſt in hot weather, and in hot climates, and after great exerciſe; and its relation to the quantity of urine has been long known. When the aqueous vapour perſpired is great, the quantity of urine is ſmall, and *vice verſa*.

The moſt accurate experiments on this matter that we have ſeen are thoſe of Mr Cruikſhank. He put his hand into a glaſs veſſel, and luted its mouth at his wriſt by means of a bladder. The interior ſurface of the veſſel became gradually dim, and drops of water trickled down. By keeping his hand in this manner for an hour, he collected 30 grains of a liquid, which poſſeſſed all the properties of pure water *. On repeating the ſame experiment at nine in the evening (thermometer 62°), he collected only 12 grains. The mean of theſe is 21 grains. But as the hand is more expoſed than the trunk of the body, it is reaſonable to ſuppoſe that the perſpiration from it is greater than that from the hand. Let us therefore take 30 grains per hour as the mean; and let us ſuppoſe, with Mr Cruikſhank, that the hand is $\frac{1}{60}$th of the ſurface of the body. The perſpiration in an hour would amount to 1800 grains, and in 24 hours to 43200 grains, or 7 pounds 6 ounces troy.

* *On Inſenſible Perſpiration*, p.

He

unctions of Animals.

He repeated the experiment again after hard exerciſe, and collected in an hour 48 grains of water *. He found alſo, that this aqueous vapour pervaded his ſtocking without difficulty; and that it made its way thro' a ſhamoy leather glove, and even through a leather boot, though in much ſmaller quantity than when the leg wanted that covering †.

On Inſen-
ſible Perſpi-
ration,
70.
Ibid. p.

It is not difficult to ſee why the quantity of watery vapour diminiſhes with cold. When the ſurface of the body is expoſed to a cold temperature, the capacity of the cutaneous veſſels diminiſhes, and conſequently the quantity which flows through them muſt decreaſe.

When the temperature, on the other hand, is much increaſed, either by being expoſed to a hot atmoſphere, or by violent exerciſe, the perſpired vapour not only increaſes in quantity, but even appears in a liquid form. This is known by the name of *ſweat*. In what manner ſweat is produced, is not at preſent known; but we can ſee a very important ſervice which it performs to the animal.

No ſooner is it thrown upon the ſurface of the ſkin than it begins to evaporate. But the change into vapour requires heat; accordingly a quantity of heat is abſorbed, and the temperature of the animal is lowered. This is the reaſon that animals can endure to remain for ſome time in a much higher temperature without injury than could have been ſuppoſed.

The experiments of Tillet, and the ſtill more deciſive experiments of Fordyce and his aſſociates, are well known. Theſe gentlemen remained a conſiderable time in a temperature exceeding the boiling point of water.

357
Carbon,

Beſides water, it cannot be doubted that *carbon* is alſo emitted from the ſkin; but in what ſtate, the experiments hitherto made do not enable us to decide. Mr Cruikſhank found, that the air of the glaſs veſſel in which his hand and foot had been confined for an hour, contained carbonic acid gas; for a candle burned dimly in it, and it rendered lime-water turbid *. And Mr Jurine found, that air which had remained for ſome time in contact with the ſkin, conſiſted almoſt entirely of carbonic acid gas †. The ſame concluſion may be drawn from the experiments of Ingenhouſz and Milly ‡.

Ibid. p.
and 81.
nc. Meth.
d. i. p.
id. p.

Now it is evident, that the carbonic acid gas which appeared during Mr Cruikſhank's experiment, did not previouſly exiſt in the glaſs veſſel; conſequently it muſt have either been tranſmitted ready formed through the ſkin, or formed during the experiment by the abſorption of oxygen gas, and the conſequent emiſſion of carbonic acid gas. The experiments of Mr Jurine do not allow us to ſuppoſe the firſt of theſe to be true; for he found, that the quantity of air allowed to remain in contact with the ſkin did not increaſe. Conſequently the appearance of the carbonic acid gas muſt be owing, either to the emiſſion of carbon, which forms carbonic acid gas by combining with the oxygen gas of the air, or to the abſorption of oxygen gas, and the ſubſequent emiſſion of carbonic acid gas; preciſely in the ſame manner, and for the ſame reaſon, that theſe ſubſtances are emitted by the lungs. The laſt is the more probable opinion; but the experiments hitherto made do not enable us to decide.

358
l an oily
ter.

Beſides water and carbon, or carbonic acid gas, the ſkin emits alſo a particular odorous ſubſtance. That every animal has a peculiar ſmell, is well known: the dog can diſcover his maſter, and even trace him to a diſtance by the ſcent. A dog, chained ſome hours after his maſter had ſet out on a journey of ſome hundred miles, followed his footſteps by the ſmell, and found him on the third day in the midſt of a crowd *. But it is needleſs to multiply inſtances of this fact, they are too well known to every one. Now this ſmell muſt be owing to ſome peculiar matter which is conſtantly emitted; and this matter muſt differ ſomewhat either in quantity or ſome other property, as we ſee that the dog eaſily diſtinguiſhes the individual by means of it. Mr Cruikſhank has made it probable that this matter is an oily ſubſtance; or at leaſt that there is an oily ſubſtance emitted by the ſkin. He wore repeatedly, night and day for a month, the ſame veſt of fleecy hoſiery during the hotteſt part of the ſummer. At the end of this time he always found an oily ſubſtance accumulated in conſiderable maſſes on the nap of the inner ſurface of the veſt, in the form of black tears. When rubbed on paper, it makes it tranſparent, and hardens on it like greaſe. It burns with a white flame, and leaves behind it a charry reſiduum †.

* Cruikſhank, ibid. p. 93.

† Ibid. p. 92.

It has been ſuppoſed that the ſkin has the property of *abſorbing moiſture* from the air; but this opinion has not been confirmed by experiments, but rather the contrary.

359
Whether the ſkin abſorbs moiſture,

The chief arguments in favour of the abſorption of the ſkin, have been drawn from the quantity of moiſture diſcharged by urine being, in ſome caſes, not only greater than the whole drink of the patient, but even than the whole of his drink and food. But it ought to be remembered that, in diabetes, the diſeaſe here alluded to, the weight of the body is continually diminiſhing, and therefore part of it muſt be conſtantly thrown off. Beſides, it is ſcarcely poſſible in that diſeaſe to get an accurate account of the food ſwallowed by the patients; and in thoſe caſes where very accurate accounts have been kept, and where deception was not ſo much practiſed, the urine was found not to exceed the quantity of drink *. In a caſe of diabetes, related with much accuracy by Dr Gerard, the patient was bathed regularly during the early part of the diſeaſe in warm water, and afterwards in cold water: he was weighed before and after bathing, and no ſenſible difference was ever found in his weight †. Conſequently, in that caſe, the quantity abſorbed, if any, muſt have been very ſmall.

* See Reil's on Diabetes.

† Ibid. ii. 73.

It is well known, that thirſt is much alleviated by cold bathing. By this plan, Captain Bligh kept his men cool and in good health during their very extraordinary voyage acroſs the South Sea. This has been conſidered as owing to the abſorption of water by the ſkin. But Dr Currie had a patient who was waſting faſt for want of nouriſhment, a tumor in the œſophagus preventing the poſſibility of taking food, and whoſe thirſt was always alleviated by bathing; yet no ſenſible increaſe of weight, but rather the contrary, was perceived after bathing. It does not appear, then, that in either of theſe caſes water was abſorbed.

Farther, Seguin has ſhewn that the ſkin does not abſorb water during bathing, by a ſtill more complete experiment: He diſſolved ſome mercurial ſalt in water, and found that the mercury produced no effect upon a perſon that bathed in the water, provided no part of the

Functions of Animals.

the cuticle was injured; but upon rubbing off a portion of the cuticle, the mercurial solution was absorbed, and the effects of the mercury became evident upon the body. Hence it follows irresistibly, that water, at least in the state of *water*, is not absorbed by the skin when the body is plunged into it, unless the cuticle be first removed.

360 Or any other substance.

This may perhaps be considered as a complete proof that no such thing as absorption is performed by the skin; and that therefore the appearance of carbonic acid gas, which takes place when air is confined around the skin, must be owing to the emission of carbon. But it ought to be considered, that although the skin cannot absorb water, this is no proof that it cannot absorb other substances; particularly, that it cannot absorb oxygen gas, which is very different from water. It is well known, that water will not pass through bladders, at least for some time; yet Dr Priestly found that veinous blood acquired the colour of arterial blood from oxygen gas, as readily when these substances were separated by a bladder as when they were in actual contact. He found, too, that when gases were confined in bladders, they gradually lost their properties. It is clear from these facts, that oxygen gas can pervade bladders; and if it can pervade them, why may it not also pervade the cuticle? Nay, farther, we know from the experiments of Cruikshank, that the vapour perspired passes through leather, even when prepared so as to keep out moisture, at least for a certain time. It is possible, then, that water, when in the state of vapour, or when dissolved in air, may be absorbed, although water, while in the state of water, may be incapable of pervading the cuticle. The experiments, then, which have hitherto at least been made upon the absorption of the skin, are altogether insufficient to prove that air and vapour cannot pervade the cuticle; provided at least there be any facts to render the contrary supposition probable.

Now that there are such facts cannot be denied. We shall not indeed produce the experiment of Van Mons as a fact of that kind, because it is liable to objections, and at best is very undecisive. Having a patient under his care who, from a wound in the throat, was incapable for several days of taking any nourishment, he kept him alive during that time, by applying to the skin in different parts of the body, several times a day, a sponge dipt in wine or strong soup *. A fact mentioned by Dr Watson is much more important, and much more decisive. A lad at Newmarket, who had been almost starved in order to bring him down to such a weight as would qualify him for running a horse race, was weighed in the morning of the race day; he was weighed again just before the race began, and was found to have gained 30 ounces of weight since the morning: yet in the interval he had only taken a single glass of wine. Here absorption must have taken place, either by the skin, or lungs, or both. The difficulties in either case are the same; and whatever renders absorption by one probable, will equally strengthen the probability that absorption takes place by the other (R).

* Phil. Mag. vi. 95.

16. We have now seen the process of digestion, and the formation of blood, as far at least as we are acquainted with it. But to what purposes is this blood employed, which is formed with so much care, and for the formation of which so great an apparatus has been provided? It answers two purposes. The parts of which the body is composed, bones, muscles, ligaments, membranes, &c. are continually changing. In youth, they are increasing in size and strength, and in mature age they are continually acting, and consequently continually liable to waste and decay. They are often exposed to accidents, which render them unfit for performing their various functions; and even when no such accident happens, it seems necessary for the health of the system that they should be every now and then renewed. Materials therefore must be provided for repairing, increasing, or renewing all the various organs of the body. Phosphat of lime and gelatine for the bones, fibrina for the muscles, albumen for the cartilages and membranes, &c. Accordingly all these substances are laid up in the blood; and they are drawn from that fluid as from a storehouse whenever they are required. The process by which the different parts of the blood are made part of the various organs of the body is called *assimilation*.

361 Blood supplies the waste of the system.

362 Assimilation.

Over the nature of assimilation the thickest darkness still hangs; there is no key to explain it, nothing to lead us to the knowledge of the instruments employed. Facts, however, have been accumulated in sufficient numbers to put the existence of the process beyond the reach of doubt. The healing, indeed, of every fractured bone, and every wound of the body, is a proof of its existence, and an instance of its action.

363 Every assimilating organ produces a peculiar change,

Every organ employed in assimilation has a peculiar office; and it always performs this office whenever it has materials to act upon, even when the performance of it is contrary to the interest of the animal. Thus the stomach always converts food into chyme, even when the food is of such a nature that the process of digestion will be retarded rather than promoted by the change. If warm milk, for instance, or warm blood, be thrown into the stomach, they are always decomposed by that organ, and converted into chyme; yet these substances are much more nearly assimilated to the animal before the action of the stomach than after it. The same thing happens when we eat animal food.

364 And no other change.

On the other hand, a substance introduced into an organ employed in assimilation, if it has undergone precisely the change which that organ is fitted to produce, is not acted upon by that organ, but passed on unaltered to the next assimilating organ. Thus it is the office of the intestines to convert chyme into chyle. Accordingly, whenever chyme is introduced into the intestines, they perform their office, and produce the usual change; but if chyle itself be introduced into the intestines, it is absorbed by the lacteals without alteration. The experiment, indeed, has not been tried with true chyle, because it is scarce possible to procure it in sufficient quantity; but when milk, which resembles chyle pretty accurately, is thrown into the jejunum, it is absorbed unchanged by the lacteals *.

* Fordyce Digestion, 189.

Again,

(R) The Abbé Fontana also found, after walking in moist air for an hour or two, he returned home some ounces heavier than he went out, notwithstanding he had suffered considerable evacuation from a brisk purge purposely taken for the experiment. This increase, indeed, might be partly accounted for by the absorption of moisture by his clothes.

Functions of Animals.

Again, the office of the blood veſſels, as aſſimilating organs, is to convert chyle into blood. Chyle, accordingly, cannot be introduced into the arteries without undergoing that change; but *blood* may be introduced from another animal without any injury, and conſequently without undergoing any change. This experiment was firſt made by Lower, and it has ſince been very often repeated.

Alſo, if a piece of freſh muſcular fleſh be applied to the muſcle of an animal, they adhere and incorporate without any change, as has been ſufficiently eſtabliſhed by the experiments of Mr J. Hunter. And Buvina has aſcertained, that freſh bone may, in the ſame manner, be engrafted on the bones of animals of the ſame or of different ſpecies †.

† Phil. Mag. vi. 98.

In ſhort, it ſeems to hold, at leaſt as far as experiments have hitherto been made, that foreign ſubſtances may be incorporated with thoſe of the body, provided they be preciſely of the ſame kind with thoſe to which they are added, whether fluid or ſolid. Thus chyle may be mixed with chyle, blood with blood, muſcle with muſcle, and bone with bone. The experiment has not been extended to the other animal ſubſtances, the nerves, for inſtance; but it is extremely probable that it would hold with reſpect to them alſo.

On the other hand, when ſubſtances are introduced into any part of the body which are not the ſame with that part, nor the ſame with the ſubſtance upon which that part acts; provided they cannot be thrown out readily, they deſtroy the part, and perhaps even the animal. Thus foreign ſubſtances introduced into the blood very ſoon prove fatal; and introduced into wounds of the fleſh or bones, they prevent theſe parts from healing.

365 Their power limited.

Although the different aſſimilating organs have the power of changing certain ſubſtances into others, and of throwing out the uſeleſs ingredients, yet this power is not abſolute, even when the ſubſtances on which they act are proper for undergoing the change which the organs produce. Thus the ſtomach converts food into chyme, the inteſtines chyme into chyle, and the ſubſtances which have not been converted into chyle are thrown out of the body. If there happen to be preſent in the ſtomach and inteſtines any ſubſtance which, though incapable of undergoing the changes, at leaſt, by the action of the ſtomach and inteſtines, yet has a ſtrong affinity, either for the whole chyme and chyle, or for ſome particular part of it, and no affinity for the ſubſtances which are thrown out, that ſubſtance paſſes along with the chyle, and in many caſes continues to remain chemically combined with the ſubſtance to which it is united in the ſtomach, even after that ſubſtance has been completely aſſimilated, and made a part of the body of the animal. Thus there is a ſtrong affinity between the colouring matter of madder and phoſphat of lime. Accordingly, when madder is taken into the ſtomach, it combines with the phoſphat of lime of the food, paſſes with it through the lacteals and blood veſſels, and is depoſited with it in the bones, as was proved by the experiments of Duhamel. In the ſame manner muſk, indigo, &c. when taken into the ſtomach, make their way into many of the ſecretions.

Theſe facts ſhew us, that aſſimilation is a chemical proceſs from beginning to end; that all the changes are produced according to the laws of chemiſtry; and that we can even derange the regularity of the proceſs by introducing ſubſtances whoſe mutual affinities are too ſtrong for the organs to overcome.

366 Aſſimilation a chemical proceſs;

It cannot be denied, then, that the aſſimilation of food conſiſts merely in a certain number of chemical decompoſitions which that food undergoes, and the conſequent formation of certain new compounds. But are the *agents* employed in aſſimilation merely chemical agents? We cannot produce any thing like theſe changes on the food out of the body, and therefore we muſt allow that they are the conſequence of the action of the animal organs. But this action, it may be ſaid, is merely the ſecretion of particular juices, which have the property of inducing the wiſhed-for change upon the food; and this very change would be produced out of the body, provided we could procure theſe ſubſtances, and apply them in proper quantity to the food. If this ſuppoſition be true, the ſpecific action of the veſſels conſiſts in the ſecretion of certain ſubſtances; conſequently the cauſe of this ſecretion is the *real* agent in aſſimilation. Now, can the cauſe of this ſecretion be ſhewn to be merely a chemical agent? Certainly not. For in the ſtomach, where only this ſecretion can be ſhewn to exiſt, it is not always the ſame, but varies according to circumſtances. Thus eagles at firſt cannot digeſt grain, but they may be brought to do it by perſiſting in making them uſe it as food. On the contrary, a lamb cannot at firſt digeſt animal food, but habit will alſo give it this power. In this caſe, it is evident that the gaſtric juice changes according to circumſtances. Now this is ſo far from being a caſe of a chemical law, that it is abſolutely incompatible with every ſuch law. The agent in aſſimilation, then, is not a chemical agent, but one which acts upon different principles. It is true, indeed, that every ſtep in the proceſs is chemical; but the agent which regulates theſe chemical proceſſes, which prevents them from acting, except in particular circumſtances and on particular ſubſtances, and modifies this action according to circumſtances, is not a mere chemical agent, but endowed with very different properties.

367 But the agent not chemical.

The preſence and power of this agent will be ſtill more evident, if we conſider the immunity of the ſtomach of the living animal during the proceſs of digeſtion. The ſtomach of animals is as fit for food as any other ſubſtance. The gaſtric juice, therefore, muſt have the ſame power of acting on it, and of decompoſing it, that it has of acting on other ſubſtances; yet it is well known that the ſtomach is not affected by digeſtion while the animal retains life; though, as Mr Hunter aſcertained, the very gaſtric juice which the living ſtomach ſecretes often diſſolves the ſtomach itſelf after death. Now what is the power which prevents the gaſtric juice from acting on the ſtomach during life? Certainly neither a chemical nor mechanical agent, for theſe agents muſt ſtill retain the ſame power after death. We muſt, then, of neceſſity conclude, that there exiſts in the animal an agent very different from chemical and mechanical powers, ſince it controuls theſe powers according to its pleaſure. Theſe powers therefore in the living body are merely the ſervants of this ſuperior agent, which directs them ſo as to accompliſh always one particular end. This agent ſeems to regulate the chemical powers, chiefly by bringing only certain ſubſtances together which are to be decompoſed, and by keeping at a diſtance thoſe ſubſtances which would interfere with, or diminiſh, or ſpoil the product, or injure

Functions of Animals.

injure the organ. And we fee that this feparation is always attended to even when the fubftances are apparently mixed together. For the very fame products are not obtained which would be obtained by mixing the fame fubftances together out of the body that are produced by mixing them in the body; confequently all the fubftances are not left at full liberty to obey the laws of their mutual affinities. The fuperior agent, however, is not able to exercife an unlimited authority over the chemical powers; fometimes they are too ftrong for it: fome fubftances accordingly, as madder, make their way into the fyftem; while others, as arfenic, decompofe and deftroy the organs of the body themfelves.

But it is not in digeftion alone that this fuperior agent makes the moft wonderful difplay of its power; it is in the laft part of affimilation that our admiration is moft powerfully excited. How comes it that the precife fubftances wanted are always carried to every organ of the body? How comes it that fibrina is always regularly depofited in the mufcles, and phofphat of lime in the bones? And what is ftill more unaccountable, how comes it that prodigious quantities of fome one particular fubftance are formed and carried to a particular place in order to fupply new wants which did not before exift? A bone, for example, becomes difeafed and unfit for the ufe of the animal; a new bone therefore is formed in its place, and the old one is carried off by the abforbents. In order to form this new bone, large quantities of phofphat of lime are depofited in a place where the fame quantity was not before neceffary. Now, who informs this agent that an unufual quantity of phofphat of lime is neceffary, and that it muft be carried to that particular place? Or granting, as is moft probable, that the phofphat of lime of the old bone is partly employed for this purpofe, who taught this agent that the old bone muft be carried off, new modelled, and depofited, and affimilated anew? The fame wonders take place during the healing of every wound, and the renewing of every difeafed part.

Thefe operations are incompatible with the fuppofition that the body of animals is a mere chemical and mechanical machine; and demonftrate the prefence of fome agent befides, which acts according to very different laws.

But neither in this cafe is the power of this agent over the chemical agents, which are employed, abfolute. We may prevent a fractured bone from healing by giving the patient large quantities of acids. And unlefs the materials for the new wanted fubftances be fupplied by the food, they cannot, in many cafes, be formed at all. Thus the canary bird cannot complete her eggs unlefs fhe be furnifhed with lime.

It is evident that the fupreme agent of the animal body, whatever that agent may be, acts according to fixed laws; and that when thefe laws are oppofed by thofe which are more powerful, it cannot overcome them. Thefe laws clearly indicate defign; and the agent has the power of modifying them fomewhat according to circumftances. Thus more phofphat of lime is fent to a limb which requires a new bone, and more lime than ufual is taken into the fyftem when the hen is laying eggs. Defign and contingency are confidered by us as infallible marks of confcioufnefs and intelligence. That they are infallible marks of the agency of mind is certain: but that they are in all cafes the proofs of immediate confcioufnefs and intelligence, as the Stahlians fuppofed, cannot be affirmed with outrunning into inconfiftencies. For we ourfelves are not confcious of thofe operations which take place during *affimilation.*

To fay that a being can act with defign without intelligence, we allow to be a flat contradiction, becaufe defign always implies intelligence. There muft therefore be intelligence fomewhere. But may not this intelligence exift, not in the agent, but in the being who formed the agent? and may not the whole of the defign belong in reality to that being?

368 Nor material.

May not this agent, then, be material, and may not the whole of affimilation be performed by mere matter, acting according to laws given it by its maker? We anfwer, that what is called *matter*, or the fubftances enumerated in the firft part of CHEMISTRY (*Suppl.*) act always according to certain attractions and repulfions, which are known by the name of mechanical and chemical laws.

The phenomena of affimilation are fo far from being cafes of thefe laws, that they are abfolutely inconfiftent with them, and contrary to them; confequently the agent which prefides over *affimilation* is not *matter.* Concerning the nature of this fubftance it is not the bufinefs of this article to inquire; but as it poffeffes properties different from matter, and acts according to very different laws, it would be an abufe of terms to call it *matter.* 369

Animal principle.

We fhould give it the name of *mind*, were it not that metaphyficians have chofen to confider intelligence as the effence of mind; whereas this fubftance may be conceived to act, and really does act, without intelligence. There is no reafon, however, to fuppofe, with fome, that there are two fubftances in animals: one poffeffed of confcioufnefs as its effence, and therefore called *mind* or *foul* in man; another, deftitute of confcioufnefs, called the *living principle*, &c. employed in performing the different functions of affimilation, abforption, &c. It is much more reafonable to fuppofe, that in every animal and vegetable there is a peculiar fubftance, different from matter, to which their peculiar properties are owing; that this fubftance is different in every fpecies of animal and vegetable; that it is capable of acting according to certain fixed laws which have been impofed upon it by its Creator, and that thefe laws are of fuch a nature that it acts in fubfervience to a particular end; that this fubftance in plants is probably deftitute of intelligence; that in man and other animals it poffeffes intelligence to a certain extent, but that this intelligence is not effential to its exiftence nor to its activity; that it may be deprived of intelligence altogether, and afterwards recover it without altering its nature. Phyfiologifts have given it the name of *living principle*, becaufe its prefence conftitutes life. Perhaps it would be proper to diftinguifh that of animals by the name of *animal principle.* Upon what the intelligence of the animal principle depends, it is impoffible to fay; but it is evidently connected with the ftate of the brain. During a trance, or an apoplectic fit, it has often been loft for a time, and afterwards recovered.

370 Secretion.

17. Befides affimilation, the blood is alfo employed in forming all the different fecretions which are neceffary for the purpofes of the animal economy. Thefe have been enumerated in the laft chapter. The procefs is fimilar to that of affimilation, and undoubtedly the agents in both cafes are the fame; but we are equally

ecompofi-on of Ani-al Sub-ances. equally ignorant of the precife manner in which fecretion is performed as we are of affimilation.

371. Animals at length die, and why. 18. After thefe functions have gone on for a certain time, which is longer or fhorter according to the nature of the animal, the body gradually decays, at laft all its functions ceafe completely, and the animal dies. The caufe of this muft appear very extraordinary, when we confider the power which the animal has of renewing decayed parts; for it cannot be doubted that death proceeds, in moft cafes at leaft, from the body becoming incapable of performing its function. But if we confider that this power is limited, and that it muft ceafe altogether, when thofe parts of the fyftem begin to decay which are employed in preparing materials for future affimilation, our furprife will, in fome meafure, ceafe. It is in thefe parts, in the organs of digeftion and affimilation accordingly, that this decay ufually proves fatal. The decay in other parts deftroys life only when the wafte is fo rapid that it does not admit of repair.

What the reafon is that the decay of the organs caufes death, or, which is the fame thing, caufes the living principle either to ceafe to act, or to leave the body altogether, it is perfectly impoffible to fay, becaufe we know too little of the nature of the living principle, and of the manner in which it is connected with the body. The laft is evidently above the human underftanding, but many of the properties of the living principle have been difcovered; and were the facts already known properly arranged, and fuch general conclufions drawn from them as their connection with each other fully warrant, a degree of light would be thrown upon the animal economy which thofe, who have not attended to the fubject, are not aware of.

No fooner is the animal dead, than the chemical and mechanical agents, which were formerly fervants, ufurp the fupreme power, and foon decompofe and deftroy that very body which had been in a great meafure reared by their means. But the changes which take place upon animal bodies after death, are too important, and too intimately connected with the fubject of this article to be paffed over flightly. They fhall therefore form the fubject of the next chapter.

CHAP. IV. OF THE DECOMPOSITION OF ANIMAL SUBSTANCES.

372 Decompofition of animal fubftances expofed to the air. ALL the foft and the liquid parts of animals, when expofed to a moderate temperature of fixty-five degrees or more, pafs with more or lefs rapidity through the following changes. Their colour becomes paler, and their confiftence diminifhes; if it be a folid part, fuch as flefh, it foftens, and a ferous matter fweats out, whofe colour quickly changes; the texture of the part becomes relaxed, and its organization deftroyed; it acquires a faint difagreeable fmell; the fubftance gradually finks down, and is diminifhed in bulk; its fmell becomes ftronger and ammoniacal. If the fubject be contained in a clofe veffel, the progrefs of putrefaction, at this ftage, feems to flacken; no other fmell but that of a pungent alkali is perceived; the matter effervefces with acids, and converts fyrup of violets to a green. But if the communication with the air be admitted, the urinous exhalation is diffipated, and a peculiar putrid fmell is fpread around with a kind of impetuofity; a fmell of the moft infupportable kind, which lafts a long time, and pervades every place, affecting the bodies of living animals after the manner of a ferment, capable of altering the fluids: this fmell is corrected, and as it were confined by ammonia. When the latter is volatilized, the putrefactive procefs becomes active a fecond time, and the fubftance fuddenly fwells up, becomes filled with bubbles of air, and foon after fubfides again. Its colour changes, the fibrous texture of the flefh being then fcarcely diftinguifhable; and the whole is changed into a foft, brown, or greenifh matter, of the confiftence of a poultice, whofe fmell is faint, naufeous, and very active on the bodies of animals. The odorant principle gradually lofes its force; the fluid portion of the flefh affumes a kind of confiftence, its colour becomes deeper, and it is finally reduced into a friable matter, rather deliquefcent, which being rubbed between the fingers, breaks into a coarfe powder like earth. This is the laft ftate obferved in the putrefaction of animal fubftances; they do not arrive at this term but at the end of a confiderable time †.

† *Fourcroy*.

373 Buried in the earth. In carcafes buried in the earth, putrefaction takes place much more flowly; but it is fcarcely poffible to obferve its progrefs with accuracy. The abdomen is gradually dilated with elaftic fluids which make their appearance in it, and at laft it burfts and difcharges a horribly fetid and noxious gas; at the fame time a dark coloured liquid flows out. If the earth be very dry, and the heat confiderable, the moifture is often abforbed fo rapidly, that the carcafe, inftead of putrefying, dries, and is transformed into what is called a *mummy*.

374 When accumulated together. Such are the phenomena when dead bodies are left to putrefy feparately. But when great numbers of carcafes are crowded together in one place, and are fo abundant as to exclude the action of external air, and other foreign agents, their decompofition is entirely the confequence of the reciprocal action of their ingredients themfelves upon each other, and the refult is very different. The body is not entirely diffipated or converted into mould, but all the foft parts are found diminifhed remarkably in fize, and converted into a peculiar *faponaceous matter*. This fingular change was firft accurately obferved in the year 1786.

375 Converted into a faponaceous matter. The burial ground of the Innocents in Paris having become noxious to thofe who lived in its neighbourhood, on account of the difagreeable and hurtful odour which it exhaled, it was found neceffary to remove the carcafes to another place. It had been ufual to dig very large pits in that burial ground, and to fill them with the carcafes of the poorer fort of people, each in its proper bier; and when they were quite full, to cover them with about a foot depth of earth, and to dig another fimilar pit, and fill it in the fame manner. Each pit held between 1000 and 1500 dead bodies. It was in removing the bodies from thefe pits that this faponaceous fubftance was found. The grave-diggers had afcertained, by long experience, that about thirty years were required before all the bodies had undergone this change in its full extent *. Every part of the body acquired the properties of this fubftance. The inteftines and vifcera of the thorax had completely difappeared; but what is fingular enough, the brain had loft but little of its fize or appearance, though it was alfo converted into the fame fubftance.

* *Fourcroy*, *Ann. de Chim.* v. 154.

376 Its properties. This faponaceous matter was of a white colour, foft and unctuous to the touch, and melted, when heated, like

Decomposition of Animal Substances.

like tallow. It exhibited all the properties of a *soap*, containing, however, an excess of fatty matter. Fourcroy, who analysed it, found that it was composed of a fatty matter combined with ammonia, and that it contained also some phosphat of lime and ammonia. Diluted acids decomposed it, and separated the fatty matter: alkalies and lime, on the other hand, drove off the ammonia. When exposed to the air, it gradually lost its white colour; the ammonia, in a great measure, evaporated, and what remained had something of the appearance of wax. It absorbed water with great avidity, and did not part with it readily. Its white colour was owing to the presence of that liquid. The oily matter, when separated by means of a diluted acid, was concrete, and of a white colour, owing to the mixture of a quantity of water. When dried, it acquires a greyish brown colour, a lamellar and crystalline texture, like that of spermaceti; but if it has been rapidly dried it assumes the appearance of wax. It melts, when heated, to 126°; when properly purified, by passing it through a linen cloth while fluid, it has scarcely any smell. Alcohol does not act upon it while cold, but at the temperature of 120° it dissolves it: when the solution cools, the fatty matter precipitates, and forms a gritty mass. With alkalies it forms a soap; and when set on fire it burns precisely like oil or fat, only that it exhales a more unpleasant odour †.

† Fourcroy, Ann. de Chim. viii. 17.

377 Produced also in running water.

Mr Smith Gibbes found the same substance in the pit into which animal matters are thrown at Oxford after dissection. A small stream of water constantly passes through this pit; a circumstance which induced him to try whether animal muscle exposed to the action of a running stream underwent the same change. The experiment succeeded completely: he attempted, in consequence, to render this substance, to which he gave the name of *spermaceti*, useful in those manufactures which required tallow; but the fetid odour which it constantly exhales was an insurmountable objection. Attempts were indeed made to get over it; but as we do not hear that Mr Smith Gibbes's spermaceti has been introduced into any manufacture, we have reason to conclude that none of these attempts succeeded ‡.

‡ Phil. Transf. 1794 and 1795.

378 Theory of putrefaction imperfect.

Such are the phenomena of putrefaction, as far as they are at present known to chemists. Any attempt to explain the manner in which these changes take place, would be exceedingly imperfect indeed; not only because we are ignorant of the strength of the affinities of the different elementary parts of animal bodies for each other, but because we do not even know the manner in which these elements are combined, and consequently we cannot know by what particular forces these compounds are destroyed. We know only that a certain degree of heat, and the presence of moisture, are in all cases necessary for the putrefactive process; for animal bodies may be kept almost any length of time, without decomposition, at the freezing temperature; and when dried quickly, and kept in that state, they undergo no farther change.

PART III. OF DYEING.

MANKIND have in all periods of society manifested a fondness for beautiful and gaudy colours. Naked savages at first applied them to their skin. This was the case with the Britons, and with the Guals, too, in the time of Cæsar; it is even still the practice in the South Sea islands, and many parts of America. When mankind had advanced so far towards civilization as to wear garments, they naturally transferred to them the colours which they admired. Hence the origin of *dyeing*; which is of such antiquity, that it precedes the earliest records left us by profane authors. We see from the book of Genesis the great progress which it had made in the time of the patriarchs.

379 Origin of dyeing.

Dyeing seems to have originated in India, and to have spread gradually from that country to the west. The Indians were the inventors of the method of dyeing cotton and linen, which was not understood in Europe before the conquests of Alexander the Great. The Phenicians excelled in the art at a very early period. It was from them that the Jews purchased all the dyed stuffs described in Exodus. The Phenician dyers seem to have confined their art to wool: silk was unknown to them, and linen was usually worn white. From them the art of dyeing passed to the Greeks and Romans.

During the fifth century, the Western Empire was overturned by the northern nations, and with it the arts and sciences, which had flourished under the protection of the Romans, disappeared. A few of the arts, indeed, were preserved in Italy, but they were obscured and degraded. By degrees, however, a spirit of industry began to revive in that country. Florence, Genoa, and Venice, becoming rich commercial cities, carried on a considerable intercourse with the Grecian empire, where many of the arts had been preserved. This intercourse was much increased by the crusades. The Italian cities became rich and powerful: the arts which distinguish civilized nations were cultivated with emulation, and dyeing, among others, was rapidly improved.

380 Its progress in modern Europe.

In the year 1429, the first treatise on dyeing made its appearance at Venice, under the name of *Moriegola del arte de tentori*. Giovanne Ventura Rosetta collected, with great industry, all the processes employed by the dyers of his time, and published them in 1548, under the title of *Plictho* *. For many years dyeing was almost exclusively confined to Italy; but it gradually made its way to France, the Low Countries, and to Britain. The minister Colbert, who employed his talents in extending the commerce and manufactures of France, paid particular attention to the art of *dyeing*. In the year 1672, he published a table of instructions, by which those who practised the art were laid under several very improper restrictions. But the bad effects of these were in a good measure obviated by the judicious appointment of men of science to superintend the art. This plan, begun by Colbert, was continued by the French government. Accordingly, Dufay, Hellot, Macquer, and Berthollet, successively filled the office. It is to this establishment, and to exertions of the celebrated chemists who have filled it, that France is indebted for the improvements she has made in the art of dyeing during the course of the 18th century. Under the direction of Dufay, a new table of regulations was published in 1737, which superseded that of Colbert.

* Berthollet on Dyeing, i. 22.

Hellot,

Substances used for Clothing.

Hellot, his fucceffor, publifhed, in 1740, an excellent fyftem of dyeing wool; and Macquer in 1763 publifhed his treatife on dyeing filk.

In Britain, though dyeing has been carried on for many years with great fuccefs, very little progrefs was made in inveftigating the theory of the art. The Royal Society, indeed, foon after its inftitution, recommended it to fome of its members; but as no treatife made its appearance in confequence of this, it feems very foon to have loft their attention. Lewis, many years after, publifhed fome very important remarks on dyeing; but they were confined to a few proceffes. The Britifh dyers fatisfied themfelves with a tranflation of Hellot. Such was the ftate of the art when the article DYEING in the *Encyclopædia* was drawn up. It confifts chiefly of an abftract of Hellot's treatife. But within the laft 30 years, the attention of men of fcience has been very much turned to this complicated art. In Sweden has appeared the treatife of Scheffer, and Bergman's notes on it; in Germany, the experiments of Beckmann, Poerner, and Vogler, and the differtation of Franchéville; in France, the treatifes of D'Ambournay, D'Apligny, Hauffmann, Chaptal, and, above all, of Berthollet; in this country, the ingenious remarks of Delaval, of Henry, and the valuable treatife of Dr Bancroft; befides many other important effays. Thefe, together with the progrefs of the fcience of chemiftry, on which the theory of dyeing depends, have thrown fo much new light upon the art, that we find ourfelves under the neceffity of tracing the whole over again. We fhall pafs over, however, very flightly thofe parts of the art which have been fufficiently explained in the article DYEING, *Encycl.*

To underftand the art of *dyeing*, we muft be acquainted with the *fubftances* on which it is practifed, with the nature of *colour*, and with the method of permanently changing the colour of bodies. Thefe three things we fhall confider in the three following chapters. In the firft, we fhall give an account of the fubftances of which garments are ufually made, with which alone the art of dyeing is concerned; in the fecond, we fhall inquire into the nature of colour; and in the third, explain the theory of dyeing, as far as it is at prefent underftood. In fome fubfequent chapters, we fhall give a general view of the proceffes by which the different colours are given to ftuffs.

CHAP. I. OF THE SUBSTANCES USED FOR CLOTHING.

THE fubftances commonly employed for clothing may be reduced to four; namely, *wool*, *filk*, *cotton*, *linen*. As there is no name in the Englifh language which includes all thefe fubftances, we fhall take the liberty, in the remainder of this article, to ufe the word *cloth* for that purpofe. They are all made into *cloth*, of fome kind or other, before they can be ufeful as articles of *clothing*.

1. WOOL, as is well known, is the hair which covers the bodies of fheep; it differs from common *hair* merely in finenefs and foftnefs. Its filaments poffefs a confiderable degree of elafticity; they may be drawn out beyond their ufual length, and afterwards recover their form when the external force is removed. The furface of wool and hair is by no means fmooth: No inequality, indeed, can be perceived by a microfcope; nor is any refiftance felt when a hair is laid hold of in one hand, and drawn between the fingers of the other, from the *root* towards the *point*; but if it be drawn from the *point* towards the *root*, a refiftance is felt which did not take place before, a tremulous motion is perceived, and a noife may be diftinguifhed by the ear. If, after laying hold of a hair between the thumb and fore finger, we rub them againft each other in the longitudinal direction of the hair, it acquires a progreffive motion *towards the root*; the *point* gradually approaches the fingers, while the *root* recedes from them; fo that the whole hair very foon paffes through between the fingers.

Thefe obfervations, firft made by Mr Monge, demonftrate that the furface of hair and wool is compofed, either of fmall laminæ, placed over each other in a flanting direction from the root towards the point, like the fcales of a fifh—or of zones, placed one above another, as takes place in the horns of animals *.

* Ann. de Chim. vi. 300.

On this ftructure of the filaments of hair and wool depend the effects of *felting* and *fulling*. In both of thefe operations, the filaments are made, by an external force, to rub againft each other; the pofition of their afperities prevents them from moving, except in one direction: they are mutually entangled, and obliged to approach nearer each other. Hence the thicknefs which cloth acquires in the fulling mill. The filaments have undergone a certain degree of felting, and are interwoven like the fibres of a hat. The cloth is contracted both in length and breadth: it may be cut without being fubject to ravel; nor is there any neceffity for hemming the different pieces employed to make a garment. See FELTING and FULLING in this *Suppl.*

Wool is naturally covered with a kind of greafe, which preferves it from moths. This is always removed before the wool is dyed; becaufe its prefence is very prejudicial to the fuccefs of that operation. The afperities of the furface of woolly fibres would impede the converting of it into thread by fpinning; but they are in a great meafure covered, previous to that operation, by foaking the wool with oil. The oil muft alfo be removed before the wool be dyed. This procefs is called SCOURING, which fee in this *Suppl.*

We have already, in the fecond part of this article, given an account of what is at prefent known concerning the compofition of wool and hair. It would be foreign to the fubject of this chapter, to defcribe the method of *fpinning* and *weaving* wool.

Wool is of different colours; but that which is white is preferred for making cloth; becaufe it anfwers better for the purpofes of dyeing than any other kind.

383 Silk.

2. SILK is a fubftance fpun in fine threads by the *filk worm*. Its fibres are not fcaly like thofe of wool; neither have they the fame elafticity: but filk, in its natural ftate, before it has undergone any preparation, has a confiderable degree of ftiffnefs and elafticity. In this ftate it is known by the name of *raw filk*. It is covered with a kind of gummy varnifh, which may be removed by fcouring with foap. The fcouring deprives it of its ftiffnefs and elafticity. Raw filk is of a yellow colour, owing to yellow refinous matter with which it is naturally combined. We have given the method of feparating this matter, and alfo the gum, in the article BLEACHING, *Supplement.*

Silk, before it is dyed, is always freed from its gum, and generally alfo from its refin. It may be dyed without

Subſtances uſed for Clothing. out the application of heat; which is not the caſe with cotton, and linen. The firſt two are animal ſubſtances; the two laſt vegetable. The animal contain much azot and hydrogen; the vegetable much carbon: The animal are readily deſtroyed by acids and alkalies; the vegetable withſtand the action of theſe ſubſtances better; even nitric acid does not readily deſtroy the texture of cotton. The animal ſubſtances are more eaſily dyed than the vegetable, and the colours which they receive are more permanent than thoſe given to cotton and linen by the ſame proceſſes.

Such are the properties of the cloths on which the art of dyeing is exerciſed. But what is the nature of theſe *colours* which it is the object of that art to communicate? We ſhall examine this ſubject in the following chapter.

Colour... wool.

384 Cotton, 3. COTTON is a fine downy ſubſtance, contained in the pods of different ſpecies of goſſypium. The ſpecies from which the greater part of the cotton brought to this country is taken is the *herbaceum*. The quantity imported annually into Britain is very great; in 1786 it amounted to 20 millions of pounds ‡. Cotton varies greatly, according to the plant on which it grows, and the climate where it is cultivated. The chief differences are in colour, and in the length, fineneſs, and ſtrength of the filaments.

‡ *Bancroft*, i. 69.

No aſperities can be diſcovered on the ſurface of theſe filaments; but Lewenhoeck obſerved, by means of a microſcope, that they are triangular, and have three ſharp edges. This is probably the reaſon of a well known fact, that cotton cloth, when applied by way of dreſſing, always irritates a ſore.

Some cottons are naturally white; others a fine light yellow, as thoſe of which nankeen is made; but moſt commonly cotton is of a dirty browniſh yellow colour, which muſt be removed before the ſtuff can be dyed. This is done by the proceſs of *bleaching*. The fibres of cotton, even after being bleached, retain almoſt always ſome lime and oxide of iron, which muſt be removed before we attempt to dye the cotton; becauſe their preſence would ſpoil the colour. This is done by ſteeping the cotton for ſome time in water acidulated with ſulphuric acid.

Cotton, like ſilk, may be dyed without the aſſiſtance of heat. It is not nearly ſo eaſy to dye cotton any particular colour as it is to dye wool or ſilk. If wool and cotton be put into the ſame dyeing veſſel, the wool frequently acquires the wiſhed-for colour before the cotton has loſt any of its original whiteneſs.

385 Linen. 4. LINT, from which *linen* is made, is the inner bark of the *linum uſitatiſſimum*, or *flax*; a plant too well known in this country to require any deſcription.

The flax, when ripe, is pulled and ſteeped for ſome days in water, in order to ſeparate the green coloured glutinous matter which adheres to the inner bark. This matter undergoes a degree of putrefaction; carbonic acid gas and hydrogen gas are diſengaged *: it is decompoſed, and carried off by the water. If the water, in which the flax is ſteeped, be completely ſtagnant, the putrefaction is apt to go too far, and to injure the fibres of the lint; but in a running ſtream, it does not go far enough, ſo that the green matter ſtill continues to adhere to the lint. Flax, therefore, ſhould be ſteeped in water neither completely ſtagnant, nor flowing too freely, like a running ſtream.

* *Rozer.*

The flax is afterwards ſpread upon the graſs, and expoſed for ſome time to the air and ſun: this improves the colour of the lint, and renders the woody part ſo brittle, that it is eaſily ſeparated by the action of the lint mill. The ſubſequent operations, of *dreſſing*, *ſpinning*, *weaving*, and *bleaching*, do not belong to this article.

The fibres of lint have very little elaſticity. They appear to be quite ſmooth; for no aſperities can be perceived by the microſcope, nor detected by the feel; nor does linen irritate ſores, as is the caſe with cotton.

Linen may be dyed without the aſſiſtance of heat; but it is more difficult to give it permanent colours than even cotton.

Thus we have given a ſhort deſcription of wool, ſilk,

CHAP. II. OF COLOURS.

ALL viſible objects, as has been long ago ſufficiently eſtabliſhed, are ſeen by means of rays of light paſſing off from them in all directions, and partly entering the eye of the ſpectator.

1. For the theory of light and viſion we are indebted to Sir Iſaac Newton. He firſt demonſtrated, that light is compoſed of ſeven rays, differing from each other in refrangibility, and other properties. Each of theſe rays is diſtinguiſhed by its particular colour. Hence their names, red, orange, yellow, green, blue, indigo, violet. By mixing together theſe different rays, in various proportions, all the colours known may be obtained. Thus red and yellow conſtitute orange; yellow and blue conſtitute green; blue and red conſtitute purple, violate, aurora, &c. according to their proportions. When all the rays are mixed together, they form a white. 386 Colour produced by light.

2. Bodies differ very much from each other in their power of reflecting light. Some reflect it in vaſt quantity, as metals; others reflect but little, as charcoal. In general, the ſmoother the ſurface of a body is, the greater is the quantity of light which it reflects. Hence the effect of poliſhing in increaſing the brightneſs of bodies. But it is not in the quantity of the light reflected alone that bodies differ from each other; they differ alſo in the quality of the light which they reflect. Some bodies reflect one or more particular ſpecies of ray to the excluſion of the reſt. This is the reaſon that they appear to us of different colours. Thoſe bodies which reflect only red rays are red; thoſe that reflect yellow rays are yellow; thoſe that reflect all the rays equally are white; thoſe that reflect too little to affect the eye are black. It is to the different combinations of rays reflected from the ſurface of bodies that all the different ſhades of colour are owing. 387 Bodies reflect different rays.

Colour, then, in *opaque* bodies, is owing to their diſpoſition to *reflect* certain rays of light, and to *abſorb* the reſt; in *tranſparent* bodies, to their diſpoſition to *tranſmit* certain rays, and to *abſorb* the others. But this ſubject has been diſcuſſed, at ſufficient length, in the article OPTICS, *Encycl.*; to which, therefore, we beg leave to refer the reader. Here we mean only to inquire into the *cauſe* of this diſpoſition of the particles of bodies. 38[8] Hence the different colours.

3. Sir Iſaac Newton, to whom we are indebted for the exiſtence of optics as a ſcience, made a ſet of experiments to aſcertain the changes of colour which thin plates of matter aſſume in conſequence of an increaſe or dimi- 3[89] Newton's theory explaining different

urs. diminution of their thicknefs. Thefe experiments were of a very delicate nature; but Newton conducted them with fo much addrefs, and varied and repeated them with fo much induftry, that he was enabled to render them furprifingly accurate.

Upon a large double convex lens of a 50 feet focus, he placed the plane furface of a planoconvex lens, and preffed the lenfes flowly together. A circle, of a particular colour, appeared in the centre, where the two glaffes touched each other. This circle gradually increafed in diameter as the preffure was augmented; and at laft a new circle, of another colour, occupied the centre, while the firft colour affumed the form of a circular ring. By increafing the preffure, a new coloured circle appeared in the centre, and the diameter of the other two increafed. In this manner he proceeded, till he produced no lefs than 25 different coloured circular rings. Thefe he divided into feven orders, on account of the repetition of the fame colour. They were as follows, reckoning from the central colour, which was always black *.

*wton's s, 191. ke's on.

1. Black, blue, white, yellow, red.
2. Violet, blue, green, yellow, red.
3. Purple, blue, green yellow, red.
4. Green, red.
5. Greenifh blue, red.
6. Greenifh blue, pale red.
7. Greenifh blue, reddifh white.

Thefe different colours were occafioned by the thin film of air between the two glaffes. Now this film varies in thicknefs from the centre of the lens towards the circumference; that part of it which caufes the black colour is thinneft, and the other coloured circles are occafioned by air gradually increafing in thicknefs. Newton meafured the *relative thicknefs* of the air which produced each of thefe coloured circles; and he found it as follows †:

†d, p.

1. Black	1	green	$25\frac{1}{5}$
blue	$2\frac{2}{5}$	yellow	$27\frac{1}{7}$
white	$5\frac{1}{3}$	red	31
yellow	$7\frac{1}{9}$	4. Green	35
red	$8\frac{1}{2}$	red	$40\frac{1}{3}$
2. Violet	$11\frac{1}{6}$	5. Gr. blue	46
blue	14	red	$52\frac{1}{2}$
green	$15\frac{1}{8}$	6. Gr. blue	$58\frac{3}{4}$
yellow	$16\frac{2}{7}$	red	65
red	$18\frac{1}{3}$	7. Gr. blue	71
3. Purple	21	reddifh white	77
blue	$23\frac{2}{5}$		

The *abfolute* thicknefs of thefe films cannot be afcertained, unlefs the diftance between the two glaffes, at that part where the black fpot appears, were known. Now there is no method of meafuring this diftance; but it certainly is not greater than the thoufandth part of an inch.

He repeated thefe experiments with films of water, and even of glafs, inftead of air; and he found, that in thefe cafes the thicknefs of the films, reflecting any particular colour, was diminifhed, and that this diminution was proportional to the denfity of the reflecting film.

From thefe experiments Sir Ifaac Newton concluded, that the difpofition of the particles of bodies to reflect or tranfmit particular rays depended upon their fize and their denfity: and he even attempted to afcertain the fize, or at leaft the thicknefs, of the particles of bodies from their colours. Thus a particle of matter, whofe denfity is the fame with that of glafs which reflects a green of the third order, is of the thicknefs of $\frac{16\frac{1}{4}}{10000000}$ of an inch *. Colours.

* Newton's Optics, 251.

In the year 1765, Mr Delaval publifhed, in the Philofophical Tranfactions, a very ingenious paper on the fame fubject. In this paper, he endeavours to prove, by experiment, that the colours of metallic bodies depend upon their denfity. He takes it for granted, at the fame time, that the fize of the particles of bodies is inverfely as the denfity of bodies. The denfeft bodies, according to him, are red; the next in denfity, orange; the next, yellow; and fo on, in the order of the refrangibility of the different rays. Some time after, the fame ingenious gentleman, in his *Experimental Inquiry into the Caufe of the Permanent Colours of Opaque Bodies*, extended his views to animal and vegetable fubftances, and endeavoured to prove the truth of Newton's theory by a very great number of experiments.

Such is a view of the opinion of Newton and Delaval refpecting the caufe of bodies reflecting or tranfmitting particular rays of light, as far, at leaft, as that theory relates to colour. They afcribed this caufe *folely* to the *fize* and the *denfity* of the particles of bodies.

By *particles*, it is evident that nothing elfe can be meant than the *integrant particles* of bodies. Newton, indeed, does not exprefs himfelf precifely in this language; but it is plain that nothing elfe could be his meaning. Mr Delaval undoubtedly is of that opinion.

According to the Newtonian theory of colour, then, it depends folely upon the *fize* of the integrant particles of bodies whofe denfity is the fame; and upon the *fize* and the *denfity* jointly of all bodies (T).

39? Examined.

It is evident that the truth of the Newtonian theory muft depend upon its coincidence with what actually takes place in nature, and that therefore it can only be determined by experiment. Newton himfelf produced but very few experiments in fupport of it; and though this deficiency was amply fupplied by Mr Delaval, it is needlefs for us to adduce any of thefe here; becaufe, from the prodigious accumulation of chemical facts fince thefe experiments were made, the very bafis upon which they ftood has been deftroyed, and confequently all the evidence refulting from them has been annihilated. They proceeded on the fuppofition, that acids render the particles of bodies *fmaller*, and alkalies *larger* than they were before, without producing any other change whatever in the bodies on which they act. To attempt a refutation of this opinion at prefent would be unneceffary, as it is well known not to be true.

Let us therefore compare the Newtonian theory of colour with thofe chemical changes which we know for certain to alter the fize of the particles of bodies, in order to fee whether they coincide with it. If the theory be true, the two following confequences muft hold

(T) Newton, however, pointed out an exception to this law, concerning which Mr Delaval has been more explicit. Combuftible bodies do not follow that law, but fome other. Mr Delaval has fuppofed, that this deviation is owing to the prefence of phlogifton.

Colours.

hold in all caſes: 1. Every alteration in the ſize of the integrant particles of bodies muſt cauſe theſe particles to aſſume a different colour. 2. Every ſuch alteration muſt correſpond preciſely with the theory; that is to ſay, the new colour muſt be the very colour, and no other, which the theory makes to reſult from an increaſe or diminution of ſize.

391
And found defective.

Now neither of theſe conſequences holds in fact. We have no method indeed of aſcertaining the ſizes of the integrant particles of bodies, nor of meaſuring the preciſe degree of augmentation or diminution which they ſuffer; but we can in many caſes aſcertain, whether any new matter has been added to a particle, or any matter abſtracted from it; and conſequently whether it has been augmented or diminiſhed; which is ſufficient for our preſent purpoſe.

For inſtance, whatever be the ſize of an integrant particle of gold, it cannot be denied that an integrant particle of oxide of gold is greater; becauſe it contains an integrant particle of gold combined with at leaſt one integrant particle of oxygen. Now the colour both of gold and of its oxide is yellow, which ought not to be the caſe, according to the Newtonian theory. In like manner, the amalgam of ſilver is white, preciſely the colour of ſilver and of mercury; yet an integrant particle of the amalgam muſt be larger than an integrant particle either of ſilver or of mercury. Many other inſtances beſides theſe will occur to every one, of changes in the ſize of the particles taking place without any change of colour. All theſe are incompatible with the Newtonian theory.

It may be ſaid, perhaps, in anſwer to this objection, that there are different orders of colours; that the ſame colour is reflected by particles of different ſizes; and that the increaſed particles, in the inſtances above alluded to, retain their former colour, becauſe the increment has been preciſely ſuch as to enable them to reflect the ſame colour in the next higher order.

This very anſwer is a complete proof that the Newtonian theory is not ſufficient to account for the colours of bodies; for if particles of *different* ſizes reflect the ſame colour, *ſize* certainly is not the only cauſe of this reflection *. There muſt be ſome other cauſe very different from ſize. Nor is this all; the moſt common colour which remains after an increaſe of the ſize of the integrant particles of bodies is white; yet white does not appear in any of the orders except the firſt, and therefore its permanence cannot be accounted for by any ſuppoſition compatible with the Newtonian theory.

* *Bancroft on Permanent Colours*, i. 7.

Even when alterations in the colour of bodies accompany the increaſe or diminution of the ſize of their particles, theſe alterations ſeldom or never follow an order which correſponds with the theory. As for metals, it is ſelf-evident that their colour does not depend upon their denſity. Platinum is the denſeſt body known, and yet it is not red, as it ought to be, but white like tin; a metal which has little more than one third of the denſity of platinum.

The green oxide of iron, when combined with pruſſic acid, becomes white; yet the ſize of its particles muſt be increaſed. Now this change of colour is incompatible with the theory; for, according to it, every change from green to white ought to be accompanied by a diminution inſtead of an increaſe of ſize. A particle of indigo, which is naturally green, becomes blue by the addition of oxygen, which muſt increaſe its ſize. This change is alſo incompatible with the theory. But it is unneceſſary to accumulate inſtances, as they will naturally occur in ſufficient number to every one.

It follows irreſiſtibly from theſe facts, that the Newtonian theory is not ſufficient to explain the *cauſe* of colour; or what cauſes bodies to reflect or tranſmit certain rays, and to abſorb the reſt.

392
Bodies owe their colour to their affinity for light.

4. We have endeavoured, in the article CHEMISTRY, *Suppl.* to ſhew, that bodies have a particular affinity for the rays of light; and that the phenomena of light depend entirely upon theſe affinities. Indeed this conſequence follows from the properties of light eſtabliſhed by Newton himſelf. We ſhall not repeat here the proofs upon which the exiſtence of theſe affinities is founded: the reader may eaſily ſatiſfy himſelf by conſulting the article above referred to.

Every coloured body, then, has a certain *affinity for* ſome of the rays of light. Thoſe rays for which it has a ſtrong affinity are abſorbed by it and retained, and the other rays for which it has no affinity are either reflected or tranſmitted, according to the nature of the body and the direction of the incident ray. Thus a red body has an affinity for all the rays except the red; it abſorbs therefore the other ſix, and reflects only the red: a green body abſorbs all but the green rays, or perhaps the red and yellow: a black body has a ſtrong affinity for all the rays, and therefore abſorbs them all; while a white body, having no ſtrong affinity for any of the rays, reflects or tranſmits them all.

If affinity, as we have endeavoured to ſhew in the article CHEMISTRY, *Suppl.* be an attraction of the ſame nature with gravitation, and increaſing as the diſtance diminiſhes, it muſt depend upon the nature of the attracting particles. Now the only differences which we can conceive to exiſt between the particles of bodies, are differences in *ſize*, in *denſity*, and in *figure*. Changes in theſe three things will account for all the varieties of affinity. Now if affinity depends upon theſe three things, and if colour depends upon the affinity between the particles of bodies and the different rays of light, as cannot be denied, it is clear that the cauſe of the colour of bodies may be ultimately reſolved into the ſize, denſity, and figure of their particles. Newton's theory, then, was defective, becauſe he omitted the *figure* of the particles, and aſcribed the whole to variations in *ſize* and *denſity*.

When we ſay, then, that colour is owing to *affinity*, we do not contradict the opinion of Newton, as ſome philoſophers have ſuppoſed, but merely extend it: Newton was *not miſtaken* in ſaying, that colour depends upon the ſize and the denſity of the particles of bodies; his miſtake lay in ſuppoſing that it depends upon theſe *alone*.

393
Why bodies change their colour.

5. Since the colour of bodies depends upon their affinity for light, and ſince every body has a certain colour, becauſe it abſorbs and retains particular rays while it tranſmits or reflects the reſt, it is evident that every body muſt continue of its firſt colour till one of two things happen; either till it be ſaturated with the rays which it abſorbs, and of courſe ceaſe to abſorb any more, or till its particles change their nature, by being either decompoſed or combined with ſome new ſubſtance. We have no poſitive proof that the firſt cauſe

lours. cauſe of change ever occurs, as many ſubſtances have been expoſed to the action of light for a very long time without any change of colour. The abſorbed light ſeems to make its eſcape, either in its own form, or in ſome unknown or unſuſpected one. The ſecond cauſe of change is very common: indeed its action may be detected in almoſt every caſe of alteration in the colour of bodies. The green oxide of iron, by combining with oxygen, becomes red; and this red oxide, when combined with pruſſic acid, aſſumes a blue colour, and with gallic acid a black colour. The cauſe of this change of colour, when the compoſition of a body changes, is obvious: every change of compoſition muſt alter the affinity, becauſe it muſt of neceſſity produce changes in the ſize, denſity, or figure of the particles, or perhaps in all of theſe. Now if the affinity of a body for other bodies be altered, it is natural to ſuppoſe that it will be altered alſo for light. Accordingly this happens in moſt inſtances. It does not, however, take place conſtantly, for very obvious reaſons. It may happen that the new denſity, ſize, or figure of the altered body is ſuch, as to render it ſtill proper for attracting the very ſame rays of light which it formerly attracted. Juſt as iron, after being combined with a certain doſe of oxygen, is converted into green oxide, which ſtill retains an affinity for oxygen.

It is evident from all this, that in moſt caſes the permanence of colour in bodies will depend upon the permanence of their compoſition, or on the degree of facility with which they are acted upon by thoſe bodies, to the agency of which they are expoſed.

394 rmanence of colour great importance in ing.

In *dyeing*, the permanence of colour is of very great importance. Of what value is the beauty of a colour, provided that colour be fugitive or liable to change into ſome other. In all caſes, therefore, it is of conſequence to attend to the ſubſtances to which dyed cloth is expoſed, and to aſcertain their action upon every particular dyeing ingredient. Now the bodies to which dyed cloth is almoſt conſtantly expoſed are *air* and *light;* the combined action of which has ſo much influence, that very few dyes can reſiſt it.

395 w dyes e their lour.

It is evident that thoſe ſubſtances cannot retain their colour, which have ſuch an affinity for oxygen as enables them to take it from atmoſpheric air. Thus the green colour of green oxide of iron and of indigo is not permanent, becauſe theſe ſubſtances readily abſorb oxygen from air. In order, then, that a colour can have any permanence, the coloured body muſt not have ſo great an affinity for oxygen as to be able to take it from air. Thoſe bodies have in general the moſt permanent colours which are already ſaturated with oxygen, and therefore not liable to abſorb more. Such is the caſe with red oxide of iron.

All coloured bodies are compounds; ſome of thoſe only excepted which ſtill retain an affinity for oxygen. Coloured bodies, therefore, are compoſed of ſeveral ingredients; and in every coloured body, at leaſt *ſome* of the ingredients have a ſtrong affinity for oxygen. Now, before the colour of a body can be permanent, its ingredients muſt be combined together by ſo ſtrong affinities, that oxygen gas is unable to decompoſe it by combining with one or more of its ingredients and carrying it off. If this decompoſition take place at once, it is impoſſible for the colour of a body to have any permanence. If it takes place ſlowly, the colour of the body gradually decays. The action of oxygen gas upon bodies is much increaſed in particular circumſtances. Almoſt all coloured bodies are decompoſed by oxygen gas by the aſſiſtance of heat. Thus if wheat flour be expoſed to the heat of 448°, it loſes its white colour, and becomes firſt brown and then black. At this temperature it is decompoſed, and a part, or even the whole of its hydrogen, combining with oxygen, flies off. Cloth is ſcarcely ever expoſed to ſo high a temperature; but there are other circumſtances in which it may be placed which may have a ſimilar effect. Thus the action of light ſeems in ſome ſubſtances to be ſimilar to that of heat, and to facilitate the decompoſition of the coloured matter by the combination of ſome of its ingredients with oxygen *.

Coloured bodies, in order to have permanent colours, muſt not be liable to be decompoſed by other ſubſtances more than by oxygen. For inſtance, if they contain oxygen and hydrogen, theſe two bodies muſt not be liable to combine together and form water, nor muſt oxygen and carbon be liable to combine and form carbonic acid gas. Light ſeems to have a tendency to decompoſe many bodies in this manner, and even to carry off oxygen from them in the form of oxygen gas. Thus it renders the nitrat of ſilver black by carrying off part of its oxygen, and it reduces oxy-muriatic acid to common muriatic acid by the ſame means.

* Berthollet on Dyeing, i. 45.

Theſe are the cauſes which induce a change in the colour of coloured bodies, as far as they have been traced; namely, the addition of oxygen, the abſtraction of oxygen, partial decompoſition by ſome one of their ingredients combining with oxygen, complete or partial decompoſition by the ingredients entering into new combinations with each other. The coloured matters uſed in dyeing are very liable to theſe changes, becauſe they are in general animal or vegetable ſubſtances of a very compound nature. Of courſe their ingredients have often no very ſtrong affinity for each other, and therefore are very liable to decompoſition; and every one of the ingredients has in general a very ſtrong affinity for oxygen. This renders the choice of proper colouring matters for dyeing a very important point. In order to have permanency, they muſt not be liable to the above changes, not to mention their being able alſo to withſtand the action of ſoap, acids, alkalies, and every other ſubſtance to which dyed cloth may be expoſed.

396 Method of aſcertaining the permanency of dyes.

It becomes therefore a point of ſome conſequence to be able to aſcertain whether cloth dyed of any particular colour be permanently dyed or not. The proper method of aſcertaining this is by actually expoſing ſuch cloth to the ſun and air; becauſe as theſe are the agents to which it is to be expoſed, and which have the moſt powerful action, it is clear, that if it withſtand them, the colour muſt be conſidered as permanent. But this is a tedious proceſs. Berthollet propoſed expoſing ſuch cloth to the action of oxy-muriatic acid; thoſe colours that withſtand it being conſidered as permanent. This method anſwers in many caſes: but it is not always to be depended on; for it deſtroys ſome permanent colours very ſpeedily, and does not alter others which are very fading *. But we ſhall have occaſion to reſume this ſubject afterwards.

* Bancroft, i. 49.

397 Diviſion of colours.

Dyers divide colours into two claſſes; namely, *ſimple* and *compound*. The ſimple colours are thoſe which cannot

cannot be produced by the mixture of other colours. They are in number four.

1. Blue, 3. Red,
2. Yellow, 4. Black.

Some add a fifth, *brown;* but it may be produced by combining two others.

The compound colours are thoſe which are produced by mixing together any two ſimple colours in various proportions. They conſtitute all the colours except the four ſimple and their various ſhades.

Thus we have examined the nature of colours; but we have ſtill to explain the method of giving permanent colours to cloth. This ſhall be the ſubject of the next chapter.

CHAP. III. OF DYEING IN GENERAL.

FROM the theory of colour laid down in the laſt chapter, it follows, that permanent alterations in the colour of cloth can only be induced two ways; either by producing a chemical change in the cloth, or by covering its fibres with ſome ſubſtance which poſſeſſes the wiſhed-for colour. Recourſe can ſeldom or never be had to the firſt method, becauſe it is hardly poſſible to produce a chemical change in the fibres of cloth without ſpoiling its texture and rendering it uſeleſs. The dyer, therefore, when he wiſhes to give a new colour to cloth, has always recourſe to the ſecond method.

398 Dye-ſtuffs

1. The ſubſtances employed for this purpoſe are called *colouring matters*, or *dye ſtuffs*. They are for the moſt part extracted from *animal and vegetable ſubſtances*, and have uſually the colour which they are intended to give to the cloth. Thus a blue colour is given to cloth by covering its fibres with indigo, a blue powder extracted from a ſhrub; a red colour, by the colouring matter extracted by water from an inſect called *cochineal*, or from the root of a plant called *madder*.

399 Do not reflect light.

2. Mr Delaval has publiſhed a very intereſting ſet of experiments on colouring matters in the ſecond volume of the Mancheſter Memoirs. He has proved, by a very numerous ſet of experiments, that they are all tranſparent, and that they do not *reflect* any light, but only tranſmit it: For every colouring matter which he tried, even when diſſolved in a liquid, and forming a tranſparent coloured ſolution, when ſeen merely by reflected light, was black, whatever was the colour of the matter; but when ſeen by tranſmitted light, it appeared of its natural colour *. This diſcovery, which Mr Delaval has eſtabliſhed very completely, and to which, as far at leaſt as dye ſtuffs are concerned, there are but few exceptions, is of very great importance to the art of dyeing, and explains ſeveral particulars which would otherwiſe be unintelligible.

* *Manch. Mem.* ii. 131.

Since the particles of the colouring matter with which cloth, when dyed, is covered, are tranſparent, it follows, that all the light reflected from dyed cloth muſt be reflected, not by the dye ſtuff itſelf, but by the fibres of the cloth below the dye ſtuff. The colour therefore does not depend upon the dye alone, but alſo upon the previous colour of the cloth. If the cloth be *black*, it is clear that we cannot dye it any colour whatever; becauſe as no light in that caſe is reflected, none can be tranſmitted, whatever dye ſtuff we employ. If the cloth were red, or blue, or yellow, we could not dye it any colour except black; becauſe as only red, or blue, or yellow rays were reflected, no other could be tranſmitted (x). Hence the importance of a fine white colour when cloth is to receive bright dyes: It then reflects all the rays in abundance: and therefore any colour may be given, by covering it with a dye ſtuff which tranſmits only ſome particular rays.

400 They muſt be combined with the cloth.

3. If the colouring matters were merely ſpread over the ſurface of the fibre of cloth by the dyer, the colours produced might be very bright, but they could not be permanent; becauſe the colouring matter would be very ſoon rubbed off, and would totally diſappear whenever the cloth was waſhed, or even barely expoſed to the weather. The colouring matter, then, however perfect a colour it poſſeſſes, is of no value, unleſs it alſo adheres ſo firmly to the cloth, that none of the ſubſtances uſually applied to cloth in order to clean it, &c. can diſplace it. Now this can only happen when there is a ſtrong *affinity* between the colouring matter and the cloth, and when they are actually combined together in conſequence of that affinity.

401 Can only be applied in a ſtate of ſolution.

4. Dyeing, then, is merely a chemical proceſs, and conſiſts in combining a certain colouring matter with the fibres of cloth. This proceſs can in no inſtance be performed, unleſs the dye ſtuff be firſt reduced to its integrant particles; for the attraction of aggregation between the particles of dye ſtuffs is too great to be overcome by the affinity between them and cloth, unleſs they could be brought within much ſmaller diſtances than is poſſible, while they both remain in a ſolid form. It is neceſſary, therefore, previouſly to diſſolve the colouring matter in ſome liquid or other, which has a weaker affinity for it than the cloth has. When the cloth is dipped into this ſolution, the colouring matter, reduced by this contrivance to a liquid ſtate, is brought within the attracting diſtance; the cloth therefore acts upon it, and by its ſtronger affinity takes it from the ſolvent, and fixes it upon itſelf. By this contrivance, too, the equality of the colour is in ſome meaſure ſecured, as every part of the cloth has an opportunity of attracting to itſelf the proper proportion of colouring particles.

The facility with which cloth imbibes a dye, depends upon two things, namely, the affinity between the cloth and the dye ſtuff, and the affinity between the dye ſtuff and its ſolvent. It is directly as the former, and inverſely as the latter. It is of importance to preſerve a due proportion between theſe two affinities, as upon that proportion much of the accuracy of dyeing depends. If the affinity between the colouring matter and the cloth be too great, compared with the affinity between the colouring matter and the ſolvent, the cloth will take the dye too rapidly, and it will be ſcarce poſſible to prevent its colour from being unequal. On the other hand, if the affinity between the colouring matter and the ſolvent be too great, compared with that

(x) Theſe remarks hold only on the ſuppoſition, that the *whole* of the ſurface is of the given colour, which in many inſtances is not the caſe.

ing in neral. that between the colouring matter and the cloth, the cloth will either not take the colour at all, or it will take it very ſlowly and very faintly.

Wool has the ſtrongeſt affinity for almoſt all colouring matters, ſilk the next ſtrongeſt, cotton a conſiderably weaker affinity, and linen the weakeſt affinity of all. Therefore, in order to dye cotton or linen, the dye ſtuff ſhould in many caſes be diſſolved in a ſubſtance for which it has a weaker affinity than for the ſolvent employed in the dyeing of wool or ſilk. Thus we may uſe oxide of iron diſſolved in ſulphuric acid, in order to dye wool; but for cotton and linen, it is better to diſſolve it in acetous acid.

2 ure of dants. 5. Were it poſſible to procure a ſufficient number of colouring matters having a ſtrong affinity for cloth, to anſwer all the purpoſes of dyeing, that art would be exceedingly ſimple and eaſy. But this is by no means the caſe: if we except indigo, the dyer is ſcarcely poſſeſſed of a dye ſtuff which yields of itſelf a good colour ſufficiently permanent to deſerve the name of a dye.

This difficulty, which at firſt ſight appears inſurmountable, has been obviated by a very ingenious contrivance. Some ſubſtance is pitched upon which has a ſtrong affinity both for the cloth and the colouring matter. This ſubſtance is previouſly combined with the cloth, which is then dipped into the ſolution containing the dye ſtuff. The dye ſtuff combines with the intermediate ſubſtance; which, being firmly combined with the cloth, ſecures the permanence of the dye. Subſtances employed for this purpoſe are denominated *mordants* (Y).

The moſt important part of dyeing is undoubtedly the proper choice and the proper application of mordants, as upon them the permanence of almoſt every dye depends. Every thing which has been ſaid reſpecting the application of colouring matters, applies equally to the application of mordants. They muſt be previouſly diſſolved in ſome liquid, which has a weaker affinity for them than the cloth has to which they are to be applied; and the cloth muſt be dipped, or even ſteeped, in this ſolution, in order to ſaturate itſelf with the mordant.

Almoſt the only ſubſtances uſed as mordants are, earths, metallic oxides, tan, and oil.

3 y ants. 6. Of earthy mordants, by far the moſt important and moſt generally uſed is alumina. It was uſed as a mordant in very early ages, and ſeems indeed to have been the very firſt ſubſtance employed for that purpoſe. Alumina has a very ſtrong affinity for wool and for ſilk; but its affinity for cotton and linen is a good deal weaker.

It is uſed as a mordant in two ſtates; either in the ſtate of alum, in which it is combined with ſulphuric acid and a little potaſs; or in the ſtate of acetite of alumina, in which it is combined with acetous acid.

Alum was employed as a mordant very early. The ancients, indeed, do not ſeem to have been generally acquainted with pure alum; they uſed it in that ſtate of impurity in which it is found native; of courſe it was uſed in dyeing long before the nature of its ingredients was underſtood, and therefore long before the part which it acts was ſuſpected. Indeed, it is but a very ſhort time ſince the office which mordants perform was ſuſpected: the firſt perſon that hit upon it was Mr Keir; he gave an account of the real uſe of mordants in his tranſlation of Macquer's Dictionary, publiſhed in 1771 *. Dyeing in General.

Alum, when uſed as a mordant, is diſſolved in water, and very frequently a quantity of tartar is diſſolved along with it. Into this ſolution the cloth is put and kept in it till it has abſorbed as much alumina as is neceſſary. It is then taken out, and for the moſt part waſhed and dried. It is now a good deal heavier than it was before, owing to the alumina which has combined with it. The tartar ſerves two purpoſes: the potaſs which it contains combines with the ſulphuric acid of the alum, and thus prevents that very corroſive ſubſtance from injuring the texture of the cloth, which otherwiſe might happen; the tartarous acid, on the other hand, combines with part of the alumina, and forms a tartrite of alumina, which is more eaſily decompoſed by the cloth than alum.

* Macquer, p. 215.

Acetite of alumina has been introduced into dyeing ſince the commencement of the 18th century; and, like many other very important improvements, we are indebted for it to the ignorance of the calico printers, who firſt introduced it. As they did not underſtand the nature nor uſe of the mordants which they employed, they were accuſtomed to mix with their alum an immenſe farrago of ſubſtances, a great proportion of which are injurious inſtead of being of ſervice. Some one or other had mixed with alum acetite of lead: the good effects of this mixture would be ſoon perceived; the quantity of acetite was gradually increaſed, and the other ingredients omitted *. This mordant is now prepared, by pouring acetite of lead into a ſolution of alum: a double decompoſition takes place, the ſulphuric acid combines with the lead, and the compound precipitates in the form of an inſoluble powder; while the alumina combines with the acetous acid, and remains diſſolved in the liquid. This mordant is employed for cotton and linen, which have a weaker affinity than wool for alumina. It anſwers much better than alum, the cloth is more eaſily ſaturated with alumina, and takes, in conſequence, both a richer and a more permanent colour.

* Bancroft, p. 176.

Beſides alumina, *lime* is ſometimes uſed as a mordant. Cloth has a ſtrong enough affinity for it; but in general it does not anſwer ſo well, as it does not give ſo good a colour. When uſed, it is either in the ſtate of lime-water or of ſulphat of lime diſſolved in water.

7. Almoſt all the metallic oxides have an affinity for cloth; but only two of them are extenſively uſed as mordants, namely, the oxides of tin and of iron. 404 Metallic mordants.

The oxide of tin was firſt introduced into dyeing by Kuffer (Z), a German chemiſt, who brought the ſecret to London in 1543. This period forms an era in the hiſtory of dyeing. The oxide of tin has enabled the moderns

4 I 2

(Y) This term, impoſed by the French dyers before the action of mordants was underſtood, ſignifies *biters* or *corroders*. Theſe bodies were ſuppoſed to act merely by corroding the *cloth*. Mr Henry of Mancheſter has propoſed to ſubſtitute the word *baſis* for *mordant*; but that word is too general to anſwer the purpoſe well.

(Z) Mr Delaval has ſuppoſed, that the Tyrians were acquainted with the uſe of tin in dyeing, and Mr Henry

Dyeing in General.

moderns greatly to furpafs the ancients in the finenefs of their colours: by means of it alone, *fcarlet*, the brighteft of all colours, is produced. The method of producing the celebrated purple dye of the ancients is underftood at prefent, and the fhell fifh which yield the dye-ftuff are found abundantly on the coafts of Britain and France; but no perfon thinks now of putting the ancient mode in practice, becaufe infinitely more beautiful colours can be produced at a fmaller price. Much of this fuperiority is owing to the employment of the oxide of tin.

Tin, as Prouft has proved, is capable of two degrees of oxydation: The firft oxide is compofed of 0.70 parts of tin, and 0.30 of oxygen; the fecond, or white oxide, of 0.60 parts of tin, and 0.40 of oxygen *. The firft oxide abforbs oxygen with very great facility even from the air, and is rapidly converted into white oxide. This fact makes it certain, that it is the white oxide of tin alone which is the real mordant: even if the other oxide were applied to cloth, as it probably often is, it muft foon be converted into white oxide, by abforbing oxygen from the atmofphere.

* *Ann. de Chim.* xxviii. 213.

Tin is ufed as a mordant in three ftates; diffolved in nitro muriatic acid, in acetous acid, and in a mixture of fulphuric and muriatic-acids. Nitro-muriat of tin is the common mordant employed by dyers. They prepare it by diffolving tin in diluted nitric acid, to which a certain proportion of muriat of foda, or of ammonia, is added. Part of the nitric acid decompofes thefe falts, combines with their bafe, and fets the muriatic acid at liberty. They prepared it at firft with nitric acid alone; but that mode was very defective; becaufe the nitric acid very readily converts tin to white oxide, and then is incapable of diffolving it. The confequence of which was, the precipitation of the whole of the tin. To remedy this defect, common falt, or fal-ammoniac, was very foon added, muriatic acid having the property of diffolving white oxide of tin very readily. A confiderable faving of nitric acid might be obtained, by employing as much fulphuric acid as is juft fufficient to faturate the bafe of the common falt, or fal-ammoniac, employed.

When the nitro-muriat of tin is to be ufed as a mordant, it is diffolved in a large quantity of water, and the cloth is dipped in the folution, and allowed to remain till fufficiently faturated. It is then taken out, and wafhed and dried. Tartar is ufually diffolved in the water along with the nitro-muriat. The confequence of this is a double decompofition; the nitro muriatic acid combines with the potafs of the tartar, while the tartarous acid diffolves the oxide of tin. When tartar is ufed, therefore, in any confiderable quantity, the mordant is not a nitro-muriat, but a tartrite of tin.

Mr Hauffman, to whom the art of dyeing lies under numerous obligations, has propofed to fubftitute acetite of tin for nitro-muriat as a mordant for cotton and linen. It may be prepared by mixing together acetite of lead and nitro-muriat of tin. This mordant is preferable for thefe ftuffs; becaufe it is much more eafily decompofed than the nitro-muriat †.

† *Ann. de Chim.* xxx. 15.

Dr Bancroft has propofed to fubftitute a folution of tin in a mixture of fulphuric and muriatic acid, inftead of nitrio-muriat of tin, as a mordant for wool. This mordant, he informs us, is much cheaper, and equally efficacious. It may be prepared by diffolving fomewhat lefs than one part of tin in two parts of fulphuric and three of muriatic acid, at the degree of concentration at which they are commonly fold in this country ‡. This mordant, like the others, muft be diffolved in a fufficient quantity of water, in order to be ufed.

‡ *Bancroft* p. 290.

Iron, like tin, is capable of two degrees of oxydation; but the green oxide abforbs oxygen fo readily from the atmofphere, that it is very foon converted into the red oxide. It is only this laft oxide which is really ufed as a mordant in dyeing. The green oxide is indeed fometimes applied to cloth; but it very foon abforbs oxygen, and is converted into the red oxide. This oxide has a very ftrong affinity for all kinds of cloth. The permanency of the iron fpots on linen and cotton is a fufficient proof of this. As a mordant, it is ufed in two ftates; in that of fulphat of iron, and acetite of iron. The firft is commonly ufed for wool. The falt is diffolved in water, and the cloth dipped in it. It may be ufed alfo for cotton; but in moft cafes acetite of iron is preferred. It is prepared by diffolving iron, or its oxide, in vinegar, four beer, &c. and the longer it is kept, the more is it preferred. The reafon is, that this mordant fucceeds beft when the iron is in the ftate of red oxide. It would be better then to oxydate the iron, or convert it into ruft, before ufing it; which might eafily be done, by keeping it for fome time in a moift place, and fprinkling it occafionally with water. Of late, pyrolignous acid has been introduced inftead of acetous. It is obtained by diftilling wood or tar.

405 Tan.

8. Tan, which has been already defcribed in the firft part of this article, has a very ftrong affinity for cloth, and for feveral colouring matters. It is therefore very frequently employed as a mordant. An infufion of *nut galls*, or of *fumach* (A), or any other fubftance containing tan, is made in water, and the cloth is dipped in this infufion, and allowed to remain till it has abforbed a fufficient quantity of tan. Silk is capable of abforbing a very great proportion of tan, and by that means acquires a very great increafe of weight. Manufacturers fometimes employ this method of increafing the weight of filk *.

* *Bertholet*, ii. 10

Tan is often employed alfo, along with other mordants, in order to produce a compound mordant. Oil is alfo ufed for the fame purpofe in the dyeing of cotton and linen. The mordants, with which tan moft frequently is combined, are alumina and oxide of iron.

406 Other mordants.

Befides thefe mordants, there are feveral other fubftances frequently ufed as auxiliaries, either to facilitate the combination of the mordant with the cloth, or to alter

---

ry has declared himfelf of the fame opinion. But this reafoning, as Dr Bancroft has fhewn, proceeds upon a miftake. He fuppofes that tin is *neceffary* for the production of red colours.

(A) Sumach is the *rhus coriaria*; a fhrub which is cultivated in the fouthern parts of Europe. Its fhoots are dried, afterwards ground to powder; in which ftate they are fold to the dyer and tanner.

'yeing in General.

alter the ſhade of colour. The chief of theſe are, *tartar, acetite of lead, common ſalt, ſal ammoniac, ſulphat* or *acetite of copper*, &c.

407 ordants ect the our.

9. Mordants not only render the dye permanent, but have alſo conſiderable influence on the colour produced. The ſame colouring matter produces very different dyes, according as the mordant is changed. Suppoſe, for inſtance, that the colouring matter be cochineal; if we uſe the aluminous mordant, the cloth will acquire a crimſon colour; but the oxide of iron produces with it a black. Theſe changes, indeed, might naturally have been expected: for ſince the colour of a dye ſtuff depends upon its affinity for light, every new combination into which it enters, having a tendency to alter theſe affinities, will naturally give it a new colour. Now, in all caſes, the colouring matter and mordant combine together: the colour of the cloth, then, muſt be that which the particles of the dye and of the mordant, when thus combined together, exhibit. Indeed ſome mordants may be conſidered in the light of colouring matters alſo, as they always communicate a particular colour to cloth. Thus, iron communicates a brown colour, and iron and tan together conſtitute a black dye.

In dyeing, then, it is not only neceſſary to procure a mordant, which has a ſufficiently ſtrong affinity for the colouring matter and the cloth, and a colouring matter which poſſeſſes the wiſhed-for colour in perfection, we muſt procure a mordant and a colouring matter of ſuch a nature, that when *combined together* they ſhall poſſeſs the wiſhed-for colour in perfection. It is evident, too, that a great variety of colours may be produced with a ſingle dye-ſtuff, provided we can change the mordant ſufficiently.

408 w applied.

10. Every thing which tends to weaken the affinity between the mordant and the cloth, or between the mordant and the colouring matter, and every thing which tends in any way to alter the nature of the mordant, muſt injure the permanency of the dye: becauſe, whenever the mordant is deſtroyed, there is no longer any thing to cauſe the dye ſtuff to adhere; and when its nature is altered, the colour of the dye muſt alter at the ſame time. All the obſervations, then, which were made in the laſt chapter, concerning the nature of colouring matters, and the changes to which they are ſubject, apply equally to mordants. Theſe ſubſtances, indeed, are ſcarcely liable themſelves to any alteration. They are of a much more ſimple nature, in general, than dye ſtuffs; and therefore not nearly ſo liable to decompoſition. But when the colouring matter itſelf is altered, it comes to the ſame thing. Its affinity for the mordant being now deſtroyed, there is nothing to retain it.

As the permanency of a dye depends upon the degree of affinity between the mordant and the colouring matter, it is clear that the dye may want permanency, even though it reſiſt the oxy muriatic acid, and all the other ſaline teſts propoſed by chemiſts. Theſe ſubſtances may happen to have very little action on the dye-ſtuff, and therefore may not affect it; yet it may ſoon diſappear, in conſequence of its want of affinity for the mordant.

11. The colouring matter with which cloth is dyed, does not cover every portion of its ſurface; its particles attach themſelves to the cloth at certain diſtances from each other: for cloth may be dyed different ſhades of the ſame colour, lighter or darker, merely by varying the quantity of colouring matter. With a ſmall quantity, the ſhade is light; and it becomes deeper as the quantity increaſes. Now this would be impoſſible, if the dye-ſtuff covered the whole of the cloth. Newton has demonſtrated, that colours are rendered faint when the rays of light which occaſion them are mixed with white rays. Conſequently, from cloth dyed of a light ſhade, a conſiderable quantity of white rays paſſes off unchanged: but this could not be the caſe if the ſtuff were covered with coloured matter; becauſe all the white rays would be decompoſed as they paſs through the coloured matter. Therefore, in light ſhades, the colouring matter does not cover the cloth; its particles adhere to it, at a certain diſtance from each other, and from every part of the cloth which is uncovered, the white rays paſs off unchanged. Even when the ſhade of colour is as deep as poſſible, the colouring particles do not cover the whole of the cloth, but are at a certain diſtance from each other. This diſtance, undoubtedly, is diminiſhed in proportion to the deepneſs of the ſhade: for the deeper the ſhade, the ſmaller is the number of white rays which eſcape undecompoſed; the more, therefore, of the ſurface is covered, and, conſequently, the ſmaller is the diſtance at which each each of them is placed. A ſhade may be even conceived ſo very deep, that not a particle of white light eſcapes the action of the colouring matter; in which caſe, the diſtance between the particles of colouring matter could not exceed double that diſtance at which a particle of matter is able to act upon light.

Dyeing in General.

409 Dye ſtuffs do not cover the whole ſurface of the cloth.

410 Compound colours.

That the particles of colouring matter, even when the ſhade is deep, are at ſome diſtance, is evident from this well-known fact, that cloth may be dyed two colours at the ſame time. All thoſe colours, to which the dyers give the name of *compound*, are in fact two different colours applied to the cloth at once. Thus cloth gets a *green* colour, by being firſt dyed *blue* and then *yellow*. The rays of light that paſs from green cloth thus dyed are blue and yellow; by the mixture of which it is well known that green is produced. In this caſe, it is clear, that each of the colouring matters performs the very ſame office as if it were alone; and that the new colour is not produced by the combination of the two colouring matters. That part of the white light, reflected from the cloth, which paſſes through the blue colouring matter, is decompoſed, and the blue rays only tranſmitted; and that part of the white light which paſſes through the yellow colouring matter is alſo decompoſed, and only the yellow rays tranſmitted. It is clear, therefore, that both of the colouring matters equally cover the naked fibres of the cloth; conſequently the one muſt be placed in the intervals of the other: wherefore the particles of each of the colouring matters are at ſome diſtance. Now the ſame effect happens how deep ſoever the ſhade be; and it makes no difference which of the two dyes be firſt given. Nay, if one of the dyes have a ſtrong affinity for the cloth, and the other only a weak affinity, the latter will ſoon diſappear, and leave the cloth of the colour which the firſt dye gives it.

The difference, then, in the ſhade of colour, and alſo the compound colours which cloth may receive, depend entirely upon the diſtance between the particles of the colouring matters attached to the cloth, and the poſſibi-

lity

Blue. lity of partly filling up the intervals, either with the ſame colouring matter, or with a different one.

Thus we have taken a view of the theory of dyeing, as far, at leaſt, as it is at preſent underſtood. It remains for us ſtill to give an account of the particular manner by which each of the colours is imparted to cloth. This ſhall be the ſubject of the three following chapters. In the *firſt*, we ſhall treat of the manner of dyeing the ſimple colours; in the *ſecond*, of dyeing the compound colours; and in the *third*, of dyeing cloth partially ſeveral different colours at the ſame time, or of that branch of the art of dyeing which is known in this country by the name of *calico printing*.

CHAP. IV. OF DYEING SIMPLE COLOURS.

THE colours denominated by dyers *ſimple*, becauſe they are the foundation of all their other proceſſes, are four; namely, *1ſt*, blue;—*2d*, yellow;—*3d*, red;—*4th*, black. To theſe they uſually add a fifth, under the name of *root*, or brown colour. Theſe ſhall form the ſubject of the following ſections.

SECT. I. *Of Blue.*

411 Blue dyes. THE only colouring matters employed in dyeing blue are *woad* and *indigo*: attempts, indeed, have been made to dye with pruſſiat of iron; but theſe attempts have hitherto failed.

412 Woad. 1. The *iſatis tinctoria*, or *woad*, is a plant commonly enough cultivated in this kingdom, and even found wild in ſome parts of England. It is of a yellowiſh colour. Some perſons think that it was this plant with which the ancient Britons ſtained their bodies, to make them appear terrible to their enemies. When arrived at maturity, this plant is cut down, waſhed, dried haſtily in the ſun, ground in a mill, placed in heaps, and allowed to ferment for a fortnight; then well mixed together, formed into balls, which are piled upon each other, and expoſed to the wind and ſun. In this ſtate they gradually become hot, and exhale a putrid ammoniacal ſmell. The fermentation is promoted, if neceſſary, by ſprinkling the balls with water. When it has continued for a ſufficient time, the woad is allowed to fall to a coarſe powder. In this ſtate it is ſold to the dyers.

413 Indigo, 2. Indigo, is a blue coloured powder extracted from the *indigofera tinctoria*, and from ſeveral other ſpecies of the ſame genus of plants, which are cultivated for that purpoſe both in the Eaſt and Weſt Indies.

414 How prepared. When the *indigofera* has arrived at maturity, it is cut a few inches above ground, placed in ſtrata in a large veſſel, and covered with water. The plants ſoon acquire heat, ferment, and diſcharge abundance of carbonic acid gas. When the fermentation is far enough advanced, which is judged of by the paleneſs of the leaves, the liquid, now of a green colour, is decanted into large flat veſſels, where it is conſtantly agitated till blue flocculæ begin to make their appearance. Lime water is now poured in, which cauſes the blue flocks to precipitate. The colourleſs liquid is decanted off, and the blue ſediment poured into linen bags. When the water has drained from it ſufficiently, it is formed into ſmall lumps, and dried in the ſhade. In this ſtate it is ſold to the dyer under the name of *indigo*.

Dr Roxbourgh, who firſt drew the attention of manufacturers to the *nerium tinctorium*, a tree very common in Indoſtan, from the leaves of which indigo may be extracted with much advantage, has given a much ſhorter method of obtaining that pigment. The leaves are kept in a copper full of water, ſupported at the temperature of 160°, till they aſſume a yellowiſh hue, and the liquid acquire a deep green colour. The liquid is then to be drawn off, agitated in the uſual manner, till the blue flocculæ appear; and then the indigo is to be precipitated with lime water *. * Bancroft i. 423.

This proceſs, which ſucceeds equally well with the indigofera, ſhews us that the plants, from which indigo may be extracted, contain a peculiar green pollen, ſoluble in water. The intention, both of the fermentation of the common method, and of the ſcalding, according to Dr Roxbourgh's method, is merely to extract this pollen. Mr Hauſſman firſt ſhewed, that this green baſis of indigo has a ſtrong affinity for oxyen; and the ſubſequent experiments of Drs Roxbourgh and Bancroft have confirmed his obſervations, and put them beyond the reach of doubt. It gradually attracts oxygen from the air; in conſequence of which it acquires a blue colour, and becomes inſoluble in water. The agitation is intended to facilitate this abſorption, by expoſing a greater ſurface to the action of the air. The lime water, by abſorbing a quantity of carbonic acid, with which the green pollen ſeems to be combined, greatly facilitates the ſeparation of the indigo.

The method of preparing indigo, and of applying it to the purpoſes of dyeing, ſeems to have been very early known in India. But in Europe, though it had been occaſionally uſed as a paint *, its importance as a dye ſtuff was not underſtood before the middle of the 16th century. It is not even mentioned in the *Plictho*, which was publiſhed in 1548. At that period, then, the uſe of indigo muſt have been unknown to the Italian dyers. The Dutch were the people who firſt imported it from India, and made its importance known in Europe. It was afterwards cultivated in Mexico and the Weſt Indies with ſuch ſucceſs, that the indigo from theſe countries was preferred to every other. In conſequence of this preference, they ſupplied almoſt the whole of the European market. But within theſe few years, the Eaſt Indian indigo, owing entirely to the enlightened exertions of ſome of our own countrymen, has recovered its character, and is now imported, in very conſiderable quantities, into Britain. * Plinii, l. 35. c. 6.

The indigo of commerce has different ſhades of colour, according to the manner in which it has been prepared, and the proportion of foreign ſubſtances with which it is mixed. The principal ſhades are copper colour, violet, and blue. That indigo, which has the ſmalleſt ſpecific gravity, is always moſt eſteemed; becauſe it is moſt free from impurities. Bergman † found the pureſt indigo of commerce which he could procure, compoſed of † Berg. v. 36.

47	pure indigo,

100 (B)	

Pure

(B) Prouſt informs us, that he found magneſia, even abundantly, in indigo.—*Nicholſon's Jour.* III. 325.

Blue.

415 Proper-ties. Pure indigo is inſoluble in water, alcohol, æther, and oils: neither alkalies nor earths have any action on it: none of the acids hitherto tried have any effect on it, except the nitric and ſulphuric. Nitric acid very ſoon converts it into a dirty white colour, and at laſt decompoſes it completely *. When the acid is concentrated, it even ſets fire to the indigo (c); when it is diluted, the indigo becomes brown, cryſtals make their appearance, reſembling thoſe of oxalic and tartarous acids: and there remains behind, after the acid and the cryſtals are waſhed off, a viſcid ſubſtance, of a very bitter taſte, and poſſeſſing many of the properties of a reſin †.

erg. v.

Hauſſman.

Concentrated ſulphuric acid diſſolves indigo readily, and much heat is evolved. The ſaturated ſolution is opaque, and conſequently black; but it aſſumes a deep blue colour when diluted with water. This ſolution is well known in commerce under the name of *liquid blue*. Bancroft has given it the name of *ſulphat of indigo*. During the ſolution of the indigo, ſome ſulphurous acid, and ſome hydrogen gas, are evolved ‡, and the blue colour of the indigo is much heightened. Theſe facts have led Bancroft to ſuppoſe, that the indigo, during its ſolution, combines with an additional quantity of oxygen *. This *may* poſſibly be the caſe, but the phenomena are not ſufficient to eſtabliſh it: for the hydrogen gas and ſulphurous acid evolved may owe their formation, not to the action of the ſulphuric acid on indigo, but upon the impurities with which it is always mixed; and the improvement of the colour may be owing to the abſence of theſe impurities. The carbonats of fixed alkalies precipitate ſlowly from ſulphat of indigo a blue coloured powder, which poſſeſſes the properties of indigo; but it is ſoluble in moſt acids and in alkalies. Pure alkalies deſtroy the colour and properties of ſulphat of indigo: they deſtroy alſo precipitated indigo §. Theſe facts give ſome probability to Bancroft's opinion; but they do not eſtabliſh it: becauſe the differences between common and precipitated indigo may depend merely on the ſtate of greater minuteneſs to which it is reduced, which prevents the attraction of aggregation from obſtructing the action of other bodies. Even ſilica, when newly precipitated, is ſoluble in many menſtrua.

Bancroft, &c. — rg v.

416 Method of dyeing with ſulphat of indigo. 3. Indigo has a very ſtrong affinity for wool, ſilk, cotton, and linen. Every kind of cloth, therefore, may by dyed with it, without the aſſiſtance of any mordant whatever. The colour thus indeed is very permanent; becauſe the indigo is already ſaturated with oxygen, and becauſe it is not liable to be decompoſed by thoſe ſubſtances, to the action of which the cloth is expoſed. But it can only be applied to cloth in a ſtate of ſolution; and the only ſolvent known being ſulphuric acid, it would ſeem at firſt ſight that the ſulphuric acid ſolution is the only ſtate in which indigo can be employed as a dye.

The ſulphat of indigo is indeed often uſed to dye wool and ſilk blue; but it can ſcarcely be applied to cotton and linen, becauſe the affinity of theſe ſubſtances for indigo is not great enough to enable them readily to decompoſe the ſulphat. The colour given by ſulphat of indigo is exceedingly beautiful: it is known by the name of Saxon blue; becauſe the proceſs, which was diſcovered by councellor Barth in 1740, was firſt carried on at Groſſenhayn in Saxony. The method of the original inventor was very complicated, from the great number of uſeleſs ingredients which were mixed with the ſulphat. But theſe ingredients were gradually laid aſide, and the compoſition ſimplified by others, after the nature of it, which was for ſome time kept ſecret, became known to the public. The beſt proceſs is that of Mr Poerner *.

One part of indigo is to be diſſolved in four parts of concentrated ſulphuric acid; to the ſolution one part of dry carbonat of potaſs is to be added, and then it is to be diluted with eight times its weight of water. The cloth muſt be boiled for an hour in a ſolution, containing five parts of alum and three of tartar for every 32 parts of cloth. It is then to be thrown into a water bath, containing a greater or ſmaller proportion of the diluted ſulphat of indigo, according to the ſhade which the cloth is intended to receive. In this bath it muſt be boiled till it has acquired the wiſhed for colour. The alum and tartar are not intended to act as mordants, but to facilitate the decompoſition of the ſulphat of indigo. Bergman aſcertained that alum poſſeſſes this property. The alkali added to the ſulphat anſwers the ſame purpoſe. Theſe ſubſtances, alſo, by ſaturating part of the ſulphuric acid, ſerve, in ſome meaſure, to prevent the texture of the cloth from being injured by the action of the acid, which is very apt to happen in this proceſs.

* *Instruction ſur l'Art de la Teinture*, p. 183.

417 Method of dyeing by decompoſing indigo.

4. But ſulphat of indigo is by no means the only ſolution of that pigment employed in dyeing. By far the moſt common method, and indeed the only method known before 1740, is to deprive indigo of the oxygen to which it owes its blue colour, and thus to reduce it to the ſtate of green pollen; and then to diſſolve it in water by means of alkalies, or alkaline earths, which in that ſtate act upon it very readily. Indigo is preciſely in the ſtate of green pollen when it is firſt extracted from the plant in the ſcalding proceſs deſcribed by Dr Roxbourgh. If, therefore, there were any method of ſtopping ſhort here, and of ſeparating the pigment while it retains its green colour, it would be preciſely in the ſtate beſt adapted for dyeing. Nothing more would be neceſſary but to diſſolve it in water by means of an alkali, and to dip the cloth into the ſolution †.

† Bancroft.

But as indigo is not brought home to us in that ſtate, the dyer is under the neceſſity of undoing the laſt part of the indgo-maker's proceſs, by ſeparating again the oxygen, and reſtoring it to its original green colour. Two different methods are employed for this purpoſe. The firſt of theſe methods is to mix with indigo a ſolution of ſome ſubſtance which has a ſtronger affinity for oxygen than the green baſis of indigo. Green oxide of iron, for inſtance, and different metallic ſulphurets. If, therefore, indigo, lime, and green ſulphat of iron, be mixed together in water, the indigo gradually

(c) The combuſtion of indigo by nitric acid, of the denſity 1.52°, was firſt publiſhed by Mr Sage; but Woulfe appears to have obſerved the fact before him, and to have pointed it out to Rouelle, who ſhewed it in his lectures. *Prouſt, Nicholſon's Jour.* III. 325.

Blue

gradually loses its blue colour, becomes green, and is dissolved, while the green oxide of iron is converted into the red oxide. The manner in which these changes take place is obvious. Part of the lime decomposes the sulphat of iron; the green oxide, the instant that it is set at liberty, attracts oxygen from the indigo, decomposes it, and reduces it to the state of green pollen. This green pollen is immediately dissolved by the action of the rest of the lime. In like manner, indigo is dissolved when mixed in water, with pure antimony and potass, or with sulphuret of arsenic and potass. For these interesting facts we are indebted to Mr Hausmann.

The second method is to mix the indigo in water with certain vegetable substances which readily undergo fermentation. During this fermentation, the indigo is deprived of its oxygen, and dissolved by means of quicklime or alkali, which is added to the solution. The first of these methods is usually followed in dyeing cotton and linen; the second in dyeing wool and silk.

418 How to induce a blue colour on wool,

5. In the dyeing of wool, woad and bran are commonly employed as vegetable ferments, and lime as the solvent of the green base of the indigo. Woad contains itself a colouring matter precisely similar to indigo; by following the common process, indigo may be extracted from it. In the usual state of woad, when purchased by the dyer, the indigo which it contains is probably not far from the state of green pollen. Its quantity in woad is but small, and it is mixed with a great proportion of other vegetable matter. Before the introduction of indigo into Europe, woad alone was employed as a blue dye; and even as late as the 17th century, the use of indigo was restricted in different countries, and dyers obliged to employ a certain quantity of woad (D). But these absurd restrictions were at last removed, and woad is now scarcely used in dyeing, except as a ferment to indigo. The blue colouring matter, however, which it contains, must, in all cases, contribute considerably to the dye.

A sufficient quantity of woad, mixed with bran, is put into a wooden vessel filled with warm water, whose temperature is kept up sufficiently to ensure fermentation. Afterwards quicklime and indigo are added. The indigo is deprived of its oxygen, and dissolved by the lime. When the solution is complete, the liquid has a green colour, except at the surface, where it is copper coloured, or blue, because the indigo at the surface absorbs oxygen from the air, and assumes its natural colour. The woollen cloth is dipped in, and passed thro' the liquid as equably as possible, piece after piece; those pieces being first dyed which are to assume the deepest shade. No part of the cloth should come in contact with the sediment, which would spoil the colour. When the cloth is first taken out of the vat, it is of a green colour; but it soon becomes blue, by attracting oxygen from the air. It ought to be carefully washed, to carry off the uncombined particles. This solution of indigo is liable to two inconveniences: 1. It is apt sometimes to run too fast into the putrid fermentation: this may be known by the putrid vapours which it exhales, and by the disappearing of the green colour. In this state it would soon destroy the indigo altogether. The inconvenience is remedied by adding more lime, which has the property of moderating the putrescent tendency. 2. Sometimes the fermentation goes on too languidly. This defect is remedied by adding more bran or woad, in order to diminish the proportion of quicklime.

6. Silk is usually dyed blue by the following process: Six parts of bran, and six of indigo, with nearly one part of madder, are stirred into a sufficient quantity of water, in which six parts of common potash of commerce is dissolved. The liquid is kept at a temperature proper for fermentation. When the indigo, deprived of its oxygen by the fermentation, is dissolved by the potass, the liquid assumes a green colour. The silk, previously well scoured, is put into the solution in small quantities at a time; then wrung out of the dye, and hung up in the open air, till the green colour which it has at first is changed into blue. By this method silk can only be made to receive a light blue colour. In order to give silk a dark blue, it must previously receive what is called a ground colour; that is, be previously dyed some other colour. A particular kind of red dye-stuff, called *archil* (E), is commonly employed for this purpose. 419 Silk,

The madder employed in the above process may, at first sight, appear superfluous: it seems, however, to contribute something to the colour.

420 Cotton, linen,

7. Cotton and linen are dyed blue by the following process: One part of indigo, one part of green sulphat of iron, and two parts of quicklime, are stirred into a sufficient quantity of water. The solution is at first green, but it gradually assumes a yellow colour, and its surface is covered with a shining copper-coloured pellicle. The cloth is to be allowed to remain in the solution for five or six minutes. When taken out, it has a yellow colour; but on exposure to the atmosphere, it soon becomes green, and then blue, in consequence of the absorption of oxygen. The indigo, in this process, seems to be deprived of a greater quantity of oxygen than is necessary to reduce it to the state of green pollen. Mr Hausman has observed, that the cloth acquires a much deeper colour, provided it be plunged, the instant it is taken out of the dyeing vat, into water acidulated with sulphuric acid. It is usual to dip the cloth into a succession of vats, variously charged with colouring matter; beginning with the vat which contains least colouring matter, and passing gradually to those which contain most. By this contrivance the cloth is dyed more equally than it probably would be, if it were plunged all at once into a saturated solution of colouring matter.

SECT. II. *Of Yellow.*

421 Yellow dyes.

THE principal colouring matters employed to dye yellow are *weld*, *fustic*, and *quercitron bark*.

1. Reseda luteola, known in this country by the name of

(D) The employment of Indigo was strictly prohibited in England in the reign of Queen Elizabeth; nor was the prohibition taken off till the reign of Charles II. It was prohibited also in Saxony. In the edict it is spoken of as a corrosive substance, and called *food for the devil*. Colbert restricted the French dyers to a certain quantity of it.

(E) This will be described in a subsequent section.

Yellow.

of *weld*, is a plant which grows wild very commonly in Scotland, and in moft European countries. Cultivated
422 Weld. weld has a more flender ftem than the wild kind, but it is more valuable, becaufe it is much more rich in colouring matter. It is an annual plant, of a yellowifh green colour, furnifhed with a great number of fmall leaves. When ripe it is pulled, dried, tied up in parcels, and in that ftate fold to the dyer.

Weld readily yields its colouring matter to water. The faturated decoction of it is brown; but when fufficiently diluted with water it becomes yellow. Acids render its colour fomewhat paler, but alkalies give it a deeper fhade. When alum is added to it, a yellow coloured precipitate falls down, confifting of alumina combined with the colouring matter of weld. The affinity therefore of this colouring matter for alumina is fo great, that it is able to abftract it from fulphuric acid. Its affinity for oxide of tin is at leaft equally great; for muriat of tin caufes a copious bright yellow precipitate, compofed of the colouring matter and the oxide combined. Moft of the metallic falts occafion fimilar precipitates, but varying in colour according to the metal employed. With iron, for inftance, the precipitate is drak grey, and with copper brownifh green *.

* Berthollet, ii. 260.

423 Fustic. 2. The *morus tinctoria* is a large tree which grows in the Weft India iflands. The wood of this tree is of a yellow colour, with orange veins. The French call it *yellow wood* (*bois jaune*); but the Englifh dyers have given it the abfurd name of *old fuftic* (F). This wood has been introduced into dyeing fince the difcovery of America. The precife time is not known; but that it was ufed in England foon after the middle of the 17th century, is evident from Sir William Petty's paper on *Dyeing*, read to the Royal Society foon after its inftitution. In that paper particular mention is made of *old fuftic*.

Fuftic gives out its colouring matter with great facility to water. The faturated decoction of it is of a deep reddifh yellow colour; when fufficiently diluted it becomes orange yellow. Acids render it turbid, give it a pale yellow colour, and occafion a flight greenifh precipitate, which alkalies rediffolve. Alkalies give the decoction a very deep colour, inclining to red; fome time after they have been added, a yellow matter feparates from the liquid, and either fwims on the furface, or adheres to the fides of the veffel. Alum, fulphat of iron, of copper, and of zinc, produce precipitates compofed of the colouring matter combined refpectively with the bafes of thefe different falts; and the colour varies according to the fubftance with which this colouring matter is combined. With alumina it is yellow; with iron, yellowifh brown; with copper, brownifh yellow; and with zinc, greenifh brown †.

† [Bancroft,] ii.

424 Quercitron. 3. The *quercus nigra*, to which Dr Bancroft has given the name of *quercitron*, is a large tree which grows naturally in North America. Dr Bancroft difcovered, about the year 1784, that the bark of this tree contains a great quantity of yellow colouring matter, and fince that time it has been introduced into dyeing with much advantage. To prepare it for the dyer, the epidermis is fhaved off, and then it is ground in a mill. It feparates partly into ftringy filaments, and partly into a fine light powder. Both of thefe contain colouring matter, and therefore are to be employed; but as they contain unequal quantities, they fhould be ufed in their natural proportions.

Quercitron bark readily gives out its colouring matter to water at the temperature of 100°. The infufion has a yellowifh brown colour, which is rendered lighter by acids, and darker by alkalies. Alum occafions a fcanty precipitate of a deep yellow colour; muriat of tin, a copious bright yellow precipitate; fulphat of tin, a dark olive precipitate; and fulphat of copper, a precipitate of a yellow colour inclining to olive ‡.

‡ Bancroft, i. 320.

425 Other yellow dyes. 4. Befides thefe dye ftuffs there are others occafionally ufed by dyers. The following are the moft remarkable:

Geniſta tinctoria, or *dyers broom*. This plant yields a very inferior yellow; it is only ufed for coarfe woollen ftuffs.

Serratula tinctoria, or *faw-wort*. This plant yields a yellow nearly of the fame nature with *weld*; for which, therefore, it is a good fubftitute.

Juglans alba, or *American hiccory*. The bark of this tree yields a colouring matter exactly fimilar to that of quercitron bark, but much fmaller in quantity.

Anotta is a name given to a red pafte formed of the berries of the bixa orellana, a tree which is a native of America. This pafte yields its colouring matter to a folution of alkali in water. The folution affords an exceedingly beautiful yellow dye, but very fading, and incapable of being fixed by any known mordant.

Turmeric is the root of the *curcuma longa*, a plant which grows both in the Eaft and Weft Indies. It is richer in colouring mater than any other yellow dye ftuff. It yields very beautiful yellows, but too fading to be of much ufe, and no mordant has any influence in contributing to their permanence.

426 Yellow requires a mordant. 5. Yellow colouring matters have too weak an affinity for cloth to produce permanent colours without the ufe of mordants. Cloth, therefore, before it be dyed yellow, is always prepared by combining fome mordant or other with it. The mordant moft commonly employed for this purpofe is alumina. Oxide of tin is fometimes ufed when very fine yellows are wanted. Tan is often employed as a fubfidiary to alumina, in order to fix it more copioufly on cotton and linen. Tartar is alfo ufed as an auxiliary to brighten the colour; and muriat of foda, fulphat of lime, and even fulphat of iron, in order to render the fhade deeper.

6. The yellow dyed by means of fuftic is more permanent, but not fo beautiful as that given by weld or quercitron. As it is permanent, and not much injured by acids, it is often ufed in dyeing compound colours where

(F) The *rhus cotinus*, or Venice fumach, is a fmall fhrub, formerly employed as a yellow dye, but now almoft out of ufe. The French call it *fuftet*, from which word it is probable, as Dr Bancroft fuppofes, that our dyers formed the term *fuftic*. When the *morus tinctoria* was introduced as a dye-ftuff, they gave it the fame name: but in order to diftinguifh the two, they called the fumach, which was a fmall fhrub, *young fuftic*; and the morus, which was a large tree, *old fuftic*. See *Bancroft*, i. 412.

Yellow.

where a yellow is required. The mordant is alumina. When the mordant is oxide of iron, fustic dyes a good permanent drab colour.

Weld and quercitron bark yield nearly the same kind of colour; but as the bark yields colouring matter in much greater abundance, it is much more convenient, and, upon the whole, cheaper than weld. It is probable therefore, that it will gradually supersede the use of that plant. The method of using each of these dye

427 stuffs is nearly the same.

Method of inducing a yellow colour on wool,

7. Wool may be dyed yellow by the following process: Let it be boiled for an hour, or more, with about $\frac{1}{5}$th of its weight of alum, dissolved in a sufficient quantity of water. It is then to be plunged, without being rinced, into a bath of warm water, containing in it as much quercitron bark as equals the weight of the alum employed as a mordant. The cloth is to be turned through the boiling liquid till it has acquired the intended colour. Then a quantity of clean powdered chalk, equal to the hundredth part of the weight of the cloth, is to be stirred in, and the operation of dyeing continued for eight or ten minutes longer. By this method a pretty deep and lively yellow may be given fully as permanent as weld yellow *.

* Bancroft, i, 352.

For very bright *orange*, or *golden yellows*, it is necessary to have recourse to the oxide of tin as a mordant. A fine orange yellow may be given to woollen cloth, by putting, for every ten parts of cloth, one part of bark into a sufficient quantity of hot water; after a few minutes, an equal weight of murio-sulphat of tin is to be added, and the mixture well stirred. The cloth acquires the wished-for colour in a few minutes when briskly turned in this bath †.

† Ibid. 329.

The same process will serve for producing *bright golden yellows*, only some alum must be added along with the tin. For the brightest golden yellow, the proportions sufficient for dyeing 100 parts of cloth are, 10 parts of bark, 7 parts of murio-sulphat of tin, and 5 parts of alum. All the possible shades of golden yellow may be given to cloth merely by varying the proportion of the ingredients according to the shade ‡.

‡ Ibid. 330.

In order to give the yellow that delicate *green* shade so much admired for certain purposes, the same process may be followed, only tartar must be added in different proportions according to the shade. Thus to dye 100 parts of cloth a *full bright yellow*, delicately inclining to *green*, 8 parts of bark, 6 of murio-sulphat, 6 of alum, and 4 of tartar, are to be employed. The tartar is to be added at the same time with the other mordants. If the proportion of alum and tartar be increased, the green shade is more lively: to render it as lively as possible, all the four ingredients ought to be employed in equal proportions. As these fine lemon-yellows are generally required only pale, 10 parts of each of the ingredients will be sufficient to dye about 300 parts of cloth §.

§ Ibid.

By adding a small proportion of cochineal, the colour may be raised to a fine orange, or even an aurora ‖.

‖ Ibid. 335.

428 Silk,

8. Silk may be dyed different shades of yellow, either by weld or quercitron bark, but the last is the cheapest of the two. The proportion should be from 1 to 2 parts of bark to 12 parts of silk, according to the shade. The bark, tied up in a bag, should be put into the dyeing vessel while the water which it contains is cold, and when it has acquired the heat of about 100°, the silk, previously alumed, should be dipped in, and continued till it assumes the wished-for colour. When the shade required is deep, a little chalk or pearlash should be added towards the end of the operation. When a very lively yellow is wanted, a little murio-sulphat of tin should be added, but not too much, because tin always injures the glossiness of silk. The proportions may be 4 parts of bark, 3 of alum, and 2 of murio-sulphat of tin ¶.

¶ Bancroft, i. 345.

Silk is dyed fine orange and aurora colours by anotta. The process is merely dipping the silk into an alkaline solution of anotta. To produce the orange shade the alkali is saturated with lemon juice. The colours thus produced are exceedingly beautiful, but they want permanency.

429 Cotton, and linen.

9. The common method of dyeing cotton and linen yellow, has been described in the article DYEING in the *Encyclopædia*. The cloth is first soaked in a solution of alum, and then dyed in a decoction of weld. After this it is soaked for an hour in a solution of sulphat of copper, and, lastly, it is boiled for an hour in a solution of hard soap. This process, besides the expence of it, is defective; because the yellow is neither so beautiful nor so permanent as it might be if the mordant were used in a different form.

The method recommended by Dr Bancroft is much more advantageous, yielding more permanent and beautiful colours at a smaller expence. The mordant should be acetite of alumina, prepared by dissolving 1 part of acetite of lead, and 3 parts of alum, in a sufficient quantity of water. This solution should be heated to the temperature of 100°, the cloth should be soaked in it for two hours, then wrung out and dried. The soaking may be repeated, and the cloth again dried as before. It is then to be barely wetted with lime water, and afterwards dried. The soaking in the acetite of alumina may be again repeated; and if the shade of yellow is required to be very bright and durable, the alternate wetting with lime water, and soaking in the mordant, may be repeated three or four times. By this contrivance a sufficient quantity of alumina is combined with the cloth, and the combination is rendered more permanent by the addition of some lime. The dyeing bath is prepared by putting 12 or 18 parts of quercitron bark (according to the depth of the shade required), tied up in a bag, into a sufficient quantity of cold water. Into this bath the cloth is to be put, and turned round in it for an hour, while its temperature is gradually raised to about 120°. It is then to be brought to a boiling heat, and the cloth allowed to remain in it after that only a few minutes. If it be kept long at a boiling heat the yellow acquires a shade of brown *.

* Ibid. 351.

Another way of dyeing cotton and linen very permanent yellows, would be to imitate the method adopted for dyeing cotton in the East. That method is indeed exceedingly tedious, but it might be very much shortened by carefully attending to the uses of the ingredients. The essential part of the process is to cause the alumina to combine in sufficient quantity with the cloth, and to adhere with sufficient firmness to ensure a permanent colour. This is accomplished by using three mordants; first oil, then tan, and lastly alum. The combination of these three substances produces a mordant which ensures a very permanent colour.

The cotton is first soaked in a bath composed of a sufficient quantity of oil, and mixed with a weak solution

Yellow. tion of soda. Animal oil seems to answer best for the purpose. Vogler found that glue answered extremely well. The soda should be caustic: In that state it combines with the oil, and enables the cloth to absorb it equally. It is then, after being washed, put into an infusion of nut galls (the whiter the better). The tan combines with the oil, while the gallic acid carries off the alkali that may remain attached to the cloth The infusion ought to be hot; and the cotton, after coming out of it, should be dried as quickly as possible Care should be taken that the quantity of galls do not exceed a just proportion compared with the oil, otherwise the colour will be darkened. The cotton, thus prepared, is to be put into a solution of alum. There is a strong affinity between tan and alumina; in consequence of which, the alum is decomposed, and the alumina combines with the tan in sufficient abundance †. The cotton, thus prepared, is to be dyed, as above described, with quercitron bark.

† *Chaptal, Ann. de Chim.* xxvi. 251.

430 Chaptal's process for cotton.

Mr Chaptal, whose ingenious labours have contributed exceedingly to elucidate the theory of dyeing, has proposed an exceedingly simple and cheap method of dyeing cotton a fine permanent nankeen yellow. His process is as follows (G).

Cotton has so strong an affinity for oxide of iron, that if put into a solution of that oxide in any acid whatever, it decomposes the salt, absorbs the iron, and acquires a yellow colour. The cotton to be dyed is to be put into a cold solution of sulphat of iron, of the sp. gr. 1.020; it is then wrung out, and put directly into a ley of potass, of the sp. gr. 1.010, into which a solution of alum has been poured till it was saturated with it. After the cotton has remained in this bath four or five hours, it may be taken out, washed, and dried. By this process cotton may be dyed all the different shades of nankeen, by varing the proportion of the sulphat of iron. This colour has the advantage of not being injured by washing, and of being exceedingly cheap §.

§ *Ibid.* 270.

SECT. III. *Of* RED.

431 Red dyes.

THE principal colouring matters employed in dyeing *red* are, *kermes*, *cochineal*, *archil*, *madder*, *carthamus*, and *Brazil wood*.

432 Kermes,

1. In different parts of Asia and the south of Europe, there grows a small species of oak, to which Linnæus gives the name of *quercus coccifera*. On this oak resides a small insect, of a reddish brown colour; in commerce it is known by the name of *kermes*. This insect is a species of *coccus*: Linnæus called it *coccus ilicis*. These insects are gathered in the month of June when the female, which alone is useful, is swelled with eggs. They are steeped for ten or twelve hours in vinegar to kill the young insects contained in the eggs, and afterwards dried on a linen cloth. In this state they are sold to the dyer.

Kermes readily gives out its colouring matter to water or alcohol. It was much used by the ancients in dyeing; the colours which it produced were highly esteemed, being inferior in price only to their celebrated purple. They gave it the name of *coccus*.

The colour which it communicates to cloth is exceedingly permanent, but being far inferior in beauty to those which may be obtained from cochineal, it has been but little employed by dyers since that splendid pigment came into common use. Red.

433 Cochineal,

2. Cochineal is likewise an insect, a species of *coccus*. Linnæus distinguishes it by the name of *coccus cacti*. It inhabits different species of cacti, but the most perfect variety is confined to the *cactus coccinillifer*. The cochineal insect was first discovered in Mexico; the natives had employed it in their red dyes before the arrival of the Spaniards. It became known in Europe soon after the conquest of Mexico; and the beauty of the colour which it communicates to cloth very soon attracted general attention For many years it was mistaken for a vegetable production, as had been the case also with the kermes. Different accounts of its real nature had indeed appeared very early in the Philosophical Transactions; but the opinion of Pomet, who insisted that it was the seed of a particular plant, gained so much credit, that it was not entirely destroyed till the publication of Mr Ellis's paper in the 52d volume of the Philosophical Transactions, which established the contrary beyond the possibility of doubt.

The female cochineal insect remains like the kermes, during her whole life adhering to a particular spot of the tree on which it feeds. After fecundation, her body serves merely as a nidus for her numerous eggs, and gradually swells as these advance towards maturity. In this state the insects are gathered, put into a linen bag, which is dipt into hot water to destroy the life of the young animals contained in the eggs, and then dried. In this state they are sent to Europe and sold to the dyer.

The quantity of cochineal disposed of in Europe is very great. Bancroft informs us, that the Spaniards annually bring to market about 600,000 lbs. of it. Hitherto the rearing of the insects has belonged almost exclusively to that nation. Other nations have indeed attempted to share it with them, but without any remarkable success; as the Spaniards use every precaution to confine the true cochineal, and even the species of cactus on which it feeds, to Mexico. Mr Thiery de Menonville was fortunate enough to procure some specimens of both, and to transfer them in safety to St Domingo; but after his death, the insects were allowed to perish. The wild cochineal insect, which differs from the cultivated kind merely in being smaller, and containing less colouring matter, was produced in St Domingo, in considerable quantities, before the commencement of the late war. Several spirited British gentlemen have lately contrived to procure the insect; and vigorous efforts are making to rear it in the East Indies. We have not yet learned the success of these attempts; but we have reason to hope every thing from the zeal and abilities of those gentlemen who have taken an active part in the enterprize.

Cochineal readily gives out its colouring matter to water. The decoction is of a crimson colour, inclining to violet: It may be kept for a long time without putrefying or losing its transparency. Sulphuric acid gives

(G) We ought to menton, that this process, or at least one very similar, has been long well known to the calico printers of this country. Most of their brown yellows, or drabs, are dyed with iron.

Red.

gives it a red colour, inclining to yellow, and occasions a small fine red precipitate. Tartar gives it a yellowish red colour, which becomes yellow after a small quantity of red powder has subsided. Alum brightens the colour of the decoction, and occasions a crimson precipitate. Muriat of tin gives a copious fine red precipitate; sulphat of iron, a brownish violet precipitate; sulphat of zinc, a deep violate precipitate; acetite of lead, and sulphat of copper, violet precipitates †.

† Berthollet, ii. 173.

Water is not capable of extracting the whole of the colouring matter of cochineal; but the addition of a little alkali or tartar enables the water to extract the whole of it *.

* Ibid. 175. and Bancroft, i. 271.

434 Archil,

3. Archil (H) is a paste formed of the *lichen roccella*, pounded and kept moist for some time with stale urine. It gives out its colouring matter to water, to alcohol (I), and to a solution of ammonia in water.

The lichen roccella grows abundantly in the Canary islands, from which it is imported and sold to the dyers. Other lichens are likewise used to dye red, especially the *parellus*, from which the pigment called *litmus*, and by chemists *turfole*, is prepared; the *omphalodes* and *tartareous*, which are often employed in this country to dye coarse cloths. To these many others might be added; but the reader may consult the treatises of Hoffman and Westring on the subject.

435 Madder,

4. The *rubia tinctorum* is a small well known plant, cultivated in different parts of Europe for the sake of its roots, which are known by the name of *madder*. They are about the thickness of a goose quill, somewhat transparent, of a reddish colour, and a strong smell. They are dried, cleaned, ground in a mill, and in that state used by dyers.

Madder gives out its colouring matter to water. The infusion is of a brownish orange-colour; alum produces in it a deep brownish red precipitate; alkaline carbonats, a blood red precipitate, which is redissolved on adding more alkali. The precipitate occasioned by acetite of lead is brownish red; by nitrat of mercury, purplish brown; by sulphat of iron, a fine bright brown. After the red colouring matter has been extracted from madder by water, it is still capable of yielding a brown colour ‡.

‡ Berthollet, ii. 115.

436 Carthamus.

5. *Carthamus tinctorious* is an annual plant, cultivated in Spain, Egypt, and the Levant, for the sake of its flowers, which alone are used in dyeing. After the juice has been squeezed out of these flowers, they are washed repeatedly with salt water, pressed between the hands, and spread on mats to dry. Care is taken to cover them from the sun during the day, and to expose them to the evening dews, in order to prevent them from drying too fast. Such is the method followed in Egypt.

The flowers of carthamus contain two colouring matters; a yellow, which is soluble in water, and a red, insoluble in water, but soluble in alkaline carbonats. The method of preparing them above described, is intended to carry off the yellow colouring matter, which is of no use, and to leave only the red. After the flowers are thus prepared, they are of a red colour, and have lost nearly one-half of their weight. An alkaline ley readily extracts their colouring matter, which may be precipitated by saturating the alkali with an acid. Lemon juice is commonly used for this purpose, because it does not injure the colour of the dye. Next to citric, sulphuric acid is to be preferred, provided too great a quantity be not used. The red colouring matter of carthamus, extracted by carbonat of soda, and precipitated by lemon juice, constitutes the *rouge* employed by the ladies as a paint. It is afterwards ground with a certain quantity of talc. The fineness of the talc, and the proportion of it mixed with the carthamus, occasion the difference between the cheaper and dearer kinds of *rouge*.

6. *Brazil wood*, or *fernambouc*, as it is called by the French, is the wood of the *cæsalpinia crista*, a tree which grows naturally in America and the West Indian islands. It is very hard; its specific gravity is greater than that of water; its taste is sweetish: its colour, when fresh cut, is pale; but after exposure to the atmosphere, it becomes reddish. 437 Brazil wood.

Brazil wood yields its colouring matter to alcohol, and likewise to boiling water. The decoction is of a fine red colour. The mineral acids make it yellow, and occasion a reddish brown precipitate. Oxalic acid causes an orange red precipitate. Fixed alkali gives the decoction a crimson colour, inclining to brown; ammonia, bright purple. Alum occasions a copious crimson precipitate, especially if alkali is added at the same time. Sulphat of iron renders the decoction black. The precipitate produced by muriat of tin is rose coloured; that by acetite of lead of a fine deep red *.

The decoction of Brazil wood is fitter for dyeing after it has stood some time, and undergone a kind of fermentation.

* Berthollet, ii. 240.

7. None of the red colouring matters has so strong an affinity for cloth as to produce a permanent red, without the assistance of mordants. The mordants employed are alumina and oxide of tin; oil and tan, in certain processes, are also used; and tartar and muriat of soda are frequently called in as auxiliaries. 438 Red requires a mordant.

8. Coarse woollen stuffs are dyed red with madder or

(H) If we believe Tournefort, this dye-stuff was known to the ancients. They employed it to dye the colour known by the name of *purple* of Amorgos, one of the Cyclades islands. If this account be accurate, the knowledge of it had been lost during the dark ages. It was accidentally discovered by a Florentine merchant about the year 1300, who observed, that urine gave a very fine colour to the lichen roccella. Mr Dufay discovered, that archil possesses the property of tinging indelibly white marble, of forming veins, and giving it the appearance of jasper. See *Mem. Par.* 1732.

(I) The tincture of archil is used for making *spirit of wine thermometers*. It is a singular fact, that this tincture becomes gradually colourless when excluded from the contact of air, and that it again recovers its colour when exposed to the atmosphere. The phenomenon was first observed by the Abbé Nollet, and described by him in an essay, published among the memoirs of the Academy of Sciences for 1742.

Red. or archil; but fine cloth is almost exclusively dyed with cochineal; though the colour which it receives from kermes is much more durable. Brazil wood is scarcely used, except as an auxiliary; because the colour which it imparts to wool is not permanent.

439 Wool how dyed crimson, Wool is dyed *crimson*, by first impregnating it with alumina by means of an alum bath, and then boiling it in a decoction of cochineal till it has acquired the wished-for colour. The crimson will be finer if the tin mordant be substituted for alum: indeed it is usual with dyers to add a little nitro-muriat of tin when they want fine crimsons. The addition of archil and potass to the cochineal, both renders the crimson darker and gives it more bloom; but the bloom very soon vanishes. For paler crimsons, one-half of the cochineal is withdrawn, and madder substituted in its place.

440 And scarlet. Wool may be dyed *scarlet*, the most splendid of all colours, by first boiling it in a solution of murio-sulphat of tin; then dyeing it pale yellow with quercitron bark, and afterwards crimson with cochineal: For scarlet is a compound colour, consisting of *crimson* mixed with a little *yellow*. This method was suggested by Dr Bancroft, who first explained the nature of the common method. The proportions which he gives are eight parts of murio-sulphat of tin for a 100 parts of cloth. After the cloth has been boiled in this solution for a quarter of an hour, it is to be taken out, and about four parts of cochineal, and two and a half parts of quercitron bark, are to be thrown into the bath. After these are well mixed, the cloth is to be returned again to the bath, and boiled in it, till it has acquired the proper colour *.

* Bancroft, i. 291.

The common process for dyeing scarlet is as follows: Twelve parts of tartar are dissolved in warm water; then one part of cochineal is added, and soon after ten parts of nitro-muriat of tin. When the bath boils, 100 parts of cloth are put in, turned briskly through the bath, boiled in it for two hours; then taken out, aired, washed, and dried. Into another bath eleven parts of cochineal are put; and after its colouring matter is sufficiently extracted, 28 parts of nitro-muriat of tin are added. In this bath the cloth is boiled for an hour, and then washed and dried.

Every preceding writer on dyeing took it for granted, that the yellow tinge necessary for scarlet was produced by the nitro-muriat of tin, or rather by the nitric acid of that compound, and that the tartar was only useful in enlivening the colour. But Dr Bancroft ascertained, by actual experiment, that nitro-muriat of tin has no such effect; that cloth, impregnated with this or any other tin mordant, and afterwards dyed with cochineal, acquires only a crimson colour, unless tartar be added; that the tartar has the property of converting part of the cochineal to yellow; and therefore is the real agent in producing the scarlet colour. Good scarlet, indeed, cannot be made without tin; because every other mordant sullies the colour, and renders it dull †.

† Ibid. 288.

441 Red dyes employed for silk, 9. Silk is usually dyed red with cochineal or carthamus, and sometimes with Brazil wood. Kermes does not answer for silk; madder is scarcely ever used for that purpose, because it does not yield a bright enough colour. Archil is employed to give silk a bloom; but it is scarcely used by itself, unless when the colour wanted is lilac.

Silk may be dyed crimson by steeping it in a solution of alum, and then dyeing it in the usual way in a cochineal bath. But the common process is to plunge the silk, after it has been alumed, into a bath formed of the following ingredients: Two parts of white galls, three parts of cochineal, three-sixteenths of tartar, and three sixteenths of nitro-muriat of tin, for every sixteen parts of silk. The ingredients are to be put into boiling water in the order they have been enumerated; the bath is then to be filled up with cold water; the silk put into it, and boiled for two hours. After the bath has cooled, the silk is usually allowed to remain in it for three hours longer. Red. 442 In dyeing crimson,

The colours known by the names of poppy, cherry, rose, and flesh colour, are given to silk by means of carthamus. The process consists merely in keeping the silk, as long as it extracts any colour, in an alkaline solution of carthamus, into which as much lemon juice as gives it a fine cherry colour has been poured. To produce a deep poppy red, the silk must be put successively into a number of similar baths, and allowed to drain them. When the silk is dyed, the colour is brightened by plunging it into hot water acidulated with lemon juice. The silk ought to be previously dyed yellow with anotta. 443 Poppy,

Cherry red is produced the same way, only the anotta ground is omitted, and less colouring matter is necessary. When a flesh colour is required, a little soap should be put into the bath, which softens the colour, and prevents it from taking too quickly. 444 Cherry, 445 Flesh red,

To lessen the expence, some archil is often mixed with carthamus for dark shades.

The same shades may be dyed by means of Brazil wood, but they do not stand.

Silk cannot be dyed a full scarlet; but a colour approaching to scarlet may be given it, by first impregnating the stuff with murio-sulphat of tin, and afterwards dyeing it in a bath composed of four parts of cochineal and four parts of quercitron bark. To give the colour more body, both the mordant and the dye may be repeated *. A colour approaching scarlet may be also given to silk, by first dyeing it crimson, then dyeing it with *carthamus*, and lastly yellow without heat †. 446 Scarlet.

* Bancroft, i. 312.

† Berthollet, ii. 203.

10. Cotton and linen are dyed red with madder. The process was borrowed from the East; hence the colour is often called *Adrianople* or *Turkey red*. The cloth is first impregnated with oil, then with galls, and lastly with alum, in the manner described in the last section. It is then boiled for an hour in a decoction of madder, which is commonly mixed with a quantity of blood. After the cloth is dyed, it is plunged into a soda ley, in order to brighten the colour. The red given by this process is very permanent, and when properly conducted it is exceedingly beautiful. The whole difficulty consists in the application of the mordant, which is by far the most complicated employed in the whole art of dyeing. 447 How to dye cotton and linen red.

Cotton may be dyed scarlet by means of murio-sulphat of tin, cochineal, and quercitron bark, used as for silk; but the colour is too fading to be of any value *.

* Bancroft, i. 316.

SECT. IV. *Of Black.*

448 Black dyes. 1. THE substances employed to give a black colour to cloth are red oxide of iron and tan. These two substances

Black. ftances have a ftrong affinity for each other; and when combined, affume a deep black colour, not liable to be deftroyed by the action of air and light. The affinity which each of them has for the different kinds of cloth has been already mentioned.

2. Logwood is ufually employed as an auxiliary, becaufe it communicates luftre, and adds confiderably to the fulnefs of the black. It is the wood of the tree called by Linnæus *hæmatoxylum campechianum*, which is a native of feveral of the Weft India iflands, and of that part of Mexico which furrounds the bay of Honduras. It yields its colouring matter to water. The decoction is at firft a fine red bordering on violet, but if left to itfelf it gradually affumes a black colour. Acids give it a deep red colour; alkalies a deep violet, inclining to brown. Sulphat of iron renders it as black as ink, and occafions a precipitate of the fame colour. The precipitate produced by alum is dark red; the fupernatent liquid becomes yellowifh red *.

* *Berthollet*, ii. 255.

3. Cloth, before it receive a black colour, is ufually dyed blue. This renders the colour much fuller and finer than it otherwife would be. If the cloth be coarfe, the blue dye may be too expenfive; in that cafe a brown colour is given by means of walnut peels.

449 How to induce a black on wool, 4. Wool is dyed black by the following procefs. It is boiled for two hours in a decoction of nut galls, and afterwards kept for two hours more in a bath compofed of logwood and fulphat of iron, kept during the whole time at a fcalding heat, but not boiled. During the operation it muft be frequently expofed to the air; becaufe the green oxide of iron, of which the fulphat is compofed, muft be converted into red oxide by abforbing oxygen, before the cloth can acquire a proper colour. The common proportions are five parts of galls, five of fulphat of iron, and 30 of logwood for every 100 of cloth. A little acetite of copper is commonly added to the fulphat of iron, becaufe it is thought to improve the colour.

450 Silk, 5. Silk is dyed nearly in the fame manner. It is capable of combining with a very great deal of tan; the quantity given is varied at the pleafure of the artift, by allowing the filk to remain a longer or fhorter time in the decoction. After the galling, the filk is put into a folution of fulphat of iron, which is ufually mixed with a certain quantity of iron filings and of gum. It is occafionally wrung out of the bath, expofed for fome time to the air, and again immerfed. When it has acquired a fufficiently full colour, it is wafhed in cold water, and afterwards fteeped in a decoction of foap to take off the harfhnefs, which filk always has after being dyed black.

451 Linen, and cotton. 6. It is by no means fo eafy to give a full black to linen and cotton. The cloth, previoufly dyed blue, is fteeped for 24 hours in a decoction of nut galls. A bath is prepared, containing acetite of iron, formed by faturating acetous acid with brown oxide of iron. Into this bath the cloth is put in fmall quantities at a time, wrought with the hand for a quarter of an hour, then wrung out and aired, again wrought in a frefh quautity of the bath, and aftewards aired. Thefe alternate proceffes are repeated till the colour wanted is given. A decoction of alder bark is ufually mixed with the liquor containing the nut galls.

It would probably contribute to the goodnefs and permanence of the colour, if the cloth, before being galled, were impregnated with oil, by being fteeped in a mixture of alkaline ley and oil combined, as is practifed for dyeing cotton red.

SECT. V. *Of Brown*.

Brown. THAT particular *brown* colour, with a caft of *yellow*, which the French call *fauve*, and to which the Englifh writers on *dyeing* have appropriated the word *fawn*, though in fact a compound, is commonly ranked among fimple colours; becaufe it is applied to cloth by a fingle procefs. The fubftances employed to produce this colour are numerous; but we fhall fatisfy ourfelves with enumerating the following:

Walnut peels are the green covering of the walnut, When firft feparated, they are white internally; but foon affume a brown, or even a black colour, on expofure to the air. They readily yield their colouring matter to water. They are ufually kept in large cafks, covered with water, for above a year, before they are ufed. To dye wool brown with them, nothing more is neceffary than to fteep the cloth in a decoction of them till it has acquired the wifhed-for colour. The depth of the fhade is proportional to the ftrength of the decoction. The root, as well as the peel of the walnut tree, contains the fame colouring matter, but in fmaller quantity. The bark of the birch, alfo, and many other trees, may be ufed for the fame purpofe. 452 Brown dyes.

It is very probable, that the brown colouring matter is in thefe vegetable fubftances combined with tan. This is certainly the cafe in fumach, which is often employed to produce a brown. This combination explains the reafon why no mordant is neceffary; the tan has a ftrong affinity for the cloth, and the colouring matter for the tan. The dye ftuff and the mordant are already, in fact, combined together.

CHAP. V. Of Compound Colours.

COMPOUND colours are produced by mixing together two fimple ones; or, which is the fame thing, by dyeing cloth firft one fimple colour, and then another. The refult is a compound colour, varying in fhade according to the proportions of each of the fimple colours employed.

Compound colours are exceedingly numerous, varying almoft to infinity, according to the proportions of the ingredients employed. They may be all arranged under the four following claffes: 453 Division of compound colours.

Mixtures of 1. blue and yellow,
2. blue and red,
3. yellow and red,
4. black and other colours.

To defcribe all the different fhades which belong to each of thefe claffes, would be impoffible; and even if it were poffible, it would be unneceffary; becaufe all the proceffes depend upon the principles laid down in the preceding chapters, and may eafily be conceived and varied by thofe who underftand thefe principles. In the following fections, therefore, it will be fufficient to mention the principal compound colours produced by the mixture of fimple colours, and to exhibit a fpecimen or two of the mode of producing them.

SECT. I. *Of Mixtures of Blue and Yellow*.

THE colour produced by mixtures of blue and yellow is

Mixtures of Blue and Yellow. is *green;* which is diſtinguiſhed by dyers by a great variety of names, according to the depth of the ſhade, or the prevalence of either of the component parts. Thus we have *ſea green*, *meadow* or *graſs green*, *pea green*, &c. &c.

454 How to induce green 455 On wool, Wool is uſually dyed green by giving it firſt a blue colour, and afterwards dyeing it yellow; becauſe, when the yellow is firſt given, ſeveral inconveniences follow: the yellow partly ſeparates again in the blue vat, and communicates a green colour to it; and thus renders it uſeleſs for every other purpoſe, except dyeing green. Any of the proceſſes for dyeing blue, deſcribed in the laſt chapter, may be followed; care being taken always to proportion the depth of the blue to the ſhade of green which is required. The cloth thus dyed blue may receive a yellow colour, by following the proceſſes deſcribed in the laſt chapter for that purpoſe. When the ſulphat of indigo is employed, it is uſual to mix all the ingredients together, and to dye the cloth at once: the colour produced is known by the name of *Saxon*, or *Engliſh green*. One of the moſt convenient methods of conducting this proceſs is the following:

Six or eight parts of quercitron bark, tied up in a bag, are to be put into the dyeing veſſel, which ſhould contain only a ſmall quantity of warm water. When the water boils, ſix parts of murio ſulphat of tin, and four parts of alum, are to be added. In a few minutes, the dyeing veſſel ſhould be filled up with cold water, till the temperature is reduced to about 130°. After this, as much ſulphat of indigo is to be poured in as is ſufficient to produce the intended ſhade of green. When the whole has been ſufficiently ſtirred, a hundred parts of cloth are to be put in, and turned briſkly for about fifteen minutes, till it has acquired the wiſhed-for ſhade *. By this method, a much more beautiful colour is obtained than is given by the uſual proceſs, in which fuſtic is employed to give the yellow ſhade.

* Bancroft, ii. 336.

456 Silk, Silk, intended to receive a green colour, is uſually dyed yellow firſt, by means of weld, according to the proceſs deſcribed in the laſt chapter; afterwards, it is dipped into the blue vat, and dyed in the uſual manner. To deepen the ſhade, or to vary the tint, decoctions of logwood, anotta, fuſtic, &c. are added to the yellow bath. Or ſilk may be dyed at once green, by adding ſuitable proportions of ſulphat of indigo to the common quercitron bark bath, compoſed of four parts of bark, three parts of alum, and two parts of murio-ſulphat of tin †.

† Ibid. 346.

457 Cotton and linen, Cotton and linen muſt be firſt dyed blue, and then yellow, according to the methods deſcribed in the laſt chapter. It is needleſs to add, that the depth of each of theſe colours muſt be proportioned to the ſhade of green colour which it is the intention of the dyer to give.

SECT. II. *Of Mixtures of BLUE and RED.*

458 Violet, purple, lilac, THE mixture of blue and red produces *violet*, *purple*, and *lilac*, of various ſhades, and known by various names, according to the proportion of the ingredients employed. When the colour is deep, and inclines moſt to blue, it is called *violet;* but when the red is prevalent, it gets the name of *purple*. When the ſhade is light, the colour is uſually called *lilac*. For violet, therefore, the cloth muſt receive a deeper blue; for purple, a deeper red; and for lilac, both of theſe colours muſt be light.

Wool is uſually dyed firſt *blue;* the ſhade, even for violet, ought not to be deeper than that called *ſky blue;* afterwards it is dyed ſcarlet, in the uſual manner. The violets and purples are dyed firſt; and when the vat is ſomewhat exhauſted, the cloth is dipped in which is to receive the lilac, and the other lighter ſhades. By means of ſulphat of indigo, the whole proceſs may be performed at once. The cloth is firſt alumed, and then dyed in a veſſel, containing cochineal, tartar, and ſulphat of indigo, in proportions ſuited to the depth of the colour required *. A violet colour may alſo be given to wool, by impregnating it with a mordant compoſed of tin diſſolved in a mixture of ſulphuric and muriatic acids, formed by diſſolving muriat of ſoda in ſulphuric acid: to which ſolution a quantity of tartar and ſulphat of copper is added. The wool is then boiled in a decoction of logwood till it has acquired the wiſhed-for colour †.

Mixtures of Blue and Red. 459 How induced on wool,

* Poerner.

† Decroyzille, Berthollet, ii. 331.

Silk is firſt dyed crimſon, by means of cochineal, in the uſual way, excepting only that no tartar, nor ſolution of tin, is employed: It is then dipped into the indigo vat till it has acquired the wiſhed-for ſhade. The cloth is often afterwards paſſed through an archil bath, which greatly improves the beauty of the colour. Archil is often employed as a ſubſtitute for cochineal: The ſilk firſt receives a red colour, in the uſual way, by being dyed in an archil bath; afterwards it receives the proper ſhade of blue. The violet, or purple, given by this proceſs is very beautiful, but not very laſting ‡. 460 Silk,

‡ Berthollet, ii. 327.

Silk may be dyed violet or purple at once, by firſt treating it with a mordant, compoſed of equal parts of nitro-muriat of tin and alum, and then dipping it into a cochineal bath, into which a proper quantity of ſulphat of indigo has been poured. But this dye is fading; the blue colour ſoon decays, and the ſilk becomes red *.

* Guehliche, Berthollet, ii. 329.

Cotton and linen are firſt dyed blue, then galled, then ſoaked in a decoction of logwood; ſome alum and acetite of copper are added to the decoction, and the cloth is ſoaked again. This proceſs is repeated till the proper colour is obtained †. The colour produced by this method is not nearly equal in permanency to that deſcribed in this *Supplement* under the word IRON; to which we beg leave to refer the reader. The proceſs there deſcribed has been long known; but Mr Chaptal has ſimplified it ſomewhat. 461 Cotton, and linen,

† Berthollet, ii. 337.

SECT. III. *Of Mixtures of YELLOW and RED.*

THE colour produced by the mixture of *red* and *yellow* is *orange;* but almoſt an infinity of ſhades reſults from the different proportions of the ingredients, and from the peculiar nature of the yellow employed. Sometimes *blue* is combined with red and yellow on cloth: the reſulting colour is called *olive*. 462 Orange and olive,

Wool may be dyed orange by preciſely the ſame proceſs which is uſed for ſcarlet, only the proportion of red muſt be diminiſhed, and that of yellow increaſed. When wool is firſt dyed red with madder, and then yellow with weld, the reſulting colour is called *cinnamon colour*. The mordant, in this caſe, is a mixture of alum and tartar. The ſhade may be varied exceedingly, by uſing other yellow dye ſtuffs inſtead of weld, and by varying the proportions, according to circumſtances. Thus a reddiſh yellow may be given to cloth, by firſt dyeing it yellow, and then paſſing it through a madder bath. 463 How induced on wool,

Silk is dyed orange by means of carthamus: the 464 Silk, method

Mixtures of Black with other Colours.

method has been defcribed in the laft chapter. Cinnamon colour is given to it by dyeing it, previoufly alumed, in a bath compofed of the decoctions of logwood, Brazil wood, and fuftic, mixed together.

465 Cotton and linen. Cotton and linen receive a cinnamon colour by means of weld and madder. The procefs is complicated. The cloth is firft dyed with weld and acetite of copper, then dipped in a folution of fulphat of iron, then galled, then alumed, and then dyed in the ufual way with madder *.

For *olive*, the cloth is firft dyed blue, then yellow, and laftly paffed through a madder bath. The fhade depends upon the proportion of each of thefe colours. For very deep fhades the cloth is alfo dipped into a folution of fulphat of iron. Cotton and linen may be dyed *olive* by dipping them into a bath, compofed of the decoction of four parts of weld and one of potafs, mixed with the decoction of Brazil wood and a little acetite of copper †.

* *Bertholl*et, ii. 344.

† *D'Apligny, ibid.* 345.

SECT. IV. *Of Mixtures of* BLACK *with other Colours.*

466 Greys, drabs, and browns. STRICKLY fpeaking, the mixtures belonging to this fection are not mixtures of *black colours* with other colours, but combinations of the *black dye* with other colours; the ingredients of which, galls and brown oxide of iron, being both mordants, varioufly modify other colouring matters by combining with them. Thus if cloth be previoufly combined with brown oxide of iron, and afterwards dyed yellow with quercitron bark, the refult will be a *drab* of different fhades, according to the proportion of mordant employed. When the proportion is fmall, the colour inclines to olive or yellow; on the contrary, the drab may be deepened or faddened, as the dyers fpeak, by mixing a little fumach with the bark *. The precautions formerly mentioned in applying the oxide muft be obferved.

It is very common to dip cloth already dyed fome particular colour into a folution of fulphat of iron, and galls or fome other fubftance containing tan, called the *black bath*, in order to alter the fhade, and to give the colour greater permanency. We fhall give a few inftances: greater minutenefs would be inconfiftent with the nature of this article.

Cloth dyed blue, by being dipped into the *black* bath, becomes *bluifh grey*. Cloth dyed *yellow*, by the fame procefs, becomes *blackifh grey*, *drab*, or *yellowifh brown*. Cloth previoufly alumed, and dyed in a decoction of cochineal and acetite of iron, acquires a permanent *violet colour* inclining to *brown*, or a *lilac*, if the dyeing veffel be fomewhat exhaufted *. Cloth fteeped in a mordant, compofed of alum and acetite of iron diffolved in water, and afterwards dyed in a bath compofed of the decoction of galls and madder mixed together, acquires a fine deep *brown*. The method of varying the fhades of linen and cotton will be readily conceived, after we have given an account of calico printing, which forms the fubject of the next chapter.

* *Bancroft*, i. 343.

* *Gubliche, Bertholl*et, ii. 349.

CHAP. VI. OF CALICO PRINTING.

CALICO printing is the art of communicating different colours to particular fpots or figures on the furface of cotton or linen cloth, while the reft of the ftuff retains its original whitenefs.

Calico Printing.

467 Origin of calico printing. This ingenious art feems to have originated in India, where we know it has been practifed for more than 2000 years. Pliny indeed informs us, that the Egyptians were acquainted with calico printing; but a variety of circumftances combine to render it more than probable that they borrowed it from India. The art has but lately been cultivated in Europe; but the enlightened induftry of our manufacturers has already improved prodigioufly upon the tedious proceffes of their Indian mafters. No art has rifen to perfection with greater celerity: a hundred years ago it was fcarcely known in Europe; at prefent, the elegance of the patterns, the beauty and permanency of the colours, and the expedition with which the different operations are carried on, are really admirable.

A minute detail of the proceffes of calico printing would not only be foreign to the plan of this article, but of very little utility. To the artift the proceffes are already known; an account of them therefore could give him no new information; while it would fatigue and difappoint thofe readers who wifh to underftand the principles of the art. We fhall content ourfelves, therefore, with a fhort view of thefe principles.

468 It confifts in applying mordants partially to cotton, Calico printing confifts in impregnating thofe parts of the cloth which are to receive a colour with a mordant, and then dyeing it as ufual with fome dye ftuff or other. The dye ftuff attaches itfelf firmly only to that part of the cloth which has received the mordant. The whole furface of the cotton is indeed more or lefs tinged; but by wafhing it, and bleaching it for fome days on the grafs with the wrong fide uppermoft, all the unmordanted parts refume their original colour, while thofe which have received the mordant retain it. Let us fuppofe that a piece of white cotton cloth is to receive red ftripes; all the parts where the ftripes are to appear are penciled over with a folution of acetite of alumina. After this, the cloth is dyed in the ufual manner with madder. When taken out of the dyeing veffel, it is all of a red colour; but by wafhing and bleaching, the madder leaves every part of the cloth white except the ftripes impregnated with the acetite of alumina, which remain red. In the fame manner, may yellow ftripes, or any other wifhed-for figure, be given to cloth, by fubftituting quercitron bark, weld, &c. for madder.

469 Which is afterward dyed and bleached.

When different colours are to be given to different parts of the cloth at the fame time, it is done by impregnating it with various mordants. Thus if ftripes be drawn upon a cotton cloth with acetite of alumina, and other ftripes with acetite of iron, and the cloth be afterwards dyed in the ufual way with madder, and then wafhed and bleached, it will be ftriped *red* and *brown*. The fame mordants with quercitron bark give *yellow*, and *olive* or *drab*.

470 Mordant employed. The mordants employed in calico printing are acetite of alumina and acetite of iron, prepared in the manner defcribed in the third chapter of this part. Thefe mordants are applied to the cloth, either with a pencil or by means of blocks, on which the pattern, according to which the cotton is to be printed, is cut. As they are applied only to particular parts of the cloth, care muft be taken that none of them fpread to the part of the cloth which is to be left white, and that they do not interfere with one another when more than one are applied.

Calico Printing.

applied. If theſe precautions be not attended to, all the elegance and beauty of the print muſt be deſtroyed. It is neceſſary, therefore, that the mordants ſhould be of ſuch a degree of conſiſtence that they will not ſpread beyond thoſe parts of the cloth on which they are applied. This is done by thickening them with flour or ſtarch when they are to be applied by the block, and with gum arabic when they are to be put on with a pencil. The thickening ſhould never be greater than is ſufficient to prevent the ſpreading of the mordants; when carried too far, the cotton is apt not to be ſufficiently ſaturated with the mordant; of courſe the dye takes but imperfectly.

471 How applied.

In order that the parts of the cloth impregnated with mordants may be diſtinguiſhed by their colour, it is uſual to tinge the mordants with ſome colouring matter or other. The printers commonly uſe the decoction of Brazil wood for this purpoſe; but Bancroft has objected to this method, becauſe he thinks that the Brazil wood colouring matter impedes the ſubſequent proceſs of dyeing. It is certain, that the colouring matter of the Brazil wood is diſplaced during that operation by the ſuperior affinity of the dye ſtuff for the mordant. Were it not for this ſuperior affinity, the colour would not take at all. Dr Bancroft * adviſes to colour the mordant with ſome of the dye ſtuff afterwards to be applied; and he cautions the uſing of more for that purpoſe than is ſufficient to make the mordant diſtinguiſhable when applied to the cloth. The reaſon of this precaution is obvious. If too much dye be mixed with the mordant, a great proportion of the mordant will be combined with colouring matter; which muſt weaken its affinity for the cloth, and of courſe prevent it from combining with it in ſufficient quantity to enſure a permanent dye.

* *Bancroft*, 373.

Sometimes theſe two mordants are mixed together in different proportions; and ſometimes one or both is mixed with an infuſion of ſumach or of nut galls. By theſe contrivances, a great variety of colours are produced by the ſame dye ſtuff.

472 Subſequent treatment of the cloth.

After the mordants have been applied, the cloth muſt be completely dried. It is proper for this purpoſe to employ artificial heat, which will contribute ſomething towards the ſeparation of the acetous acid from its baſe, and towards its evaporation; by which the mordant will combine in a greater proportion, and more intimately with the cloth.

When the cloth is ſufficiently dried, it is to be waſhed with warm water and cow dung, till all the flour or gum employed to thicken the mordants, and all thoſe parts of the mordants which are uncombined with the cloth, are removed. The cow dung ſerves to entangle theſe looſe particles of mordants, and to prevent them from combining with thoſe parts of the cloth which are to remain white. After this the cloth is thoroughly rinſed in clean water.

473 Dye ſtuffs uſed.

Almoſt the only dye ſtuffs employed by calico printers are, indigo, madder, and quercitron bark or weld. This laſt ſubſtance, however, is now but little uſed by the printers of this country, except for delicate greeniſh yellows. The quercitron bark has almoſt ſuperſeded it; becauſe it gives colours equally good, and is much cheaper, and more convenient, not requiring ſo great a heat to fix it. Indigo, not requiring any mordant, is commonly applied at once either with the block or a pencil. It is prepared by boiling together indigo, potaſs made cauſtic by quicklime, and orpiment: the ſolution is afterwards thickened with gum (K). It muſt be carefully ſecluded from the air, otherwiſe the indigo would ſoon be regenerated, which would render the ſolution uſeleſs. Dr Bancroft has propoſed to ſubſtitute coarſe brown ſugar for orpiment. It is equally efficacious in decompoſing the indigo and rendering it ſoluble; while it likewiſe ſerves all the purpoſes of gum *.

* *Bancroft*, i. 120.

When the cloth, after being impregnated with the mordant, is ſufficiently cleanſed, it is dyed in the uſual manner. The whole of it is more or leſs tinged with the dye ſtuff. It is well waſhed, and then ſpread out for ſome days on the graſs, and bleached with the wrong ſide uppermoſt. This carries the colour off completely from all the parts of the cotton which has not imbibed the mordant, and leaves them of their original whiteneſs, while the mordanted ſpots retain the dye as ſtrongly as ever.

Let us now give an example or two of the manner in which the printers give particular colours to calicoes. Some calicoes are only printed of one colour, others have two, others three, or more, even to the number of eight, ten, or twelve. The ſmaller the number of colours, the fewer in general are the proceſſes.

474 Method of printing drabs.

1. One of the moſt common colours on cotton prints is a kind of nankeen yellow, of various ſhades, down to a deep yellowiſh brown or drab. It is uſually in ſtripes or ſpots. To produce it, the printers beſmear a block, cut out into the figure of the print, with acetite of iron thickened with gum or flour; apply it to the cotton; which, after being dried and cleaned in the uſual manner, is plunged

(K) Different proportions are uſed by different perſons. Mr Hauſſman mixes 25 gallons of water with 16 pounds of indigo well ground (or a greater or ſmaller quantity, according to the quality of the indigo and the depth of colour wanted); to which he adds 30 pounds of good carbonat of potaſs, placing the whole over a fire; and as ſoon as the mixture begins to boil, he adds, by a little at a time, 12 pounds of quicklime, to render the alkali cauſtic, by abſorbing its carbonic acid. This being done, 12 pounds of red orpiment are alſo added to the mixture; which is then ſtirred, and left to boil for ſome little time, that the indigo may be perfectly diſſolved; which may be known by its giving a yellow colour immediately upon being applied to a piece of white tranſparent glaſs. M. Oberkampf, proprietor of the celebrated manufactory at Jouy near Verſailles, uſes a third more of indigo; and others uſe different proportions, not only of indigo, but of lime, potaſs, and orpiment; which all ſeem to anſwer with nearly equal ſucceſs: but with the beſt copper-coloured Guatamala indigo, it is certain that a good blue may be obtained from only half the quantity preſcribed by Mr Hauſſman, by uſing as much ſtone, or oyſter ſhell lime, as of indigo, nearly twice as much potaſs, and a fourth part leſs of orpiment than of indigo. See *Bancroft*, I. 113.

Calico Printing.

plunged into a potafs ley. The quantity of acetite of iron is always proportioned to the depth of the intended fhade.

475 Yellow, 2. For yellow, the block is befmeared with acetite of alumina. The cloth, after receiving this mordant, is dyed with quercitron bark, and then bleached.

476 Red, 3. Red is communicated by the fame procefs, only madder is fubftituted for the bark.

477 Blue, 4. The fine light blues, which appear fo often on printed cottons, are produced, by applying to the cloth a block befmeared with a compofition, confifting partly of wax, which covers all thofe parts of the cloth which are to remain white. The cloth is then dyed in a cold indigo vat; and after it is dry, the wax compofition is removed by means of hot water.

478 Lilac, brown, 5. Lilac, flea brown, and blackifh brown, are given by means of acetite of iron; the quantity of which is always proportioned to the depth of the fhade. For very deep colours, a little fumach is added. The cotton is afterwards dyed in the ufual manner with madder, and then bleached.

479 And dove. 6. Dove colour and drab, by acetite of iron and quercitron bark.

480 Application of different colours to the fame cloth. When different colours are to appear in the fame print, a greater number of operations are neceffary. Two or more blocks are employed, upon each of which that part of the print only is cut which is to be of fome particular colour. Thefe are befmeared with different mordants and applied to the cloth, which is afterwards dyed as ufual. Let us fuppofe, for inftance, that three blocks are applied to cotton; one with acetite of alumina, another with acetite of iron, a third with a mixture of thefe two mordants, and that the cotton is then dyed with quercitron bark, and bleached. The parts impregnated with the mordants would have the following colours.

Acetite of alumina,	- -	Yellow,
iron,	- - -	Olive, drab, dove (L),
The mixture,	- - - -	Olive green, olive.

If part of the yellow be covered over with the indigo liquor, applied with a pencil, it will be converted into *green*: By the fame liquid, blue may be given to fuch parts of the print as require it.

If the cotton be dyed with madder inftead of quercitron bark, the print will exhibit the following colours:

Acetite of alumina,	- - -	Red,
iron,	- - - -	Brown, black,
The mixture,	- - - - -	Purple.

When a greater number of colours are to appear; for inftance, when thofe communicated by bark and thofe by madder are wanted at the fame time, mordants for part of the pattern are to be applied; the cotton is then to be dyed in the madder bath and bleached; then the reft of the mordants, to fill up the pattern, are added, and the cloth is again dyed with quercitron bark and bleached. This fecond dyeing does not much affect the madder colours; becaufe the mordants, which render them permanent, are already faturated. The yellow tinge is eafily removed by the fubfequent bleaching. Sometimes a new mordant is alfo applied to fome of the madder colours; in confequence of which they receive a new permanent colour from the bark. After the laft bleaching, new colours may be added by means of the indigo liquor. The following table will give an idea of the colours which may be given to cotton by thefe complicated proceffes.

I. *Madder dye.*		*Colours.*
Acetite of alumina,	- - -	Red,
iron,	- - - -	Brown, black,
Ditto diluted	- - - -	Lilac,
Both mixed,	- - - - -	Purple.
II. *Bark dye.*		
Acetite of alumina,	- - -	Yellow,
iron,	- - - -	Dove, drab,
Lilac and acetite of alumina,		Olive,
Red and acetite of alumina,		Orange.
III. *Indigo dye.*		
Indigo,	- - -	Blue,
Indigo and yellow,	- -	Green.

Thus no lefs than 12 colours may be made to appear together in the fame print by thefe different proceffes.

Thefe inftances will ferve to give the reader an idea of the nature of calico printing, and at the fame time afford an excellent illuftration of the importance of mordants in dyeing.

If it were poffible to procure colours fufficiently permanent, by applying them at once to the cloth by the block or the pencil, as is the cafe with the mordants, the art of calico printing would be brought to the greateft poffible fimplicity: but at prefent this can only be done in one cafe, that of indigo; every other colour requires dyeing. Compofitions indeed may be made by previoufly combining the dye ftuff and the mordants. Thus *yellow* may be applied at once by employing a mixture of the infufion of quercitron bark and acetite of alumina; *red*, by mixing the fame mordant with the decoction of alumina, and fo on. Unfortunately the colours applied in this way are far inferior in permanency to thofe produced when the mordant is previoufly combined with the cloth, and the dye ftuff afterwards applied feparately. In this way are applied almoft all the fugitive colours of calicoes which wafhing or even expofure to the air deftroys. 481 Colours fo penciling.

As the application of colours in this way cannot always be avoided by calico printers, every method of rendering them more permanent is an object of importance. We fhall therefore conclude this chapter with a defcription of feveral colours of this kind propofed by Dr Bancroft, which have a confiderable degree of permanence.

A *yellow* printing colour may be formed by the following method: Let three pounds of alum, and three ounces of clean chalk, be firft diffolved in a gallon of hot water, and then add two pounds of fugar of lead; ftir this mixture occafionally during the fpace of 24 or 36 hours, then let it remain 12 hours at reft, and afterwards decant and preferve the clear liquor; this being

(L) According to the proportion of acetite of iron employed

Calico Printing.

ing done, pour ſo much more warm water upon the remaining ſediment, as after ſtirring and leaving the mixture to ſettle will afford clear liquor enough to make, when mixed with the former, three quarts of this aluminous mordant or acetite of alumine. Then take not leſs than ſix, nor more than eight, pounds of quercitron bark properly ground; put this into a tinned copper veſſel, with four or five gallons of clean ſoft water, and make it boil for the ſpace of one hour at leaſt, adding a little more water, if at any time the quantity of liquor ſhould not be ſufficient to cover the ſurface of the bark: the liquor having boiled ſufficiently, ſhould be taken from the fire, and left undiſturbed for half an hour, and then the clear decoction ſhould be poured off through a fine ſieve or canvas ſtrainer. This being done, let ſix quarts more of clear water be poured upon the ſame bark, and made to boil ten or fifteen minutes, both having been firſt well ſtirred; and being afterwards left a ſufficient time to ſettle, the clean decoction may then be ſtrained off, and put with the former into a ſhallow wide veſſel to be evaporated by boiling, until what remains, being joined to the three quarts of aluminous mordant before mentioned, and to a ſufficient quantity of gum or paſte for thickening, will barely ſuffice to make three gallons of liquor in the whole. It will be proper, however, not to add the aluminous mordant, until the decoction is ſo far cooled as to be but little more than blood warm; and theſe being thoroughly mixed by ſtirring, may afterwards be thickened by the gum of Senegal or by gum arabic, if the mixture is intended for penciling; or by a paſte made with ſtarch or flour, if it be intended for printing.

By ſubſtituting a pound of murio ſulphat of tin for the aluminous mordant in the above compoſition, a mixture may be formed which affords a very bright and full yellow, of conſiderable durability.

Sulphat of tin, mixed with a decoction of quercitron bark, communicates to cotton a *cinnamon* colour, which is ſufficiently permanent*.

When the decoctions of quercitron bark and logwood are boiled together, and ſuitable proportions of ſulphat of copper and of verdigris are added to them, with a little carbonat of potaſs, a compound is formed which gives a *green* colour to cotton. Bancroft has made trial of this; and though it has not fully anſwered his expectation, his attempts were attended with ſufficient ſucceſs to determine him to perſevere in his experiments†.

If acetite of iron be mixed with a decoction of quercitron bark, and the mixture be properly thickened, the compound will communicate to cotton a *drab* colour of ſome durability. This compound, mixed with the olive colouring liquor above deſcribed, will produce an olive. If a ſolution of iron, by a diluted muriatic acid, or by a diluted nitric acid, be employed for this purpoſe inſtead of iron liquor, it will produce colours a little more laſting; but theſe ſolutions ſhould be employed ſparingly, that they may not hurt the texture of the linen or cotton to which they are intended to be applied.

* *Bancroft*, i. 400.

† *Ibid*, 401.

Subtriple || Sulphuret.

SUBTRIPLE, is when one quantity is the 3d part of another; as 2 is ſubtriple of 6. And *Subtriple Ratio* is the ratio of 1 to 3.

SUBTRIPLICATE RATIO, is the ratio of the cube roots. So the ſubtriplicate ratio of a to b, is the ratio of $\sqrt[3]{a}$ to $\sqrt[3]{b}$, or of $a^{\frac{1}{3}}$ to $b^{\frac{1}{3}}$.

SUCCESSION OF SIGNS, in aſtronomy, is the order in which they are reckoned, or follow one another, and according to which the ſun enters them; called alſo *conſequentia*. As Aries, Taurus, Gemini, Cancer, &c.

SULPHURET OF LIME having lately been recommended by an eminent chemiſt* as a ſubſtitute for *potaſh* in the new method of bleaching, which, if it anſwer, may certainly be afforded at leſs expence, we ſhall here give the method of preparing the ſulphuret.

* *W. Higgins, M. R. I. A.*

Take of ſulphur, or brimſtone in fine powder, four pounds; lime, well ſlaked and ſifted, twenty pounds; water ſixteen gallons:—theſe are all to be well mixed and boiled for about half an hour in an iron veſſel, ſtirring them briſkly from time to time. Soon after the agitation of boiling is over, the ſolution of the ſulphuret of lime clears, and may be drawn off free from the inſoluble matter, which is conſiderable, and which reſts upon the bottom of the boiler (A). The liquor in this ſtate is pretty nearly of the colour of ſmall beer, but not quite ſo tranſparent.

Sulphuret, Sun.

Sixteen gallons of freſh water are afterwards to be poured upon the inſoluble dregs in the boiler, in order to ſeparate the whole of the ſulphuret from them. When this clears (being previouſly well agitated), it is alſo to be drawn off and mixed with the firſt liquor; to theſe again thirty-three gallons more of water may be added, which will reduce the liquor to a proper ſtandard for ſteeping the cloth.

Here we have (an allowance being made for evaporation, and for the quantity retained in the dregs) ſixty gallons of liquor from four pounds of brimſtone.

Although ſulphur by itſelf is not in any ſenſible degree ſoluble in water, and lime but very ſparingly ſo, water diſſolving but about one ſeven-hundredth part of its weight of lime; yet the ſulphuret of lime is highly ſoluble.

When the above proportion of lime and ſulphur is boiled with only twelve gallons of water, the ſulphuret partly cryſtallizes upon cooling; and when once cryſtallized it is not eaſy of ſolution.

SUN (ſee ASTRONOMY-*Index*, Encycl.) is certainly that celeſtial body which, of all others, ſhould moſt attract our attention. It has accordingly employed much of

(A) Although lime is one of the conſtituent principles of the ſulphuret, yet being ſo intimately united to the ſulphur, it has no longer the property of lime; upon the ſame principle that ſulphuric acid in ſulphat of potaſh has not the property of that acid.

of the time and meditation, not only of the aſtronomer but alſo of the ſpeculative philoſopher, in all ages of the world; and many hypotheſes have been formed, and ſome diſcoveries made, reſpecting the nature and the uſes of this vaſt luminary.

Sir Iſaac Newton has ſhewn, that the ſun, by its attractive power, retains the planets of our ſyſtem in their orbits: he has alſo pointed out the method whereby the quantity of matter which it contains may be accurately determined. Dr Bradley has aſſigned the velocity of the ſolar light with a degree of preciſion exceeding our utmoſt expectation. Gallileo, Scheiner, Hevelius, Caſſini, and others, have aſcertained the rotation of the ſun upon its axis, and determined the poſition of its equator. By means of the tranſit of Venus over the diſk of the ſun, our mathematicians have calculated its diſtance from the earth, its real diameter and magnitude, the denſity of the matter of which it is compoſed, and the fall of heavy bodies on its ſurface. We have therefore a very clear notion of the vaſt importance and powerful influence of the ſun on its planetary ſyſtem; but with regard to its internal conſtruction, we are yet extremely ignorant. Many ingenious conjectures have indeed been formed on the ſubject; a few of which we ſhall mention as an introduction to Dr Herſchel's, of which, as it is the lateſt, and perhaps the moſt plauſible, we ſhall give a pretty full account nearly in his own words.

The dark ſpots in the ſun, for inſtance, have been ſuppoſed to be ſolid bodies revolving very near its ſurface. They have been conjectured to be the ſmoke of volcanoes, or the ſcum floating upon an ocean of fluid matter. They have alſo been taken for clouds. They were explained to be opaque maſſes ſwimming on the fluid matter of the ſun, dipping down occaſionally. It has been ſuppoſed that a fiery liquid ſurrounded the ſun, and that by its ebbing and flowing the higheſt parts of it were occaſionally uncovered, and appeared under the ſhape of dark ſpots: and that by the return of the fiery liquid, they were again covered, and in that manner ſucceſſively aſſumed different phaſes. The ſun itſelf has been called a globe of fire, though perhaps metaphorically. The waſte it would undergo by a gradual conſumption, on the ſuppoſition of its being ignited, has been ingeniouſly calculated; and in the ſame point of view its immenſe power of heating the bodies of ſuch comets as draw very near to it has been aſſigned.

In the year 1779 there was a ſpot on the ſun which was large enough to be ſeen with the naked eye. By a view of it with a ſeven feet reflector, charged with a very high power, it appeared to be divided into two parts. The largeſt of the two, on the 19th of April, meaſured 1′ 8″.06 in diameter, which is equal in length to more than 31,000 miles. Both together muſt certainly have extended above 50,000. The idea of its being occaſioned by a volcanic exploſion violently driving away a fiery fluid, ought to be rejected (ſays Dr Herſchel) on many accounts. "To mention only one, the great extent of the ſpot is very unfavourable to ſuch a ſuppoſition. Indeed a much leſs violent and leſs pernicious cauſe may account for all the appearances of the ſpot. When we ſee a dark belt near the equator of the planet Jupiter, we do not recur to earthquakes and volcanoes for its origin. An atmoſphere, with its natural changes, will explain ſuch belts. Our ſpot on the ſun may be accounted for on the ſame principles. The earth is ſurrounded by an atmoſphere compoſed of various elaſtic fluids. The ſun alſo has its atmoſphere; and if ſome of the fluids which enter into its compoſition ſhould be of a ſhining brilliancy, in the manner that will be explained hereafter, while others are merely tranſparent, any temporary cauſe which may remove the lucid fluid will permit us to ſee the body of the ſun through the tranſparent ones. If an obſerver were placed on the moon, he would ſee the ſolid body of the earth only in thoſe places where the tranſparent fluids of our atmoſphere would permit him. In others, the opaque vapours would reflect the light of the ſun without permitting his view to penetrate to the ſurface of our globe. He would probably alſo find, that our planet had occaſionally ſome ſhining fluids in its atmoſphere; as, not unlikely, ſome of our northern lights might not eſcape his notice, if they happened in the unenlightened part of the earth, and were ſeen by him in his long dark night. Nay, we have pretty good reaſon to believe, that probably all the planets emit light in ſome degree; for the illumination which remains on the moon in a total eclipſe cannot be entirely aſcribed to the light which may reach it by the refraction of the earth's atmoſphere. For inſtance, in the eclipſe of the moon October 22. 1790, the rays of the ſun refracted by the atmoſphere of the earth towards the moon, admitting the mean horizontal refraction to be 30′ 50″.8, would meet in a focus 189,000 miles beyond the moon; ſo that conſequently there could be no illumination from rays refracted by our atmoſphere. It is, however, not improbable, that about the polar regions of the earth there may be refraction enough to bring ſome of the ſolar rays to a ſhorter focus. The diſtance of the moon at the time of the eclipſe would require a refraction of 54′ 6″, equal to its horizontal parallax at that time, to bring them to a focus ſo as to throw light on the moon.

The unenlightened part of the planet Venus has alſo been ſeen by different perſons; and not having a ſatellite, thoſe regions that are turned from the ſun cannot poſſibly ſhine by a borrowed light; ſo that this faint illumination muſt denote ſome phoſphoric quality of the atmoſphere of Venus.

In the inſtance of the large ſpot on the ſun already mentioned, Dr Herſchel concludes, from appearances, that he viewed the real body of the ſun itſelf, of which we rarely ſee more than its ſhining atmoſphere. In the year 1783 he obſerved a fine large ſpot, and followed it up to the edge of the ſun's limb. Here he took notice that the ſpot was plainly depreſſed below the ſurface of the ſun, and that it had very broad ſhelving ſides. He alſo ſuſpected ſome part, at leaſt, of the ſhelving ſides to be elevated above the ſurface of the ſun; and obſerved that, contrary to what uſually happens, the margin of that ſide of the ſpot which was fartheſt from the limb was the broadeſt.

The luminous ſhelving ſide of a ſpot may be explained by a gentle and gradual removal of the ſhining fluid, which permits us to ſee the globe of the ſun. As to the uncommon appearance of the broadeſt margin being on that ſide of the ſpot which was fartheſt from the limb when the ſpot came near the edge of it, we may ſurmiſe that the ſun has inequalities on its ſurface, which may

may poſſibly be the cauſe of it. For when mountainous countries are expoſed, if it ſhould chance that the higheſt parts of the landſcape are ſituated ſo as to be near that ſide of the margin or penumbra of the ſpot which is towards the limb, they may partly intercept our view of it when the ſpot is ſeen very obliquely. This would require elevations at leaſt five or ſix hundred miles high; but conſidering the great attraction exerted by the ſun upon bodies at its ſurface, and the ſlow revolution it has upon its axis, we may readily admit inequalities to that amount. From the centrifugal force at the ſun's equator, and the weight of bodies at its ſurface, he computes, that the power of throwing down a mountain by the exertion of the former, balanced by the ſuperior force of keeping it in its place of the latter, is near $6\frac{1}{2}$ times leſs on the ſun than on our equatorial regions; and as an elevation ſimilar to one of three miles on the earth would not be leſs than 334 miles on the ſun, there can be no doubt but that a mountain much higher would ſtand very firmly. The little denſity of the ſolar body ſeems alſo to be in favour of the height of its mountains; for, *cæteris paribus*, denſe bodies will ſooner come to their level than rare ones. The difference in the vaniſhing of the ſhelving ſide, inſtead of explaining it by mountains, may alſo, and perhaps more ſatisfactorily, be accounted for from the real difference of the extent, the arrangement, the height, and the intenſity of the ſhining fluid, added to the occaſional changes that may happen in theſe particulars during the time in which the ſpot approaches to the edge of the diſk. However, by admitting large mountains on the face of the ſun, we ſhall account for the different opinions of two eminent aſtronomers; one of whom believed the ſpots depreſſed below the ſurface of the ſun, while the other believed them elevated above it. For it is not impoſſible that ſome of the ſolar mountains may be high enough occaſionally to project above the ſhining elaſtic fluid, when, by ſome agitation or other cauſe, it is not of the uſual height; and this opinion is much ſtrengthened by the return of ſome remarkable ſpots which ſerved Caſſini to aſcertain the period of the ſun's rotation. A very high country, or chain of mountains, may oftener become viſible, by the removal of the obſtructing fluid, than the lower regions, on account of its not being ſo deeply covered with it.

In 1791 the Doctor examined a large ſpot on the ſun, and found it evidently depreſſed below the level of the ſurface. In 1792 he examined the ſun with ſeveral powers from 90 to 500, when it appeared evidently, that the black ſpots are the opaque ground, or body of the ſun; and that the luminous part is an atmoſphere, which, being interrupted or broken, gives us a tranſient glimpſe of the ſun itſelf. He perceived likewiſe, that the ſhining ſurface of the ſun is unequal, many parts of it being elevated and others depreſſed; and that the elevations, to which Hevelius gave the name of *faculæ*, ſo far from reſembling torches, were rather like the ſhrivelled elevations upon a dried apple, extended in length, and moſt of them joined together, making waves or waving lines. The faculæ being elevations, very ſatisfactorily explains the reaſon why they diſappear towards the middle of the ſun, and reappear on the other margin; for about the place where we loſe them, they begin to be edgewiſe to our view; and if between the faculæ ſhould lie dark ſpots, they will moſt frequently break out in the middle of the ſun, becauſe they are no longer covered by the ſide-views of theſe faculæ.

The Doctor gives a very particular account of all his obſervations, which ſeem to have been accurately made, and we need ſcarcely add with excellent teleſcopes. For that account, however, we muſt refer to the memoir itſelf, and haſten to lay before our readers the reſult of his obſervations. "That the ſun (ſays he) has a very extenſive atmoſphere, cannot be doubted; and that this atmoſphere conſiſts of various elaſtic fluids, that are more or leſs lucid and tranſparent, and of which the lucid one is that which furniſhes us with light, ſeems alſo to be fully eſtabliſhed by all the phenomena of its ſpots, of the faculæ, and of the lucid ſurface itſelf. There is no kind of variety in theſe appearances but what may be accounted for with the greateſt facility, from the continual agitation which, we may eaſily conceive, muſt take place in the regions of ſuch extenſive elaſtic fluids.

"It will be neceſſary, however, to be a little more particular as to the manner in which I ſuppoſe the lucid fluid of the ſun to be generated in its atmoſphere. An analogy that may be drawn from the generation of clouds in our own atmoſphere, ſeems to be a very proper one, and full of inſtruction. Our clouds are probably decompoſitions of ſome of the elaſtic fluids of the atmoſphere itſelf, when ſuch natural cauſes, as in this grand chemical laboratory are generally at work, act upon them: we may therefore admit, that in the very extenſive atmoſphere of the ſun, from cauſes of the ſame nature, ſimilar phenomena will take place; but with this difference, that the continual and very extenſive decompoſitions of the elaſtic fluids of the ſun are of a phoſphoric nature, and attended with lucid appearances, by giving out light.

"If it ſhould be objected, that ſuch violent and unremitting decompoſitions would exhauſt the ſun, we may recur again to our analogy, which will furniſh us with the following reflections. The extent of our own atmoſphere, we ſee, is ſtill preſerved, notwithſtanding the copious decompoſitions of its fluids in clouds and falling rain; in flaſhes of lightning, in meteors, and other luminous phenomena; becauſe there are freſh ſupplies of elaſtic vapours continually aſcending to make good the waſte occaſioned by thoſe decompoſitions. But it may be urged, that the caſe with the decompoſition of the elaſtic fluids in the ſolar atmoſphere would be very different, ſince light is emitted, and does not return to the ſun, as clouds do to the earth when they deſcend in ſhowers of rain. To which I anſwer, that, in the decompoſition of phoſphoric fluids, every other ingredient but light may alſo return to the body of the ſun. And that the emiſſion of light muſt waſte the ſun, is not a difficulty that can be oppoſed to our hypotheſis: for as it is an evident fact that the ſun does emit light, the ſame objection, if it could be one, would equally militate againſt every other aſſignable way to account for the phenomenon.

"There are, moreover, conſiderations that may leſſen the preſſure of this alledged difficulty. We know the exceeding ſubtility of light to be ſuch, that in ages of time its emanation from the ſun cannot very ſenſibly leſſen the ſize of this great body. To this may be added, that very poſſibly there may always be ways of reſtoration to compenſate for what is loſt by the emiſ-

ſion

ſion of light, though the manner in which this can be brought about ſhould not appear to us. Many of the operations of Nature are carried on in her great laboratory which we cannot comprehend, but now and then we ſee ſome of the tools with which ſhe is at work. We need not wonder that their conſtruction ſhould be ſo ſingular as to induce us to confeſs our ignorance of the method of employing them; but we may reſt aſſured that they are not a mere *luſus naturæ*." Here he alludes to the great number of ſmall teleſcopic comets; which he ſuppoſes, as others had done before him, may be employed to reſtore to the ſun what had been loſt by the emiſſion of light. "My hypotheſis, however, (continues he) does not lay me under any obligation to explain how the ſun can ſuſtain the waſte of light, nor to ſhew that it will ſuſtain it for ever; and I ſhould alſo remark that, as in the analogy of generating clouds, I merely allude to their production as owing to a decompoſition of ſome of the elaſtic fluids of our atmoſphere, that analogy, which firmly reſts upon the fact, will not be leſs to my purpoſe, to whatever cauſe theſe clouds may owe their origin. It is the ſame with the lucid clouds, if I may ſo call them, of the ſun. They plainly exiſt, becauſe we ſee them; the manner of their being generated may remain an hypotheſis—and mine, till a better can be propoſed, may ſtand good; but whether it does or not, the conſequences I am going to draw from what has been ſaid will not be affected by it."

Before he proceeds to draw theſe conſequences, he informs us that, according to the above theory, a dark ſpot in the ſun is a place in its atmoſphere, which happens to be free from luminous decompoſitions; that faculæ are, on the contrary, more copious mixtures of ſuch fluids as decompoſe each other; and that the regions, in which the luminous ſolar clouds are formed, adding thereto the elevation of the faculæ, cannot be leſs than 1843, nor much more than 2765 miles in depth. It is true, continues he, that in our atmoſphere the extent of the clouds is limited to a very narrow compaſs; but we ought rather to compare the ſolar ones to the luminous decompoſitions which take place in our *aurora borealis*, or luminous arches, which extend much farther than the cloudy regions. The denſity of the luminous ſolar clouds, though very great, may not be exceedingly more ſo than that of our *aurora borealis*. For if we conſider what would be the brilliancy of a ſpace two or three thouſand miles deep, filled with ſuch corruſcations as we ſee now and then in our atmoſphere, their apparent intenſity, when viewed at the diſtance of the ſun, might not be much inferior to that of the lucid ſolar fluid.

From the luminous atmoſphere of the ſun, he proceeds to its opaque body; which, by calculation from the power it exerts upon the planets, we know to be of great ſolidity; and from the phenomena of the dark ſpots, many of which, probably on account of their high ſituations, have been repeatedly ſeen, and otherwiſe denote inequalities in their level, we ſurmiſe that its ſurface is diverſified with mountains and valleys.

What has been ſaid, enables us to come to ſome very important concluſions, by remarking, that this way of conſidering the ſun and its atmoſphere removes the great diſſimilarity we have hitherto been uſed to find between its condition and that of the reſt of the great bodies of the ſolar ſyſtem.

The ſun, viewed in this light, appears to be nothing elſe than a very eminent, large, and lucid planet, evidently the firſt, or, in ſtrictneſs of ſpeaking, the only primary one of our ſyſtem, all others being truly ſecondary to it. Its ſimilarity to the other globes of the ſolar ſyſtem with regard to its ſolidity, its atmoſphere, and its diverſified ſurface, the rotation upon its axis, and the fall of heavy bodies, leads us on to ſuppoſe that it is moſt probably alſo inhabited, like the reſt of the planets, by beings whoſe organs are adapted to the peculiar circumſtances of that vaſt globe.

It may, however, not be amiſs to remove a certain difficulty, which ariſes from the effect of the ſun's rays upon our globe. The heat which is here, at the diſtance of 95 millions of miles, produced by theſe rays, is ſo conſiderable, that it may be objected, that the ſurface of the globe of the ſun itſelf muſt be ſcorched up beyond all conception.

This may be very ſubſtantially anſwered by many proofs drawn from natural philoſophy, which ſhew that heat is produced by the ſun's rays only when they act upon a calorific medium; they are the cauſe of the production of heat, by uniting with the matter of fire which is contained in the ſubſtances that are heated; as the colliſion of flint and ſteel will inflame a magazine of gunpowder, by putting all the latent fire it contains into action. But an inſtance or two of the manner in which the ſolar rays produce their effect, will bring this home to our moſt common experience.

On the tops of mountains of a ſufficient height, at an altitude where clouds can very ſeldom reach to ſhelter them from the direct rays of the ſun, we always find regions of ice and ſnow. Now if the ſolar rays themſelves conveyed all the heat we find on this globe, it ought to be hotteſt where their courſe is leaſt interrupted. Again, our aëronauts all confirm the coldneſs of the upper regions of the atmoſphere; and ſince, therefore, even on our earth, the heat of any ſituation depends upon the aptneſs of the medium to yield to the impreſſion of the ſolar rays, we have only to admit, that on the ſun itſelf, the elaſtic fluids compoſing its atmoſphere, and the matter on its ſurface, are of ſuch a nature as not to be capable of any exceſſive affection from its own rays: and indeed this ſeems to be proved by the copious emiſſion of them; for if the elaſtic fluids of the atmoſphere, or the matter contained on the ſurface of the ſun, were of ſuch a nature as to admit of an eaſy chemical combination with its rays, their emiſſion would be much impeded.

Our author then proceeds to ſupport his theory by analogical reaſonings; but as theſe will occur to ſuch of our readers as are converſant with the ſpeculations of aſtronomers, we paſs on to his reflections upon the conſequences of this theory. "That the ſtars are ſuns can hardly admit of a doubt. Their immenſe diſtances would perfectly exclude them from our view, if the light they ſend us were not of the ſolar kind. Beſides, the analogy may be traced much farther. The ſun turns on its axis; ſo does the ſtar Algol; ſo do the ſtars called β Lyræ, δ Cephei, η Antinoi, o Ceti, and many more; moſt probably all. From what other cauſe can we ſo probably account for their periodical changes? Again, our

Sun.

our fun has fpots on its furface; fo has the ftar Algol, and fo have the ftars already named, and probably every ftar in the heavens. On our fun thefe fpots are changeable; fo they are on the ftar ο Ceti, as evidently appears from the irregularity of its changeable luftre, which is often broken in upon by accidental changes while the general period continues unaltered. The fame little deviations have been obferved in other periodical ftars, and ought to be afcribed to the fame caufe. But if ftars are funs, and funs are inhabitable, we fee at once what an extenfive field for animation opens itfelf to our view.

"It is true, that analogy may induce us to conclude, that fince ftars appear to be funs, and funs, according to the common opinion, are bodies that ferve to enlighten, warm, and fuftain a fyftem of planets, we may have an idea of numberlefs globes that ferve for the habitation of living creatures. But if thefe funs themfelves are primary planets, we may fee fome thoufands of them with our own eyes, and millions by the help of telefcopes, when at the fame time the fame analogical reafoning ftill remains in full force with regard to the planets which thefe funs may fupport."

The Doctor then obferves, that from other confiderations, the idea of funs or ftars being *merely* the fupporters of fyftems of planets, is not abfolutely to be admitted as a general one. "Among the great number of very compreffed clufters of ftars I have given (fays he) in my catalogues, there are fome which open a different view of the heavens to us. The ftars in them are fo very clofe together, that, notwithftanding the great diftance at which we may fuppofe the clufter itfelf to be, it will hardly be poffible to affign any fufficient mutual diftance to the ftars compofing the clufter, to leave room for crowding in thofe planets, for whofe fupport thefe ftars have been, or might be, fuppofed to exift. It fhould feem, therefore, highly probable, that they exift for themfelves; and are, in fact, only very capital *lucid*, primary planets, connected together in one great fyftem of mutual fupport.

"The fame remark may be made with regard to the number of very clofe double ftars, whofe apparent diameters being alike, and not very fmall, do not indicate any very great mutual diftance: from which, however, muft be deducted all thofe where the different diftances may be compenfated by the real difference in their refpective magnitudes.

"To what has been faid may be added, that, in fome parts of the milky way, where yet the ftars are not very fmall, they are fo crowded, that in the year 1792, Aug. 22. I found by the gauges that, in 41 minutes of time, no lefs than 258,000 of them had paffed through the field of view of my telefcope.

"It feems, therefore, upon the whole, not improbable, that in many cafes ftars are united in fuch clofe fyftems as not to leave much room for the orbits of planets or comets; and that confequently, upon this account alfo, many ftars, unlefs we would make them mere ufelefs brilliant points, may themfelves be lucid planets, perhaps unattended by fatellites."

What a magnificent idea does this theory give of the univerfe, and of the goodnefs, as well as power, of its Author? And how cold muft be that heart, and clouded that underftanding, who, after the contemplation of it, can for one moment liften to the atheiftical doctrines of thofe men who prefume to account for all the phenomena of nature by chemical affinities and mechanical attraction? The man who, even in his heart, can fay, that fuch an immenfe fyftem, differing fo widely in the ftructure of the different parts of it, but everywhere crowded with life, is the effect of unintelligent agency, is indeed, to ufe the emphatic language of an ancient aftronomer—*a fool.*

Sunda || Sutton.

SUNDA, Straits of, are formed by the approach of the fouth-eaft extremity of the ifland of Sumatra to the north-weft extremity of the ifland of Java (See thefe iflands, *Encycl.*). The ftraits are interfperfed with a number of fmall ifles; the whole difplaying a fcenery fcarcely to be exceeded in the foftnefs, richnefs, and gaiety of its appearance. The two great iflands, which are low, and in fome places marfhy near the fhore, rife afterwards, in a gradual flope, towards the interior of the country, admitting in their afcent every variety of fituation, and all the different tints of verdure. Of the fmaller iflands, a few have fteep and naked fides, fuch as one in the middle of the ftrait, which the Englifh navigators have diftinguifhed, on that account, by the name of Thwart-the-way, and two very fmall round ones, called, from their figures, the Cap and Button (fee thefe iflands, *Suppl.*); but moft of the others are entirely level, founded upon beds of coral, and covered with trees. Some of thefe iflands are furrounded with a white fandy beach, vifited frequently by turtle; but moft of them are adorned with thick fhrubbery to the water's edge, the roots being wafhed by the fea, or the branches dipping into it; and on the outfide are fhoals, in which a multitude of little aquatic animals are bufied in framing calcareous habitations for their refidence and protection. Thofe fabrics gradually emerge above the furface of the water, and at length, by the adventitious adhefion of vegetable matter, giving birth to plants and trees, become new iflands, or add to the fize of thofe already produced by the fame means. It is impoffible not to be ftruck with the diverfified operations of Nature for obtaining the fame end, whether employed in originally fixing the granite foundation of the Brazils, or in throwing up, by fome fudden and fubfequent convulfion, the ifland of Amfterdam, or in continuing to this hour, through the means of animated beings, the formation of new lands in the Straits of Sunda.—*Sir George Staunton's Account of the Britifh Embaffy to China.*

SUNNUD, a grant, patent, or charter, in Bengal.

SUPERPARTICULAR Proportion, or Ratio, is that in which the greater term exceeds the lefs by unit or 1. As the ratio of 1 to 2, or 2 to 3, or 3 to 4, &c.

SUPERPARTIENT Proportion, or Ratio, is when the greater term contains the lefs term once, and leaves fome number greater than 1 remaining. As the ratio

of 3 to 5, which is equal to that of 1 to $1\frac{2}{3}$;

of 7 to 10, which is equal to that of 1 to $1\frac{3}{7}$; &c.

SUPPLEMENT, of an Arch or Angle, in geometry or trigonometry, is what it wants of a femicircle, or of 180°; as the *complement* is what it wants of a quadrant, or of 90°. So, the fupplement of 50° is 130°; as the complement of it is 40°.

SUTTON (Thomas, Efq;), founder of the charterhoufe, was born at Knaith in Lincolnfhire, in 1532, of an

Sutton.

an ancient and genteel family. He was educated at Eton ſchool, and probably at Cambridge, and ſtudied the law in Lincoln's Inn; but this profeſſion not ſuiting his diſpoſition, he travelled into foreign countries, and made ſo long a ſtay in Holland, France, Spain, and Italy, as to acquire the languages of thoſe various nations. During his abſence, his father died, and left him a conſiderable fortune. On his return home, being a very accompliſhed gentleman, he became ſecretary to the earl of Warwick and his brother the earl of Leiceſter. By the former of theſe noblemen, in 1569, he was appointed maſter of the ordnance at Berwick; and diſtinguiſhing himſelf greatly in that ſituation, on the rebellion which at that time broke out in the north, he obtained a patent for the office of maſter-general of the ordnance for that diſtrict for life. He is named as one of the chiefs of thoſe 1500 men who marched into Scotland, by the order of Queen Elizabeth, to the aſſiſtance of the regent, the earl of Morton, in 1573; and he commanded one of the five batteries which obliged the ſtrong caſtle of Edinburgh to ſurrender to the Engliſh. He purchaſed of the biſhop of Durham the manors of Gateſhead and Wickham; which, producing coal-mines, became to him a ſource of extraordinary wealth. In 1580, he was reputed to be worth L. 50,000

Soon after this, he married a rich widow, who brought him a conſiderable eſtate; and taking up the buſineſs of a merchant, riches flowed in to him with every tide. He is ſaid to have had no leſs than thirty agents abroad. He was likewiſe one of the chief victuallers of the navy; and ſeems to have been maſter of the barque called Sutton, in the liſt of volunteers attending the Engliſh fleet againſt the Spaniſh armada. It is probable, alſo, that he was a principal inſtrument in the defeat of it, by draining the bank of Genoa of that money with which Philip intended to equip his fleet, and thereby hindering the invaſion for a whole year. He is likewiſe ſaid to have been a commiſſioner for prizes under Lord Charles Howard, High Admiral of England; and going to ſea with letters of marque, he took a Spaniſh ſhip worth L. 20,000. His whole fortune, at his death, appears to have been in land L. 5000 *per annum*; in money, upwards of L. 60,000; the greateſt eſtate in the poſſeſſion of any private gentleman till much later times. He lived with great munificence and hoſpitality; but loſing his lady in 1602, he retired from the world, leſſened his family, and lived in a private frugal manner; and, having no iſſue, reſolved to diſtinguiſh his name by ſome important charity. Accordingly, he purchaſed of the Earl of Suffolk Howward-Houſe, or the late diſſolved charter-houſe, near Smithfield, for the ſum of L. 13,000, where he founded the preſent hoſpital, in 1611, for the relief of poor men and children. Before he had fixed upon this deſign, the court endeavoured to divert him from his purpoſe, and to engage him to make Charles I. then Duke of York, his heir, by conferring on him a peerage; but being free from ambition, and now near his grave, the luſtre of the coronet could not tempt him to change his plan. He died the 11th of December, 1611, at Hackney, aged 79. His body was conveyed, with the moſt ſolemn proceſſion, to Chriſt-church in London, and there depoſited, till 1614, when it was removed to the charter-houſe, and interred in a vault on the north ſide of the chapel, under a magnificent tomb.

Suworow.

SUWOROW (A) RIMNIKSKY (Count Alexander), was a man ſo eminent in his profeſſion, that, if war be an art founded on ſcience, it would be improper not to give ſome account of his life in a Work of this nature. Various accounts of him, indeed, are already in the hands of the public: but they differ ſo much from one another in the pictures which they preſent of the *man*, that it is not eaſy, if it be always poſſible, to diſtinguiſh truth from falſehood. With reſpect to the talents of the *General*, there is not room for the ſame difference of repreſentation; becauſe a train of military ſucceſſes, almoſt unrivalled, has rendered theſe conſpicuous to all Europe. In the ſhort detail that our limits permit us to give of the life of this ſingular man, we ſhall avail ourſelves of all the information, public and private, which we have been able to obtain, and believe to be authentic; and we hope to make our readers acquainted with ſome particulars reſpecting his perſon and domeſtic habits which are not yet generally known.

The family of Suworow is ſaid to have been from Sweden, and of a noble deſcent. The firſt of this name ſettled in Ruſſia about the latter end of the laſt century; and having engaged in the wars againſt the Tartars and the Poles, were rewarded by the Czars of that period with lands and peaſants. Baſil, the father of our hero, is ſaid to have been the godſon of Peter the Great; to have been held in high eſtimation for his political knowledge and extenſive erudition; and to have enjoyed, at his death, the two-fold rank of General and Senator*.

* See *the Hiſtory of the Campaigns of Count Alexander Suworow, by Frederick Antbing.*

As this account is given by a man who profeſſes to have formed an intimate acquaintance with Suworow himſelf, it ought to be correct; and yet we cannot help entertaining ſome doubts of its truth, or at leaſt of its accuracy. It is well known, that extenſive erudition was in no eſteem in Ruſſia at the period when Baſil Suworow is here ſaid to have been ſo learned; and it is likewiſe known, that if, by erudition, be meant a knowledge of ancient literature, it was even deſpiſed, at a much later period, by all who were at once noble, and poſſeſſed of lands and peaſants (See RUSSIA, *Encycl.*). The truth is, as we have learned from unqueſtionable authority, that the family of Suworow was ancient and reſpectable; but being far from affluent, and their little property lying at the very extremity of the empire, we have reaſon to believe, that the ſubject of this memoir was the firſt of the family that ever was at court. Baſil, however, if his anceſtors were from Sweden, may have been free from the Ruſſian prejudices againſt Greek and Latin; and this is the more probable, that he certainly gave a learned education to his ſon.

That ſon, Alexander Baſilowitch Suworow, was, according to the author already quoted, born in the year

1730;

(A) This name is ſpelled ſometimes as we have ſpelled it, ſometimes SUWARROW, and ſometimes SUVOROF. This laſt is according to the pronunciation; but we have adopted the orthography of the General himſelf, in his letter to Charette, the hero of Vendee.

Suworow. 1730: we have some reason to believe that he was not born before 1732. His father had destined him, we are told, for the robe; but his early inclinations impelled him to the profession of a soldier; and in 1742 he was enrolled as a fusilier in the guards of Seimonow. He was afterwards a corporal, then a serjeant, and, in 1754, he quitted the guards with the brevet of Lieutenant in the army. He made his first campaign in the seven years war against the Prussians, in the year 1759, entering upon actual service under Prince Wolgonski. As senior officer on duty, he attended on the commander in chief Count Fermor, who, admiring the consummate resolution which he appeared to possess, favoured him with his particular confidence. In 1761, he was ordered on service in the light troops under General Berg; and with the rank of a field officer (we think that of Lieutenant-colonel) he performed prodigies of valour, and exhibited much of that character which was afterwards so fully developed and displayed. Even then he seems to have formed the resolution of dying on the field of battle rather than suffer himself to be taken prisoner; for when, with a handful of troops, he was once surrounded by a large detachment of Prussians, he determined to cut his way through them, or perish in the attempt. In this daring enterprise he was not only successful, but contrived to carry off with him twenty prisoners, though he was obliged to abandon two field pieces, which he had a little before taken from a smaller detachment.

At the peace of 1762, he received from the Empress a colonel's commission, written with her own hand; and being advanced, in 1768, to the rank of brigadier, he was, in the month of November, ordered to repair, with all possible speed, to the frontiers of Poland. At that unfavourable season he crossed rivers and morasses, whose passage was rendered more difficult by slight frosts; and, in the course of a month, traversed 500 English miles, with the loss of only a few men in the environs of Smolensko.

The object of the Empress, at this time, was to subdue the Polish confederates, and to possess herself of certain provinces of that ill-fated kingdom. How completely she and her two allies, the Emperor of Germany and the King of Prussia, succeeded in their enterprise, has been related elsewhere (see Poland, *Encycl.*). It is sufficient, in this memoir, to observe, that the successes of the Russians were chiefly owing to the military skill and intrepidity of Suworow, who was their only active General, and was indeed, for four years, almost constantly employed in offensive operations against the confederates. Not to mention the numerous actions and skirmishes of an inferior kind, in which his conduct and courage were always displayed, the victory at Staloviz, over a superior force, ably commanded, and the capture of Cracow, were alone sufficient to intitle him to the character which he ever afterwards so well supported. The former of these drew the highest encomiums from the great Frederick of Prussia; and the latter decided the fate of Poland. It is proper to add, that Suworow, on these occasions, did not tarnish his laurels by unnecessary cruelty. When a French officer, who surrendered at Cracow, offered him his sword, according to the custom of war, he refused it, saying, that he would not take the sword of a brave man, whose master was not at war with his sovereign: and, even to the leaders of the confederates, he granted better terms of capitulation than they had the presumption to ask. Suworow.

In the year 1770, he had been promoted to the rank of Major general; and for his exploits in the Polish war, the Empress conferred upon him, at different times, the orders of St Ann, St George, and Alexander Newsky.

After performing some important services on the frontiers of Sweden, Suworow received orders, in the beginning of 1773, to join the army in Moldavia, under the command of Field-marshal Romanzow; and there he began that glorious career, which soon made his name a terror to the Turks. His first exploit was the taking of Turtukey; of which he wrote the following laconic account to the commander in chief:

"Honour and glory to God! Glory to you, Romanzow! We are in possession of Turtukey, and I am in it! "Suworow."

During the remainder of the war, which was of short continuance, Suworow was constantly engaged, and constantly successful. In the beginning of the year 1774, he was promoted to the rank of Lieutenant-general; and on the 11th of June of the same year, he defeated the Turks in a great battle, in which they lost 3000 men killed, some hundreds of prisoners, 40 pieces of artillery, and 80 standards, with their superb camp. Soon after this victory, peace was concluded between the two courts; and Lieutenant-general Suworow was ordered to proceed with all possible haste to Moscow, to assist in appeasing the interior troubles of that part of the empire.

These troubles were occasioned by a Cossac rebel, of the name of *Pugatchew*, or *Pugatcheff*, who, at the head of a party of his discontented countrymen, had long eluded the vigilance of Count Panin, the commander in chief in Muscovy, and frequently cut off detachments of the army which were sent out in quest of him. The chace of Pugatcheff, for such it may be called, was now wholly entrusted to the well-known activity of Suworow; and that General, after pursuing the rebel with inconceivable rapidity, through woods and deserts, came up with him at a place called Urlask, and carried him prisoner to Count Panin, who sent him to Moscow, where he suffered the punishment due to his crimes. This insurgent, it is said, had at one time collected such a force, and was followed with such enthusiasm, that, if his understanding had been equal to his courage, and his moderation had kept pace with his power, he might have possessed himself of Moscow, and made the Imperial Catharine tremble on her throne.

For several years after the taking of Pugatcheff, Suworow was employed in the Crimea, on the Cuban, and against the Nogay Tartars, in a kind of service which, though it was of the utmost importance to the Empress, and required all the address of the Lieutenant-general, furnished no opportunities for that wonderful display of promptitude and resource which had characterised his more active campaigns. One incident, however, must be mentioned, even in this short memoir, because it shews the natural disposition of the man. During the winter that Suworow passed among the Tartars, he was frequently visited by the chiefs of that nation; and at one of these visits, Mechmed Bey, the chief of the Gedissens, often joked with Mussa Bey, another chief, on his inclination to marry. Mussa Bey

Suworow. was fo extremely old, that Suworow thought the converfation ridiculous; and one day afked him, What ground Mechmed could have for fuch idle talk? Muffa replied, that Mechmed Bey was right; that he wifhed to marry; and that he hoped the General would make him a prefent of a beautiful Tartar girl of fixteen! Suworow immediately bought a young Tartar flave of a Coffac for 100 rubles, and fent her to Muffa Bey; who married her, lived with her a very few years, and died at the age of one hundred and eight! regretted, we are told, by the Lieutenant-general, who regarded him with great efteem and attachment.

In the end of the year 1786, Suworow was promoted to the rank of General in Chief; and, at the breaking out of the war with the Turks in 1787, he fhewed how well he was intitled to that rank, by his mafterly defence of Kinburn; a place of no ftrength, but of great importance, as it is fituated at the mouth of the Dneiper, oppofite to Oczakow. For the zeal and abilities which he difplayed on this occafion, the Emprefs decorated him with the order of St Andrew; gave him fix croffes of the order of St George, to be diftributed, according to his judgment, among fuch of his officers as had moft diftinguifhed themfelves; and, in a very flattering letter, regretted the wounds which he had received in defending the place.

At the fiege of Oczakow, Suworow, who commanded the left wing of the army under Prince Potemkin, received a dangerous wound in the nape of the neck, which was followed by fo fmart a fever, that, for fome time, his life was defpaired of; but he perfevered in his long accuftomed practice of preferring regimen to medicine, and his health was gradually re-eftablifhed. In the year 1789, he was appointed to the command of the army which was to co-operate with the Prince of Saxe Cobourg in Walachia; and, by marches of inconceivable rapidity, he twice, in the fpace of two months, preferved the army of that Prince from inevitable deftruction. Putting himfelf at the head of 8000 Ruffians, and literally running to the aid of his ally, he came up with the Turks in time to change the fate of the day at the battle of Forhani, which was fought on the 21ft of July; and again at Rymnik, which, with 7000 men, he had reached with equal celerity, he gained, on the 22d of September, in conjunction with the Prince, one of the greateft victories that have ever been atchieved. According to the leaft exaggerated account, the Turkifh army, commanded by the Grand-Vifier in perfon, amounted to 90.000 or 100,000 men; of which 70,000 were chofen troops; whilft the army of the allies exceeded not 25,000. At the commencement of the attack, Suworow, who had reconnoitered the country, and formed the plan of the battle, called out to his Ruffians, "My friends, look not at the eyes of your enemies, but at their breafts; it is there that you muft thruft your bayonets." No quarter was given to the Turks; and on this account the Ruffian General has been charged with favage ferocity: but the charge, if not groundlefs, muft be fhared equally between him and the Prince of Cobourg. The commanders of the allied army, aware of the immenfe fuperiority of their enemies, had refolved, before the engagement, not to encumber themfelves with prifoners, whom they could not fecure without more than hazarding the fate of the day: And where is the man, who admits the lawfulnefs of war, that will condemn fuch conduct in fuch critical circumftances? Suworow.

The taking of Bender and Belgrade were the immediate confequences of the victory of Rymnic; and fo fenfible was the Emperor Jofeph how much the rapid movements and military fkill of Suworow had contributed to that victory, that he immediately created him a Count of the Roman empire, and accompanied the diploma with a very flattering letter. Similar honours were conferred upon him by his own fovereign, who fent him the diploma of Count of the empire of Ruffia, with the title of Rymnikfki, and the order of St Andrew of the firft clafs.

In the autumn of 1790, Prince Potemkin wrote to Count Suworow, requefting a particular conference. The General, who conjectured the object of it, fent him the following anfwer: "The flotilla of row-boats will get poffeffion of the mouths of the Danube; Tulcia and Ifaccia will fall into our power; our troops, fupported by the veffels, will take Ifmailow and Brahilow, and make Tchiftow tremble." He was perfectly right in his conjecture: it was to concert with him meafures for the taking of Ifmailow that the Prince had requefted the conference. He did not, however, receive orders to undertake that defperate enterprife till the beginning of November, when he rapidly approached towards the fortrefs. His army, by fea and land, confifted of 23,000 men; of whom one-half were Coffacs, and of thefe many were fick. The troops of the garrifon, which were under the orders of feven Sultans, amounted to 43,000 men, of whom nearly one-half were Janiffaries; the fortrefs was by much the ftrongeft of any on the Turkifh frontier: it was under the command of an old warrior, who had twice refufed the dignity of Grand Vifier, and had difplayed againft the Auftrians confiderable abilities, as well as the moft intrepid courage; and the Grand Seignior had publifhed a firman, forbidding the garrifon, on pain of death without trial, to furrender on any terms whatever.

Potemkin, knowing that Suworow had with him no battering cannon, and dreading the confequences of a repulfe, wrote to the General, that if he was not certain of fuccefs, he would do well not to rifk an affault. The laconic reply was; "My plan is fixed. The Ruffian army has already been twice at the gates of Ifmailow; and it would be fhameful to retreat from them the third time without entering the place." To fpare the effufion of blood, however, if poffible, he fent a note to the Serafkier who commanded in Ifmailow, to affure him, upon Count Suworow's word of honour, that if he did not hang out a white flag that very day, the place would be taken by affault, and all the garrifon put to the fword. The Serafkier returned no anfwer to the note; but another commander was pleafed to fay, that "The Danube would ceafe to flow, or the heavens bow down to the earth, before Ifmailow would furrender to the Ruffians!"

Having concerted with the Admiral proper meafures for the affault, Suworow paffed the night with fome officers of his fuite, in impatient vigilance for the appointed hour when the fignals were to be given. Thefe were the firing of a mufket at three, four, and five in the morning, when the army rufhed upon the place; and notwithftanding the defperate oppofition of the Turks, the depth of the moat, and the height of the ramparts, Suworow. ramparts, they were completely masters of Ismailow by four o'clock P. M. In this one dreadful day the Ottomans lost 33,000 men killed or dangerously wounded; 10,000 who were taken prisoners; besides 6000 women and children, and 2000 Christians of Moldavia, who fell in the general massacre. The place was given up to plunder for three days, according to agreement with the army before the assault; but we have authority to say, that no person was murdered in cold blood, who did not prefer his property to his life.

The Russians found in Ismailow 232 pieces of cannon, many large and small magazines of gunpowder, an immense quantity of bombs and balls, 345 standards almost all stained with blood, provisions for the Turkish army for six months, and about 10,000 horses, of which many were extremely beautiful. Suworow, who was inaccessible to any views of private interest, did not appropriate to himself a single article, not so much as a horse; but having, according to his custom, rendered solemn thanks to God for his victory, wrote to Prince Potemkin the following Spartan letter: "The Russian colours wave on the ramparts of Ismailow."

Peace being concluded with the Turks in December 1791, no political events occurred from that period to call forth the military talents of Suworow till 1794. In the beginning of that year mutinies having broken out among the Polish troops in the service of Russia, and the Empress, with her two potent allies, having digested the plan for the partition of Poland, Count Suworow received orders, in the month of May, to proceed, by forced marches, into Red Russia, with a corps of 15,000 men, and to disarm all the Polish troops in that province. This service he performed without the effusion of blood, disarming in less than a fortnight 8000 men, dispersed over a country of 150 miles in circuit. Soon afterwards he was ordered to march into the interior of Poland; the King of Prussia having been obliged to raise the siege of Warsaw, and the Empress perceiving that more vigorous measures than had hitherto been pursued, were necessary to accomplish her designs.

To give a detailed account of his route to Warsaw, would be to write the history of the Polish war, and not the memoirs of Count Suworow. It has been rashly supposed, that he had to contend only with raw troops, commanded by inexperienced leaders, who were not cordially united among themselves; but the fact is otherwise, and Suworow never displayed greater resource in the day of danger, than in the numerous battles and skirmishes in which he was engaged on his march to the capital of Poland. At last, after surmounting every obstacle, he sat down, on the 22d of October, before Praga, a strongly fortified suburb of Warsaw, defended by a formidable artillery, and a garrison of 30,000 men, rendered desperate by their situation. The Russian army exceeded not 22,000; and with that comparatively small force he resolved to storm Praga, as he had stormed Ismail. Having erected some batteries to deceive the garrison into a belief that they were to be regularly besieged, he concerted with the other Generals the mode of assault; and when every thing was ready, he gave his orders in these words: "Storm, and take the batteries, and cut down all who resist; but spare the inhabitants, unarmed persons, and all who shall ask for quarter."

There are but few examples of a military operation so boldly conceived, so skilfully performed, or so important in its consequences, as the taking of Praga. The assault was made at once in seven different places at five in the morning; and at nine the Russians were masters of the place, having penetrated by pure force a triple entrenchment. Of the Poles 13,000 lay dead on the field of battle, one third of whom were the flower of the youth of Warsaw; above 2000 were drowned in the Vistula; and 14,680 were taken prisoners, of whom 8000 were disarmed and immediately set at liberty, and the remainder the next day. We mention these circumstances, because they completely refute the tales of those Jacobin scribblers, who have so strenuously endeavoured to tarnish the laurels of the Russian hero, by representing him as having ordered a general massacre of men, women, and children. The artillery taken from the enemy consisted of 104 pieces of cannon and mortars, chiefly of large calibre. The Russians had 580 men killed, of whom eight were superior and staff officers, and 900 wounded, of whom 23 were officers.

Soon after the storming of Praga, Warsaw capitulated, and Suworow was received into the city by the magistrates in a body, and in their ceremonial habits. When the president presented to him the keys of the city, he pressed them to his lips, and then, holding them up towards heaven, he said, "Almighty God, I render thee thanks, that I have not been compelled to purchase the keys of this place as dear as . . . . ." Turning his face towards Praga, his voice failed him, and his cheeks were instantly bathed with tears. As he rode through the streets, the windows were filled with spectators, who were delighted with the return of order, and the assurance of peace; and the air resounded with the exulting exclamations of "Long live Catharine! Long live Suworow!"

Thus did Count Suworow, in the course of a very few months, overturn the kingdom and republic of Poland. It is not our business, in this article, to decide on the justice of the cause in which he was embarked. Of the Polish revolution, which gave rise to the war that subverted the republic, and swept it from the number of sovereign states, the reader will find some account under the title POLAND in the *Encyclopædia*; but it is here proper to acknowledge, that we do not now think so favourably, as when we wrote that article, of the views and principles of those who framed the constitution, which brought upon them the Russian and Prussian arms. Subsequent events seem to have proved completely, that if Poland had not been conquered by the allied powers, it would soon have been involved, under Kosciusko and his Jacobinical adherents, in all the horrors of revolutionary France; and the unhappy king, instead of being carried captive into Russia, would probably have finished his course on a scaffold. Suworow, who never concerned himself with the intrigues of courts, and expressed on all occasions the most sovereign contempt of those Generals who affected to possess the secrets of statesmen, probably never enquired into the final object of the war, but thought it his duty to execute, in his own sphere, the orders of his Imperial mistress. So sensible was Catharine of the propriety of this conduct, and of the zeal and abilities which he had displayed in the Popish campaign, that immediately on receiving accounts of the storming of Praga

Suworow. Praga and the fubmiffion of Warfaw, fhe announced to him, in a letter written with her own hand, his well-earned advancement to the rank of Field-marfhal General. Nor did her munificence ftop there ; fhe loaded him with jewels, and prefented him with an eftate of 7000 peafants, in the diftrict of Kubin, which had been the fcene of his firft battle in the courfe of the campaign.

From the fubjugation of Poland we hear little more of Field-marfhal Suworow till he entered upon his glorious career in Italy. He is faid, indeed, to have given offence to the prefent Emperor foon after his acceffion to the throne, by affording protection to fome meritorious officers, whom his Majefty had in an arbitrary manner difmiffed from his fervice ; but that offence was overlooked, and Suworow called again into action, when Paul joined the coalition againft France.

Of the exploits of the Field-marfhal in Italy, where, to ufe his own words, he deftroyed armies and overturned ftates, we have given a full account under the title Revolution in this *Supplement*. In his former campaigns, the wifdom of his meafures, the diftribution of his forces, the undaunted character of his operations, and the progreffive continuance of his fucceffes, furnifh proofs of the fuperiority of his talents hardly to be paralleled in the annals of modern war ; but, animated by the noblenefs of his caufe, and confiding, as he faid, in the God of battles, he feems i. his laft campaign to have furpaffed himfelf. It would appear, however, that his own Sovereign thought otherwife ; and if he did, he was certainly as fingular in that opinion as he is faid to have been in many others. Confidering the Field-marfhal as the conqueror of Italy, he had indeed created him a Prince by the ftyle and title of Prince Suworow-*Italifki ;* but how did he receive him, when he returned into the Ruffian dominions at the head of his veteran and victorious bands ?

Though the old warrior thought himfelf almoft betrayed at the end of the campaign by the crooked policy of the court of Vienna, he doubtlefs hoped to be received at the Court of St Peterfburgh, if not with triumphal arches, at leaft with the moft public teftimonies of his Sovereign's approbation. It is faid that he expected to be fent back at the head of a large army, with full powers to act as he fhould judge proper for bringing the war to a happy termination, and reftoring peace and order to Europe ; and he certainly expreffed, in letters to different correfpondents, his earneft wifh to conclude his military career with contributing to the accomplifhment of fo defirable an object. What then muft have been his difappointment, when the Ruffian Emperor would not fee him, and pofitively forbad his appearance at court ? To the meffenger who brought the order, the Field-marfhal gave a purfe of money, turned his carriage another way, and drove to a wooden houfe, at a diftance from the court, and from his former friends, "where burft his mighty heart ;" and the conqueror of the Turks, the Poles, and the French republicans, died, almoft unattended, on the 18th of May 1800. The fovereign, who thus difgraced him at the end of his life, gave him a magnificent funeral !

In his perfon Suworow was tall, confiderably exceeding fix feet, and full chefted. His countenance was Suworow. ftern ; but among his friends his manners were pleafant, and his difpofitions were kind. His temper was naturally violent ; but that violence he conftantly laboured to moderate, though he was never able completely to extinguifh it. According to M. Anthing, an effervefcent fpirit of impatience predominated in his character ; and it perhaps never happened (fays that author) that the execution of his orders equalled the rapidity of his wifhes. Though he difliked all public entertainments, yet when circumftances led him to any of them, he appeared to partake, and endeavoured to promote, the general pleafure. Sometimes he condefcended even to dance and play at cards, though very rarely, and merely that he might not interrupt the etiquette of public manners, to which, when not in the field, he was very attentive. In the field he may be faid to have fpent the whole of his life from the period at which he firft joined the army in the feven years war ; for during the time that he was not engaged in actual warfare, and that time, taken altogether, did not exceed twelve years, he was always placed at the head of armies ftationed on the frontier of fome enemy's country. He was therefore a mere warrior, and as fuch had no fixed habitation. With refpect to his table and lodging, he contented himfelf with whatever he found, requiring nothing but what abfolute neceffity demands, and what might be tranfported with eafe from one place to another. Frequently he caufed the window-fafhes to be taken away, and fometimes the doors : faying, on the former occafion, that he was not cold ; and, on the latter, that he was not afraid. His couch confifted of a heap of frefh hay fufficiently elevated, and fcattered into confiderable breadth, with a white fheet fpread over it, with a cufhion for his pillow, and with a cloak for his coverlid. He has been reprefented as dirty (c) ; but the reprefentation is falfe. M. Anthing afferts, that he was clean in his perfon, and that, when not on actual fervice, he wafhed himfelf frequently during the courfe of the day. It is among the fingular, though unimportant circumftances of his life (fays the fame author), that, for the laft twenty years, he had not made ufe of a looking-glafs, or incumbered his perfon with either watch or money.

He was fincerely religious ; took every opportunity of attending the offices of public devotion ; and has been known, on Sundays and feftivals, to deliver lectures on piety to thofe whom duty called to attend on him. We are told by an anonymous writer, in a mifcellany not very forward to praife fuch men as Suworow, or indeed to praife piety in men of any defcription, that chancing one evening to overhear a captain abridge the prayer which his duty required him to repeat at the guard, the Field-marfhal called out to him, "Thou unconfcionable, abominable, impious man, thou wouldft cheat Heaven ! Thou wouldft, no doubt, cheat likewife the Emprefs and me ! I fhall difmifs thee." His regard for facred things is indeed very apparent in the elegant letter which, on the 1ft of October 1795, he wrote to Charette, the hero of Vendee, whom he congratulates upon taking up arms to reftore the temples of the God of his fathers. Alluding to this trait of his

(c) By the anonymous author of the life of Catharine II.

his character, and to his detestation of Jacobinism under every form, a late writer in a most respectable miscellany has well characterised him as the

"Foe to religion's foe; of Russia's throne
The prop, th' avenger, and the pride in one;
Whose conquering arms, in bold defiance hurl'd,
Crushed the rude monster of the western world."

We have already, when we thought not that we should so soon be called upon to write his life, observed, that he was a scholar, a man of science, and a poet. M. Anthing assures us, that from his earliest years he was enamoured of the sciences, and improved himself in them; but that as the military science was the sole object of his regard, those authors of every nation who investigate, illustrate, or improve it, engrossed his literary leisure. Hence Cornelius Nepos was with him a favourite classic; and he read, with great avidity and attention, the histories of Montecuculi and Turenne. Cæsar, however, and Charles XII. (says the same author) were the heroes whom he most admired, and whose activity and courage became the favourite objects of his imitation.

With respect to his moral character, we have every reason to believe that he was a man of the most incorruptible probity, immoveable in his purposes, and inviolable in his promises; that the cruelties of which he has been accused were the cruelties of Potemkin, and that by those who knew him he was considered as a man of unquestionable humanity. The love of his country, and the ambitiou to contend in arms for its glory, were the predominant passions of his active life; and to them, like the ancient Romans, he sacrificed every inferior sentiment, and consecrated, without reserve, all the powers of his body and mind. His military career was one long and uniform course of success and triumph, produced by his enterprising courage and extraordinary presence of mind; by his personal intrepidity and promptitude of execution; by the rapid and unparalleled movements of his armies; and by their perfect assurance of victory when fighting under his banners. I know not, says a writer *, by no means partial to him or to the cause for which he last fought, whether Suworow was invincible; but it is certain that he died unconquered. No general can boast of having beaten Suworow; and very few, like him, have carried that reputation to the grave, after having, like him, waged war for the space of fourty years, sometimes against the most barbarous people, and sometimes against the most civilized nations. Such was Alexander Besilovitch Count Suworow. In the year 1774 he married a daughter of the General Prince Iwan Prosorowski, by whom he had two children, now living: Natalia, married to General Count Nicolai Zubow; and Arcadius Count Suworow, a youth of great promise, who accompanied his father in his unparalleled march from Italy to Switzerland.

* *Secret Memoirs of the Court of St Petersburgh.*

SWALLOW's-Tail, in fortification, is a single tenaille, which is narrower towards the place than towards the country.

SWAN (See Anas, *Encycl.*). It is now ascertained, beyond the possibility of doubt, that there are *black* swans, of equal size, and the same habitudes, with the common white swan of this island. These fowls have been seen chiefly in New Holland; and Captain Vancouver, when there, saw several of them in very stately attitudes, swimming on the water; and, when flying, discovering the under part of their wings and breasts to be white. Black swans were likewise seen in New Holland by Governor Philips, Captain White, and by a Dutch navigator, so long ago as in 1697. Governor Philips describes the black swan as a very noble bird, larger than the common swan, and equally beautiful in form. Mr White indeed says, that its size is not quite equal to that of the European swan; but both these authors agree with Captain Vancouver in mentioning some white feathers in its wings.

SWINTON (John), a very celebrated English antiquary, was a native of the county of Chester, the son of John Swinton of Bexton in that county, gent. He was born in 1703. The circumstances of his parents were probably not affluent, as he was entered at Oxford in the rank of a servitor at Wadham college. This was in October 1719. It may be presumed that he recommended himself in that society by his talents and behaviour, as on June 30. 1723 he was elected a scholar on a Cheshire foundation in the college. In the December following, he took his first degree in arts. Before he became master of arts (which was on December 1. 1726), he had chosen the church for his profession, and was ordained deacon by the bishop of Oxford, May 30. 1725; and was afterwards admitted to priest's orders on May 28. 1727. He was not long without some preferment, being admitted to the rectory of St Peter le Bailey in Oxford (a living in the gift of the crown), under a sequestration, and instituted to it in February 1728. In June the same year, he was elected a fellow of his college; but, desirous probably to take a wider view of the world, he accepted, not long after, the appointment of chaplain to the English factory at Leghorn, to which he had been chosen. In this situation he did not long enjoy his health; and leaving it on that account, he was at Florence in April 1733, where he attended Mr Coleman, the English envoy, in his last moments. Mr Swinton returned thro' Venice and Vienna; and, in company with some English gentlemen of fortune, visited Presburgh in Hungary, and was present at one of their assemblies.

Biog. Dict.

It is possible that he had not quitted England in the summer of 1730, for he was elected a fellow of the Royal Society in June that year, and admitted about three months later. It was probably while he was abroad that he was admitted into some foreign societies; namely, the academy *degli Apatisti* at Florence, and the *Etruscan Academy* of Cortona. On his return, he seems to have taken up his abode at Oxford, where he resided all the latter part of his life, and was for many years chaplain to the gaol in that city. It many be presumed that he married in 1743; it was then, at least, that he gave up his fellowship. In 1759 he became bachelor of divinity: in 1767, he was elected *Custos Archivorum*, or keeper of the university records: and, on April 4. 1777, he died; leaving no children. His wife survived till 1784, and both were buried, with a very short and plain inscription, in the chapel of Wadham college.

It remains to take notice of the most important monuments of a literary man's life, his publications. These were numerous and learned, but not of great magnitude. He published, 1. "De Linguæ Etruriæ Regalis vernacula Dissertatio," 4to, 19 pages, Oxon, 1738.

2. "A

Swinton. 2. "A critical essay concerning the words Δαιμων and Δαιμονιον, occasioned by two late inquiries into the meaning of the demoniacs in the New Testament," 8vo, London, 1739. 3. "De priscis Romanorum literis dissertatio," 4to, 20 pages, Oxon, 1746. 4. "De Primogenio Etruscorum Alphabeto, dissertatio," Oxon, 1746. 5. "Inscriptiones Citieæ: sive in binas Inscriptiones Phœnicias, inter rudera Citii nuper repertas, conjecturæ. Accedit de nummis quibusdam Samaritanis et Phœniciis, vel insolitam præ se literaturam ferentibus, vel in lucem hactenus non editis, dissertatio," 4to, 87 pages, Oxon, 1750. 6. "Inscriptiones Citieæ: sive in binas alias Inscriptiones Phœnicias, inter rudera Citii nuper repertas, conjecturæ," 4to, 19 pages. 7. "De nummis quibusdam Samaritanis et Phœniciis, vel insolitam præ se literaturam ferentibus, vel in lucem hactenus non editis, dissertatio secunda," 4to, 36 pages. 8. "Metilia: sive de quinario Gentis Metiliæ, è nummis vetustis cæteroquin minimum notæ, dissertatio," 4to, 22 pages, Oxon, 1750. 9. Several dissertations published in the Philosophical Transactions of the Royal Society. As, "A dissertation upon a Parthian Coin; with characters on the reverse resembling those of the Palmyrenes," vol. xlix. p. 593. "Some remarks on a Parthian Coin, with a Greek and Parthian legend, never before published," vol. l. p. 16. "A dissertation upon the Phœnician numeral characters anciently used at Sidon, vol. l. p. 791. "In nummum Parthicum hactenus ineditum conjecturæ," vol. li. p. 683. "A dissertation upon a Samnite Denarius, never before published," vol. lii. p. 28. "An account of a subærated Denarius of the Plætorian family, adorned with an Etruscan inscription on the reverse, never before published or explained," vol. lxii. p. 60. "Observations upon five ancient Persian Coins, struck in Palestine or Phœnicia before the dissolution of the Persian empire," vol. lxii. p. 345. Other papers by him may be found in the general index to the Philosophical Transactions. 10. A part of the Ancient Universal History, contained in the sixth and seventh volumes of that great work. The particulars of this piece of literary history were communicated by Dr Johnson to Mr Nichols, in a paper printed in the Gentleman's Magazine for December 1784, p. 892. The original of that paper, which affords a strong proof of the steady attachment of Johnson to the interests of literature, has been, according to his desire, deposited in the British Museum. The letter is as follows:

"To Mr Nichols.

"The late learned Mr Swinton of Oxford having one day remarked, that one man, meaning, I suppose, no man but himself, could assign all the parts of the Universal History to their proper authors, at the request of Sir Robert Chambers, or of myself, gave the account which I now transmit to you in his own hand, being willing, that of so great a work the history should be known, and that each writer should receive his due proportion of praise from posterity. I recommend to you to preserve this scrap of literary intelligence, in Mr Swinton's own hand, or to deposite it in the Museum, that the veracity of the account may never be doubted.—I am, Sir, your most humble servant,

Dec. 6. 1784. SAM. JOHNSON."

The paper alluded to, besides specifying some parts written by other persons, assigns the following divisions of the history to Mr Swinton himself. "The history of the Carthagians, Numidians, Mauritanians, Gætulians, Garamantes, Melano-Gætulians, Nigritæ, Cyrenaica, Marmarica, the Regio Syrtica, Turks, Tartars, and Moguls, Indians, and Chinese, a dissertation on the peopling of America, and one on the independency of the Arabs.

In the year 1740, Mr Swinton was involved in a law suit, in consequence of a letter he had published. It appears from a paper of the time *, that a letter from the Rev. Mr Swinton, highly reflecting on Mr George Baker, having fallen into the hands of the latter, the court of King's Bench made the rule absolute for an information against Mr Swinton. These two gentlemen were also engaged for some time in a controversy at Oxford; which took its rise from a matter relative to Dr Thistlethwaite, some time warden of Wadham, which then attracted much attention. Mr Swinton had the manners, and some of the peculiarities, often seen in very recluse scholars, which gave rise to many whimsical stories. Among the rest, there is one mentioned by Mr Boswell, in the Life of Johnson, as having happened in the year 1754. Johnson was then on a visit in the university of Oxford. "About this time (he says) there had been an execution of two or three criminals at Oxford, on a Monday. Soon afterwards, one day at dinner, I was saying that Mr Swinton, the chaplain of the gaol, and also a frequent preacher before the university, a learned man, but often thoughtless and absent, preached the condemnation sermon on repentance, before the convicts, on the preceding day, Sunday; and that, in the close, he told his audience, that he should give them the remainder of what he had to say on the subject the next Lord's day. Upon which, one of our company, a doctor of divinity, and a plain matter-of-fact man, by way of offering an apology for Mr Swinton, gravely remarked, that he had probably preached the same sermon before the university. Yes, Sir (says Johnson); but the university were not to be hanged the next morning!

* *The Champions, or Evening Advertiser*, June 17th 1740.

TACQUET

T.

TACQUET (Andrew), a Jesuit of Antwerp, who died in 1660. He was a moſt laborious and voluminous writer in mathematics. His works were collected, and printed at Antwerp, in one large volume in folio, 1669.

TALLOW-Tree. See Croton (*Encycl.*), where, however, we have fallen into a miſtake, which it is here our duty to correct. We learn from Sir George Staunton, that the candles made of the vegetable tallow are firmer than thoſe made of animal tallow, and free from all offenſive ſmell, contrary to what was raſhly ſaid in the article referred to. They are not, however, equal to thoſe of wax or ſpermaceti; but the latter of theſe ſubſtances is not within the reach of the Chineſe, and the art of blanching the former is little known to them. The tallow tree is ſaid to have been tranſplanted to Carolina, and to flouriſh there as well as in China.

TALOOK, an Arabic word, which ſignifies literally attachment, connection, dependence. In Bengal, however, where it occurs perpetually in the enumeration of the diſtricts, and ſubdiviſions of that province contained in the inſtitutes of Akber, it ſignifies a tenure of land. Hence the *talook* of Caſhinat, the *talook* of Meheys the headman, the *talook* of Ahmed Khan, &c. See *A Diſſertation concerning the Landed Property of Bengal*, by Sir Charles Rouſe Boughton.

TALOOKDAR, the poſſeſſor of a talook.

TALOOKDARY, tenure of a talookdar.

TALUS, or Talud, in architecture, the inclination or ſlope of a work; as of the outſide of a wall, when its thickneſs is diminiſhed by degrees, as it riſes in height, to make it the firmer.

Talus, in fortification, means alſo the ſlope of a work, whether of earth or maſonry.

TAMASCAL, the name given in California to a kind of ſand-bath employed by the natives in the cure of the venereal diſeaſe. It is prepared by ſcooping a trench in the ſand, two feet wide, one foot deep, and of a length proportioned to the ſize of the patient; a fire is then made through the whole extent of it, as well as upon the ſand which was dug out of the hollow. When the whole is thoroughly heated, the fire is removed, and the ſand ſtirred about, that the warmth may be equally diffuſed. The ſick perſon is then ſtripped, laid down in the trench, and covered up to his chin with heated ſand. In this poſition a very profuſe ſweat ſoon breaks out, which gradually diminiſhes according as the ſand cools. The patient then riſes and bathes in the ſea, or the neareſt river. This proceſs is repeated till a complete cure is obtained. While the patient is undergoing the operation of the tamaſcal, he drinks a conſiderable quantity of a warm ſudorific, prepared by the decoction of certain herbs, chiefly of the ſhrub called by the Spaniards Gouvernante, which ſee in this *Supplement*.

TAN is a ſubſtance found in moſt vegetables, which not having hitherto been reſolved into component parts, is therefore conſidered as ſimple. See *Vegetable and Animal Substances* in this *Suppl.*

TANNING is an art, of which a full account, according to the general practice in London and its vicinity, has been given under the proper title in the *Encyclopædia*. But ſince that article was written, the ſuperior knowledge which has been obtained of the tanning principal, as well as of the compoſition of the ſkins of animals (See *Vegetable and Animal Substances, Suppl.*), has ſuggeſted to ſcientific artiſts various methods of ſhortening the proceſs by which leather is manufactured. M. Seguin is ſaid to have thrown much light upon the art of the tanner as it is practiſed in France; and in 1795 Mr William Deſmond obtained a patent for practiſing Seguin's method in England. He obtains the tanning principle by digeſting oak bark, or other proper material, in cold water, in an apparatus nearly ſimilar to that uſed in the ſaltpetre works. That is to ſay, the water which has remained upon the powdered bark for a certain time, in one veſſel, is drawn off by a cock, and poured upon freſh tan. This is again to be drawn off, and poured upon other freſh tan; and in this way the proceſs is to be continued to the fifth veſſel. The liquor is then highly coloured, and marks, as Mr Deſmond ſays, from ſix to eight degrees on the hydrometer for ſalts. He calls this the tanning lixivium. The criterion to diſtinguiſh its preſence is, that it precipitates glue from its aqueous ſolution, and is alſo uſeful to examine how far other vegetable ſubſtances, as well as oak bark, may be ſuitable to the purpoſe of tanning. The ſtrong tanning liquor is to be kept by itſelf. It is found by trials with the glue, that the tanning principle of the firſt digeſter which receives the clear water, is, of courſe, firſt exhauſted. But the ſame tan will ſtill give a certain portion of the aſtringent principle, or gallic lixivium, to water. The preſence of this principle is aſcertained by its ſtriking a black colour when added to a ſmall quantity of the ſolution of vitriol of iron or green copperas. As ſoon as the water from the digeſter ceaſes to exhibit this ſign, the tan is exhauſted, and muſt be replaced with new. The gallic lixivium is reſerved for the purpoſe of taking the hair off from hides.

Strong hides, after waſhing, cleaning, and fleſhing, in the uſual way, are to be immerſed for two or three days in a mixture of gallic lixivium and one thouſandth part by meaſure of denſe vitriolic acid. By this means the hair is detached from the hides, ſo that it may be ſcraped off with a round knife. When ſwelling or raiſing is required, the hides are to be immerſed for ten or twelve hours in another vat filled with water and one five-hundredth part of the ſame vitriolic acid. The hides being then repeatedly waſhed and dreſſed, are ready for tanning; for which purpoſe they are to be immerſed for ſome hours in a weak tanning lixivium of only one or two degrees; to obtain which, the latter portions of the infuſions are ſet apart; or elſe ſome of that which has been partly exhauſted by uſe in tanning. The hides are then to be put into a ſtronger lixivium, where in a few days they will be brought to the ſame degree of ſaturation with the liquor in which they are immerſed. The ſtrength of the liquor will by this means be conſiderably diminiſhed, and muſt therefore be renewed. When the hides are by this means completely ſaturated, that is to ſay, perfectly tanned, they are to be removed, and ſlowly dried in the ſhade.

Calf ſkins, goat ſkins, and the like, are to be ſteeped

Tanning, Taffie.

in lime-water after the ufual flefhing and wafhing. Thefe are to remain in the lime water, which contains more lime than it can diffolve, and requires to be ftirred feveral times a-day. After two or three days, the fkins are to be removed, and perfectly cleared of their lime by wafhing and preffing in water. The tanning procefs is then to be accomplifhed in the fame manner as for the ftrong hides, but the lixivium muft be confiderably weaker. Mr Defmond remarks, that lime is ufed inftead of the gallic lixivium for fuch hides as are required to have a clofe grain: becaufe the acid mixed with that lixivium always fwells the fkins more or lefs; but that it cannot with the fame convenience be ufed with thick fkins, on account of the confiderable labour required to clear them of the lime; any part of which, if left, would render them harfh and liable to crack. He recommends, likewife, as the beft method to bring the whole furface of the hides in contact with the lixivium, that they fhould be fufpended vertically in the fluid by means of tranfverfe rods or bars, at fuch a diftance as not to touch each other. By this practice much of the labour of turning and handling may be faved.

Mr Defmond concludes his fpecification, by obferving, that in fome cafes it will be expedient to mix frefh tan with the lixivium; and that various modifications of ftrength, and other circumftances, will prefent themfelves to the operator. He affirms that, in addition to the great faving of time and labour in this method, the leather, being more completely tanned, will weigh heavier, wear better, and be lefs fufceptible of moifture than leather tanned in the ufual way; that cords, ropes, and cables, made of hemp or fpeartery, impregnated with the tanning principle, will fupport much greater weights without breaking, be lefs liable to be worn out by friction, and will run more fmoothly on pulleys; infomuch that, in his opinion, it will render the ufe of tar in many cafes, particularly in the rigging of fhips, unneceffary; and, laftly, that it may be fubftituted for the prefervation of animal food inftead of falt.

Mr Nicholfon, from whofe Philofophical Journal we have taken this account of Mr Defmond's method of tanning, made fome very proper enquiries at one of the firft manufacturing houfes in the borough of Southwark, concerning its value. He was told by one of the partners, that the principle upon which the new procefs is founded had been long known to them; but that they preferred the old and flower method, becaufe the hides are found to feed and improve in their quality by remaining in the pit. He could gain no fatisfactory information of what is meant by this feeding and improving; and, without taking upon us to decide between the advantages peculiar to Defmond's method and thofe of the common practice, we cannot help faying that this objection of the tanner at Southwark appears to us to be that of a man who either underftands not the principles of his own art, or has fome reafon for oppofing the progrefs of improvement, if it do not originate in his own houfe.

TASSIE (James) modeller, whofe hiftory is intimately connected with a branch of the fine arts in Britain, was born in the neighbourhood of Glafgow of obfcure parents: and began his life as a country ftone-mafon, without the expectation of ever rifing higher. Going to Glafgow on a fair day, to enjoy himfelf with his companions, at the time when the Foulis's were attempting to eftablifh an academy for the fine arts in that city, he faw their collection of paintings, and felt an irrefiftible impulfe to become a painter. He removed to Glafgow; and in the academy acquired a knowledge of drawing, which unfolded and improved his natural tafte. He was frugal, induftrious, and perfevering; but he was poor, and was under the neceffity of devoting himfelf to ftone-cutting for his fupport: not without the hopes that he might one day be a ftatuary if he could not be a painter. Reforting to Dublin for employment, he became known to Dr Quin, who was amufing himfelf in his leifure hours with endeavouring to imitate the precious ftones in coloured paftes, and take accurate impreffions of the engravings that were on them.

That art was known to the ancients; and many fpecimens from them are now in the cabinets of the curious. It feems to have been loft in the middle ages; was revived in Italy under Leo X. and the Medici family at Florence; became more perfect in France under the regency of the Duke of Orleans, by his labours and thofe of Homberg. By thofe whom they inftructed as affiftants in the laboratory it continued to be practifed in Paris, and was carried to Rome. Their art was kept a fecret, and their collections were fmall. It is owing to Quin and to Taffie that it has been carried to fuch high perfection in Britain, and attracted the attention of Europe.

Dr Quin, in looking out for an affiftant, foon difcovered Taffie to be one in whom he could place perfect confidence. He was endowed with fine tafte: he was modeft and unaffuming: he was patient; and poffeffed the higheft integrity. The Doctor committed his laboratory and experiments to his care. The affociates were fully fuccefsful; and found themfelves able to imitate all the gems, and take accurate impreffions of the engravings.

As the Doctor had followed the fubject only for his amufement, when the difcovery was completed, he encouraged Mr Taffie to repair to London, and to devote himfelf to the preparation and fale of thofe paftes as his profeffion.

In 1766 he arrived in the Capital. But he was diffident and modeft to excefs; very unfit to introduce himfelf to the attention of perfons of rank and of affluence: befides, the number of engraved gems in Britain was fmall; and thofe few were little noticed. He long ftruggled under difficulties which would have difcouraged any one who was not poffeffed of the greateft patience, and the warmeft attachment to the fubject. He gradually emerged from obfcurity, obtained competence; and what to him was much more, he was able to increafe his collection, and add higher degrees of perfection to his art. His name foon became refpected, and the firft cabinets in Europe were open for his ufe; and he uniformly preferved the greateft attention to the exactnefs of the imitation and accuracy of the engraving, fo that many of his paftes were fold on the Continent by the fraudulent for real gems. His fine tafte led him to be peculiarly careful of the impreffion; and he uniformly deftroyed thofe with which he was in the leaft diffatisfied. The art has been practifed of late by others; and many thoufands of paftes have been fold as Taffie's, which he would have confidered as injurious to his fame. Of the fame of others he was not envious; for he uniformly fpake with franknefs in praife of thofe who executed them well, though they were endeavouring to rival himfelf.

To

To the ancient engravings he added a numerous collection of the moft eminent modern ones; many of which approach in excellence of workmanfhip, if not in fimplicity of defign and chaftity of expreffion, to the moft celebrated of the ancient. Many years before he died he executed a commiffion for the late Emprefs of Ruffia, confifting of about 15,000 different engravings (See Gem, *Encycl.*). At his death, in 1799, they amounted to near 20,000; a collection of engravings unequalled in the world. Every lover of the fine arts muft be fenfible of the advantage of it for improvement in knowledge and in tafte. The collection of Feloix at Paris confifted of 1800 articles; and that of Dehn at Rome of 2500.

For a number of years, Mr Taffie practifed the modelling of portaits in wax, which he afterwards moulded and caft in pafte. By this, the exact likenefs of many eminent men of the prefent age will be tranfmitted to pofterity as accurately as thofe of the philofophers and great men have been by the ancient ftatuaries. In taking likeneffes he was, in general, uncommonly happy; and it is remarkable, that he believed there was a certain kind of infpiration (like that mentioned by the poets) neceffary to give him full fuccefs. The writer of this article, in converfing with him repeatedly on the fubject, always found him fully perfuaded of it. He mentioned many inftances in which he had been directed by it; and even fome, in which, after he had laboured in vain to realize his ideas on the wax, he had been able, by a fudden flafh of imagination, to pleafe himfelf in the likenefs feveral days after he had laft feen the original.

He poffeffed alfo an uncommonly fine tafte in architecture, and would have been eminent in that branch if he had followed it.

In private life Mr Taffie was univerfally efteemed for his uniform piety, and for the fimplicity, the modefty, and benevolence, that fhone in the whole of his character.

TASTELESS Earth (*aguft erde*), the name given by Profeffor Trommfdorff to a new fimple earth, which he difcovered in the Saxon beryl. It is diftinguifhed (he fays) from other earths by the following properties: It is white, and totally infoluble in water. In a frefh ftate, when moiftened with water, it is fomewhat ductile. In the fire it becomes tranfparent and very hard, fo as to fcratch glafs, but remains infipid and infoluble in water. The burnt earth diffolves very eafily in acids, and produces with them peculiar falts, which are entirely devoid of tafte; and hence he gave it the name of *taftelefs earth*. Fixed alkalies do not diffolve this earth either in the dry or in the wet way; and it is equally infoluble with the carbonic acid and with cauftic ammonia. It has a greater affinity to the oxalic than to other acids. Profeffor Trommfdorff informs us, that a full account of this earth, accompanied with an accurate defcription, by Dr Bernhardi, of the foffil in which it is found, will appear in the firft part of the eighth volume of his *Journal of Pharmacy*.

TEETH, of various forts of machines, as of mill wheels, &c. Thefe are often called cogs by the workmen; and by working in the pinions, rounds or trundles, the wheels are made to turn one another. Mr Emerfon (in his Mechanics, prop. 25.) treats of the theory of teeth, and fhews that they ought to have the figure of epicycloids, for properly working in one another.

TEKAWY, in Bengal, money advanced by government to the proprietors or cultivators of land to affift them under circumftances of diftrefs.

TELESCOPE, is an inftrument which has been fo completely defcribed in the *Encyclopædia*, that it is introduced into this place merely to notice an ingenious fuggeftion of Mr Nicholfon's for improving the achromatic telefcope, by adding an artificial iris to the object glafs. Suppofe (fays he) a brafs ring to furround the object end of the telefcope, and upon this let eight or more triangular flips of brafs be fixed, fo as to revolve on equi-diftant pins paffing through each triangle near one of its corners. If the triangles be flided inwards upon each other, it may readily be apprehended that they will clofe the aperture; and if they be all made to revolve or flide backwards alike, it is clear that their edges will leave an octagonal aperture, greater or lefs according to circumftances. The equable motion of all the triangles may be produced either by pinions and one concave toothed wheel, or by what is called fnail-work. Another kind of iris, more compact, may be made, by caufing thin elaftic flips of brafs to flide along parallel to the tube, and be conducted each through a flit in a brafs cap which fhall lead them acrofs the aperture in a radial direction. It is probable alfo that the artift, who fhall carry thefe hints into effect, may alfo think of feveral other methods.

This thought occurred to the author, from contemplating the contraction and dilatation of the iris of the eye, according as we look at an object more or lefs luminous. Thefe variations are fo great, that in the obfervable variations of the human eye, the aperture is thirty times as large at one time as at another, whilft in the cat the proportion is greater than a hundred to one.

TEMPERAMENT of the scale of music. Introduction.

When the confiderate reader reflects on the large and almoft numberlefs differtations on this fubject, by the moft eminent philofophers, mathematicians, and artifts, both of ancient and modern times, and the important points which divided, and ftill divide, their opinions, he will not furely expect, in a Work like our's, the decifion of a queftion which has hitherto eluded their refearches. He will rather be difpofed, perhaps, to wonder how a fubject of this nature ever acquired fuch importance in the minds of perfons of acknowledged talents (for furely no perfon will refufe this claim to Pythagoras, to Ariftotle, Euclid, Ptolemy, Galileo, Wallis, Euler, and many others, who have written elaborate treatifes on the fubject); and his furprife will increafe, when he knows that the treatifes on the fcale of mufic are as numerous and voluminous in China, without any appearance of their being borrowed from the ingenious and fpeculative Greeks.

The ingenious, in all cultivated nations, have remarked the great influence of mufic; and they found no difficulty in perfuading the nations that it was a gift of the gods. Apollo and his facred choir are perhaps the moft refpectable inhabitants of the mythological heavens of the Greeks. Therefore all nations have confidered mufic as a proper part of their religious worfhip. We doubt not but that they found it fit for exciting or fupporting thofe emotions and fentiments which were fuited to adoration, thanks, or petition. Nor would the Greeks have admitted mufic into their ferious dramas, if they had not perceived that it heightened the effect.

Temperament of the Scale of Muſic.

The ſame experience made them employ it as an aid to military enthuſiaſm; and it is recorded as one of the reſpectable accompliſhments of Epaminondas, that he had the muſical inſtructions of the firſt maſters, and was eminent as a performer.

Thus was the ſtudy of muſic ennobled, and recommended to the attention of the greateſt philoſophers. Its cultivation was held an object of national concern, and its profeſſors were not allowed to corrupt it in order to gratify the faſtidious taſte of the luxurious or the ſenſualiſt, who ſought from it nothing but amuſement. But its influence was not confined to theſe public purpoſes; and, while the men of ſpeculation found in muſic an inexhauſtible fund of employment for their genius and penetration, and their poets felt its aid in their compoſitions, it was hailed by perſons of all ranks as the ſoother of the cares and anxieties, and ſweetener of the labours of life. *O Phœbe decus!—laborum dulce lenimen.* Poor Ovid, the victim of what remained of good in the cold heart of Octavius, found its balm.

Exul eram (ſays he): *requieſque mihi, non fama petita eſt.*
Mens intenta ſuis ne foret uſque malis.
Hoc eſt cur cantet vinctus quoque compede foſſor,
Indocili numero cum grave mollit opus.
Cantet et innitens limoſæ pronus arenæ
Adverſo tardam qui trahit amne ratem,
Quique ferens pariter lentos ad pectora remos,
In numerum pulſâ brachia verſat aquâ.
Feſſus ut incubuit baculo, ſaxove reſedit
Paſtor; arundineo carmine mulcet oves.
Cantantis pariter, pariter data penſa trahentis
Fallitur ancillæ, decipiturque labor.

2 Scale of muſic. It requires temperament.

It is chiefly in this humble department of muſical influence that we propoſe at preſent to lend our aid. What has been ſaid in the article Music, *Encycl.* is ſufficient for informing the reader of what is received as the ſcale of muſic, and the inequality of its different ſteps, the tones major and minor, ſemitone, comma, &c. We ſhall only obſerve, that what is there delivered on temperament by M. d'Alembert, after Rameau, bears the evident mark of uncertainty or want of confidence in the principle adopted as the rule of temperament; and we have learned, ſince the printing of that article, that the inſtructions there delivered have not that perſpicuity and preciſion that are neceſſary for enabling a perſon to execute the temperament recommended by Rameau; that is, to tune a keyed inſtrument with certainty, according to that ſyſtem or conſtruction of the ſcale.

If ſuch be the caſe, we are in ſome meaſure diſappointed; becauſe we ſelected that treatiſe of D'Alembert as the performance of a man of great eminence as a mathematician and philoſopher, aiming at public inſtruction more than his own fame, by this elementary abſtract of the great work of the moſt eminent muſician in France.

Few can tune a harpſichord;

To be able to tune a harpſichord with certainty and accuracy, ſeems an indiſpenſable qualification of any perſon worthy of the name of a *muſician.* It would certainly be thought an unpardonable deficiency in a violin performer if he could not tune his inſtrument; yet we are well informed, that many profeſſional performers on the harpſichord cannot do it, or cannot do it any other way than by uncertain and painful trial, and, as it were, groping in the dark; and that the tuning of harpſichords and organs is committed entirely to tuners by profeſſion. This is a great inconvenience to perſons reſiding in the country; and therefore many take leſſons from the profeſſed harpſichord tuners, who alſo profeſs to teach this art. We have been preſent during ſome of theſe leſſons; but it did not appear to us that the inſtructions were ſuch as could enable the ſcholar to tune an inſtrument when alone, unleſs the leſſons had been ſo frequent as to form the ear to an inſtantaneous judgment of tune by the ſame habit that had inſtructed the teacher. There ſeemed to be little principle that could be treaſured up and recollected when wanted.

3 Yet Nature furniſhes abundant means of doing this.

Yet we cannot help thinking that there are phenomena or facts in muſic, ſufficiently preciſe to furniſh principles of abſolute certainty for enabling us to produce temperaments of the ſcale which ſhall have determined characters, and among which we may chooſe ſuch a one as ſhall be preferable to the others, according to the purpoſes we have in view; and we think that theſe principles are of ſuch eaſy application, that any perſon, of a moderate ſenſibility to juſt intonation, may, without much knowledge or practice in muſic, tune his harpſichord with all deſirable accuracy. We propoſe to lay theſe before the reader. We might content ourſelves with ſimply giving the practical rules deduced from the principles; but it is ſurely more deſirable to perceive the validity of the principles. This will give us confidence in the deduced rules of practice. In the employment of ſacred muſic, an inſpired writer counſels us to ſing, not only "with the heart, but with the underſtanding alſo." We may, without irreverence, recommend the ſame thing here. Let us therefore attend a little to the dictate of untutored Nature, and ſee how ſhe teaches all mankind to form the ſcale of melody.

4 All nations ſing by one ſcale.

It is a moſt remarkable fact, that, in all nations, however they may differ in the ſtructure of that chaunt which we call the accent, or tone, or twang, in the colloquial language of a particular nation, or in the favourite phraſes or paſſages which are moſt frequent in their ſongs, all men make uſe of the ſame riſes and falls, or inflections of voice, in their muſical language or airs. We have heard the ſongs of the Iroquois, the Cherokee, and the Eſquimaux, of the Carib, and the inhabitant of Paraguay; of the African of Negroland and of the Cape, and of the Hindoo, the Malay, and the native of Otaheite—and we found none that made uſe of a different ſcale from our own, although ſeveral ſeemed to be very ſorry performers by any ſcale. There muſt be ſome natural foundation for this uniformity. We may never diſcover this; but we may be fortunate enough to diſcover facts in the phenomena of ſound which invariably accompany certain modifications of muſical ſentiment. If we ſucceed, we are intitled to ſuppoſe that ſuch inſeparable companions are naturally connected; and to conclude, that if we can inſure the appearance of thoſe facts in ſound, we ſhall alſo give occaſion to thoſe muſical ſentiments or impreſſions.

5 Muſical pitch, what?

There is a quality in lengthened or continued ſound which we call its pitch or note, by which it may be accounted ſhrill or hoarſe. It may be very hoarſe in the beginning, and during its continuance it may grow more and more ſhrill by imperceptible gradations. In this caſe we are ſenſible of a kind of progreſs from the one

Temperament of the Scale of Muſic.

one ſtate of ſound to the other. Thus, while we gently draw the bow acroſs the ſtring of a baſs viol, if we at the ſame time ſlide the finger ſlowly along the ſtring, from the nut toward the bridge, the ſound, from being hoarſe, becomes gradually acute or ſhrill. Hoarſe and ſhrill therefore are not different qualities, although they have different names, but are different ſtates or degrees of the ſame quality, like cold and heat, near and far, early and late, or, what is common to all theſe, little and great. A certain ſtate of the air is accounted neither hot nor cold. All ſtates on one ſide of this are called warm, or hot; and all on the other are cold. In like manner, a certain ſound is the boundary between thoſe that are called hoarſe and thoſe called ſhrill. The chemiſt is accuſtomed to ſay, that the temperature of a body is higher when it is warmer, and lower when colder. In like manner, we are accuſtomed to ſay, that a perſon raiſes or depreſſes the pitch of his voice when it becomes more ſhrill or more hoarſe. The ancient Greeks, however, called the ſhriller ſounds *low*, and the hoarſer ſounds *high*; probably becauſe the hoarſer ſounds are generally ſtronger or louder, which we are alſo accuſtomed to conſider as higher. In common language, a low pitch of voice means a faint ſound, but in muſical language it means a hoarſer ſound. The ſound that is neither hoarſe nor ſhrill is ſome ordinary pitch of voice, but without any preciſe criterion.

6. The change obſerved in the pitch of a violin ſtring, when the finger is carried along the finger-board with a continued motion, is alſo continuous; that is, not by ſtarts: we call it gradual, for want of a better term, although gradual properly means *gradatim*, by degrees, ſteps, or ſtarts, which are not to be diſtinguiſhed in this experiment. But we may make the experiment in another way. After ſounding the open ſtring, and while the bow is yet moving acroſs it, we may put down the finger about $1\frac{2}{3}$ inches from the nut. This will change the ſound into one which is *ſenſibly* ſhriller than the former, and there is a manifeſt ſtart from the one to the other. Or we may put down the finger $2\frac{1}{2}$ inches from the nut; the ſound of the open ſtring will change to a ſhriller ſound, and we are ſenſible that this change or ſtep is greater than the former. Moreover, we may, while drawing the bow acroſs the ſtring, put down one finger at $1\frac{2}{3}$ inches, and, immediately after, put down another finger at $2\frac{1}{2}$ inches from the nut. We ſhall have three ſounds in ſucceſſion, each more ſhrill than the preceding, with two manifeſt ſteps, or ſubſultory changes of pitch.

7. Now ſince the laſt ſound is the ſame as if the ſecond had not been ſounded, we muſt conceive the ſum of the two ſucceſſive changes as equivalent or equal to the change from the firſt to the third. This change ſeems ſomehow to include the other two, and to be made up of them, as a whole is made up of its parts, or as $2\frac{1}{2}$ inches are made up of $1\frac{2}{3}$ and $\frac{5}{6}$ of an inch, or as the ſum 15 is made up of 10 and 5.

8

We have a notion of ſomething like an interval between the notes of muſic.

Thus it happens that thinking perſons conceive ſomething like or analogous to a diſtance, or interval, between theſe ſounds. It is plain, however, that there can be no real diſtance or ſpace interpoſed between them; and it is not eaſy to acquire a diſtinct notion of the bulk or magnitude of theſe intervals. This conception is purely figurative and analogical; but the analogy is very good, and the obſervation of it, or conjecture about it, has been of great ſervice in the ſcience of muſic, by making us ſearch for ſome preciſe meaſure of thoſe manifeſt intervals of muſical ſounds.

Temperament of the Scale of Muſic.

It muſt now be remarked, that it is in this reſpect alone that ſounds are ſuſceptible of muſic. Nor are all ſounds poſſeſſed of this quality. The ſmack of a whip, the exploſion of a muſket, the ruſhing of water or wind, the ſcream of ſome animals, and many other ſounds, both momentary and continuous, are mere noiſes; and can neither be called hoarſe nor ſhrill. But, on the other hand, many ſounds, which differ in a thouſand circumſtances of loudneſs, ſmoothneſs, mellowneſs, &c. which make them pleaſant or diſagreeable, have this quality of muſical pitch, and may thus be compared. The voice of a man or woman, the ſound of a pipe, a bell, a ſtring, the voice of an animal, nay, the ſingle blow on an empty caſk—may all have one pitch, or we may be ſenſible of the interval between them. We can, in all caſes, tighten or ſlacken the ſtring of a violin, till the moſt uninformed hearer can pronounce with certainty that the pitch is the ſame. We are indebted to the celebrated Galileo for the diſcovery of that phyſical circumſtance in all thoſe ſounds which communicates this remarkable quality to them, and even enables us to induce it on any noiſe whatever, and to determine, with the utmoſt preciſion, the muſical pitch of the ſound, and the interval between any two ſuch ſounds. Of this we ſhall ſpeak fully hereafter; and at preſent we only obſerve, that two ſounds, having the ſame pitch, are called UNISONS by muſicians, or are ſaid to be in *uniſon* to one another. 9.

When two untaught men attempt to ſing the ſame air together, they always ſing in uniſon, unleſs they expreſsly mean to ſing in different pitches of voice. Nay, it is an extremely difficult thing to do otherwiſe, except in a few very peculiar caſes. Alſo, when a man and woman, wholly uninſtructed in muſic, attempt to ſing the ſame air, they alſo *mean* to ſing the ſame muſical notes through the whole air; and they generally imagine that they do ſo. But there is a manifeſt difference in the ſounds which they utter, and the woman is ſaid to ſing more SHRILL, and the man more HOARSE. A very plain experiment, however, will convince them that they are miſtaken. *N. B.* We are now ſuppoſing that the performers have ſo much of a muſical ear, and flexible voice, as to be able to ſing a common ballad, or a pſalm tune, with tolerable exactneſs, and that they can prolong or dwell upon any particular note when deſired. 10.

Let them ſing the common pſalm tune called St David's, in the ſame way that they practiſe at church; and when they have done it two or three times, in order to fix their voices in tune, and to feel the general impreſſion of the tune, let the woman hold on in the firſt note of the tune, which we ſuppoſe to be *g*, while the man ſings the firſt three in ſucceſſion, namely *g*, *d*, *g*. He will now perceive, that the laſt note ſung by himſelf is the ſame with that ſung by the woman, and which ſhe thinks that ſhe is ſtill holding on in the firſt note of the tune. Let this be repeated till the performance becomes eaſy. They will then perceive the perfect ſameneſs, in reſpect of muſical pitch, of the woman's firſt note of this tune and the man's third note. Some difference, however, will ſtill be perceived; but it will not be in the pitch, but in the ſmoothneſs, or clearneſs, or other agreeable quality of the woman's note.

When

When this is plainly perceived, let the man try by what continued ſteps he muſt raiſe his pitch, in order to arrive at the woman's note from his own. If he is accuſtomed to common ballad ſinging, he will have no great difficulty in doing this; and will find that, beginning with his own note, and ſinging gradually up, his eighth note will be the woman's note. In ſhort, if two flutes be taken, one of which is twice as long as the other, and if the man ſing in uniſon with the large flute, the woman, while ſinging, as ſhe thinks, the ſame notes with the man, will be found to be ſinging in uniſon with the ſmaller flute.

11 There are ſeven ſteps in the natural ſcale, and eight notes.

12 OCTAVE.

This is a remarkable and moſt important fact in the phenomena of muſic. This interval, comprehending and made up of ſeven ſmaller intervals, and requiring eight ſounds to mark its ſteps, is therefore called an OCTAVE. Now, ſince the female performer follows the ſame dictates of natural ear in ſinging her tune that the man follows in ſinging his, and all hearers are ſenſible that they are ſinging the ſame tune, it neceſſarily follows, that the two ſerieſes of notes are perfectly ſimilar, though not the ſame: For there muſt be the ſame interval of an octave between any ſtep of the lower octave and the ſame ſtep of the upper one. In whatever way, therefore, we conceive one of theſe octaves to be parcelled out by the different ſteps, the partition of both muſt be ſimilar. If we repreſent both by lines, theſe lines muſt be ſimilarly divided. Each partial interval of the one muſt bear the ſame relation to the whole, or to any other interval, as its ſimilar interval in the other octave bears to the whole of that octave, or to the other correſponding interval in it.

13 All octaves are ſimilar.

Farther, we muſt now obſerve, that although this ſimilarity of the octaves was firſt obſerved or diſcovered by means of the ordinary voices of man and woman, and is a legitimate inference from the perfect ſatisfaction that each feels in ſinging what they think the ſame notes, this is not the only foundation or proof of the ſimilarity. Having acquired the knowledge of that phyſical circumſtance, on which the pitch of muſical ſounds depends, we can demonſtrate, with all the rigour of geometry, that the ſeveral notes in the man and woman's octave *muſt* have the ſame relation to their reſpective commencements, and that theſe two great intervals are ſimilarly divided. But farther ſtill, we can demonſtrate that this ſimilarity is not confined to theſe two octaves. This may even be proved, to a certain extent, by the ſame original experiment. Many men can ſing two octaves in ſucceſſion, and there are ſome rare examples of perſons who can ſing three. This is more common in the female voice. This being the caſe, it is plain that there will be two octaves common to both voices; and therefore four octaves in ſucceſſion, all ſimilar to each other. The ſame ſimilarity may be obſerved in the ſounds of inſtruments which differ only by an octave. And thus we demonſtrate that all octaves are ſimilar to each other. This ſimilarity does not conſiſt merely in the ſimilarity of its diviſion. The ſound of a note and its octave are ſo like each other, that if the ſtrength or loudneſs be properly adjuſted, and there be no difference in kind, or other circumſtances of clearneſs, ſmoothneſs, &c. the two notes, when ſounded together, are indiſtinguiſhable, and appear only like a more brilliant note. They coaleſce into one ſound. Nay, moſt clear mellow notes, ſuch as thoſe of a fine human voice, really contain each two notes, one of which is octave to the other.

We ſaid that this reſemblance of octaves is an important fact in the ſcience of muſic. We now ſee why it is ſo. The whole ſcale of muſic is contained in one octave, and all the reſt are only repetitions of this ſcale. And thus is the doctrine of the ſcale of melody brought within a very moderate compaſs, and the problem is reduced to that of the repartition of a ſingle octave, and ſome attention to the junction with the ſimilar ſcales of the adjoining octaves. This partition is now to be the ſubject of diſcuſſion.

14 All muſic contained in the octave; hence called DIAPASON.

15 Melodies, or tunes, or airs, were the firſt muſic.

In the infancy of ſociety and cultivation, it is probable that the melodies or tunes, which delighted the ſimple inhabitants, were equally ſimple. Being the ſpontaneous effuſions of individuals, perhaps only occaſional, and never repeated, they would periſh as faſt as produced. The airs were probably connected with ſome of the rude rhimes, or gingles of words, which were banded about at their feſtivals; or they were aſſociated with dancing. In all theſe caſes they muſt have been very ſhort, conſiſting of a few favourite paſſages or muſical phraſes. This is the caſe with the common airs of all ſimple people to this day. They ſeldom extend beyond a ſhort ſtanza of poetry, or a ſhort movement of dancing. The artiſt who could compoſe and keep in mind a piece of conſiderable length, muſt have been a great rarity, and a minſtrel fit for the entertainment of princes; and therefore much admired, and highly rewarded: his excellencies were almoſt incommunicable, and could not be preſerved in any other way but by repeated performance to an attentive hearer, who muſt alſo be an artiſt, and muſt patiently liſten, and try to imitate; or, in ſhort, to get the tune by heart. It muſt have been a long time before any diſtinct notion was formed of the relation of the notes to each other. It was perhaps impoſſible to recollect today the preciſe notes of yeſterday. There was nothing in which they were fixed till inſtrumental muſic was invented. This has been found in all nations; but it appears that long continued cultivation is neceſſary for raiſing this from a very ſimple and imperfect ſtate. The moſt refined inſtrument of the Greek muſicians was very far below our very ordinary inſtruments. And, till ſome method of notation was invented, we can ſcarcely conceive how any determined partition of the octave could be made generally known.

16 KEY-NOTE or FUNDAMENTAL.

Accordingly, we find that it was not till after a long while, and by very rude and awkward ſteps, that the Greeks perceived that the whole of muſic was compriſed in the octave. The firſt improved lyre had but four ſtrings, and was therefore called a TETRACHORD; and the firſt flutes had but three holes, and four notes; and when more were added to the ſcale, it was done by joining two lyres and two flutes together. Even this is an inſtructive ſtep in the hiſtory of muſical ſcience: For the four ſounds of the inſtrument have a natural ſyſtem, and the awkward and groping attempts to extend the muſic, by joining two inſtruments, the ſcale of the one following, or being a continuation of that of the other, pointed out the DIAPASON or *totality* of the octave, and the relation of the whole to a principal ſound, which we now call the *fundamental* or *key*, it being the loweſt note of our ſcale, and the one to which the other notes bear a continual reference. It would far exceed the

limits

Tempera-ment of the Scale of Muſic.

limits of this Work to narrate the ſucceſſive changes and additions made by the Greeks in their lyre; yet would this be a very ſure way of learning the natural formation of our muſical ſcale. We muſt refer our readers to Dr Wallis's Appendix to his edition of the Commentary of Porphyrius in Ptolemy's Harmonics, as by far the moſt perſpicuous account that is extant of the Greek muſic. We ſhall pick out from among their different attempts ſuch plain obſervations as will be obvious to the feelings of any perſon who can ſing a common tune.

17
The octave is naturally divided into two TETRACHORDS.

Let ſuch a perſon firſt ſing over ſome plain and cheerful, or at leaſt not mournful, tune, ſeveral times, ſo as to retain a laſting impreſſion of the chief note of the tune, which is generally the laſt. Then let him begin, on the ſame note, to ſing in ſucceſſion the riſing ſteps of the ſcale, pronouncing the ſyllables *do*, *re*, *mi*, *fa*, *ſol*, *la*, *ſi*, *do*. He will perhaps obſerve, that this chaunt naturally divides itſelf into two parts or phraſes, as the muſicians term it. If he does not, of himſelf, make this remark, let him ſing it, however, in that manner, pauſing a little after the note *fa*. Thus, *do*, *re*, *mi*, *fa*; *ſol*, *la*, *ſi*, *do*.—*Do*, *re*, *mi*, *fa*; *ſol*, *la*, *ſi*, *do*.

Having done this ſeveral times, and then repeated it without a pauſe, he will become very ſenſible of the propriety of the pauſe, and of this natural diviſion of the octave. He will even obſerve a conſiderable ſimilarity between theſe two muſical phraſes, without being able, at firſt, to ſay in what it conſiſts.

18
The ſteps of the ſcales are unequal, and the two tetrachords are ſimilar.

Let him now ſtudy each phraſe apart, and try to compare the magnitude of the changes of ſound; or ſteps which he makes in riſing from *do* to *re*, from *re* to *mi*, and from *mi* to *fa*. We apprehend that he will have no difficulty in perceiving, after a few trials, that the ſteps *do re*, and *re mi*, are ſenſibly greater than the ſtep *mi fa*. We feel the laſt ſtep as a ſort of ſlide; as an attempt to make as little change of pitch as we can. Once this is perceived, it will never be forgotten. This will be ſtill more clearly perceived, if, inſtead of theſe ſyllables, he uſe only the vowel *a*, pronounced as in the word *hall*, and if he ſing the ſteps, ſliding or ſlurring from the one to the other. Taking this method, he cannot fail to notice the ſmallneſs of the third ſtep.

19
Let the ſinger farther conſider, whether he does not feel this phraſe muſical or agreeable, making a ſort of tune or chaunt, and ending or cloſing agreeably after this ſlide of a ſmall, or, as it were, half ſtep. It is generally thought ſo; and is therefore called a CLOSE, a CADENCE, when we end with a half ſtep aſcending.

20
Let the ſinger now reſume the whole ſcale, ſinging the four laſt notes *ſol*, *la*, *ſi*, *do*, louder than the other four, and calling off his attention from the low phraſe, and fixing it on the upper one. He will now be able to perceive that this, like the other, has two conſiderable ſteps; namely, *ſol*, *la*, and *la ſi*, and then a ſmaller ſtep, *ſi do*. A few repetitions will make this clear, and he will then be ſenſible of the nature of the ſimilarity between theſe two phraſes, and the propriety of this great diviſion of the ſcale into the intervals *do*, *fa*, and *ſol*, *do*, with an interval *fa*, *ſol* between them.

This was the foundation of the tetrachords, or lyres of four ſtrings, of the Greeks. Their earlieſt muſic or modulation ſeems to have extended no farther than this phraſe. It pleaſed them, as a ring of four bells pleaſes many country pariſhes.

21
Close of cadence.

The ſinger will perceive the ſame ſatisfaction with the cloſe of this ſecond phraſe as with that of the former: and if he now ſing them both, in immediate ſucceſſion, with a ſlight pauſe between, we imagine that he will think the cloſe or cadence on the upper *do* even more ſatisfactory than that on the *fa*. It ſeems to us to complete a tune. And this impreſſion will be greatly heightened, if another perſon, or an inſtrument, ſhould ſound the lower *do*, while he cloſes on the upper *do* its octave. *Do* ſeems to be expected, or looked for, or ſought after. We take *ſi* as a ſtep to *do*, and there we reſt.

22
The third and ſeventh ſtep are the ſmalleſt.

Thus does the octave appear to be naturally compoſed of ſeven ſteps, of which the firſt, ſecond, fourth, fifth, and ſixth, are more conſiderable, and the third and ſeventh very ſenſibly ſmaller. Having no direct meaſures of their quantity, nor even a very diſtinct notion of what we mean by their quantity, magnitude, or bulk, we cannot pronounce, with any certainty, whether the greater ſteps are equal or unequal; and we preſume them to be equal. Nor have we any diſtinct notion of the proportion between the larger and ſmaller ſteps. In a looſe way we call them half notes, or ſuppoſe the riſe from *mi* to *fa*, or from *ſi* to *do*, to be one-half of that from *do* to *re*, or from *re* to *mi*.

23
The Pythagorean diſcoveries did not improve the Greek muſic.

Accordingly, this ſeems to have been all the muſical ſcience attained by the Greek artiſts, or thoſe who did not profeſs to ſpeak philoſophically on the ſubject. And even after Pythagoras publiſhed the diſcovery which he had made, or more probably had picked up among the Chaldeans or Egyptians, by which it appeared, that accurate meaſures of ſounds, in reſpect to gravity and acuteneſs, were attainable, it was affirmed by Ariſtoxenus, a ſcholar of Ariſtotle, and other eminent philoſophers, that theſe meaſures were altogether artificial, had no connection with muſic, and that the ear alone was the judge of muſical intervals. The artiſt had no other guide in tuning his inſtrument; becauſe the ratios, which were ſaid to be inherent in the ſounds (though no perſon could ſay how), were never perceived by the ear. The juſtice of this opinion is abundantly confirmed by the awkward attempt of the Greeks to improve the lyre by means of theſe boaſted ratios. Inſtead of illuſtrating the ſubject, they ſeem rather to have brought an additional obſcurity upon it, and threw it into ſuch confuſion, that although many voluminous diſſertations were written on it, and on the compoſition of their muſical ſcale, the account is ſo perplexed and confuſed, that the firſt mathematicians and artiſts of Europe acknowledged, that the whole is an impenetrable myſtery. Had the philoſophers never meddled with it, had they allowed the practical muſicians to conſtruct and tune their inſtruments in their own way, ſo as to pleaſe their ear, it is ſcarcely poſſible that they ſhould not have hit on what they wanted, without all the embarraſſment of the chromatic and enharmonic ſcales of the lyre. It is ſcarcely poſſible to contrive a more cumberſome method of extending the ſimple ſcale of Nature to every caſe that could occur in their muſical compoſitions, than what aroſe from the employment of the muſical ratios. This ſeems a bold aſſertion; but we apprehend that it will appear to be juſt as we proceed.

24
The tranſpoſition of muſic made intercalary notes neceſſary in the octave.

The practical muſicians could not be long of finding the want of ſomething more than the mere diatonic ſcale of their inſtruments. As they were always accompanied by the voice, it would often happen that a lyre or flute, perfectly tuned, was too low or too high for

Temperament of the Scale of Mufic.

for the voice that was to accompany it. A finger can pitch his tune on any found as a key; and if this be too high for the finger who is to accompany him, he can take it on a lower note. But a lyrift cannot do this. Suppofe his inftrument two notes too low, and that his accompanyift can only fing it on the key which is the *fi* of the lyre. Should the lyrift begin it on that key, his very firft ftep is wrong, being but a half ftep, whereas it fhould be a whole one. In fhort, all the fteps but one will be found wrong, and the lyrift and finger will be perpetually jarring. This is an evident confequence of the inequality of the fourth and feventh fteps to the reft. And if the other fteps, which we imagine to be equal, be not exactly fo, the difcordance will be ftill greater.

Difputes of the Pythagoreans and Ariftoxeneans about mufical ratios.

The method of remedying this is very obvious. If the intervals *mi fa* and *fi do*, are half notes, we need only to interpofe other founds in the middle between each of the whole notes; and then, in place of feven unequal fteps, we fhall have twelve equal ones, or twelve intervals, each of them equal to a femitone. The lyre thus conftructed will now fuit any voice whatever. It will perfectly refemble our keyed inftruments, the harpfichord, or organ, which have twelve feemingly equal intervals in the octave. Accordingly, it appears that fuch additions were practifed by the muficians of Greece, and approved of by Ariftoxenus, and by all thofe who referred every thing to the judgment of the ear. And we are confident that this method would have been adopted, if the philofophers had had lefs influence, and if the Greeks had not borrowed their religious ceremonies along with their mufical fcience. Both of thefe came from the fame quarter; they came united; and it was facrilegious to attempt innovations. The doctrine of mufical ratios was an occupation only for the refined, the philofophers; and by fubjecting mufic to this myfterious fcience, it became myfterious alfo, and fo much the more venerable. The philofophers faw, that there was in Nature a certain infcrutable connection between mathematical ratios and thofe intervals which the ear relifhed and required in melody; but they were ignorant of the nature and extent of this connection.

Ratios of octave, diapente, and diateffaron.

What is this connection, or what is meant when we fpeak of the ratios of founds? Simply this:—Pythagoras is faid to have found, that if two mufical cords be ftrained by equal weights, and one of them be twice the length of the other, the fhort one will found the octave to the note of the other. If it be two-thirds of the length of the long ftring, it will found the fifth to it. If the long ftring found *do*, the fhort one will found *fol* If it be three-fourths of the length, it will found the fourth or *fa*. Thus the ratio of 2 : 1 was called the ratio of the DIAPASON; that of 3 : 2 was called the DIAPENTE; and that of 4 : 3 the DIATESSARON. Moreover, if we now take all the four ftrings, and make that which founds the graveft note, and is the longeft, twelve inches in length; the fhort or octave ftring muft be fix inches long, or one-half of twelve; the diapente muft be eight inches, or two-thirds of twelve; and the diateffaron muft be nine inches, which is three-fourths of twelve. If we now compare the diapente, not with the graveft ftring, but with the octave of fix inches, we fee that they are in the ratio of 4 to 3, or the ratio of diateffaron. And if we compare the diateffaron with the octave, we fee that their ratio is that of 9 : 6, or of 3 : 2, or the ratio of diapente. Thus is the octave divided into a fifth and a fourth, *do fol*, and *fol do*, in fucceffion. Alfo the fourth *do fa*, and the fifth *fa do*, make up the octave. The note which ftands as a fifth to one of the extreme founds of the octave, ftands as a fourth to the other. And, laftly, the two fourths *do fa*, and *fol do*, leave an interval *fa fol* between them; which is alfo determined by nature, and the ratio correfponding to it is evidently that of 9 to 8.

25 The difcovery of Pythagoras is either a fable, or falfely narrated.

This is all that was known of the connection of mufic with mathematical ratios. It is indeed faid by Iamblichus, that Pythagoras did not make this difcovery by means of ftrings, but by the founds made by the hammers on the anvil in a fmith's fhop. He obferved the founds to be the key, the diateffaron, and the diapente of mufic; and he found, that the weights of the hammers were in this proportion; and as foon as he went home, he tried the founds made by cords, when weights, in the proportions above-mentioned, were appended to them. But the whole ftory has the air of a fable, and of ignorance. The founds given by a fmith's anvil have little or no dependence on the weight of the hammers; and the weights which are in the proportions of the numbers mentioned above will by no means produce the founds alleged. It requires *four* times the weight to make a ftring found the octave, and *twice and a quarter* will produce the diapente, and *one and feven-ninths* will produce the diateffaron. It is plain, therefore, that they knew not of what they were fpeaking: yet, on this flight foundation, they erected a vaft fabric of fpeculation; and in the courfe of their refearches, thefe ratios were found to contain all that was excellent. The attributes of the Divinity, the fymmetry of the univerfe, and the principles of morality, were all refolvable into the harmonic ratios.

26 Conjoined and disjoined tetrachords.

In the attempts to explain, by means of the myfterious properties of the ratios 2 : 1, 3 : 2, 4 : 3, and 9 : 8, which were thus defined by Nature, it was obferved, that their favourite lyres of four ftrings could be combined in two principal manners, fo as to produce an extenfive fcale. One lyre may contain the notes *do, re, mi, fa*; and the acuter lyre may contain the notes *fol, la, fi, do*; and, being fet in fucceffion, having the interval *fa fol* between the higheft note of the one and the loweft of the other, they make a complete octave. Thefe were called *disjoined tetrachords*. Again, a third tetrachord may be joined with the upper tetrachord laft mentioned, in fuch fort, that the loweft note of the third tetrachord may be the fame with the higheft of the fecond. Thefe were called *conjoined* tetrachords (A).

27 The lyres were tuned entirely by the ear.

By thus confidering the fcale as made up of tetrachords, the tuning of the lyre was reduced to great fimplicity. The mufician had only to make himfelf perfect in the fhort chant *do, re, mi, fa*, or to get it by

(A) This is the *principle*, but not the precife *form*, of the disjoined and conjunct tetrachords. The Greeks did not begin the tetrachord with what we make the firft note of our chaunt of four notes, but began one of them with *mi*, and the other with *fi*; to which they afterwards added a note below. This beginning feems to have been directed by fome of their favourite cadences; but it would be tedious to explain it.

Temperament of the Scale of Music.

by heart, and to fing it exactly. This intonation would apply equally to the other *fol*, *la*, *fi*, *do*. We are well informed that this was really the practice. The directions given by Ariftoxenus, Nicanor, and others, for varying the tuning, according to certain occafional accommodations, fhew diftinctly that they did not tune as we do, founding the two ftrings together, except in the cafe of the diapafon or octave. It was all done by the judgment of the ear in melody. The moft valuable circumftance in the difcovery of Phythagoras was the determination of the interval between the fourth and the fifth, by which the tetrachords were feparated. The filling up of each tetrachord was left entirely to the ear; and when the doctrine of the mathematical ratios fhewed that the large intervals *do re*, *re mi*, *fa fol*, *fol la*, *la fi*, fhould not be precifely equal, Ariftoxenus refufed the authority of the reafons alleged for this inequality, becaufe the ear perceived none of the ratios as ratios, and could judge only of founds. He farther affeited, that the inequalities which the Pythagoreans enjoined, were fo trifling, that no ear could poffibly perceive them. And accordingly, the theorifts difputed about the refpective fituations of the greater and fmaller tones (fo they named the great fteps) fo much fpoken of, and had different fyftems on the fubject.

28 And by melody alone:

But the ftrongeft proof of the indiftinct notion that the theorifts entertained about the influence of thefe ratios in mufic is, that they would admit no more but thofe introduced by Pythagoras; and their reafons for the rejection of the ratio of 5 to 4, and of 6 to 5, were either the moft whimfical fancies about the perfections of the facred ratios, or affumptions exprefsly founded on the fuppofition, that the ear perceives and judges of the ratios as ratios; than which nothing can be more falfe. Had they admitted the ratio of 5 to 4, they would have obtained the third note of the fcale, and would at once have gotten the whole fcale of our mufic. The ratios of 6 : 5, and 16 : 15, follow of courfe; and every found of the tetrachords would have been determined. For 5 : 4 being the ratio of the major third, which is perfectly pleafing to the ear, as the *mi* to the note *do*, and 3 : 2 being the ratio of the fifth *do fol*, there is another interval *mi fol* determined; and this ratio, being the difference between *do fol* and *do mi*, or between 3 : 2 and 5 : 4, is evidently 6 : 5. In like manner, the interval *mi fa* is determined, and its ratio, being 4 : 3—5 : 4, is 16 : 15.

But farther; we fhall find, upon trial, that if we put in a found above *fol*, having the relation 5 : 4 to *fa*, it will be perfectly fatisfactory to the ear if fung as the note *la*. And if, in like manner, we put in a note above *la*, having the relation 5 : 4 to *fol*, we find it fatisfactory to the ear when ufed as *fi*. If we now examine the ratios of thefe artificial notes, we fhall find the ratio of the notes *fol la* to be 10 : 9, and that of *la fi* to be 9 : 8, the fame with that *fa fol*; alfo *fi do* will appear to be 16 : 15, like that of *mi fa*.

We have no remains of the mufic of the Greeks, by which we can learn what were their favourite paffages or mufical phrafes; and we cannot fee what caufed them to prefer the fourth to the major third. Few muficians of our times think the fourth in any degree comparable with the major third for melodioufnefs, and ftill fewer for harmonioufnefs. The piece or tune publifhed by Kircher from Alypius is very fufpicious, as no other perfon has feen the MS.; and the collection found at Buda is too much disfigured, and probably of too late a date, to give us any folid help. In all probability, the common melodies of the Greeks abounded in eafy leaps up and down on the third and fifth, and on the fourth and fixth, juft as we obferve in the airs for dancing among all fimple people. Their accomplifhed performers had certainly great powers both of invention and execution; and the chromatic and enharmonic divifions of the fcale were certainly practifed by them, and not merely the fpeculations of mathematicians. To us, the enharmonic fcale appears the moft jarring difcord; but this is certainly owing to our not feeing any pieces of the mufic fo compofed, and becaufe we cannot in the leaft judge by harmony what the effect of enharmonic melody would be. But we have fufficient evidence, from the writings of the ancient Greeks, that the enharmonic mufic fell into difufe even before the time of Ptolemy, and was totally and irrecoverably loft before the 5th century. Even the chromatic was little practifed, and was chiefly employed for extending the common fcale to keys which were feldom ufed. The uncertainties refpecting even the common fcale remained the fame as ever; and although Ptolemy gives (among others) the very fame that is now admitted as the only perfect one, namely, his *diatonicum intenfum*, his reafons of preference, though good, are not urged with ftrong marks of his confidence in them, nor do they feem to have prevailed.

These obfervations fhew clearly, that the perception of melody alone is not fufficiently precife for enabling us to acquire exact conceptions of the fcale of mufic. The whole of the practicable fcience of the ancients feems to amount to no more than this, that the octave contained five greater and two fmaller intervals, which the voice employed, and the ear relifhed. The greater intervals feemed all of one magnitude; and the fmaller intervals appeared alfo equal, but the ear cannot judge what proportion they bear to the larger ones. The muficians thought them larger than one-half of the great intervals (and indeed the ratio 16 : 15 of the artificial *mi fa* and *fi do*, is greater than the half of 9 : 8 or 10 : 9). Therefore they allowed the theorifts to call them *limmas* inftead of *hemitones*; but they, as well as the theorifts, differed exceedingly in the magnitudes which they affigned them. 29 But melody is quite infufficient.

The beft way that we can think of for expreffing the fcale of the octave is, by dividing the circumference of a circle in the points C, D, E, F, G, A, and B, (fig. 1.), in the proportion we think moft fuitable to the natural fcale of melody. According to the practical notion now under our confideration, the arches CD, DE, FG, GA, and AB, are equal, containing nearly 59°; and the arches EF and BC are alfo equal, but fmaller than the others, containing about $33\frac{1}{2}$. Now, fuppofe another circle, on a piece of card paper, divided in the fame manner, to move round their common centre, but inftead of having its points of divifion marked C, D, E, &c. let them be marked *do*, *re*, *me*, *fa*, *fol*, *la*, *fi*. It is plain, that to whatever point of the outer circle we fet the point *do* of the inner one, the other points of the outer circle will fhew the common notes which are fit for thofe fteps of the fcale. The fimilarity of all octaves makes this fimple octave equivalent to a rectilineal fcale fimilarly divided, and repeated as often 30 Circular reprefentation of the fcale Plate XLIV.

Tempera-ment of the Scale of Music.

as we pleafe. Fig. 1. reprefents this inftrument, and will be often referred to. A fort of fymmetry may be obferved in it. The point D feems to occupy the middle of the fcale, and *re* feems to be the middle note of the octave. The oppofite arch GA, and the correfponding interval *fol la*, feems to be the middle interval of the octave. The other notes and intervals are fimilarly difpofed on each fide of thefe. This circumftance feems to have been obferved by the Greeks, by the inhabitants of India, by the Chinefe, and even by the Mexicans. The note *re*, and the interval *fol la*, have gotten diftinguifhed fituations in their inftruments and fcales of mufic.

31 Ariftoxenean fcale of mean tones and limmas.

With refpect to the divifion of the circles, we fhall only obferve at prefent, that the dotted lines are conformable to the principles of Ariftoxenus, the whole octave being portioned out into five larger and equal intervals, and two fmaller, alfo equal. The larger are called *mean* or *medium tones*; and the fmaller are called *limmas* or *femitones*. The full lines, to which the letters and names are affixed, divide the octave into the artificial portions, determined by means of the mufical ratios, the arches being made proportional to the meafures of thofe ratios. Thus the arches CD, FG, AB, are proportional to the meafure or logarithm of the ratio 9 : 8; GA and DE are proportional to the logarithm of 10 : 9; and the arches EF and BC are proportional to the logarithm of 16 : 15. We have already mentioned the way in which thofe ratios were applied, and the authority on which they were felected. We fhall have occafion to return to this again. The only farther remark that is to be made with propriety in this place is, that the divifion on the Ariftoxenean principles, which is expreffed in this figure, is one of an indefinite number of the fame kind. The only principle adopted in it is, that there fhall be five mean tones, and two fmall equal femitones; but the magnitude of thefe is arbitrary. We have chofen fuch, that two mean tones are exactly equal to the arch CE, determined by the ratio 5 : 4. The reafons for this preference will appear as we proceed (B).

By this little inftrument (the invention, we believe, of a Mr D'Ormiffon, about the beginning of laft century), we fee clearly the infufficiency of the feven notes of the octave for performing mufic on different keys. Set the flower de luce at the Ariftoxenean B, and we fhall fee that E is the only note of our lyre which will do for one of the fteps of the octave in which we intend to fing and accompany. We have no founds in the lyre for *re*, *mi*, *fol*, *la*, *fi*. The remedy is as clearly pointed out. Let a fet of ftrings be made, having the fame relation to *fi* which thofe of the prefent lyre have to *do*, and infert them in the places pointed out by the Ariftoxenean divifions of the moveable octave. We need only five of them, becaufe the *fi* and *fa* of the prefent lyre will anfwer. Thefe new founds are marked by a +.

32 Found imperfect, and required TEMPERAMENT.

But it was foon found, that thefe new notes gave but indifferent melody, and that either the ear could not determine the equality of the tones and femitones exactly enough, or that no fuch partition of the octave would anfwer. The Pythagoreans, or partifans of the mufical ratios, had told them this before. But they were in no better condition themfelves; for they found, that if a feries of founds, in perfect relation to the octave, be inferted in the manner propofed, the melody will be no better. They put the matter to a very fair trial. It is eafy to fee, that no fyftem of mean tones and limmas will give the fame mufic on every key, unlefs the tones be increafed, and the limmas diminifhed, till the limma becomes juft half a tone. Then all the intervals will be perfectly equal. The mathematicians computed the ratios which would produce this equality, and defired the Ariftoxeneans to pronounce on the mufic. It is faid, that they allowed it to be very bad in all their moft favourite paffages. Nothing now remained to the Ariftoxeneans but to attempt occafional methods of tuning. They faw clearly, that they were making the notes unequal which Nature made equal. The Pythagoreans, in like manner, pointed out many alterations or corrections of intervals which fuited one tetrachord, or one part of the octave, but did not fuit another. Both parties faw that they were obliged to deviate from what they thought natural and perfect: therefore they called thefe alterations of the natural or perfect fcale *temperament*.

The accomplifhed performers were the beft judges of the whole matter, and they derived very little affiftance from the mathematicians: For although the rigid rules delivered by them be acknowledged to be perfectly exact, the execution of thofe rules is not fufceptible of the fame exactnefs. Their lyres are tuned, not by mathematical operations, but by the ear. It does not appear that they had mufical inftruments with divided finger-boards, like our bafs viols and guitars; and even on thefe, it is well known that the preffure and touch of the finger may vary fo much, that the moft exact placing of the frets will not infure the nice degrees of the founds. The flutes are the only inftruments of the ancients that are capable of accurate founds. But flutemakers know very well, that they cannot be tuned by mathematical operations, but by the ear alone. This accounts for the great prices paid for a well-tuned flute. Some have coft L. 700, and L. 50 was a very common price.

33 The Greeks did not cultivate the harmony of fimultaneous founds.

Such feems to have been the ftate of the ancient mufic. There was little or no fcience in it. There was, indeed, a moft abftrufe and refined fcience coupled with it; but by a very flight connection: and it feems to have been nothing more than an amufement for the ingenious and fpeculative Greeks. Nor could it, in our opinion, be better, fo long as they had no guide in tuning but the judgment of the ear in melody. Many writers infift that the Greeks had a knowledge of what *we* call *harmony* alfo. The word ἁρμονια is conftantly ufed by them: but it does not mean what we call harmony, the pleafant coalefcence of fimultaneous founds. It comes from ἁρμος, or from ἁρμοζω, and fignifies *aptitude*, *fitnefs*, and would, in general, be better tranflated by *fymmetry*. But we cannot conceive that they paid any marked attention to the effect of fimultaneous founds, fo as to enjoy the pleafure of certain confonances, and employ them in their compofitions. We judge in this way from the rank which they gave them in their

(B) We fhall be abundantly exact, if we make CD=61°,72; CE=115°,9; CF=149°,42; CG=210°,58; CA=265°,3; and CB=326°,48.

Tempera-ment of the Scale of Mufic.

their fcale. To prefer the fourth to the major third feems to us to be impoffible, if it be meant of fimultaneous founds. And the reafon which is affigned for the preference can have no value in the opinion of a mufician. It is becaufe the ratio of 4 : 3 is fimpler than that of 5 : 4. For the fame reafon, the fifth is preferred to both, and the octave to all the three, and unifon to every other confonance. They would not allow the major third 5 : 4 to be a concord at all. We have made numberlefs trials of the different concords with perfons altogether ignorant of mufic. We never faw an inftance of one who thought that mere unifon gave any pofitive pleafure. None of all whom we examined had much pleafure from an octave. All, without exception, were delighted with a fifth, and with a major third; and many of them preferred the latter. All of them agreed in calling the pleafure from the fifth a *fweetnefs*, and that from the major third a *cheerfulnefs*, or *fmartnefs*, or by names of fimilar import. The greater part preferred even the major fixth to the fourth, and fome felt no pleafure at all from the fourth. Few had much pleafure from the minor third or minor fixth. *N. B.* Care was taken to found thefe concords without any preparation—merely as founds—but not as making part of any mufical paffage. This circumftance has a great effect on the mind. When the minor third and fixth were heard as making part of the minor mode, all were delighted with it, and called it fweet and mournful. In like manner, the chord $\frac{6}{4}$ never failed to give pleafure. Nothing can be a ftronger proof of the ignorance of the ancients of the pleafures of harmony.

34 The pleafures of harmony feem to be modern difcovery.

We do not profefs to know when this was difcovered. We think it not unlikely that the Greeks and Italians got it from fome of the northern nations whom they called *Barbarians*. We cannot otherwife account for its prevalence through the whole of the Ruffian empire—the ancient Slavi had little commerce with the empire of Rome or of Conftantinople; yet they fung in parts in the moft remote periods of their hiftory of which we have any account; and to this day, the moft uncultivated boor in the Ruffian empire would be afhamed to fing in unifon. He liftens a little while to a new tune, holding his chin to his breaft; and as foon as he has got a notion of it, he burfts out in concert, throwing in the harmonic notes by a certain rule which he feels, but cannot explain. His harmonics are generally alternate major and minor thirds, and he feldom miffes the proper cadences on the fifth and key. Perhaps the invention of the organ produced the difcovery. We know that this was as early as the fecond century (c). It was hardly poffible to make much ufe of that inftrument without perceiving the pleafure of concordant founds.

35 Harmony made a great change in the fcience of mufic.

The difcovery of the pleafures of harmony occafioned a total change in the fcience of mufic. During the dark ages of Europe, it was cultivated chiefly by the monks: the organ was foon introduced into the churches, and the choral fervice was their chief and almoft their only occupation. The very conftruction of this inftrument muft have contributed to the improvement of mufic, and inftructed men in the nature of the fcale. The pipes are all tuned by their lengths; and thefe lengths are in the ratios of the ftrings which give the fame notes, when all are equally ftretched. This muft have revived the ftudy of the mufical ratios. The tuning of the organ was performed by confonance, and no longer depended on the nice judgment of founds in fucceffion. The dulleft ear, even with total ignorance of mufic, can judge, without the fmalleft error, of an exact octave, fifth, third, or other concord; and a very mean mufician could now tune an organ more accurately than Timotheus could tune his lyre. Other keyed inftruments, refembling our harpfichord, were invented, and inftruments with fretted finger-boards. Thefe foon fupplanted the lyres and harps, being much more compendious, and allowing a much greater variety and rapidity of modulation. All thefe inftruments were the fruits of harmony, in the modern fenfe of that word. The deficiences of the old diatonic fcale were now more apparent, and the neceffity of a number of intercalary notes. The finger-board of an organ or harpfichord, running through a feries of octaves, and admitting much more than the accompanyment of one note, pointed out new fources of mufical pleafure arifing from the fulnefs of the harmony; and, above all, the practice of choral finging fuggefted the poffibility of a pleafure altogether new. While a certain number of the choir performed the Cantus or Air of the mufic, it was irkfome to the others to utter mere founds, fupporting or compofing the harmony of the Cantus, without any melody or air in their own parts. It was thought probable that the harmonic notes might be fo portioned out among the reft of the choir, that the fucceffion of founds uttered by each individual might alfo conftitute a melody not unpleafant, and perhaps highly grateful. On trial it was found very practicable. Canons, motets, fugues, and other harmonics, were compofed, where the airs performed by the different parts were not inferior in beauty to the principal. The notes which could not be thrown into this agreeable fucceffion, were left to the organift, and by him thrown into the bafs.

By all thefe practices, the imperfections of the fcale of fixed founds became every day more fenfible, efpecially in full harmony. Scientific mufic, or the properties of the ratios, now recovered the high eftimation in which they were held by the ancient theorifts; and as the muficians were now very frequently men of letters, chiefly monks, or fober characters and decent manners, mufic again became a refpectable ftudy. The organift was generally a man of fcience, as well as a performer. At the firft revival of learning in Europe, we find mufic ftudied and honoured with degrees in the univerfities, and very foon we have learned and excellent differtations on the principles of the fcience. The inventions of Guido, and the differtations of Salinas, Zarlino, and Zoni, are among the moft valuable publications that are extant on mufic. The imporvements introduced by Guido are founded on a very refined examina- 36

(c) It is faid that the Chinefe had an inftrument of this kind long before the Europeans. Caufeus fays, that it was brought from China by a native, and was fo fmall as to be carried in the hand. It is certain that the Emperor Conftantine Copronymus fent one to Pepin king of France in 757, and that his fon Charlemagne got another from the Emperor Michael Paleologus. But they appear to have been known in the Englifh churches before that time.

Temperament of the Scale of Music.

examination of the fcale; and the temperaments propofed by the other two have fcarcely been improved by any labours of modern date. Both thefe authors had ftudied the Greek writers with great care, and their improvements proceed on a complete knowledge of the doctrines of Pythagoras and Ptolemy.

37 Galileo difcovered that mufical pitch confifted in the frequency of the aëreal undulations.

At laft the celebrated Galileo Galilei put the finifhing hand to the doctrines of thofe ancient philofophers, by the difcovery of the connection which fubfifts in nature between the ratios of numbers and the mufical intervals of founds. He difcovered, that thefe numbers exprefs the frequency of the recurring pulfes or undulations of air which excite in us the fenfation of found. He demonftrated that if two ftrings, of the fame matter and thicknefs, be ftretched by equal weights, and be twanged or pinched fo as to vibrate, the times of their vibrations will be as their lengths, and the frequency or number of ofcillations made in a given time will be inverfely as their lengths. The frequency of the fonorous undulations of the air is therefore inverfely as the length of the ftring. When therefore we fay that 2 : 1 is the ratio of the octave, we mean, that the undulations which produce the upper found of this interval are twice as frequent as thofe which produce its fundamental found. And the ratio 3 : 2 of the diapente or fifth, indicates, that in the fame time that the ear receives three undulations from the upper found, it receives only two from the lower. Here we have a natural connection, not peculiar to the founds produced by ftrings; for we are now able to demonftrate, that the founds produced by bells are regulated by the fame law. Nay, the improvements which have been made in the fcience of motion fince the days of Galileo, fhew us that the undulations of the air in pipes, where the air is the *only* fubftance moved, is regulated by the fame law. It feems to be the general property of founds which renders them fufceptible of mufical pitch, of acutenefs, or gravity; and that a certain frequency of the fonorous undulations gives a determined and unalterable mufical note. The writer of this article has verified this by many experiments. He finds, that *any noife whatever*, if repeated 240 times in a fecond, at equal intervals, produces the note C *fol fa ut* of the Gindonian gamut. If it be repeated 360 times, it produces the G *fol re ut*, &c. It was imagined, that only certain regular agitations of the air, fuch as are produced by the tremor or vibration of elaftic bodies, are fitted for exciting in us the fenfation of a mufical note. But he found, by the moft diftinct experiments, that any noife whatever will have the fame effect, if repeated with due frequency, not lefs than 30 or 40 times in a fecond. Nothing furely can have lefs pretenfion to the name of a mufical found than the folitary fnap which a quill makes when drawn from one tooth of a comb to another: but when the quill is held to the teeth of a wheel, whirling at fuch a rate, that 720 teeth pafs under it in a fecond, the found of *g in alt.* is heard moft diftinctly; and if the rate of the wheel's motion be varied in any proportion, the noife made by the quill is mixed in the moft diftinct manner with the mufical note correfponding to the frequency of the fnaps. The *kind* of the original noife determines the kind of the continuous found produced by it, making it harfh and fretful, or fmooth and mellow, according as the original noife is abrupt or gradual: but even the moft abrupt noife produces a tolerably fmooth found when fufficiently frequent. Nothing can be more abrupt than the fnap juft now mentioned; yet the *g* produced by it has the fmoothnefs of a bird's chirrup. An experiment was made, which was lefs promifing of a found than any that can be thought of. A ftop-cock was fo conftructed, that it opened and fhut the paffage through a pipe 720 times in a fecond. This apparatus was fitted to the pipe of a conduit leading from the bellows to the wind-cheft of an organ. The air was fimply allowed to pafs gently along this pipe by the opening of the cock. When this was repeated 720 times in a fecond, the found *g in alt.* was moft fmoothly uttered, equal in fweetnefs to a clear female voice. When the frequency was reduced to 360, the found was that of a clear but rather harfh man's voice. The cock was now altered in fuch a manner, that it never fhut the hole entirely, but left about one third of it open. When this was repeated 720 times in a fecond, the found was uncommonly fmooth and fweet. When reduced to 360, the found was more mellow than any man's voice at the fame pitch. Various changes were made in the form of the cock, with the intention of rendering the primitive noife more analogous to that produced by a vibrating ftring. Sounds were produced which were pleafant in the extreme. The intelligent reader will fee here an opening made to great additions to practical mufic, and the means of producing mufical founds, of which we have at prefent fcarcely any conception; and this manner of producing them is attended with the peculiar advantage, that an inftrument fo conftructed can never go out of tune in the fmalleft degree. But of this enough at prefent.

38 This frequency is expreffed by the mufical ratios of Pythagoras.

This difcovery of Galileo's completed the Pythagorean theories, by fupplying the only thing wanted for procuring confidence in them. We now fee that the mufic of founds depends on principles as certain and as plain as the elements of Euclid, and that every thing relating to the fcale of mufic is attainable by mathematics. It is very true that we do not perceive the ratio 3 : 2 in the diapente, as having any relation to the numbers 3 and 2. But we perceive the fweetnefs of found which characterifes this concord. This is undoubtedly the perception of a certain phyfical fact involving this ratio, as much as the fweetnefs on our tongue is the perception of a certain manner of acting of the particles of fugar during their diffolution in the faliva.

Concord, Discord, are properties of particular ratios of frequency.

The pleafure arifing from certain confonances, fuch as *do fol*, is not more diftinctly perceived than is the difagreeable feeling which other confonances produce, fuch as *do re*; and it was a fair field of difquifition to difcover why the one pleafed and the other difpleafed. We cannot fay that this queftion has been completely decided. It has been afcribed to the coincidence of vibrations. In the octave, every fecond vibration of the treble note may be made to coincide with every vibration of the bafs. But the pleafure arifing from the different confonances does by no means follow the proportions of thofe coincidences of vibrations; for when two notes are infinitely near to the ftate which would produce a complete coincidence, the actual coincidence is then exceedingly rare; and yet we know that fuch founds yield very fine harmony. In tuning any concord, when the two notes are very difcordant, the coinciding vibrations recur very frequently; and as we approach

Tempera-ment of the Scale of Mufic.

proach nearer and nearer to perfect concord, thefe coincidences become rarer and rarer; and if it be infinitely near to perfect concord, the coincidences of vibration will be infinitely diftant from each other. This, and many other irrefragable arguments, demonftrate that coalefcence of found, which makes the pleafing harmony of a fifth, for example, does not arife from the coincidence of vibrations; and the only thing which we can demonftrate to obtain in all the cafes where we enjoy this pleafure, is a certain arrangement of the component pulfes, and a certain law of fucceffion of the diflocations or intervals between the non-coinciding pulfes. We are perfectly able to demonftrate that when, by continually fcrewing up one of the notes of a confonance, we render the real coincidence of pulfes lefs frequent; the diflocations, or deviations from perfect coincidence, approach nearer and nearer to a certain defineable law of fucceffion; and that this law obtains completely, when the perfect ratio of the duration of the pulfe is attained, although perhaps at that time not one pulfe of the one found coincides with a pulfe of the other. Suppofe two organ pipes, founding the note C *fol fa ut*, at the diftance of ten feet from each other, and that their pulfes begin and end at the fame inftant, making the moft perfect coincidence of pulfes—there is no doubt but that there will be the moft perfect harmony; and we learn by experience that this harmony is perfectly the fame, from whatever part of the room we hear it. This is an unqueftionable fact. A perfon fituated exactly in the middle between them will receive coincident pulfes. But let him approach one foot nearer to one of the pipes, it is now demonftrable that the pulfes, at their arrival at his ear, will be the moft diftant from coincidence that is poffible; for every pulfe of one pipe will bifect the pulfe from the other: but the law of fucceffion of the deviations from coincidence will then obtain in the moft perfect manner. A mufical found is the fenfation of a certain form of the aerial undulation which agitates the auditory organ. The perception of harmonious found is the fenfation produced by another definite form of the agitation. This is the compofition of two other agitations; but it is the compound agitation only that affects the ear, and it is its form or kind which determines the fenfation, making it pleafant or unpleafant.

39 [...]nce a-[...]s the [...]at ufe of [...]thema-[...] in mu-[...]

Our knowledge of mechanics enables us to defcribe this form, and every circumftance in which one agitation can differ from another, and to difcover general features or circumftances of refemblance, which, in fact, accompany all perceptions of harmony. We are furely intitled to fay that thefe circumftances are fure tefts of harmony; and that when we have enfured their prefence, we have enfured the hearing of harmony in the adjufted founds. We can even go farther in fome cafes: We can explain fome appearances which accompany imperfect harmony, and perceive the connection between certain diftinct refults of imperfect coincidences, and the magnitude of the deviations from perfect harmony which are then heard. Thus, we can make ufe of thefe phenomena, in order to afcertain and meafure thofe deviations; and if any rules of temperament fhould require a certain determinate deviation from perfect harmony in the tuning of an inftrument, we can fecure the appearance of that phenomenon which correfponds to the deviation, and thus can produce the precife temperament fuggefted by our rules. We can, for example, deftroy the perfect harmony of the fifth C *g*, and flatten the note *g* till it deviates from a perfect fifth in the exact ratio of 320 to 321, which the muficians call the one-fourth of a comma. The moft exquifite ear for melody is almoft infenfible of a deviation four times greater than this; and yet a perfon who has no mufical ear at all, can execute this temperament by the rules of harmony without the error of the fortieth part of a comma.

40 Beatings of imperfect confonances.

For this moft valuable piece of knowledge we are indebted to the late Dr Robert Smith of Cambridge, a very eminent geometer and philofopher, and a good judge of mufic, and very pleafing performer on the organ and harpfichord. This gentleman, in his Differtation on the Principles of Harmonics, publifhed for the firft time in 1749, has paid particular attention to a phenomenon in coexiftent founds, called a *beating*. This is an alternate enforcement and diminution of the ftrength of found, fomething like what is called a clofe fhake, but differing from it in having no variation in the pitch of the founds. It is a fort of undulation of the found, in which it becomes alternately louder and fainter. It may be often perceived in the found of bells and mufical glaffes, and alfo in the founds of particular ftrings. It is produced in this way: Suppofe two unifons quite perfect; the vibrations of each are either perfectly coincident, or each pulfe of one found is interpofed in the fame fituation between each pulfe of the other. In either cafe they fucceed each other with fuch rapidity, that we cannot perceive them, and the whole appears an uniform found. But fuppofe that one of the founds has 240 pulfes in a fecond, which is the undulation that is produced in a pipe of 24 inches long; fuppofe that the other pipe is only 23 inches and $\frac{7}{10}$ths long. It will give 243 pulfes in a fecond. Therefore the 1ft, the 80th, the 160th, and the 240th pulfe of the firft pipe will coincide with the 1ft, the 81ft, the 162d, and the 243d pulfe of the other. In the incidents of coincidence, the agitation produced by one pulfe is increafed by that produced by the other. The commencement of the next two pulfes is feparated a little, and that of the next is feparated ftill more, and fo on continually: the *diflocations* of the pulfes, or their deviations from perfect coincidence, continually increafing, till we come to the 40th pulfe of the one pipe, which will commence in the middle of the 41ft pulfe of the other pipe; and the pulfes will now bifect each other, fo that the agitations of the one will counteract or weaken thofe of the other. Thus the compounded found will be ftronger at the coincidences of the pulfes, and fainter when they bifect each other. This reinforcement of found will therefore recur thrice in every fecond. The frequency of the pulfes are in the ratio of a comma, or 81 : 80. Therefore this conftitutes an *unifon imperfect by a comma*. If therefore any circumftance fhould require that thefe two pulfes fhould form an unifon imperfect by a comma, we have only to alter one of the pipes, till the two, when founded together, beat thrice in a fecond. Nothing can be plainer than this Now let us fuppofe a third pipe tuned an exact fifth to the firft of thefe two. There will be no beating obfervable; becaufe the recurrence of coincident pulfes is fo rapid as to appear a continued found. They recur at every fecond vibration of the bafs, or 120 times in a fecond.

But

But now, inſtead of ſounding the third pipe along with the firſt, let it ſound along with the ſecond. Dr Smith demonſtrates, that they will beat in the ſame manner as the uniſons did, but thrice as often, or nine times in a ſecond. When therefore the fifth C *g* beats nine times in a ſecond, we know that it is too ſharp or too flat (very nearly) by a comma.

41
Dr Smith applies them to the ſcience and practice of muſic with great effect.

Dr Smith ſhews, in like manner, what number of beats are made in any given time by any concord, imperfect or tempered, in any aſſigned degree. We humbly think that the moſt inattentive perſon muſt be ſenſible of the very great value of this diſcovery. We are obliged to call it *his* diſcovery. Merſennus, indeed, had taken particular notice of this undulation of imperfect conſonances, and had offered conjectures as to their cauſe; conjectures not unworthy of his great ingenuity. Mr Sauveur alſo takes a ſtill more particular notice of this phenomenon *, and makes a moſt ingenious uſe of it for the ſolution of a very important muſical problem; namely, to determine the preciſe number of pulſes which produce any given note of the gamut. His method is indeed operoſe and delicate, even as ſimplified and improved by Dr Smith. The following may be ſubſtituted for it, founded on the mechaniſm of ſounding chords. Let a violin, guitar, or any ſuch inſtrument, be fixed up againſt a wall, with the finger-board downward, and in ſuch a manner, that a violin ſtring, ſtrained by a weight, may preſs on the bridge, but hang free of the lower end of the finger-board. Let another ſtring be ſtrained by one of the tuning pins till it be in uniſon with ſome note (ſuppoſe C) of the harpſichord. Then hang weights on the other ſtrings, till, upon drawing the bow acroſs both ſtrings, at a ſmall diſtance below the bridge, they are perfect uniſons, without the ſmalleſt beating or undulation, and taking care that the preſſure of the bow on that ſtring which is tuned by the pin be ſo moderate as not to affect its tenſion ſenſibly. Note exactly the weight that is now appended to it. Now increaſe this weight in the proportion of the ſquare of 80 to the ſquare of 81; that is, add to it its 40th part very nearly. Now draw the bow again acroſs the ſtrings with the ſame caution as before. The ſounds will now beat remarkably; for the vibrations of the loaded ſtring are now accelerated in the proportion of 80 to 81. Count the number of undulations made in ſome ſmall number (ſuppoſe 10) of ſeconds. This will give the number of beats in a ſecond; 80 times this number are the ſingle pulſes of the loweſt ſound; and 81 times the ſame number gives the pulſes of the higheſt of theſe imperfect uniſons.

Pulſes of  = 140.

* *Mem. Acad. Par.* 1701, 1701, 1707, and 1713.

If this experiment be tried for the C in the middle of our harpſichords, it will be found to contain 240 pulſes very nearly; for the ſtrings will beat thrice in a ſecond. The beats are beſt counted by means of a little ball hung to a thread, and made to keep time with the beats.

42
They afford exact meaſures of the temperament of concords,

Here, then, is a phenomenon of the moſt eaſy obſervation, and requiring no ſkill in muſic, by which the pitch of any ſound, and the imperfection of any concord, may be diſcovered with the utmoſt preciſion; and by this method may concordant ſounds be produced, which are abſolutely perfect in their harmony, or having any degree of imperfection or temperament that we pleaſe. An inſtrument may generally be tuned to perfect harmony, in ſome of its notes, without any difficulty, as we ſee done by every blind Crouder. But if a certain determinate degree of imperfection, different perhaps in the different concords, be neceſſary for the proper performance of muſical compoſitions on inſtruments of fixed ſounds, ſuch as thoſe of the organ or harpſichord kind, we do not ſee how it can be diſputed that Dr Smith's theory of the beating of imperfect conſonances is one of the moſt important diſcoveries, both for the practice and the ſcience of muſic, that have been offered to the public. We are inclined to conſider it as the moſt important that has been made ſince the days of Galileo. The only rivals are Dr Brook Taylor's mechanical demonſtration of the vibrations of an elaſtic cord, and its companion, and of the undulations of the air in an organ pipe, and the beautiful inveſtigations of Daniel Bernoulli of the harmonic ſounds which frequently accompany the fundamental note. The muſical theory of Rameau we conſider as a mere whim, not founded in any natural law; and the theory of the grave harmonics by Tartini or Romieu is included in Dr Smith's theory of the beating of imperfect conſonances. This theory enables us to execute any harmonic ſyſtem of temperament with preciſion, and certainty, and eaſe, and to decide on its merit when done.

We are therefore ſurpriſed to ſee this work of Dr Smith greatly undervalued, by a moſt ingenious gentleman in the Philoſophical Tranſactions for 1800, and called a large and obſcure volume, which leaves the matter juſt as it was, and its reſults uſeleſs and impracticable. We are ſorry to ſee this; becauſe we have great expectations from the future labours of this gentleman in the field of harmonics, and his late work is rich in refined and valuable matter. We preſume humbly to recommend to him attention to his own admonitions to a very young and ingenious gentleman, who, he thinks, proceeded too far in animadverting on the writings of Newton, Barrow, and other eminent mathematicians. We alſo beg his leave to obſerve, that Dr Smith's application of his theory may be very erroneous (we do not ſay that it is perfect), in conſequence of his notion of the proportional effects produced on the general harmony by equal temperaments of the different concords. But the theory is untouched by this improper uſe, and ſtands as firmly as any propoſition in Euclid's Elements. We are bound to add to theſe remarks, that we have oftener than once heard muſic performed on the harpſichord deſcribed in the ſecond edition of Dr Smith's Harmonics, both before it was ſent home by the maker (the firſt in his profeſſion), and afterwards by the author himſelf, who was a very pleaſing performer, and we thought its harmony the fineſt we ever heard. Mr Watt, the celebrated engineer, and not leſs eminent philoſopher, built a handſome organ for a public ſociety, and, without the leaſt ear or reliſh for muſic, tuned three octaves of the open diapaſon by one of Dr Smith's tables of beats, with the help of a variable pendulum. Signior Doria, leader of the Edinburgh concert, tried it in preſence of the writer of this article, and ſaid, "Belliſſima—ſopra modo belliſſima!" Signior Doria attempted to ſing along with it, but would not continue, declaring it impoſſible, becauſe the organ was ill-tuned. The truth was, that, on the major key of E^b, the tuning was exceedingly different from what ſhe was accuſtomed to, and ſhe would not try another key. We mention this particular, to ſhew how accurately

rately Mr Watt had been able to execute the temperament he intended.

43 And accurate methods of temperament.

This theory is valuable, therefore, by giving us the management of a phenomenon intimately connected with harmony, and affording us precise and practicable measures of all deviations from it. It bids fair, for this reason, to give us a method of executing any system of temperament which we may find reason to prefer. But we have another ground of estimation of this theory. By its assistance, we are able to ascertain with certainty and precision the true untempered scale of music, which eluded all the attempts of the ingenious Greeks; and we determine it in a way suited to the favourite music of modern times, of which almost all the excellencies and pleasures are derived from harmony. We do not say that this *total* innovation in the principle of musical pleasure is unexceptionable; we rather think it very defective, believing that the thrilling pleasures of music depend more upon the melody or air. We appeal even to instructed musicians, whether the heart and affections are not more affected *(and with much more distinct variety of emotion)* by a fine melody, supported, but not observed, by harmonics judiciously chosen? It appears to us that the effect of harmony, always filled up, is more uniformly the same, and less touching to the soul, than some simple air sung or played by a performer of sensibility and powers of utterance. We do not wonder, then, that the ingenious Greeks deduced all their rules from this department of music, nor at their being so satisfied with the pleasures which it yielded, that they were not solicitous of the additional support of harmony. We see that melody has suffered by the change in every country. There is no Scotchman, Irishman, Pole, or Russian, who does not lament that the skill in composing heart-touching airs is degenerated in his respective nation; and all admire the productions of their muse of "the days that are past." They are "pleasant and mournful to the soul."

But we still prefer the harmonical method of forming the scale, on account of its precision and facility: and we prefer the theory of beats, *because it also gives us the most satisfactory scale of melody*; and this, not by repeated corrections and recorrections, but by a direct process. By a table of beats, every note may be fixed at once, and we have no occasion to return to it and try new combinations; for the beatings of the different concords to one bass being once determined, every beating of any one note with any other is also fixed.

44 Fundamental experiment.

We therefore request the reader's patient attention to the experiment which we have now to propose. This experiment is best made with two organ pipes equally voiced, and pitched to the note C in the middle of our harpsichords. Let one of them at least be a stopped pipe, its piston being made extremely accurate, and at the same time easily moved along the pipe. Let the shank of it be divided into 240 equal parts. The advantage of this form of the experiment is, that the sounds can be continued, with perfect uniformity, for any length of time, if the bellows be properly constructed. In default of this apparatus, the experiment may be made with two harpsichord wires in perfect unison, and touched by a wheel rubbed with rosin instead of a bow, in the way the sounds of the vielle or hurdygurdy are produced. This contrivance also will continue the sounds uniformly at pleasure. A scale of 240 parts must be adapted to one string, and numbered from that end of the string where the wheel or bow is applied to it. Great care must be taken that the shifting of the moveable bridge do not alter the strain on the wire. We may even do pretty well with a bow in place of the wheel; but the sound cannot be long held on in any pitch. In describing the phenomena, we shall rather abide by the string, because the numbers of the scale, or length of the sounding part of the wire, correspond, in fact, much more exactly with the sounds. The deviations of the scale of the pipe do not in the least affect the conclusions we mean to draw, but would require to be mentioned in every instance, which would greatly complicate the process.

Having brought the two open strings into perfect unison, so that no beating whatever is observed in the consonance, slide the moveable bridge slowly along the string while the wheel is turning, beginning the motion from the end most remote from the bow. All the notes of the octave, and all kinds of concords and discords, will be heard; each of the concords being preceded and followed by a ruffling beating, and that succeeded by a grating discord. After this general view of the whole, let the particular harmonious stations of the bridge be more carefully examined as follows.

45 Determination of the octave, and character of concord.

I. Shift the moveable bridge to the division 120. If it has been exactly placed, we shall hear a perfect octave without any beating. It is, however, seldom so exactly set, and we generally hear some beating. By gently shifting the bridge to either side, this beating becomes more or less rapid; and when we have found in which direction the bridge must be moved, we can then slide it along till the beating cease entirely, and the sounds coalesce into one sound. We can scarcely hear the treble or octave note as distinguishable from the bass or fundamental afforded by the other string. If the notes are duly proportioned in loudness, we cannot hear the two as distinct sounds, but a note seemingly the same with the fundamental, only more brilliant. (*N. B.* It would be a great improvement of the apparatus to have a micrometer screw for producing those small motions of the bridge.)

Having thus produced a fine octave, we can now perceive that, as we continue to shift the bridge from its proper place, in either direction, the beating becomes more and more rapid, changes to a violent rattling flutter, and then degenerates into a most disagreeable jar. This phenomenon is observed in the deviation of every concord whatever from perfect harmony, and must be carefully kept in remembrance.

46 Harmony is more strict than melody.

Before we quit this concord, the octave, produced by the bisection of the pipe or string, we must observe, that, with respect to ourselves, the octave $c\ \bar{c}$ must beat almost twice in a second, before we can observe clearly any mis-tune in it, by sounding the notes in succession, or as steps in the scale of melody. We never knew any ear so nice as to discover a mis-tuning when it beats but once in three seconds. We think ourselves intitled therefore to say, that we are insensible of a temperament in melody amounting to one-third of a comma; and we never knew a person sensible of a temperament half this bulk.

When the imperfection of the octave is clearly sensible by sounding the notes in succession, it is extremely disagreeable, feeling like a struggle or endeavour to attain

Temperament of the Scale of Music.

tain a certain note, and a failure in the attempt. This seems owing to the familiar similarity of octaves, in the habitual talking and singing of men and women together. But when the notes are sounded together, although we are not much more sensible of the imperfection of the harmony directly, as a failure in the sweetness of the concord, we are very sensible of this phenomenon of beating; and any person who can distinguish a weak sound from a stronger one, can easily perceive, in this indirect manner, any fraction of a comma, however minute. This makes the tuning by harmony much more exact than by melody alone. It is also much more accommodated to the genius of modern music. The ancients had favourite passages, which were frequently introduced into their airs, and they were solicitous to have these in good tune. It appears from passages in the writings of Galen, that different performers excelled chiefly in their skill in making those occasional temperaments which their music required. Our music is much more strict, by reason of our harmonic accompanyments, which are an abominable noise when mis-tuned in a degree, which would have passed with the ancients for very good melody. Aristoxenus says, that the ear cannot discover the error of a comma. This would now be intolerable.

47 It gives the best scale for melody.

But another advantage attends our method. We obtain, by its assistance, the most perfect scale of melody; perfect in a degree attainable only by chance by the Greeks. This is now to be our business to unfold.

48 Determination of the Vth.

II. Set the moveable bridge at 158, and sound the two strings. They will beat very disagreeably, being plainly out of tune. Slide it gradually toward 160, and the beats will grow slower and slower; will change to a gentle and not unpleasant undulation; and at last, when the bridge is at 160, will vanish entirely, and the two sounds will coalesce into one sweet concord, in which neither of the component sounds can be distinguished. If the sound given by the short string be now examined as a step in the scale of melody, it will be found a fifth to the sound of the long string or fundamental note, perfectly satisfactory to the nicest ear. Thus one step of the scale has been ascertained.

III. Slide the bridge slowly along the string. The beating will recommence, will become the flutter, and then a jarring noise; and will again change to an angry flutter, beating about eight times in a second, when the bridge stands at 169 nearly. Pushing it still on, but very slowly, the flutter will become an indistinct jarring noise; which, by continuing the motion, will again become a flutter, or beat about six in the second. The bridge is now about 171.

49 Determination of the 4th.

IV. Still continuing the motion, the flutter becomes a jarring noise, which continues till the bridge is near to 180, when the rapid flutter will again be heard. This will become slower and slower as we approach to 180; and when the bridge reaches that point, all beating vanishes, and we have a soft and agreeable concord, but far inferior to the former concord in that cheering sweetness which characterises the fifth. When this note is compared with that of the fundamental string as a step in the scale of melody, it is found to correspond to the note *fa*, or the fourth step in the scale, and in that employment to give complete satisfaction to the ear.

V. Still advancing the moveable bridge toward the nut, we shall hear the beatings return again; and after fluttering and degenerating to a jarring noise, by a very small motion of the bridge, they will again be heard, will grow slower, accompanied with a sort of angry expression, and will cease entirely when the bridge reaches the 192d division of our scale. Here we have another concord of very peculiar character, being remarkably enlivening and gay. This sound gives perfect satisfaction to the ear, if employed as the third step in the scale of melody, being the note *mi* of that series, at least in all gay or cheerful airs. 50

Determination of the IIId.

VI. As we move the bridge from 192 to 200, we hear again the same beatings, which, in the immediate vicinity to 192, have a peevish fretful expression, instead of the angry waspish expression before mentioned. When the bridge has passed that situation which produces only grating discordance, we hear the beatings again, and they become slower, and cease altogether when the bridge arrives at 200. Here we have another consonance, which must be called a *concord*, because it is rather agreeable than otherwise, but strongly marked by a mournful melancholy in the expression. In the scale of melody, it forms the third step in those airs which express lamentation or grief. It is called the *minor third*, to distinguish it from the last enlivening concord, which, being a larger interval, is called the *major third*. 51

52 Determination of the 3d.

It is well known, that these two thirds give the distinguishing characters to the only two modes of melodious composition that are admitted into modern music. The series containing the major third is called the *major*, and that containing the minor third is called the *minor mode*. It is worthy of remark, that the fanatical preachers, in their conventicles and field sermons, affect this mode in their harangues, which are often distinctly musical, modulating entirely by musical intervals, and keeping the whole of their chaunt in subordination to a fundamental or key note. This is not unnatural, when we consider the general scope of their discourses, namely, to inspire melancholy and humiliating thoughts, awakening sorrow, and the like. It is not so easy to account for the usual whine of a beggar, who generally craves charity in the major third. This is the case, at least, in the northern parts of this island.

If we continue to shift the bridge still nearer to the end of the string, we shall hear nothing but a succession of vile discordant noises, somewhat less offensive when the bridge is about the divisions 213 and 216, but even there are very unpleasant. 53

54 Determination of the 6th.

VII. Let us therefore change our manner of proceeding a little, and again place the bridge at 160, which will give us the pleasing concord of the fifth. Instead of pushing it from that place toward the nut, let it be moved toward the wheel or bow. Without repeating what we have said of the appearance of the beatings, their acceleration, and their degenerating into a jarring discord, to be afterwards succeeded by another beating, &c. &c. we shall only observe, that when we place the bridge at 150, we have no beatings, and we hear a consonance, which is in a slight degree pleasant, and may therefore be called a *concord*. It has the other marks of a concord which we have been making so much use of; for the beatings recommence when we shift the bridge to either side of 150. This note makes the sixth step in the descending scale of mournful melody;

Temperament of the Scale of Muſic.

lody; that is, when we are paſſing from the acute to the graver notes, with the intention of putting an emphaſis on the third and the fundamental. Although not eminent as a concord with the fundamental alone, it has a moſt pleaſing effect when liſtened to in ſubordination to the whole ſeries, or when ſounded along with other proper accompanyments of the fundamental.

55 Determination of the VIth.

VIII Placing the bridge at 144, we obtain another very pleaſing concord, differing in its expreſſion from any of the foregoing. We find it difficult to expreſs its character. It is greatly inferior to the fifth in ſweetneſs, and to the major third in gaiety, but ſeems to poſſeſs, in a lower degree, both of theſe qualities. In the ſcale of cheerful melody, it is the ſixth note, which we have diſtinguiſhed by the ſyllable *la*. It is alſo uſed even in mournful melody, when we are aſcending, with the intention of cloſing with the octave.

56 Scale of the upper octave.

In ſhifting the bridge from 144 to 120, we obtain nothing but diſcordant, or at leaſt diſagreeable conſonances. And, laſtly, if we move the bridge beyond 120, to diviſions which are reſpectively the halves of thoſe numbers which produced the concords already treated of, we obtain the ſame ſteps in the ſcale of the upper octave. Thus if the bridge be at 80, we have the fifth to the octave note, or twelfth to the fundamental. If it be at 60, we obtain the double octave, &c. &c. &c.

57 Characters of the different concords.

We have perhaps been raſh in affixing certain moral or ſentimental characters to certain concords; for we have ſeen inſtances of perſons who gave them different denominations; but theſe were never contradictory to ours, but always expreſſed ſome ſentiment allied to that which we have aſſigned. We never met with an inſtance of a perſon capable of a little diſcriminating reflection, who did not acknowledge a manifeſt ſentimental diſtinction among the different concords which could not be confounded. We doubt not but that the Greeks, a people of exquiſite ſenſibility to all the beauties of taſte and ſentiment, paid much attention to theſe characters, and availed themſelves of them in their compoſitions. We do not think it at all unlikely, that greater effects have been produced by their muſic, which was ſtudied with this expreſs view, than have ever been produced by the modern muſic, with all the addition of harmony. We have allowed too great a ſhare of our attention to mere harmony. Our great authors are much leſs ſolicitous to compoſe an enchanting air, than to conſtruct a full ſcore of rich and well conducted harmony. We do not profeſs to be nice judges in muſical compoſition, but we may tell what we ourſelves experience. We find our minds worked up by a continuance of fine harmony into a *general* ſenſibility; into a frame of mind which would prepare and fit us for receiving ſtrong impreſſions of moral ſentiment, if theſe were diſtinctly made. But we have ſeldom felt any diſtinct emotions excited by mere inſtrumental muſic. And when the harmonies have been merely to ſupport the performance of a voice, the words have been either ſo frittered by muſical diviſions, as to become in ſome meaſure ludicrous—or have been ſo indiſtinct; and made ſo trifling a part of the muſic, that there was nothing done to give a particular ſhape to the moral impreſſion on our mind. We have generally been ſtrongly affected by ſome of the anthems which were in vogue in former times; and we think that we perceived the cauſe of this difference: There was a great ſimplicity in the voice parts: the ſyllables were not drawled out into long muſical phraſes, but pronounced nearly according to their proper quantities; ſo that the ſentiment of the ſpeaker was expreſſed with all the force of good declamation, and the harmony of the accompanyment then ſtrengthened the appropriate effect of the melody. We mean not to offer theſe obſervations as of much authority, but merely to mention ſome facts, and to aſſign what we felt to be their cauſes, in order to promote, in ſome degree, however inſignificant, the cultivation of muſical ſcience. With this view, we venture to ſay, that ſome of the beſt compoſitions of Knapp of York *uniformly* affect us more than the more admired anthems of Bird and Tallis. A cadence, which Knapp gives almoſt entirely to the melody, is laboured by Bird or Tallis with all the rules of art; and you have its characters of perfect or imperfect, full or diſappointed, cadences, and ſuch an apparatus of preparation and reſolution of diſcords, that you foreſee it at the diſtance of ſeveral bars, and then the part aſſigned to the voice ſeems a very trifle, and merely to fill up a blank in the harmony. Such compoſitions ſmell of the lamp, and fail of their purpoſe, that of charming the *learned* ear. But enough of this digreſſion.

58

Thus have we found a natural relation between certain ſounds ſtrongly marked by very preciſe characters. The concordance of ſound is marked by the abſence of all undulation, and the deviations from this harmony are ſhewn to be meaſurable by the frequency of thoſe undulations. We have alſo found, that the notes, which are thus harmonious along with the fundamental, are ſteps in the ſcale of natural muſic (for we muſt acknowledge melody to be the primitive muſic, dictated by nature). We have got the notes—*do*—*mi*, *fa*, *ſol*, *la*—*do*, aſcertained in a way that can no longer be miſtaken.

59 Ratios belonging to the concords, &c.

Let us now examine what phyſical or mechanical relations theſe ſounds ſtand into each other. Our monochord gives us the lengths of the ſtrings; and the diſcovery of Galileo ſhews us, that theſe are alſo the durations of the aërial pulſes which produce the ſenſations of muſical notes. Their ratios may therefore be truly called the ratios of the ſounds. Now we ſee that the ſtrings which produce the ſounds *do ſol* are 240 and 160. Theſe are in the ratio of 3 to 2. In this manner we may ſtate all the ratios obſerved in our experiment, *viz.*

Do : *mi* have the ratio of	240 to 192, or of	5 to 4
Do : *fa*	240 : 180	4 : 3
Do : *ſol*	240 : 160	3 : 2
Do : *la*	240 : 144	5 : 3
Mi : *ſol*	192 : 160	6 : 5, = *do* : *mi*^{b}
Fa : *ſol*	180 : 160	9 : 8
Sol : *la*	160 : 144	10 : 9
Mi : *fa*	192 : 180	16 : 15

Here we get the ſight of all the ratios which the ingenious and unwearied ſpeculations of the Greek mathematicians enliſted into the ſervice of muſic, without being able to give a good reaſon why. The ratio 5 : 4, which their faſtidious metaphyſicians rejected, and which others wiſhed to introduce from motives of mere neceſſity to fill up a blank, is pointed out to us by one of the fineſt concords. The interval between the fourth and fifth is, *very fortunately*, a ſtep of the ſcale.

The

Temperament of the Scale of Music.

The next ſtep *ſol la* is more important. For the ear for melody would have been very well ſatisfied with an interval equal to *fa ſol*, or 9 : 8 ; but if the moveable bridge be ſet at the diviſion $142\frac{2}{9}$, correſponding to ſuch a ſtep, we ſhould have a very offenſive fluttering. It is reaſonable therefore to conclude, *from analogy*, that the interval *ſol la* does not correſpond to the ratio 9 : 8 ; and that 10 : 9, which is, at leaſt, equally ſatisfactory to the ear, is the proper ſtep, even in the ſcale of melody. If we conſider what may be called the ſcale of harmony, there is no room left for doubt. To enjoy the greateſt poſſible pleaſure of harmony, we muſt not only take each note as it is related to the fundamental, but alſo as it is related to other notes of the ſcale. It may chance to be convenient to aſſume for the fundamental of our occaſional ſcale of modulation, the ſtring of the lyre which is tuned as *fa* to its proper fundamental ; or it may increaſe the harmony (and we know that it does), if we accompany the note *do* with both of the notes *fa* and *la*. To have the fine concord of the major third, it is neceſſary that the interval *fa la* be equivalent to the ratio 5 : 4. Now *fa* is 180, and 5 : 4 = 180 : 144. Therefore, by making the ſtep *ſol la* equal to 9 : 8, we ſhould loſe this agreeable concord, and get diſcord in its place.

60 Obſervations on the ſtep *ſol la*.

And thus is evinced, in oppoſition to Ariſtoxenus, the propriety of having both a major and a minor tone ; the firſt expreſſed by 9 : 8, and the laſt by 10 : 9. The difference between theſe ſteps is the ratio 81 : 80, called a comma by the Greek theoriſts.

61 Determination of the VIIth.

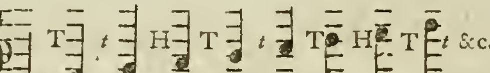
We ſtill want two ſteps of the ſcale, and two ſounds or notes correſponding to them, namely *re* and *ſi* ; and we wiſh to eſtabliſh them on the ſame authority with the reſt. We ſee that this cannot be done by a concordance with the fundamental *do*. The ear ſufficiently informs us that the ſteps *do re* and *la ſi* muſt be tones, and not ſemitones, like *mi fa*. The ſenſible ſimilarity of the two tetrachords, *do re mi fa* and *ſol la ſi do*, alſo teaches us that the ſtep *ſi do* ſhould be a ſemitone like *mi fa*. This ſeems to be all that mere melody can teach us. But we have little information whether we ſhall make *la ſi* a major or a minor tone. If we copy the tetrachord *do re mi fa* exactly, we ſhall make the ſtep *ſi do* like *mi fa*, and equivalent to the ratio 16 : 15. This requires the moveable bridge to be placed at 128. The ſound produced by this diviſion is perfectly ſatisfactory to the ear as a ſtep of the ſcale of melody. Moreover, our ſatisfaction is not confined to the compariſon of it with the note *do*, into which we ſlide by this gentle ſtep. It makes agreeable melody when uſed as the third to the note *ſol*. If we examine it mathematically, we find it a perfect major third to *ſol* ; for *ſol* requires the 160th diviſion. Now 160 : 128 = 5 : 4, which is the ratio of the pulſes of a major third. All theſe reaſons ſeem enough to make us adopt this determination of the note *ſi*.

62 Determination of the IIId.

It remains to conſider how we ſhall divide the interval *do*—*mi*. It is a perfect major third. So is *fa la*, and ſo is *ſol ſi*. But in the firſt of theſe two, we have ſeen that it muſt be compoſed of a major tone with a minor tone above it ; and in the ſecond we have a minor tone followed by a major tone above. We are left uncertain therefore whether *do re* ſhall reſemble *fa la* or *ſol ſi* in the poſition of its two parts. Ariſtoxenus and his followers declared the ear to be equally pleaſed with both. Ptolemy's *Syſtema Diatonicum Intenſum* makes *do re* a major tone, and other ſyſtems make it minor. Even in modern times it has been conſidered as uncertain ; and the only reaſon which we have to offer for a preference of the major tone for the firſt ſtep is, that, ſo far as we can judge by our own feelings, the ſounds in the relation of 9 : 8 are leſs diſcordant than ſounds in the relation of 10 : 9, and becauſe all the other ſteps have been determined by means of concords with the key. We refer, for a more particular examination of the principles on which theſe arrangements are valued, to *Dr Smith's Harmonics*, Prop. I. where he ſhews how one is preferable to another, in proportion as it affords a greater number of perfect concords among the neighbouring notes, which is the favourite object in all modern muſic. Upon this principle our arrangement is by far the beſt, becauſe it admits five more concords in the octave than the other. But we have conſidered the ſubject in a different manner, merely to avail ourſelves of the phenomenon by which all the ſteps, except one, ſeem to be naturally aſcertained, and by which the connection between harmony and melody ſeems to be pointed out to us.

It will be convenient to repreſent the tones major and minor and the hemitone, by the ſymbols T, *t*, and H. Alſo to mark the notes by the Roman numerals, or by cyphers according as they are the extremes of major or minor intervals. By this notation the octave may be repreſented thus: 63

C D E F G A B *c* *d* *c*



$\frac{8}{9}$ $\frac{9}{10}$ $\frac{15}{16}$ $\frac{8}{9}$ $\frac{9}{10}$ $\frac{8}{9}$ $\frac{15}{16}$ $\frac{8}{9}$ &c.

K II III 4 V VI VII VIII IX X &c.

The reader will remark, that the primary diviſions which we aſſigned to the repreſentation of an octave in fig. 1. by the circumference of a circle, are in conformity to this Ptolemaic partition of the octave. He will alſo be ſenſible, that the diviſion into five equal mean tones and two equal hemitones, which is expreſſed by the dotted lines, agreeing with the Ptolemaic diviſion only at C and E, is effected by biſecting the arch CE ; and therefore the deviation of the ſound ſubſtituted for the Ptolemaic D is half the difference of CD and DE, that is, half a comma. The deviations therefore at F, G, A, and B, are each a quarter of a comma.

Logarithmic meaſures of muſical intervals.

It is well known, that if the logarithm of the length of one ſtring be ſubtracted from that of another, the difference is a meaſure of the ratio between them. Therefore 30103 is the meaſure of the muſical interval called the octave, and then the meaſures of the

Comma . .	540 or	54
Hemitone . .	2803	280
Minor tone . .	4576	458
Major tone . .	5115	512
3d . . .	7918	792
IIId . . .	9691	969
4th . . .	12494	1249
Vth . . .	17609	1761
6th . . .	20412	2041
VIth . . .	22185	2219
VIIth . .	27300	2730
VIIIth . .	30103	3010

This is a very convenient circumſtance. If we take only the four firſt figures as integers, and make the octave

Temperament of the Scale of Music.

octave consist of 3010 parts, we have a scale more exact than the nicest harmony requires. The circumference of a circle may be so divided into 301 degrees, and the moveable circle have a nonius, subdividing each into 10 Or it may be divided into 55,8 degrees, each of which will be a comma. Either of these divisions will make it a most convenient instrument for expeditiously examining all temperaments of the scale that can be proposed. Or a straight line may be so divided, and repeated thrice. Then a sliding ruler, divided in the same manner, and applied to it, will answer the same purpose. We shall see many useful employments of these instruments by and by.

64 Having thus endeavoured to communicate some plain notion of the formation and singular nature of that gradation of sounds which produces all the pleasures of music, and of the manner of obtaining the steps of this gradation with certainty and precision, we proceed to consider how those musical passages may be performed on such keyed instruments as the organs and harpsichords, as they are now constructed. These instruments have twelve sounds and intervals in every octave, in order that an air may be performed in any pitch; that is, taking any one of the sounds as a key note. It is plain that this cannot be done with accuracy; for we have now seen that the interval *mi fa* is bigger than half of *do re* or *re mi*, &c. and therefore the intercalary sound formerly mentioned to be inserted between C and D, D and E, &c. will not do indiscriminately for the sharp of the sound below and the flat of the sound above it. When the tones are reduced to a mean size, the ear is scarcely sensible of the change in melody, and the harmony of the fifths and fourths is not greatly hurt. But when the half notes are inserted, and employed to make up harmonious intervals, as recommended by Zarlino, the harmony is very coarse indeed.

65 Why temperament necessary.

But we must make the reader sensible of the necessity of some temperament, even independent of those artificial notes. Therefore

Let the scholar tune upwards the four Vths $c\,g$, $g\,\bar{d}$, $\bar{d}\,\bar{a}$, $\bar{a}\,\bar{\bar{e}}$, all perfect, admitting no beating whatever. This is easily done, either with the organ or the wheel monochord already described. Then tune downwards the perfect octaves $\bar{\bar{e}}\,\bar{e}$, $\bar{e}\,e$. Now examine the IIId $c\,e$ which results from this process. If the instrument be of the pitch hitherto supposed (c making 240 pulses in a second,) this IIId will be heard beating 15 times in a second, which is a discordance altogether intolerable, the note e being too sharp in the ratio of 81 to 80, which makes a comma. It is easily found, by calculation, that e makes $303\frac{3}{4}$ pulses, instead of 300, required for the IIId to c.

N. B. It may not be amiss to inform our readers, that if any concord, whose perfect ratio is $\frac{m}{n}$ (m being the greatest term of the smallest integers expressing that ratio), be tempered sharp by the fraction $\frac{p}{q}$ of a comma, and if M and N be the pulses made by the acute and grave notes of the concord during any number of seconds, the number b of beats made in the same time by this concord will be $= \frac{2\,q\,m\,\mathrm{N}}{161\,p-q}$, or $\frac{2\,q\,n\,\mathrm{M}}{161\,p+q}$; and if it be tempered flat, then $b = \frac{2\,q\,m\,\mathrm{N}}{161\,p+q}$, or $\frac{2\,q\,n\,\mathrm{M}}{161\,p-q}$ (*Smith's Harm.* 2d edit. p. 82, &c.)

65. It is impossible, therefore, to have perfect Vths and perfect IIIds at the same time. And it will be found, that the 3d $e\,g$ resulting from this process, and the VIth $c\,\bar{a}$, are still more discordant, rattling at an intolerable rate. Now the major and minor thirds, alternately succeeding each other, form the greatest part of our harmonies; and the VIth is also a very frequent accompanyment. It is necessary therefore to sacrifice somewhat of the perfect harmony of the Vths, in order that we may not be disgusted with the discord of those other harmonies: and it is this mutual accommodation, and not the changes made necessary by the introduction of intercalary notes, which is properly called TEMPERAMENT. It will greatly assist us in understanding the effects of the temperaments of the different concords, if we examine all the divisions of the circular representation of the octave and musical scale given in fig. 1. by placing the index of the moveable circle on that note of the outer circle for which we want the proper harmonies, or accompanyments, which are either the IIId and Vth, or the 4th and VIth. We shall thus learn, in the *first* place, the deviations of the different perfect notes of the scale from the notes required for this new fundamental; and we must then study what effect the same temperament produces on the agreeableness of the harmony of different concords having the same bass or the same treble, taking it for granted that the hurt to the harmony of any individual concord is proportional to its temperament.

67 How this may be obtained by the beats.

It is in this delicate department of musical science that we think the great merit of Dr Smith's work consists. We see that the deviation from perfect harmony is always accompanied with beats, and increases when they increase in frequency—whether it increases in the same proportion may be a question. We think that Dr Smith's determination of the equality of imperfect harmony in his 13th proposition, includes every mathematical or physical circumstance that appears to have any concern in it. What relates immediately to our sensations is, as yet, an impenetrable secret. The theory of beats, as delivered by this author, affords very easy, though sometimes tedious, methods of measuring and of ensuring all the varieties which can obtain in the beating of imperfect consonances. It appears to us therefore very unjust to say, with the late writer in the Philosophical Transactions, that this obscure volume has left the matter where it found it. The author has given us *effective* principles, although he may have been mistaken in the application; which however we are far from affirming. Our limits will not allow us to give any account of that theory; and indeed our chief aim in the present article is to give a method of temperament which requires no scientific knowledge of the subject. But we could not think of losing the opportunity of communicating, by the way, to unlearned persons, some more distinct notions of the scale of musical sounds, and of its foundation in nature, than scholars usually receive from the greater number of mere music masters. The acknowledged connection of the musical ratios with the pleasures of harmony

Temperament of the Scale of Muſic.

harmony and melody, has (we hope) been employed in an eaſy and not obſcure manner; and the phenomena which we have faithfully narrated, ſhew plainly that, by diminiſhing the rattling undulations of tempered concords, we are certain of improving the harmony of our inſtruments. We ſhall proceed therefore on this principle for the uſe of the mere performer, but at the ſame time introducing ſome very ſimple deductions from Smith's theory, for which we expect the thanks of all ſuch readers as wiſh to ſee a little of the reaſons on which they are to proceed.

68 Method in practice.

The experiment, of which we have juſt now given an account, ſhews that four conſecutive fifths compoſe a greater interval than two octaves and a major third. Yet, in the conſtruction of our muſical inſtruments of fixed ſounds, they muſt be conſidered as of equal extent; ſince we have 7 half intervals in the Vth, and 12 in the octave, and four in the IIId, four Vths contain 28, and two octaves contain 24; and theſe, with the four which compoſe a IIId, make alſo 28. It is plain, therefore, that whatever we do with the IIIds, we muſt leſſen the Vths. If therefore we keep the IIId perfect, we muſt leſſen each of the Vths by $\frac{1}{4}$th of a comma; for we learned, by the beating of the imperfect IIId $c\,e$, that the whole exceſs of the four Vths was a comma. Therefore the Vth $c\,g$ muſt be flattened $\frac{1}{4}$th of a comma. But how is this to be done with accuracy? Recollect the formula given a little ago, where the number of beats b in any number of ſeconds is $= \frac{2\,q\,m\,N}{161 \times p = q}$. In the preſent caſe $q = 1$, $m = 3$, $N = 240$ per ſecond, and $p = 4$. Therefore the formula is $= \frac{2 \times 3 \times 240}{161 \times 4 + 1} = \frac{1440}{645} = 2{,}25$ in a ſecond, or 9 beats in four ſeconds very nearly.

In like manner, the next Vth $g\,\bar{d}$ muſt be flattened $\frac{1}{4}$th of a comma, by making it beat half as faſt again, or $13\frac{1}{2}$ beats in four ſeconds (becauſe in this Vth $N = 360$. But as this beating is rather too quick to be eaſily counted, it will be better to tune downwards the perfect octave g G, which will reduce N to 180 for the Vth G d. This will give us 1,68 per ſecond, or 10 beats in 6 ſeconds very nearly.

There is another way of avoiding the employment of too quick beats. Inſtead of tuning the octave g G, make c G beat as often as $c\,g$. This is even more exactly an octave to g than can be eſtimated by a good ear. Dr Smith has demonſtrated, that when a note makes a minor concord with another note below it, and therefore a major concord with the octave to that note, it beats equally with both; but if the major concord be below, it beats twice as faſt with the octave above. Now in the preſent caſe, $c\,g$ is a Vth, and c G a 4th. For the ſame reaſon $c\,f$ would beat twice as faſt as c F.

In the next place, the Vth $d\,\bar{a}$ muſt be made to beat flat 15 times in 6 ſeconds.

In like manner, inſtead of tuning upward the Vth $\bar{a}\,\bar{\bar{e}}$, tune downward the octave $\bar{a}\,a$, and then tune upward the Vth $a\,e$, and flatten it till it beat 15 times in 8 ſeconds.

If we take 15 ſeconds for the common period of all theſe beats, we ſhall have

Temperament of the Scale of Muſic.

The beats of $c\,g = 34$.
G $d = 25$.
$d\,\bar{a} = 37\frac{1}{2}$.
$a\,e = 28$.

69

We ſhall now find $c\,e$ to be a fine IIId, without any ſenſible beating; and then we proceed in the ſame way, always tuning upward a perfect Vth; and when this would lead us too high, and therefore produce too quick beating, we ſhould tune downward an octave. Do this till we reach b ✻, which ſhould be the ſame with $\bar{c}$, or a perfect octave above c. This will be a full proof of our accurate performance. But the beſt proceſs of tuning is to ſtop when we get to g ✻. Then we tune Vths downward from c, and octaves upward when the Vths would lead us too low. Thus we get c F, F f, $f\,b^b$, $b^b\,\bar{b^b}$, $\bar{b^b}\,e^b$, and thus complete the tuning of an octave. We take this method, inſtead of proceeding upwards to $\bar{b}$ ✻; becauſe thoſe notes marked ſharp or flat are, when tuned in this way, in the beſt relation to thoſe with which they are moſt frequently uſed as IIIds.

70 Uſe of a variable pendulum.

This proceſs of temperament will be greatly expedited by employing a little pendulum, made of a ball of about two ounces weight, ſliding on a light deal rod, having at one end a pin hole through it. To prepare this rod, hang it upon a pin ſtuck into the wainſcoating, and ſlide the ball downward, till it makes 20 vibrations in 15″, by comparing it with a houſe clock. In this condition mark the rod at the upper edge of the ball. In like manner, adjuſt it for 24, 28, 32, 36, 40, 44, 48, vibrations, making marks for each, and dividing the ſpaces between them by the eye, noticing their gradual diminution. Then, having calculated the beats of the different Vths, ſet the ball at the mark ſuited to the particular concord, and temper the ſound till the beats keep pace exactly with the pendulum.

71 Abſolute number of pulſes how known.

But previous to all this, we muſt know the number of pulſes made in a ſecond by the C of our inſtrument. For this purpoſe we muſt learn the pulſes of our tuning fork. To learn this, a harpſichord wire muſt be ſtretched by a weight till it be uniſon or octave below our fork: then, by adding $\frac{1}{40}$th of the weight to what is now appended, it will be tempered by a comma, and will beat, when it is ſounded along with the fork; and we muſt multiply the beats by 80: The product is the number of pulſes required. And hence we calculate the pulſes of the C of our inſtrument when it is tuned in perfect concord with the fork.

The uſual concert pitch and the tuning forks are ſo nearly conſonant to 240 pulſes for C, that this proceſs is ſcarcely neceſſary, a quarter of a tone never occaſioning the change of an entire beat in any of our numbers.

72 Syſtem of temperament with perfect IIIds.

The intelligent reader cannot but obſerve, that this ſyſtem of tuning with perfect IIIds, which is preferred to all others by many great maſters, is the one repreſented by our circular figure of the octave. The IIId is there perfect, and the Vth CG is deficient by a quarter of a comma. We cannot here omit taking notice of a moſt valuable obſervation of Dr Smith's on this temperament, and, in general, on any diviſion of the octave into mean tones and equal limmas.

73 Proportional variations of temperament.

The octave being made up of five mean tones and two limmas, it is plain that, by enlarging the tones, we diminiſh the limmas, and that the increment of the tone is two-fifths of the contemporaneous diminution of the

Temperament of the Scale of Music.

the limma. If, therefore, we employ the symbol v to express any minute variation of this temperament, and make the increment of a mean tone $= 2v$, the contemporaneous variation which this induces on a limma will be $= -5v$; and if the tone be diminished by the same quantity $-2v$, the limma will increase by the quantity $5v$. Let us see what are the contemporaneous changes made on all the intervals of the octave when the tone is diminished by $2v$.

1. A Vth is made up of three tones and a limma. Therefore the variation of its temperament is $= -6v + 5v$, or is $= -v$. That is, the Vth is flattened from its former temperament, whatever that may have been, by the quantity $-v$. Consequently the 4th, which is always the complement of the Vth to the octave, has its temperament sharpened by the quantity v.

2. A IId, being a tone distant from the fundamental, has its temperament changed by $-2v$.

Therefore a minor 7th is raised by $2v$.

3. A minor 3d is made up of a tone and a limma: therefore its variation is $= -2v + 5v$. or $= 3v$.

Therefore a major VIth (its complement) loses $-3v$.

4. A maj. IIId, or two tones, has its variation $= -4v$.

Therefore a minor 6th has its variation $= 4v$.

5. A maj. VIIth, the complement of a limma has $-5v$.

6. A tritone, or IVth, must have the variation $= -6v$.

Therefore the false 5th must have - - - $6v$.

74 Geometrical construction founded on this.

From this observation, Dr Smith deduces the following simple mathematical construction: In the strait line CE (fig. 2.) take the six equal parts Cg, g d, d a, a E, E b, b t, and draw through the points of division the six parallel lines g G, d D, &c. Let these lines represent so many scales of the octave, so placed that the points C, g, d, &c. may represent the points C, g, d, &c. of the circular scale in fig. 1 where it is cut by the dotted lines representing the system of mean tones and limmas. Then, *1st*, take a certain length d G on the first line, to the right hand of the line CE, to represent a quarter of a comma. G will mark the place of the perfect Vth, while g represents that of the mean or tempered Vth. *2dly*, Set off d D, double of g G, in like manner, to the right hand on the second parallel. This will be the place of the perfect IId to the key note C. *3dly*, Also set off a A, on the third parallel, to the left hand, equal to g G. This will mark the place of A, the VIth to the key note C. *4thly*, Place E on the point e, because, in the system of mean tones represented in fig. 1. the IIIds were kept perfect. *5thly*, Make b B, to the right hand on the 5th line, equal to g G, to mark the place of the perfect VIIth to the key note C. And, *6thly*, make t T, to the right hand on the sixth line, equal to twice g G. This will serve for shewing the contemporaneous temperament of the tritone, or IVth, contained between F and B, as also of its complement, the false 5th in fig. 1.

It is evident that the temperament of all the notes of the octave, according to the above mentioned system, are properly represented in this figure. The Vth is tempered flat by the quarter comma G g; the IId is tempered flat by the half comma D d; the VIth is tempered sharp by a quarter comma A a; the IIId is perfect; the VIIth is flat by a quarter comma B b; and the 4th is sharp by a quarter comma G g.

75 The Temperer.

Now, let any other straight line C t' be drawn from C across these parallels. This will mark, by the intervals g' G, d D, &c. the temperaments of another system of mean tones and limmas. For it is evident, that the contemporaneous variations g g', d d', &c. from the former temperament, are in the just proportions to each other; g g' being $= -v$, the variation proper for the Vth, and the opposite temperament for its complement or 4th. In like manner, a a' is $= 3v$, the variation competent to the VIth; and E e' is $= 4v$, the proper variation for the IIId.

In like manner, b b' is $= 5v$, the variation of the VIIth and 2d. And, lastly, t t' is the variation $6v$ of the tritone, and its complement, the false fifth.

For all these reasons, any straight line C e' or C e'', drawn from C across the parallels, may justly be called the TEMPERER.

This is a very useful construction: For it is plain, 76
that the sounds which can be placed in our organs and harpsichords, which have only twelve keys for an octave, must approach to a system of mean tones. The division of the octave into twelve equal intervals is such a system of mean tones exactly. Now, in such systems, when a line is drawn from C across the parallels, we see, at one glance, not only all the temperaments of the notes with the key note, but also the temperaments of those concords which the notes employed in full harmony make with each other. Thus, in the harmony of K — III — V, the III and V make a minor 3d with each other; and in the harmony of K — 4 — VI, the 4 and VI make a major 3d with each other. Now the reader will easily see, that the first of these concords has its interval diminished on both sides, when the IIId is tempered sharp, but only on one side when it is tempered flat. The mathematical reader will also easily see, that the contemporaneous temperament A a' of the VIth is always equal to the sum g' G and E e', and that A a'' is equal to the difference of g'' G and E e''. Therefore the temperament of this subordinate concord, in the full harmony K — III — V, is, in all cases, the same with the contemporaneous temperament of the VIth.

In like manner, he will perceive that the temperament of the subordinate IIId, in the harmony of K — 4 — VI, is equal to the contemporaneous temperament of the III

We also see, in general, that the whole harmony is more hurt when the temperer lies in the angle ECK, with the IIId tempered sharp, than when it is in the angle ACE, when the IIId is flat; and that the sum of all the temperaments of the concords with the key is the smallest when the IIIds are perfect. This system of mean tones, with perfect IIIds, would therefore be the best, if the harmony of different concords were equally hurt by the same temperament.

77 Certain scales of great use.

We do not know any thing that has been published on the science of music that gives more general and speedy instruction than this simple figure. If it be drawn of such a size as to allow the comma EK to be divided into a number of equal parts, sufficiently sensible, all trouble of calculation will be saved.

We would therefore propose to accompany this figure with proper scales.

The *first* scale should have G g divided into $13\frac{1}{2}$ parts. This will express the logarithmic measures of the temperaments mentioned in n° 63. a comma being $= 54$.

The *second* scale should have g G divided into 36 parts.

 This

Temperament of the Scale of Music.

This gives the beats made in 16 feconds by the notes c, g, when tempered by any quantity $G\,g'$.

The *third* fcale fhould have g G divided into 60 parts, for the beats made by the notes c, e, or the notes c, $\bar{a}$.

The *fourth* fcale fhould have g G divided into 72 parts. This gives the beats made by the key note C, with its minor third e^b,

The *fifth* fcale fhould have g G divided into 48 parts, for the beats made by the notes c, f.

The *fixth* fcale fhould have g G divided into 89 parts, on which A a' is meafured, to get the beats of the fubordinate concord formed by g and e in the harmony of K — III — V.

And, *laftly*, g G, divided into 80 parts, will give the beats made by f and $\bar{a}$ in the harmony of K — 4 — VI.

78 Harmonioufnefs, what?

We are ignorant of the immediate efficient caufes of the pleafure we receive from certain confonances, and fhould therefore receive, with fatisfaction, any thing that can help us to approximate to a meafure of its degrees. We know that, in fact, the pleafantnefs of any individual concord increafes as the undulations called *beats* diminifh in frequency. It is probable that we fhall not deviate very far from the truth, if we fuppofe the harmonioufnefs of an individual tempered concord to be proportional to the flownefs of thefe undulations. But it by no means follows, that a temperate Vth and a IIId are equally pleafant, each in its kind, when they beat equally flow. There is a difference *in kind* in the pleafures of thefe concords : and this muft arife from the peculiar manner in which the component pulfes of each concord divide each other. We are certain that this is all the difference that obtains between them in Nature. But the harmonioufnefs here fpoken of is the arrangement which produces this pleafure. We are intitled to fay, that this is equal in two given inftances, when the arrangements are precifely fimilar ; and when the things arranged are the fame, nothing feems to remain in which the inftances can differ.

At any rate, it is of confequence to be able to proportion and diftribute thefe undulations at pleafure. They are unpleafant ; and when reinforced by uniting, muft be more fo. The theory puts it in our power to prevent this union : perhaps by making them very unequal ; or, if this fhould give a chance of periodical accumulation, we may find it better to make them all equal. Surely to have all this in our power is very defirable ; and this is obtained by the theory of the beats of imperfect confonances.

79 Temperament of a whole octave by beats.

But we are forgetting the procefs of tuning, and have only tuned three or four notes of our octave. We muft tune the reft by confidering their relation to notes already tuned. Thus, if g c makes 36 beats in 16 feconds, F c fhould make one third lefs, or about 24 in the fame time ; becaufe N in the formula is now 160 inftead of 240. Proceeding in this way, we fhall tune the octave C $\bar{\bar{c}}$ moft accurately as a fyftem of mean tones with perfect IIIds, by making the notes beat as follows. A point is put over the note that is to be tuned from the other, and a +, or a —, means that the concord is to be tempered fharp or flat. Thus g is tuned from c,

Make	$c\,\dot{g}$ beat	—	36 times in 16 feconds
	$\dot{G}\,c$	+	36
	$G\,\dot{d}$	—	27, *i. e.* $\frac{3}{4}$ths of $g\,c$.
	$c\,\dot{f}$	=	48

Make	$\dot{c}\,\bar{a}$ beat	+	60 times in 16 feconds
	$c\,\dot{e}$		o, *i. e.* a perfect IIId
	$d\,\dot{f}$※		o
	$\underline{e}\,\dot{g}$※		o
	$\underline{a}\,\dot{\bar{c}}$※		o
	$b^b\,\dot{f}$ downward	—	24 *i. e.* $\frac{8}{9}$ths of $c\,g$
	$\underline{b}^b\,\dot{\bar{b}}^b$		o, *i. e.* a perfect octave
	$\bar{b}^b\,\dot{e}^b$ downward	—	43, *i. e.* $\frac{6}{5}$ths of $c\,g$
	C $\dot{\bar{c}}$		o an octave.

Temperament of Scale of Mufic.

Other proceffes may be followed, and perhaps fome of them better than the procefs here propofed. Thus, b^b and e^b may be tuned as perfect IIIds to d and g downwards. Alfo, as we proceed in tuning, we can prove the notes, by comparing them with other notes already tuned, &c. &c. &c.

We have directed to tune the two notes b^b and e^b by taking the leading Vth downwards. We fhould have come at the fame pipes in the character of a※ aud d※ in the procefs of tuning upwards by Vths. But this would not have produced precifely the fame founds, although, in our imperfect inftruments, one key muft ferve for a※ and b^b. By tuning them as here directed, they are better fitted for the places in which they will be moft frequently employed in our ufual modulations.

80 Another fyftem very fit for our inftruments.

It may reafonably be afked, Why fo much is facrificed in order to preferve the IIIds perfect ? Were they allowed to retain fome part of the fharp temperament that is neceffary for preferving the Vths perfect, we fhould perhaps improve the harmony. And fince enlarging the Vth makes the tone greater, and therefore the limma *mi fa* much fmaller, it will bring it nearer to the magnitude of a half tone ; and this will be better fuited for its double fervice of the fharp of the note below, and the flat of the note above. Accordingly, fuch a temperament is in great repute, and indeed is generally practifed, although the VIths and the fubordinate chords of full harmony are evidently hurt by it. Even Dr Smith recommends it as well fuited to our defective inftruments, and gives an extremely eafy method of executing it by means of the beats. His method is to make the Vth and IIId beat equally faft, along with the key, the Vth flat, and the third fharp. He demonftrates (on another occafion), that concords beat equally faft with the fame bafs when their temperaments are inverfely as the major terms of their perfect ratios. Therefore draw EG, and divide it in p, fo that E p may be to pG as 3 to 5. Then draw C p, cutting gG in g', and E K in e'; and this temperer will produce the temperament we want. It will be found, that E e' and G g' are each of them 32 of their refpective fcales. Fig. 2.

Therefore make $c\,g$ beat 32 times in 16 feconds

G c'	32
G d	24
G b	24 and tune $b\,\bar{b}$
$\dot{d}\,\bar{a}$	36, and tune $a\,\bar{a}$
$d\,f$※	36
$a\,e$	27
$a\,\underline{c}$※	27
$e\,\bar{b}$	40 $\frac{1}{2}$, proving $b\,\bar{b}$
$e\,g$※	40$\frac{1}{2}$
F c	21$\frac{1}{3}$, and tune $F\,f$

ɪmpera-nt of the cale of Mufic.

F a	beat $21\frac{1}{5}$, proving a	
$b^b\ \underline{f}$	$28\frac{1}{5}$, and tune $b^b\ \overline{b^b}$	
$e^b\ \overline{b^b}$	$38\frac{1}{4}$	
$c\ \overline{c}$	0.	

It may be proper to add to all thefe inftructions a caution about the manner of counting the clock while the tuner is counting the beats. If this is to continue for 16 feconds, let the perfon who counts the clock fay *one* at the beat he begins with, and then telling them over *to himfelf*, let him fay *done* inftead of 17. Thus 16 intervals will elapfe while the tuner is counting the beats. Were he to begin to count at *one*, and ftop when he hears fixteen, he would get the number of beats in 15 feconds only.

81. We do not hefitate to fay, that this method of tuning by beats is incomparably more exact than by the mere judgment of the ear. We cannot miftake more than one beat. This miftake in the concord of the Vth amounts to no more than $\frac{1}{108}$th of a comma; and in the IIId it is only $\frac{1}{180}$.

82 actical truc-ns. It may be objected that it is fit only for the organ and inftruments of continued founds, but will not do for the quickly perifhing founds of the harpfichord. True, it is the only method worthy of that noble inftrument, and this alone is a title to high regard. But farther; the accuracy attainable by it, renders it the only method fit for the examination of fyftems of temperament. Even for the harpfichord it is much more exact, and more certain in its procefs, than any other. It does not proceed, by a random trial of a flattened feries of Vths, and a comparifon with the refulting IIId, and a fecond trial, if the firft be unfatisfactory. It fays at once, let the Vth beat fo many times in 16 feconds. Even in the fecond method, without counting, and merely by the equality of the beats of the Vth and IIId, the progrefs is eafy. Both are tuned perfect. The Vth is then flattened a little, and the IIId fharpened;—if the Vth beat fafter than the IIId, alter it firft.

All difficulty is obviated by the fimple contrivance of a variable pendulum, already defcribed. This may be made exact by any perfon that will take a little pains; and when once made, will ferve for every trial. When the ball is fet to the proper number, and the pendulum fet a fwinging, we can come very near the truth by a very few trials.

N. B. In tuning a piano forte, which has always two ftrings to a key, we muft never attempt tuning them both at once; the back unifon of both notes of the concord muft be damped, by fticking in a bit of foft paper behind it.

We hope that the inftructions now given, and the application of them to two very refpectable fyftems of temperament, are fufficient for enabling the attentive reader to put this method of tuning fuccefsfully in practice, and that he perceives the efficiency of it for attaining the defired end. But before we take leave of it, we beg leave to mention another circumftance, which evinces the juft value of the general theory of the beats of imperfect confonances as delivered by Dr Smith.

83 gin of Tarti-n founds. Thefe reinforcements of found, which are called *beatings*, are noifes. If any noife whatever be repeated, with fufficient frequency, at equal intervals, it becomes a mufical note, of a certain determinate pitch. If it recur 60 times in a fecond, it becomes the note C *fa ut*, or the double octave below the middle C of our harpfichords, or the note of an open pipe eight feet long. Now there is a fimilar (we may call it the very fame) reinforcement of found in every concord. Where the pulfe of one found of the concord bifects the pulfe of the other, the two founds are more uniformly fpread: but where they coincide, or almoft coincide, the condenfation of one undulation combines with that of the other, and there comes on the ear a ftronger condenfation, and a louder found. This may be called a *noife*; and the equable and frequent recurrence of this noife fhould produce a mufical note. If, for inftance, c and a are founded together: There is this noife at every third pulfe of c, and every fifth pulfe of a; that is, 80 times in a fecond. This fhould produce a note which is a 12th below c, and a 17th major below a; that is, the double octave below f, which makes 320 vibrations in a fecond. That is to fay, along with the two notes c and a of the concord, and the compound found, which we call the *concord of the VIth*, we fhould hear a third note FF in the bafs. Now this is known to be a fact, and it is the grave harmonic obferved by Romieu and Tartini about the year 1754, and verified by all muficians fince that time. Tartini prized this obfervation as a moft important difcovery, and confidered it as affording a foundation for the whole fcience of mufic. We fee that it is all included in the theory of beats publifhed five years before, namely, in 1749; and every one of thefe grave harmonics, or Tartinian founds, as they have been called, are immediate confequences of this theory. The fyftem of harmonious compofition which Tartini has, with wonderful labour and addrefs, founded on it, has therefore no folidity. It is, however, preferable to Rameau's, becaufe it proceeds on a fact founded on the nature of mufical founds; whereas Rameau's is a mere whim, proceeding on a falfe affumption; namely, "that a mufical found is effentially accompanied by its octave, 12th, and 17th *in alto*."—This is not true, though fuch accompanyment be very frequent, and it be very difficult to prevent it. Mr Rameau ought to have feen this. Are thefe acute harmonics mufical founds or not? He furely will not deny this. Therefore they, too, are effentially accompanied by *their* harmonics, and this abfolutely and neceffarily *ad infinitum*; which is certainly abfurd. We fhall have a better occafion for confidering this point when we defcribe the *Trumpet Marigni* in a future article.

We have taken notice of only two fyftems of temperament; both of them are fyftems of mean tones, and are in good repute as practicable methods. It would be almoft an endlefs tafk to mention all the fyftems of temperament which have been propofed. Dr Smith, after having, with great ingenuity, appreciated the changes of harmonioufnefs that are induced on the different concords by the fame temperament, and having affigned that proportion of temperament which renders them equally harmonious, each in its kind, gives a fyftem of temperament, which he calls EQUAL HARMONY. Each concord, (excepting the octave) is tempered in the inverfe proportion of the product of the terms of its perfect ratio. It is very nearly equivalent to a divifion of the octave into 50 equal parts. We do not give any farther account of it here, although we think its harmony preferable to any thing that we have ever heard. We heard it, as executed for him, and under his infpection, by the celebrated harpfichord-maker Kirkmann, 84 Dr Smith's fyftem of EQUAL HARMONY.

Temperament of the Scale of Mufic.

Temperament of the Scale of Muſic.

mann, both when the inſtrument was yet in the hands of the maker, and afterwards by the ingenious author. We have alſo heard ſome excellent muſicians declare, that the organ of Trinity college chapel at Cambridge was greatly improved in its harmony by the change made on its temperament under the inſpection of Dr Smith. When we name Stanley, we preſume that the authority will not be diſputed. We mention this, becauſe the writer in the Philoſophical Tranſactions ſpeaks of this ſyſtem, with flattened major thirds, as of no value. But we do not give any farther account of it, becauſe it is not ſuited to our inſtruments, which have but twelve ſounds in the octave.

85.

The reader will pleaſe to recollect, that the great object of temperament is twofold. Firſt, to enable us to tranſpoſe muſic from one pitch to another, ſo that we may make any note of the organ the fundamental of the piece. This undoubtedly requires a ſyſtem approaching to one of mean tones, becauſe the harmony muſt be the ſame in every key. This requires temperament, becauſe a ſound muſt be occaſionally conſidered, either as the ſharp of the note below it, or the flat of the one above. This cannot produce perfect harmony, becauſe the limma of the perfect diatonic ſcale is greater than a half tone. Thus a temperament is neceſſary merely for the ſake of the melody. But, *ſecondly*, the nature of modern muſic requires every note to be accompanied, or conſidered as accompanied, with full harmony. This is, in fact, the ſame thing with modulating on every different note as a fundamental; but it requires a much cloſer attention to the perfection of the intervals, becauſe a defect or exceſs in an interval that would ſcarcely offend the ear, if the notes were heard in ſucceſſion, is quite intolerable when they are ſounded together. Here the difference between the major and minor tone is of almoſt as great moment as the difference of the limma from a ſemitone. The ſecond object, therefore, is to obtain, in the compaſs of three octaves, as many good concords of full harmony; that is, conſiſting of a fundamental with its major third and its fifth, erect or inverted, as poſſible. There is no other harmony, although our notes have frequently a different ſituation and appearance.

86
Maxims of temperament very gratuitous.

It is no wonder that, in a ſubject where we are yet to ſeek for a principle, the attempts to attain this object have been very various, and very gratuitous. The mathematicians, even in modern times, have allowed themſelves to be led away by fancies about the ſimplicity and conſequent perfection of ratios; and having no clear principle, it is no wonder that ſome of their deductions are contrary to experience. According to Euler, thoſe ratios which are moſt perfect, that is, moſt ſimple, admit of leaſt temperament. The octave is therefore infinitely perfect; for it is allowed by all, that it muſt not have the ſmalleſt temperament. A Vth muſt be leſs tempered than a IIId. Even the practical muſician thinks that he has tempered theſe two concords equally, when the offenſive quality of each is made equally ſo; but in this caſe it is demonſtrable, that the Vth has been much more tempered than the IIId. But this could not be diſcovered till we got the theory of beats.

Moſt of the mathematical muſicians adhered to ſyſtems of mean tones; or, which are equivalent, to ſuch ſyſtems, giving ſimilar harmonies on every key of the harpſichord. This is ſurely the moſt natural, and is peculiarly ſuggeſted by the tranſpoſing of muſic from one pitch to another: but they differ exceedingly, and without giving any convincing arguments, in their eſtimation of the effects of the ſame temperament on different concords. Much of this, we apprehend, ariſes from diſpoſition. Perſons of a gay diſpoſition reliſh the harmony of the IIId, and prefer a ſharp to a flat temperament of this concord. Perſons of a more penſive diſpoſition, prefer ſuch temperaments as allow the minor thirds to be more perfect.

87
Equal harmony rejected.

But there are many, eminent both as performers and as theoriſts, who reject any ſyſtem which gives the ſame harmonies on every note of the octave. They obſerve, that in the progreſs of the cultivation of muſic in Europe, the melodies of all nations have gradually approached to a certain uniformity. Certain cadences, cloſes, ſtrains, and phraſes, are becoming every day more common; and even in the conduct of a conſiderable piece of muſic, and the gradual but ſlow paſſage of the modulation from one key into another, there is a certain regularity. Nay, they add, that this cannot be greatly deviated from without becoming very offenſive. We may remain ignorant of the cauſe of this uniformity; but its exiſtence ſeems to prove that it ariſes from ſome natural principle; and therefore it ought to be complied with, and our temperaments ſhould be accommodated to it. The reſult of this uniformity in the muſic of our times is, that the modulation on ſome keys is much leſs frequent than on others, and this frequency decreaſes in a certain order. Suppoſing that we begin on C. A piece of plain muſic ſeldom goes farther than G and F. A little more fancy and refinement leads the compoſer into D, or into B^b, &c. &c. It would therefore be deſirable to adjuſt our temperaments ſo, that the harmonies in C ſhall be the beſt poſſible, and gradually leſs perfect in the order of modulation. Thus we ſhall, in our general practice, have finer harmony than if it were made equal throughout the octave; becauſe the unavoidable imperfections are thrown into the leaſt frequented places of the ſcale. The practical muſicians add to this, that by ſuch a temperament the different keys acquire characters, which fit each of them more particularly for the expreſſion of different ſentiments, and for exciting different emotions. This is very perceptible in our harpſichords as they are generally tuned. The major key of A is remarkably brilliant; that of F is as remarkably ſimple, &c.

We cannot ſay that we are altogether convinced by theſe arguments. The violin is unqueſtionably the inſtrument of the greateſt powers. A concert of inſtruments of this kind, unembarraſſed by the harpſichord, or any inſtruments incapable of occaſional temperament, is the fineſt muſic we have. The performers make no ſuch degradations of harmony, but keep it as perfect as poſſible throughout; and a violin performer is ſenſible of violence and conſtraint when he accompanies a keyed inſtrument into theſe unfrequented paths. Let him play the ſame muſic alone, and he will play it quite differently, and much more to his own ſatisfaction. We imagine, too, that much of the uniformity ſpoken of is the reſult of imitation and faſhion, and even of the temperaments that we have preferred. There is an evident diſtinction in the native muſic of different nations. An experienced muſician will know, from a few bars, whether

Tempera-ent of the Scale of Music.

ther an air is Irish, Scotch, or Polish. This distinction is in the modulation; which, in those nations, follows different courses, and should therefore, on the same principle, lead to different temperaments.

With respect to the variety of characters given to the different keys, we must acknowledge the fact. We have tuned a piano forte in the usual manner; but instead of beginning the process with C, we began it with D. An excellent performer of voluntaries sat down to the instrument, and began to indulge his rich fancy; but he was confounded at every step: he thought the instrument quite out of tune. But when he was informed how it had been tuned, and then tried a known plain air on it, he declared it to be perfectly in tune. It is still very doubtful, however, whether we should not have much finer music, by equalising the harmony in the different keys, and trusting for the different expression so much spoken of to a judicious mixture of other notes called *discords*.

88
ause of is uncer-inty ow re-oved by r Smith's eory.

After all, the great uncertainty about the most proper temperament has remained so long undetermined, because we had no method of executing with certainty any temperament that was offered to the public. What signifies it on what principle it may be proper to flatten a Vth one-fifth of a comma, and sharpen a VIth one-seventh of a comma, unless we are able to do both the one and the other? Till Dr Smith published the theory of beats, the monochord was the only assistance we had: but however nicely it may be divided, it is scarcely possible to make the moveable bridge so steady and so accurate in its motion, that it will not sensibly derange the tension of the string. We have seen some very nice and costly monochords; but not one of them could be depended on to one-eighth of a comma. Even if perfect, they gave but momentary sounds by pinching. The bow cannot be trusted, because its pressure changes the tension. Mr Watt's experiments with his monochord of continued sound shewed this evidently. A pitch-pipe with a sliding piston promises the greatest accuracy; but we are sadly disappointed, because the graduation of the piston cannot be performed by any mathematical rule. It must be pushed more than half way down to produce the octave, more than one-third to produce the Vth, &c. and this without any rule yet discovered. Thanks to Dr Smith we can now produce an instrument tuned exactly, according to any proposed system, and then submit it to the fair examination of musicians. Even the speculatist may now form a pretty just opinion of the merits of a system, by calculating, or measuring by such scales as we have proposed, the beats produced by the tempered concords in all parts of the octave. No one who has listened with attention to the rattling beats of a full organ, with its twelfth and sesquialter stops all sounding, will deny that they are hostile to all harmony or good music. We cannot be much mistaken in preferring any temperament in proportion as it diminishes the number of those beats. We should therefore examine them on this principle alone; attending more particularly to the beats of the third major, because these are in fact the loudest and most disagreeable: and we must not content ourselves with the beats of each concord with the fundamental of the full harmony, whether K—III—V, or K—4—VI, or K—3—V, or K—4—6, which sometimes occurs. We must attend equally to the beats of the two notes of accompanyment with each other: these are generally the most faulty.

Temperament of the Scale of Music.

89.

This examination is neither difficult nor tedious. 1. Write down, in one column, the lengths of the strings or divisions of the monochord; in another write their logarithms; in a third the remainders, after subtracting each from the logarithm of the fundamental. 3. Have at hand a similar table for the perfect diatonic scale. 4. Compare these, one by one, and note the difference, + or —, in a 4th column. These are the temperaments of each note of the scale. 5. Compare every couple of notes which will compose a major or minor third, or a fifth, by subtracting the logarithm of the one note from that of the other. The differences are the intervals tempered. 6. Compare these with the perfect intervals of the diatonic scale, and note the differences, + or —, and set them down in a fifth column. These are all the temperaments in the system. 7. If we have used logarithms consisting of five decimal places, which is even more than sufficient, consider these numeral temperaments as the q of the formula given in nº 65. for calculating the beats, and then p is always $= 540$. Or we may make another column, in which the temperaments are reduced to some easy fraction of a comma.

90
System of Dr Young.

We shall content ourselves with giving one example; of the temperament proposed by Mr Young in the Philosophical Transactions for 1800. It is contained in the following table:

1.	2.	3.	4.	5.		
				IIIds upward on		
C	100000	5.00000		C	135	
C※	94723	4.97645	2355	G. F.	190	
D	89304	4.95087	4913	D. B♭	245	
E♭	83810	4.92330	7670	A. E♭	346	Sharp.
E	79752	4.90174	9826	E. A♭	448	
F	74921	4.87461	12539	B. C※	494	
F※	71041	4.85151	14849	F※	540	
G	66822	4.82492	17508	3ds upward on		
G※	63148	4.80036	19964	A. E.	236	
A	59676	4.77580	22420	D. B.	291	
B♭	56131	4.74921	25079	G. F※	346	
B	53224	4.72610	27390	C. C※	448	Flat.
C	50000	4.69897	30103	F. G※	494	
				B♭ E♭	540	

Vths upward on

E♭. G※. C※. F※	perfect	
F. B♭. E. B	46	Flat.
C. G. D. A	116	

Interval of a comma	540
minor third . . .	7918
major third . . .	9691
fifth	17609

The first column of the above table contains the ordinary designations of the notes. The second contains the corresponding lengths of the monochord. The third contains the logarithms of column second. The fourth contains the difference of each logarithm from the first. The next column contains, first, the temperaments of all the major thirds, having for their lowest note the sound corresponding to the letter. Thus 494, or $\frac{494}{540}$ of a comma, Temperament of the Scale of Muſic, Templars.

comma, is the temperament of the IIId, B — D※, and C※ — F. Secondly, it contains all the minor thirds formed on the notes repreſented by the letters. The column below contains the temperaments of the Vths. *N. B.* Theſe temperaments are calculated by the author. We have found ſome of them a little different. Thus we make the temperament of C — G only 108. Below this we have ſet down the meaſures of the perfect intervals, which are to be compared with the differences of the logarithms in column third.

91 Syſtem of Kirnbergher.

We preſume not to decide on the merits of this temperament: Only we think that the temperaments of ſeveral thirds, which occur very frequently, are much too great; and many inſtances of the 6th, which is frequent in the flat key, are ſtill more ſtrongly tempered. A temperament, however, which very nearly coincides with Dr Young's, has great reputation on the continent. This is the temperament by Mr Kirnbergher, publiſhed at Berlin in 1771, in his book called *Die Kunſt des reinen Satzes in der Muſik*. The eminent mathematician Major Templehoff has made ſome important obſervations on this temperament, and on the ſubject in general, in an eſſay publiſhed in 1775, Berlin. Dr Young's is certainly preferable.

The monochord is thus divided by Kirnbergher:

C =	1,0000	F =	7500	B♭ =	5625
C※	9492	F※	7111	B	5313
D	8889	G	6667	*c*	5000
E♭	8437	G※	6328		
E	8000	A	5963		

We conclude this article (perhaps too long) by earneſtly recommending to perſons who are not mathematically diſpoſed, the ſliding ſcales, either circular or rectilineal, containing the octave divided into 301 parts; and a drawing of fig. 2. on card paper, of proper ſize, having the quarter comma about two inches, and a ſeries of ſcales correſponding to it. This will ſave almoſt the whole of the calculation that is required for calculating the beats, and for examining temperaments by this teſt. To readers of more information, we earneſtly recommend a careful peruſal of Smith's Harmonics, ſecond edition. We acknowledge a great partiality for this work, having got more information from it than from all our patient ſtudy of the moſt celebrated writings of Ptolemy, Huyghens, Euler, &c. It is our duty alſo to ſay, that we have got more information concerning the muſic of the Greeks from Dr Wallis's appendix to his edition of Porphyrius's Commentary on Ptolemy's Harmonics, than from any other work.

TEMPLARS. In the account of this order, which is publiſhed in the *Encyclopædia*, we have, with many others, ſuppoſed that the guilt of which they were accuſed at the ſuppreſſion of the order was leſs enormous than their enemies alleged. For the honour of human nature, we are ſtill unwilling to believe that this was not the caſe. Juſtice, however, compels us to admit, that the Abbé Barruel has brought together ſuch a cloud of witneſſes againſt the Templars, that we know not how to reſiſt their evidence; and that he has completely proved that *Philip le Bel* was not influenced by avarice when he ſuppreſſed that order in France. "It has been ſaid that he and Clement V. had concerted between them the diſſolution of the Templars. The falſity of ſuch an aſſertion is evident on the inſpection of their letters. Clement V. at firſt will give no credit to the accuſations againſt the Templars; and even when he receives inconteſtable proofs from Philip le Bel, he had ſtill ſo little concerted the plan with that Prince, that every ſtep taken by the one or the other occaſions diſputes on the rights of the church or of the throne.

Templars.

"It was alſo ſaid, that the king wiſhed to ſeize on the great riches of theſe knights: but at the very commencement of his proceedings againſt the order, he ſolemnly renounced all ſhare in their riches; and perhaps no prince in Chriſtendom was truer to his engagement. Not a ſingle eſtate was annexed to his domain; and all hiſtory bears teſtimony to the fact.

"We next hear of a ſpirit of revenge which actuated this prince; and during the whole courſe of this long trial, we do not hear of a ſingle perſonal offence that he had to revenge on the Templars. In their defence, not the moſt diſtant hint, either at the revengeful ſpirit, or at any perſonal offence againſt the king, is given; ſo far from it, until the period of this great cataſtrophe, the grand maſter of the order had been a particular friend of the king's, who had made him godfather to one of his children.

"In fine, the rack and torture is ſuppoſed to have forced confeſſions from them which otherwiſe they never would have made: and in the minutes, we find the avowal of at leaſt 200 knights all made with the greateſt freedom, and without any coercion. Compulſion is mentioned but in the caſe of one perſon; and he makes exactly the ſame avowal as 12 other knights, his companions, freely made (A). Many of theſe avowals were made in councils where the biſhops begin by declaring, that all who had confeſſed through fear of the torture ſhould be looked upon as innocent, and that no Knight Templar ſhould be ſubjected to it (B). The Pope Clement V. was ſo far from favouring the king's proſecutions, that he began by declaring them all to be void and null. He ſuſpended the archbiſhops, biſhops, and prelates, who had acted as inquiſitors in France. The king accuſes the Pope in vain of favouring the Templars; and Clement is only convinced after having been preſent at the interrogatories of 72 knights at Poictiers, in preſence of many biſhops, cardinals, and legates. He interrogated them, not like a judge who ſought for criminals, but like one who wiſhed to find innocent men, and thus exculpate himſelf from the charge of having favoured them. He hears them repeat the ſame avowals, and they are freely confirmed. He deſired that theſe avowals ſhould be read to them after an interval of ſome days, to ſee if they would ſtill freely perſevere in their depoſitions. He hears them all confirmed. *Qui perſeverantes in illis, eas expreſſe et ſponte prout recitatæ fuerant approbârunt.* He wiſhed ſtill further to interrogate the grand maſter and the principal ſuperiors, *præceptores majores*, of the divers provinces of France, Normandy, Poitou, and of the Tranſmarine countries. He ſent the moſt venerable perſons to interrogate thoſe of the ſuperiors, whoſe age or infirmities hindered them from

(A) *Layette*, No. 20. *Interrog. made at Caen.*

Templars. from appearing before him. He ordered the depofitions of their brethren to be read to them, to know if they acknowledged the truth of them. He required no other oath from them than to anfwer freely and without compulfion; and both the grand mafter and the fuperiors of thefe divers provinces, depofe and confefs the fame things, confirm them fome days after, and approve of the minutes of their depofitions taken down by public notaries. Nothing lefs than fuch precautions could convince him of his error: it was then only that he revoked his menaces and his fufpenfion of the French bifhops, and that he allows the king to proceed in the trials of the Templars.

"Let fuch pretexts be forgotten, and let us only dwell on the avowals which truth alone forced from thefe criminal knights.

"Their depofitions declare, that the Knights Templars, on their reception, denied Chrift, trampled on the crofs, and fpit upon it; that Good Friday was a day which was particularly confecrated to fuch outrages; that they promifed to proftitute themfelves to each other for the moft unnatural crimes; that every child begotten by a Templar was caft into the fire; that they bound themfelves by oath to obey, without exception, every order coming from the grand mafter; to fpare neither facred nor prophane; to look upon every thing as lawful when the good of the order was in queftion; and, above all, never to violate the horrible fecrets of their nocturnal myfteries, under pain of the moft terrible chaftifements (c).

"In making their depofitions, many of them declared they had only been forced into thefe horrors by imprifonment and the moft cruel ufage; that they wifhed, after the example of many of their brethren, to pafs into other orders, but that they did not dare, fearing the power and vengeance of their order; that they had fecretly confeffed their crimes, and had craved abfolution. In this public declaration, they teftified, by their tears, the moft ardent defire of being reconciled to the church.

"All repeat the fame depofition, except three, who declare they have no knowledge of the crimes imputed to their order. The Pope, not content with this information taken by men of religious orders and by French noblemen, requires that a new trial fhould take place in Poitou before cardinals and others whom he himfelf nominates: Again, with the fame freedom, and for the third time, the grand mafter and other chiefs, in prefence of Clement V. repeat their depofitions. Molay even requefted, that one of the lay brothers, who was about his perfon, fhould be heard, and this brother confirms the declaration. During many years thefe informations were continued and renewed at Paris, in Champagne, in Normandy, in Quercy, in Languedoc, in Provence. In France alone, above 200 avowals of the fame nature are to be found: nor did they vary in England, where, at the fynod of London held in 1311, 78 Englifh knights were heard and two whole months were fpent in taking informations and in verifying their declarations. Fifty-four Irifh were alfo heard, and many Scotch, in their refpective countries. It was in confequence of thefe declarations that the order of the Templars was abolifhed in thofe kingdoms, and that the parliament difpofed of their goods (D). The fame declarations were taken and proved in Italy, at Ravenna, at Bologna, at Pifa, and at Florence, though in all thefe councils the prelates were very ready to abfolve all thofe knights who could fucceed in their juftifications. Templars, Templeman.

"I would willingly affert (continues the Abbé), that it was the fmaller part of the Templars who fuffered themfelves to be carried away by fuch abominations. Some even at Paris were declared innocent. In Italy a ftill greater number were abfolved; of all thofe who were judged at the councils of Mayence and Salamanca, none were condemned: and hence we may conclude, that of the 9000 houfes belonging to the order, many had not been tainted, and that whole provinces were to be excepted from the general ftain of infamy. But the condemnations, the juridical depofitions, the method of initiating the knights, almoft became general; the fecrecy of their receptions, where neither prince, nor king, nor any perfon whatever, could be prefent during the laft half century, are fo many teftimonies which corroborate the divers accufations contained in the articles fent to the judges; that is to fay, that at leaft two-thirds of the order knew of the abominations practifed without taking any fteps to extirpate them. *Quod omnes, vel quafi duæ partes ordinis fcientes dictos errores corrigere neglexerint.*

"This certainly cannot mean that two thirds of the knights had equally partaken of thefe abominations. It is evident, on the contrary, that many detefted them as foon as they were acquainted with them; and that others only fubmitted to them, though initiated, after the harfheft treatment and moft terrible threats. Neverthelefs, this proves, that the greateft part of thefe knights were criminal, fome through corruption, others through weaknefs or connivance; and hence the diffolution of the order became neceffary."

TEMPLEMAN (Peter). M. D. the fon of an eminent attorney at Dorchefter in the county of Dorfet, by Mary daughter of Robert Haynes, was born March 17, 1711, and was educated at the Charter-houfe (not on the foundation), whence he proceeded to Trinity-college, Cambridge, and there took his degree of B. A. with diftinguifhed reputation. During his refidence at Cambridge, by his own inclination, in conformity with that of his parents, he applied himfelf to the ftudy of divinity, with a defign to enter into holy orders; but after fome time, from what caufe we know not, he altered his plan, and applied himfelf to the ftudy of phyfic. In the year 1736, he went to Leyden, where he attended the lectures of Boerhaave, and the profeffors of the other branches of medicine in that celebrated univerfity, for the fpace of two years or more. About the beginning of 1739, he returned to London, with a view to enter on the practice of his profeffion, fupported by a handfome allowance from his father. Why he did not fucceed in that line was eafy to be accounted for by thofe who knew him. He was a man of a very liberal *Biog. Dict.*

(c) See the *Vouchers brought by Dupuy*, and *Extract of the Regifters*.

(D) Vide *Valfinger in Edvardum* II. *et Ypodigma Neuftriæ apud Dupuy.—Effai de Fred. Nicolai.*

liberal turn of mind, of general erudition, with a large acquaintance among the learned of different profeſſions, but of an indolent, inactive diſpoſition; he could not enter into juntos with people that were not to his liking; nor cultivate the acquaintance to be met with at tea-tables; but rather choſe to employ his time at home in the peruſal of an ingenious author, or to ſpend an attic evening in a ſelect company of men of ſenſe and learning. In this he reſembled Dr Armſtrong, whoſe limited practice in his profeſſion was owing to the ſame cauſe. In the latter end of the year 1750 he was introduced to Dr Fothergill by Dr Cuming, with a view of inſtituting a Medical Society, in order to procure the earlieſt intelligence of every improvement in phyſic from every part of Europe. At the ſame period he tells his friend, "Dr Mead has very generouſly offered to aſſiſt me with all his intereſt for ſucceeding Dr Hall at the Charter houſe, whoſe death has been for ſome time expected. Inſpired with gratitude, I have ventured out of my element (as you will plainly perceive), and ſent him an ode." Dr Templeman's epitaph on Lady Lucy Meyrick (the only Engliſh copy of verſes of his writing that we know of), is printed in the eighth volume of the "Select Collection of Miſcellany Poems, 1781." In 1753 he publiſhed the firſt volume of "Curious Remarks and Obſervations in Phyſic, Anatomy, Chirurgery, Chemiſtry, Botany, and Medicine; extracted from the Hiſtory and Memoirs of the Royal Academy of Sciences at Paris;" and the ſecond volume in the ſucceeding year. A third was promiſed, but we believe never printed. It appears, indeed, that if he had met with proper encouragement from the public, it was his intention to have extended the work to twelve volumes, with an additional one of index, and that he was prepared to publiſh two ſuch volumes every year. His tranſlation of "Norden's Travels" appeared in the beginning of the year 1757; and in that year he was editor of "Select Caſes and Conſultations in Phyſic, by Dr Woodward," 8vo. On the eſtabliſhment of the Britiſh Muſeum, in 1753, he was appointed to the office of keeper of the reading-room, which he reſigned on being choſen, in 1760, ſecretary to the then newly inſtituted Society of Arts, Manufactures, and Commerce. In 1762, he was elected a correſponding member of the Royal Academy of Science of Paris, and alſo of the Œconomical Society at Berne. Very early in life Dr Templeman was afflicted with ſevere paroxyſms of an aſthma, which eluded the force of all that either his own ſkill, or that of the moſt eminent phyſicians then living, could ſuggeſt to him; and it continued to haraſs him till his death, which happened September 23, 1769. He was eſteemed a man of great learning, particularly with reſpect to languages; ſpoke French with great fluency, and left the character of a humane, generous, and polite member of ſociety.

TERANE', a town in Egypt, ſituated on what Mr Browne calls the *left* of the moſt weſtern mouth of the Nile, at a very ſmall diſtance from the river. Its latitude is 30° 24′. The buildings are chiefly unburned brick, though there are alſo ſome of ſtone. The town and diſtrict, containing ſeveral villages, belonged, before the French invaſion, to Murad Bey, who uſually entruſted its government, and the collection of its revenue, to one of his Caſhefs. That revenue ariſes principally from natrôn (See. NATRUM, *Encycl.*), found in great quantities in certain lakes about thirty five miles from Terané; and it is on account of theſe lakes only that the town is worthy of notice in this work; for though there are many columns in its neighbourhood, which indicate the ſite of ancient ſtructures, none of them have inſcriptions aſcertaining their antiquity.

The eaſtern extremity of the moſt weſtern lake Mr Browne found to be 30° 31′ North. No vegetation appears, except reeds, on the margin of the lake, which is very irregular in its form; ſo that it is not eaſy to ſay what may be the quantity of ground covered with water. It is higher in winter than in ſummer; and when it was viſited by our author its breadth did not exceed a mile, though its length was nearly four. Towards the end of the ſummer, it is ſaid theſe lakes are almoſt dry; and the ſpace that the water has retired from is then occupied by a thick depoſition of ſalt. Not far removed from the eaſtern extremity, a ſpring riſes with ſome force, which much agitates the reſt of the water. Cloſe to that ſpring the depth was far greater than Mr Browne's height; in other parts it was obſervable that it did not generally exceed three feet. The thermometer near this ſpring ſtood at 76, while in the open air it was 87. The more weſtern lake differs not materially from the eaſtern in ſize, form, or productions. The colour of the water in both is an imperfect red; and where the bottom is viſible, it appears almoſt as if covered with blood. Salt, to the thickneſs of five or ſix inches, lies conſtantly in the more ſhallow parts. The ſurface of the earth, near the lake, partakes more or leſs generally of the character of natrôn, and, in the parts fartheſt removed, offers to the foot the ſlight reſiſtance of ploughed ground after a ſlight froſt. The ſoil is coarſe ſand. The water of the lake, on the ſlighteſt evaporation, immediately depoſits ſalt. There is a mountain not far from the lakes, where natrôn is found in inſulated bodies, near the ſurface, of a much lighter colour than that produced in the lake, and containing a greater portion of alkali. How thick the ſubſtance of natrôn commonly is in the lake, our author did not accurately determine; but thoſe employed to collect it report, that it never exceeds a cubit, or common pike; but it appears to be regenerated as it is carried away. If ever it ſhould be brought to ſuperſede the uſe of barilla, the quantity obtainable ſeems likely to anſwer every poſſible demand.

TEREBRATULÆ (ANOMIÆ, *Lin.* ſee that article *Encycl.*) have been ſuppoſed not to exiſt now but as petrified ſhells. This, however, is a miſtake. The anomia is an inhabitant of every region, and has exiſted in every age. As many terebratulæ were caught by Perouſe's people during his voyage of diſcovery, and as Lamanon the naturaliſt thought they ſhould be conſidered as a genus by themſelves, he has given us the following deſcription of the *anomia*, or, as he calls it, *terebratula*, on the coaſt of Tartary:

The length of the ſhell varies from ſix to twenty lines, and its breadth from five to eighteen; there are, however, conſiderable varieties of proportion between different individuals, beſides thoſe ariſing from the different ages of the animal. It would be improper, therefore, to diſtinguiſh the various ſpecies of anomiæ by the proportion of their ſhells. The waving lines on the edges of the ſhell are equally defective, as diſtinctive

Terebratulæ.

stinctive characters; for our author observed in the same species the shell approaching or receding indifferently from the circular form, and, in some, the edges of the valves are on the same plane; whereas in others, one of the valves forms a salient angle in the middle of its curve, and the other a re-entering angle.

The shell is of a moderate thickness, about that of a common muscle; it is somewhat transparent, convex like the cockle: neither of the shells is more sensibly arched than the other; that, however, which has the spur, is rather the most so, especially in the superior part.

On the surface of the shell are seen a number of slight transverse depressions, of a semicircular waved form, which reach the part where the shell ceases to be circular, in order to form the angle which supports the summit.

These striæ are covered with a very thin and slightly-adhering periosteum; in some specimens there are from one to three shallow broad depressions, radiating insensibly from the centre of the shell, and becoming more marked as they approach the edges, where they form, with the corresponding parts of the other shell, those salient and re-entering angles which have been mentioned. The periosteum is rather more firmly fixed on the latter angles than on the former.

The shells are equal in the rounded part of their edge, and close very exactly; however, towards the summit, the spur of one of the shells reaches considerably beyond the other shell, consequently they are unequal, as in oysters.

The spur, or summit, is formed by the folding from within of the edge of the shell, and the elongation of its upper part. The folded edges form an oval aperture of a moderate size, through which the animal extends the muscle, by means of which it attaches itself to other substances. This shell is not, therefore, perforated, as its name of terebratula would seem to imply, the opening not being worked in one of the shells, but formed by the elongation of one shell, the folding in of its edges, and the approach of the other shell. The summit is not pointed, but round.

The ligament, as in the oyster, is placed between the summits, and does not appear on the outside; it adapts itself to the pedicle of the animal. As the summit takes up a considerable part of the shell, the valves are only capable of opening a very little without running the risk of being broken. It is very firm, though slender, and not easily to be discovered, being fixed in a small groove, which is filled up when the shell is shut by the corresponding part of the opposite shell. This ligament preserves its texture, even for a considerable time after the shell is emptied and become dry.

Oysters are without a hinge, the teeth which form it in many other shells not existing in them. The anomia has been considered as an oyster, because its hinge or teeth have not been examined: they are not visible indeed in the fossil specimens; but in opening them when alive, the teeth composing the hinge are sufficiently visible, being even much larger than in the greater part of bivalve shells. The fossil terebratulæ are almost always found with their shells closed; whereas the other bivalves have usually theirs either open or separated: the reason of this seems to arise from the nature of the hinge, that of the anomia not allowing it to separate, and the ligament, which is very tight, contributing to keep the two shells united. The teeth which form the hinge of the anomia approach very near to those of the *spondyle*, described by M. Adanson. In this last they are formed by two rounded projections, and in the anomia by the same a little elongated. It is above these teeth that the ligament is placed in the larger shell: there are between it and the teeth two cavities, one on each side, which serve to receive the teeth of the other valve. The teeth of the larger shell have, besides, a slight projection, which fits into a longitudinal furrow in the other shell in front of the teeth.

The substance which covers the inside of the shell holds, as in oysters, a middle place between *nacre* and the interior substance of shells, which are destitute of it. The degree of its lustre, polish, and thickness, varies with the age and circumstances of individuals.

The colour of the teeth is always white; that of the outer surface of the shell verges more or less to the ochry red, especially on the border. The inside has also a very slight tint of this colour, on a varying greyish-white ground.

There is visible on each side of the shell the impression of two very distinct tendons; a circumstance which forms a very essential difference between this genus and that of the oyster: this latter having only one tendon arising from the middle of the body. The impressions of the tendon in the largest shell are oblong, situate near the summit, and hollowed; each of them has curved transverse ridges, divided into two parts by a longitudinal furrow, representing the wings of certain insects. In the other valve the insertions have a different form; their situation is the same, but they are very irregularly rounded and encompassed by two fulcations, which are separated from each other by an intervening ridge, and then are continued in a right line towards the opening of the shell as far as about two thirds of its length. That part of the summit of the shell along which the pedicle of the animal passes, is longitudinally striated in the larger shell, of which the middle stria is the deepest: the longitudinal striæ are divided into equal parts by a transverse depression. There are no similar marks on the other shell.

Our author dissected the animal itself, and found what he calls the *manteau* of the anomia, formed of a very fine membrane, lining the inside of both shells, and containing the body of the animal. Its origin is of the same breadth as the hinge of the shell, whence it divides into two lobes, lining both the shells: it forms, therefore, only a single aperture, terminating at each end of the hinge, and of the same breadth with the interior surface of the shell: it appears to have only one trachea, which is formed by the two lobes of the manteau.

Our naturalist having opened the shell, divided the ligament as delicately as possible, unfixed the hinge, and detaching from the larger shell the lobe of the manteau, turned over the body of the animal. This operation exposed to view the large muscles which adhered to the shell; they are soft, membranous, and, as it were, fleshy on the inside, being covered with small sanguiferous glands. From the lower part of each muscle there proceeds a pretty strong tendon, which reaches to the extremity of the manteau; they run parallel to the edge of the shell, and at a considerable distance from each other; and are each enclosed in a sort of flatted sac, of the

the ſhape of a ribbon, which is filled with a red viſcid matter. It appears that the place of inſertion of the muſcles, as well as the muſcles themſelves, which extend along the lob of the manteau, furniſh real blood, which is contained in three ſmall fleſhy red glandular bodies of unequal ſize, which are viſible after having taken off the muſcles; perhaps theſe conſtitute the heart of the animal.

The muſcles which are inſerted into the other ſhell are alſo divided into ſeveral parts; ſome are ſeen extending along the correſponding lobe of the manteau; many others riſe up in a kind of tuft, which is fixed into the ſhell above: ſome again ſubdivide into ſuch minute ramifications as not to allow of tracing their courſe, even with the aſſiſtance of a microſcope; but others, more apparent, contribute to the formation of the pedicle which paſſes through the opening left between the two ſhells, is connected to each of them by ſeveral fibres, and fixes itſelf to ſome external body, principally to other bivalves. The muſcles of the anomia have therefore three attachments, namely, to the inner ſurface of each ſhell, and to ſome external body.

The form of the pedicle is cylindrical, being encloſed in a muſcular ſubſtance, which contains ſeveral fibres; it is from a line to a line and a half long, and two thirds in diameter. It adheres ſo forcibly to different ſubſtances, as that the animal, and all the muſcles which contribute to the formation of the pedicle, may more eaſily be torn through than the pedicle detached from the place of its adheſion. The gluntinous ſubſtance which connects them to each other, reſiſts even the heat of boiling water. It is by means of this pedicle that the animal raiſes its ſhell ſo as to be, while in the water, in a poſition inclined to the horizon. The ſmalleſt valve is always the loweſt, being that upon which the animal reſts; the ſuperior one being the larger, and ſerving as a covering. Our author thinks the animal has the power of loco-motion.

After raiſing the lobe of the manteau he obſerved the ears. They are large, compoſed of two membranaceous laminæ on each ſide, of which the ſuperior is the narrower. Theſe laminæ are connected to each other by a thin membrane, ſo as to form only a ſingle pouch. They have on their edges long fringes, which hang looſe upon the manteau; but a very remarkable circumſtance is, that their ears are ſupported by little bones like thoſe of fiſh. The form of the ears is that of an arch; they are ſeparated from each other on their lower part, where the fringes are the longeſt; ſo that the two ears on one ſide are perfectly diſtinct from thoſe on the other ſide. The commencement of the ears is at the teeth of the hinge.

Between the ears are ſituate the ſtomach, œſophagus, and mouth; the whole forming a triangle, of which the mouth is the baſe. It is placed at the ſide of the hinge, and conſiſts of a large tranſverſe opening without lips or jaw-bone. The œſophagus is very ſhort, but is capable of elongation when the animal opens its mouth. The ſtomach, which is of the ſhape of a pointed ſac, is connected by a membrane to the bones of the ear. On opening the ſtomach, he found a ſmall ſhrimp half digeſted.

At the bottom of the ſtomach is ſeen the inteſtine, of which it is, as it were, a continuation. It is extremely ſhort, not exceeding half a line in a ſhell fifteen lines acroſs, and is compoſed of a very ſlender membrane. The excrements are diſcharged upon the lobes of the manteau, but they are eaſily thrown out by the motions of the two lobes.

The little bones of the ears, already mentioned, had not formerly been obſerved in any of the teſtaceous animals; whence the terebratulæ approach nearer to fiſh than the inhabitants of any other ſhell. In the anomiæ which are preſerved in cabinets, there is found only a very ſmall portion of theſe bones, whence they have obtained the improper appellations of *tongue* or *fork*, which indicate only the form of the fragments, and not their uſe.

The ſmall bones of the ears are compoſed of ſeveral pieces, the principal of which is of an oval form; it ſprings from the ſide of the hinge, of which it appears to be a continuation; thence it extends about two-thirds of the breadth of the ſhell, where it is reflected, and reſts againſt the upper part of the fork, to the branches of which it is united by a ſimple ſuperpoſition; a kind of articulation very common among the numerous ſmall bones that compoſe the heads of fiſh. The fork extends from the ſummit a little more than one-third of the breadth of the ſhell: it is formed by a pivot which divides into two long and pointed branches; theſe are remarkably brittle, and ſupport the extremities of the bones of the larger ears. The lamina, which compoſes a ſecond ſet of ears, reſts upon a curved bone, which on one ſide is attached to the inferior internal part of the bone of the larger ears, and on the other reaches to the ſide of the mouth of the animal, where it is united to another flat little bone, which is applied to a ſimilar bone on the other ſide. Theſe laſt little bones are exactly below the membrane which forms the mouth. All theſe bones are flat, very brittle, and ſurrounded with fibres and membranes. By their articulations the ears are enabled to move; they alſo ſupport the body of the animal, which touches neither of the ſhells, but remains between them as upon treſſels. The ſpace between the branches of the bones of the ears is filled up with a tranſparent firm membrane; at the baſe of the fork is a ſimilar one, and a perpendicular partition dividing the ſpace occupied by the body of the animal from the reſt of the ſhell. There are two orifices in this membrane communicating with the ſpace between the two lobes of the manteau, and which ſerves as a trachea; for we have remarked, in the deſcription of the manteau, that the two lobes are entirely ſeparated from each other, and therefore do not form a real trachea.

From this deſcription, it follows that the anomia ought to be ſeparated from the genus oyſter, ſince it has a toothed hinge, ſeveral ligaments, and an interior organization wholly different; neither ought it to be confounded with the cockle, the ſhells of which are both equal, and are deſtitute of any ſenſible perioſteum, without reckoning other differences. It has ſtill leſs analogy with the other bivalves, and therefore ought to conſtitute a peculiar genus; the ſpecies of which, both foſſil and living, are very numerous.

See Plate XLIII. where fig. 1. is a front view of a terebratula of middle ſize. Fig. 2. is a view of the internal ſtructure.—AA, laminæ of the ſuperior ears—BB, laminæ of the inferior—C, the ſtomach—D, the anus—E E, the manteau—F, the œſophagus.

TERNAI, the name given by Perouſe to a very fine

fine bay which he discovered on the coast of Tartary, in Lat. 45° 13′ North, and in Long. 135° 9′ East from Paris. The bottom is sandy, and diminishes gradually to six fathoms within a cable's length of the shore. The tide rises five feet; it is high water at 8h 15m at full and change; and the flux and reflux do not alter the direction of the current at half a league from the shore.

"Five small creeks (says La Perouse), similar to the sides of a regular polygon, form the outline of this roadstead; these are separated from each other by hills, which are covered to the summit with trees. Never did France, in the freshest spring, offer gradations of colour of so varied and strong a green; and though we had not seen, since we began to run along the coast, either a single fire or canoe, we could not imagine that a country so near to China, and which appeared so fertile, should be entirely uninhabited. Before our boats had landed, our glasses were turned towards the shore, but we saw only bears and stags, which passed very quietly along the sea side. The same plants which grow in our climates carpeted the whole soil, but they were stronger, and of a deeper green; the greater part were in flower. Roses, red and yellow lilies, lilies of the valley, and all our meadow flowers in general, were met with at every step. Pine trees covered the tops of the mountains; oaks began only half way down, and diminished in strength and size in proportion as they came nearer the sea; the banks of the rivers and rivulets were bordered with willow, birch, and maple trees, and on the skirts of the forests we saw apple and medlar trees in flower, with clumps of hazle nut trees, the fruit of which already made its appearance. Our surprise was redoubled, when we reflected on the population which overburdens the extensive empire of China, so that the laws do not punish fathers barbarous enough to drown and destroy their children, and that this people, whose polity is so highly boasted of, dares not extend itself beyond its wall, to draw its subsistence from a land, the vegetation of which it would be necessary rather to check than to encourage. At every step after we had landed, we perceived traces of men by the destruction they had made; several trees, cut with sharp-edged instruments; the remains of ravages by fire were to be seen in several places, and we observed some sheds, which had been erected by hunters in a corner of the woods. We also found some small baskets, made of the bark of birch trees, sewed with thread, and similar to those of the Canadian Indians; rackets for walking on the snow; in a word, every thing induced us to think that the Tartars approach the borders of the sea in the season for hunting and fishing; that they assemble in colonies at that period along the rivers; and that the bulk of the nation live in the interior of the country on a soil perhaps better calculated for the multiplication of their immense flocks and herds."

Our navigators caught in the bay vast quantities of fine fish, such as cod, harp-fish, trout, salmon, herrings, and plaice; but though game was plenty on shore, they had no success in hunting. The meadows, so delightful to the sight, could scarce be crossed; the thick grass was three or four feet high, so that they found themselves in a manner buried in it, and they were under the perpetual dread of being bitten by serpents, of which they saw a great number on the banks of the rivulets. They found, however, immense quantities of small onions, sorrel, and celery; which, together with the fresh fish, served as antidotes against the scurvy.

TERRE-PLEIN, or TERRE-PLAIN, in fortification, the top, platform, or horizontal surface of the rampart, upon which the cannon are placed, and where the defenders perform their office. It is so called because it lies level, having only a little slope outwardly to counteract the recoil of the cannon. Its breadth is from 24 to 30 feet; being terminated by the parapet on the outer side, and inwardly by the inner talus.

TERRELLA, or little earth, is a magnet turned of a spherical figure, and placed so as that its poles, equator, &c. do exactly correspond with those of the world. It was so first called by Gilbert, as being a just representation of the great magnetic globe we inhabit. Such a terrella, it was supposed, if nicely poised, and hung in a meridian like a globe, would be turned round like the earth in 24 hours by the magnetic particles pervaiding it; but experience has shewn that this is a mistake.

TETRAEDRON, or TETRAHEDRON, in geometry, is one of the five Platonic or regular bodies or solids, comprehended under four equilateral and equal triangles. Or it is a triangular pyramid of four equal and equilateral faces.

TETRAGON, in geometry, a quadrangle, or a figure having four angles. Such as a square, a parallelogram, a rhombus, and a trapezium. It sometimes also means peculiarly a square.

TETRAGON, in astrology, denotes an aspect of two planets with regard to the earth, when they are distant from each other a fourth part of a circle, or 90 degrees. The tetragon is expressed by the character □, and is otherwise called a square or quartile aspect.

THEBES, in Egypt. Having in the *Encyclopædia* given Mr Bruce's account of this ancient city, which represents it as having been a paltry place, so contrary to the description of Homer, justice to the father of poetry requires that we here notice what has been said of it by a subsequent traveller, who remained three days among its ruins. According to Mr Browne, "the massy and magnificent forms of the ruins that remain of ancient Thebes, the capital of Egypt, the city of Jove, the city with 100 gates, must inspire every intelligent spectator with awe and admiration. Diffused on both sides of the Nile, their extent confirms the classical observations, and Homer's animated description rushes into the memory:

'Egyptian Thebes, in whose palaces vast wealth is stored; from each of whose hundred gates issue two hundred warriors, with their horses and chariots.'

"These venerable ruins, probably the most ancient in the world, extend for about three leagues in length along the Nile. East and west they reach to the mountains, a breadth of about two leagues and a half. The river is here about three hundred yards broad. The circumference of the ancient city must therefore have been about twenty-seven miles.

"In sailing up the Nile, the first village you come to within the precincts is Kourna, on the west, where there are few houses, the people living mostly in the caverns. Next is Abuhadjadj, a village, and Karnac, a small district, both on the east. Far the largest portion of the city ftood on the eaftern fide of the river. On the fouth-weft Medinet-Abu marks the extremity of the ruins; for Arment, which is about two leagues to the fouth, cannot be confidered as a part.

"In defcribing the ruins, we fhall begin with the moft confiderable, which are on the eaft of the Nile. The chief is the Great Temple, an oblong fquare building of vaft extent, with a double colonnade, one at each extremity. The mafly columns and walls are covered with hieroglyphics; a labour truly ftupendous. 1. The Great Temple ftands in the diftrict called *Karnac*. 2. Next in importance is the temple at *Abuhadjadj*. 3. Numerous ruins, avenues marked with remains of fphinxes, &c. On the weft fide of the Nile appear, 1. Two coloffal figures, apparently of a man and woman, formed of a calcareous ftone like the reft of the ruins. 2. Remains of a large temple, with caverns excavated in the rock. 3. The magnificent edifice ftyled the *palace of Memnon*. Some of the columns are about forty feet high, and about nine and a half in diameter. The columns, and walls are covered with hieroglyphics. This ftands at *Kourna*. 4. Behind the palace is the paffage ftyled *Bibân-el-Moluk*, leading up the mountain. At the extremity of this paffage, in the fides of the rock, are the celebrated caverns known as the fepulchres of the ancient kings."

Though Mr Browne agrees with Pococke and Bruce, that the paffage in Homer refers not to the gates of the city, he is yet of opinion, contrary to them, that Thebes had been a walled town. He fays, indeed, that fome faint remains of its furrounding wall are vifible at this day; and he thinks that he difcovered the ruins of three of its gates, though he does not affirm this with abfolute confidence.

THEODOSIUS, a celebrated mathematician, flourifhed in the times of Cicero and Pompey; but the time and place of his death are unknown. This Theodofius the Tripolite, as mentioned by Suidas, is probably the fame with Theodofius, the philofopher of Bythinia, who, Strabo fays, excelled in the mathematical fciences, as alfo his fons; for the fame perfon might have travelled from the one of thofe places to the other, and fpent part of his life in each of them; like as Hipparchus was called by Strabo the Bythinian, but by Ptolemy and others the Rhodian.

Biog. Dict.

Theodofius chiefly cultivated that part of geometry which relates to the doctrine of the fphere, concerning which he publifhed three books. The firft of thefe contains 22 propofitions; the fecond, 23; and the third, 14; all demonftrated in the pure geometrical manner of the ancients. Ptolemy made great ufe of thefe propofitions, as well as all fucceeding writers. Thefe books were tranflated by the Arabians, out of the original Greek, into their own language. From the Arabic the work was again tranflated into Latin, and printed at Venice. But the Arabic verfion being very defective, a more complete edition was publifhed, in Greek and Latin, at Paris 1558, by John Pena, Regius Profeffor of aftronomy. And Vitello acquired reputation by tranflating Theodofius into Latin. This author's works were alfo commented on and illuftrated by Clavius, Heleganius, and Guarinus, and laftly by De Chales, in his Curfus Mathematicus. But that edition of Theodofius's Spherics, which is now moft in ufe, was tranflated and publifhed by our countryman the learned Dr Barrow, in the year 1675, illuftrated and demoftrated in a new and concife method. By this author's account, Theodofius appears, not only to be a great mafter in this more difficult part of geometry, but the firft confiderable author of antiquity who has written on that fubject.

Theodofius, too, wrote concerning the Celeftial Houfes; alfo of Days and Nights; copies of which, in Greek, were in the King's library at Paris. Of which there was a Latin edition, publifhed by Peter Dafypody, in the year 1572.

THEON, of Alexandria, a celebrated Greek philofopher and mathematician, who flourifhed in the 4th century, about the year 380, in the time of Theodofius the Great; but the time and manner of his death are unknown. His genius and difpofition for the ftudy of philofophy were very early improved by clofe application to all its branches; fo that he acquired fuch a proficiency in the fcience as to render his name venerable in hiftory, and to procure him the honour of being prefident of the famous Alexandrian fchool. One of his pupils was the admirable Hypatia, his daughter, who fucceeded him in the prefidency of the fchool; a truft which, like himfelf, fhe difcharged with the greateft honour and ufefulnefs. See her life, *Encycl.*

The ftudy of Nature led Theon to many juft conceptions concerning God, and to many ufeful reflections in the fcience of moral philofophy. Hence, it is faid, he wrote with great accuracy on Divine Providence. And he feems to have made it his ftanding rule, to judge the truth of certain principles, or fentiments, from their natural or neceffary tendency. Thus, he fays, that a full perfuafion that the Deity fees every thing we do, is the ftrongeft incentive to virtue; for he infifts, that the moft profligate have power to refrain their hands, and hold their tongues, when they think they are obferved, or overheard, by fome perfon whom they fear or refpect. With how much more reafon then, fays he, fhould the apprehenfion and belief, that God fees all things, reftrain men from fin, and conftantly excite them to their duty? He alfo reprefents this belief concerning the Deity as productive of the greateft pleafure imaginable, efpecially to the virtuous, who might depend with greater confidence on the favour and protection of Providence. For this reafon, he recommends nothing fo much as meditation on the prefence of God: and he recommended it to the civil magiftrate as a reftraint on fuch as were profane and wicked, to have the following infcription written, in large characters, at the corner of every ftreet—GOD SEES THEE, O SINNER.

Theon wrote notes and commentaries on fome of the ancient mathematicians. He compofed alfo a book, intitled *Progymnafmata*, a rhetorical work, written with great judgment and elegance; in which he criticifed on the writings of fome illuftrious orators and hiftorians; pointing out, with great propriety and judgment, their beauties and imperfections; and laying down proper rules for propriety of ftyle. He recommends concifenefs of expreffion, and perfpicuity, as the principal ornaments. This book was printed at Bafle in the year 1541; but the beft edition is that of Leyden, in 1626, in 8vo.

THEOPHILANTHROPISTS, a fect of deifts, who, in September 1796, publifhed at Paris a fort of catechifm or directory for focial worfhip, under the title

Theophilanthropists.

title of *Manuel des Theanthrophiles*. This religious breviary found favour; the congregation became numerous; and in the second edition of their manuel they assumed the less harsh denomination of *Theophilanthropes, i.e.* lovers of God and man. A book of hymns, a liturgy for every decade of the French year, and an homiletical selection of moral lessons, are announced, or published, by their unknown synod. Thus they possess a system of pious services adapted to all occasions, which some one of the individuals who attend reads aloud; for they object to the employment of a regular lecturer, in consequence of their hostility to priests.—This novel sect was countenanced by Lareveillere Lepaux, one of the Directory, and, soon after its formation, opened temples of its own in Dijon, and in other provincial towns. They had declamations, in the spirit of sermons, which abounded with such phrases as *l'eternal geometre*, and the like, and which have long since been familiar to those who frequent the lodges of free masonry. Whether the sect now exists, or fell at the last revolution which annihilated the directory, we have not learned; but a translation of its *Manuel* into English, for the use, we suppose, of our Jacobins, was made so early as the year 1797. From this contemptible performance, we learn that the creed of the Theophilanthropists is comprised in the four following propositions:

The Theophilanthropists believe in the existence of God, and the immortality of the soul.

The spectacle of the universe attests the existence of the First Being.

The faculty which we possess of thinking, assures us that we have, within ourselves, a principle which is superior to matter, and which survives the dissolution of the body.

The existence of God, and the immortality of the soul, do not need long demonstrations; they are sentimental truths, which every one may find written in his heart, if he consult it with sincerity.

Thus a sort of religious instinct is set up as the sole foundation of piety, which every one has as much right to disavow as another to assert; and the obligations of which, therefore, can in no way be shewn to be incumbent on those to whom this novel illumination is not vouchsafed. Society, under such a system, gains no means of influencing the conduct of refractory members.

The morality of the Theophilanthropists is founded on one single precept: *Worship God, cherish your kind, render yourselves useful to your country!*

Among the duties comprehended under the denomination of cherishing our kind, we find that of *not lending for usury*: the others are chiefly extracted from the gospels, and do not interfere with the province of the civil magistrate. The question of monogamy is not discussed.

Among the duties to our country are placed those of fighting in its defence, and of paying the taxes. It was certainly prudent in the statesman to slide these duties into the catalogne of his established maxims of morality; and he ran thereby little risk of provoking heretical animadversions on his creed in France.

The following inscriptions are ordered to be placed above the altars in the several temples or synagogues of the Theophilanthropists; but for what reason altars are admitted into such synagogues we are not informed:

First inscription, "We believe in the Existence of God, in the immortality of the soul"

Second inscription, "Worship God, cherish your kind, render yourselves useful to the country."

Third inscription, "Good is every thing which tends to the preservation or the perfection of man.—Evil is every thing which tends to destroy or to deteriorate him."

Fourth inscription, "Children, honour your fathers and mothers. Obey them with affection. Comfort their old age.—Fathers and mothers, instruct your children."

Fifth inscription, "Wives, regard in your husbands the chiefs of your houses.—Husbands, love your wives, and render yourselves reciprocally happy."

This pentalogue is chiefly objectionable on account of the vague drift of the fifth commandment: the whole has too general a turn for obvious practical application. The introduction of ceremonies, of sculpture, of painting, and of engraving, is forbidden. If poetry and music may concur to render the worship impressive, why not the other fine arts? The fine arts have never illustrated a country which excluded them from the public temples. Are they to be extinguished in France by Theophilanthropic iconoclasts?

At p. 28. of the Manuel, this surprising maxim occurs: *Avoid innovations!* A sect fifteen months old grown as testy as the church of Rome! They acknowledge, that perhaps better inscriptions may be found; yet they forbid the exchange. They prefer *mumpsimus* to the *sumpsimus* of genuine Christianity!

Theophilus.

THEOPHILUS, a writer and bishop of the primitive church, was educated a Heathen, and afterwards converted to Christianity. Some have imagined that he is the person to whom St Luke dedicates the Acts of the Apostles: but they are grossly mistaken; for this Theophilus was so far from being contemporary with St Luke and the apostles, that he was not ordained bishop of Antioch till *anno* 170; and he governed this church twelve or thirteen years. He was a vigorous opposer of certain heretics of his time, and composed a great number of works; all of which are lost, except three books to Autolycus, a learned Heathen of his acquaintance, who had undertaken to vindicate his own religion against that of the Christians. The first book is properly a discourse between him and Autolycus, in answer to what this Heathen had said against Christianity. The second is to convince him of the falsehood of his own, and the truth of the Christian religion. In the third, after having proved that the writings of the Heathens are full of absurdities and contradictions, he vindicates the doctrine and the lives of the Christians from those false and scandalous imputations which were then brought against them. Lastly, at the end of his work, he adds an historical chronology from the beginning of the world to his own time, to prove that the history of Moses is at once the most ancient and the truest; and it appears from this little epitome, how well this author was acquainted with profane history. These three books are filled with a great variety of curious disquisitions concerning the opinions of the poets and philosophers, and there are but few things in them relating immediately to the doctrines of the Christian religion. Not that Theophilus was ignorant of these doctrines, but, having composed his works for the *Biog. Dict.*

Therapeutæ.

the converſion of a Pagan, he inſiſted rather on the external evidence or proofs from without, as better adapted, in his opinion, to the purpoſe. His ſtyle is elegant, and the turn of his thoughts very agreeable; and this little ſpecimen is ſufficient to ſhew that he was indeed a very eloquent man.

The piece is intitled, in the Greek manuſcripts, "The books of Theophilus to Autolycus, concerning the Faith of the Chriſtians, againſt the malicious detractors of their religion." They were publiſhed with a Latin verſion, by Conradus Geſner, at Zurich, in 1546. They were afterwards ſubjoined to Juſtin Martyr's works, printed at Paris in 1615 and 1636; then publiſhed at Oxford, 1684, in 12mo, under the inſpection of Dr Fell; and, laſtly, by Jo. Chriſt. Wolfius, at Hamburgh, 1723, in 8vo.

It is remarkable, that this patriarch of Antioch was the firſt who applied the term *Trinity* to expreſs the Three Perſons in the Godhead.

THERAPEUTÆ, ſo called from the extraordinary purity of their religious worſhip, were a Jewiſh ſect, who, with a kind of religious phrenzy, placed their whole felicity in the contemplation of the Divine nature. Detaching themſelves wholly from ſecular affairs, they transferred their property to their relations or friends, and withdrew into ſolitary places, where they devoted themſelves to a holy life. The principal ſociety of this kind was formed near Alexandria, where they lived, not far from each other, in ſeparate cottages, each of which had its own ſacred apartment, to which the inhabitant retired for the purpoſes of devotion. After their morning prayers, they ſpent the day in ſtudying the law and the prophets, endeavouring, by the help of the commentaries of their anceſtors, to diſcover ſome allegorical meaning in every part. Beſides this, they entertained themſelves with compoſing ſacred hymns in various kinds of metre. Six days of the week were, in this manner, paſſed in ſolitude. On the ſeventh day they met, clothed in a decent habit, in a public aſſembly; where, taking their places according to their age, they ſat, with the right hand between the breaſt and the chin, and the left at the ſide. Then ſome one of the elders, ſtepping forth into the middle of the aſſembly, diſcourſed, with a grave countenance and a calm tone of voice, on the doctrines of the ſect; the audience, in the mean time, remaining in perfect ſilence, and occaſionally expreſſing their attention and approbation by a nod. The chapel where they met was divided into two apartments; one for the men, the other for the women. So ſtrict a regard was paid to ſilence in theſe aſſemblies, that no one was permitted to whiſper, or even to breathe aloud; but when the diſcourſe was finiſhed, if the queſtion which had been propoſed for ſolution had been treated to the ſatisfaction of the audience, they expreſſed their approbation by a murmur of applauſe. Then the ſpeaker, riſing, ſung a hymn of praiſe to God, in the laſt verſe of which the whole aſſembly joined. On great feſtivals, the meeting was cloſed with a vigil, in which ſacred muſic was performed, accompanied with ſolemn dancing: and theſe vigils were continued till morning, when the aſſembly, after a morning prayer, in which their faces were directed towards the riſing ſun, was broken up. So abſtemious were theſe aſcetics, that they commonly ate nothing before the ſetting ſun, and often faſted two or three days. They abſtained from wine, and their ordinary food was bread and herbs.

Thermometric.

Much diſpute has ariſen among the learned concerning this ſect. Some have imagined them to have been Judaizing Gentiles; but Philo ſuppoſes them to be Jews, by ſpeaking of them as a branch of the ſect of Eſſenes, and expreſsly claſſes them among the followers of Moſes. Others have maintained, that the Therapeutæ were an Alexandrian ſect of Jewiſh converts to the Chriſtian faith, who devoted themſelves to a monaſtic life. But this is impoſſible; for Philo, who wrote before Chriſtianity appeared in Egypt, ſpeaks of this as an eſtabliſhed ſect. From comparing Philo's account of this ſect with the ſtate of philoſophy in the country where it flouriſhed, we conclude that the Therapeutæ were a body of Jewiſh fanatics, who ſuffered themſelves to be drawn aſide from the ſimplicity of their ancient religion by the example of the Egyptians and Pythagoreans. How long this ſect continued is uncertain; but it is not improbable that, after the appearance of Chriſtianity in Egypt, it ſoon became extinct.

THERMOMETRIC SPECTRUM, is a name given to the ſpace in which a thermometer may be placed, ſo that it ſhall be affected by the ſun's rays refracted by a priſm. It is, in part, the ſame with the PRISMATIC SPECTRUM, which exhibits the different colours produced by the ſolar light.

The philoſophical inſtrument now called a *thermometer*, was firſt named THERMOSCOPE; and was prized by the naturaliſt, becauſe it gave him indications of the preſence and agency of fire in many caſes where our ſenſation of warmth or heat was unable to diſcover it. It was not long before it was obſerved that it alſo affords us meaſures of the changes which take place either in the quantity or the activity of the cauſe of heat, and of many other important phenomena uſually accompanied by heat They were then called *thermometers*. But in both of theſe offices, it is ſtill a doubt whether it indicates and meaſures any real ſubſtance, a being *ſui generis*, to which we may give the name *fire*, *phlogiſton*, *caloric*, *heat*, or any other; or only indicates and meaſures certain ſtates or conditions, in which all bodies may be found, without the addition or abſtraction of any material ſubſtance.

We think that this queſtion has a greater chance now of being decided than in any former time, in conſequence of a recent and very important diſcovery made by that unwearied obſerver of the works of God, the celebrated Dr Herſchel. Being greatly incommoded when looking at the ſun, by the great heats produced in the eye-pieces of his teleſcopes, he thought that the laws of refraction enabled him to diminiſh them by a proper conſtruction of his eye-pieces. He began his attempts like a philoſopher, by examining the heat produced in the various parts of the priſmatic ſpectrum. Comparing the gradation of heat with that of illumination, he found that they did not, by any means, follow the ſame law. The illumination increaſed gradually from the violent end of the ſpectrum, where it was exceedingly faint, to the boundary of the green and yellow, where it was the moſt remarkable; and after this it decreaſed as the illuminated object approached the red extremity of the ſpectrum. But the calorific power of the refracted light increaſed all the way from the extreme violet to the extreme red; and its laſt augmentations

Thermometric.

tations were confiderable, and therefore unlike the ufual approaches of a quantity to its maximum ftate. This made him think of placing the thermometer a little way beyond the extremity of the vifible fpectrum. To his great aftonifhment, he found that the thermometer was more affected there than in the hotteft part of the *illuminated* fpectrum. Expofing the thermometer at various diftances beyond the extreme red, but in the plane of refraction, he found that it was moft ftrongly affected when placed beyond that extremity, about one-fifth of the whole length of the fpectrum; from thence the calorific influence of the fun gradually diminifhed, but was ftill very confiderable, at a diftance from the extreme red equal to three-fifths of the length of the luminous fpectrum. Thefe firft fuggefted modes of trial appeared to Dr Herfchel to be too rude to intitle him to fay that the warming influence did not extend ftill farther. Indeed the inftrument fcarcely performed the part of a thermometer, but merely that of an indicator of heat, or a thermofcope.

Here is a very new, and wonderful, and important, piece of information. We apprehend that all the philofophers of Europe, as well as the unlearned of all nations, believe that the *warming* influence of the fun, and of other luminous bodies, is conjoined with their power of *illumination*. Moft of the philofophers admitted the emiffion of a matter called *light*, projected from the fhining body, and moving with aftonifhing velocity, in thofe lines which the mathematicians called *rays*, becaufe they diverged from the fhining point, as the *radii* or fpokes of a wheel diverge from the nave. This notion feems to be the fimple fuggeftion of Nature; and it alfo feems to be the opinion entertained by Sir Ifaac Newton. His demonftration of the laws of reflection and refraction proceeds on this fuppofition alone, and the particles of light are held by him to be affected by accelerating and deflecting forces, in the fame way as a ftone thrown from the hand is affected by gravity. Huyghens, indeed, Dr Hooke, and Euler, imagined that vifion and illumination were effected in the fame way that hearing, and refonance, and echo, are effected—that there is no matter projected from the fhining body; but that we are furrounded by an elaftic fluid, which is thrown into vibrations by certain tremors of the vifible object—and that thofe vibrations of this fluid affect our eye in the fame way as the undulation of elaftic air, produced by the tremors of a ftring or a bell, affect our ear. According to thefe philofophers, a ray of vifion is merely the line which paffes through all thefe undulations at right angles.

Thefe two opinions ftill divide the mathematical philofophers of Europe; but the majority, and particularly the moft eminent for mathematical and mechanical fcience, are (with the exception of Huyghens and Euler) on the fide of the vulgar. This opinion has been greatly ftrengthened of late years by the difcoveries in chemiftry. The influence of light on the growth of plants, the total want of aromatic oils in fuch as grow in the dark, and their formation and appearance in the very fame plant, along with the green colour, as foon as the plant is placed in the light (even that of open day without funfhine, or in the light of a candle), is a ftrong indication of fome fubftance being obtained from the light, abforbed by the plant, and combined with its other ingredients. The fame conclufion is drawn from the effects of the fun's light on vegetable colours, on the nitric and nitrous acids, on manganefe, on the calces or oxides of metals, and numberlefs other inftances, which all concur in rendering it almoft unqueftionable that the fun's rays, and thofe of other fhining bodies, may be, and daily are, combined with the other fubftances of which bodies are compofed, and may be again feparated from them. And, fhould any doubts remain, it would feem that the theory of combuftion, firft conceived and imperfectly publifhed by Dr Hooke in his *Micrography*, p. 103. and in his *Lampus*, p. 1. &c. adopted by Mayow (fee Hooke and Mayow in this *Suppl.*), forgotten, and lately revived and confirmed by Mr Lavoifier, removes them entirely. In the beautiful and well-contrived experiments of the laft gentleman, the light, accompanied by its heat, which had been abforbed in the procefs of growth or other natural operations, re-appeared in their primitive form, and might again be abforbed and made to undergo the fame round of changes.

Scheele, not inferior to Newton in caution, patience, and accuracy, and attentive to every thing that occurred in his experiments, difcovered the feparability of the illuminating and the warming influences of fhining bodies. He remarked, that a plate of glafs, the moft colourlefs and pellucid that can be procured, when fuddenly interpofed between a glowing fire and the face, inftantly cuts off the warming power of the fire, without caufing any fenfible diminution of its brilliancy. He followed this difcovery into many obvious confequences, and found them all fully confirmed by obfervation and experiment. The writer of this article, immediately on hearing of Scheele's experiments, repeated them with complete fuccefs: but he found, that when the glafs plate had acquired the higheft temperature which it could acquire in that fituation, it did not any longer intercept the heat, or at leaft in a very fmall and almoft infenfible degree. It feemed to abforb the heat, till faturated, without abforbing any confiderable portion of the light.

This feparability of heat from light does not feem to have met with the attention it deferved. Dr Scheele's untenable theories on thefe fubjects turned away the attention of the chemifts from this difcovery, and the mathematical philofophers feem not to have heard of it at all. The late Dr Hutton of Edinburgh was more fenfible of its importance; and in his laft endeavours to fupport the falling caufe of phlogifton, makes frequent allufions to it. But in his attempts to explain the curious obfervations of Meffrs Sauffure and Pictet, in which there are unqueftionable appearances of radiated heat, he reafons fo unconfequentially, that few readers proceed farther, fo as to notice feveral obfervations of facts where the illuminating and warming influences are plainly feparated. In all thefe inftances, however, Dr Hutton confiders the invifible rays as light, but not as heat; maintaining that they are invifible, or do not render bodies vifible, only becaufe our eyes are infenfible to their feeble action.

It was referved for Dr Herfchel to put this matter beyond difpute by thefe valuable experiments. For did the invifibility of any of the light beyond the extreme red of the prifmatic fpectrum arife from the infenfibility of our organs, the fpectrum would gradually fade away beyond the red; but it ceafes abruptly. Thefe thoughts could

could not efcape this attentive obferver. He therefore examined more particularly thofe invifible rays, caufing them to be reflected by mirrors, and refracted through lenfes; and, in fhort, he fubjected them to all the fubfequent treatments which Newton applied to the colouring rays. He found them retain their fpecific refrangibilities and reflexibilities with as much uniformity and obftinacy as Newton had obferved in the colour-making rays. They were made to pafs through lenfes while the illuminating rays were intercepted by an opaque body, and the invifible rays were then collected into a focus. They were reflected, both by the anterior and pofterior furfaces of tranfparent bodies. In all thefe trials they retained their power of expanding the liquor of a thermometer, and exciting the fenfation of heat.

Thefe trials were not confined to the folar light or the folar rays: They were alfo made on the emanations from a candle, from an open fire, and from red-hot iron; then they were made with bodies not hot enough to fhine; with the heat of a common ftove, and the heat from iron which was not vifible in the dark. The event was the fame in all; and it was clearly proved that heat, or the caufe of heat, is as fufceptible of radiation as light is; and that this radiation is performed in both according to the fame laws.

We look with impatience for the fubfequent experiments of this celebrated philofopher on this fubject; for we confider them as of the greateft and moft extenfive importance for explaining the operations of Nature. We fee, with indifputable evidence, that there are rays from the fun, and other bodies, which do not illuminate. It does not follow, however, that there are rays which do not warm; for the thermometer was affected in every part of the coloured fpectrum. Dr Herfchel feems to think that the power of affecting the organ of fight depends on the particular degrees of mechanical momentum which are indicated by the different degrees of refrangibility. We confefs that we think it unlikely that fuch a power fhould terminate abruptly. We do not obferve this in analogous phenomena: the evanefcence of our fenfations of found, of mufical pitch, of heat, &c. are all gradual. We think it more likely that illuminating and warming are fpecific effects of different things. We fhould have entertained this opinion independent of all other experience: and we think it ftrongly confirmed by the experiments of Dr Scheele already mentioned. We are difpofed therefore to believe that there are rays which illuminate, but which do not warm; and rays which warm without illuminating. We have experiments in profpect, by which we hope to put this to the teft.

Thefe experiments of Dr Herfchel afford another good argument for the common opinion concerning light, namely, that *it is a matter emitted from the fhining body*, and not merely the undulations of an elaftic medium; for if it were undulation, then, fince there is heat in the yellow light, it would follow that a certain frequency of undulation produces both the fenfation of heat and the fenfation of a yellow colour. In this cafe they fhould be infeparable.

This follows, in the ftricteft manner, from the principles or affumptions adopted by Euler in his mechanical theory of undulations. The chromatic differences in the rays of light are affirmed to arife entirely from the different frequencies of the æthereal undulations; and he endeavours to fhew that thefe differences in frequency produce a difference in refrangibility. It is evident that this reafoning is equally conclufive with refpect to the calorific or heating power of the rays. The light and the heat are both undulations: thefe differ only in frequency; and this frequency is indicated (according to Euler) by the refrangibility. There is a certain frequency therefore which excites the fenfation of yellow. The fame frequency, indicated by the fame refrangibility, produces heat; therefore the frequency which produces this degree of heat alfo produces the fenfation of yellow. We muft not fay that the momentum of the undulation may produce heat, but is infufficient for the production of light, as a ftring may vibrate too feebly for being heard; for we fee, by Dr Herfchel's experiments, that, with a momentum fufficient for making the moft brilliant fpectrum, there are rays (and thofe which have the greateft momentum) which produce heat, and yet are invifible.

It does not follow, from any of Dr Herfchel's experiments, that the rays emitted by iron, which is not hot enough to fhine in a dark room, have *all* the different degrees of refrangibility obferved by him. Perhaps none of them would fall on the chromatic fpectrum. We think, however, that this is not probable. It may be tried by collecting them to a focus by a lenfe, intercepting, however, all thofe which are lefs refrangible than the red-making rays. We truft that the thermometer in the focus will ftill be affected.

This is but a very imperfect account of this important difcovery: but we thought that it would be highly interefting to our readers. The prefs was employed on this very fheet when we received the information from a friend, who had feen Dr Herfchel's Differtation, which will appear in the firft volume publifhed by the Royal Society. We truft that the ingenious author will foon follow it up with the inveftigation of the fubject in all its confequences. 1800.

We hope that he will examine what will refult from mixing fome of the invifible rays with fome of the coloured ones. We know that the yellow and the blue, when mixed, produce the fenfation of green. Perhaps the invifible rays may alfo change the appearance. We do not, however, expect this.

We alfo hope that Dr Herfchel will examine whether the invifible rays of the fun produce any effect on vegetable colours; whether they blacken the calces of filver and bifmuth, luna cornea, and decompofe the nitrous and the oxygenated muriatic acid, &c. &c. We fhould thus get more infight into the nature of caloric and of combuftion. Combuftion may perhaps be reftored to its rank in the phenomena of Nature, and no longer be funk in the general gulph of oxygenation, and thus obliterated from the memory of chemifts. It is perhaps the moft remarkable phenomenon of material Nature; and *fire* and burning will never go out of the language of plain men. Fire, and all its concomitants, have, in all times, been confidered as even the *chief* objects of chemical attention; and an unlearned perfon will ftare, when a chemift tells him that there is no fuch thing, and that what he calls the burning of a piece of coal is only the making it four. He will perhaps fmile; but it will not be a fmile of affent.

It was one darling object of the Revolutionary Committee of Chemifts, affembled at Paris in 1787, to banifh from our minds, *by means of a new language*, all remembrance

remembrance of any thing which we did not derive from the philofophers of France. We think ourfelves in a condition to prove this by letters to this country from the fcene of action; in which the expected victory is fpoken of in terms of exultation, and with fo little reftraint, that the writer forgets that it is Dr Black whom he is informing that *l'air fixe* and *la pauvre phlogiftique* will foon be forgotten; and yet the writer was a gentleman of uncommon modefty and worth, and fincerely attached to Dr Black. We give this as a remarkable inftance of the *efprit de corps*, and of the nature and towering ambition of that nation. From this they have not fwerved; and they hope to gain this fummit of fcientific dominion in the fame way as *the fame philofophers* hope to banifh Chriftianity by means of their new kalendar. It may, however, turn out that both Dr Hooke and Mr Lavoifier are miftaken, when they make the oxygen gas the fole fource of both the light and the heat which accompany combuftion. One of them may perhaps be furnifhed by the body which all, except the new philofophers, call combuftible.

The objections which may be made to the theory of Huyghens and Euler, on the acknowledged principles of mechanics, appear to us unanfwerable. Euler has never attempted to anfwer thofe taken from the different difperfing powers of different fubftances. The objections made to the Newtonian, or vulgar theory of emiffion, are not fuch as imply abfurdity; they are only difficulties. The chief of them, *viz.* the famenefs of velocity in all lights whatever, is of this kind. It is merely an improbability. But the objections to the theory of undulation, deduced from the chemical effects of light, are not lefs ftrong than thofe deduced from mechanical principles. It is quite inconceivable that the undulation of a medium, which pervades all bodies, fhall produce aromatic oils in fome, a green fæcula in others, fhall change fulphuric acid into fulphur, &c. &c. No effects are produced by the undulations of air, or the tremors of elaftic bodies, which have the moft diftant analogy or refemblance to thefe.

That the fun and other fhining bodies emit the matter of light and heat, feems therefore to merit the general reception which it meets with from the philofophers. But even of this clafs there are differences in opinion. Some imagine that light only is emitted, and that the heat which we feel is occafioned by the action of the luminous rays on our atmofphere, or on the ground. Were the fun's calorific rays as denfe at the furface of the fun as his luminous rays are, the heat there muft exceed (fay they) all that we can form any conception of. Yet we fee, that when the nucleus of the fun is laid bare by fome natural operation, which, like a volcanic explofion, throws afide the luminous ocean which covers it to a prodigious depth, the naked parts of this nucleus are black. Therefore the intenfe heat in that place is not able to make it fhining hot, as it does in all our experiments with intenfe heats, giving a dazzling glare. This is thought highly improbable; and it is therefore fuppofed that there is, primitively, no heat in the fun's rays, but that they act on our air, or other terreftrial matter, combining with it, and difengaging heat from it, or producing that particular ftate and condition which we call *heat*.

We think that Dr Herfchel's difcovery militates ftrongly and irrefiftibly againft this opinion; and fhews, that whatever reafon we have for faying that the fun's rays bring light from the fun, we have the fame authority for faying, that they bring heat, fire, caloric, phlogifton, or by whatever other name we choofe to diftinguifh the caufe of warmth, expanfion, liquefaction, ebullition, &c.

We muft either fay that light and heat are not fubftances of a peculiar kind, fufceptible of union with the other ingredients of bodies, but merely a ftate of undulation of an elaftic medium, as found is the undulation of air; or we muft fay that the fun's rays contain light and heat, in a detached ftate, fit for appearing in their fimpleft form, producing illumination and expanfion, and for uniting chemically with other matter. Whichever of thefe opinions we adopt, it is pretty clear that all attempts to difcover a difference in the weight of hot and cold bodies may be given over. In the firft cafe, it is felf-evident; in the fecond, we have abundant evidence, that if light and heat, being gravitating matter, like all other bodies, were added to, or abftracted from bodies, in fufficient quantity to be fenfibly heavy, the rays of the fun, or even the light of a candle, would occafion inftant deftruction by its mere momentum; fince every particle of radiated light and heat moves at the rate of 200,000 miles in a fecond.

This difcovery of Dr Herfchel's adds greatly to the probability of the opinion which we expreffed on another occafion, that the forces or powers of natural fubftances, which are the immediate caufes of the chemical phenomena, are no way different from the mechanical forces which render bodies heavy, coherent, elaftic, expanfive, &c.; in fhort, that they are what we call *accelerating forces*. We deduced this from the fact, that mechanical force can be oppofed to them, fo as to prevent their action in circumftances where it would otherwife certainly take place. Thus by external preffure, we can prevent that union of water and caloric which would convert it into elaftic fteam. We can even difunite them again, when fteam is already produced, by forcibly condenfing it into a fmaller fpace. Now, the refraction and reflection of heat are performed according to the fame precife laws which we obferve in the refraction and reflection of light; and Sir Ifaac Newton has demonftrated that thofe phenomena arife from the action of accelerating forces, whofe direction is perpendicular to the acting furfaces. The matter of heat, therefore, is like other matter in its mechanical properties; and, in the motion of refraction, it is acted on and deflected, juft as a projectile is acted on and deflected by gravity. It continues in motion till its velocity and direction are changed by deflecting forces, exerted by the particles of the tranfparent medium or the reflecting furface. It would take up too much room, but it is a very eafy procefs, to demonftrate that this regular refraction of heat is altogether incompatible with the ufually fuppofed notion of caloric; namely, that it is an expanfive fluid like air, but incomparably more elaftic: from which property very plaufible explanations have been given of the elafticity of gafes, fteams, and fuch like fluids. Every intelligent mechanician will be fenfible, that all this fort of chemical fcience falls to the ground, when it is proved, by exhibition of the fact, that radiated heat is refracted in the fame way with radiated light. We muft look for the explanation of the immenfe explofive force of fulminating filver, gold, &c. in fome

 very

very different principles from those which are now in vogue. We apprehend, too, that the very phenomenon of this refraction gives indication of forces which are sufficiently powerful for this explanation: For when we reflect on the astonishing velocity of the ray of heat; on the minute space along which it is deflected, and consequently the time of this action, minute beyond all imagination; and when we compare these circumstances with the deflection produced by gravity in the motion of a projectile—it is evident that the deflecting force of refraction must exceed the greatest force that we have any knowledge of, in a greater proportion than the weight of Mount Ætna exceeds that of a particle of sand. We would desire Mr de la Place to suspend his hopes of establishing universal fatalism, till he can reconcile these phenomena with his fundamental principle, "*that all forces which are diffused from a single point, necessarily and essentially diminish in the inverse duplicate ratio of the distances.*" Till he can do this, he had better still allow, with Newton, that the selection of the duplicate ratio for the action of gravity (by which alone the solar system can be rendered permanent and orderly) is a mark of wisdom and benevolence. We would advise him to reconcile his mind to this; and perhaps, like the modest and admiring Newton, he may, in good time, find comfort in the thought.

It is also highly worthy of remark, that this refracting force, almost immense, which is so plainly exerted between the particles of bodies and light, when considered as of the same kind with those that produce chemical union, appears abundantly sufficient for explaining some of the most wonderful phenomena of chemistry; such as the prodigious elasticity of steam, of gunpowder, and the still more astonishing explosion of fulminating gold and silver. Some of the phenomena of deflected light are produced by these optical forces acting at distances sufficiently great to admit of measurement; as in the Newtonian observations on the passage of light near the edges of opaque bodies. These deflections enable us to compare the deflecting forces with gravity. The *refracting* force, however, is vastly greater than even this, as may be seen by the greater deflection which is produced by it; and, being exerted along a space incomparably smaller, it must be greater still. Here, then, are forces fully adequate to the phenomena of fulmination. And we would again desire Mr De la Place to remark that, although these exploding forces are irresistible, their action seems to vanish entirely beyond the limits of mathematical contact. This is plain from the fact, that those explosions do not project the fragments to great distances. This is remarkably the case in all the most eminent of them. Common or nitric gunpowder is perhaps the only great exception. This particular circumstance will surely suggest to this eminent analyst the *inverse triplicate* ratio of the distance as more likely to explain the phenomena than his favourite law.

We trust that our readers will not be displeased with this short sketch of Dr Herschel's discovery, and the few reflections which it naturally suggested to our minds. We shall not be greatly surprised, although it should produce a sort of counter-revolution in chemical science, in consequence of new conceptions which it may give us of the union of bodies with light and heat. The phenomena of the vegetable and animal economy shew that they are susceptible of combination with other substances besides the basis of vital air. Whatever changes this may produce in the great revolution which has already taken place in chemical science, they will (in our opinion) be favourable to true philosophy; because Dr Herschel's discovery co-operates with other arguments of sound mathematical reasoning, to overturn that principle on which De la Place hopes to found his atheistical doctrine of fate and necessity. It contributes therefore to restore to the face of Nature that smiling feature of providential WISDOM which Newton had the honour of exhibiting to the view of rational men. The sun is the source of light and genial warmth to a vast system, which is held together, in almost eternal order and beauty, by a law of attraction selected by Infinite Wisdom, as the only one adequate to this magnificent purpose.

THEVENOT (Melchisedec), librarian to the king of France, and a celebrated writer of travels, was born at Paris in 1621, and had scarcely gone through his academical studies, when he discovered a strong passion for visiting foreign countries. At first he saw only part of Europe; but then he took great care to procure very particular informations and memoirs from those who had travelled over other parts of the globe, and out of those composed his "Voyages and Travels."—He laid down, among other things, some rules, together with the invention of an instrument, for the better finding out of the longitude, and the declination of the needle; and some have thought that these are the best things in his works, since travels, related at second-hand, can never be thought of any great authority or moment; not but Thevenot travelled enough to relate some things upon his own knowledge. Another passion in him, equally strong with that for travelling, was to collect scarce books in all sciences, especially in philosophy, mathematics, and history; and in this he may be said to have spent his whole life. When he had the care of the King's library, though it was one of the best furnished in Europe, he found 2000 volumes wanting in it which he had in his own. Besides printed books, he bought a great many manuscripts in French, English, Spanish, Italian, Latin, Greek, Hebrew, Syriac, Arabic, Turkish, and Persic. The marbles presented to him by Mr Nointel, at his return from his embassy to Constantinople, upon which there are bas-reliefs and inscriptions almost 2000 years old, may be reckoned among the curiosities of his library. He spent most of his time among his books, without aiming at any post of figure or profit: he had, however, two honourable employments; for he assisted at a conclave held after the death of Pope Innocent X. and was the French king's envoy at Genoa. He was attacked with what is called a slow fever in 1692, and died October the same year, at the age of 71. According to the account given, he managed himself very improperly in this illness; for he diminished his strength by abstinence, while he should have increased it with hearty food and generous wines, which were yet the more necessary on account of his great age.—Thevenot's Travels into the Levant, &c. were published in English in the year 1687, folio; they had been published in French at Paris 1663, folio. He wrote also "L'Art de Nager," the Art of Swimming, 12mo, 1696.

THOMAS (Christian). was born at Leipsic 1655, and

Thomas Thomas, Thornton.

and was well educated, first under his father, and afterwards in the Leipsic university. At first he acquiesced in the established doctrines of the schools; but upon reading Puffendorf's "Apology for rejecting the Scholastic Principles of Morals and Law," light suddenly burst upon his mind, and he determined to renounce all implicit deference to ancient dogmas. He read lectures upon the subject of Natural Law, first from the text of Grotius, and afterwards from that of Puffendorf, freely exercising his own judgment, and, where he saw reason, advancing new opinions. Whilst his father was living, paternal prudence and moderation restrained the natural vehemence and acrimony of the young man's temper, which was too apt to break out, even in his public lectures. But when he was left to himself, the boldness with which he advanced unpopular tenets, and the severity with which he dealt out his satirical censures, soon brought upon him the violent resentment of theologians and professors.

An "Introduction to Puffendorf," which Thomas published in the year 1687, wherein he deduced the obligation of morality from natural principles, occasioned great offence. The following year he became still more unpopular, by opening a monthly literary journal, which he intitled "Free Thoughts, or Monthly Dialogues on various Books, chiefly new;" in which he attacked many of his contemporaries with great severity. The raillery of this satirical work was too provoking to be endured: complaints were lodged before the ecclesiastical court of Dresden; the bookseller was called upon to give up the author; and it was only through the interest of the Mareschal that Thomas escaped punishment. The title of the work was now changed; but its spirit remained. A humorous and satirical life of Aristotle, and several other sarcastic papers, kept alive the flame of resentment, till at length it again burst forth, on a charge brought against him before the same court by the clergy of Leipsic, for contempt of religion: but he defended himself with such ability, that none of his adversaries chose to reply, and the matter was dropped.

A satirical review, which he wrote, of a treatise "On the Divine Right of Kings," published by a Danish divine; "A Defence of the Sect of the Pietists," and other eccentric and satirical publications, at last inflamed the resentment of the clergy against Thomas to such a degree, that he was threatened with imprisonment. To escape the storm which thickened about him, he entreated permission from the Elector of Brandeburg, in whose court he had several friends, that he might read private lectures in the city of Hall. This indulgence being obtained, Thomas became a voluntary exile from Leipsic. After a short interval, he was appointed public professor of jurisprudence, first in Berlin, and afterwards at Hall. In these situations, he found himself at full liberty to indulge his satirical humour, and to engage in the controversies of the times: and as long as he lived, he continued to make use of this liberty in a manner which subjected him to much odium. At the same time, he persevered in his endeavours to correct and subdue the prejudices of mankind, and to improve the state of philosophy. He died at Hall in the year 1728.

Besides the satirical journal already mentioned, Thomas wrote several treatises on logic, morals, and jurisprudence; in which he advanced many dogmas contrary to received opinions. In his writings on Physics, he leaves the ground of experiment and rational investigation, and appears among the mystics. His later pieces are in many particulars inconsistent with the former.—His principal philosophical works are, "An Introduction to Aulic Philosophy, or Outlines of the Art of Thinking and Reasoning;" "Introduction to Rational Philosophy;" "A Logical Praxis;" "Introduction to Moral Philosophy;" "A Cure for Irregular Passions, and the Doctrine of Self-Knowledge;" "The new Art of discovering the secret Thoughts of Men;" "Divine Jurisprudence;" "Foundations of the Law of Nature and Nations;" "Dissertation on the Crime of Magic;" "Essay on the Nature and Essence of Spirit, or Principles of Natural and Moral Science;" "History of Wisdom and Folly."

From the specimen given by Dr Enfield of his more peculiar tenets (for we have read none of his books), Thomas appears to have been a man of wonderful inconsistency in his opinions; teaching on one subject rational piety and true science, and on another absurdity and atheism. "No other rule (he says) is necessary in reasoning, than that of following the natural order of investigation; beginning with those things which are best known, and proceeding, by easy steps, to those which are more difficult." This is perfectly consistent with the foundation of the Baconian logic; and is indeed the only foundation upon which a system of science can possibly be built. Yet could the man, who professes to proceed from a principle so well established, gravely advance, as conclusions of science, the following absurdities: "Perception is a passive affection, produced by some external object, either in the intellectual sense, or in the inclination of the will. God is not perceived by the intellectual sense, but by the inclination of the will: for creatures affect the brain; but God, the heart. All creatures are in God: nothing is exterior to him. Creation is extension produced from nothing by the divine power. Creatures are of two kinds, passive and active; the former is matter, the latter spirit. Matter is dark and cold, and capable of being acted upon by spirit, which is light, warm, and active. Spirit may subsist without matter, but desires a union with it. All bodies consist of matter and spirit, and have therefore some kind of life. Spirit attracts spirit, and thus sensibly operates upon matter united to spirit. This attraction in man is called *love;* in other bodies, *sympathy*. A finite spirit may be considered as a limited sphere, in which rays, luminous, warm, and active, flow from a centre. Spirit is the region of the body to which it is united. The region of finite spirits is God. The human soul is a ray from the divine nature; whence it desires union with God, who is love. Since the essence of spirit consists in action, and of body in passion, spirit may exist without thought: of this kind are light, ether, and other active principles in nature." Fortunately, this jargon is as unintelligible as the categories of Kant, and the blasphemies of Spinoza; for an account of which, the reader is referred to *Critical Philosophy* in this *Suppl.* and to Spinoza in the *Encycl.*

THORNTON (Bonnel), a modern poet, the intimate friend of Lloyd and Colman, and justly classed with them in point of talents, was born in Maidenlane, London, in the year 1724. He was the son of *Biographical Dictionary.*

an

Thornton.

an apothecary; and being educated at Weſtminſter ſchool, was elected to Chriſt-Church, Oxford, in the year 1743. He was thus eight years ſenior to Colman, who was elected off in 1751. The firſt publication in which he was concerned was, "The Student, or Oxford and Cambridge Miſcellany," which appeared in monthly numbers; and was collected in two volumes 8vo, in 1748. Smart was the chief conductor of the work; but Thornton, and other wits of both univerſities, aſſiſted in it. He took his degree of maſter of arts in 1750; and as his father wiſhed him to make phyſic his profeſſion, he took the degree of bachelor of that faculty in 1754. In the ſame year he undertook the periodical paper called *The Connoiſſeur*, in conjunction with Colman, which they continued weekly to the 30th of September 1756. In the concluding paper, the different ages and purſuits of the two authors are thus jocularly pointed out, in the deſcription of the double author, Mr Town. "Mr Town is a fair, black, middle-ſized, very ſhort man. He wears his own hair and a periwig. He is about thirty years of age (literally thirty-two), and not more than four-and twenty. He is a ſtudent of the law and a bachelor of phyſic. He was bred at the univerſity of Oxford, where, having taken no leſs than three degrees, he looks down on many learned profeſſors as his inferiors: yet, having been there but little longer than to take the firſt degree of bachelor of arts, it has more than once happened that the cenſor-general of all England has been reprimanded by the cenſor of his college, for neglecting to furniſh the uſual eſſay, or, in the collegiate phraſe, the theme of the week." Engaged in purſuits of this kind, Bonnel Thornton did not very cloſely follow the profeſſion to which his father deſtined him, but lived rather a literary life, employing his pen on various ſubjects. To the daily paper called the *Public Advertiſer*, then in high reputation, he was a frequent contributor; and he once had it in contemplation to treat with Mr Rich for the patent of Covent Garden theatre. In 1764, Mr Thornton married Miſs Sylvia Brathwaite, youngeſt daughter of Colonel Brathwaite, who had been governor of a fort in Africa. In 1766, encouraged, as he ſays himſelf, by the ſucceſs of his friend Colman's Terence, he publiſhed two volumes of a tranſlation of Plautus in blank verſe; propoſing to complete the whole if that ſpecimen ſhould be approved. Theſe volumes contained ſeven plays, of which the *Captive* was tranſlated by Mr Warner, who afterwards completed all that Thornton had left unfiniſhed; and the *Mercator* by Mr Colman. The remaining five are, the *Amphitryon*, *Miles Glorioſus*, *Trinummus*, *Aulularia*, *Rudens*. Some parts of the remaining plays which Thornton had tranſlated are preſerved by his continuator. There can be no doubt that this is the beſt way of tranſlating the old comedies, and that Thornton was well qualified for the taſk; but the work has never been in high favour with the public. Yet Warburton ſaid of it, that "he never read ſo juſt a tranſlation, in ſo pure and elegant a ſtyle." Thornton publiſhed in 1767, *The Battle of the Wigs*, as an additional canto to Garth's Diſpenſary; the ſubject of which was the diſputes then ſubſiſting between the fellows and licentiates.

The life of Thornton was not deſtined to attain any great extenſion: in the prime of his days, while he was ſurrounded by domeſtic felicity, the comforts of fortune, and the reſpect of ſociety, ill health came upon him; and medical aid proving inefficient, he died, of the gout in his ſtomach, May 9. 1768, at only 44 years of age. His wife, a daughter, and two ſons, ſurvived him. Beſides the productions already mentioned, he wrote the papers in the Adventurer marked A; "An Ode to St Cecilia's day, adapted to the ancient Britiſh Muſic," a burleſque performance; "The Oxford Barber;" with many detached eſſays in the public papers. A few letters addreſſed to his Sylvia before they were married, diſplay great tenderneſs, expreſſed with frankneſs and eaſe. A ſmall edition of his works might, with much propriety, be preſented to the public, before it ſhall be too late to aſcertain them all. His character may be taken from his epitaph, written in Latin by his friend Dr Warton, and placed on his monument in Weſtminſter Abbey. It is to this effect: "His genius, cultivated moſt happily by every kind of polite literature, was accompanied and recommended by manners open, ſincere, and candid. In his writings and converſation he had a wonderful livelineſs, with a vein of pleaſantry peculiarly his own. In ridiculing the failings of men, without bitterneſs, and with much humour, he was ſingularly happy; as a companion, he was delightful."

Thornton, Thunder.

THUNDER. There is not one of the appearances of nature which has ſo much engaged the attention of mankind as thunder. The ſavage, the citizen, and the philoſopher, have obſerved it with dread, with anxiety, and with curioſity; and the philoſopher of our times treats the others with a ſmile of condeſcenſion, while he here enjoys the fulleſt triumph of his ſuperiority. 1.

> *Felix qui potuit rerum cognoſcere cauſas,*
> *Atque metus omnes et inevitabile fulmen*
> *Subjecit pedibus.*

But though this grand phenomenon has long engaged the curious attention of philoſophers, it is but very lately that they have been able to explain it; that is, to point out the more general law of nature of which it is a particular inſtance. Inflammable vapours had long furniſhed them with a ſort of explanation. The diſcovery of gunpowder, and ſtill more that of inflammable air, gave ſome probability to the exiſtence of extenſive ſtrata of inflammable vapours in the upper regions of the atmoſphere, which, being ſet on fire at one end, might burn away in rapid ſucceſſion, like a train of gunpowder. But the ſmalleſt inveſtigation would ſhew ſuch a diſſimilarity in the phenomena, and in the general effects, that this explanation can have no value in the eyes of a true naturaliſt. Horrid exploſion, and a blaſt which would ſweep every thing from the ſurface of the earth, muſt be the effects of ſuch inflammation. The very limited and capricious nature of the ravages made by thunder, render them altogether unlike exploſions of elaſtic fluids.

2 Thunder reſembles the electrical ſhock

No ſooner were the wonderful effects of the charged electrical phial obſerved, than naturaliſts began to think of this as exhibiting ſome reſemblance to a thunder-ſtroke (ſee Electricity, *Encycl.* n° 12.); but it was not till toward the year 1750 that this reſemblance was viewed in a proper light by the celebrated Franklin. In a diſſertation written that year, he delivers his opinion at large, and notices particularly the following circumſtances of ſimilarity.

1. The

Thunder. Several remarkable particulars.

1. The colour and crooked form of lightning, perfectly fimilar to that of a vivid electrical fpark between diftant bodies, and unlike every other appearance of light. This angular, defultory, capricious form of an electrical fpark, and of forked lightning, is very fingular. No two fucceffive fparks have the fame form. Their fharp angles are unlike every appearance of motion through unrefifting air. Such motions are always curvilineal. The fpark is like the fimultaneous exiftence of the light in all its parts: and the fact is, that no perfon can pofitively fay in which direction it moves.

2. Lightning, like electricity, always ftrikes the moft advanced objects—hills, trees, fteeples.

3. Lightning affects to take the beft conductors of electricity. Bell wires are very frequently deftroyed by it. At Leven houfe in Fifefhire, in 1733, it ran along a gilded moulding from one end of the houfe to the other, exploding it all the way, as alfo the tinfoil on the backs of feveral mirrors, and the gilding of fcreens and leather hangings.

4. It burns, explodes, and deftroys thefe conductors precifely as electricity does. It diffolves metals; melts wires; it explodes and tears to pieces bodies which contain moifture. When a perfon is killed by lightning, his fhoes are commonly burft. When it falls on a wet furface, it fpreads along it. The Royal William, in Louifburgh harbour, in 1758, received a thunder-ftroke, which diffipated the maintop-gallant maft in duft, and came down on the wet decks in one fpark, which fpread over the whole deck as a fpout of water would have done. This is quite according to electrical laws.

5. It has fometimes ftruck a perfon blind. Electricity has done the fame to a chicken which it did not kill.

6. It affects the nervous fyftem in a way refembling fome of the known effects of electricity. The following is a moft remarkable inftance: —— Campbell, Efq. of Succoth, in Dunbartonfhire, had been blind for feveral years. The diforder was a gutta ferena. He was led one evening along the ftreets of Glafgow by his fervant Alexander Dick, during a terrible thunder ftorm. The lightning fometimes fluttered along the ftreets for a quarter of a minute without ceafing. While this fluttering lafted, Mr Campbell faw the ftreet diftinctly, and the changes which had been made in that part by taking down one of the city gates. When the ftorm was over, his entire blindnefs returned.—We have from a friend another inftance, no lefs remarkable. One evening in autumn he was fitting with a gentleman who had the fame diforder, and he obferved feveral lambent flafhes of lightning. Their faces were turned to the parlour window; and immediately after a flafh, the gentleman faid to his wife "Go, my dear, make them fhut the white gate; it is open, you fee." The lady did fo, and returned; and, after a little, faid, "But how did you know that the gate was open?" He exclaimed, "My God! I faw it open, and two men look in, and go away again," (which our friend alfo had obferved). The gentleman, on being clofe queftioned, could not recollect having had another glance, nor why it had not furprifed him; but of the glimpfe itfelf he was certain, and defcribed the appearance very exactly.

7. Lightning kills; and the appearances perfectly refemble thofe of a mortal ftroke of electricity. The mufcles are all in a ftate of perfect relaxation, even in thofe fituations where it is ufually otherwife.

8. Lightning is well known to deftroy and to change the polarity of the mariner's needle.

3 Dr Franklin difcovered that it was the fame.

Dr Franklin was not contented with the bare obfervation of thefe important refemblances. He availed himfelf of many curious difcoveries which he had made of electrical laws. In particular, having obferved that electricity was drawn off at a great diftance, and without the leaft violence of action, by a fharp metallic point, he propofed to philofophers to erect a tall maft or pole on the higheft part of a building, and to furnifh the top of it with a fine metalline point, properly infulated, with a wire leading to an infulated apparatus for exhibiting the common electrical appearances. To the whole of this contrivance he gave the name of *thunder-rod*, which it ftill retains. He had not a proper opportunity of doing this himfelf at the time of writing his differtation in a letter from Philadelphia to the Royal Society of London; but the contents were fo fcientific, and fo interefting, that in a few weeks time they were known over all Europe. His directions were followed in many places. In particular, the French academicians, encouraged by the prefence of their monarch, and the great fatisfaction which he expreffed at the repetition of Dr Franklin's moft inftructive experiments, which difcovered and eftablifhed the theory of pofitive and negative electricity, as it is ftill received, were eager to execute his orders, making his grand experiment, which promifed fo fairly to bring this tremendous operation of nature not only within the pale of fcience, but within the management of human power.

But, in the mean time, Dr Franklin, impatient of delay, and perhaps incited by the honourable defire of well-deferved fame, put his own fcheme in practice. His inventive mind fuggefted to him a moft ingenious method of prefenting a point to a thunder cloud at a very great diftance from the ground. This was by fixing his point on the head of a paper kite, which the wind fhould raife to the clouds, while the wet ftring that held it fhould ferve for a conductor of the electricity. We prefume that it was with a palpitating heart that Dr Franklin, unknown to the neighbours, and accompanied only by his fon, went into the fields, and fent up his meffenger that was to bring him fuch news from the heavens. He told a perfon, who repeated it in the hearing of the prefent writer, that when he faw the fibres of the cord raife themfelves up like hogs briftles, he uttered a deep figh, and would have wifhed that moment of joy to have been his laft. He obtained but a few faint fparks from his apparatus that day; but returned to his houfe in a ftate of perfect happinefs, now feeling that his name was never to die. Thus did the foap-bubble, and the paper-kite, from being the playthings of children, become, in the hands of Newton and of Franklin, the means of acquiring immortal honour, and of doing the moft important fervice to fociety.

We may juftly confider this as one of the greateft of philofophical difcoveries, and as doing the higheft honour to the inventor; for it was not a fuggeftion from an accidental obfervation, but arofe from a fcientific comparifon of facts, and a fagacious application of the doctrine of pofitive and negative electricity; a doctrine wholly

Thunder. wholly Dr Franklin's, and the refult of the moft acute and difcriminating obfervation. It was this alone that fuggefted the whole; and by explaining to his fatisfaction the curious property of fharp points, gave him the courage to handle the thunderbolt of Jove.

It is then a point fully afcertained, that thunder and lightning are the electric fnap and fpark, as much fuperior to our puny imitations as we can conceive from the immenfe extent of the inftruments in the hands of Nature. If, fays Dr Franklin, a conductor one foot thick and five feet long will produce fuch fnaps as agitate the whole human frame, what may we not expect from a furface of 10,000 acres of electrified clouds? How loud muft be the explofion? how terrible the effects?

4
Electrical ftate of the atmofphere.

This difcovery immediately directed the attention of philofophers to the ftate of the atmofphere with refpect to electricity; and in this alfo Dr Franklin led the way. He immediately erected his thunder rods; and they have been imitated all over the world, with many alterations or improvements, according to the different views and fkill of their authors. It is needlefs to infift here on their conftruction. They have been defcribed in the article Electricity, *Encycl.*; and any perfon well acquainted with its theory, as laid down in the *Supplementary* article Electricity, will be at no lofs to accommodate his own conftruction to his fituation and purpofes.

Dr Franklin took the lead, as we have already obferved, in this examination of the electrical ftate of the atmofphere. He feldom found it without giving figns of electricity, and this was generally negative. See *Phil. Tranf.* Vol. XLVIII. p. 358 and 785.

Mr Canton repeated thofe experiments, and found the fame refults; both, however, found that the electricity would frequently change from pofitive to negative, and from negative to pofitive, in very fhort fpaces of time, as different portions of clouds or air paffed the thunder-rod.

5
Cautions to be obferved in this examination by a thunder rod.

We muft here remark, that our acquaintance with the laws of electricity fufficiently informs us, that the electricity of our thunder-rod may frequently be of a different kind from that of the cloud which excites the appearances at our apparatus. We know that air, like glafs, is a non-conductor; and that when it is brought into any ftate of electricity, either by communication, or by mere induction, it will remain in that ftate for fome time, and that it always changes its electricity *per ftratum.* A pofitive cloud, in the higher regions of the atmofphere, will render the air immediately below it negative, and a ftratum below that pofitive. If the thunder rod be in this pofitive ftratum, it will exhibit pofitive electricity; but if the cloud be confiderably nearer, the rod, by being in the adjoining negative ftratum, may fhew a negative electricity, which will exceed the pofitive electricity which the diftant pofitive cloud would have induced on its lower end by mere pofition, had the intervening air been away. This excefs of negative electricity muft depend on the degree in which the furrounding ftratum of air has been rendered negative. If this has been the almoft inftantaneous effect of the prefence of the pofitive cloud, it cannot be rendered fo negative as to produce negative electricity in the lower end of the thunder-rod. But if the ftratum of air has for fome confiderable time accompanied the pofitive cloud, its negative electricity has been increafing, and fome would remain, even if the cloud were removed. We muft, at all times, confider the thunder rod as affected by *all* the electricity in its neighbourhood. The diftant pofitive cloud would at any rate render the lower end of the rod pofitive, without communication, by merely difplacing the electricity in the rod itfelf, juft as the north pole of a loadftone would make the remote end of a foft iron rod a north pole. In like manner, the negative ftratum of air immediately adjoining to the pofitive cloud would make the lower end of the rod negative, without communication. A pofitive ftratum of air below this would have the contrary effect. The appearances, then, at the end of the rod, muft be the refult of the prevalence of one of thefe above the others; and many intervening circumftances muft be underftood, before we can infer with certainty the ftate of a cloud from the appearances at the lower end of the apparatus. It would, therefore, be a moft inftructive addition to a thunder rod to have an electrofcope at both ends. If they fhew the fame kind of electricity, we may be affured that it is by communication, and is the fame with that of the furrounding ftratum of air: But if they fhew oppofite electricities (which is generally the cafe), then we learn that it is by pofition or induction. We recommend this to the careful attention of the philofopher.

In this way we perfectly explain an appearance which puzzled both of the above-mentioned obfervers. When a fingle low cloud approached the rod, the electrofcope would fhew pofitive electricity, but negative when the cloud was in the zenith, and pofitive again when it had paffed by. We alfo learn from this the caufe of Dr Franklin's difappointment in his expectations of very remarkable phenomena by means of his kite. He imagined that it would be vaftly fuperior to the apparatus which he had recommended to the philofophers of Europe. But the ftring of the kite, traverfing feveral ftrata in different ftates of electricity, ferved as a conductor between them, and he could only obtain the fuperplus; which might be nothing, even when the clouds were ftrongly electrified.

The moft copious and curious obfervations on the electrical ftate of the atmofphere are thofe by Profeffor Beccaria of Turin. He had connected the tops of feveral fteeples of the city by infulated wires. He did the fame thing at a monaftery on a high hill in the neighbourhood. Each of thefe collected the electricity of a feparate ftratum of confiderable extent. He frequently found thefe two ftrata in oppofite ftates of ftrong electricity.

6
Beccaria's general laws of atmofpheric electricity.

The following general obfervations are made out from a comparifon of a vaft variety of more particular ones made in different places:

1. The air is almoft always electrical, efpecially in the day time and dry weather; and the electricity is generally pofitive. It does not become negative, unlefs by winds from places where it rains, fnows, or is foggy.

2. The moifture of the air is the conftant conductor of its electricity in clear weather.

3. When dark or wet weather clears up, the electricity is always negative. If it has been very moift, and dries very faft, the electricity is very intenfe, and diminifhes

Thunder.

niſhes when the air attains its greateſt dryneſs; and may continue long ſtationary, by a ſupply of air in a drying ſtate from diſtant places.

4. If, while the ſky overcaſts in the zenith, only a high cloud is formed, without any ſecondary clouds under it, and if this cloud is not the extenſion of another which rains in ſome remote place, the electricity (if any) is always poſitive.

5. If the clouds, while gathering, are ſhaped like locks of wool, and are in a ſtate of motion among each other; or if the general cloud is forming far aloft, and ſtretches down like deſcending ſmoke, a frequent poſitive electricity prevails, more intenſe as the changes in the atmoſphere are quicker; and its intenſity predicts the great quantity of ſnow or rain which is to follow.

6. When an extenſive, thin, level cloud forms, and darkens the ſky, we have ſtrong poſitive electricity.

7. Low thick fogs, riſing into dry air, carry up ſo much electricity as to produce ſparks at the apparatus. If the fog continues round the apparatus without riſing, the electricity fails.

8. When, in clear weather, a cloud paſſes over the apparatus, low and tardy in its progreſs, and far from any other, the poſitive electricity gradually diminiſhes, and returns when the cloud has gone over.

9. When many white clouds gather over head, continually uniting with and parting from each other, and thus form a body of great extent, the poſitive electricity increaſes.

10. In the morning, when the hygrometer indicates dryneſs equal to that of the preceding day, poſitive electricity obtains, even before ſunriſe.

11. As the ſun gets up, this electricity increaſes; more remarkably if the dryneſs increaſes. It diminiſhes in the evening.

12. The mid-day electricity, of days equally dry, is proportional to the heat.

13. Winds always leſſen the electricity of a clear day, eſpecially if damp: therefore they do not electrify the air by friction on ſolid bodies.

14. In cold ſeaſons, with a clear ſky and little wind, a conſiderable electricity ariſes after ſunſet, at dew falling.

The ſame happens in temperate and warm weather.

If, in the ſame circumſtances, the general dryneſs of the air is leſs, the electricity is alſo leſs.

15. The electricity of dew, like that of rain, depends on its quantity. This electricity of dew may be imtitated by electrifying the air of a cloſe room (not too dry), and filling a bottle with very cold water, and ſetting it in the upper part of the room. As the damp condenſes on its ſides, an electrometer will ſhew very vivid electricity.

Such a collection of obſervations, to be fit for inference, requires very nice diſcrimination. It is frequently difficult to diſcover electricity in damp air, though it is then generally ſtrongeſt; becauſe the inſulation of the apparatus is hurt by the dampneſs. To make the obſervation with accuracy, requires a portable apparatus, whoſe inſulation can be made good at all times. With ſuch apparatus we ſhall never miſs obſerving electricity in fogs, or during ſnow.

[Cu]rious [ph]enomenon of a [tick]ling

There is a very curious phenomenon, which may be frequently obſerved in Edinburgh, and no doubt in other towns ſimilarly ſituated. In a clear day of the month of May, an eaſterly wind frequently brings a fog with it, which advances from the ſea in a denſe body; and when it comes up the High ſtreet, it chills the body exceedingly, while it does not greatly affect the thermometer. Immediately before its gaining the ſtreet, one feels like a tickling on the face, as if a cobweb had fallen on it, and naturally puts up his hand, and rubs the face. We have never found this to fail, and have often been amuſed with ſeeing every perſon rubbing his face in his turn. The writer of this article has obſerved the ſame thing at St Peterſburgh, in a ſummer's evening when a low fog came on about ten o'clock.

The general appearances of a thunder ſtorm are nearly as follows: 7

Phenomena of a thunder ſtorm.

For the moſt part the wind is gentle, or it is calm. A low denſe cloud begins in a place previouſly clear: this increaſes faſt in ſize; but this is only upwards, and in an arched form, like great bags of cotton. The lower ſurface of the cloud is commonly level, as if it reſted on a glaſs plane.

Soon after appear numberleſs ſmall ragged clouds, like flakes of cotton teazled out. Theſe are moving about in various uncertain directions, and continually changing their ragged ſhape. This change, however, is generally by augmentation. Whatever occaſions the precipitation of the diſſolved water ſeems to gain ground. As theſe clouds move about, they approach each other, and then ſtretch out their ragged arms toward each other. This is not by an augmentation, but by a real bending of theſe tatters towards the other cloud They ſeldom come into contact; but after coming very near in ſome parts, they as plainly recede, either in whole, or by bending their arms away from each other.

But during this confuſed motion, the whole maſs of ſmall clouds approaches the great one above it; and when near it, the clouds of the lower maſs frequently coaleſce with each other before they finally coaleſce with the upper cloud: But as frequently the upper cloud increaſes without them. Its lower ſurface, from being level and ſmooth, now becomes ragged, and its tatters ſtretch down towards the others, and long arms are extended towards the ground. The heavens now darken apace, the whole maſs ſinks down; and ariſes, and frequently ſhifts in ſqualls; ſmall clouds are now moving ſwiftly in various directions; lightning now darts from cloud to cloud. A ſpark is ſometimes ſeen co-exiſtent through a vaſt horizontal extent, of a crooked ſhape, and of different brilliancy in its different parts. Lightning ſtrikes between the clouds and the earth—frequently in two places at once. A continuation of theſe ſnaps rarifies the cloud; and in time it diſſipates. This is accompanied by heavy rain or hail; and then the upper part of the clouds is high and thin.

During this progreſs of the ſtorm, the thunder rod is ſtrongly electrified; chiefly when the principal cloud is over head. The ſtate of the electricity frequently changes from poſitive to negative—almoſt every flaſh, however diſtant, occaſions a ſudden ſtart of the electroſcope, and then a change of the electricity. When the cloud is more uniform, the electricity is ſo too. 8

Sources of atmoſpheric electricity.

The queſtion now is, In what manner does the air acquire this electricity? How come its different parts to be in different ſtates, and to retain this difference for a length of time? and how is the electric equilibrium reſtored

Thunder.

reſtored with that rapidity, and that extent, that we obſerve in a thunder ſtorm? For we know that air is a very imperfect conductor, and tranſmits electricity to ſmall diſtances only, and very ſlowly. We ſhall mention ſeveral circumſtances, which are known facts in electricity, and muſt frequently concur, at leaſt, with the other cauſes of this grand phenomenon.

Air is rendered electrical in a great variety of ways.

1. All operations which excite electricity in other bodies have the ſame effect on air. It is electrified by friction. When blown on any body, ſuch as glaſs, &c. that body exhibits electricity by a ſenſible electroſcope. We therefore conclude that the air has acquired the oppoſite electricity from this rubber. A glaſs veſſel, exhauſted of air, and broken in the dark, gives a loud crack, and a very ſenſible flaſh of light. An air-gun, diſcharged (without a ball) in the dark, does the ſame. Blowing on an electric with a pair of bellows never fails to excite it. In ſhort, the facts to this purpoſe are numberleſs.

2. Electricity is produced by a number of chemical operations, which are continually going on. The melting and freezing of electric bodies in contact with each other, ſuch as chocolate in its moulds, wax-candles in their moulds, ſealing wax, &c. Nay, it is highly probable that any body, in paſſing from its fluid to its ſolid form, or the contrary, is electrical. This is the caſe when a ſolution of Glauber's ſalt, or of nitre, in water, is made to cryſtallize all at once by agitation.

The ſolution of bodies in their menſtrua is, in like manner, productive of electricity in many caſes. Thus iron or chalk, while diſſolving in the ſulphuric acid, produce negative electricity in the mixture, and poſitive in the electric vapours which ariſe from them.

A moſt copious ſource of electricity is the converſion of water into elaſtic ſteam by violent heats. When this is done in a proper apparatus, the electricity of the liquid is negative, and the vapour is poſitive. But if this be accompanied by a decompoſition of the water, the liquid is ſometimes ſtrongly negative. Thus, when water evaporates ſuddenly from a red hot ſilver cup, the cup is ſtrongly negative; but if from clean red hot iron, ſo that the iron is calcined, and inflammable air produced, the iron is poſitive. If the decompoſition of the water is ſufficiently copious to do more than compenſate for the negative electricity produced by the mere expanſion of the water into ſteam, the electricity is poſitive; but not otherwiſe. Water expanded from a piece of red hot coal always gives negative electricity, and this frequently very ſtrong. Theſe experiments ſhould always be made in metalline veſſels. If made in glaſs veſſels, the glaſs takes a charge, which expends the produced electricity, and remains neary neutral, ſo that the production of electricity is not obſerved. Theſe facts are to be found among many experiments of Mr Sauſſure. But there is here a very wide field of new inquiry, which cannot fail of being very inſtructive, and particularly in the preſent queſtion. We ſee ſome of the effects very diſtinctly in ſeveral phenomena of thunder and lightning. Thus, the great eruptions of Ætna and Veſuvius are always accompanied by forked lightnings, which are ſeen darting among the volumes of emitted ſmoke and ſteam. Here is a very copious converſion of water into elaſtic ſteam; and here alſo it is moſt reaſonable to expect a copious decompoſition of water, by the iron and coally matters, which are expoſed to the joint action of fire and water. Theſe two electricities will be oppoſite; or when not oppoſite, will not be equal: in either of which caſes, we have vaſt maſſes of ſteam in ſtates fit for flaſhing into each other.

A fact more to our purpoſe is, that if a ſilk or linen cloth, of a downy texture, be moiſtened or damped, and hung before a clear fire to dry, the fibres briſtle up, and on bringing the finger, or a metal knob, near them, they are plainly attracted by it. We found them negatively electric. This ſhews that the ſimple ſolution of water in air produces electricity. And this is the chief operation in Nature connected with the ſtate of the atmoſphere. It is thus that the watery vapours from all bodies, and particularly the copious exſudation of plants, diſappear in our atmoſphere. There can be no doubt but that the oppoſite electricity will be produced by the precipitation of this vapour; that is, by the formation of clouds in clear air. When damp, but clear air in one veſſel expands into an adjoining veſſel, from which the air has been exhauſted, a cloud appears in both, and a delicate electrometer is affected in both veſſels; but our apparatus was not fitted for aſcertaining the kind of electricity produced. Here then is another unexplored field of experiment. We got two veſſels made, having diaphragms of thin ſilk. Theſe were damped, and ſet into two tubs of water, of very different temperatures. Dry air was then blown thro' them, and came from their ſpouts ſaturated with water. The ſpouts were turned toward each other. Being of very different temperatures, the ſtreams produced a cloud upon mixing together, and a ſtrong negative electricity was produced. We even found that an electrometer, placed in a veſſel filled with condenſed air, was affected when this air was allowed to ruſh out by a large hole.

Laſtly, we know that the tourmaline, and many of the columnar cryſtals, are rendered electrical by merely heating and cooling. Nay, Mr Canton found that dry air became negative by heating, and poſitive by cooling, even when it was not permitted to expand or contract.

When water is precipitated, and forms a cloud, it is reaſonable to expect that it will have the electricity of the air from which it is precipitated. This may be various, but in general negative: For the heat by which the air was enabled to diſſolve the water made it negative; and much more the friction on the ſurface of the earth. But as heat cauſed it to diſſolve the water, cold will make it precipitate it; and we ſhould therefore expect that the air will be in the ſtate in which it was when it took up the water. But if it be cooled ſo faſt as to precipitate it in the form of rain, or ſnow, or hail, we may expect poſitive electricity. Accordingly, in ſummer, hail ſhowers always ſhew ſtrong poſitive electricity; ſo does ſnow when falling dry.

Here, then, are copious ſources of atmoſpheric electricity. The mere expanſion and condenſation of the air, and ſtill more the ſolution and precipitation of watery vapours in it, are perhaps ſufficient to account for all the inequality of electric ſtate that we obſerve in the atmoſphere.

The maſſes of air thus differently conſtituted are evidently diſpoſed in ſtrata. The clouds are ſeen to be ſo. Theſe clouds are not the ſtrata, but the boundaries of ſtrata;

Thunder.

ftrata; which, from the very nature of things, are in different ftates with refpect to the fufception or precipitation of water. When two fuch ftrata are thus adjoining, they will flowly act on each other's temperature, and by mixing will form a thin ftratum of cloud along their mutual confines. If the one ftratum has any motion relative to the other, and be in the fmalleft degree difturbed, they will mix to a greater depth in each; and this mixture will not be perfectly uniform. The extreme mobility of air will greatly increafe this jumble of the adjoining parts of the two ftrata, and will give the cloud a greater thicknefs. If the jumble has been very great, fo as to pufh one of them through the other, we fhall have great towering clouds, perhaps pervading the whole thicknefs of the ftratum of air. We take thefe clouds to be like great foggy bladders, fuperficially opaque where they have come into contact with the furrounding ftratum of air, but tranfparent within.

9 Strata of the atmofphere are in different ftates of electricity, and are tranfparent.

When the wind, or ftratum in motion, does not pufh all the quiefcent air before it, it generally gets over it, and then flows along its upper fide, and, by a partial mixing, produces a fleecy cloud, as already defcribed. We may obferve here, by the way, that the motion of thofe fleecy clouds is by no means a juft indication of the motion of the ftratum; it is nearly the motion compofed of the half of the motions of the two.

10 Thefe ftrata have ftrata of clouds interpofed

This is in all probability the ftate of the atmofphere, confifting of ftrata of clear air many hundred yards thick, feparated from each other by thin fleeces of clouds, which have been produced by the mixture of the two adjoining ftrata. This is no fancy; for we actually fee the fky feparated by ftrata of clouds at a great diftance from each other. And we fee that thefe ftrata maintain their fituations, without farther admixture, for a long time, the bounding clouds continuing all the while to move in different directions. In the year 1759, during the fiege of Quebec, a hard gale blew one day from the weftward, which made it almoft impracticable to fend a number of provifion boats to our troops ftationed above the town. While the men were tugging hard at the oars againft the wind, and hardly advancing, though the tide of flood favoured them, the French threw fome bombs to deftroy the boats. One of thefe burft in the air, near the top of its flight, which was about a quarter of a mile high. The round ball of fmoke produced by the explofion remained in the fame fpot for above feven minutes, and difappeared by gradual diffufion. The lower air was moving to the eaftward at leaft 30 feet per fecond.

In 1783, when a great fleet rendezvoufed in Leith Roads, the fhips were detained by an eafterly wind, which had blown for fix weeks without intermiffion. The fky was generally clear; fometimes there was a thin fleece of clouds at a great height, moving much more flowly in the fame direction with the wind below. During the laft eight days, the upper current was from the weftward, as appeared by the motion of the upper clouds. High towering clouds came down the river, with a little rain; the ftrata were jumbled, and the whole atmofphere grew hazy and uniform; then came thunder, and heavy rain, and the wind below fhifted to the weftward.

Thus it is fufficiently evinced, that the atmofphere frequently confifts of fuch ftrata, well diftinguifhed from each other: their appearance and progrefs leave us no room to doubt but that they come from different quarters, and had been taken up or formed at different places, and in different circumftances, and therefore differing in refpect of their electrical ftates.

11 The electric equilibrium is reftored very flowly in general.

The confequence of their continuing long together would be a gradual but flow progrefs of their electricity to a ftate of equilibrium. The air is perhaps never in a perfectly dry ftate, and its moifture will caufe the electricity to diffufe itfelf gradually. It is not beyond the power of our mathematics to afcertain the progrefs of this approximation to the electric equilibrium. We fee fomething very like it in the curious experiments of Beccaria with mirror plates laid together, and charged by means of a coating on the outer plates. Thefe plates were found to confift of alternate ftrata of pofitive and negative electricity. which gradually penetrated through the plates, and coalefced till they were reduced to two ftrata; perhaps in time the electricity would have difappeared entirely by thefe two alfo coalefcing. In the fame manner there would be a flow transfufion of fenfible electricity through thefe ftrata without any fenfible appearances. If any collateral caufes fhould make a part more damp than the reft, there would be a more brifk transference through it, accompanied with faint flafhes of lambent lightning.

12 A rapid and extenfive reftoration in a thunder clap.

But thunder requires a rapid communication, and a reftoration of electric equilibrium in an inftant, and to a vaft extent. The means for this are at hand, furnifhed by Nature. The ftrata of charged air are furnifhed with a coating of cloud. The lower ftratum is coated on the underfide by the earth.

13 Manner in which this is effected by a coating of cloud.

When a jumble is made in any of the ftrata, a precipitation of vapour muft generally follow. Thus a conductor is brought between the electrical coatings. This will quickly enlarge, as we fee that in our little imitations the knobs of our conductors inftantaneoufly arrange any particles of duft which chance to lie in the way, in fuch a manner as to complete the line of conduct, and occafion a fpark to fly to a much greater diftance than it would have leaped if no duft had been interpofed. We have often procured a difcharge between two knobs which were too far afunder, by merely breathing the damp air between them. In this manner the interpofed cloud immediately attracts other clouds, grows ragged by the paffage of electricity through clear air, where it caufes a precipitation by altering the natural equilibrium of its electricity; for a certain quantity of electricity may be neceffary for air's holding a certain quantity of vapour. Accordingly we fee in a thunder ftorm that fmall clouds continually and fuddenly form in parts formerly clear. Whatever caufes thunder does in fact promote this precipitation.

Thefe clouds have the electricity of the furrounding air, and muft communicate it to others in an oppofite ftate, and within reach. They muft approach them, and muft afterwards recede from them, or from any that are in the fame ftate of electricity with themfelves. Hence their ragged forms, and the fimilar form of the under furface of the great cloud; hence their continual and capricious fhifting from place to place: they are carriers, which give and take between the other clouds. and they may become ftepping ftones for the general difcharge.

If a fmall cloud form a communication with the ground.

Thunder. ground, and the great cloud be poſitive or negative, we muſt have a complete diſcharge, and all the electrical phenomena, with great violence; for this coating of vapour is abundantly complete for the purpoſe. It conſiſts of ſmall veſicles, which are ſufficiently near each other for diſcharging the whole air that is in their interſtices. A phial coated with amalgam is by no means fully coated. If we hold it between the eye and the light, we ſhall ſee that it is only covered with a number of detached points of amalgam, which looks like a cobweb. Yet this glaſs is almoſt completely diſcharged by a ſingle ſpark, the reſiduum being hardly perceptible.

14 The diſcharge is commonly between the clouds, The general ſcene of thunder is the heavens; and it is by no means a frequent caſe that a diſcharge is made into the earth. The air intervening between the earth and the loweſt coating is commonly very much confuſed in conſequence of the hills and dales, which, by altering the currents of the winds, toſs up the inferior parts, and mix them with thoſe above. This generally keeps the earth pretty much in the ſame electrical ſtate as the loweſt ſtratum of clouds.

15 Which are horizontally diſtant. Nor are the great thunder ſtorms in general inſtances of the reſtoration of equilibrium between two ſtrata immediately incumbent on each other. They ſeem, for the moſt part, to be ſtrokes between two parcels of air which are horizontally diſtant. This, however, we do not affirm with great confidence. Our chief reaſon for thinking ſo is, that in theſe great ſtorms the ſpark or ſhaft of forked lightning is directed horizontally, and ſometimes is ſeen at once through an extent of ſeveral miles.

16 Particular account of forked lightning, and explanation of the long continued and rumbling noiſe of thunder. The nature of this ſpark has not, we think, been properly conſidered. It is ſimply compared to a long electrical ſpark, which we conceive to be drawn thro' pure air, and is conſidered as marking the actual transference of electricity from one end to the other. But this we doubt very much. We are certain of having obſerved ſhafts of lightning at one and the ſame inſtant ſtretching horizontally, though with many capricious zigzags and lateral ſputterings, at leaſt five miles. We cannot conceive this to have been the ſtriking diſtance, becauſe the greateſt vertical diſtance of the ſtrata is not the half of this. We rather think that it is a ſimultaneous range of diſcharges, each accompanied with light, differently bright, according to the electrical capacity of the cloud into which it is made; and if there is a real transference of electric matter on this occaſion (which we do not affirm), it is only of a ſmall quantity from one cloud to the next adjoining. This we think confirmed by the ſound of thunder. It is not a ſnap, incomparably louder than our loudeſt ſnap from coated glaſs; but a long continued, rumbling, and *very unequable* noiſe. There is no doubt but that this ſnap was almoſt ſimultaneous through the whole extent of the ſpark; but its different parts are conveyed to our ear in time, and are therefore heard by us in ſucceſſion; and it is not an uniform roar, but a rumbling noiſe, unequally loud, according as the different parts of the ſnap are indeed differently loud. We ſhould hear a noiſe of the ſame kind if we ſtood at one end of a long line of ſoldiers, who diſcharged their muſkets (differently loaded) in the ſame inſtant. When any part of the ſpark is very near us, and is not very diffuſe, the ſnap begins with great ſmartneſs, and continues for ſome time, not unlike the violent tearing of a piece of ſtrong ſilk; after which it becomes more and more mellow as it comes from a greater diſtance. We do not, however, affirm, that the whole extenſive ſpark and ſnap are co-exiſtent or ſimultaneous. The cloud is, in all probability, but an indifferent conductor, and even a ſenſible time may elapſe during the propagation of the ſpark to a great diſtance. Beccaria obſerved this in a line of 250 feet of chain, lying looſely on the ground, and conſiſting of near 6000 links. He thought that it employed a full ſecond; but when the chain was gently ſtretched, the communication ſeemed inſtantaneous.

17 Obſervations on the electric ſpark. We cannot help thinking that even the electrical ſnap between two metal knobs is of the ſame kind. Not a quantity of luminous matter which iſſues from the one and goes to the other, but a light that is excited or produced in different material interjacent particles of air or other interpoſed matter. The angular and ſputtering form is quite incompatible with the motion of a ſimple luminous point. Nay, our chemical knowledge here comes in aid, and obliges us to ſpeculate about the manner in which this light is produced. Whence does it come? It may be produced by two knobs of ice. We know that water conſiſts of vital and inflammable air, which have already emitted the light which made an ingredient of their compoſition. The ſpark therefore does not come from the ice. Is it then from the air? If ſo, perhaps water is produced, or rather ſomething elſe, for there is not always inflammable air at hand to compoſe water. Yet the transference of electricity has decompoſed the air, or has robbed it of part of its light. The remainder may not be water; but it is no longer air. Is not this confirmed by the peculiar ſmell which always accompanies electric ſparks? and the peculiar taſte, not unlike the taſte felt on the tongue when it is touched by the zinc in the experiments on GALVANISM? Even the fine pencil of light which flows from a point poſitively electrified, appears through a magnifying glaſs to conſiſt, not of luminous lines, but of lines of luminous points. And theſe points are of different brilliancy and different colour, both of which are inceſſantly changing. And be it farther obſerved, that theſe lines are curves, diverging from each other, and convex to the axis. This circumſtance indicates a mutual repulſion, ariſing, in all probability, from the expanſion of the air. And, laſtly, no ſpark nor light of any kind can be obtained in a ſpace perfectly void of air.

All theſe circumſtances concur in explaining the nature of the ſhaft of forked lightning. It is a ſeries of appearances excited in the intervening medium, and which produces ſome chemical change in it. Thunder, when it ſtrikes a houſe, always leaves a peculiar ſmell. Inflammable air has alſo a peculiar and very diſagreeable ſmell. The ſmell produced by electricity greatly reſembles the ſmell produced by ſtriking two pieces of quartz together.

18 Deluc's notion of thunder not probable. Mr Deluc ſuppoſes that the electrical ſpark, as it is exhibited in thunder, is always accompanied by the decompoſition of air now ſo familiarly known, and that this is the origin of the deluge of rain which commonly finiſhes the ſtorm. But this is not in the ſmalleſt degree probable. The decompoſition extends ſurely no farther than where the light is ſeparated; and we ſhould no more expect a deluge of rain, even if we had inflammable air ready at hand, than we expect drops of water in our electrical experiments. Something different from water

water follows this decompoſition, total or partial, of the vital air; and the water which we do obſerve to accompany thunder, is no more than what we ſhould expect from the copious precipitation of water in a cloudy form. Mr Sauſſure's obſervations aſſure us, that the particles of a cloud are veſicles. Indeed no perſon who has looked narrowly at a fog, or has obſerved how large the particles are of the cloud which forms in a receiver when we ſuddenly diminiſh the denſity of the air, and who obſerves how ſlowly theſe particles deſcend, can doubt of their being hollow veſicles. We cannot perhaps explain their formation; but there they are. We can hardly conceive them receiving the commotion which accompanied the ſnap without collapſing by the agitation. Perhaps the very ceſſation of their electricity may produce this effect. They will therefore no longer float in the air, but fall, and unite, and come to the ground in rain. We may expect this rain to be copious, for it is the produce of two ſtrata of clouds. It greatly contributes to the putting an end to the ſtorm, by paſſing through the ſtrata, and helping to reſtore the equilibrium.

19
Why and how thunder may continue for ſome time.

One may at firſt expect that a ſingle clap of thunder will reſtore the equilibrium of any extent of clouds, and we require an explanation of their frequent repetition before this is accompliſhed. This is not difficult, and the fact is a confirmation of the above theory, which is conſiderably different from the generally received notions of the ſubject. We conſider the ſtratum of clear air as the charged electric; poſitive on one ſide, and negative on the other, and coated with conducting clouds. When the diſcharge is made, the ſtate of electricity is indeed changed through the whole ſtratum, but the equilibrium is by no means completed. The ſtratum is perhaps a quarter of a mile in thickneſs. The diſcharge does not immediately affect all this; but does it ſuperficially, leaving the reſt unbalanced. It is like the reſiduum which is left in a Leyden phial when the diſcharge has been made by means of a ſpark drawn at a diſtance. It is ſtill more like the reſiduum of the diſcharge of a Leyden phial that is coated only in patches on one ſide. Each of theſe patches diſcharge what is immediately under it and round it to a certain ſmall diſtance, but leaves a part beyond this ſtill charged. This redundant electricity gradually diffuſes itſelf into the ſpaces juſt now diſcharged; and, after ſome conſiderable time has elapſed, another diſcharge may be made. In like manner, the electricity remaining in the interior of the ſtratum diffuſes itſelf, comes within the action of the coating, and may be again diſcharged by a clap of thunder. We have a ſtill better parallel to this in Beccaria's experiments with two or more plates of glaſs laid together. After the firſt diſcharge, the internal ſurfaces will exhibit certain electricity. Lay the plates together, and, after ſome time, the electricity of the inner ſurfaces will be different, and another diſcharge may be obtained.

Magnetiſm affords the beſt illuſtration of this. If a magnet be brought near a piece of ſoft iron, lying below a paper on which iron filings are lightly ſtrewed, it will inſtantly induce a north pole on one end and a ſouth pole on the other; and this will be diſtinctly obſerved by the way in which theſe filings will arrange themſelves. But if, inſtead of ſoft iron, we place a bar of hard tempered ſteel, the ſouth pole will be but a ſmall matter removed from the north pole; but by continuing the magnet long in the ſame place, the diſtribution of magnetiſm in the piece of hard ſteel will gradually advance along the bar, and after a long time the neutral point will be almoſt in the middle of the bar, and the ſouth pole will be at the farther end. See MAGNETISM, in this *Suppl.*

20
Moſt thunder ſtrokes are RETURNING STROKES.

We ſaid that the clouds were the uſual ſcenes of the violent electric phenomena. We imagine that the greateſt part of the thunder ſtrokes which have been felt have been of the kind which Lord Mahon, now Lord Stanhope, calls the returning ſtroke. If two clouds A and B are incumbent over the plain a and b; and if A be poſitive and B negative, the earth will be maintained in a negative ſtate at a, and a poſitive ſtate at b. If the diſcharge be now made between the clouds A and B, the electricity muſt inſtantly ruſh up through a conductor at a, and down through one at b, and each place will have a ſtroke. The ſame thing will happen if the negative cloud B is above the poſitive cloud A, but not in ſo great a degree; for the negative electricity at a will now be much leſs than in the other caſe, becauſe it is induced only by the prevalence of the poſitive cloud A over the more remote negative cloud B.

A + —B

a — +b

This returning ſtroke explains, much better than we can by any direct ſtroke, the capricious effects of thunder. A perſon at Vienna received a terrible ſhock by having his hand on a thunder-rod during a violent exploſion which he ſaw above three miles diſtant. Sparks are obſerved at thunder-rods at every the moſt diſtant flaſh of lightning.

21
Beccaria's theory of thunder not juſt.

Beccaria has a different theory of thunder. He imagines that the different parts of the earth are in different ſtates of electricity, and that the clouds are the reſtoring conductors. But this does not accord with what we know of electricity. The earth is ſo good a conductor, that Dr Watſon could not obſerve any time loſt in communicating the electricity to the diſtance of more than four miles. It is very true, that the earth is almoſt always in a ſtate of very unequal, and even oppoſite, electricity in its different parts; but this ariſes from the variety of clouds ſtrongly electrified in the oppoſite way. This induces electricity, or diſturbs the natural uniform diffuſion of electricity, juſt as the bringing magnets or loadſtones into the neighbourhood of a piece of iron, without touching it, renders it magnetical in its different parts. While they continue in their places, the piece of iron will be magnetical, and differently ſo in its different parts.

Such are the thoughts which occur to us on this ſubject. But we by no means affirm that we have given a full account of the procedure of Nature; we have only pointed out ſeveral neceſſary conſequences of the known laws of electricity, and of its production in the atmoſphere by means of natural operations which are continually going on. Theſe *muſt* operate, and produce an electrical ſtate of the atmoſphere greatly reſembling what we obſerve: and we have ſhewn, from the acknowledged doctrines of electricity, how this want of equilibrium may be removed, and muſt be removed, by the ſame operations of Nature. The equilibrium muſt be reſtored by means of the conducting coating furniſhed by the clouds. But theſe may be the leaſt conſiderable of Nature's reſources; and the ſubject is ſtill an unexplored

Thunder.

unexplored field, in the examination of which we may hope to make great progrefs, in confequence of our daily increafing knowledge of the chemical ftate of the atmofphere.

22 Dr Franklin's invention of a guard againft thunder.

Knowledge is valuable chiefly as it is ufeful. No man ever faw the propriety of this apothegm more ftrongly than Dr Franklin, or more affiduoufly adhered to it in the courfe of a long and ftudious life. However greatly we may admire his fagacity, penetration, and logical difcrimination, in the difcoveries he has made in the fcience of electricity, and his difcovery of the identity of electricity and thunder, we muft acknowledge infinitely greater obligations to him for putting it in our power to ward off the fatal, and formerly inevitable ftroke, of this awful agent in the hands of Nature.

Dr Franklin confiders the earth as performing the office of a conductor in reftoring the electric equilibrium of the atmofphere, which has been difturbed by the inceffant action of the unwearied powers of Nature.

He obferves that the ufual preference will be given to the beft conductors. In this refpect, a metal rod far furpaffes the brick, ftone, timber, and other materials which compofe our buildings, efpecially when they are dry, as is ufually the cafe in the thundery feafon. He therefore advifes us to place metalline conductors in the way of the atmofpherical electricity, in thofe places where it is moft likely to ftrike, and to continue them down to the moift earth, at fome depth under the furface. Nay, as it has been found that thunder has not in every inftance ftruck the higheft parts of buildings, he advifes to raife the metalline conductors to fome confiderable height above the building, the more certainly to invite the electricity to take this courfe.

23 Directions for conftructing it.

To enfure fuccefs, he obferves that the electrical fhock diffipates water, and even metalline conductors, when too fmall. He therefore advifes to make the conductor at leaft half an inch fquare, none of that fize having ever been deftroyed, though fmaller have, by the thunder; yet even thefe had conducted the thunder to the ground with perfect fafety to the building.

No part of a conductor muft terminate in the building; for the electricity accumulates exceedingly at the remote extremities of all long rods, and tends to fly off with great force, efpecially if another conductor is near. This aids the accumulation, by acquiring at its upper end an electricity oppofite to that of the lower end of the other: and this effect, produced by the influence of a pofitive cloud, makes the upper and negative end of the lower portion of a divided conductor draw more electricity to the lower end of the upper portion. This redundant electricity, ftrongly attracted by the negative lower portion, flies off with great violence through the air; or if furrounded with any matter capable of converfion into elaftic vapour by heat, burfts it with irrefiftible force. Thus the thunder, acting on the vane fpindle of St Bride's fteeple in London, fprung from its lower end to the upper end of an iron window bar, and burft the ftone in which it was fixed, by expanding the moifture into fteam. In like manner it burft the ftone at the lower end of this bar, to make its way to an iron cramp which connected the oppofite fides of the fteeple; from this it ftruck to another cramp; and fo from cramp to cramp, till it reached the gutter-leads of the church, burfting and throwing off the ftonework in many places.

All interruptions muft therefore be carefully avoided, and the whole muft be made as much as poffible one continued metal rod.

Farther, Dr Franklin, obferving the fingular property which fharp points poffefs of drawing off the electricity in filence, advifes us to finifh our conductor with a fine point of gilt copper, which cannot be blunted by ruft.

24 Is the thunder rod an effectual and fafe contrivance?

But as thus raifing the conductor, and pointing it, are fo many invitations to the thunder to take this courfe; and as we cannot be certain that the quantity thus invited may not be more than what the rod can conduct with fafety—it has appeared to Dr Wilfon, and other able electricians, that it will be fafer to give abundance of conduct to what may unavoidably vifit us, without inviting what might otherwife have gone harmlefsly by.

This was attentively confidered by Dr Franklin, Dr Watfon, Mr Canton, Dr Wilfon, and others, met as a committee of the Royal Society, at the defire of the Board of Ordnance, to contrive a conductor for the powder magazine at Purfleet.

We think that the theory of induced electricity, founded on Dr Franklin's difcoveries, and confirmed by all the later inventions of the electrophorus, condenfer, &c. will decide this queftion in the moft fatisfactory manner.

25 Scientific account of the ftate of electricity induced on a building by a thunder cloud,

When a cloud pofitively electrified comes over a building, it renders it negatively electrical in all its parts, if of conducting materials, and even the ground on which it ftands. This effect is more remarkably produced if the ftructure is of a tall and flender fhape, like a fteeple or a rod. Therefore the external electrical fluid is attracted by the building with greater force than if it had confifted of materials lefs conductive. A difcharge will therefore be made through it in preference to any neighbouring building, becaufe it is more eminently negative. For the fame reafon, if there are two buildings equal and fimilar, one of them being a good conductor, and the other being a lefs perfect one, the perfect conductor, becoming more powerfully negative, the cloud will become more ftrongly pofitive over this houfe than over the other, and the ftroke will be made through it.

26 And on the thunder rod.

The fame thing muft obtain in a perfect conductor continued from the top to the foundation of a houfe, built of worfe conducting materials. The conductor becoming more eminently negative than any other part of the building, the electric fluid will be more ftrongly attracted by it, accumulated in its neighbourhood, and will all be difcharged through it, fo long as it is able to conduct.

If the building is of great extent, the proximity of one part of the building to the thunder cloud may produce an accumulation of electrical fluid in its neighbourhood, in preference to a more perfect, but remote, conductor. But when the diftances from the cloud are not very unequal, the accumulation will always be in the neighbourhood of the perfect conductor; and this will determine the difcharge that way. The accumulation in the neighbourhood of the rod will be fmall indeed, when the rod is fmall; but then it is denfe, and the whole of electric phenomena fhew that it is the denfity,

denfity, and not the quantity, of accumulation which produces the violent tendency to fly off: it is this alone which makes it impoffible to confine electricity in a body which terminates in a fharp point.

For the fame reafon, bodies of the fame materials and fhape will increafe the accumulation in the adjoining part of the cloud in proportion as they are nearer to it, or more advanced beyond the reft of the building.

And bodies of flender fhape, and pointed, will produce this accumulation in their neighbourhood in a ftill more remarkable degree, and determine the courfe of the difcharge with ftill greater certainty.

But it is evident that a metallic rod, no higher than the reft of the building, may occafion an accumulation in the adjoining part of a near thunder cloud fufficient to produce a difcharge, when the building itfelf, confifting of imperfect conductors, would not have provoked the difcharge at all. It may therefore be doubted whether we have derived any advantage from the conductor.

27 Effect of all interruptions in the conductor.

To judge properly of this, we muft confider houfes as they really are, confifting of different materials, in very different fhapes and fituations; and particularly as having many large pieces of metal in their conftruction, in various pofitions with regard to the cloud, the ground, and to each other. Suppofe all the reft of the building to be of non-conducting materials. When a pofitive thunder cloud comes overhead, every piece of metal in the building becomes electrical, without having received any thing as yet from the cloud; that end of each which is neareft the cloud becoming negative, and the remote end pofitive. But, moreover, the electricity of one increafes the electricity of its neighbour. Then the moft elevated becomes more ftrongly attractive at its upper end than it would have been had the others been away; and therefore produces a greater accumulation in the nearer part of the thunder cloud than it would otherwife have done, and it will receive a fpark. By this its lower end becomes more overcharged, and this makes the upper end of the next more undercharged, and the fpark is communicated to it, and fo on to the ground; which would not have happened without this fucceffion of conductors. Thus it is eafy to conceive, that the accumulation in the cloud is juft infufficient to produce a difcharge—While things are in this ftate, juft ready to fnap, fhould a man chance to pafs under a bell wire, or under a luftre hanging by a chain, his body will immediately augment the pofitive electricity of the lower end of the conductor above him, and thus will augment the negative electricity of its upper end. This again will produce the fame effect in the conductor above it: and thus each conductor becomes more overcharged at its lower end, and more undercharged at the upper end. Before this, every thing was juft ready to fnap. All will now ftrike at once. The cloud will be difcharged through the houfe, and the man will be the facrifice, the whole difcharge being made through his body. This needs no demonftration for any well-informed electrician. Thofe who have only fuch a knowledge of the theory as can be gathered from the writings of Prieftley, Cavallo, and other popular authors, may convince themfelves of the truth of what is here delivered in the following manner.

In dry weather, and the moft favourable circumftances for good electrical experiments, let a very large globe, fmoothly covered with metal, and well infulated, be as highly electrified as poffible, without expofing it to a rapid diffipation. To enfure this circumftance (which is important) let it be electrified till it begins to fputter, and note the ftate of the electrometer. Difcharge this electricity, and electrify it to about half of this intenfity. Provide three or four infulated metal conductors, about three inches long and an inch diameter, terminated by hemifpheres, and all well polifhed.

Having electrified the globe, as above directed, bring one of the infulated conductors flowly up to it, and note its diftance when it receives a fpark. In doing this, take care that there be no conducting body near the remote end of the infulated conductor. It will be beft to pufh it gradually forward by means of a long glafs rod. Withdraw the conductor, difcharge its electricity, reftore the globe to its former electricity, indicated by an electrometer, and repeat this experiment till the greateft ftriking diftance is exactly difcovered. Now fet another of the infulated conductors about half an inch behind the firft, and pufh them forward together, by a glafs rod, till a fpark is obtained. The ftriking diftance will be found greater than before. Then repeat this laft experiment, with this difference, that the two conductors are pufhed forward by taking hold of the remote one. The ftriking diftance will be found much greater than before. Laftly, pufh forward the two conductors, the remote one having a wire communicating with the ground, till they are a fmall matter *without* the ftriking diftance; and, leaving them in this fituation, take any little conducting body, fuch as a brafs ball fixed on the end of a glafs rod, and pafs it brifkly through between the globe and the neareft conductor, or through between the two conductors, taking care that it touch neither of them in the paffage. It will be feen that, however fwift the paffage is made, there will be a difcharge through all the four bodies. The inference from this is obvious and demonftrative.

A very remarkable inftance of this fact was feen at the chapel in Tottenham Court Road, London. A man going into the chapel by the eaft door, was killed by the thunder, which came down from the little bellhoufe, along the bell-wire, and the rod of the clock pendulum, from the end of which it leaped to fome iron work above the door, and from thence, from nail to nail, till it reached the man's head.

This interruption of conduct, which is almoft unavoidable in the conftruction of any building, is the caufe of moft of the accidents that are recorded; for when the ends of thofe communicating conductors are inclofed in materials of lefs conducting power, the electricity, in making its way to the next in a very denfe ftate, never fails to explode every thing which can be converted into elaftic vapour by heat. There is always a fufficient quantity of moifture in the ftone or brickwork for this purpofe; and moft vegetable fubftances contain moifture or other expanfible matter. The ftone, brick, or timber, is burft, and thrown to a confiderable diftance; or if kept together by a weight of wall, the wall is fhattered. It is worth remarking, that although no force whatever feems able to prevent this explofion, the quantity of matter exploded is extremely fmall; for the ftones are never thrown to a greater diftance than they would have been by two or three grains of gunpowder properly confined.

All

All thefe accidents will be prevented by giving a fufficient uninterrupted conduct; and it is proper to make ufe of fuch a conductor, although it may invite many difcharges which would not otherwife happen. So long as the conductor is fufficient for the purpofe, there feems to be no doubt of the propriety of this maxim.

28
A thunder rod will protect even when it is not able to difcharge the whole thunder.

But the moft ferious objection remains. As we are certain that thefe conductors, whether raifed above the building or not, will produce difcharges through them which otherwife would not have happened, and as we are quite uncertain whether the quantity contained in a thunder cloud may not greatly exceed what the thunder rod can conduct without being diffipated in fmoke, it feems very dangerous thus to invite a ftroke which our conductor may not be able to difcharge. In particular, it is reafonable to believe that the ftrata of electrified clouds which come near the earth lofe much of their electricity by paffing over the fharp points of trees, &c. while thofe which are much higher may retain their electricity undiminifhed, and pafs on. May it not therefore happen, that our conductor will invite a fatal ftroke, which would have gone harmlefs by?

The doubt is natural, and it is important.

Let us fuppofe a very extenfive and highly electrified cloud, in a pofitive ftate, to come within fuch a diftance from a building as *juft not to ftrike it*, if unprovided with a conductor, but which will moft certainly ftrike the fame building furnifhed with a conductor; and let the electricity be fo great that the conductor fhall be diffipated in fmoke before even a fmall part of it is difcharged—What will be the fate of the building? We believe that it will be perfectly fafe.

However rapid we may fuppofe that motion by which electricity is communicated, it is ftill motion, and time elapfes during the propagation. The cloud is difcharged, not in a very inftant, but in a very fhort time. Part of the cloud is therefore difcharged, while it explodes the conductor, and the electricity of the remainder is now too weak (by our fuppofition) to ftrike the building no longer furnifhed with a conductor. This muft be the cafe, however large and powerful the cloud may be, and however fmall the conductor.

But fuppofe that the cloud has come fo near as to ftrike the building unprovided with a conductor. Then as much will be difcharged through the building as it can conduct; and if the quantity be too great, the building will be deftroyed: but let a conductor (tho' infufficient) be added. The difcharge will be made through it as long as it lafts, and the remainder only will be difcharged through the houfe, furely with much lefs danger than before.

The truth of thefe conclufions from theory is fully verified by fact. When the church of Newbury in New England was ftruck by lightning in 1755, a bell wire, no bigger than a knitting needle, conducted the thunder with perfect fafety to the building as far down the fteeple as the wire reached, though the ftroke was fo great that the wire had been exploded, and no part of it remained, but only a mark along the wall occafioned by its fmoke. From the termination of the wire to the ground the fteeple was exceedingly fhattered, and ftones of great weight were thrown out from the foundation (where they were probably moifter) to the diftance of 20 and 30 feet.

Another remarkable inftance happened in the fummer palace at St Peterfburg. A Heyduk and a foldier of a foot regiment were ftanding centinels at the door of the jewel-chamber: the Heyduk, with his fcimitar refting on his arm, was carelefsly leaning on the foldier, who had his mufket fhouldered. Both were ftruck down with lightning; and the foldier was killed, his left leg fcorched, and his fhoes burft. The Heyduk had received no damage, but felt himfelf tripped up, as if a great dog had run againft him. A narrow flip of gold lace, which was fewed along the feam of his jacket and pantaloon breeches, reaching to his fhoes, had been exploded on the left fide. This feems to have been his protection. In all probability, the ftroke came to both along the mufket (or perhaps to the Heyduk along the fcimitar). The Heyduk had a complete, though infufficient, conductor, and was fafe. The foldier had not, and was killed. The pufh felt by the former probably arofe from the explofion of the lace.

It feems therefore plain that metalline conductors are always a protection; that advancing them above the building, increafes their protection; and that pointing them may fometimes enable them to diminifh a ftroke, by difcharging part of the electricity filently.

Dr Franklin having formed all his notions of thunder from his pre-eftablifhed theory, and having feen the principal phenomena fo conformable to it, was naturally led to expect this conformity in cafes which he could not eafily examine precifely by experiment. Accordingly in his firft differtation, he affirmed that a fine point always difcharges a thunder cloud filently, and at a great diftance. The analogous experiments in artificial electricity are fo beautiful and fo perfpicuous, that this confidence in the protecting power of fine points is not furprifing: and this confidence was rendered almoft complete by a moft fingular cafe which fell under his own obfervation. He was awakened one night by loud cracks in his ftair-cafe, as if fome perfon had been lafhing the wainfcoating with a great horfewhip. He thought it fo, and got up in anger to chide the idle fool. On looking out at his chamber door, he faw that the difturbance proceeded from electric explofions at fome interruptions of his conductor. He faw the electricity pafs, fometimes in bright fparks, producing thofe loud thwacks, and fometimes in a long continued ftream of denfe white dazzling light as big as his finger, illuminating the ftair-cafe like funfhine, and making a loud noife like a cutler's wheel. Had the cloud (fays he) retained all this till it came within ftriking diftance, the confequences would have been inconceivably dreadful. Yet not long after this he found that he had been in a miftake; for the houfe of Mr Watt in Philadelphia, furnifhed with a finely pointed conductor, was ftruck by a terrible clap of thunder, and the point of the conductor was melted down about two inches. This is perhaps the only inftance on record of a finely-pointed *conductor* being ftruck. The board room at the powder magazine at Purfleet was indeed ftruck, though provided with a conductor; but the ftroke was through another part of the building. St Peter's church, Cornhill, has been eight times ftruck between 1772 and 1787; while St Michael's, in its neighbourhood, and much higher, has never had a ftroke fince 1772, when it was furnifhed with an excellent pointed conductor by Mr Nairne.

Dr

Thunder.

29 Pointed conductor may sometimes be struck.

Dr Franklin having feen the above exception to his rule, and reflected on it, acknowledges that there are cafes where a pointed conductor may be ftruck, viz. when it ferves as a ftepping ftone, to *complete* a canal of conveyance already near completed. A *fmall* cloud may fometimes ferve as a ftepping ftone (like the man coming under a luftre) for the electricity to come out of a great cloud, and difcharge through the pointed conductor. Whenever it comes to the ftriking diftance from the conductor, it will explode at once: whereas the great cloud itfelf muft have come nearer, and had its force gradually diminifhed. It is remarkable that a point, employed in this way in artificial electricity, muft be brought nearer to another body than a ball need be, before it can receive a ftroke. The difference is about one third of the whole Nairne found, that a ball one nine-tenths inches in diameter, exploded at the diftance of nine inches, and a point at fix inches diftance.

We muft alfo obferve that a pointed conductor can have no advantage over a blunt one in the cafe of a returning ftroke; which is perhaps the moft common of any. This depends on another difcharge, which is made perhaps at a great diftance. This was moft diftinctly the cafe in the inftance mentioned fome time ago, of the perfon at Vienna who had a fhock from a thunder rod by an explofion far diftant. This thunder rod was a very fine one, furnifhed with five gilt points

30 Franklin over-rated the protection of pointed conductors.

Still, however, this property of fharp points was greatly over-rated by Dr Franklin, and thofe who took all their notions of electricity from the fimple difcoveries of his fagacious mind. Unfortunately Dr Franklin had not cultivated mathematical knowledge; and, ever eager after difcovery, and ardent in all his purfuits, his wonderful penetration carried him through, and feldom allowed him to reft long on falfe conclufions. He was certainly one of the greateft *philofophers*; and a little erudition would perhaps have brought him fide by fide with Newton. It was referved, however, for Lord C. Cavendifh and for Æpinus, to fubject the inveftigations of Franklin to number and meafure. By ftudying what they have written on the fubject, or even the view which we have given of their theory in the article ELECTRICITY *(Suppl.)*, the reader will be fully convinced, that a point has little or no advantage over a ball, with refpect to a thunder cloud which is brought to the thunder rod by a brifk wind; although, when it comes flowly up during an almoft perfect calm, it may difcharge all that can be difcharged without a fnap. The conftipation in a point is indeed very great, but the quantity conftipated is moderate; and therefore its action, at any confiderable diftance, is but trifling. All this is fully verified by Dr Wilfon's judicious experiments in the Pantheon. He had a prodigious quantity of electrified furface fufpended there, and made a pointed apparatus come to its ftriking diftance with a motion which he could regulate and meafure. And he found that with the very moderate velocity of twelve feet in a fecond, he never failed of procuring a very fmart ftroke. The experiments made in the ufual way by the partifans of fharp points (for it became a matter of indecent party) were numberlefs, and decidedly in their favour. The great and juft authority of Dr Franklin, who was one of the committee, procured them ftill more confideration, or at leaft hindered people from feeing the force of Dr Wilfon's reafoning. It is fomewhat furprifing, that Dr Wilfon, a lover of mathematical learning, and a good judge, as appears from his publication of the papers of Mr Robins, did not himfelf fee the full force of his own experiments. He had not furely ftudied either Æpinus or Cavendifh. He indeed frequently fays, that the ftate of the electricity in a thunder cloud, and in coated glafs, is exceedingly different; and that the firft extends its fenfible influence much farther than the laft, when both have the fame quantity of electricity. But he feems not to have formed to himfelf any adequate notion of the difference. Had he done this, he would have feen that he has difpofed his great electrified furface very improperly. It fhould have been collected much nearer his pointed apparatus, that this might, if poffible, have been within the fphere of attraction of every part of his artificial cloud. He would then have found refults, fome of which would have been much more favourable to his own general opinion, while others would have exhibited the peculiarities of the fharp point in a more fhowy manner than any thing we have feen.

31 Thunder cloud very unlike coated glafs;

Reafoning from the true theory of coated glafs, we fhall learn that, when the glafs is exceedingly thin, the accumulation of electricity, or the charge, will be exceedingly great; while the external appearance, or apparent energy, of the electricity may be hardly fenfible, and will extend to a very fmall diftance. Thus, a circular plate of coated glafs, fix inches in diameter and one-twentieth thick, when electrified fo as to make an electrometer diverge 50 degrees, contains about 60 times as much electricity as a brafs plate, of the fame diameter, electrified to the fame degree; and thefe two will have the fame influence on an electrometer placed at a diftance from them, and will give a fpark nearly at the fame diftance. The fpark from the coated glafs will be bright, and will give a fhock; while that from the brafs plate will be trifling. The caufe of the equality of influence is, that the pofitive electricity of the one fide of the coated glafs is almoft balanced by the negative electricity of the other fide, and the unbalanced part is about $\frac{1}{59}$th of the whole. If we now take a brafs plate of $46\frac{1}{2}$ inches in diameter, and electrify it to the fame degree with the coated glafs, we fhall find that it will require the fame number of turns of the machine to bring it to this ftate, or to charge the coated glafs. They contain the fame quantity of electricity, and the fpark of both will give the fame fhock. But this large plate will have a much wider influence: a perfon coming within ten feet of it will fee his hair bend towards it, and feel like a cobweb on his face.

32 And the influence of fharp points is trifling.

It may be farther demonftrated that the power of a point to abftract the electricity to a given degree from the large plate, is vaftly fmaller than its power to abftract it to the fame degree from the coated plate. This is different in the different degrees of the abftraction, and cannot be expreffed by any one number.

All thefe confiderations taken together, fhew us that the pointed conductor has little advantage over the ball in the circumftance above-mentioned. It has, however, an advantage, and therefore fhould be employed; and in the cafe of a calm, or very gentle progrefs of the thunder cloud, the advantage may be very great.

Thus we think the queftion decided; and the only remaining confideration is the quantity of metallic conduct that fhould be given. Prudence teaches us not to fpare, Thunder || Tiberias.

33 An extensive and substantial metalline conductor is the chief security.

fparc, efpecially in very lofty buildings. The conductor on the dome of St Paul's in London confifts of four iron ftraps, each four inches broad and one half an inch thick. This conductor was once made red hot by a thunder ftroke. No inftance has been found of a rod one-half an inch fquare being exploded. The accident at Mr Watt's houfe in Philadelphia is curious. The brafs wire which terminated the rod had been ten inches long and one-fourth thick at the bafe, and two one-half inches were melted. It was unable, therefore, to conduct that ftroke when its diameter was lefs than one-fixteenth of an inch.

We recommend lead or copper in preference to iron. Iron waftes by ruft, and by exfoliating retains water, which may be dangerous by its expanfion. A ftrap of lead, two inches broad and one-fourth thick, ftapled down to the roof or wall with brafs ftaples, fecures us from all rifks from neglect. An iron rod, or one faftened with iron cramps, requires frequent infpection, to fee that nothing has failed or wafted by ruft. The point or points fhould furely be copper. It would be very proper to connect all the leads of the ridges, gutters, and fpouts, with the conductor, by ftraps of lead. This will greatly extend its protection.

A great extent of building is not fufficiently fecured by one conductor. And a powder magazine fhould have fome erected round it at a diftance on mafts.

Maxims in a Thunder Storm.

Avoid being under trees—but be near them: do not avoid rain. When in a room, avoid the fire-fide, which would bring you into the neighbourhood of the higheft part of the houfe, viz. the ftack of chimneys. The bell-wire, the grate, the fire irons—are bad neighbours. Nay, the foot of the chimney is not a good one, efpecially if it has ever caked together by burning (A). Go to the middle of the room, and fit down, if not near a luftre, or any thing hanging from the ceiling. Avoid mirrors, or gilded mouldings.

Thunder Clouds, in phyfiology, are thofe clouds which are in a ftate fit for producing lightning and thunder. See the preceding article.

THUS, in fea language, a word ufed by the pilot in directing the helmfman or fteerfman to keep the fhip in her prefent fituation when failing with a fcant wind, fo that fhe may not approach too near the direction of the wind, which would fhiver her fails, nor fall to leeward, and run farther out of her courfe.

TIBERIAS (anc. geog.), the laft town of Gallilee, fituated on the fouth fide of the lake Tiberias; built by Herod the Tetrarch, and called *Tiberias* in honour of the Emperor Tiberius; diftant 30 ftadia from Hippus, 60 from Gadara, and 120 from Scythopolis: whence it appears to have been at no great diftance from where the Jordan runs out of the lake. It is a number of times mentioned by St John the Evangelift. Pliny places it on the weft extremity of the lake, commending the falubrity of its hot waters. Jerome fays, the ancient name was *Chennereth*; which, if true, will account for the name of the lake.

Tierra Fuego || Tillandsia.

TIERRA del Fuego, feveral iflands at the fouthern extremity of America. They take their name from a volcano on the largeft of them. They are all very barren and mountainous; but from what Mr Forfter fays, in his Voyage to the South Sea, the climate does not appear to be fo rigorous and tempeftuous as it is reprefented in Anfon's Voyage. Upon the lower grounds and iflands, that were fheltered by the high mountains, Mr Forfter found feveral forts of trees and plants, and a variety of birds. Among the trees was Winter's bark-tree, and a fpecies of *arbutus*, loaded with red fruit of the fize of fmall cherries, which were very well tafted. In fome places there is alfo plenty of celery. Among the birds was a fpecies of duck, of the fize of a goofe, which ran along the fea with amazing velocity, beating the water with its wings and feet. It had a grey plumage, with a yellow bill and feet, and a few white quill feathers. At the Falkland iflands it is called a *loggerhead-duck*. Among the birds are alfo plenty of geefe and falcons. The rocks of fome of the iflands are covered with large mufcle-fhells, the fifh of which is well-flavoured. The natives of this country are fhort in their perfons, not exceeding five feet fix inches at moft, their heads large, their faces broad, their cheek bones prominent, and their nofes flat. They have little brown eyes, without life; their hair is black and lank, hanging about their heads in diforder, and befmeared with train-oil. On the chin they have a few ftraggling fhort hairs inftead of a beard. The whole affemblage of their features forms the moft loathfome picture of mifery to which human nature can poffibly be reduced. Thofe which Mr Forfter faw had no other clothing than a fmall piece of feal-fkin, which hung from their fhoulders to the middle of their back, being faftened round the neck with a ftring: the reft of their body was perfectly naked. Their natural colour feems to be an olive brown, with a kind of glofs, refembling that of copper; but many of them difguife themfelves with ftreaks of red paint, and fometimes, though feldom, with white. Their whole character is a ftrange compound of ftupidity, indifference, and inactivity. They have no other arms than bows and arrows; and their inftruments for fifhing are a kind of fifh-gigs. They live chiefly on feals flefh, and like the fat oily part moft. There is no appearance of any fubordination among them; and their mode of life approaches nearer to that of brutes than that of any other nation.

TILLANDSIA, the large barren wild pine of the

(A) In the terrible thunder ftroke on Leven Houfe in Scotland, the two great ftreams of electricity had taken the courfe of the vents which had been moft in ufe, but not to get at the iron work, for it had branched off from the vents, at a great diftance from the bottom. The chief conductors through the building had been various gilded mouldings, gilded leather hangings, gilded fkreens, picture frames, and the foil of mirrors. In this progrefs the fteps have been fo many, and fo capricious, that no line of progrefs can be traced, according to any principle. The thunder feems to have electrified at once the whole of the leaden roof, and, befides the two main tracks along the vents, to have afterwards darted at every metal thing in its way. The loweft point of the track was a leaden water ciftern; which, however, received no damage; but a thick ftone wall was burft through to get at it.

the West Indies; a genus of the monogynia order, belonging to the hexandria class of plants. It is called *Caragatua* by Father Plumier, and is a parasitic plant, and ought perhaps, in strict propriety, to be denominated an *aquatic:* for although it is suspended in the air among the branches of lofty trees, to whose boughs it is fastened by its numerous roots; yet it is not indebted to those boughs, like the misletoe and other parasitic plants, for nourishment, but merely for support; provident Nature having, in a very extraordinary manner, supplied this with other means to preserve its existence: For the leaves, which much resemble those of the pine-apple, but are larger, surround this plant in a circular manner; each leaf being terminated near the stalk with a hollow bucket, which contains about half a pint of water. It is by these numerous small reservoirs of water that the roots, as well as every other part of this plant, are supplied with nourishment without the help of any earth. The flourishing condition of this plant, as well as the great growth of fig-trees, upon barren rocks, shews that water is of greater use to vegetation than earth.

One contrivance of Nature in this vegetable, says Dr Sloane, is truly admirable. The seed is crowned with many long downy threads, not only that it may be carried everywhere by the wind, but that by those threads, when driven through the boughs, it may be held fast, and stick to the arms and prominent parts of the barks of trees. So soon as it sprouts or germinates, although it be on the under part of a bough, its leaves and stalks rise perpendicular or erect: if they assumed any other direction, the cistern or reservoir just mentioned, made of the hollow leaves, could not hold water, which is necessary to the life and nourishment of the plant. In scarcity of water this reservoir is useful, not to the plant only, but to men, and even to birds and all sorts of insects, which come thither in troops, and seldom go away without refreshment.

To the same purpose, Dampier, in his voyage to Campeachy, relates, "that the wild pine has leaves that will hold a pint and a half or quart of rain-water, which refreshes the leaves, and nourishes the roots. When we find these pines, we stick our knives into the leaves, just above the root; and the water gushing out, we catch it in our hats, as I myself have frequently done, to my great relief."

TIMÆUS, a Greek historian, the son of Andronicus, who was eminent for his riches and excellent qualities, was born at Tauromentum in Sicily, and flourished in the time of Agathocles. He wrote several books, and among the rest an history of his own country; but they are all lost.

TIMÆUS, a famous Pythagorean philosopher, was born at Locres in Italy, and lived before Plato. There is still extant a small treatise of his on Nature and the Soul of the World, written in the Doric dialect. This treatise, which is to be found in the works of Plato, furnished that great philosopher with the subject of his treatise intitled *Timæus.*

TINNING, the covering or lining of any thing with melted tin, or with tin reduced to a very fine leaf. Looking-glasses are foliated or *tinned* with thin plates of beaten tin, by a process described under the title FOLIATING, *Encycl.*

Kettles, sauce-pans, and other kitchen utensils, which are usually made of copper, are tinned by the following process: The surface to be tinned, if of new copper, should first be cleaned or scoured with salt and sulphuric acid (vitriolic acid) dilated with water. This, however, is not always done; some workmen contenting themselves with scouring it with sand perfectly dry, or with scales of iron. Powdered rosin is often strewed over it; and when the vessel or utensil is considerably heated, melted tin is poured into it, and rubbed with flax coiled hard over the surface to be coated. This tin may be either pure, such as that known by the name of *grain-tin;* or a composition consisting of two parts of tin and one of lead. For very obvious reasons, we should certainly prefer the pure tin; but the generality of workmen give the preference to the composition, because the surface coated with it appears more brilliant. The tin is not always put into the vessel in a liquid state; for some workmen strew it in small pieces over the surface to be coated, and then heat the vessel till the tin melt, when they rub it as formerly.

In tinning old vessels which have been tinned before, the process is somewhat different. In these cases, the surface is first scraped with an instrument proper for the purpose, or scoured with the scales of iron, which may be always found in a blacksmith's shop: it is then strewed over with sal-ammoniac in powder, instead of rosin, or an infusion of sal-ammoniac in stale urine is boiled in it till the urine be evaporated, and it is then tinned with pure tin; the composition of tin and lead being in this case never used. The tin, while liquid, is rubbed into the surface with a piece of sal-ammoniac, instead of a bundle of flax. When iron vessels are to be tinned, they are first cleaned with muriatic acid, after which the process is the same as in the tinning of old copper.

In the year 1785, Mr John Poulain of Mortlake, Surrey, obtained a patent for the discovery of a new composition for tinning vessels, especially such as are used for culinary purposes. This composition consists of grain-tin one pound, good malleable iron one ounce and a half, platinum one drachm, silver one pennyweight, gold three grains: the whole must be well fused together in a crucible, with one ounce of pounded borax, and two ounces of pounded glass, and then cast in small ingots. The composition, to be fit for use, must be heated and put in a metal mortar, also heated over a fire, and well pounded with a heated metal pestle; when it is well pounded, make an ingot of it, by putting it on the fire in a mould made of iron plate, in which mould the composition must be well stirred and let to cool; then it is fit for use. To apply the composition, first tin the utensil or vessel with grain-tin and sal ammoniac, as is usually done in the common way of tinning; clean well the tinned part of the metal utensil or vessel, and then apply a coat of the composition with sal ammoniac, as is usually done in the common way of tinning; and when the composition is well spread, let it cool; then make it a little red-hot in all its parts, to neal it, and plunge the metal utensil or vessel, while yet hot, in cold water; then, with a sharp scraper, scrape and rub off the rough or grumous particles of the composition applied on the metal utensil or vessel, and scour it well with sand. The same operation must be re-

 peated

peated for every coat of the compofition that is applied; two coats of the compofition are quite fufficient for culinary utenfils or veffels, and a thin coat of grain-tin may be applied over the laft coat of the compofition, to fmooth it. The author adds, that his compofition may be employed for covering or plating the furface of all materials made of copper, brafs, iron, and other metals or mixtures of metals, and that it fhould be applied with a charcoal fire in preference to any other fire. All this may be true, and it may be a very valuable coating to copper; but the fcarcity, high price, and infufibility of platinum, muft for ever prevent it from coming into very general ufe.—We think that even the *Enamelling of Veffels for the Kitchen* muft be more common. See that article in this *Supplement.*

The following procefs is lefs expenfive, whilft the coating given by it is exceedingly durable, adds ftrength to the copper veffel, and fecures it much longer than the common tinning from the action of acids:

When the veffel has been prepared and cleaned in the ufual manner, it muft be roughened on the infide by being beat on a rough anvil, in order that the tinning may hold better, and be more intimately connected with the copper. The procefs of tinning muft then be begun with perfectly pure grained tin, having an addition of fal ammoniac inftead of the common colophonium or refin. Over this tinning, which muft cover the copper in an even and uniform manner throughout, a fecond harder coat muft be applied, as the firft forms only a kind of medium for connecting the fecond with the copper. For this fecond tinning you employ pure grained-tin mixed with zinc in the proportion of two to three, which muft be applied alfo with fal ammoniac, fmooth and even, fo that the lower ftratum may be entirely covered with it. This coating, which, by the addition of the zinc, becomes pretty hard and folid, is then to be hammered with a fmoothing hammer, after it has been properly rubbed and fcoured with chalk and water; by which means it becomes more folid and acquires a fmooth compact furface.

Veffels and utenfils may be tinned in this manner on both fides. In this cafe, after being expofed to a fufficient heat, they muft be dipped in the fluid tin, by which means both fides will be tinned at the fame time.

As this tinning is exceedingly durable, and has a beautiful colour, which it always retains, it may be employed for various kinds of metal inftruments and veffels which it may be neceffary to fecure from ruft.

TINPLATE, called in Scotland *White iron*, is a thin plate of iron covered with tin, to which it is united by chemical affinity. See Chemistry, n° 122. *Suppl.*

TIPRA, the name of certain mountainous diftricts to the eaftward of Bengal, inhabited by a people of very fingular manners. As every thing which contributes a fingle fact to the hiftory of human nature is interefting to the philofopher, the reader will be pleafed with the following account of the religion, laws, and manners of thefe people, taken from the 2d volume of the *Afiatic Refearches.*

Though they acknowledge one Creator of the univerfe, to whom they give the name of Pa'tiyan, they believe that a deity exifts in every tree, that the fun and moon are gods, and that whenever they worfhip thofe fubordinate divinities Pátiyan is pleafed. This is very fimilar to the religious creed of ancient Greece and Rome, differing only with refpect to creation, which, in the proper fenfe of the word, the Greeks and Romans feem not to have admitted.

If any one of thefe mountaineers, called in the memoir Cucis, put another to death, the chief of the tribe, or other perfons who bear no relation to the deceafed, have no concern in punifhing the murderer; but if the murdered perfon have a brother or other heir, he may take blood for blood; nor has any man whatever a right to prevent or oppofe fuch retaliation.

When a man is detected in the commiffion of theft or other atrocious offence, the chieftain caufes a recompence to be given to the complainant, and reconciles both parties; but the chief himfelf receives a cuftomary fine, and each party gives a feaft of pork or other meat to the people of his refpective tribe.

In ancient times, it was not a cuftom among them to cut off the heads of the women whom they found in the habitations of their enemies; but it happened once that a woman afked another, why fhe came fo late to her bufinefs of fowing grain? fhe anfwered, that her hufband was gone to battle, and that the neceffity of preparing food and other things for him had occafioned her delay. This anfwer was overheard by a man at enmity with her hufband; and he was filled with refentment againft her, confidering, that as fhe had prepared food for her hufband for the purpofe of fending him to battle againft his tribe, fo, in general, if women were not to remain at home, their hufbands could not be fupplied with provifion, and confequently could not make war with advantage. From that time it became a conftant practice to cut off the heads of the enemy's women, efpecially if they happen to be pregnant, and therefore confined to their houfes; and this barbarity is carried fo far, that if a Cuci affail the houfe of an enemy, and kill a woman with child, fo that he may bring two heads, he acquires honour and celebrity in his tribe, as the deftroyer of two foes at once.

As to the marriages of this wild nation, when a rich man has made a contract of marriage, he gives four or five head of *gayáls* (the cattle of the mountains) to the father and mother of the bride, whom he carries to his own houfe: Her parents then kill the *gayáls;* and having prepared fermented liquors and boiled rice with other eatables, invite the father, mother, brethren, and kindred of the bridegroom to a nuptial entertainment. When a man of fmall property is inclined to marry, and a mutual agreement is made, a fimilar method is followed in a lower degree; and a man may marry any woman except his own mother. If a married couple live cordially together, and have a fon, the wife is fixed and irremovable; but if they have no fon, and efpecially if they live together on bad terms, the hufband may divorce his wife, and marry another woman.

They have no idea of heaven or hell, the reward of good, or the punifhment of bad, actions; but they profefs a belief, that when a perfon dies, a certain fpirit comes and feizes his foul, which he carries away; and that whatever the fpirit promifes to give at the inftant when the body dies, will be found and enjoyed by the dead; but that if any one fhould take up the corfe and carry it off, he would not find the treafure.

The food of this people confifts of elephants, hogs, deer,

deer, and other animals; of which if they find the carcases or limbs in the forests, they dry them, and eat them occasionally.

When they have resolved on war, they send spies, before hostilities are begun, to learn the stations and strength of the enemy, and the condition of the roads; after which they march in the night, and two or three hours before daylight make a sudden assault with swords, lances, and arrows: if their enemies are compelled to abandon their station, the assailants instantly put to death all the males and females, who are left behind, and strip the houses of all their furniture; but should their adversaries, having gained intelligence of the intended assault, be resolute enough to meet them in battle, and should they find themselves overmatched, they speedily retreat and quietly return to their own habitations. If at any time they see a star very near the moon, they say, "to-night we shall undoubtedly be attacked by some enemy;" and they pass that night under arms with extreme vigilance. They often lie in ambush in a forest near the path, where their foes are used to pass and repass, waiting for the enemy with different sorts of weapons, and killing every man or woman who happens to pass by: in this situation, if a leech, or a worm, or a snake, should bite one of them, he bears the pain in perfect silence; and whoever can bring home the head of an enemy, which he has cut off, is sure to be distinguished and exalted in his nation. When two hostile tribes appear to have equal force in battle, and neither has hopes of putting the other to flight, they make a signal of pacific intentions, and, sending agents reciprocally, soon conclude a treaty; after which they kill several head of *gayáls*, and feast on their flesh, calling on the sun and moon to bear witness of the pacification: but if one side, unable to resist the enemy, be thrown into disorder, the vanquished tribe is considered as tributary to the victors; who every year receive from them a certain number of *gayáls*, wooden dishes, weapons, and other acknowledgments of vassalage. Before they go to battle, they put a quantity of roasted *álus* (esculent roots like potatoes), and paste of rice-flour, into the hollow of bamboos, and add to them a provision of dry rice with some leathern bags full of liquor: then they assemble, and march with such celerity, that in one day they perform a journey ordinarily made by letter-carriers in three or four days, since they have not the trouble and delay of dressing victuals. When they reach the place to be attacked, they surround it in the night, and at early dawn enter it, putting to death both young and old, women and children, except such as they choose to bring away captive: they put the heads, which they cut off, into leathern bags; and if the blood of their enemies be on their hands, they take care not to wash it off. When after this slaughter they take their own food, they thrust a part of what they eat into the mouths of the heads which they have brought away, saying to each of them, "Eat, quench thy thirst, and satisfy thy appetite; as thou hast been slain by my hand, so may thy kinsmen be slain by my kinsmen!" During their journey, they have usually two such meals; and every watch, or two watches, they send intelligence of their proceedings to their families. When any one of them sends word that he has cut off the head of an enemy, the people of his family, whatever be their age or sex, express great delight, making caps and ornaments of red and black ropes; then filling some large vessels with fermented liquors, and decking themselves with all the trinkets they possess, they go forth to meet the conqueror, blowing large shells, and striking plates of metal, with other rude instruments of music. When both parties are met, they shew extravagant joy, men and women dancing and singing together; and if a married man has brought an enemy's head, his wife wears a head dress with gay ornaments, the husband and wife alternately pour fermented liquor into each other's mouths, and she washes his bloody hands with the same liquor which they are drinking. Thus they go revelling, with excessive merriment, to their place of abode; and having piled up the heads of their enemies in the court-yard of their chieftain's house, they sing and dance round the pile; after which they kill some *gayáls* and hogs with their spears; and having boiled the flesh, make a feast on it, and drink the fermented liquor. The richer men of this race fasten the heads of their foes on a bamboo, and fix it on the graves of their parents, by which act they acquire great reputation. He who brings back the head of a slaughtered enemy, receives presents from the wealthy of cattle and spirituous liquors; and if any captives are brought alive, it is the prerogative of those chieftains, who were not in the campaign, to strike off the heads of the captives. Their weapons are made by particular tribes; for some of them are unable to fabricate instruments of war.

In regard to their civil institutions; the whole management of their household affairs belongs to the women; while the men are employed in clearing forests, building huts, cultivating land, making war, or hunting game and wild beasts. Five days (they never reckon by months or years) after the birth of a male child, and three days after that of a female, they entertain their family and kinsmen with boiled rice and fermented liquor; and the parents of the child partake of the feast. They begin the ceremony with fixing a pole in the court-yard; and then killing a *gayál* or a hog with a lance, they consecrate it to their deity; after which all the party eat the flesh and drink liquor, closing the day with a dance and with songs. If any one among them be so deformed, by nature or by accident, as to be unfit for the propagation of his species, he gives up all thought of keeping house, and begs for his subsistence, like a religious mendicant, from door to door, continually dancing and singing. When such a person goes to the house of a rich and liberal man, the owner of the house usually strings together a number of red and white stones, and fixes one end of the string on a long cane, so that the other end may hang down to the ground; then, paying a kind of superstitious homage to the pebbles, he gives alms to the beggar; after which he kills a *gayál* and a hog, and some other quadrupeds, and invites his tribe to a feast: the giver of such an entertainment acquires extraordinary fame in the nation, and all unite in applauding him with every token of honour and reverence.

When a *Cúci* dies, all his kinsmen join in killing a hog and a *gayál*; and, having boiled the meat, pour some liquor into the mouth of the deceased, round whose body they twist a piece of cloth by way of shroud: all of them taste the same liquor as an offering to his soul; and this ceremony they repeat at intervals for several days.

Tirefias, Tifri.

days. Then they lay the body on a ftage, and kindling a fire under it, pierce it with a fpit and dry it; when it is perfectly dried, they cover it with two or three folds of cloth, and enclofing it in a little cafe within a cheft, bury it under ground. All the fruits and flowers that they gather within a year after the burial they fcatter on the grave of the deceafed: but fome bury their dead in a different manner; covering them firft with a fhroud, then with a mat of woven reeds, and hanging them on a high tree. Some, when the flefh is decayed, wafh the bones, and keep them dry in a bowl, which they open on every fudden emergence; and, fancying themfelves at a confultation with the bones, purfue whatever meafures they think proper; alleging that they act by the command of their departed parents and kindfmen. A widow is obliged to remain a whole year near the grave of her hufband; where her family bring her food: if fhe die within the year, they mourn for her; if fhe live, they carry her back to her houfe, where all her relations are entertained with the ufual feaft of the *Cücis*.

If the deceafed leave three fons, the eldeft and the youngeft fhare all his property; but the middle fon takes nothing: if he have no fons, his eftate goes to his brothers; and if he have no brothers, it efcheats to the chief of the tribe.

TIRESIAS, a famous foothfayer of antiquity, was the fon of Everes and the nymph Chariclo. Pherecydes fays, that Minerva being accidentally feen by Tirefias, as fhe was bathing with Chariclo in the fountain of Hippocrene, the goddefs was enraged, and declared that he fhould fee nothing more: on which he inftantly loft his fight; but afterwards received from the goddefs fuperior endowments. Others fay, that Juno ftruck him ftone-blind for deciding a cafe between Jupiter and her, to her diffatisfaction; for which Jupiter gave him the faculty of divination: He was the moft celebrated prophet in the Grecian annals. Ulyffes is ordered by Circe to confult him in the fhades.

> There feek the Theban bard depriv'd of fight,
> Within irradiate with prophetic light.

But, befides the honour done to him by Homer, Sophocles makes him act a venerable and capital part in his tragedy of Oedipus. Callimachus afcribes to Minerva the gift of his fuperior endowments; the preeminence of his knowledge is likewife mentioned by Tully in his firft book of Divination. And not only Tirefias is celebrated by Diodorus Siculus, but his daughter Daphne, who, like her father, was gifted with a prophetic fpirit, and was appointed prieftefs at Delphos. She wrote many oracles in verfe, from whence Homer was reported to have taken feveral lines, which he interwove in his poems. As fhe was often feized with a divine fury, fhe acquired the title of *fibyl*, which fignifies "enthufiaft." She is the firft on whom it was beftowed: in aftertimes this denomination was given to feveral other females that were fuppofed to be infpired, and who uttered and wrote their predictions in verfe; which verfe being fung, their function may be juftly faid to unite the priefthood with prophecy, poetry, and mufic.

TISRI, or Tizri, in chronology, the firft Hebrew month of the civil year, and the 7th of the ecclefiaftical or facred year. It anfwered to part of our September and October.

Tithing-Men || Tombuctoo.

TITHING-Men, are now a kind of petty conftables, elected by parifhes, and fworn in their offices in the court leet, and fometimes by juftices of the peace, &c. There is frequently a tithing-man in the fame town with a conftable, who is, as it were, a deputy to execute the office in the conftable's abfence; but there are fome things which a conftable has power to do, that tithing-men and head-boroughs cannot intermeddle with. When there is no conftable of a parifh, his office and the authority of a tithing-man feems to be all one under another name.

TITHONUS, in fabulous hiftory, the fon of Laomedon king of Troy, and the brother of Priamus; was beloved by Aurora, who carried him to Delos, thence to Ethiopia, and at laft to heaven, where fhe prevailed on the Deftinies to beftow upon him the gift of immortality; but forgot to add that of youth, which could only render the prefent valuable. At length Tithonus grew fo old that he was obliged to be rocked to fleep like an infant; when Aurora, not being able to put an end to his mifery by death, transformed him into a grafshopper; which renews its youth by cafting his fkin, and in its chirping retains the loquacity of old age.

TITLE for orders, in the church of England, is an affurance of being employed and maintained as an officiating clergyman in fome cathedral or parochial church, or other place of Divine worfhip. And, by the 33*d Canon*, "no one is to be ordained but in order to be a curate or incumbent, or to have fome minifter's place in fome church, or except he be fellow, conduct, or chaplain, in fome college in one of the univerfities, or be mafter of arts of five years ftanding, and live there at his own coft." By the fame canon, the bifhop, who ordains a clerk without title, is bound to keep him till he prefer him to fome ecclefiaftical living.

TOD of wool, is mentioned in the ftatute 12 Carol. II. c. 32. as a weight containing 2 ftone, or 28 pounds.

TOMBUCTOO, a large city in North Africa, and capital of a kingdom of the fame name. It has for fome years paft been the great object of European refearch, being one of the principal marts for that extenfive commerce which the Moors carry on with the Negroes. The hopes of acquiring wealth in this purfuit, and zeal for propagating their religion, have filled this extenfive city with Moors and Mahomedan converts; the king himfelf, and all the chief officers of ftate are Moors; and they are faid to be more fevere and intolerant in their principles than any other of the Moorifh tribes in this part of Africa. Mr Park was informed, by a venerable old Negro, that when he firft vifited Tombuctoo, he took up his lodging at a fort of public inn, the landlord of which, when he conducted him into his hut, fpread a mat on the floor, and laid a rope upon it; faying, "if you are a Muffulman, you are my friend, fit down; but if you are a Kafir, you are my flave; and with this rope I will lead you to market." The reigning fovereign of Tombuctoo, when Mr Park was in Africa, was named *Abu Abrahima*. He was reported to poffefs immenfe riches, and his wives and concubines were faid to be clothed in filk, and the chief officers of ftate live in confiderable fplendour. The whole expence of his government is defrayed by a tax upon merchandize, which is collected at the gates of the city.

Of

Of that city very little is known with accuracy, as it has never been visited by any European. It is the largest on the Niger, Houssa only excepted; and probably contains from 60,000 to 80,000 inhabitants. In some of the Gazetteers, its houses are said to be built in the form of bells; but they are probably such buildings as those of Sego, which see in this *Supplement*. Tombuctoo, according to Major Rennel, is in 16° 30′ N. Lat. and 1° 33′ E. Long. from Greenwich.

TOMSOOK, in the language of Bengal, a bond.

TOOTH-ache, a well known excruciating pain (see *Encycl.*), for the alleviation, and even the cure of which, many specifics have been offered to the public. Of one of the most extraordinary of these, there is an account, in a small work published at Florence in 1794, by professor Gerbi, who gives the description of an insect, a kind of *curculio*, which, from its property of allaying the tooth-ache, has received the epithet of *antiodontalgicus*, and which is found on a species of thistle, *carduus spinosissimus*. The flowers of this thistle, when analysed, gave the acid of galls, the muriatic acid, oxalat of lime, extractive matter, and a very little resin. On the bottom of the calyx, which supports the flowers, there are often found excrescences like the gall nut, which are at first spheroidal, afterwards cylindric, and at length assume the figure of two hemispheres: they consist of the like component parts with the flowers, but contain more resin, and far more oxalat of lime; as the gall apple of the oak, according to the experiments of M. Branchi, which are here mentioned, contains more of the acid of galls than the bark and other parts of the oak, in which he could discover no sulphuric acid. The insect, according to the author's observations, eats not only the parenchyma, but also the vessels and fibres of the leaves. The egg, before the worm makes its appearance, is nourished by the sap of the plant, and of the above excrescences, in which it resides, by means of the attractive power that the egg possesses for certain vegetable juices and substances. The excrescences arise by the accumulation of a solid substance, which is precipitated from the nourishing juices of the thistle, diminished by nourishing the egg and the worm. This insect, the eggs of which are deposited in these excrescences, is, together with the *curculio* of the centuary, a new species. It is of a longish figure; covered below with short yellow hair, and above with golden yellow velvety spots. Its corslet is variegated with specks; and the covering of its wings with specks and stripes. It has a short proboscis, and shews some likeness to the *curculio villosus* of Geoffroy. Its larva represents a sort of ichneumon. By chemical analysis it exhibits some traces of common salt; by distillation with a strong dry heat, some volatile lixivious salts; and it contains, besides these, some gelatinous, and a little sebaceous and slimy extractive matter. If about a dozen or fifteen of these insects, when in the state of larva, or even when come to perfection, be bruised and rubbed slowly between the fore-finger and the thumb, until they have lost their moisture, and if the painful tooth, where it is hollow, be touched with that finger, the pain ceases, sometimes instantaneously. This power or property the finger will retain for a year, even though it be often washed and used. A piece of shamoy leather will serve equally well with the finger. Of 629 experiments, 401 were attended with complete success. In two of these cases, the hollow teeth arose from some fault in the juices: in the rest they were merely local. If the gums are inflamed, the remedy is of no avail.

To the truth of this tale the reader will give what credit he pleases; but it is surely very difficult to believe, that a living finger, continually perspiring, can retain for a year the moisture imbibed from this insect. But it seems there are other insects which have the property of curing the tooth ache; such as the *carabus chrysocephalus* of Rossi; the *carabus ferrugineus* of Fabricius; the *coccinella septem punctata* (the lady bird); the *chrysomela populi*, and the *chrysomela sanguinolenta*. It would appear, therefore, that this property belongs to various kinds of the *coleoptera*.

The idea of these insects being endowed with the property of curing the tooth-ache is not confined to Italy; for Dr Hirsch, dentist to the court of Weimar, asserts (*Verkundiger*, September 24, 1798) that he employed them with the happiest effect, except in some cases where his patients were females. He says, that he took that small insect, found commonly among corn, *coccinella septem punctata*, and bruised it between his fingers. He then rubbed the fingers with which he had bruised it, till they became warm at the points, and touched with them the unsound parts of the gums, as well as the diseased tooth. Dr Hirsch adds, that he made the same experiment a few days after with equal success, though he had not bruised a new insect with his fingers. He seems to think that, to insure the efficacy of the process, the insect should be alive; because, when dead, its internal parts, in which he presumes the virtue chiefly resides, become dried up, leaving only the wings and an empty shell; and therefore proposes to physicians to turn their attention to the finding out of some method for preserving the virtue of the insect, so that its efficacy may be in full vigour throughout the year.

Besides these beetles, charcoal has been recommended as an anodyne in the tooth-ache; but whether it operates merely by filling the hollow of the tooth, and thereby preventing the access of atmospheric air to the nerve, or by any of its singular and hitherto unknown qualities, seems not to have been well ascertained.

TOR, a town of Asia, in Arabia Petræa, seated on the Red Sea, with a good harbour, defended by a castle. There is a handsome Greek convent, in whose garden are fountains of bitter water, which they pretend are those rendered sweet by Moses, by throwing a piece of wood into them. Some think that this town is the ancient Elana. E. Long. 31. 25. N. Lat. 28. 0.

TORELLI (Joseph), was born at Verona on the 4th of November 1721. His father Lucas Torelli, who was a merchant, dying when young Torelli was but an infant, he was left entirely to the care of his mother Antonia Albertini, a Venetian lady of an excellent character. After receiving the first rudiments of learning, he was placed under the Ballerini, who, observing the genius of the boy, prevailed upon his mother to send him to complete his education at Patavia. Here he spent four years entirely devoted to study, all his other passions being absorbed by his thirst for knowledge.

The unsullied innocence of his life, and the prudence and gravity of his conduct, soon attracting the attention of his masters, they not only commended him with eagerness, but performed to him the part of parents,

conversed

Torelli. conversed with him familiarly about their respective sciences, and read over to him privately the lectures which they had to deliver. This was the case particularly with Hercules Dondinus, under whom Torelli studied jurisprudence. But he by no means confined himself to that science alone. The knowledge which he acquired was so general, that upon whatever subject the conversation happened to turn, he delivered his sentiments upon it in such a manner that one would have thought he had bestowed upon it his whole attention.

After receiving the degree of Doctor, he returned home to the enjoyment of a considerable fortune; which putting it into his power to choose his own mode of living, he determined to devote himself entirely to literary pursuits. He resolved, however, not to cultivate one particular branch to the exclusion of every other, but to make himself master of one thing after another, as his humour inclined him; and he was particularly attentive to lay an accurate and solid foundation. Tho' he declined practising as a lawyer, he did not, on that account, relinquish the study of law. The Hebrew, Greek, Latin, and Italian languages, occupied much of his time. His object was to understand accurately the two first, and to be able to write and speak the two last with propriety and elegance. Besides these languages, he learned French, Spanish, and English. On the last, in particular, he bestowed uncommon pains; for he was peculiarly attached to the British nation, and to British writers, whom he perused with the greatest attention; not merely to acquire the language, but to imbibe also that force and loftiness of sentiment for which they are so remarkable. Nay, he even began an Italian translation of Paradise Lost.

He likewise made himself acquainted with ethics, metaphysics, and polemical divinity; to which last subject he was induced to pay attention by the custom of his country. With ancient history he was very familiarly acquainted, calling in to his assistance, while engaged in that study, the aids of chronology, geography, and criticism. This last art, indeed, by means of which what is counterfeit may be distinguished from what is genuine, what is interpolated from what is uncorrupted, and what is excellent from what is faulty, he carried about with him as his counsellor and his guide upon all occasions.

The theory of *music* he studied with attention, preferring those powerful airs which make their way into the soul, and rouse the passions at the pleasure of the musician. His knowledge of *pictures* was held in high estimation by the artists themselves, who were accustomed to ask his opinion concerning the fidelity of the design, the harmony of colours, the value of the picture, and the name of the painter. He himself had a collection, not remarkably splendid indeed, but exceedingly well chosen. *Architecture* he studied with still greater attention, because he considered it as of more real utility. Nor did he neglect the pursuits of the *antiquarian*, but made himself familiarly acquainted with coins, gems, medals, engravings, antique vessels, and monuments. Indeed scarce any monumental inscriptions were engraved at Verona which he had not either composed or corrected. With the *antiquities* of his own country he was so intimately acquainted, that every person of eminence, who visited Verona, took care to have him in their company when they examined the curiosities of the city.

But these pursuits he considered merely as amusements; mathematics and the belles lettres were his serious studies. These studies are, in general, considered as incompatible; but Torelli was one of the few who could combine the gravity of the mathematician with the amenity of the muses and graces, and who handle the compass and the plectrum with equal skill. Of his progress in mathematics, several of his treatises, and especially his edition of Archimedes, published since his death by the university of Oxford, are sufficient proofs. Nor was his progress in the more pleasing parts of literature less distinguished. In both these studies he was partial to the ancients, and was particularly hostile to the poetry and the literary innovations of the French.

Nothing could be purer or more elegant than his Latin style, which he had acquired at the expence of much time and labour. His Latin translation of Archimedes is a sufficient proof of this, and is indeed really wonderful, if we consider that the Romans, being far inferior to the Greeks in mathematical knowledge, their language was of necessity destitute of many necessary words and phrases. He wrote the Italian language with the classic elegance of the 14th and 15th centuries. Witness his different works in that language, both in prose and verse. He translated the whole of Æsop's Fables into Latin, and Theocritus, the *Epithalamium* of Catullus, and the *comedy* of Plautus, called *Pseudolus*, into Italian verse. The two first books of the Æneid were also translated by him with such exactness, and so much in the style of the original, that they may well pass for the work of Virgil himself.

His life, like his studies, was drawn after the model of the ancient sages. Frugal, temperate, modest, he exhibited a striking contrast to the luxurious manners of his age. In religion he adhered strictly, though not superstitiously, to the opinions of his ancestors. He was firm to his resolutions, but not foolishly obstinate; and so strict an observer of equity, that his probity would have remained inviolate, even though there had been no law to bind him to justice. He never married, that he might have leisure to devote himself, with less interruption, to his favourite studies. Every one readily found admission to him, and no man left him without being both pleased and instructed; such was the sweetness of his temper, and the readiness with which he communicated information. He adhered with great constancy to his friendships. This was particularly exemplified in the case of Clemens Sibiliatus, who has favoured the world with the life of Torelli. With him he kept up the closest connection from a school-boy till the day of his death. He was peculiarly attached likewise to many men of distinction, both in Italy and Britain. He died in August 1781, in the 70th year of his age.

The following is a complete list of his works, his edition of Archimedes excepted, which was not published till after his death:

1. "Lucubratio Academica, sivi Somnium Jacobi Pindemontii, &c." Patavii, 1743.—2. "Animadversiones in Hebraicum Exodi Librum et in Græcum lxx Interpretationem;" Veronæ, 1744.—3. "De principe Gulæ incommodo, ejusque remedio, Libri duo;" Coloniæ

Torpedo. niæ Agrippinæ, 1744.—4. "De Probabili Vitæ Morumque Regula;" Coloniæ, 1747. 5. "Li due primi Canti dell' Iliade (di Scipione Maffei) e li due primi dell' Eneide di Giuseppe Torelli tradotti in verſi Italiani;" Verona, 1749.—6. "Gli ſteſſi due canti dell' Eneide riſtampati ſoli lo ſteſſo anno per lo ſteſſo Ramanzini."—7. "Scala de Meriti a capo d'anno Trattato Geometrico;" Verona. 1751.—8. "De Nihilo Geometrico, lib. 2.;" Verone, 1758.—9. "Lettera intorno a due paſſi del Purgatorio di Dante Alighiero;" *ib.* 1760.—10. "Della Denominazione del corrente anno vulgarmente detto 1760 in Bologna per Lelio della Volpe."—11. "Il pſeudolo. Comedia, &c. e ſi aggiunge la traduzione d'alcuni Idilli di Teocrito e di Moſco;" Firenzi, 1765.—12. "Inno a Maria Virgine nella Feſtivita della ſua Concezione;" Verona, 1766.—13. "Lettera a Miladi Vaing-Rveit premeiſſa al libro che ha per titalo xii. lettere Ingleſi, con altra lettera all'autore della ſuddetta;" Verona, 1767.—14. "Elegia di Tommaſo Gray, Poeta Ingleſe, in un Cimetero Campeſtre in verſi Italiani rimati;" Verona, 1767.—15. "Geometrica;" Veronæ. 1769.—16. TORPEDO, or Cramp fish, has been deſcribed under the generic title Raja; and an attempt made to explain its electrical phenomena in the article Electricity, n° 258, &c. (Both theſe articles are in the *Encyclopædia*). From ſome late diſcoveries, however, of Volta and others, the ſhock given by the torpedo appears much more analogous to the ſhock of Galvanism than to that of common electricity; and even the electrical organs of the fiſh ſeem to reſemble the apparatus with which thoſe diſcoveries in galvaniſm were made.

In the 63d volume of the Philoſophical Tranſactions, Mr Hunter deſcribes the electric organ of the torpedo as conſiſting of a number of columns, varying in their length from an inch and a half to a quarter of an inch, with diameters about two-tenths of an inch. The number of columns in each organ of the torpedo which he preſented to the Royal Society was about 470; but in a very large torpedo which he diſſected, the number of columns in one organ was 1182. Theſe columns were compoſed of films parallel to the baſe of each; and the diſtance between each partition of the columns was $\frac{1}{150}$th of an inch. From theſe facts, the reader will find the anomalies of torpedinal electricity (ſuppoſing it the ſame with common electricity) accounted for in a very ingenious and philoſophical manner by Mr Nicholſon, at p. 358 of the firſt volume of his valuable Journal. We paſs on, however, to point out the reſemblance between it and the lately diſcovered phenomena in galvaniſm.

Take any number of plates of copper, or, which is better, of ſilver, and an equal number of tin, or, which is much better, of zinc, and a like number of diſcs, or pieces of card, or leather, or cloth (A), or any porous ſubſtance capable of retaining moiſture. Let theſe laſt be ſoaked in pure water, or, which is better, ſalt and water, or alkaline leys. The ſilver or copper may be pieces of money. Build up a pile of theſe pieces; namely, a piece of ſilver, a piece of zinc, and a piece of wet card: then another piece of ſilver, a piece of zinc, and a piece of wet card: and ſo forth, in the ſame order (or any other order, provided the pieces ſucceed each other in their turn), till the whole number intended to be made uſe of is builded up. The inſtrument is then completed.

In this ſtate it will afford a perpetual current of the galvanic influence through any conductor communicating between its upper and lower plates; and if this conductor be an animal, it will receive an electrical ſhock as often as the touch is made, by which the circuit is completed. Thus if one hand be applied to the lower plate, and the other to the upper, the operator will receive a ſhock, and that as often as he pleaſes to lift his finger and put it down again.

This ſhock reſembles the weak charge of a battery of immenſe ſurface; and its intenſity is ſo low that it cannot make its way through the dry ſkin. It is therefore neceſſary that a large ſurface of each hand ſhould be well wetted, and a piece of metal be graſped in each, in order to make the touch; or elſe that the two extremities of the pile ſhould communicate with ſeparate veſſels of water, in which the hands may be plunged.

The commotion is ſtronger the more numerous the pieces. Twenty pieces will give a ſhock in the arms, if the above precautions be attended to. One hundred pieces may be felt to the ſhoulders. The current acts on the animal ſyſtem while the circuit is complete, as well as during the inſtant of commotion, and the action is abominably painful at any place where the ſkin is broken.

It is eſſential to the ſucceſs of the experiment, that the contiguous ſurfaces of the metallic plates be perfectly dry during its whole continuance; for the introduction of water or any liquid immediately deſtroys the energy of the pile. It is neceſſary that one of the metals employed ſhould be much more eaſily oxidated than the other, and that the liquid with which the card or cloth is moiſtened ſhould be capable of oxidating it. Hence when zinc and ſilver are uſed, the pile does not act if the cloth be moiſtened with newly boiled diſtilled water; and it ſoon ceaſes to act if it be covered with a receiver and ſeparated from the external air.

The Galvanic pile not only gives ſhocks to animal bodies, but it exhibits all the phenomena of common electricity. A viſible ſpark is emitted on completing the broken circle, metals are eaſily made red hot and ſet on fire by it; and Van Marum aſcertained that it charges a battery, however large, to its own intenſity in an inſtant. Now, as it poſſeſſes exactly the properties of electricity and no other properties, it can ſcarcely be doubted that the fluid which circulates in the Galvanic pile is common electricity. To explain the cauſe of the current

(A) Woollen or linen cloth appears to be more durable, and more ſpeedily ſoaked, than card.

current indeed may be a difficult taſk: and hitherto it muſt be acknowledged, that no explanation has been offered that is perfectly ſatisfactory. But this is no reaſon for denying the identity of Galvaniſm and electricity; and accordingly, this identity ſeems now admitted by all thoſe philoſophers who have given themſelves the trouble to repeat the experiments.

Though Mr Volta's celebrated experiments have not removed all uncertainty, and though he has drawn his conſequences too far, they muſt certainly be conſidered as a very important ſtep towards a theory of the Galvanic pile. Theſe experiments are in ſubſtance as follows: If two different metals, inſulated, and having only their natural quantity of electricity, are brought into contact, they aſſume, when again ſeparated, different electric ſtates; the one is poſitive and the other negative. This difference, which in each contact is very ſmall, becomes, when ſucceſſively accumulated by means of an electrical condenſer, ſufficiently ſtrong to ſeparate the electrometer very ſenſibly. The action does not take place at a diſtance, but only upon the contact of the different metals: it exiſts as long as the contact continues; but its intenſity is not the ſame for all metals. It will be ſufficient to take for example copper and zinc. In their mutual contact, the copper becomes negative and the zinc poſitive.

After having proved the developement of metallic electricity, independently of any humid conductor, Mr Volta next introduces ſuch conductors. If we form a metallic plate of two portions, the one of zinc, the other of copper, by ſoldering their ends together, and taking the zinc between our fingers, touch with the copper the upper plate of the condenſer, which is alſo of copper, the condenſer becomes negative. This agrees obviouſly with the former experiment. But if, on the contrary, we hold the copper in our fingers, and touch the upper plate of the condenſer with the zinc, upon removing the metals and raiſing the upper plate of the condenſer, it indicates no electricity, notwithſtanding the lower plate is connected with the common reſervoir in the earth. But as ſoon as we interpoſe between the zinc and the plate of the condenſer a piece of paper moiſtened with pure water, or any other moiſt conductor, the condenſer becomes charged with poſitive electricity. It becomes alſo charged, but negatively, when we hold the zinc in our fingers, and touch, with the copper, the humid conductor laid on the condenſer.

Mr Volta thus explains theſe facts—Metals, and probably all other ſubſtances, exert, as we have juſt ſeen, a reciprocal action on their reſpective electricities at the moment of contact. When we hold the metallic plate by the copper, a part of its electric fluid paſſes into the zinc; but if this zinc is in immediate contact with the condenſer, which is alſo of copper, the condenſer tends with equal force to diſcharge its own fluid into the zinc, and therefore can receive nothing from the zinc; conſequently, after the contact, it muſt remain in its natural ſtate. If, on the contrary, we place wet paper between the zinc and the copper of the condenſer, the force tending to diſplace the electricity, which exiſts only upon the contact of the two metals, is now deſtroyed; the water, which appears to poſſeſs this property, but in a very weak degree, with regard to the metallic ſubſtances, very little impedes the tranſmiſſion of the fluid of the zinc to the condenſer, and the condenſer is at liberty to become poſitively charged. Finally, when we touch the condenſer with the end which is of copper, the interpoſition of the wet paper, of which the proper action is very weak, does not prevent the tranſition of a part of the poſitive electricity of the condenſer into the plate of zinc: ſo that after ſeparation, the condenſer is found to be charged negatively.

From this theory, Mr Volta finds no difficulty in explaining the pile. For the ſake of ſimplicity, we will ſuppoſe it to be inſulated, and we will repreſent by unity the exceſs of the electricity of a piece of zinc above that of a piece of copper in immediate contact with it.

If the pile is compoſed but of two pieces, the lower one of copper, the upper one of zinc, the electric ſtate of the firſt will be repreſented by $-\frac{1}{2}$, and that of the ſecond by $+\frac{1}{2}$. If we add a third piece, which muſt be of copper, we muſt ſeparate it, in order that the fluid may be diſplaced, by wet paſteboard, from the piece of zinc below it; and in this caſe it will acquire the ſame ſtate of electricity with the zinc; at leaſt neglecting the proper action of the water, which appears to be very feeble, and alſo the ſlight degree of reſiſtance which the water may oppoſe to the communication as an imperfect conductor of electricity. The apparatus being inſulated, the exceſs of the upper piece can only be acquired at the expence of the lower piece of copper: and, in this caſe, the charges of the reſpective pieces will be different from the former experiment. The lower piece of copper will be $-\frac{2}{3}$; the piece of zinc, which is in immediate contact with it $-\frac{2}{3}+1$, or $\frac{1}{3}$; and the upper piece of copper, ſeparated from the zinc by wet paſteboard, will have the ſame charge, that is $+\frac{1}{3}$; ſo that the negative charge of the lower piece will be equal to the ſum of the poſitive charges of the two others, the whole quantity being the ſame as in the natural ſtate.

If on this pile we place another piece of zinc, this piece will demand a greater quantity of electricity by unity than the copper on which it is placed: but ſince this exceſs can only be obtained at the expence of the pieces below, the pile being inſulated, we ſhall have,

For the lower piece of copper, -1

For the ſecond piece, which is of zinc, 0

that is, it will be neutral.

For the third piece, which is of copper, ſeparated from the ſecond piece by wet paſteboard 0

For the upper piece, which is of zinc, and in contact with the third, $+1$

By purſuing the ſame mode of reaſoning, we may find the electrical ſtate of each piece of the pile, ſuppoſing it inſulated and formed of any given number of pieces; the quantities of electricity will increaſe at each ſtep, from the baſe to the ſummit of the pile, in an arithmetical progreſſion, of which the ſum will vaniſh.

Suppoſing, for the ſake of ſimplicity, the number of conſtituent parts to be even, we may diſcover, by a very eaſy calculation, that the piece of copper, which is the firſt, and the piece of zinc, which is the laſt of the pile, muſt be equally electrified, the one poſitively, the other negatively; and the ſame will be true of any pieces taken at equal diſtances from the extremities of the

the pile. Between the positive and the negative states, the electricity will vanish; and there will always be two pieces, one of zinc, the other of copper, which will be in the natural state. They will be in the middle of the pile, as has already been shown in the example of four pieces.

Let us now make a communication between the lower part of the pile and the earth: it is evident, that then the lower piece of copper, which is negatively electrified, will tend to absorb from the ground what it has lost; but its electrical state cannot change, unless that of the superior pieces be also varied, since the difference of the pieces must always be the same in the state of equilibrium. Therefore all the negative quantities of the lower half of the pile must be neutralised at the expence of the common reservoir; and in this case, the lowest piece, which is of copper, will have the electricity of the earth, which we call o. The second piece, which is of zinc, and in immediate contact with the first, will have + 1. The third, which is of copper, and separated from the zinc below it by wet pasteboard, will also have + 1. The fourth, which is of zinc, and in immediate contact with the third, will have + 2. And in the same manner the electricity of the different elements will continue to increase in arithmetical progression.

If we then touch, with our hands, the two extremities of the pile, these excesses of electricity will be discharged through our bodies into the common reservoir, and will produce a shock so much the more sensible, as the loss is quickly repaired from the earth, and an electrical current is formed, of which the rapidity is greater within the pile than within the animal body, which is an imperfect conductor; so that the internal parts of the pile are at liberty to resume a degree of tension approaching to that which they had when in the state of equilibrium. The communication with the earth being still preserved, if we bring the summit of the pile into contact with the upper plate of a condenser, of which the lower is connected with the ground, the electricity, which was accumulated at the summit with a very slight degree of tension, will pass into the condenser, where the tension may be considered as evanescent; but the pile not being insulated, this loss will be repaired from the earth: the new portions of electricity recovered by the upper part of the pile will pass into the condenser like the preceding, and will at last be so accumulated there, that when we remove the plate of the condenser, we may find in it very evident marks of electricity, and we may even take sparks from it.

Such is Mr Volta's theory; but the experiments of Mr Davy are sufficient to demonstrate that the ideas of this celebrated electrician require some modification. His theory must at least be extended to the imperfect conductors as well as the metals. Mr Davy has shewn that two kinds of galvanic circles may be formed. The first is composed of two different metallic substances, or one metallic substance and charcoal, and a peculiar fluid. The second is composed by two different fluids and one metallic substance.

The following table of some circles of the first kind, in which the different substances are arranged according to the order of their known galvanic powers, will show how intimately chemical agencies are related to the production of galvanism.

TABLE *of some Galvanic Circles. Composed of two perfect Conductors and one imperfect Conductor.*

More oxidable substances.	Less oxidable substances.	Oxidating fluids.
Zinc.	With gold, charcoal, silver, copper, tin, iron, mercury.	Solutions of nitric acid in water, of muriatic acid and sulphuric acid &c. Water holding in solution oxygen, atmospheric air, &c.
Iron.	. . . gold, charcoal, silver, copper, tin,	
Tin.	. . gold, silver, charcoal.	
Lead	. . . gold, silver.	
Cop.	. . . gold, silver.	Solution of nitrate of silver and mercury. Nitric acid, acetous acid.
Silv.	. . . gold.	Nitric acid.

The most active single circles of the second order are those in which the two imperfect conductors are capable of exerting different chemical agencies on the perfect conductor, at the same time that they are possessed of power of action on each other. But even circles in which only one of the fluid parts is decomposable by the solid, are possessed of power of action. Thus copper, silver, or lead, acts very powerfully when connected in the proper order with solutions of alkaline sulphurets and of nitrous acid; both of which fluids are possessed of distinct chemical agencies upon them. And copper or silver acts, though with less intensity, when water, or a fluid which they are incapable of decomposing, is substituted for one of the chemical agents.

The following table contains some powerful galvanic combinations of the second order, arranged according to the intensity of their action.

TABLE *of some Galvanic Circles. Composed of two imperfect Conductors and one perfect Conductor.*

Perfect conductors.	Imperfect conductors.	Imperfect conductors.
Cop. Silv. Lead Tin. Iron. Zinc.	Solutions of alkaline fulphurets, capable of acting on the first three metals but not on the last three.	Solutions of nitrous acid, oxygenated muriatic acid, &c. capable of acting on all the metals.

Messrs Nicholson and Carlisle constructed an apparatus similar to that of Volta, which gave them a shock as before described, and a very acute sensation whereever the skin was broken. Very early in the course of this experiment, the contacts being made sure by placing a drop of water upon the upper plate, Mr Carlisle observed a disengagement of gas round the touching wire. This gas, though very minute in quantity, evidently seemed to have the smell afforded by hydrogen when the wire of communication was steel. This, with some other facts, led Mr Nicholson to propose to break the circuit by the substitution of a tube of water between

tween two wires. They therefore inferted a brafs wire through each of two corks inferted in a glafs tube of half an inch internal diameter. The tube was filled with New River water, and the diftance between the points of the wires in the water was one inch and three quarters. This compound difcharger was applied fo that the external ends of its wire were in contact with the two extreme plates of a pile of 36 half crowns, with the correfpondent pieces of zinc and pafteboard. A fine ftream of minute bubbles immediately began to flow from the point of the lower wire in the tube which communicated with the filver, and the oppofite point of the upper wire became tarnifhed, firft deep orange and then black. On reverfing the tube, the gas came from the other point, which was now loweft; while the upper, in its turn, became tarnifhed and black. Reverfing the tube again, the phenomena again changed their order. In this ftate the whole was left for two hours and a half. The upper wire gradually emitted whitifh filmy clouds, which, towards the end of the procefs, became of a pea-green colour, and hung in perpendicular threads from the extreme half inch of the wire, the water being rendered femiopaque by what fell off, and in a great part lay, of a pale green on the lower furface of the tube, which, in this difpofition of the apparatus, was inclined about forty degrees to the horizon. The lower wire, of three quarters of an inch long, conftantly emitted gas, except when another circuit, or complete wire, was applied to the apparatus; during which time the emiffion of gas was fufpended. When this laft mentioned wire was removed, the gas re-appeared as before, not inftantly, but after the lapfe of four beats of a half fecond clock ftanding in the room. The product of gas, during the whole two hours and a half, was two-thirtieths of a cubic inch. It was then mixed with an equal quantity of common air, and exploded by the application of a lighted waxed thread.

Thefe experiments were immediately repeated and varied by other philofophers. Meffrs Cruickfhank, Haldane, Davy, Henry, Wollafton, Fourcroy, and Vauquelin, are the moft diftinguifhed.

Mr Cruickfhank afcertained, that when the wire coming from the zinc end of the pile is plunged into infufion of litmus, the infufion becomes red, and an acid, which appears to be the nitric, is formed; that the wire from the filver end reddens the infufion of brazil wood, and of courfe an alkali is formed. This alkali has been fuppofed to be fixed; but in our experiments it was obvioufly ammonia, for the change on the infufion of mallows (the colouring matter which we ufed) was not permanent. He afcertained alfo, that the filver end wire revives metals from their falts, as had been previoufly known to happen whenever nafcent hydrogen comes in contact with them. He thought alfo, that he had afcertained that all liquids containing no oxygen are nonconductors of galvanifm.

To avoid the trouble of conftantly repiling the pieces of filver and zinc, Mr Cruickfhank conftructed a kind of trough of baked wood, 26 inches in length. 1.7 inches deep, and 1.5 inches wide: in the fides of this trough grooves were made oppofite to each other, about the tenth of an inch in depth, and fufficiently wide to admit one of the plates of zinc and filver when foldered together; three of thefe grooves were made in the fpace of one inch and the tenths, fo that the whole machine contained 60 pair of plates. A plate of zinc and filver, each 1.6 inches fquare, well cemented together, were introduced into each of thefe grooves or notches, and afterwards cemented into the trough by a compofition of rofin and wax, fo perfectly that no water could pafs from one cell to the other, nor between the plates of zinc and filver. This circumftance muft be ftrictly attended to, elfe the machine will be extremely imperfect. When all the plates were thus fecured in the trough, the interftices or cells formed by the different pairs of plates were filled with a folution of the muriat of ammonia, which here fupplied the place of the moiftened papers in the pile, but anfwered the purpofe much better. It is hardly neceffary to obferve, that in fixing the zinc and filver plates, they muft be placed regularly, as in the pile, *viz.* alternately zinc and filver, the filver plate being always on the fame fide. When a communication was made between the firft and laft cell, a ftrong fhock was felt in the arms, but fomewhat different from that given by the pile, being quicker, lefs tremulous, and bearing a greater refemblance to the common electrical fhock. He conftructed two of thefe machines, which contained in all 100 pair of plates; thefe when joined together gave a very ftrong fhock, and the fpark could be taken in the day-time at pleafure; but what furprifed him not a little, was the very flender power which they poffeffed in decompofing water: in this refpect they were certainly inferior to a pile of 30 pair, although fuch a pile would not give a fhock of one third the ftrength.

This apparatus retained its power for many days, and would in all probability have retained it much longer, had not the fluid got between the dry furfaces of the metals. To remedy this defect, he foldered the zinc and filver plates together, and found that this method anfwers very well. The zinc plates may be cleaned at any time, by filling the different cells for a few minutes with the dilute muriatic acid. Although this apparatus may not entirely fuperfede the pile, efpecially if it fhould be found to decompofe water, &c. but flowly, yet in other refpects it will no doubt be found very convenient and portable.

Colonel Haldane proved, as might have been expected, that the pile does not act under water, nor in vacuo, nor when furrounded by a gas which contains no oxygen, and found it more powerful when placed in oxygen gas.

Mr Henry found that more oxygen was obtained from fulphuric acid than from water by the agency of the pile. He deoxydated nitric and oxymuriatic acid by means of it, and obtained gafes by the decompofition of the water of liquid muriatic acid. The gafes he found incapable of tranfmitting the galvanic influence.

Mr Davy found, that if the zinc end wire be plunged into one glafs of water, and the filver end wire into another, and the circle be completed by plunging a finger into each glafs, the hydrogen gas is evolved in one glafs and the oxygen in the other. He proved that the action of the pile is proportional to the oxydation of the zinc; that its action is increafed by interpofing acids, becaufe they increafe the rapidity of oxydation, and that with acids the pile acts even in vacuo. He found alfo that a pile of zinc and charcoal has very great

great energy. To him we are indebted for the pile with one metal formerly defcribed, and he has more lately proved that charcoal or plumbago may be fubftituted for the metal. A pile of charcoal, plumbago, and cloth, moiftened with muriat of lime, retains its energy for a long time.

Dr Wollafton proved, that when common electricity is paffed through water by means of two very fine metallic points, chemical changes are effected by it, analagous to thofe occafioned by the tranfmiffion of the galvanic influence. This fact, fingly, prefents a very ftrong analogy between galvanifm and the common electrical influence; and when compared with the other facts, it amounts almoft to a demonftration of their identity. Dr Wollafton likewife afcertained that electricity is evolved during oxydation. He found that an electrical machine cannot be excited when plunged into any gas that does not contain oxygen; and fuppofes the excitation in a great meafure owing to the oxydation of the amalgam.

Fourcroy and Vauquelin made ufe of metallic plates about a foot fquare, and obferved that a much fmaller number of fuch plates than are fufficient to produce fhocks, give fparks, and even fet fire to the metals when prefented in fine wires or leaves. By twelve pairs of fuch plates, a mixture of oxygen and hydrogen gas may be exploded, and iron wire fet on fire in oxygen gas. All the metals may be fet on fire.

Such is a fhort fketch of the new facts which have been difcovered in galvanifm; but the examination of the fubject has not proceeded far enough to admit of a fatisfactory explanation of them. The facts relating to the feparate production of oxygen and hydrogen, acid and alkali, in water, are totally incommenfurable with the ufually received theory of chemiftry. And even fuppofing that the appearance of the two laft of thefe bodies is connected with the prefence of atmofpheric air, it is ftill extremely difficult to conceive, that either oxygen or hydrogen can pafs in an invifible form through fluids or organic bodies. Common phyfical facts prefent us with no analogies fufficiently diftinct to enable us to reafon on this fubject; and the elucidation of it will probably be connected with perfectly new views of corpufcular action.

If this article be thought long, and if we appear to have loft fight of our original fubject, the *Torpedo*, we have only to plead in excufe for our conduct, that whilft we could not avoid pointing out the refemblance between the fhock given by the torpedo and that by Volta's apparatus, we felt it a kind of duty to embrace the only opportunity that we fhall have of laying before our readers the additional information refpecting the phenomena of Galavnism which we have received fince the publication of that article. Thefe phenomena are yet new, and they are unqueftionably important; indeed fo very important, that to us it appears neither impoffible, nor even improbable, that to the galvanic agency of metals and minerals may be attributed volcanoes and earthquakes.

TOUCAN, or American Goose, is one of the modern conftellations of the fouthern hemifphere, confifting of nine fmall ftars.

TRACTORS, Metallic. See Perkinism in this *Suppl.*

TRACTRIX, in geometry, a curve line, called alfo Catenaria; which fee, *Encyclopædea* and Arch, *Suppl.*

TRADESCANT (John), an ingenious naturalift and antiquary, was, according to Anthony Wood, a Fleming or a Dutchman. We are informed by Parkinfon, that he had travelled into moft parts of Europe, and into Barbary; and from fome emblems remaining upon his monument in Lambeth church-yard, it plainly appears that he had vifited Greece, Egypt, and other eaftern countries. In his travels, he is fuppofed to have collected, not only plants and feeds, but moft of thofe curiofities of every fort which, after his death, were fold by his fon to the famous Elias Afhmole, and depofited in his mufeum at Oxford. When he firft fettled in this kingdom cannot, at this diftance of time, be afcertained. Perhaps it was at the latter end of the reign of Queen Elizabeth, or the beginning of that of King James I. His print, engraven by Hollar before the year 1656, which reprefents him as a perfon very far advanced in years, feems to countenance this opinion. He lived in a great houfe at South Lambeth, where his mufeum was frequently vifited by perfons of rank, who became benefactors thereto: among thefe were King Charles I. (to whom he was gardener), Henrietta Maria his Queen, Archbifhop Laud, George Duke of Buckingham, Robert and William Cecil, Earls of Salifbury, and many other perfons of diftinction. John Tradefcant may therefore be juftly confidered as the earlieft collector (in this kingdom) of every thing that was curious in natural hiftory, viz. minerals, birds, fifhes, infects, &c. He had alfo a good collection of coins and medals of all forts, befides a great variety of uncommon rarities. A catalogue of thefe, publifhed by his fon, contains an enumeration of the many plants, fhrubs, trees, &c. growing in his garden, which was pretty extenfive. Some of thefe plants are, if not totally extinct, at leaft become very uncommon, even at this time: though this able man, by his great induftry, made it manifeft, in the very infancy of botany, that there is fcarce any plant extant in the known world that will not, with proper care, thrive in this kingdom.

When his houfe at South Lambeth, then called *Tradefcant's Ark*, came into Afhmole's poffeffion, he added a noble room to it, and adorned the chimney with his arms, impaling thofe of Sir William Dugdale, whofe daughter was his third wife; where they remain to this day.

It were much to be wifhed, that the lovers of botany had vifited this once famous garden before, or at leaft in the beginning of the 17th century. But this feems to have been totally neglected till the year 1749, when Dr Watfon and the late Dr Mitchell favoured the Royal Society with the only account now extant of the remains of Tradefcant's garden.

When the death of John Tradefcant happened is not known; no mention being made thereof in the regifter-book of Lambeth church.

TRAJECTORY, a term often ufed, generally for the path of any body, moving either in a void, or in a medium that refifts its motion; or even for any curve paffing through a given number of points. Thus Newton, Princip. lib. 1. prop. 22. propofes to defcribe a trajectory that fhall pafs through five given points.

TRAITOR's

TRAITOR's ISLAND, one of the Archipelago called *NAVIGATORS Islands*, in the South Sea (See that article *Suppl.*). It is low and flat, with only a hill of some height in the middle; and is divided into two parts by a channel, of which the mouth is about 150 toises wide. It abounds with bananas, yams, and the finest cocoa-nuts, which Perouse says he ever saw. About twenty canoes approached the French ships without dread, traded with a good deal of honesty, and never refused, like the natives of the archipelago of Navigators, to give their fruit before they were paid for it; nor, like them, did they give a preference to beads over nails and pieces of iron. They spoke, however, the same language, and had the same ferocious look; their dress, their manner of tatowing, and the form of their canoes, were the same; nor could we (says the author) doubt that they were one and the same people: they differed, indeed, in having universally two joints cut off from the little finger of the left hand; whereas, in the islands of Navigators, I only perceived two individuals who had suffered that operation. They were also of much lower stature, and far less gigantic make; a difference proceeding, no doubt, from the soil of these islands, which being less fertile, is consequently less favourable to the expansion of the human frame.

TRAMMELS, in mechanics, an instrument used by artificers for drawing ovals upon boards, &c. One part of it consists of a cross with two grooves at right angles; the other is a beam carrying two pins, which slide in those grooves, and also the describing pencil. All the engines for turning ovals are constructed on the same principles with the trammels: the only difference is, that in the trammels the board is at rest, and the pencil moves upon it; in the turning engine, the tool, which supplies the place of the pencil, is at rest, and the board moves against it. See a demonstration of the chief properties of these instruments by Mr Ludlam, in the *Phil. Transf.* vol. lxx. p. 378, &c.

TRANSFORMATION, in geometry, is the changing or reducing of a figure, or of a body, into another of the same area, or the same solidity, but of a different form. As, to transform or reduce a triangle to a square, or a pyramid to a parallelopipedon.

TRANSFORMATION of Equations, in algebra, is the changing equations into others of a different form, but of equal value. This operation is often necessary, to prepare equations for a more easy solution.

TRANSLATION, in literature, is a matter of so much importance, that no other apology can be made for the very imperfect manner in which it is treated in the *Encyclopædia*, than a candid declaration that it was impossible to enter at all upon the subject within the narrow limits to which we were then restricted by the proprietors of the work. The fundamental laws of translation, which we gave in that article, we believe indeed to be incontrovertibly just; but we are sorry that our inaccurate expressions have led some of our readers to suppose that Mr Tytler, in his essay, has done nothing more than illustrate the ideas that were suggested to him by Dr Campbell. The truth is, that the same ideas of a just translation occurred to these two ingenious writers at the same time, without the smallest communication with each other; and this fact, which consists with our own knowledge, is surely a corroboration of the laws laid down by both; but the question is, how are these laws to be obeyed?

In order that a translator may be enabled to give a complete transcript of the ideas of the original work, it is almost needless to observe, that he must possess a perfect knowledge of both languages, *viz.* that of his author, and that into which he is to translate; and that he must have a competent acquaintance with the subject of which his author treats. These propositions we consider as self-evident; but if any of our readers shall be of a different opinion, we refer them to an *Essay on the Principles of Translation*, published 1797 by Cadell and Davies, London, where they will find our doctrine very clearly illustrated. It may be proper to add, that such a knowledge of the Greek and Latin languages as merely enables a man to read them with ease and entertainment to himself, is by no means sufficient to qualify him for translating every Greek and Latin book, even though it treats of a subject with which he has a general acquaintance. The religious rites and ceremonies of the Greeks and Romans, as well as the radical words of their language, were derived from the East; and he who is an absolute stranger to oriental literature, will be very liable to mistake occasionally the sense of Greek and Roman authors who treat of religious subjects. We could illustrate the truth of this position by quotations from some of the most admired modern translations of the Greek Scriptures, which we have no hesitation to say fall very short of the authorised version in accuracy as well as in elegance. The divines employed by King James to translate the Old and New Testaments were profoundly skilled in the learning, as well as in the languages, of the East; whilst some of those who have presumed to improve their version seem not to have possessed a critical knowledge of the Greek tongue, to have known still less of the Hebrew, and to have been absolute strangers to the dialect spoken in Judea in the days of our Saviour, as well as to the manners, customs, and peculiar opinions of the Jews sects. Neither metaphysical acuteness, nor the most perfect knowledge of the principles of translation in general, will enable a man who is ignorant of these things to improve the authorised version either of the Gospels or the Epistles; for such a man knows not accurately, and therefore cannot give a complete transcript of the ideas of the original work.

But supposing the translator completely qualified with respect to knowledge, it becomes a question, whether he may, in any case, add to or retrench the ideas of his author? We are strongly inclined to think, that, in no case, it is allowable to take such liberties; but the ingenious and elegant essayist, whose work on the principles of translation we must always quote with respect, is of a different opinion. "To give a general answer (says he) to this question, I would say, that this liberty may be used, but with the greatest caution. It must be further observed, that the superadded idea shall have the most necessary connection with the original thought, and actually increase its force. And, on the other hand, that whenever an idea is cut off by the translator, it must be only such as is an accessory, and not a principle, in the clause or sentence. It must likewise be confessedly redundant, so that its retrenchment shall not impair or weaken the original thought. Under these

limitations,

Tranflation.

limitations, a tranflator may exercife his judgment, and affume to himfelf, in fo far, the character of an original writer."

Of the judicious ufe, as he thinks it, of this liberty, the author quotes many examples, of which we fhall felect three, as well calculated to illuftrate our own ideas of the fubject.

In the firft book of the Iliad, Achilles, having refolved, though indignantly, to give up Brifeis, defires Patroclus to deliver her to the heralds of Agamemnon :

> Ὡς φατο· Πατροκλος δε φιλω επεπειθεθ' ἑταιρω·
> Εκ δ' αγαγε κλισιης Βρισηιδα καλλιπαρηον,
> Δωκε δ' αγειν· τω δ' αυτις ιτην παρα νηας Αχαιων·
> Ἡ δ' αεκουσ' ἁμα τοισι γυνη κιεν· *Ilias*, A. 345.

> Patroclus now th' unwilling beauty brought ;
> She in foft forrows, and in penfive thought,
> Paft filent, as the heralds held her hand,
> And oft look'd back, flow moving o'er the ftrand.
> Pope.

Our author thinks, and we heartily agree with him, that the amplification in the three laft lines of this verfion highly improves the effect of the picture ; but we cannot confider this amplification as a new idea fuperadded. It was the object of Homer to inform his countrymen, that Brifeis went with the heralds *unwillingly*. This he does by the words ἡ δ' αεκουσ' ἁμα τοισι γυνη κιεν·, and it is by no means improbable, that the rhythmical movement of the verfe may have prefented to the ancient Greeks the image of the lady walking flowly and reluctantly along. This image, we are fure, is not produced by a literal tranflation of the Greek words into Englifh ; and therefore it was Pope's duty, not to add to the ideas of the original, but, by amplification, to prefent to his own countrymen the picture which Homer, by the fuperiority of the Greek language and rhythm, had prefented to his.

In the ninth book of the Iliad, where Phœnix reminds Achilles of the care he had taken of him while an infant, one circumftance, extremely mean, and even difgufting, is found in the original :

> ———ὁτε δη σ' επ' εμοισιν εγω γουνασσι καθισσας
> Οψου τ' ασαιμι προταμων, και οινον επισχων·
> Πολλακι μοι κατεδευσας επι στηθεσσι χιτωνα,
> Οινου αποβλυζων εν νηπιεη αλεγεινη.

The literal verfion of thefe lines is indeed very grofs : "When I placed you before my knees, I crammed you with meat, and gave you wine, which you often vomited upon my bofom, and ftained my clothes, in your troublefome infancy :" but we cannot agree with our author, that the Englifh reader is obliged to Pope for having altogether funk this naufeous image. What is, or ought to be, our object in reading Homer ? If it be merely to delight our ear with fonorous lines, and pleafe our fancy with grand or fplendid images, the tranflator certainly did right in keeping out of view this difgufting picture of favage life ; but when he did fo, he cannot be faid to have given a complete tranfcript of his author's ideas. To pleafe ourfelves, however, with fplendid images, is not our only object when ftudying the works of the ancient poets. Another, and in our opinion a more important object, is to acquire a lively notion of ancient manners ; and if fo, Pope grofsly milleads the mere Englifh reader, when, inftead of the beaftly image of Homer, he prefents him with the following fcene, which he may daily meet with in his own family, or in the families of his friends :

> Thy infant breaft a like affection fhow'd,
> Still in my arms, an ever pleafing load ;
> Or at my knee, by Phœnix would'ft thou ftand,
> No food was grateful but from Phœnix hand :
> I pafs my watchings o'er thy helplefs years,
> The tender labours, the compliant cares.

This is a picture of the domeftic manners of Great Britain in the 19th century, and not of Greece in the heroic ages.

In the beginning of the eighth book of the Iliad, Homer puts into the mouth of Jove a very ftrange fpeech, ftuffed with braggart vaunting and ludicrous images. This, as our author obferves, is far beneath the dignity of the thunderer ; but it is only beneath the dignity of the thunderer as our habits and modes of thinking compel *us* to conceive fuch a being. The thunderer of the Greeks was a notorious adulterer and fodomite, whofe moral character finks beneath that of the meaneft of our bravos ; and as he had dethroned his father, and waged for fome time a doubtful war with certain *earthly* giants, it does not appear to us that the boafting fpeech which Homer puts into his mouth is at all unfuitable to his acknowledged attributes. But whether it be or not, was not the tranflator's concern. Homer, when he compofed it, certainly thought it not unworthy of the thunderer ; and whatever Pope's opinion might be, he had no right to fubftitute his own notions of propriety for thofe of his author. The mythological tales of the poets, and more efpecially of Homer and Hefiod, conftituted, as every one knows, the religious creed of the vulgar Greeks (fee Polytheism, n° 33. *Encycl.*) ; and this circumftance makes it doubly the duty of a tranflator to give, on fuch fubjects, a fair tranfcript of his author's ideas, that the mere Englifh reader, for whom he writes, may know what the ancients really thought of the objects of their idolatrous worfhip. This Pope has not done in the fpeech under confideration ; and has therefore, in our opinion, deviated widely from the firft and moft important of the three general laws of tranflation. Johnfon has apologized, we think fufficiently, for many of Pope's embellifhments of his author ; but he has not attempted to make an apology for fuch embellifhments as alter the fenfe. We cannot indeed conceive a pretence upon which it can ever be allowable in a tranflator to add to the ideas of his author, to retrench, or to vary them. If he be tranflating hiftory, and find his author advancing what he *believes* to be falfe, he may correct him in a note ; but he has no right to make one man utter, as his own, the belief or the fentiments of another, when that belief, and thofe fentiments, are *not* his own. If he be tranflating a work of fcience, he may likewife correct the errors of his author in notes, as Dr Clerke corrected thofe of Rohault ; but no man has a right to give to a Rohault the fcience of a Newton. The tranflator of a poem may certainly employ amplification to place in a ftriking light the images or the fentiments of the original work ; but he muft not alter thofe images or fentiments fo as to make that appear grand or elegant in the verfion, which is mean or difgufting in the original. On every occaſion on which he takes ſuch liberties as theſe, he ceaſes to be a tranſlator, and becomes a faithleſs paraphraſt.

The ſecond general law of tranſlation, though certainly leſs important, is perhaps more difficult to be obſerved than the firſt. We have ſtated it in theſe words: (See Translation, *Encycl.*) "The ſtyle and manner of the original ſhould be preſerved in the tranſlation;" but it is obvious, that this cannot be done by him who poſſeſſes not ſufficient taſte and judgment to aſcertain with preciſion to what claſs the ſtyle of the original belongs. "If a tranſlator fail in this diſcernment, and want this capacity, let him be ever ſo thoroughly maſter of the ſenſe of his author, he will preſent him through a diſtorting medium, or exhibit him in a garb that is unſuitable to his character." It would obviouſly be very improper to tranſlate the elegantly ſimple language of Cæſar into rounded periods like thoſe of *The Rambler*, or the Orations of Cicero into the language of Swift.

The chief characteriſtic of the hiſtorical ſtyle of the ſacred Scriptures is its ſimplicity; and that ſimplicity is, for the moſt part, well preſerved in the authoriſed verſion. It is, however, loſt in many of the modern verſions. Caſtalio's, for inſtance, though intitled to the praiſe of elegant latinity, and though, in general, faithful to the ſenſe of the original, yet exhibits numberleſs tranſgreſſions of the law which is now under conſideration. Its ſentences are formed in long and intricate periods, in which many ſeparate members are artfully combined; and we obſerve a conſtant endeavour at claſſical phraſeology and ornamented diction, inſtead of the beautiful ſimplicity of the original.

The verſion of the Scriptures by Arias Montanus is, in ſome reſpects, a contraſt to that of Caſtalio. By adopting the literal mode of tranſlation, Arias undoubtedly intended to give as faithful a picture as he could, both of the ſenſe and of the manner of the original. Not attending to the peculiar idioms of the Hebrew, Greek, and Latin tongues, which, in ſome reſpects, are very different from each other, he has, by giving to his Latin the combination and idioms of the two firſt of theſe languages, ſometimes made the ſacred writers talk abſurdly. In Latin, as every ſchool-boy knows, two negatives make an affirmative, whilſt in Greek they add force to the negation. Χωρις εμου ου δυνασθε ουδεν ſignifies, "Without me ye can do nothing," or, "Ye cannot *poſſibly* do any thing;" but Arias has tranſlated the words *ſine me non poteſtis facere nihil*, *i. e.* "without me ye cannot do nothing," or, "ye *muſt* do ſomething," which is directly contrary to the meaning of our Lord. It is not therefore by tranſlating literally or verbally that we can hope to preſerve the ſtyle and manner of the original.

To expreſs in florid or elevated language the ideas of an author who writes himſelf in a ſimple ſtyle, is not to give in the verſion a juſt picture of the original; but to attempt, for the ſake of verbal accuracy, to introduce into one language the peculiar idioms or conſtruction of another, is ſtill worſe; as in this mode of tranſlation the ſenſe, as well as the manner of the original, is loſt. The rule obviouſly is to uſe, in the verſion, the words and phraſeology which we have reaſon to believe that the author would himſelf have uſed, had he been maſter of the language into which we are tranſlating his ideas. Thus, if we are to tranſlate into Engliſh a piece of elegantly ſimple Greek or Latin, we muſt make ourſelves completely maſter of the author's meaning, and, neglecting the Greek or Latin *idioms*, expreſs that meaning in elegantly ſimple Engliſh. We need not add, that when the language of the original is florid or grand, if that ſtyle be ſuited to the ſubject, the language of the tranſlation ſhould be florid or grand likewiſe; but care muſt always be taken that perſpicuity be not ſacrificed to ambitious ornaments of any kind; for ornaments which obſcure the ſenſe are worſe than uſeleſs.

If theſe reflections be juſt, it is obvious that a poem cannot be properly tranſlated into proſe. The mere ſenſe may doubtleſs be thus transferred from one language into another, as has generally been done by Macpherſon in his hobbling verſion of the Iliad, and perhaps more completely by a late tranſlator of Anacreon; but in ſuch a verſion, the ſtyle and manner of the original muſt neceſſarily be loſt. Of this the following accurate proſe tranſlation of Anacreon's ninth ode (on a dove) is a ſtriking inſtance:

"O lovely Pigeon! whence, whence do you fly? Whence, ſpeeding through the air, do you breathe, and diſtil ſo many perfumes? Who is your maſter? For it concerns me to know. 'Anacreon ſent me to a youth, —to Bathyllus, at preſent the prince, and diſpoſing of all things. Venus ſold me, receiving a little hymn in return. And I ſerve Anacreon in ſuch tranſactions as theſe: and now I carry his letters, ſuch as you ſee: and he affirms that he will immediately make me free. But I will remain a ſervant with him although he may diſmiſs me: For wherefore does it behove me to fly, both over mountains, and fields, and to perch on trees, devouring ſome ruſtic food? Now indeed I eat bread, ſnatching it from the hands of Anacreon himſelf; and he gives to me the wine to drink which he drinks before me; and having drunk, I perhaps may dance, and cover my maſter with my wings: then going to reſt, I ſleep upon the lute itſelf. You have it all;—begone: you have made me more talkative, O mortal! than even a jay *."

How inferior is the general effect of this piece of proſe to that of the well known poetical verſions of Addiſon and Johnſon? and yet the mere *ideas* of the original are perhaps more faithfully tranſcribed by this anonymous writer than by either of thoſe elegant tranſlators. The emotions indeed excited by the original are not here brought into view.

* *The Ode of Anacre[on] tranſlated into Engli[ſh] proſe, prin[t]ed at York* 1796.

The third general law of tranſlation is ſo nearly allied to the ſecond, that we have very few directions to give for the obſervation of it. He who, in his verſion, preſerves the ſtyle and manner of the original, as we have endeavoured to ſhew that they *ought* to be preſerved, will, of courſe, give to the tranſlation the eaſe of original compoſition. The principal difficulty that he has to encounter in this part of his taſk, will occur in the tranſlating of idiomatical and proverbial phraſes. Hardly any two languages are conſtructed preciſely in the ſame way; and when the ſtructure of the Engliſh language is compared with that of the Greek and Latin, a remarkable difference between the ancient and modern tongues is found to pervade the whole. This muſt occaſion very conſiderable difficulty; but it is a difficulty which will be removed by a due obſervance of the

former

former law, which directs the translator to make his author speak English in such a style to Englishmen as he spoke his own tongue to his own countrymen, and of course to use the English idiom with English words. But what is to be done with those proverbial phrases of which every language has a large collection, and which allude to local customs and manners?

The ingenious author of the Essay so often quoted, very properly observes, in answer to this question, that the translation is perfect when the translator employs, in his own language, an idiomatic phrase corresponding to that of the original. "It is not (says he) possible perhaps to produce a happier instance of translation by corresponding idioms, than Sterne has given * in the translation of Slawkenbergius's tale. *Nihil me penitet hujus nasi*, quoth Pamphagus; that is, "My nose has been the making of me." *Nec est cur pœniteat*; that is, "How the deuce should such a nose fail?" *Miles peregrini in faciem suspexit!* "The centinel looked into the stranger's face. Never saw such a nose in his life!"

* *Tristram Shandy.*

"As there is nothing (continues our author) which so much conduces both to the ease and spirit of composition as a happy use of idiomatic phrases, there is nothing which a translator, who has a moderate command of his own language, is so apt to carry to an extreme." Of this he gives many striking examples from Echard's translations of Terence and Plautus, for which we must refer the reader to the Essay itself. He observes, likewise, that in the use of idiomatic phrases, a translator frequently forgets both the country of his original author, and the age in which he wrote; and while he makes a Greek or Roman speak French or English, he unwittingly puts into his mouth allusions to the manners of modern France or England. This, to use a phrase borrowed from painting, may be termed an offence against the *costume* The proverbial expression βατραχῳ ὑδωρ, in Theocritus, is of similar import with the English proverb, *to carry coals to Newcastle*; and the Scotch, *to drive salt to Dysart*; but it would be a gross impropriety to use either of these expressions in the translation of an ancient classic. Of such improprieties our author points out many instances both in French and English translations of the classics; and he might have increased the number by quotations from Blackwell's Memoirs of the Court of Augustus, where, instead of Roman senators and their wives, we meet with modern gentlemen and ladies, with *secretaries at war*, *paymasters*, *commissary generals*, and *lord high admirals*. It is true the Memoirs of the Court of Augustus is no translation; but with respect to costume, it is necessarily subject to the laws of translation.

Offences against costume are often committed by the use of improper words as well as of improper phrases. To introduce into dignified and solemn composition words associated with mean and ludicrous subjects, is equally a fault in an original author and in a translator; and it is obviously improper, in the translation of works of very high antiquity, to make use of words which have but lately been admitted into the language of the translator. Faults of this kind are very frequent in Dr Geddes's translation of the Bible, as when the *passover* is called the *skipover*; the tabernacle of the congregation, the *convention tent*; and a burnt-offering, a *holocaust*. The first of these expressions presents to the imagination an image profanely ludicrous; the second, brings into our view the French Convention, which, we suspect, occupied no small portion of the Doctor's thoughts, when they should have been wholly employed on the sacred text; and the word *holocaust*, which must be unintelligible to the mere English reader, is, in the mind of every man of letters, closely associated with the abominable rites performed at the sacrifices of the ancient heathens. But it is needless to point out faults of this kind in a work which is open to more serious objections, and which, we trust, shall never be generally read. We are sorry that truth compels us to say, that the novel expressions introduced by Dr Campbell into his version of the gospels—such as *confluence* for multitude, and *reign* for kingdom—are, to say the best of them, no improvements of the authorised version. We will not rank them with Dr Geddes's innovations, because we will not class the great author of the *Dissertation on Miracles* with a paradoxical Christian of no communion; but we do not think that Dr Campbell's laurels were freshened on his brow by the translation of the Gospels.

We shall conclude this article with the following reflections, taken from the Essay which has been so often quoted:

"If the order in which we have classed the three general laws of translation be their just and natural arrangement, which, we presume, will hardly be denied, it follows, that, in every case where it is necessary to make a sacrifice of one of these laws to another, a due regard ought to be paid to their rank and comparative importance. When the genius of the original language differs much from that of the translation, it is often necessary to depart from the author's manner in order to convey a faithful picture of his sense; but it would be highly preposterous to depart, in any case, from the sense, for the sake of imitating the manner. Equally improper would it be, to sacrifice either the sense or manner of the original, if these can be preserved consistently with purity of expression, to a fancied ease or superior gracefulness of composition; and it is certain that the sense may always be preserved, though to purity of expression the manner of the original must sometimes be sacrificed."

TRAPEZOID, sometimes denotes a trapezium that has two of its sides parallel to each other; and sometimes an irregular solid figure, having four sides not parallel to each other.

TRAVERSE, in gunnery, is the turning a piece of ordnance about, as upon a centre, to make it point in any particular direction.

TRAVERSE, in fortification, denotes a trench with a little parapet, sometimes two, one on each side, to serve as a cover from the enemy that might come in flank.

TRAVERSE, in a wet foss, is a sort of gallery, made by throwing saucissons, joists, fascines, stones, earth, &c. into the foss, opposite the place where the miner is to be put, in order to fill up the ditch, and make a passage over it.

TRAVERSE also denotes a wall of earth, or stone, raised across a work, to stop the shot from rolling along it.

TRAVERSE also sometimes signifies any retrenchment, or line fortified with fascines, barrels, or bags of earth, or gabions.

TRAVESTY, or burlesque translation, is a species of writing which, as it partakes, in a great degree, of original composition, is not to be measured by the laws of serious translation. It conveys neither a just picture of of the fentiments, nor a faithful reprefentation of the ftyle and manner of the original; but pleafes itfelf in exhibiting a ludicrous character of both. It difplays an overcharged and grotefque refemblance, and excites our rifible emotions by the incongruous affociation of dignity and meannefs, wifdom and abfurdity. This affociation forms equally the bafis of travefty and of ludicrous parody, from which it is no otherwife diftinguifhed than by its affuming a different language from the original. In order that the mimickry may be underftood, it is neceffary that the writer choofe, for the exercife of his talents, a work that is well known, and of great reputation. Whether that reputation is deferved or unjuft, the work may be equally the fubject of burlefque imitation. If it has been the fubject of general but undeferved praife, a parody or a travefty is then a fair fatire on the falfe tafte of the original author and his admirers, and we are pleafed to fee both become the objects of a juft caftigation. The *Rehearfal*, *Tom Thumb*, and *Crononhotonthologos*, which exhibit ludicrous parodies of paffages from the favourite dramatic writers of the times, convey a great deal of juft and ufeful criticifm. If the original is a work of real excellence, the travefty or parody detracts nothing from its merit, nor robs the author of the fmalleft portion of his juft praife. We laugh at the affociation of dignity and meannefs; but the former remains the exclufive property of the original, the latter belongs folely to the copy. We give due praife to the mimical powers of the imitator, and are delighted to fee how ingenioufly he can elicit fubjects of mirth and ridicule from what is grave, dignified, pathetic, or fublime.

But this fpecies of compofition pleafes only in a fhort fpecimen. We cannot bear a lengthened work in travefty. The incongruous affociation of dignity and meannefs excites rifibility chiefly from its being unexpected. Cotton's and Scarron's Virgil entertain but for a few pages: the compofition foon becomes tedious, and at length difgufting. We laugh at a fhort exhibition of buffoonery; but we cannot endure a man who, with good talents, is conftantly playing the fool.

TREACLE (fee *Encycl.*) or MELASSES, is a fubftance very wholefome, but of a tafte difagreeably fweet. Methods have accordingly been propofed for purifying it, fo as that it may, on many occafions, fupply the place of refined fugar, which has long been at a price which a great number of poor perfons cannot afford to pay for what muft now be confidered as a neceffary of life. The following is the procefs for purifying treacle, given by the M. Cadet (Devaux) in the *Feuille du Cultivateur*, founded upon experiments made by Mr Lowitz of Peterfburgh:

Take of treacle 24 lbs. of water 24 lbs. of charcoal, thoroughly burnt, 6 lbs. Bruife the charcoal grofsly, mix the three fubftances in a caldron, and let the mixture boil gently upon a clear wood fire. After it has boiled for half an hour, pour the liquor through a ftraining-bag, and then replace it upon the fire, that the fuperfluous water may be evaporated, and that the treacle may be brought to its original confiftence. There is little or no lofs by this operation, as 24 lbs. of treacle give nearly the fame quantity of fyrup.

This procefs has been repeated in the large way, and has fucceeded: the treacle is fenfibly ameliorated, fo that it may be ufed for many difhes; neverthelefs, thofe with milk, and the fine or aromatic *liqueurs*, are not near fo good as with fugar.

TREBISOND, a large, populous, and ftrong town of Turkey in Afia, in the province of Jenich, with a Greek archbifhop's fee, a harbour and a caftle. It is feated at the foot of a very fteep hill. The walls are fquare and high, with battlements; and are built with the ruins of ancient ftructures, on which are infcriptions not legible. The town is not populous; for there are more woods and gardens in it than houfes, and thefe but one ftory high. The caftle is feated on a flat rock, with ditches cut therein. The harbour is at the eaft end of the town, and the mole built by the Genoefe is almoft deftroyed. It ftands on the Black Sea, 104 miles north-weft of Erzerum, and 440 eaft of Conftantinople. E. Lon. 40° 25′. N. lat. 40° 45′.

TREE. Under this title (*Encycl.*) we gave an account of the method recommended by Meffrs Forfyth and Hitt for curing injuries and defects in trees. The actual cautery is employed in Cevennes, and in the department de l'Allier, in France, for ftopping the progrefs of rottennefs in large trees. When they perceive that this very common and deftructive difeafe begins to make fome progrefs in the chefnut-tree, by excavating its trunk, they collect heath and other combuftible vegetables, and burn them in the very cavity, till the furface is completely converted into a coal. It feldom happens that the tree perifhes by the effect of this operation, and it is always found that this remedy fufpends the progrefs of the decay. It is practifed in the fame manner, and with fimilar fuccefs, on the white oak. When we compare the effects of the actual cautery on the animal fyftem, in fimilar difeafes, a new refemblance is feen between the difeafes which affect the organic beings of both kingdoms, as well as between the remedies by which they may be oppofed.—*Nicholfon's Journal.*

TRIANGLE, ARITHMETICAL, a kind of numeral triangle, or triangle of numbers, being a table of certain numbers difpofed in form of a triangle. It was fo called by Pafcal; but he was not the inventor of this table, as fome writers have imagined, its properties having been treated of by other authors fome centuries before him, as is fhewn in Dr Hutton's Mathematical Tracts, vol. i. p. 69. &c.

The form of the triangle is as follows:

1					
1	1				
1	2	1			
1	3	3	1		
1	4	6	4	1	
1	5	10	10	5	1
1	6	15	20	&c.	
1	7	21	&c.		
1	8	&c.			
1	9				

And it is conftructed by adding always the laft two numbers of the next two preceding columns together, to give the next fucceeding column of numbers.

The firft vertical column confifts of units; the fecond, a feries of the natural numbers 1, 2, 3, 4, 5, &c.; the third, a feries of triangular numbers 1, 3, 6, 10, &c.; the fourth, a feries of pyramidal numbers, &c. The oblique diagonal rows, defcending from left to right, are alfo the fame as the vertical columns. And the numbers taken on the horizontal lines are the co-efficients of the different powers of a binomial. Many other properties and ufes of thefe numbers have been delivered by various authors, as may be feen in the Introduction to Hutton's Mathematical Tables, pages 7, 8, 75, 76, 77, 89, second edition.

TRIANGULAR COMPASSES, are such as have three legs or feet, by which any triangle, or three points, may be taken off at once. These are very useful in the construction of maps, globes, &c.

TRIANGULAR Numbers, are a kind of polygonal numbers; being the sums of arithmetical progressions, which have 1 for the common difference of their terms.

Thus, from these arithmeticals 1 2 3 4 5 6, are formed the triangular numbers 1 3 6 10 15 21, or the third column of the arithmetical triangle above-mentioned.

The sum of any number n of the terms of the triangular numbers, 1, 3, 6, 10, &c. is =

$$\frac{n^3}{6}+\frac{n^2}{2}+\frac{n}{3}, \text{ or } \frac{n}{1}\times\frac{n+1}{2}\times\frac{n+2}{3}$$

which is also equal to the number of shot in a triangular pile of balls, the number of rows, or the number in each side of the base, being n.

The sum of the reciprocals of the triangular series, infinitely continued, is equal to 2; viz.

$$1+\tfrac{1}{3}+\tfrac{1}{6}+\tfrac{1}{10}+\tfrac{1}{15}, \&c. = 2.$$

For the rationale and management of these numbers, see *Malcolm*'s *Arith.* book 5. ch. 2.; and *Simpson*'s *Algeb.* sec. 15.

TRIESTE, a small, but strong and ancient seaport of Italy, in Istria, on the gulph of Venice, with a bishop's see. It is beautifully situated on the side of a hill, about which the vineyards form a semicircle. The streets are narrow; but there is a large square, where they keep the annual fair. The harbour is spacious, but not good; because it is open to the W. and S. W. winds. The inhabitants have a good trade in salt, oil, almonds, iron, &c. brought from Laubach; and they make good wines. The cathedral, and the late Jesuits church, are the two best buildings. It belongs to the House of Austria, and is eight miles north of Capo d'Istria, and 80 north-east of Venice. E. Long. 14. 4. N. Lat. 45. 56.

TRINITARIANS (Order of), was instituted at Rome in the year 1198, under the pontificate of Innocent III. the founders whereof were John de Matha and Felix de Valois. His Holiness gave them permission to establish this order for the deliverance of captives, who groaned under the tyranny of the infidels: he gave them as a habit a white gown, ornamented with a red and blue cross. After the death of the two founders, Pope Honorious III. continued the order; and their rule was approved by his successor Clement IV. in 1367. At first they were not permitted to eat flesh; and when they travelled, were to ride only upon asses. But their rule was corrected and mitigated by the bishop of Paris, and the abbots of St Victor and St Genevieve, who allowed them to eat any kind of food, and to use horses. This order possessed, at one time, about 250 convents in 13 different provinces: six of which were in France; namely, France, Normandy, Picardy, Champaine, Languedoc, and Provence; three in Spain, viz. New Castile, Old Castile, and Arragon; one in Italy, and one in Portugal. There was formerly the province of England, where this order had 43 houses; that of Scotland, where it had nine; and that of Ireland, where it had 52; besides a great number of monasteries in Saxony, Hungary, Bohemia, and other countries. The convent of Cerfroy in France was head of the order. It is impossible for us to say what is now the state of the order, which can have no visible existence in France, and is probably suppressed even in Italy.

TRIONES, in astronomy, a sort of constellation, or assemblage of seven stars in the Ursa Major, popularly called *Charles's Wain.*—From the *septem triones* the north pole takes the denomination *septentrio.*

TRIPOLI OF SYRIA is, according to Mr Browne, by no means so populous a place as we were led to represent it in the *Encyclopædia.* It is indeed, he says, a city of some extent, situated about a mile and a half from the sea; but instead of sixty, he estimates its population at about sixteen thousand. The air is rendered unwholesome by much stagnant water. The town is placed on a slight elevation, the length considerably exceeding the breadth. On the highest ground, to the south, is the castle, formerly possessed by the earls of Tripoli; it is large and strong. Hence is visible a part of mount Libanus, the summit of which is covered with snow. The gardens in the vicinity are rich in mulberry and other fruit trees. The city is well built, and most of the streets are paved.

Here is found a number of Mahommedan merchants, some of the richest and most respectable in the empire. Silk is the chief article of commerce.

The *miri*, or fixed public revenue paid by Tripoli to Constantinople, is only about L.1000 Sterling, 20 purses, a-year. Syria at present contains only four Pashaliks, Damascus, Aleppo, Acré, and Tripoli; the last of which is the smallest in territory and power. Our author observed no antiquities at Tripoli; but the country round it is noted for producing the best tobacco in Syria.

TRISECTION, the dividing a thing into three equal parts. The term is chiefly used in geometry, for the division of an angle into three equal parts. The *trisection of an angle* geometrically, is one of those great problems, whose solution has been so much sought for by mathematicians for 2000 years past; being, in this respect, on a footing with the famous quadrature of the circle, and the duplicature of the tube.

TRISTAN D'ACHUNA, the largest of three islands which were visited by Lord Macartney and his suite on the 31st of December 1792. The other two are distinguished by the names of *Inaccessible* and *Nightingale* islands. "Inaccessible (as Sir Erasmus Gower observed) seems to deserve that name, being a high, bluff, as well as apparently barren plain, about nine miles in circumference, and has a very forbidding appearance. There is a high rock detached from it at the south end. Its latitude is 37° 19′ south; its longitude 11° 50′ west from Greenwich. This rude-looking spot may be seen at 12 or 14 leagues distance. Nightingale island is irregular in its form, with a hollow in the middle, and is about seven or eight miles in circumference, with small rocky isles at its southern extremity. It is described as having anchorage on the north-east side. Its latitude is 37° 29′ south; and longitude 11° 48′ west from Greenwich. It may be seen at seven or eight leagues distance. The largest of these three islands, which comparatively may be called the great isle of *Tristan d'Acunha*, is very high, and may be seen at 25 leagues distance. It seems not to exceed in circumference 15 miles. A part of the island towards the north rises perpen-

perpendicularly from the fea to a height apparently of a thoufand feet or more. A level then commences, forming what among feamen is termed *table land*, and extending towards the centre of the ifland; from whence a conical mountain rifes, not unlike in appearance to the Peak of Teneriffe, as feen from the bay of Santa Cruz. Boats were fent to found and to examine the fhore for a convenient place to land and water. In confequence of their report, the Lion (a fhip of 64 guns) ftood in, and came to anchor in the evening on the north fide, in 30 fathoms water, one mile from the fhore; the bottom black fand with flime; a fmall rock, off the weft point, bearing fouth-weft by fouth, juft open with the weftern extremity of the ifland; a cafcade, or fall of water, emptying itfelf upon the beach, fouth by eaft. All the fhore, from the fouthern point to the eaftern extremity, appears to be clear of danger, and fteep, except the weft point, where there are breakers about two cables length, or near 500 yards from the fhore. The fhip, when anchored, was overfhadowed by the dark mafs of that portion of the ifland whofe fides feemed to rife, like a mofs-grown wall, immediately from the ocean. On the right the elevation was lefs rapid, and between the rifing part and the fea was left a flat, of fome extent, covered with fedge grafs, interfperfed with fmall fhrubs, which, being perfectly green, looked from the fhip like a pleafant meadow, watered by a ftream that fell, afterwards, from its banks upon the beach. The officers, who went afhore, reported, that the cafks might be filled with frefh water by means of a long hofe, without moving them from the boats. The landing place thereabouts was alfo defcribed as being fafe, and fuperior to any other that had been examined. From the plain, the land rofe gradually towards the central mountain, in ridges covered with trees of a moderate fize and height. The coaft abounded with fea lions and feals, penguins and albatroffes. One of the latter was brought on board, his wings meafuring ten feet from tip to tip; but others are faid to have been found much larger. The coaft was covered with a broad fea weed, feveral fathoms long, and defervedly by naturalifts termed *gigantic fucus*. Some good fifh was caught with the hook and line.

"The accident of a fudden guft, by which the anchor was in a few hours driven from its hold, and the fhip forced out to fea, prevented the ifland from being explored, as was intended. It is probable that had the Lion anchored in 20, inftead of 30 fathoms water, the anchor would have held firmly. Some advantage was obtained, however, from coming to this place. The juft pofition of thofe iflands, in refpect to their longitude, was afcertained, by the mean of feveral time-pieces, to be about two degrees to the eaftward of the place where they are laid down in charts, taken from obfervations made at a period when the inftruments for this purpofe were lefs accurate than at prefent. The fpot where the Lion anchored was determined, by good meridional obfervations, and by accurate time-pieces, to be 37° 6′ fouth latitude, and 11° 43′ weft longitude from Greenwich. The compafs had feven degrees of variation weftward from the pole. Fahrenheit's thermometer ftood at 67 degrees. It was ufeful alfo to have afcertained, that a fafe anchorage, and plenty of good water, were to be found here. Thefe iflands are certainly worthy of a more particular inquiry; for they are not 50 leagues from the general track of veffels bound to China, and to the coaft of Coromandel, by the outer paffage. In war time, an excellent rendezvous might be fettled there, for fhips that wanted no other fupply but that of water. When circumftances require particular difpatch, it is practicable to come from England to Triftan d'Acunha without ftopping in the way, and afterwards to the end of the voyage to India or China."

Thefe iflands are feparated by a fpace of about fifteen hundred miles from any land to the weftward or northward of them. They are fituated in that part of the fouthern hemifphere, in the neighbourhood of which a continent, to balance the quantity of land in the northern hemifphere, was once expected to be found, but where it has been fince difcovered that there is none. Of what extent, however, the bafes of thefe iflands are under the furface of the fea, cannot be afcertained; or whether they may, or may not, be fufficient to make up for the defect of land appearing above water. Navigators report, that to the eaftward of them are other fmall iflands, differing not much in latitude, fuch as Gough and Alvarez iflands, and the Marfouines; as well as extenfive fhoals, lying due fouth of the moft foutherly point of Africa, and extending eafterly feveral degrees. That all thefe together form a chain, fome of fubaqueous, and fome of fuperaqueous mountains, but all connected by their roots, is perhaps a conjecture lefs improbable, than that they fhould feparately arife, like tall columns, from the vaft abyfs.

A fettlement in Triftan d'Acunha is known to have been twice in the contemplation of adventurers, but not as yet to have been carried into execution. One had the project of rendering it a mart for the change of the light manufactures of Hindoftan, fuited to hot climes, for the filver of the Spanifh fettlements in South America; in the route between which places it is conveniently fituated. The other plan meant is only as a fuitable fpot for drying and preparing the furs of fea lions and feals, and for extracting the fpermaceti of the white or long-nofed whale, and the whale-bone and oil of the black fpecies. Whales of every kind were feen fporting about Triftan d'Acunha, particularly near the fetting of the fun; and the fword-fifh likewife made its appearance occafionally.—*Sir George Staunton's Account of the Embaffy to China.*

TRITON, in zoology, a genus belonging to the order of vermes mollufca. The body is oblong; the tongue is fpiral; it has twelve tentacula, fix on each fide, the hindmoft ones having claws like a crab. There is but one fpecies, found in holes of rocks about the fhore.

TROTTER (Mrs Catharine), was the daughter of Captain David Trotter, a Scotch gentleman. He was a commander in the royal navy in the reign of Charles II. and at his death left two daughters, the youngeft of whom, Catharine, our celebrated author, was born in London, Auguft 1679. She gave early marks of her genius; and learned to write, and alfo made herfelf miftrefs of the French language, by her own application and diligence, without any inftructor; but fhe had fome affiftance in the ftudy of the Latin grammar and logic; of which latter fhe drew up an abftract for her own ufe. The moft ferious and important fubjects, and efpecially religion, foon engaged her attention.—But notwithftanding her education, her intimacy with feveral families of diftinction of the Romifh perfuafion, expofed her, while very young, to impreffions in favour of

Trotter. of that church; which not being removed by her conferences with some eminent and learned members of the church of England, she embraced the Romish communion, in which she continued till the year 1707. In 1695, she produced a tragedy called *Agnes de Castro*, which was acted at the theatre-royal when she was only in her 17th year. The reputation of this performance, and the verses which she addressed to Mr Congreve upon his Mourning Bride, in 1697, were probably the foundation of her acquaintance with that celebrated writer. Her second tragedy, *Fatal Friendship*, was acted in 1698, at the new theatre in Lincoln's-Inn-Fields. This tragedy met with great applause, and is still thought the most perfect of her dramatic performances. Her dramatic talents not being confined to tragedy, she brought upon the stage, in 1701, a comedy called *Love at a loss*, or *Most votes carry it*. In the same year she gave the public her third tragedy, entitled the *Unhappy Penitent*, acted at the theatre-royal in Drury-lane. But poetry and dramatic writing did not so far engross the thoughts of our author but that she sometimes turned them to subjects of a very different nature; and distinguished herself in an extraordinary manner in defence of Mr Locke's writings; a female metaphysician being a remarkable phenomenon in the republic of letters.

She turned to the exercise of her dramatic genius in 1703, and fixed upon the revolution of Sweden, under Gustavus Erickson, for the subject of a tragedy. This tragedy was acted, in 1706, at the Queen's theatre in the Hay-Market. In 1707, her doubts concerning the Romish religion, which she had so many years professed, having led her to a thorough examination of the grounds of it, by consulting the best books on both sides of the question, and advising with men of the best judgment, the result was a conviction of the falseness of the pretensions of that church, and a return to that of England, to which she adhered during the remainder of her life. In 1708, she was married to the Rev. Mr Cockburn, then curate of St Dunstan's in Fleet-street, but he afterwards obtained the living of Long-Horsely, near Morpeth in Northumberland. He was a man of considerable abilities; and, among several other things, wrote an account of the Mosaic Deluge, which was much approved by the learned.

Mrs Cockburn's remarks upon some writers in the controversy concerning the foundation of moral duty and moral obligation, were introduced to the world, in August 1743, in the Literary Journal, intitled *The History of the Works of the Learned.* The strength, clearness, and vivacity shewn in her remarks upon the most abstract and perplexed questions, immediately raised the curiosity of all good judges about the concealed writer; and their admiration was greatly increased when her sex and advanced age were known. Dr Rutherforth's Essay on the Nature and Obligations of Virtue, published in May 1744, soon engaged her thoughts; and notwithstanding the asthmatic disorder which had seized her many years before, and now left her small intervals of ease, she applied herself to the confutation of that elaborate discourse, and finished it with a spirit, elegance, and perspicuity equal, if not superior, to all her former writings.

The loss of her husband in 1748, in the 71st year of his age, was a severe shock to her; and she did not long survive him, dying on the 11th of May 1749, in her 71st year, after having long supported a painful disorder with a resignation to the Divine will, which had been the governing principle of her whole life, and her support under the various trials of it.

Her works are collected into two large volumes 8vo, by Dr Birch; who has prefixed to them an account of her life and writings.

Trumpet Marine. TRUMPET Marine, or Marigny. This is a stringed instrument, invented in the 16th century by an Italian artist Marino or Marigni, and called a *trumpet*, because it takes only the notes of the trumpet, with all its omissions and imperfections, and can therefore execute only such melodies as are fitted for that instrument. It is a very curious instrument, though of small musical powers, because its mode of performance is totally unlike that of other stringed instruments; and it deserves our very particular attention, because it lays open the mechanism of musical sounds more than anything we are acquainted with; and we shall therefore make use of it in order to communicate to our readers a philosophical theory of music, which we have already treated in detail as a liberal or scientific art.

The trumpet marine is commonly made in the form of a long triangular pyramid, ABCD, fig. A. on which a single string EFG is strained over a bridge F by means of the finger pin L. At the narrow end are several frets 1, 2, 3, 4, 5, &c. between E and K, which divide the length EF into aliquot parts. Thus E 1 is $\frac{1}{11}$ of EF, E 2 is $\frac{1}{11}$, and so on. The bow is drawn lightly across the cord at H, and the string is stopped by pressing it with the finger immediately above the frets, but not so hard as to make it touch the fret. When the open string is sounded, it gives the fundamental note. If it be stopped, in the way now described, at $\frac{1}{3}$d of its length from E, it yields the 12th of the fundamental; if stopped at $\frac{1}{4}$th, it gives the double octave; if at $\frac{1}{5}$th, it gives the 17th major, &c. In short, it always gives the note corresponding to the length of the part between the fret and the note E. The sounds resemble those of a pipe, and are indeed the same with those known by the name *harmonics*, and now executed by every performer on instruments of the viol or violin species. But in order to increase the noise, the bridge F is constructed in a very particular manner. It does not rest on the sound-board of the instrument through its whole breadth, but only at the corner *a*, where it is firmly fixed. The other extremity is detached about $\frac{1}{100}$th of an inch from the sound board; and thus the bridge, being made to tremble by the strong vibration of the thick cord, rattles on the sound-board, or on a bit of ivory glued to it. The usual way in which this motion is procured, is to have another string passing under the middle of the bridge in such a manner that, by straining it tight, we raise the corner *b* from the sound board to the proper height. This contrivance increases prodigiously the noise of the instrument, and gives it somewhat of the smart sound of the trumpet, tho' very harsh and coarse. But it merits the attention of every person who wishes to know any thing of the philosophy of musical sounds, and we shall therefore say as much on the subject as will conduce to this effect. Plate XLV.

Galileo, as we have observed in the article Temperament, *Suppl.* was the first who discovered the real connection between mathematics and music, by demonstrating that the times of the vibrations of elastic cords of of the fame matter and fize, and ftretched by equal weights, are proportional to the lengths of the ftrings. He inferred from this that the mufical pitch of the found produced by a ftretched cord depended folely on the frequency of the vibrations. Moreover, not being able to difcover any other circumftance in which thofe founds phyfically refembled each other, and reflecting that all founds are immediately produced by agitations of air acting on the ear, he concluded that each vibration of the cord produced a fonorous pulfe in the air, and therefore that the pitch of *any* found whatever depended on the frequency of the aerial pulfes. In this way alone the found of a ftring, of a bell, of an organ pipe, and the bellow of a bull, may have the fame pitch. He could not, however, demonftrate this in any cafe but the one above mentioned. But he was encouraged to hope that mathematicians would be able to demonftrate it in all cafes, by his having obferved that the fame proportions obtained in organ pipes as in ftrings ftretched by equal weights. But it required a great progrefs in mechanical philofophy, from the ftate in which Galileo found it, before men could fpeculate and reafon concerning the pulfes of air, and difcover any analogy between them and the vibrations of a ftring. This analogy, however, was difcovered, and its demonftration completed, as we fhall fee by and by. In the mean time, Galileo's demonftration of the vibrations of elaftic cords became the foundation of all mufical philofophy. It muft be thoroughly underftood before we can explain the performance of the trumpet marine.

The demonftration of Galileo is remarkable for that beautiful fimplicity and perfpicuity which diftinguifh all the writings of that great mechanician, and it is the elementary propofition in all mechanical treatifes of mufic. Few of them indeed contain any thing more; but it is extremely imperfect, and is juft only on the fuppofition that all the matter of the ftring is collected at its middle point, and that the reft of it has elafticity without *inertia*. This did not fuit the accurate knowledge of the 17th century, after Huyghens and Newton had given the world a tafte of what might be done by profecuting the Galilean mechanics. When a mufical cord has its middle point drawn afide, and it is strained into the fhape of two ftrait lines, if it be let go, it will be obferved not to vibrate in this form. It may eafily be feen in the extremity of its excurfions, where it refts, before it return by its elafticity. The reafon is this (fee fig. B.) When the middle point C of the cord is drawn afide, and the cord has the form of two ftraight lines AC, CB, this point C, being pulled in the directions CA, CB, at once, is really accelerated in the direction CD, which bifects the angle ACB; and if it were then detached from the reft of the material cord, it would move in that direction. But any other point *f* between C and B has no accelerating force whatever acting on it. It is equally pulled in the directions *f* C and *f* B. The particle C therefore is obliged to drag along with it the inert matter of the reft of the cord; and when it has come to any intermediate fituation *c*, the cord cannot have the form of two ftraight lines A *c*, *c* B, with the particle *f* fituated in *f*. This particle will be left fomewhat behind, as in φ, and the cord will have a curved form A *c* φ B; and in this form it will vibrate, going to the other fide, and affuming, not the rectilineal form ADB, but the curved form A δ B. That every particle of the curve A *e c* φ *f* B is now accelerated toward the axis AB is evident, becaufe every part is curved, and the whole is ftrained toward A and B, which tends to ftraiten every part of it. But in order that the whole may arrive at the axis in one moment, and conftitute a ftraight line AB, it is evidently neceffary that the accelerating force on every particle be as the diftance of the particle from that point of the axis at which it arrives. It is well known to the mathematician that the accelerating force by which any particle is urged towards a rectilineal pofition, with refpect to the adjoining particles, is proportional to the curvature. Our readers, who are not familiar with fuch difcuffions, may fee the truth of this fundamental propofition by confidering the whole of A *c* B as only a particle or minute portion of a curve, magnified by a microfcope. The force which ftrains the curve may be reprefented by *c* A or AE. Now it is well known (and is the foundation of Galileo's demonftration) that the ftraining force is to the force with which *c* is accelerated in the direction *c* E as A *c* to *c* D, or as AE to *c* D, or as AE to twice *c* E. Now *c* E is the meafure of the curvature of A *c* B, being its deflection from a right line. Therefore when the ftraining force is the fame all over the curve, the accelerating force, by which any portion of it tends to become ftraight, is proportional to the curvature of that portion. And if *r* be the radius of a circle paffing through A, *c*, and B, and coinciding with this element of a curve, it is plain that $c\,D : c\,A = c\,A : r$, or that the radius of curvature is to the element *c* A as the extending force to the accelerating force; and $c\,D = \frac{c\,A^2}{r}$; and is inverfely as *r*, or directly as the curvature.

Hence we fee the nature of that curve which a mufical cord muft have, in order that all its parts may arrive at the axis at once. The curvature at *c* muft be to the curvature at *f* as E *c* to *g f*. But this may not be enough. It is farther neceffary that when *c* has got half way to E, the curvature in the different points of the new curve into which the cord has now arranged itfelf, be alfo, in every point, proportional to the diftance from the axis. Now this *will* be the cafe if the extreme curve has been fuch. For, taking the cord in any other fucceffive fhape, the diftance which each point has gone in the fame moment muft be proportional to the force which impelled it; therefore the remaining diftances of all the points from the axis will have the fame proportions as before. And the geometrical and evident confequence of this is, that the curvatures will alfo be in the fame proportion.

Therefore a cord that is once arranged in this form will always preferve it, and will vibrate like a cycloidal pendulum, performing its ofcillations in equal times, whether they be wide or narrow. Therefore fince this perfect ifochronifm of vibrations is all that is wanted for preferving the fame mufical pitch or tone, this cord will always have the fame note.

This propofition was the difcovery of Dr Brooke Taylor, one of the ornaments of our country *, and is publifhed in his celebrated work *Methodus Incrementorum*. The inveftigation, however, and the demonftration in that work, are fo obfcure and fo tedious that few had patience to perufe them. It was more elegantly treated afterwards by the Bernoullis and others. The curve

* See his life, *Encyc.*

curve got the name of the *Taylorean curve;* and is considered by many eminent mathematicians as a trochoid, *viz.* the curve defcribed by a point in the nave or fpoke of a wheel while the wheel rolls along a ftraight line. But this is a miftake, although it is allied to the trochoid in the fame manner that the figure of fines is allied to the cycloid. Its phyfical property intitles it to the name of the HARMONICAL CURVE. As this curve is not only the foundation of all our knowledge of the vibration of elaftic cords, but alfo furnifhes an equation which will lead the mathematician through the whole labyrinth of aereal undulations, and be of ufe on many other occafions; and as the firft mathematicians have, through inattention, or through enmity to Dr Taylor, affected to confider it as the trochoid already well known to themfelves—we fhall give a fhort account of its conftruction and chief properties, fimplified from the elegant defcription given by Dr Smith in his Harmonics.

Let SDTV, QERP (fig. C.), be circles defcribed round the centre C. Draw the diameters QCR, ECP, cutting each other at right angles. From any point G in the exterior circle draw the radius GC, cutting the interior circle in F, draw KHFI parallel to QCR, and make HI, HK, each equal to the arch EG. Let this be done for every point of the quadrantal arch EGR. The points I, K, are in the harmonic curve; that is, the curve AKDIB paffing through the points K and I, determined by this conftruction, has its curvature in every point K proportional to the diftance KN from the bafe AB.

To demonftrate this, draw FL perpendicular to the axis, and join EL. Take another point g in the outer circle indefinitely near to G. Draw $g\,c$, cutting the inner circle in f, and $f\,h$ and $f\,l$ perpendicular to DC, CT, and join E l. Then fuppofe two lines K m' K m' perpendicular to the curve in K and k. They muft meet in m', the centre of the equicurve circle. Draw KN n' perpendicular to the bafe, and $m'\,n'$ parallel to it, and join $k\,n$. Laftly, draw XL x perpendicular to EL.

It is plain that k O, the difference of HK and $h\,k$, is equal to Gg, the difference of GE and g E, and that KO is equal to F r, and L l to $r\,f$. Alfo, becaufe ELX is a right angle, $\text{EX} = \frac{\text{EL}^2}{\text{EC}}$.

We have $\text{F}r : \text{F}f = \text{CL} : \text{CF}, = \text{CL} : \text{CD}$.

$\text{F}f : \text{G}g = \quad \text{CD} : \text{CE}$.

Therefore $\text{F}r : \text{G}g$, or $\text{KO} : \text{O}k = \text{CL} : \text{CE}$.

The triangles ECL and k OK are therefore fimilar, as are alfo k OK and K$n\,m$, and confequently ECL and K $n\,m$; and becaufe EC is parallel to K n, EL is parallel to Km. For the fame reafon km is parallel to El, and the triangles E $l\,x$ and m K k are fimilar, and

$$\text{L}x : \text{K}k = \text{LE} : \text{K}m$$

and $\text{L}x : \text{K}k = \text{EC} : \text{K}n$. But farther,

$$\text{L}x : \text{L}l = \text{CE} : \text{CL}$$

$$\text{L}l : \text{F}f = \text{KN} : \text{CD}, \text{ being } = \text{FL} : \text{FC}$$

$$\text{F}f : \text{G}g = \text{CD} : \text{CE}, \text{ being } = \text{F}f : k\text{O}$$

$$\text{G}g : \text{K}k = \text{CE} : \text{CL}, \text{ being } = \text{KO} : \text{K}k.$$

Therefore $\text{L}x : \text{K}k = \text{KN}\times\text{CE} : \text{EL}^2, = \text{KN} : \text{EX}$.

Therefore $\text{KN} : \text{EX} = \text{LE} : \text{K}m$, and $\text{K}m = \frac{\text{EX}\cdot\text{LE}}{\text{KN}}$,

and $\text{KN} : \text{EX} = \text{CE} : \text{K}n$, and $\text{K}n = \frac{\text{EX}\cdot\text{CE}}{\text{KN}}$.

In the very narrow vibrations of mufical cords, CD is exceedingly fmall in comparifon with C E, fo that EX·EL, or EX·CE, may, without fenfible error, be taken for CE², and then we obtain K m or K n (which hardly differ) $= \frac{\text{CE}^2}{\text{KN}}$, and therefore the curvature is proportional to KN. The fmall deviation from this ratio would feem to fhew that this conftruction does not give the harmonic curve with accuracy. But it is not fo. For it will be found, that although the curvature is not as KN, it is ftill proportional to the fpace which any particle K muft really defcribe in order to arrive at the axis. Thefe paths are lines whofe curvatures diminifh as they approach to DC.

We fee 1*ft*, that the bafe ACB of the curve is equal to the femicircular arch QER.

2*d*, Alfo that the tangent KZ in any point K is perpendicular to EL.

3*d*, We learn that the curvature at A and B is nothing, for in thefe two points KN is nothing.

4*th*, The radius of curvature at D is precifely $= \frac{\text{CE}^2}{\text{CD}}$.

Therefore, as the ftring approaches the axis, and CD diminifhes, the curvature diminifhes in the fame proportion. The vibrations therefore are performed like thofe of a pendulum in a cycloid, and are ifochronous, whether wide or narrow, and therefore the mufical pitch is conftant.

This is not ftrictly true, becaufe in the wide vibrations the extenfion or extending force is fomewhat greater. Hence it is that a ftring when violently twanged founds a little fharper at the beginning. Dr Long made a harpfichord whofe ftrings were ftretched by weights, by which this imperfection was removed.

It is proper to exhibit the curvature at D in terms of the length AB, and of the greateft excurfion c D. Therefore let c be the circumference of a circle whofe diameter is 1. Let AB the length of the cord be $=$ L, and let CD the $\frac{1}{2}$ breadth of the vibration be B. We had a little ago $\text{D}\,m = \frac{\text{CE}^2}{\text{CD}}$, but $c : 1 = \text{AB} : \text{CE}$, and $\text{CE} = \frac{\text{AB}}{c}$, and $c\,\text{E}^2 = \frac{\text{AB}c}{c^2}$. Therefore $\text{D}m = \frac{\text{AB}^2}{c^2\times\text{CD}} = \frac{\text{L}^2}{9{,}87\text{CD}}$ nearly.

We can now tell the number of vibrations made in a fecond by a ftring. This we obtain by comparing its motion, when impelled by the accelerating force which acts on it, with its motion when acted on by its weight only. Therefore let L be the length of a ftring, and W its weight, and let E be the ftraining weight, or extending force: Let f be the force which accelerates the particle D d of the cord, and w the weight of that particle, while W is the weight of the whole cord. Let z be the fpace which the particle D d would defcribe during the time of one vibration by the uniform action of the force f, and let S be the fpace which it would defcribe in the fame time by its weight w alone. Then (DYNAMICS, *Suppl.* n° 103. cor. 6.) the time in which f would impel the particle D d along $\frac{1}{2}$ DC, is to the time of one vibration as $1 : c$. And $\frac{1}{2}$ DC is to z as the fquare of the time of defcribing $\frac{1}{2}$ DC is to the fquare of the time of defcribing z; that is, $1 : c^2 = \frac{1}{2}\text{DC} : 2\,z$, and $c^2\,\text{DC} = 2\,z$.

Now, by the property of the harmonic curve,

$$AB : Dm = 2z : AB$$
$$\text{But } Dm : Dd = E : f$$
$$\text{And } Dd : AB = w : W$$
$$\text{Therefore } 2z \cdot E \cdot w = AB \cdot f \cdot W$$
$$\text{And } f : w = 2z \times E : AB \times W$$
$$\text{But } w : f = 2S : 2z$$
$$\text{Therefore } 2S \times E = AB \times W$$
$$\text{And } 2E : W = AB : S.$$

That is, a mufical chord, extended by a force E, performs one vibration DCV in the time that a heavy body defcribes a fpace S, which is to the length of the cord as its weight is to twice the extending force.

Now let g be the fpace through which a heavy body falls in one fecond, and let the time of vibration (eftimated in parts of a fecond) be T. We have

$$AB : S = 2E : W$$
$$S : g = T^2 : 1^2$$
$$\text{Therefore } AB : g = 2E \cdot T^2 : W$$
$$\text{And } AB \times W = T^2 \times 2E \times g$$
$$\text{Therefore } T^2 = \frac{AB \times W}{2g.E}, \text{ and } T = \sqrt{\frac{AB \times W}{2g.E}}$$

Let n be the number of vibrations made in a fecond.

$$n = \frac{1}{T} = \sqrt{\frac{2g.E}{AB.W}} = \sqrt{\frac{2gE}{L.W}}.$$

If the length of the cord be meafured in feet, $2g$ is very nearly 32. If in inches, $2g$ is 386, more nearly. Therefore $n = \sqrt{\frac{32\,E}{L \cdot W}}$ or $\sqrt{\frac{386\,E}{L \cdot W}}$. This may eafily be compared with obfervation. Dr Smith hung a weight of 7 pounds, or 49,000 grains, on a brafs wire fufpended from a finger pin, and fhortened it till it was in perfect unifon with the double octave below the open ftring D of a violin. In this ftate the wire was 35,55 inches long, and it weighed 31 grains.

Now $\sqrt{\frac{384 \times 49000}{35{,}55 \times 31}} = 130{,}7 = n$. This wire, therefore, ought to make 130,7 vibrations in a fecond. Dr Smith proceeded to afcertain the number of aereal pulfes made by this found, availing himfelf of the theory of the beats of tempered confonances invented by himfelf. On his fine chamber organ he tuned upwards the perfect fifths DA, A e, e b, and then tuned downward the perfect 6th e d. Thus he obtained an octave to D, which was too fharp by a comma, and he found that it beat 65 times in 20 feconds. Therefore the number of vibrations was $\frac{65}{20}$ 81, or 263,25. Thefe were complete pulfes or motions from D to V and back again, and therefore contained $526\frac{1}{2}$ fuch vibrations as we have now been confidering. The double octave below fhould make $\frac{1}{4}$th of this, or 131,6, which is not a complete vibration more than the above theory requires: more accurate coincidence is needlefs.

This theory is therefore very completely eftablifhed, and it may be confidered as one of the fineft mechanical problems which has been folved in laft century. We mention it with greater minutenefs, becaufe the merit of Dr Taylor is not fufficiently attended to. Mr Rameau, and the other great theorifts in mufic, make no mention of him; and fuch as have occafion to fpeak of the abfolute number of vibrations made by any mufical note, always quote Mr Sauveur of the French academy. This gentleman has written fome very excellent differtations on the theory of mufic, and Sir Ifaac Newton in his *Principia* often quotes his authority. He has given the actual determination of the number of vibrations of the note C, obtained in a manner fimilar to that practifed by Dr Smith on his chamber organ, and which agrees extremely well with that meafure. But Mr Sauveur has alfo given a mechanical inveftigation of the problem, which gives the fame number of vibrations that he obferved. We prefume that Rameau and others took the demonftration for good; and thus Mr Sauveur paffes on the Continent for the difcoverer of this theorem. But it was not publifhed till 1716, though read in 1713; whereas Dr Taylor's demonftration was read to the Royal Society in May 1714. But this demonftration of Mr Sauveur is a mere paralogifm, where errors compenfate errors; and the affumption on which he proceeds is quite gratuitous, and has nothing to do with the fubject. Yet John Bernoulli, from enmity to Taylor and the Englifh mathematicians, takes not the leaft notice of this fophifticated demonftration, accommodated to the experiment, and fo devoid of any pretenfions to argument that this fevere critic could not but fee its falfity.

Sauveur was one of the firft who obferved diftinctly that remarkable fact which Mr Rameau made the foundation of his mufical theory, *viz.* that a full mufical note is accompanied by its octave, its twelfth, and its feventeenth major. It had been cafually obferved before, by Marfennus, by Perrault, and others; but Sauveur tells diftinctly how to make the obfervation, and affirms it to be true in all deep notes. Rameau afferts it to be univerfally and neceffarily true in all notes, and the foundation of all mufical pleafure.

It had been difcovered before this time, that not only a full note caufed its unifon to refound, but alfo that a 12th, being founded near any open ftring, the ftring *refounded* to this 12th. It does the fame to a 15th, a 17th major, a 22d, &c.

Dr Wallis added a very curious circumftance to this obfervation. Two of his pupils, Mr Noble and Mr Pigott, in 1673, amufing themfelves with thefe refonnances, obferved, that if a fmall bit of paper be laid on the ftring of a violin which is made to refound to its unifon, the paper is thrown off: a proof that the ftring refounded by really vibrating, and that it is thrown into thefe vibrations by the pulfes of the air produced by the other ftring. In like manner the paper is thrown off when the ftring refounds to its octave. But the young gentlemen obferved, that when the paper was laid on the middle point of the ftring, it remained without agitation, although the ftring ftill refounded. They found the fame thing when they made the ftring refound to its 12th: papers laid on the two points of divifion lay ftill, but were thrown off when laid on any other place. In fhort, they found it a general rule, that papers laid on any points of divifion correfponding to the note which was refounded, were not agitated.

Dr Wallis (the greateft theorift in mufic of the 17th century) juftly concluded that thefe points of the refounding ftring were at reft, and that the intermediate parts were vibrating, and producing the notes correfponding to their lengths.

From this Mr Sauveur, with great propriety, deduced the

Trumpet Marine.

the theory of the performance of the trumpet marine, the vielle, the clavichord, and fome other inftruments.

When the ftring of the trumpet marine is gently ftopped at $\frac{1}{2}$, and the bow drawn lightly acrofs it at H (fig. A), the full vibration at the finger is ftopped; but the ftring is thrown into vibrations of fome kind, which will either be deftroyed or may go on. It is of importance to fee what circumftance will permit their continuance.

Suppofe an elaftic cord put into the fituation ABCDE (fig. D), fuch that AB, BC, CD, DE, are all equal, and that BCD is a ftraight line. Let the point C be made faft, and the two points B and D be let go at once. It is evident that the two parts will immediately vibrate in two harmonical curves A b C and CDE, which will change to ABC and C d E, and fo on alternately. It is alfo evident that if a line FCG be drawn touching the curve ABC, it will alfo touch the curve CDE; and the line which touches the curve A b C in C, will alfo touch the curve C d E. In every inftant the two halves of the cord will be curves which have a common tangent in the point C. The undoubted confequence of this is, that the point C will not be affected by thefe vibrations, and its fixure may be taken away. The cord will continue to vibrate, and will give the found of the octave to its fundamental note.

The condition; then, which muft be implemented, in order that a ftring may refound to its octave, or take the found of its octave, is fimply this, that its two parts may vibrate equally in oppofite directions. This is evidently poffible; and when the bow is drawn acrofs the ftring of the trumpet marine at H, and irregular vibrations are produced in the whole ftring, thofe which happen to be in one direction on both fides of the middle point, where it is gently ftopped by the finger, will deftroy each other, and the confpiring ones will be inftantly produced, and then every fucceeding action of the bow will increafe them.

The fame thing muft happen if a ftring is gently ftopped at one-third of its length; for there will be the fame equilibrium of forces at the two points of divifion, fo that the fixures of thefe points may be removed, and the ftring will vibrate in three parts, founding the 12th of the fundamental.

We may obferve, by the way, that if the bow be drawn acrofs the ftring at one of the points of divifion, correfponding to the ftopping at the other end of the ftring, it will hardly give any diftinct note. It rattles, and is intolerably harfh. The reafon is plain: The bow takes fome hold of the point C, and drags it along with it. The cord on each fide of C is left behind, and therefore the two curves cannot have a common tangent at C. The vibrations into which it is thus jogged by the bow deftroy each other.

We now fee why the trumpet marine will not found every note. It will found none but fuch as correfpond to a divifion of the ftring into a number of equal parts, and its note will be in unifon with a ftring equal to one of thofe parts. Therefore it will *firft* of all found the fundamental, by its whole length;

2. Its octave, correfponding to - $\frac{1}{2}$ its length
3. The 12th, - - - $\frac{1}{3}$
4. The 15th, or double octave, - $\frac{1}{4}$
5. The 17th, - - - $\frac{1}{5}$
6. The 19th, - - - $\frac{1}{6}$

Mufical Trumpet.

7. The 21ft, which is not in the diatonic fcale of our mufic. - $\frac{1}{7}$ its length
8. The triple octave, or 22d, - $\frac{1}{8}$
9. The 23d, or 2d in the fcale of the triple octave, - - $\frac{1}{9}$
10. The 24th, or 3d in this fcale, $\frac{1}{10}$
11. The 25th, a falfe 4th of this fcale, $\frac{1}{11}$
12. The 26th, a perfect 5th of this fcale, $\frac{1}{12}$
13. The 27th, a falfe 6th of ditto, $\frac{1}{13}=\frac{3}{39}$ or $\frac{2}{26}$
14. The 28th, a falfe 7th minor, $\frac{1}{14}$
15. The 28th, a perfect 7th major, $\frac{1}{15}$
16. The quadruple octave, - $\frac{1}{16}$

Thus we fee that this inftrument will not execute all mufic, and indeed will not complete any octave, becaufe it will neither give a perfect 4th nor 6th. We fhall prefently fee that thefe are the very defects of the trumpet.

This fingular ftringed inftrument has been defcribed in this detail, chiefly with the view of preparing us for underftanding the real trumpet. The Vielle, Savoyarde, or Hurdygurdy, performs in the fame manner. While the wheel rubs one part of the ftring like a bow, the keys gently prefs the ftrings, in points of aliquot divifion, and produce the harmonic notes.

It is to prevent fuch notes that the part of harpfichord wires, lying between the bridge and the pins, are wrapped round with lift. Thefe notes would frequently difturb the mufic.

Laftly on this head, the Æolian harp derives its vaft variety of fine founds from this mode of vibration. Seldom do the cords perform their fundamental or fimple vibrations, They are generally founding fome of the harmonies of their fundamentals, and give us all this variety from ftrings tuned in unifon.

Trumpet, Mufical, is a wind inftrument which founds by preffing the clofed lips to the fmall end, and forcing the wind through a very narrow aperture between the lips. This is one of the moft ancient of mufical inftruments, and has appeared in all nations in a vaft variety of forms. The conch of the favage, the horn of the cow-herd and of the poftman, the bugle horn, the lituus and tuba of the Romans, the military trumpet, and the trombone, the *cor de chaffe* or French horn—are all inftruments winded in the fame manner, producing their variety of tones by varying the manner and force of blowing. The ferpent is another inftrument of the fame kind, but producing part of its notes by means of holes in the fides.

Although the trumpet is the fimpleft of all mufical inftruments, being nothing but a long tube, narrow at one end and wide at the other, it is the moft difficult to be explained. To underftand how fonorous and regulated undualtions can be excited in a tube without any previous vibration of reeds to form the waves at the entry, or of holes to vary the notes, requires a very nice attention to the mechanifm of aereal undulations, and we are by no means certain that we have as yet hit on the true explanation. We are certain, however, that thefe aereal undulations do not differ from thofe produced by the vibration of ftrings; for they make ftrings refound in the fame manner as vibrating cords do. Galileo, however, did not know this argument for his affertion that the mufical pitch of a pipe, like that of a cord, depended on the frequency alone of the aereal undulations; but he thought it highly

 probable,

probable, from his obfervations on the ftructure of organs, that the notes of pipes were related to their lengths in the fame manner as thofe of wires, and he exprefsly makes this remark. Newton, having difcovered that found moved at the rate of about 960 feet per fecond, obferved that, according to the experiments of Mr Sauveur, the length of an open pipe is half the length of an aereal pulfe. This he could eafily afcertain by dividing the fpace defcribed by found in a fecond by the number of pulfes.

Daniel Bernoulli, the celebrated promoter of the Newtonian mechanics, difcovered, or at leaft was the firft who attentively marked, fome other circumftances of refemblance between the undulations of the air in pipes and the vibrations of wires. As a wire can be made, not only to vibrate in its full length, founding its fundamental note, but can alfo be made to fubdivide itfelf, and vibrate like a portion of the whole, with points of reft between the vibrating portions, when it gives one of its harmonic notes; fo a pipe cannot only have fuch undulations of air going on within it as are competent to the production of its fundamental note, but alfo thofe which produce one of its harmonic notes. Every one knows that when we force a flute, by blowing too ftrongly, it quits its proper note, and gives the octave above. Forcing ftill more, produces the 12th. Then we can produce the double octave or 15th, and the 17th major, &c. In fhort, by attending to feveral circumftances in the manner of blowing, all the notes may be produced from one very long pipe that we produce from the trumpet marine, and in precifely the fame order, and with the fame omiffions and imperfections. This alone is almoft equivalent to a proof that the mechanifm of the undulations of air in a pipe are analogous to that of the vibrations of an elaftic cord. Having with fo great fuccefs inveftigated the mechanifm of the partial vibrations of wires, and alfo another kind of vibrations which we fhall mention afterwards, incomparably more curious and more important in the philofophy of mufical founds, Mr Bernoulli undertook the inveftigation of thofe more myfterious motions of air which are produced in pipes; and in a very ingenious differtation, publifhed in the Memoirs of the Academy of Paris for 1762, &c. he gives a theory of them, which tallies in a wonderful manner with the chief phenomena which we obferve in the wind inftruments of the flute and trumpet kind. We are not, however, fo well fatisfied with the truth of his *affumptions* refpecting the ftate of the air, and the precife form of the undulations which he affigns to it; but we fee that, notwithftanding a probability of his being miftaken in thefe circumftances (it is with great deference that we prefume to fuppofe him miftaken), the chief propofitions are ftill true; and that the changes from note to note muft be produced in the order, tho' perhaps not in the precife manner, affigned by him.

It is by no means eafy to conceive, with clearnefs, the way in which mufical undulations are excited in the various kinds of trumpets. Many who have reputation as mechanicians, fuppofe that it is by means of vibrations of the lips, in the fame manner as in the hautboy, clarionette, and reed pipes of the organ, where the air, fay they, is put in motion by the trembling reed. But this explanation is wrong in all its parts; even in the reed pipes of an organ, the air is *not* put in motion by the reeds. They are indeed the *occafions* of its mufical undulation, but they do not *immediately impel* it into thofe waves. This method (and indeed all methods but the vibrations of wires, bells, &c.) of producing found is little underftood, though it is highly worthy of notice, being the origin of animal voice, and becaufe a knowledge of it would enable the artifts to entertain us with founds hitherto unknown, and thus add confiderably to this gift of our Bountiful Father, who has fhewn, in the ftructure of the larynx of the human fpecies, that he intended that we fhould enjoy the pleafures of mufic as a *laborum dulce lenimen*. He has there placed a micrometer apparatus, by which, *after* the other mufcles have done their part in bringing the glottis nearly to the tenfion which the intended note requires, we can eafily, and inftantly, adjuft it with the utmoft nicety.

We truft, therefore, that our readers will indulge us while we give a very curfory view of the manner in which the tremulous motion of the glottis, or of a reed in an organ pipe, produces the fonorous undulations with a conftant or uniform frequency, fo as to yield a mufical note.

If we blow through a fmall pipe or quill, we produce only a whizzing or hiffing noife. If, in blowing, we fhut the entry with our tongue, we hear fomething like a folid blow or tap, and it is accompanied with fome faint perception of a mufical pitch, juft as when we tap with the finger on one of the holes of a flute when all the reft are fhut. We are then fenfible of a difference of pitch according to the length of the pipe; a longer pipe or quill giving a graver found. Here, then, is like the *beginning* of a fonorous undulation. Let us confider the ftate of the air in the pipe: It was filled by a column of air, which was moving forward, and would have been fucceeded by other air in the fame ftate. This air was therefore nearly in its ftate of natural denfity. When the entry is fuddenly ftopped by the tongue, the included air, already in motion, continues its motion. This it cannot do without growing rarer, and then it is no longer a balance for the preffure of the atmofphere. It is therefore retarded in its motion, totally ftopped (being in a rarefied ftate), and is then preffed back again. It comes back with an accelerated motion, and recovers its natural denfity, while the ftate of rarefaction goes forward through the open air like any other aereal pulfe. Its motions are fomewhat, but not altogether, like that of a fpiral wire, which has been in like manner moving uniformly along the pipe, and has been ftopped by fomething catching hold of its hindermoft extremity. This fpring, when thus catched behind, ftretches itfelf a little, then contracts *beyond* its natural ftate, and then expands again, quivering feveral times. It can be demonftrated that the column of air will make but one quiver. Suppofe this accomplifhed in the hundredth part of a fecond, and that at that inftant the tongue is removed for the hundredth part of a fecond, and again applied to the entry of the pipe. It is plain that this will produce fuch another pulfe, which will join to the former one, and force it out into the air, and the two pulfes together will be like two pulfes produced by the vibration of a cord. If, inftead of the tongue, we fuppofe the flat plate of an organ-reed to be thus alternately applied to the hole and removed, at the exact moments that the renewals of air are wanted, it is plain that we fhall have *fonorous* undulations of *uniform* frequency, and therefore a mufical note. This is the way in which reeds produce

duce their effect, not by *impelling* the air into alternate states of motion to and fro, and alternate strata of rarefied and condensed air, but by giving them time to acquire this state by the combination of the air's elasticity with its progressive motion.

The adjustment of the succeeding puff of air to the pulse which precedes it, so that they may make one smooth and regular pulse, is more exact than we have yet remarked; for the stoppage of the hole not only *occasions* a rarefaction *before it*, but by checking the air which was just going to enter, makes a condensation *behind the door* (so to speak); so that, when the passage is again opened, the two parcels of air are fitted for supporting each other, and forming one pulse.

Suppose, in the next place, that the reed, instead of completely shutting the hole each time, only half shuts it. The same thing must still happen, although not in so remarkable a degree. When the passage is contracted, the supply is diminished, and the air now in the pipe must rarefy, by advancing with its former velocity. It must therefore retard; by retarding, regain its former density; and the air, not yet got into the pipe, must condense, &c. And if the passage be again opened or enlarged in the proper time, we shall have a complete pulse of condensed and rarefied air; and this must be accompanied by the beginning of a musical note, which may be continued like the former.

This will be a softer or more mellow note than the other; for the condensed and rarefied air will not be so suddenly changed in their densities. The difference will be like the difference of the notes produced by drawing a quill along the teeth of a comb, and that produced by the equally rapid vibrations of a wire. For let it be remarked here, that musical notes are by no means confined, as theorists commonly suppose, to the regular cycloidal agitations of air, such as are produced by the vibrations of an elastic cord; but that any crack, snap, or noise whatever, when repeated with sufficient frequency, becomes *ipso facto* a musical sound, of which we can tell the pitch or note. What can be less musical than the solitary cracks or snaps made by a stiff door when very slowly opened? Do this briskly, and the creak changes to a chirp, of which we can tell the note. The sounds will be harsh or smooth, according as the snaps of which they are composed are abrupt or gradual.

This distinction of sounds is most satisfactorily confirmed by experiment. If the tongue of the organ reed is quite flat, and if, in its vibrations, it apply itself to the whole margin of the hole at once, so as completely to shut it (as is the case in the oldfashioned regal stop of the organ), the note is clear, smart, and harsh or hard: but if the lips of the reed are curved, or the tongue properly bent backward, so that it applies itself to the edges of the hole *gradatim*, and never completely shuts the passage, the note may have any degree of mellow sweetness. This remark is worth the attention of the instrument-makers or organ-builders, and enables them to vary the VOICE of the organ at pleasure. We only mention it here as introductory to the explanation of the sounds of the trumpet.

We trust that the reader now perceives how the air, proceeding along a pipe, may be put in the state of alternate strata of condensed and rarefied air, the particles, in the mean time, proceeding along the pipe with a very moderate velocity; while the *state of undulation* is propagated at the rate of eleven or twelve hundred feet in a second; just as we may sometimes see a stream of water gliding gently down a canal, while a wave runs along its surface with much greater rapidity.

It will greatly assist the imagination, if we compare these aereal undulations with the undulations of water in an open canal. While the water is flowing smoothly along, suppose a sluice to be thrust up from the bottom quite to the surface, or beyond it. This will immediately cause a depression on the lower side of the sluice, by the water's going along the canal, and a heaping up of the water on the other side. By properly timing the motion of this sluice up and down, we can produce a series of connected waves. If the sluice be not pushed up to the surface but only one-half way, there will be the same succession of waves, but much smoother, &c. &c.

It is in this state, though not by such means, that the air is contained in a sounding trumpet. It is not brought into this state by any tremor of the lips. The trumpeter sometimes feels such a tremor; but whenever he feels it, he can no longer sound his note. His lips are painfully tickled, and he must change his manner of winding.

When blowing with great delicacy and care, the deepest notes of a French horn, or trombone, we sometimes can feel the undulations of the air in the pipe distinctly fluttering and beating against the lips; and it is difficult to hinder the lips from being affected by it: but we feel plainly, that it is not the lips which are fluttering, but the air before them. We feel a curious instance of this when we attempt to whistle in concert. If our accompanier intonates with a certain degree of incorrectness, we feel something at our own lips which makes it impossible to utter the intended note. This happens very frequently to the person who is whistling the upper note of a greater third. In like manner, the undulations in a pipe react on the reed, and check its vibrations. For if the dimensions of a pipe are such that the undulations formed by the reed cannot be kept up in the pipe, or do not suit the length of the pipe, the reed will either not play at all, or will vibrate only in starts. This is finely illustrated by a beautiful and instructive experiment. Take a small reed of the *vox humana* stop of an organ, and set it in a glass foot, adapted to the windbox of the organ. Instead of the common pipe above it, fix on it the sliding tube of a small telescope. When all the joints are thrust down, touch the key, and look attentively to the play of the reed. While it is sounding, draw out the joints, making the pipe continually longer. We shall observe the reed thrown into strange fits of quivering, and sometimes quite motionless, and then thrown into wide sonorous vibrations, according as the *maintainable* pulse is commensurate or not with the vibrations of the reed. This plainly shews that the air is not impelled into its undulations by the reed, but that the reed accommodates itself to the undulations in the pipe.

We acknowledge that we cannot explain with distinctness in what manner the air in a trumpet is first put into musical undulations. We see that it is only in very long and slender tubes that this can be done. In short tubes, of considerable diameter, like the cowherd's horn, we obtain only one or two very indistinct notes, of which it is difficult to name the pitch; and this requires great force of blast; whereas, to bring out the deep notes of the French horn, a very gentle

and

Musical Trumpet.

and well-regulated blast is necessary. The form of the lips, combined with the force of the blast, form all the notes. But this is in a way that cannot be taught by any description. The performer learns it by habit, and *feels* that the instrument leaps into its note without him, when he gradually varies his blast, and continues sounding the same note; although he, in the mean time, makes some small change in his manner of blowing. This is owing to what Mr Bernoulli observed. The tube is suited only to such pulses, and can only maintain such pulses as correspond to aliquot parts of its length: and when the embouchure is very nearly, but not accurately, suited to a particular note, that note *forms itself* in the tube, and, resting on the lips, brings them into the form which can maintain it with ease. We have a proof of this when we attempt to sound the note corresponding to one seventh of the length. Not having a distinct notion of this note, which makes no part of our scale of melody, we cannot easily prepare for it in the way that habit teaches us to prepare for the others: whereas, from what we shall see presently, the notes *one sixth* and *one eighth* are both familiar to the mind, and easily produced. When, therefore, we attempt to produce the note *one-seventh*, we slide, against our will, into the *one sixth* or *one eighth*.

Nor can we completely illustrate the formation of musical pulses by waves in water. A canal is equally susceptible of every height and length of progressive waves; whereas we see that a certain length of tube will maintain only certain determined pulses of air.

We must therefore content ourselves for the present with having learned, by means of the reed pipes, how the air may exist progressively in a tube, in an alternate state of condensation and rarefaction; and we shall now proceed to consider how this state of the air is related to the length of the tube. And here we can do no more than give an outline of Mr Bernoulli's beautiful theory of flutes and trumpets, but without a mathematical examination of the particular motions. We can, however, shew, with sufficient evidence, how the different notes are produced from the same tube. It requires, however, a very steady attention from the reader to enable him to perceive how the different portions of this air act on each other. We trust that this will now be given.

The conditions which must be implemented, in order to maintain a musical pulse, are two: 1. That the vibrations of the different plates of air be performed in equal times, otherwise they would all mix and confound each other. 2. That they move all together, all beginning and all ending at the same instant. It does not appear that any other state of vibration can exist and be maintained.

The column of air in a tube may be considered as a material spring (having weight and inertia.) This spring is compressed and coiled up by the pressure of the atmosphere. But in this coiled state it can vibrate in its different parts, as a long spiral wire may do, though pressed a little together at the ends. It is evident that the air within a pipe, shut at both ends, may be placed in such a situation, *in a variety of ways*, that it will vibrate in every part, in the same manner as a chord of the same length and weight, strained by a force equal to the pressure of the atmosphere. Thus, in the shut pipe AB (fig. 1.), suppose a harmonic curve ACB, or a wire of the same weight with the air, throwing itself into the form of this curve. The force which impels the point C to the axis is to that which impels the point c as CE to $c\,e$. Now, suppose the air in this pipe divided into parallel strata or plates, crossing the tube like diaphragms. In order that these may vibrate in the same manner (not across the tube, but in the direction of its axis), all that is necessary for the moment is, that the excess of the pressure of the stratum $d\,d$ above that of the stratum $f\,f$ may be to the excess of the pressure of DD above that of FF as $c\,e$ to CE. In this case, the stratum $c\,e$ will be accelerated in the direction $e\,f$, and the stratum EE is accelerated in the same direction, and in the due proportion. Now this may be done in an infinite variety of ways for a single moment. It depends, not on the absolute density, but on the *variation* of density; because the pressure by which a particle of air is urged in any direction arises from the *difference* of the distances of the adjoining particles on each side of it. But in order to *continue* this vibration, or in order that it may obtain at once in the whole pipe, this variation of density must continue, and be according to some connected law. This circumstance greatly limits the ways in which the vibration may be kept up. Mr Bernoulli finds that the isochronism and synchronism can be maintained in the following manner, and in no other that he could think of:

Plate XLV.

Let AB (fig. 2.) be a cylindrical pipe, shut at A, and open at B. Then, in whatever manner the sound is produced in the pipe, the undulations of the contained air must be performed as follows: Let $a\,a$ be a plate of air. This plate will approach to, and recede from, the shut end A, vibrating between the situations $b\,b$ and $c\,c$, the whole vibration being $b\,c$, and the plate will vibrate like a pendulum in a cycloid. The greater we suppose the excursions $a\,b$, $a\,c$, the louder will the sound be; but the duration of them all must be the same, to agree with the fact that the tone remains the same. The motion will be accelerated in approaching to $a\,a$ from either side, and retarded in the recess from it. Let us next consider a plate $\alpha\,\alpha$, more remote from A. It must make similar vibrations from the situation $\beta\,\beta$ to the situation $\gamma\,\gamma$. But these vibrations must be greater in proportion as the plate is farther from A. It cannot be conceived otherwise: For suppose the plate $\alpha\,\alpha$ to make the *same* excursions with $a\,a$, and that the rest do the same. Then they will all retain the same distances from each other; and thus there will be no force whatever acting on any particles to make them vibrate. But if every particle make excursions proportional to its distance from A, the *variation* of density will, in any instant, be the same through the whole pipe, and each particle in the vibrating plate $\beta\,\beta$ will be accelerated or retarded in proportion to its distance from A; while the accelerations and retardations over all will, in any instant, be proportional to the distance of each particle from its place of rest. All this will appear to the mathematician, who attentively considers any momentary situation of the particles. In this manner all the particles will support each other in their vibrations.

It follows from this description that the air in the tube is alternately rarefied and condensed. But these changes are very different in different parts of the tube. They must be greatest of all at A; because, while all the plates approach to A, they concur in condensing the air immediately adjoining to A; while the air in

$a\,a$

$a\,a$ and $\alpha\,\alpha$ is less condensed by the action of the plates beyond it. The air at B is always of its natural density, being in equilibrio with the surrounding air. At B, therefore, there is a small parcel of air, of its natural density, which is alternately going in and out.

This account is confirmed by many facts. If the bottom of the pipe be shut by a fine membrane, stretched across it like a drumhead, with a wire stretched over it, either externally or internally, in the same manner as the catgut is stretched across the bottom of a drum, it will be thrown into strong vibrations, making a very loud noise, by rattling against the cross wire. The same thing happens if the membrane be pasted over a hole close to the bottom, leaving a small space round the edge of the hole without paste, so that the membrane may play out and in, and rattle on the margin of the hole. This also makes a prodigious noise. Now, if the membrane be pasted on a hole far from the bottom, the agitations will be much fainter; and when the hole is near the mouth of the pipe, there will be none. —When a pipe has its air agitated in this manner, it is giving the lowest note of which it is susceptible.

Let us next consider a pipe open at both ends. Let CB (fig. 3) be this pipe. It is plain that, if there be a partition A in the middle, we shall have two pipes AB, AC, each of which may undulate in the manner now described, if the undulations in each be in opposite directions. It is evidently possible, also, that these undulations may be the same in point of strength in both, and that they may begin in the same instant. In this case, the air on each side of the partition will be in the same state, whether of condensation or rarefaction, and the partition A itself will always be in equilibrio. It will perfectly resemble the point C of the musical cord BFCGH (fig. 6.), which is in equilibrio between the vibrating forces of its two parts. In the pipe, the plates of air on each side are either both approaching it, or both receding from it, and the partition is either equally squeezed from both sides, or equally drawn outwards. Consequently this partition may be removed, and the parcels of air on each side will, in any instant, support each other. There seems no other way of conceiving these vibrations in open pipes which will admit of an explanation by mechanical laws. The vibrations of all the plates must be obtained without any mutual hinderence, in order to produce the tone which we really hear; and therefore such vibrations are impressed by Nature on each plate of air.

But if this explanation be just, it is plain that this pipe CB must give the same note with the pipe AB (fig. 2.) of half the length, shut at one end. But the sound, being doubled, with perfect consonance, must be clear, strong, and mellow. Now this is perfectly agreeable to observation; and this fact is an unequivocal confirmation of the justness of the theory. If we take a slender pipe, about six inches long and one half of an inch wide, shut at one end, and sound it by blowing across its mouth, as we whistle on the pipe of a key, or across a hole that is close to the mouth, and formed with an edge like the sound-hole of a German flute, we shall get a very distinct and clear tone from it. If we now take a pipe of double the length, open at both ends, and blow across its mouth, we obtain the same note, but more clear and strong. And the note produced by blowing across the mouth is not changed by a hole made exactly in the middle, in respect of its musical pitch, although it is greatly hurt in point of clearness and strength. Also a membrane at this hole is strongly agitated. All this is in perfect conformity to this mechanism.

Thus we have, in a great measure, explained the effect of an open and a shut pipe. The shut pipe is always an octave, graver than an open pipe of the same length; because the open pipe is in unison with a shut pipe of half the length.

Let AC (fig. 4.) be a pipe shut at both ends. We may consider it as composed of two pipes AB, BC, stopped at A and C, and open at B. Undulations may be performed in each half, precisely as in the pipe AB of fig. 2.; and they will not, in the smallest degree, obstruct each other, if we only suppose that the plates in each half are vibrating at once in the *same* direction. The condensation in AB will correspond with the rarefaction in BC, and the middle parcel B will maintain its natural density, vibrating to, and again across the middle; and two plates $a\,a$, $\alpha\,\alpha$, which are equally distant from B, will make equal excursions in the same direction.

We may produce sound in this pipe by making an opening at B. Its note will be found to be the same with that of BC of fig. 2. or of AB of fig. 2.

In the next place, let a pipe, shut at one end, be considered as divided into any odd number of equal parts, and let them be taken in pairs, beginning at the stopped end, so that there may be an odd one left at the open end. It is plain that each of these pairs may be considered as a pipe stopped at both ends, as in fig. 4.

For the partitions will, of themselves, be in equilibrio, and may be removed, and vibrations may be maintained in the whole, consistent with the vibration of the odd part at the open end; and these vibrations will all support each other, and the plates of air which are at the points of division will remain at rest. Conceive the pipe AB of fig. 2. to be added to the pipe AC of fig. 4. the part A of the first being joined to A of the other. Now, suppose the vibrations to be performed in both, in such a manner that the simultaneous undulations on each side of the junction may be in opposite directions. It is plain that the partition will be in equilibrio, and may be removed; and the plate of air will perform the same office, being alternately the middle plate of a condensed and of a rarefied parcel of air. The two pipes CA, AB will together give the same note that AB would have given alone, but louder.

In like manner may another pipe, equal to AC, be joined to the shut end of this compound pipe, as in fig. 5. and the three will still give the same note that AB would have done alone.

And in the same manner may any number of pipes, each equal to AC, be added, and the whole will give still the same note that AB would have given alone.

Hence it legitimately follows, that if the undulations can be once begun in this manner in a pipe, it may give either the sound competent to it, as a single pipe AB (fig. 2.); or it may give the sound competent to a pipe of $\frac{1}{3}$d, $\frac{1}{5}$th, $\frac{1}{7}$th, &c. of its length; the undulations in each part AB, BC, CD, maintaining themselves in the manner already described. This seems the only way in which they can be preserved, both isochronous and synchronous.

It is known that the gravest tones of pipes are as the lengths

lengths of the pipes, or the frequency of the undulations are inversely as their lengths. (This will be *demonstrated* presently). Therefore these accessory tones should be as the odd numbers 3, 5, 7, &c. and the whole tones, including the fundamental, should form the progression of the odd numbers 1, 3, 5, 7, &c.

This is abundantly confirmed by experiment. Take a German flute, and stop all the finger-holes. The flute, by gradually forcing the blast, will give the fundamental, the 12th, the 17th, the 21st, &c. (A).

Again, let AD (fig. 6.) represent the length of a pipe. Construct on AD an harmonic curve AEBFCGHD, in such a manner that HD may be $\frac{1}{2}$ AB, $= \frac{1}{2}$ BC, $= \frac{1}{2}$ CH The small ordinates *m n* will express the total excursion of the plates of air at the points *m m*, &c. and those ordinates which are above the axis will express excursions on one side of the place of rest, and the ordinates below will mark the excursions in the opposite directions, in the same manner as if this harmonic curve were really a vibrating cord. These excursions are nothing in the points A, B, C, H, and are greatest at the points E, F, G, D, where the little mass of air retains its natural density, and travels to and again, condensing the air at B, or rarefying it, according as the parcels E and F are approaching to or receding from each other. The points A, B, C, H, may be called Nodes, and the parts E, F, G, D, may be called Bights or Loops. This represents very well to the eye the motion of the plates of air. The density and velocity need not be minutely considered at present. It is enough that we see that when the density is increasing at A, by the approach of the parcel E, it is diminishing at B by the recess of E and F; and increasing at C, by the approach of F and G, and diminishing at H, by the recess of G. In the next vibration it will be diminishing at A and C, and increasing at B and H. And thus the alternate nodes will be in the same state, and the adjoining nodes in opposite states.

The reader must carefully distinguish this motion from the undulatory motion of a pulse, investigated by Newton, and described in the article Acoustics, *Encycl.* That undulation is going on at the same time, and is *a result* of what we are now considering, and the cause of our hearing this undulation. The undulation we are now considering is the original agitation, or rather it is the sounding body, as much as a vibrating string or bell is; for it is not the trumpet that we hear, but the air trembling in the trumpet. The trumpet is performing the office, not of the string, but of the pin and bridge on which the string is strained. This is an important remark in the philosophy of musical sounds.

There is yet another set of notes producible from a pipe besides those which follow in the order of frequency 1, 3, 5, 7. &c.

Suppose a pipe open at both ends, sounding by blowing across the end, and undulating, as already described, with a node in the middle A (fig. 3.) If we still express the fundamental note of the pipe AB of fig. 2. by 1, it is plain that the fundamental of an open pipe of the same length will have the frequency of its undulations expressed by 2; because an open pipe of twice the length of AB (fig. 2.) will be 1, the two pipes AB (fig. 2.), and CB (fig. 3.), being in unison.

But this open pipe may be made to undulate in another manner; for we have seen that AB of fig. 2. joined to CA of fig. 4. may sound altogether when the partition A is removed, still giving the note of AB (fig. 2.) Let such another as AB (fig. 2.) be added to the end C, and let the partition be removed. The whole may still undulate, and still produce the same note; that is, a pipe open at both ends may sound a note which is the fundamental of a pipe like AB (fig. 2.), but only one-fourth of its length. The pipe CB of fig. 3. may thus be supposed to be divided into four equal parts, CE. EA, AF, FB, of which the extreme parts EC and FB contain undulations similar to those in AB (fig. 2.); and the two middle parts contain undulations like those in CA (fig. 4.) The partitions at E and F may be removed, because the undulations in EC and EA will support each other, if they are in opposite directions; and those in FB and FA may support each other in the same manner.

It must here be remarked, that in this state of undulation the direction of the agitations at the two extremities is the same; for in the middle piece EF the particles are moving one way, condensing the air at E, while they rarefy it at F. Therefore, while the middle parcel is moving from E towards F, the air at B must be moving towards F, and the air at C must be moving from E. In short, the air at the two extremities must, in every instant, be moving in the opposite direction to that of the air in the middle.

In like manner, if the pipe CB of fig. 3. be divided into six parts, the two extreme parts may undulate like AB of fig. 2. and the four inner parts may undulate like two pipes, such as CA of fig. 4. and the whole will give the sound which makes the fundamental of a pipe of one-sixth of the length, or having the frequency 6.

We may remark here, that the simultaneous motion of the air at the extremities is in opposite directions, whereas in the last case it was in the same direction. This is easily seen; for as the partition which is between the two middle pieces must always be in equilibrio, the air must be coming in or going out at the extremities

(A) A little reflection will teach us that these tones will not be perfectly in the scale. A certain proportion between the diameter and length of the pipe produces a certain tone. Making the pipe wider or smaller flattens or sharpens this tone a little, and also greatly changes its clearness. Organ-builders, who have tried every proportion, have adopted what they found best. This requires the diameter to be about $\frac{1}{11}$th or $\frac{1}{12}$th of the length. Therefore, when we cause the same pipe to sound different notes, we neglect this proportion; and the notes are false, and even very coarse, when we produce one corresponding to a very small portion of the pipe. For a similar reason, Mr Lambert found that, in order to make his pitch-pipe sound the octave to any of its notes, it was not sufficient to shorten its capacity one-half by pushing down the piston; he found that the part remaining must be less than the part taken off by a fixed quantity $1\frac{5}{11}$ inches. Or, the length which gave any note being x, the length for its octave must be $\frac{x - 1\frac{5}{11}}{2}$.

tremities together. This circumstance must give some sensible difference of character to the sounds 4 and 6. In the one, the agitations at each end of the tube are in the same direction, and in the other they are in the opposite. Both produce pulses of sound which are conveyed to the ear. Thus we see that the air in a pipe open at both ends may undulate in two ways. It may undulate with a node in the middle, giving the note of AB (fig. 2.), or of its 3d, 5th, 7th, &c. part; and it may undulate with a loop or bight in the middle, sounding like $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{6}$, &c. of AB, fig. 2.

In like manner may this pipe produce sounds whose frequency are expressed by 8, 10, &c. and proceed as the even numbers.

This state of agitation may be represented in the same way that we represented the sounds 1, 3, 5, &c. by constructing on AM (fig. 7.) an harmonic curve, with any number of nodes and loops. Divide the parts AF, FD, DE, EM, equally in C, O, P, B. CB will correspond to the pipe, and the ordinates to the curve GFHDLEN will express the excursions of the plates of air.

If the pipe gives its fundamental note, its length must be represented by CO, and the undulations in it will resemble the vibrations of part CO of a cord, whose length AD is equal to 2CO, and which has a node in F.

If the pipe is sounding its octave, it will be represented by CP, and its indulations will resemble the vibrations of a cord CP, whose length AE is $\frac{3}{2}$ of CP, having nodes at F and D, &c. &c.

We can now see the possibility of such undulations existing in a pipe as will be permanent, and produce all the variety of notes by a mere change in the manner of blowing, and why these notes are in the order of the natural numbers, precisely as we observe to happen in winding the trumpet or French horn. We have, *1st*, the fundamental expressed by 1; then the octave 2; then the 12th, 3; the double octave 4; then the third major of that octave 5, or 17th of the fundamental; then the octave of the 12th, or the 5th of this double octave, = 6. We then jump to the triple octave 8, without producing the intermediate sound corresponding to $\frac{1}{7}$th of the pipe. With much attention we can hit it; and it is a fact that a person void of musical ear stumbles on it as easily as on any other. But the musician, finding this sound begin with hum, and his ear being grated with it, perhaps thinks that he is mistaking his embouchure, and he slides into the octave. After the triple octave, we easily hit the sounds corresponding to $\frac{1}{9}$ and $\frac{1}{10}$, which are the 2d and 3d of this octave. The next note $\frac{1}{11}$ is sharper than a just 4th. We easily produce the note 12, which is a just 5th; 13 is a false 6th; 14 is a sound of no use in our music, but easily hit; 15 and 16 give the exact 7th and 8th of this octave.

Thus, as we ascend, we introduce more notes into every octave, till at last we can nearly complete a very high octave; but in order to do this with success, and tolerable readiness, we must take an instrument of a very low pitch, that we may be able nearly to fill up the steps of the octave in which our melody lies. Few players can make the French horn or trombone sound its real fundamental, and the octave is generally mistaken for it. The proof of this is, that most players can give the 5th of the lowest note that they are able to produce; whereas the 5th of the real fundamental cannot be uttered. Therefore that lowest note is not the fundamental, but the octave to the fundamental.

Few performers can sound even this second octave on a short instrument, such as the ordinary military trumpet; and what they imagine to be the fundamental sound of this instrument is the double octave above it. This appears very strange; and it may be asked, how we know what is really the fundamental note of a trumpet? The answer to this is to be obtained only by demonstrating, on mechanical principles, what is the frequency of undulation corresponding to a given length of pipe. This is a proposition equally fundamental with its corresponding one in the theory of musical cords; but we have reserved it till now, because many readers would stop short at such an investigation, who are able to understand completely what we have now delivered concerning the music of the trumpet.

Suppose therefore a pipe shut at both ends, and that the whole weight of the contained air is concentrated in its middle point, the rest retaining its elasticity without inertia; or (which is a more accurate conception), let the middle point be conceived as extending its elasticity to the two extremities of the pipe, being repelled from each by a force inversely as the distance. Let the length of this pipe be L. This may also express the weight of the middle plate of air, which will always be proportional to the length of the pipe, because all is supposed to be concentrated there. Let E be the elasticity of the air. This must be measured by the pressure of the atmosphere, or by the weight of the column of mercury in the barometer. Perhaps the rationale of this will be better conceived by some readers by considering E as the height of a homogeneous atmosphere. Then it is plain that E is to L as the weight of this atmospheric column to the weight of the column of the same air which fills the pipe whose length is L. Then it is also plain that E is to L as the external pressure; and consequently, as the elasticity which supports that pressure is to the weight or inertia of the matter to be moved. Let this middle plate or diaphragm be withdrawn from its place of rest to the very small distance a. The elasticity or repulsion will be augmented on one side and diminished on the other; and the difference between them is the only force which impels the diaphragm toward the middle point, and causes it to vibrate, or produces the undulation. It is plain that the repulsion on one side is $\frac{\frac{1}{2}\mathrm{L}}{\frac{1}{2}\mathrm{L}-a}\times\mathrm{E}$, or $\frac{\mathrm{L}}{\mathrm{L}-2a}\,\mathrm{E}$ $\left(\text{for } \frac{1}{2}\mathrm{L}-a : \frac{1}{2}\mathrm{L} = \mathrm{E} : \frac{\frac{1}{2}\mathrm{LE}}{\frac{1}{2}\mathrm{L}-a}\right)$, and the repulsion on the other side is $\frac{\frac{1}{2}\mathrm{L}}{\frac{1}{2}\mathrm{L}+a}\times\mathrm{E}$, or $\frac{\mathrm{L}}{\mathrm{L}+2a}\,\mathrm{E}$. The difference of these repulsions is $\mathrm{E}\times\mathrm{L}\times\frac{4a}{\mathrm{L}^2-4a^2}$. But as we suppose a exceedingly small in comparison with L, this difference, or the accelerating force, may safely be expressed by $\mathrm{E}\,\frac{4a}{\mathrm{L}}$, or $4a\,\frac{\mathrm{E}}{\mathrm{L}}$.

Hence we deduce, in the first place, that the undulations will be isochronous, whether wide or narrow; because the accelerating force is always proportional to the distance a from the middle point.

Now,

Musical Trumpet.

Now, let a pendulum, whose quantity of matter is L, and length a, be supposed to vibrate in a cycloid by the force $\frac{4a}{L}$ E, or $\frac{4E}{L}a$. It must perform its vibrations in the same time with the plate of air; because the moving force, the matter to be moved, and the space along which they are to be similarly impelled, are the same in both cases. Let another pendulum, having the same quantity of matter L, vibrate by its weight L alone. In order that these two pendulums may vibrate in equal times, their lengths must be as the accelerating forces. Therefore we must have $\frac{4E}{L}a : L = a : \frac{aL^2}{4Ea}, = \frac{L^2}{4E}$, which is therefore the length of the synchronous pendulum.

Now, a cord without weight and inertia, but loaded with the weight L at its middle point, and strained by a weight E, and drawn from the axis to the distance a, is precisely similar in its motion to the diaphragm we are now considering, and must make its oscillations in the same time.

This is applicable to any number of plates of air, by substituting in the cord a loaded point for each of the plates; for when the case is thus changed, both in the pipe and the cord, the space to be passed over by the plate of air bears the same proportion to a, which is passed over by the whole air concentrated in the middle point, which the space to be passed over by the corresponding loaded point of the cord bears to that passed over by the whole matter of the cord concentrated in the middle point; and the same equality of ratios obtains in the accelerating forces of the plate of air and the corresponding loaded point of the cord. Suppose, then, a pipe divided into 2, 3, 4, &c. equal parts, by 1, 2, 3, diaphragms, each of which contains the air of the intervening portion of the pipe, the whole weight L being equally divided among them. If there be but one diaphragm, its weight must be L; if two, the weight of each must be $\frac{1}{2}$ L; if three, the weight of each must be $\frac{1}{3}$ L; and so on for any number.

By considering this attentively, we may infer, without farther investigation, what will be the undulations of all the different plates of air in a pipe stopped at both ends. We have only to compare it with a cord similarly divided and loaded. Increase the number of loaded points, and diminish the load on each, continually—it is evident that this terminates in the case of a simple cord, with its matter uniformly diffused; and a simple pipe, with its air also uniformly diffused over its whole length.

Therefore, if we take an elastic cord, and stretch it by such a weight that the extending weight may bear the same proportion to the accelerating force acting on the whole matter concentrated in its middle point, which the elasticity of the air bears to its accelerating force acting on the whole matter concentrated at the mouth of an open pipe, sounding its fundamental note, the cord and the air will vibrate in the same time. Moreover, since the proportion between the vibrations of a cord so constituted, and those of a cord having its matter uniformly diffused, is the same with the proportion between the undulations in a pipe so constituted, and those of a pipe in which the air is uniformly diffused—it is plain that the vibrations of the cord and of the pipe in their natural state will also be performed in equal times.

We look on this as the easiest way of obtaining a distinct perception of the authority on which we rest our knowledge of the absolute number of undulations of the air in a pipe of given length. It may be obtained directly; and Daniel Bernoulli, Euler, and others, have given very elegant solutions of this problem, without having recourse to the analogy of the vibrations of cords and undulations of a column of air But it requires more mathematical knowledge than many readers are possessed of who are fully able to follow out this analogical investigation.

Let us therefore compare this theory with experiment. What we call an open pipe of an organ is the same which we, in this theory, have considered as a pipe open at both ends; for the opening at the foot, which the organ-builders call the VOICE of the pipe, is equivalent to a complete opening. The aperture, and the sharp edge which divides the wind, may be continued all round, and the wind admitted by a circular slit, as is represented in fig. 10. We have tried this, and it gives the most brilliant and clear tones we ever heard, far exceeding the tones of the organ. An open organ pipe, therefore, when sounding its fundamental note, undulates with one node in its middle, and its undulations are analogous, in respect of their mechanism, with the vibrations of a wire of the same length, and the same weight, with the column of air in the pipe, and stretched by a weight equal to that of a column of the same air, reaching to the top of a homogeneous atmosphere, or equal to the weight of a column of mercury as high as that in the barometer.

Dr Smith (see *Harmonics*, 2d edit. p. 193.) found that a brass wire, whose length was 35,55 inches, and weight 31 troy grains, and stretched by 7 pounds avoirdupois, or 49000 grains, was in perfect unison with an open organ pipe whose length was 86,4 inches.

Now 86,4 inches of this wire weighs 75,34 grains. When the barometer stands at 30 inches, and the thermometer at 55° (the temperature at the time of the experiment), the height of a homogeneous atmosphere is 332640 inches. This has the same proportion to the length of the pipe which the pressure of the atmosphere has to the weight of the column of air contained in the pipe.

Now 86,4 : 332640 = 75,34 : 290060. This wire, therefore, should be stretched (if the theory be just) by 290060 grains, in order to be unison with the other wire, and we should have $35{,}55^2 : 86{,}4^2 = 49000 : 290060$

But, in truth, . $35{,}55^2 : 86{,}4^2 = 49000 : 289430$

The difference is 630

The error scarcely exceeds $\frac{1}{500}$, and does not amount to an error of one vibration in a second.

We must therefore account this theory as accurate, seeing that it agrees with experiment with all desirable exactness.

We may also deduce from it a very compendious rule for determining the absolute number of aereal pulses made by an open pipe of any given length. When considering the vibrations of cords, we found that the number of vibrations made in a second is $\sqrt{\frac{386\,E}{LW}}$, where E is the extending weight, W the weight of the cord, and L its length. Let H be the height of a homogeneous

neous atmosphere. We have its weight $= \frac{HW}{L}, = E$. Therefore substituting $\frac{HW}{L}$ for E in the above formula, we have the number of aerial pulses made per second $= \sqrt{\frac{386 H}{L^2}}$, or $= \frac{\sqrt{386 H}}{L}$. Now $\sqrt{386 H}$, computed in inches, is 11331. Therefore, if we also measure the length of the pipe L in inches, the pulses in a second are $= \frac{11331}{L}$. Thus, in the case before us, $\frac{11331}{86,4} = 131,12$, or this pipe produces 131 pulses in a second. Dr Smith found by experiment that it produced 130,9, differing only about $\frac{1}{5}$th of a pulse.

We see that the pitch of a pipe depends on the height of the homogeneous atmosphere. This may vary by a change of temperature. When the air is warmer it expands, and the weight of the induced column is lessened, while it still carries the same pressure. Therefore the pitch must rise. Dr Smith found his organ a full quarter tone higher in summer than in winter. The effect of this is often felt in concerts of wind instruments with stringed instruments. The heat which sharpens the tone of the first flattens the last. The harpsichord soon gets out of tune with the horns and flutes.

Sir Isaac Newton, comparing the velocity of sound with the number of pulses made by a pipe of given length, observed that the length of a pulse was twice the length of the open pipe which produced it. Divide the space passed over in a second by the number of pulses, and we obtain the length of each pulse. Now it was found that a pipe of 21,9 inches produced 262 pulses. The velocity of sound (as computed by the theory on which our investigation of the undulations in pipes proceeds) is 960 feet. Now $\frac{960 \times 12}{262} = 44$ inches very nearly, the half of which is 22, which hardly differs from 21,9. The difference of this theoretical velocity of sound, and its real velocity 1142 feet per second, remains still to be accounted for. We may just observe here, that when a pipe is measured, and its length called 21,9, we do really allow it too little. The voice-hole is equivalent to a portion, not inconsiderable of its length, as appears very clearly from the experiments of Mr Lambert on a variable pitch-pipe, and on the German flute, recorded in the Berlin Memoirs for 1775. He found it equivalent to $\frac{1}{5}$th; and this is sufficient for reconciling these measures of a pulse with the real velocity of sound.

The determination which we have given of the undulations of air in an organ pipe is indirect, and is but a sketch of the beautiful theory of Daniel Bernoulli, in which he states with accuracy the precise undulation of each plate of air, both in respect of position, density, velocity, and direction of its motion. It is a pleasure to observe how the different equations coincide with those which express the vibrations of an elastic cord. But this would have taken up much room, and would not have been suited to the information of many curious readers, who can easily follow the train of reasoning which we have employed.

Mr Bernoulli applies the same theory to the explanation of the undulations in flutes, or instruments whose sounds are modified by holes in the sides of the pipe. But this is foreign to our purpose of explaining the music of the trumpet. We shall only observe, that a hole made in that part of a pipe where a node should form itself, in order to render practicable the undulations, competent to a particular note, prevents its formation, and in its place we only get such undulations (and their corresponding sounds) as have a loop in that place. The intelligent reader will perceive that this single circumstance will explain almost every phenomenon of flutes with holes; and also the effects of holes in instruments with a reed voice, such as the hautboy or clarionette.

We now see that the sound or musical pitch of a pipe is inversely as its length, in the same manner as in strings, And we learn, by comparing them, that the sound of a trumpet has the same pitch with an open organ pipe of the same length. A French horn, 16 feet long, has the sound C *fa ut*, which is also the sound of an open flute-pipe of that length.

The TROMBONE, great trumpet, or SACKBUT, is an old instrument described by Mersennus and other authors of the last century. It has a part which slides (air-tight) within the other. By this contrivance the pitch can be altered by the performer as he plays. This is a great improvement when in good hands; because we can thus correct all the false notes of the trumpet, which are very offensive, when they occur in an emphatical or holding note of a piece of music. We can even employ this contrivance for filling up the blanks in the lower octaves.

We must not take leave of this subject without taking notice of another discovery of Mr Bernoulli's, which is exceedingly curious, and of the greatest importance in the philosophy of music.

Artists had long ago observed that the deep notes of musical instruments are sometimes accompanied by their harmonic sounds. This is most clearly perceived in bells, some of which give these harmonics, particularly the 12th, almost as strong as the fundamental. Musicians, by attending more carefully to the thing, seem now to think that this accompaniment is universal. If one of the finest sounding strings of the bases of a harpsichord be struck, we can hear the 12th very plainly as the sound is dying away, and the 17th major is the last sound that dies away on the ear. This will be rendered much more sensible, if we divide the wire into five parts, and at the points of division tie round it a thread with a fast knot, and cut the ends off very short. This makes the string false indeed by the unequal loading; but, by rendering those parts somewhat less moveable by this additional matter, the portions of the wire between these points are thus jogged, as it were, into secondary vibrations, which have a more sensible proportion to the fundamental vibration. This is still more sensible in the sound of the strings of a violincello when so loaded; but we must be careful not to load them too much, because this would so much retard the fundamental vibration, without retarding the secondary vibrations, that both cannot be maintained together. (*N. B.* This experiment always produces a beat in the sound).—Listening to a fine sounding flute-pipe of the organ, we can also very often perceive the same thing. Mr Rameau, and most other theorists in music, now assert fert that this is the effence of a mufical found, and *neceffarily* exifts in all of them, diftinguifhing them from harfh noifes. Rameau has made this the foundation of his fyftem of mufic, afferting that the pleafure of harmony refults from the fuccefsful imitation of this harmony of Nature, (fee Music, *Encycl.*). But a little logic fhould convince thefe theorifts that they muft be miftaken. If a note is mufical becaufe it has thefe accompaniments, and by this compofition alone is a mufical note, what are thefe harmonics? Are they mufical notes? This is granted. Therefore they have the fame compofition; and a mufical note muft confift at once of every poffible found; yet we know that this would be a jarring noife. A little mathematics, too, or mechanics, would have convinced them. A fimple vibration is furely a moft poffible thing, and therefore a fimple found. No, fay the theorifts; for though the vibration of the cord may be fimple, it produces fuch undulations in the air as excite in us the perception of the harmonics. But this is a mere affertion, and leaves the queftion undecided. Is not a fimple undulation of the air as poffible as the fimple vibration of a cord?

It is, however, a very curious thing, that almoft all mufical founds really have this accompaniment of the octave, 12th, double octave, and 17th major; for thefe are the harmonics that we hear.

The jealoufy of Leibnitz and of John Bernoulli, and their unfriendly thoughts refpecting all the Britifh mathematicians, made John Bernoulli do every thing in his power to leffen the value of Dr Taylor's inveftigation of the vibration of a mufical cord. Taylor gave him a good opportunity. Perhaps a little vain of his inveftigation of this abftrufe matter, he thought too much of it. He affirmed that the harmonic curve was the effential form of a ftring giving a mufical note. This was denied, without knowing at firft whether it was true or falfe. But as the analytic mathematics improved, it was at length found that there are an infinity of forms into which an elaftic cord can be thrown, which are confiftent both with ifochronous vibrations, whether wide or narrow, and alfo with the condition of the whole cord becoming a ftraight line at once. Euler, D'Alembert, and De la Grange, have profecuted this matter with great ingenuity, and it is one of the fineft problems of the prefent day.

Daniel Bernoulli, of a very different caft of mind from his illuftrious friends, admired both Newton and Taylor; and fo far from wifhing to eclipfe Dr Taylor by the additions he had made to his theory, tried whether he could not extend Taylor's doctrine as far as the author had faid. When he took a review of what he had done while explaining the partial vibrations of mufical cords, he thought it very poffible that while a cord is vibrating in three portions, with two nodes or points of reft, and founding the 12th to its fundamental, it might at the fame time be alfo vibrating as a fimple cord, and founding its fundamental note. It was poffible, he thought, that the three portions might be vibrating between the four points with a triple frequency, while the two middle nodes were vibrating acrofs the ftraight line between the two pins; and thus the vibrating cord might be a moveable axis, to which the rapid vibrations of the three parts might always be referred. This was very fpecious; and when a little more attentively confidered, became more probable: for if the cord $A p B q C r D$ (fig. 8.) be vibrating as a 12th to its fundamental AD, the points B and C are in equilibrio. If therefore thefe two points be laid hold of by hooks, and be drawn afide to β and γ, while the ftring is yet vibrating, this fhould not hinder the vibrations. If the hooks be annihilated in an inftant, the whole fhould vibrate between A and D; and this fhould be in a way very different from the fimple vibration. The queftion now is, will the cord *continue* to vibrate with the loops $\beta s \gamma$, $\beta q \gamma$, &c. in the 900th part of a fecond (for inftance), while the whole ftring vibrates from $A \beta \gamma D$ to $A \beta' \gamma' D$ in the 300th part of a fecond? or will it at once acquire the form of the fimple harmonic curve? The cafe in which it is moft likely to take the latter mode of vibration is when the points β and γ are let go at the inftant that each portion of the ftring is in the middle of its vibration, and therefore forms the line $A \beta \gamma D$. But a moment's confideration will fhew us that it cannot do this; for at that inftant the point v, for inftance, which had come from q, is moving outwards with a moft rapid motion, and therefore will continue to go outward, while β and γ are approaching the axis. The point w, on the contrary, is at this moment approaching the axis with a motion equally rapid. They cannot therefore all come to the axis at once, and the vibration muft differ greatly from a fimple one. On the other hand, let it be fuppofed that both fpecies of vibrations can be preferved, and that, at the moment of letting go the points β and γ, the cord has the form $A\, m\, \beta\, q\, \gamma\, n\, D$. Then, when β and γ have come to B and C, having made $\frac{1}{2}$ a vibration, the point m will be in the axis, having made a vibration downward, and a half vibration upwards, q, in like manner, is in the axis, having made a whole vibration upwards, and half a vibration downwards. n is like m. Thus the whole comes to the axis at once; and in fuch a manner, that if the points B and C were inftantly ftopped, the three portions would continue their partial vibrations without any new effort. The refult of this compound vibration muft be a compound pulfe of air, which will excite in us the perception of the fundamental found and of its 12th. The confequence will be the fame if the points β and γ are ftopped any where fhort of the axis; and therefore (faid Bernoulli) the ftring will really vibrate fo if not ftopped at all.

But this was refufed by Euler, who obferved that in the points β and γ of contrary flexure, having no curvature, there can be no accelerating force. This caufed Bernoulli to attempt a direct inveftigation, examining minutely the curvatures and accelerating forces in the different points.

He had the pleafure of finding that the accelerating forces arifing from the curvature in every point, were precifely fuch as would produce the accelerations neceffary in thofe points for performing the motion that was required. And he exhibited the equations expreffive of the ftate of the cord in all thefe points. And, on the faith of thefe equations, he reftored the Taylorean curve to the rank which its inventor had given it; and he afferted that in every mufical vibration the cord was difpofed in a harmonical curve either fimple or compound. He farther fhewed that the equations which Euler and D'Alembert had given for the mufical cord (at leaft in the cafes which they had publifhed)

Musical Trumpet.

ed) were included in his equations, and that their equations only exhibited its momentary ftates, while his own equations fhewed the phyfical connection of them all; which is, that the whole cord forms a harmonic curve between the two fixed pins, while its different portions form fubordinate harmonic curves on the firft as an axis Euler and D'Alembert, although they acknowledge this in the particular cafes which they had taken as examples, on account of their fimplicity, ftill infift that no fubordinate harmonic vibrations can correfpond to all the ftates of an elaftic cord which their equations exhibit as ifochronous and permanent. Mr Bernoulli's death put an end to the controverfy, and the queftion (confidered as a general theory) is perhaps ftill undecided. It may very probably be true, that as a fimple vibration may be permanent which never has the form of the fimple harmonic defcribed by Dr Taylor, fo a vibration may exift compounded of fuch vibrations, and therefore not expreffible by any equation deduced from the Taylorean curve.

But, in the mean time, Mr Bernoulli has made the moft beautiful difcovery in mechanics which has appeared in the courfe of the laft century, and has explained the moft curious phenomenon of continued founds, *viz.* the *almoft univerfal* accompaniment of the harmonic notes of any fundamental found. For this *fufceptibility* of compounded variation is not confined to a 12th, but is equally demonftrable of every other harmonic. Nay, it is evident that the fame fimple vibration of a cord may furnifh a moveable axis to more than one harmonic. For as the fimple vibration can have a fubordinate harmonic vibration fuperinduced upon it, fo may this compounded vibration have another fuperinduced on it, and fo on to any degree of compofition. And farther, as Mr Bernoulli has fhewn the complete analogy between the accelerations of the different points of an elaftic cord and of the correfponding plates of a column of air, it legitimately follows that all the confequences which we can eafily deduce, refpecting the vibrations of an elaftic cord, may be affirmed refpecting the undulations of a column of air in a pipe. Therefore this accompaniment of the harmonics muft not be confined to the mufic of ftrings and bells, but equally obtains in the mufic of wind inftruments. And thus the doctrine becomes univerfal.

Mr Bernoulli did not think it enough to fhew that thefe compound vibrations are poffible. He endeavours to fhew that this accompaniment muft be frequent. He illuftrates this very prettily, by fuppofing that a toothed wheel is turned round, and rubs with its teeth on an elaftic cord. If the fucceffive dropping of the teeth keep exactly pace with fuch vibrations as the cord can take and maintain by its elafticity, thefe will certainly be formed on it. If the intervals do not *exactly* correfpond, a little reflection will fhew that the agitation which the cord acquires will approximate to thofe which it can maintain; and, if when they are exactly fo in any place of it, and the wheel be in that inftant removed, this vibration will remain and diffufe itfelf through the reft of the cord; fo that the very laft dying quiver (fo to fpeak) will be a harmonic. Every *harmonic* agitation tends, by the very nature of the thing, to continue, while thofe that are incompatible really *do* deftroy each other; and the very laft muft be the remainder or fuperplus of fuch as could continue, over thofe which deftroyed each other. Accordingly, the harmonic notes of wires are always moft diftinctly heard as the found is dying away.

There is no occafion now to fay any thing about the fallacy of Rameau's *Generation Harmonique* as a theory of mufical pleafure. Our harmonics pleafe us, not becaufe a found is accompanied by its harmonics, but becaufe harmonics pleafe. His principle is therefore a tautology, and gives no inftruction whatever. His theory is a very *forced* accommodation of this principle to the practice of muficians, and tafte of the Public. He is exceedingly puzzled in the cafe of the *foufdominante*, or 4th of the fcale, and the 6th where there is no refonnance. He fays that thefe notes, "fremiffent, quoiqu' elles ne refonnent pas." But this mifleads us. They do not refound; becaufe a 4th and 6th cannot be produced at all by dividing the cord. They tremble; becaufe the falfe 4th and falfe 6th are very near the true ones, and the true 4th and 6th would both tremble and refound, if they were made falfe. A ftring will both tremble and refound, if very nearly true, as any one obferves the 12th and 17th on a harpfichord tremble and refound very ftrongly, though they are tempered notes. The whole theory is overturned at once by tuning the 4th falfe, fo as to correfpond to an aliquot divifion of the cord. It will then refound; and if this had happened to be agreeable, it would have been catched at as the foufdominante.

The phyfical caufe of the pleafure of harmonic founds is yet to feek, as much as our choice of thofe notes for melody which give us the beft harmony (fee Temperament, *Suppl.*). We have no hefitation in faying that, with refpect to our choice, the two are quite independent. Thoufands enjoy the higheft pleafure from melody who never heard a harmonious found. All the untaught fingers, and all fimple nations, are examples.

They not only fix on certain intervals as the fteps of their tunes, but are difgufted when other fteps are taken. Nor do we hefitate, for the very fame reafons, to fay that the rules of accompaniment are dependent on the cantus or air, and by no means on the fundamental bafs of Rameau. The dependence affumed by him, as the rule of accompaniment, would, if properly adhered to, according to his own notions of the comparative values of the harmonics, lead to the moft fantaftic airs imaginable, always jumping by large intervals, and altogether incompatible with graceful mufic. The rules of modulation which he has fqueezed out of his principle, are nothing but forced, very forced, accommodations of a very vague principle to the current practice of his contemporaries. They do not fuit the primitive melodies of many nations, and they have caufed thefe national mufics to degenerate. This is acknowledged by all who are not perverted by the prevailing habits. We have heard, and could write down, fome moft enchanting lullabies of fimple peafant women, poffeffed of mufical fenfibility, but far removed, in the cool fequeftered vale of life, from all opportunities of ftealing from our great compofers. Some of thefe lullabies never fail to charm, even the moft erudite mufician, when fung by a fine flexible voice: but it would puzzle Mr Rameau to accompany them *fecundum artem*.

We conclude this fubject by defcribing a moft beautiful and inftructive experiment.

Mr Watt, the celebrated engineer, was amufing himfelf

Musical Trumpet.

self (about the year 1765) with organ-building, and invented a monochord of continued sound, by which he could tune an organ with mathematical precision, according to any proposed system of temperament. It consisted of a covered string of a violincello, sounding by the friction of an ivory wheel. The instrument did not answer Mr Watt's purpose, by reason of the dead harshness of its tone, and a flutter in the string by the unequal action of the wheel. But Mr Watt was amused by observing the string frequently taking, of its own accord, points of division, which remained fixed, while the rest was in a state of strong vibration. The instrument came into the possession of the writer of this article. He soon saw that it gave him an opportunity of making all the experiments which Bernoulli could only relate. When the string was kept in a state of simple vibration, by a very uniform and gentle motion of the wheel, if its middle point was then gently touched with a quill, this point immediately stopped, but the string continued to vibrate in two parts, sounding the octave: And this it continued to do, however strong the vibrations were rendered afterwards by increasing the pressure and velocity of the wheel. The same thing happened if the string was gently touched at one third. It instantly divided itself into three parts, with two nodes, and sounded the 12th. In the same manner the double octave, the 17th, and all other harmonics, were produced and maintained.

But the prettiest experiment was to put something soft, such as a lock of cotton, in the way of the wide vibrations of the cord, at one-third and two-thirds of its length, so as to disturb them when they became very wide. When this was done, the string instantly put on the appearance of fig. 8. performing at once the full vibration competent to its whole length, and the three subordinate vibrations, corresponding to one-third of its length, and sounding the fundamental and the 12th with equal strength. In this manner all the different accompaniments were produced at pleasure, and could be continued, even with strong sounds. And it was amusing to observe, when the wheel was strongly pressed to the string, and the motion violent, the nodes would form themselves on various parts of the string, running from one part to another. This was always accompanied with all the jarring sounds which corresponded to them.

When the string was making very gentle, simple vibrations, and the wheel hardly touching it, if a violincello was made to sound the 12th very strongly in its neighbourhood, the string instantly divided itself, and vibrated in unison, frequently retaining its simple vibration and fundamental tone. We recommend this experiment to every person who wishes to make himself well acquainted with the mechanism of musical sounds. He will see, in a most sensible and convincing manner, how a single string of the Æolian harp gives us all the changes of harmony, sliding from one sound to another, according as it is affected in its different parts by an irregular breeze of wind. The writer of this article has attempted to regulate these sweet harmonic notes, and to introduce them into the organ. His success has been very encouraging, and the sounds far exceed in pathetic sweetness any that have yet been produced by that noble instrument. But he has not yet brought them fully under command, nor made them strong enough for any thing but the softest chamber music. Other necessary occupations prevent him from giving the attention to this subject that it deserves. He recommends it therefore to the musical instrument-makers as richly deserving their notice. His general method was this: A wooden pipe is made, whose section is a double square. A partition in the middle divides it into two pipes, along side of each other. One of them communicates with the foot and wind chest, and is shut at the upper end. The other is open at the upper, and shut at the lower end. In the partition there is a slit almost the whole length, and the sides of this slit are brought to a very smooth chamfered or feather edge. A fine catgut is strained in this slit, so as almost to touch the sides. It is evident that when the wind enters one pipe by the foot, it passes through the slit into the other, and escapes at the top, which is open. In its passage it forces the catgut into motion, and produces a musical note, having all the sweetness of the Æolian harp. The strength of sound may be increased by increasing the body of air which is made to undulate. This was done by using, instead of catgut, very narrow silk tape or ribband varnished: but the unavoidable raggedness of the edges made the sounds coarse and wheezing. Flat silver wire was not sufficiently elastic; flat wire, used for watch balance springs, was better, but still very weak sounded. Other methods were tried, which promised better. A thin round plate of metal, properly supported by a spring, was set in a round hole; made in another plate not so thin, so as just not to touch the sides. The air forced through this hole made the spring plate tremble, dancing in and out, and produced a very bold and mellow sound.—This, and similar experiments, are richly worth attention, and promise great additions to our instrumental music.

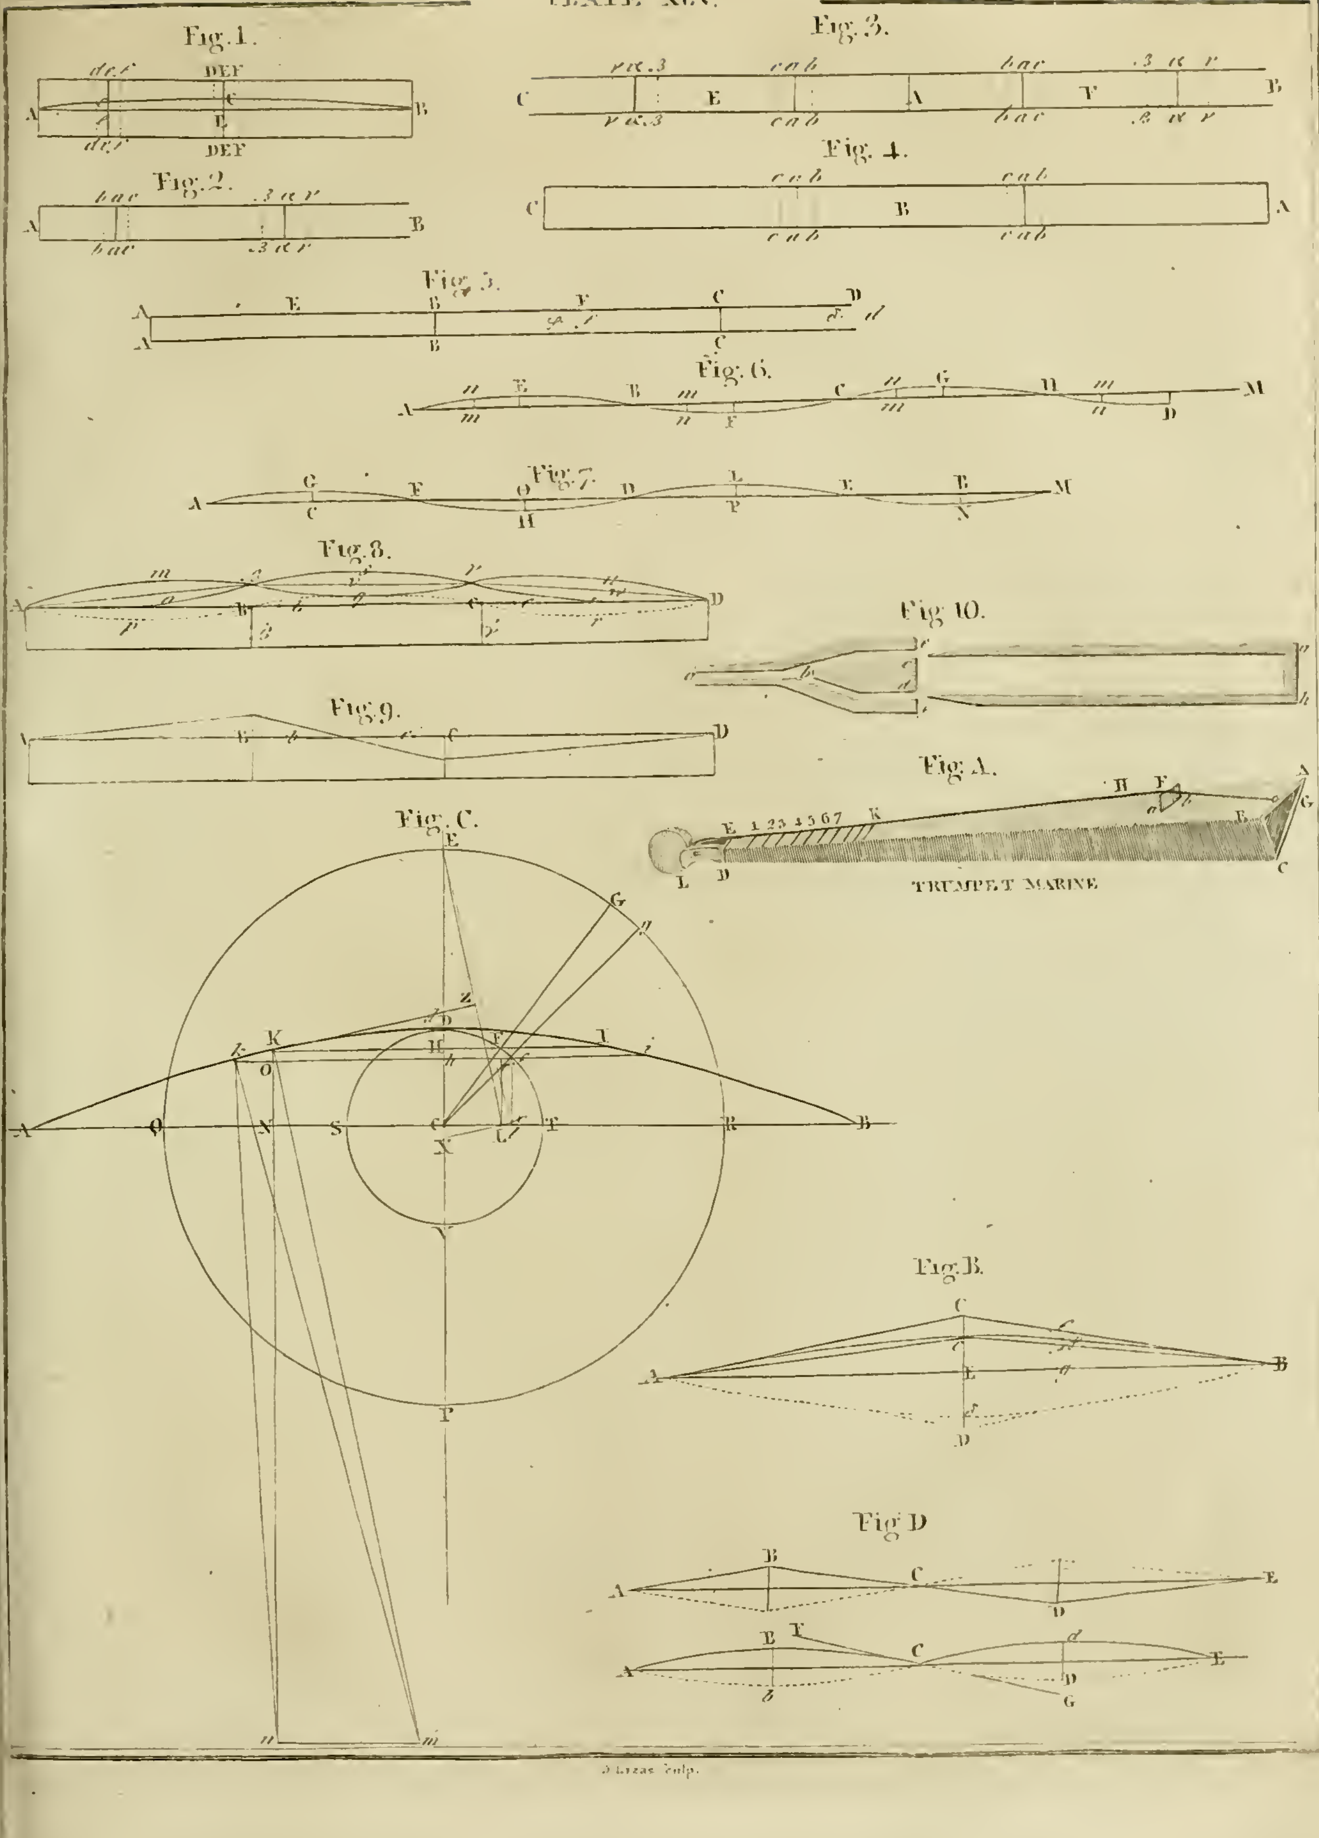
Musical Trumpet. Tschirnhaus.

TSCHIRNHAUS (Ehrenfred Walther Von), a name well known in the republic of letters, and one of the ornaments of the 17th century, was born April 10. 1651, at Kislingswald near Gorlitz in Upper Lusatia. His father was Ernest Christopher Von Tschirnhaus, Baron Kislingswald and Stoltzberg, and Obernschonfeld, privy counsellor, and in various offices of rank under the Electors George I. and II. of Saxony, the first of whom honoured him with the distinction of the gold chain and portrait, as a mark of his sense of his merits and services. The mother of the young Von Tschirnhaus was Maria Stirling, daughter of *Baro a Stirling et Achil*, Stirling of Achil, or Achyle, in Scotland, an old and respectable family, as appears by an epitaph which the Duke Christian, brother of the Elector George II. inscribed on the tomb of Johan Albert Stirling of Achil, in the cathedral of Marckspurg. This gentleman had been president of the senate of the electorate, privy counsellor, director of the imposts, and master of horse to the Prince, and had, by his faithful and useful services, acquired his highest esteem.

E. W. Von Tschirnhaus was born, as has been observed, at Kislingswald, the usual residence of the family, and possessed by it during more than 300 years. The family came originally from Bohemia, and appears to have been considerable, seeing that, from the earliest accounts of it in Lusatia, the Barons of Kislingswald are generally found in the most respectable civil offices.

The figure which Baron Von Tschirnhaus, the subject of this relation, has made in the scientific and political world, makes it superfluous to say that his early years

PLATE XLV.



J. Lizars Sculp.

years were well employed. Quick apprehenfion, a clear perception of the fubject of his thoughts, and the moft ardent and infatiable thirft for knowledge, diftinguifhed him during his academical education. When 17 years of age, he was fent to Leyden. In 1672 all ftudy was interrupted in Holland by the din of war; and Mr Von Tfchirnhaus left the univerfity for the camp. His knowledge in mathematics, mechanics, and all phyfical fcience, found ample room in the military fervice for fhewing the importance of thofe fciences; and Tfchirnhaus fo diftinguifhed himfelf by his fervice in this way, that Baron Nieuland, a general officer of great merit, and at the fame time an accomplifhed fcholar, took delight in pufhing him into every fervice where he could fhew himfelf and his talents.

After two years fervice, he returned to his father's; but finding little to intereft him in the life of a mere country gentleman, and ftill burning with the fame thirft of knowledge, he prevailed on his father to allow him to travel. His younger brother George Albrecht Von Tfchirnhaus, Baron Obernfchonfeld, which he inherited from his grandfather Stirling, loved him with the warmeft affection, and fupplied him liberally with what was required for his appearance everywhere in a manner becoming his rank, and for fully gratifying his curiofity. He ufed often to fay, "Sorry was I to lofe the company of my dear brother, and I fometimes wifhed to accompany him; but not having his thirft for knowledge, I knew that his love for me would debar him of much happinefs, which I fhould thus have obftructed." *Felices animæ!* He went to Holland, from thence into England, France, Italy, Sicily, Malta, Greece.—Returning through the Tyrol, he met his brother at Vienna, where both were in great favour at the court of Leopold. Wherever he went, he made himfelf acquainted with the moft eminent in all departments of fcience, living with them all in the mutual exchange of difcoveries and of kind offices. In Holland he was intimate with Huyghens and Hudde; in England, with Newton, Wallis, Halley, and Oldenburgh; in France, among a people who more fpeedily contract acquaintance, there was not a man of note with whom he did not cultivate an active acquaintance—and, fortunately, Leibnitz then lived at Paris: in Italy, he was particular careffed by Michaeli, foon after Cardinal; and was in the clofeft correfpondence with Kircher. His enjoyments, however, were derived folely from the communications of the moft eminent; his curiofity was directed to every thing, and wherever he faw an ingenious artifan, he was eager to learn from him fomething ufeful. In 1682, when at Paris for the third time, he communicated to his friends his celebrated theory of the cauftic curves, which marked him out as a valuable acquifition, and he was elected a member of the Royal Academy of Sciences, which was then reformed by the great minifter Colbert, and the moft illuftrious in all nations were picked out for its ornaments. There he found himfelf feated with Leibnitz, Huyghens, John Bernoulli, &c.

After twelve years employed in vifiting Europe, he returned home: but after a fhort ftay, went to Flanders, and prepared to publifh his work, intitled *Medicina Mentis*; of which the fubject may almoft be gueffed, from the way in which he had exercifed his own mind. Having the moft exalted notions of the intellectual and moral nature of man, he thought that the continual fupply of information was as neceffary as the continual fupply of food. And his great principle was TO ENLIGHTEN. This work was committed to the care of fome friends, and did not appear till 1687, at Amfterdam. A fecond edition appeared at Leipfic in 1695.

Finding now that his moderate fortune was infufficient for the great public projects he had in view, he fought for affiftance, and endeavoured to make friends by frequenting the court of the Elector at Drefden. He foon became a favourite of his Princes, George the II. and III. and was appointed to active offices of great refponfibility. By the orders and encouragement of the Elector, then king of Poland, he introduced into his native country the firft manufacture of glafs; and his project foon throve to fuch a degree, that not only Saxony was fupplied, but they even began to export the finer kinds of white glafs for windows; in which manufacture Saxony ftill excels. It was in the courfe of experiments for improving this manufacture that Tfchirnhaus made the celebrated great burning glaffes which ftill bear his name. He made two of thefe lenfes, and gave one to the Emperor, and the other to the Academy of Paris. He was eager to improve the art of forming and polifhing optical glaffes; and in the profecution of the theory on which their performance depends, he made fome beautiful difcoveries in the department of pure geometry. It is well known that all the fciences are allied, and of a family, and that eminence in one is feldom attainable without the affiftance of others. His prefent purfuits led him to the ftudy of chemiftry, which he profecuted with the fame ardour which he exhibited in every thing he undertook. But all the while, mathematics, and efpecially geometry, was his favourite ftudy; and he was anxious to make the fame advances in the general paths of mathematical inveftigation which he thought he had made in the general laws of material nature. He apprehended that only bye paths were yet known, and that many things were yet inacceffible; becaufe we had not yet found out the great roads from which thofe branches were derived. He was of Des Cartes's opinion, that the true road in mathematics muft be an eafy one, except in cafes which were, in their own nature, complicated. Very early, therefore, he began writing on mathematical fubjects, always continuing his general views of the fcience, and his endeavours to fyftematife the ftudy; but, at the fame time, beftowing a very particular attention on any branch which chanced to intereft him; each of thefe his epifodical ftudies in mathematics deferves the name of a department of the fcience. This is the cafe with his theory of cauftic curves, with his method of tangents, and his attempt to free Leibnitz's calculus from all confideration of infinitefimal quantities. Mr Tfchirnhaus feldom gave himfelf any trouble with a particular problem. In all his mathematical performances, there is an evident connection with fomething which he confidered as the great whole of the fcience; and the manner of treating the different queftions is plainly accommodated to a fyftem in his thoughts. This he intended as the third part of the Medicina Mentis; and, having nearly completed the fecond, he had propofed thefe as the occupation of the enfuing winter (1708-9). But his death, which may be called premature, has

Tfchirnhaus. has deprived the world of thefe, and other beneficent and ufeful labours.

Mr Von Tfchirnhaus was of the moft mild and gentle difpofition, as was well known to all who enjoyed his acquaintance. This difpofition was fo eminent in him, that fcarcely any perfon ever faw him angry, or even much ruffled in his temper. He forgave injuries frankly and heartily, and often ftood the friend (unknown) of thofe who had wronged him. By fuch conduct, he changed fome enmities into the moft fteady and affectionate friendfhips. As an inquirer and an inventor, he had contentions with other claimants, and fome difputes about the legitimacy of his methods; as, for example, with Nicholas Fatio Duiller, who attacked Tfchirnhaus's method of tangents; and Preftet and Rolle, who found fault with his expreffion of equations of the third degree. But thefe were all friendly debates, and never carried him beyond the limits of gentlemanly behaviour. He began to difpute with Ozanam about a quadratrix; but on being merely told that he was miftaken, by P. Souciet, he immediately acknowledged his error, and corrected it.

Many original and important mathematical performances of Mr Von Tfchirnhaus are to be feen in the Leipfic Acts, in the Memoirs of the Academy of Sciences at Paris, and other literary journals. His happy generalifation of Dr Barrow's theorem for the focus of a flender pencil of rays after reflection or refraction, and the theory of cauftic curves, in which this terminates, both conftitutes one of the moft elegant branches of optical fcience, and affords a rich harveft of very curious and unexpected geometrical truths. The manner in which he notices the rough way in which his firft and fole miftake in this theory was pointed out, is perhaps incomparable as an example of gentlemanlike reprehenfion, and is a leffon for literati of all defcriptions, higly valuable on account of the foft way in which it falls, while it is convincing as a mathematical theorem.

Tfchirnhaus was the difcoverer of the fubftance of which the celebrated Saxon porcelain is made, and of the manner of working it up; by which he eftablifhed a manufacture highly profitable to his country, and has given us the fineft pottery in the world. He never wearied in fpreading ufeful knowledge; and the fhops of our artifans of almoft all kinds were fupplied with books of inftructions and patterns, many of them written by Mr Von Tfchirnhaus, or under his infpection. Ufeful books of all kinds were tranflated out of foreign languages at his expence. Men of genius in the arts were enabled, through the encouragement of himfelf and his friends, and often by his pecuniary affiftance, to bring their talents before the public eye. In fhort, he feemed at all times to prefer the public good to his own; and never felt fo much pleafure as when he could promote fcience or the ufeful arts. He was as it were ftimulated to this by an innate propenfity. And as he was more defirous of *being* than of *appearing* the accomplifhed man, he was in no concern what notice others took of his fervices to the public. He even reprefents the defire of fame as hoftile to the improvement either of fcience or morality, in his *Medicina Mentis*; a work which is acknowledged by all who knew him to be a picture of his own amiable mind. He lightly efteemed riches; and knew not what ufe they were of, except for providing the neceffaries of life, and the means of acquiring knowledge. In perfect conformity to this maxim, he modeftly, and with elegant refpect, refufed the ample prefents made him by his affectionate fovereign; and when he was added to his cabinet council, he received the diploma, but begged and obtained to be free from the title. And when he prefented his great burning glafs to the Emperor, and got from him the dignity and infignia of Baron of the Empire, he pleaded for leave to decline it, requefting to keep the chain and portrait, which he always wore under his veft. He expended a very great portion of the ample revenue left him by his father in the fervice of his country, by promoting the ufeful arts and fciences.

Mr Von Tfchirnhaus venerated truth above all things; faying, that thofe who thought any thing comparable with it were not the fons of God, but ftep-children, and that the love of truth is the ruling affection in every man of a worthy heart. In a letter to an intimate friend, he faid that, by the age of five and-twenty, he had completely fubdued the love of glory, of riches, and of worldly pleafures; and that at no time he had found it difficult to reprefs vanity, becaufe he was every day confcious of having acted worfe than he was certain that he might and fhould have done. He felt himfelf humbled in the fight of the All-perfect Judge.

Nor was all this the vain boaft of a man averfe to bufinefs, and poffeffed of an ample fortune, which permitted him, without inconvenience, to pleafe his fancy in ftudy, and in helping others with what to himfelf was fuperfluous. Such a character, though rare, may exift, without being the object of much refpect. No: Mr Tfchirnhaus was really a philofopher of the true ftoic fect, in refpect of fortitude of mind, while a good Chriftian in modefty and diffidence. In the laft five years of his life he bore up under troubles, and embarraffments, and misfortunes in his family, which would have tried the mind of Cato himfelf. But in the midft of thefe ftorms he was unfhaken, and preferved his ferenity of mind. He was even fenfible of this being a rare gift of Providence, and ufed frequently to exprefs his thankfulnefs for a treafure fo precious. He felt deeply his relation to the Author of Nature, and rejoiced in thinking himfelf fubject to the providence of God. He faid that he was fully perfuaded that he would meet with perfect juftice, and would therefore ftrive to perform his own part to the utmoft of his power, that his future condition might be the more happy, and that he might in the mean time enjoy more fatisfaction on reflecting on his own conduct. His lot, he faid, was peculiarly fortunate: having fuch thirft for novelty, he would have been unhappy without an affluent fortune; and his own enjoyments encouraged neither vice nor idlenefs in himfelf or in the minifters to his pleafures.

This amiable perfon was of a conftitution not puny, but not robuft, and he had hurt it by too conftant ftudy. He feared no difeafe; thinking that he had a cure or an alleviation for all but one, namely, the ftone and gravel. He had a dread of this, and laboured to find a preventative or a remedy. He thought that he had alfo done a great deal here; and defcribes in his *Medicina Corpores* a preparation of whey, which he faid he ufed with great advantage to his health. But his precautions were in vain: He was attacked with the gravel, which, after three months fuffering, brought on a fuppreffion of urine. The phyficians faw that his end approached; and finding him difregard their prefcriptions, they quitted him. He treated himfelf (it is faid judicioufly) for fome time, and with fome appearance of fuccefs; but at laft he faw death not far off. He dictated a letter to his Sovereign, thanking him for all his favours and kindnefs, and recommended his children to his protection. He never fretted nor complained; but frequently, with gliftening eyes, expreffed his warmeft thanks to Providence for the wonderful track of good fortune and of happinefs that he had enjoyed; and faid that he alfo felt fome fatisfaction in the confcioufnefs that fome of this was owing to his own prudent conduct. He poffeffed his entire faculties to the laft moment; and when he felt his fpirit juft about to depart, his laft words were, "*Jö triumphè—Victoria!*" No longer able to fpeak, he made figns for what he wanted; and a little after, fhutting his eyes, as if to fleep, he gently, and without a groan, yielded up his fpirit, about four o'clock in the morning of the 11th of October 1708, aged 56.

His funeral was performed in a manner becoming his rank, and the body conveyed to the family vault. The Elector (King of Poland) defrayed the expence; for he would not allow his family to have any thing to do with the funeral of a man of fo public a character, and fo univerfally beloved.

The account of fuch a life as that of Baron Von Tfchirnhaus would, at all times, make a pleafant and ufeful impreffion. In thefe our times, in the end of the 18th century, after fociety has availed itfelf of all the acquifitions in fcience and art, furnifhed by that ardent age of the world which this gentleman contributed to adorn; in an age when we boaft of illumination unparalleled in hiftory, and of improvements almoft amounting to perfection; and in particular, of an emancipation from the prejudices which had obfcured our view of the chief good, and ftifled public fpirit—now, when we are fo full of knowledge that it is running over on all hands, in volumes of inftruction, how to make the world one happy family; in thefe bright days of philanthropifm, can the public records of Europe exhibit a fuperior character to that of Mr Von Tfchirnhaus, either in refpect of wifdom or of difpofition? Was he not a philanthropift, a fincere lover of mankind? Was he not wife, in employing his great acquired knowledge as the means of direct and active beneficence, by limiting his exertions to the extent of thofe circles where his own efforts would be effective? He did not write books, teaching others how to do good: he taught it by example; being determined that his own wifhes to fee men happier fhould not fail by the want of fuch wifhes in others, even after he fhould inftruct them. He never allowed his infatiable curiofity for frefh difcoveries to interfere with the immediate turning to the good of his own country the knowledge he had already acquired. He probably never thought of improving the fituation of the Chinefe or the Mexicans, finding that it required all his ample fortune, and all the intereft and influence he could acquire, to do the good he wifhed in Saxony. We doubt not but that he was equally attentive to the ftill narrower circle of duties formed by his own family. We fee that he was a dearly beloved brother; which could hardly be without his alfo being a loving brother and a dutiful fon. The nature of the diftreffes which he experienced in his family, and the manner in which he behaved under them, fhew him to have been an eminent Chriftian moralift. With a modefty that is unmatched by any one of the thoufands who have poured out inftructions upon us during the laft ten years, and a gracefulnefs which characterifes the gentleman, his *Medicina Mentis* is offered to public notice, merely as an experimental proof that a certain way of thinking and acting is productive of internal quiet of mind; of great mental enjoyment, both moral and intellectual; and of peace, and the good will of thofe around us: and that it did, in fact, produce a dutiful and comfortable refignation to the unavoidable trials of human life. He pretends not to be greatly fuperior in wifdom to his neighbours, but merely tells how things fucceeded with himfelf. He did not fcruple, however, to publifh to the world difcoveries in fcience, in which he had got the ftart of others during that bufy period of fcientific occupation: and thefe difcoveries in mathematics were highly prized by the firft men of the age; nor will the name of Tfchirnhaus, or his cauftic curves, ever be forgotten.

We felt ourfelves obliged to the friend who took notice of the omiffion of this gentleman's name, fo eminent in the mathematical world, in the courfe of our alphabet; but when we looked into the Memoirs of the Academy of Paris for 1709 for fome account of him, what we there faw appeared fuch a continual panegyric, that we could not take it as a fair picture of any real character. Looking about for more impartial information, we found in the *Acta Eruditorum*, Leipf. 1709, the account of which the foregoing is an abftract, except a particular or two which we have copied from an account in the Literary Journal of Breflaw, by Count Herberftein, whom we can fcarcely fufpect of undue partiality, becaufe he had fome difputes with Mr Von Tfchirnhaus on mathematical fubjects. May we not fay, "the memory of this man is fweet!"

TSCHAMIE, the Indian name of a tree in the Northern Circars of Hindoftan. It grows, fays Dr Roxburgh, to be a pretty large tree, is a native of moft parts of the coaft, chiefly of low lands at a confiderable diftance from the fea, and may be only a variety of *profopis fpecigera*, for the thorns are in this fometimes wanting; flowers during the cold and beginning of the hot feafons. *Trunk* tolerably erect, bark deeply cracked, dirty afh colour. *Branches* irregular, very numerous, forming a pretty large fhady head. *Prickles* fcattered over the fmall branches; in fome trees wanting. *Leaves* alternate, generally bipinnate, from two to three inches long; pinnæ from one to four, when in pairs oppofite, and have a gland between their infertions. *Leaflets* oppofite, from feven to ten pair, obliquely lanced, fmooth, entire, about half an inch long, and one-fixth broad. *Stipules* none. *Spikes* feveral, axillary, filiform, nearly erect. *Bracts* minute, one-flowered, falling. *Flowers* numerous, fmall, yellow, fingle, approximated. *Calyx* below, five-toothed. *Filaments* united at the bafe. *Anthers* incumbent, a white gland on the apex of each, which falls off foon after the flower expands. *Style* crooked.

Tſhutſki, Tucker.

crooked. *Stigma* ſimple. *Legume* long, pendulous, not inflated. *Seeds* many, lodged in a brown meally ſubſtance.

The pod of this tree is the only part uſed. It is about an inch in circumference, and from ſix to twelve long; when ripe, brown, ſmooth, and contains, beſides the feeds, a large quantity of a brown meally ſubſtance, which the natives eat; its taſte is ſweetiſh and agreeable; it may therefore be compared to the Spaniſh *algaroba*, or locuſt tree. (*Ceratcnia ſiliqua*, Linn.)

In compliance with Dr Kœnig's opinion, Dr Roxburgh calls this tree a *proſopis*; but as he thinks the antheral glands give it a claim to the genus *adenanthera*, we have retained the Indian name till its botanical claſſification ſhall be aſcertained by thoſe who have greater authority in the ſcience than we lay claim to.

TSHUTSKI, a people inhabiting a country ſituated on the eaſtern extremity of Aſia, oppoſite to the north weſt coaſt of America, and bounded by the Anadyr on the ſouth. The Tſhutſki nation is divided into two very diſtinct tribes: the one is called *ſtationary*, or fixed inhabitants of the coaſt; the other, *Reindeer*, or wanderers. The former occupy ſuch places as are convenient for fiſhing, and the chace of ſea-animals, from the river Anadyr to a ſmall diſtance north of the eaſtern promontory. The extent of their population, according to the beſt intelligence, amounts to about 3000 males. They are very induſtrious, and are neat workmen; which is evinced by their boats, lances, arrows, bows, apparel, utenſils, &c. with which they ſupply the wanderers. Their female priſoners are alſo a great article of trade; as they barter them for reindeer, copper and iron kettles, knives, beads, and ſuch articles as the wanderers obtain from the Ruſſian traders. Their married women are faithful to their huſbands; but chaſtity ſeems not to be a virtue among the unmarried part of the ſex, who grant any favours to ſtrangers for beads, buttons, tobacco, &c.

The aged among the Tſhutſki are ſubject to rheumatic complaints, which they cure, or attempt to cure, by lighting the dried leaves of wormwood, ſo prepared as to burn like tinder, and letting it remain till burnt out on the parts affected. In caſes of ſevere illneſs, they offer ſacrifices of deer to *the ſpirits of torture*; and ſometimes a dog is killed, when the ſick are led round it, and anointed with its blood and fat. They burn their dead to aſhes; lay ſtones on the ſpot to reſemble, in ſome degree, the form of a man; place a large ſtone at the head, which they anoint with marrow and fat; and form a pile, or heap of deers horns, at a ſmall diſtance from it. This place is viſited annually by the relatives of the deceaſed, who recapitulate the feats of their departed friend, anointing, each, the head-ſtone, and adding a horn to the heap. The wandering tribe conſider themſelves as a ſuperior race of beings, and the moſt independent of men; and it is a fact that the Ruſſians have never been able to bring them under their dominion. They call their more ſtationary neighbours *old women*, fit only to attend on them, and to guard their cattle. By Brookes the country of the Tſhutſki is placed Long. 168. 41. W. Lat. 66. 5. N.

TUCKER (Abraham), Eſq; a curious and original thinker, was a gentleman of affluent fortune, and author of "The Light of Nature purſued," 9 vols 8vo; of which the five firſt volumes were publiſhed by himſelf in 1768, under the aſſumed name of "Edward Search, Eſq." and the four laſt after his death, in 1777, as "The poſthumous Work of Abraham Tucker, Eſq. publiſhed from his manuſcript as intended for the preſs by the author." Mr Tucker lived at Betchworth-caſtle, near Dorking in Surrey; an eſtate which he purchaſed in the early part of his life. He married the daughter of Edward Barker, Eſq. by whom he had two daughters; one of whom married Sir Henry St John, and died in his lifetime; the other ſurvived, and now lives at Betchworth-caſtle. He loſt his eyeſight a few years before his death, which happened in 1775. To deſcribe him as a neighbour, landlord, father, and magiſtrate, it would be neceſſary to mention the moſt amiable qualities in each. It is unneceſſary to add, that he was very ſincerely regretted by all who had the pleaſure of his acquaintance, and who ſtood connected with him in any of thoſe relations.

Tucker.

TUCKER (Joſiah, D. D.), well known as a political and commercial writer, was born at Langhorn in Caermarthenſhire, in the year 1712. His father was a farmer, and having a ſmall eſtate left him at or near Aberyſtwith, in Cardiganſhire, he removed thither; and perceiving that his ſon had a turn for learning, he ſent him to Ruthin ſchool in Denbighſhire, where he made ſo reſpectable a progreſs in the claſſics, that he obtained an exhibition at Jeſus College, Oxford. It is generally underſtood that ſeveral of his journeys to and from Oxford were performed on foot, with a ſtick on his ſhoulder, and bundle at the end of it. Thus it might be ſaid by him, as by Simonides, "*Omnia mea mecum porto.*"

At the age of 23 he entered into holy orders, and ſerved a curacy for ſome time in Glouceſterſhire. About 1737 he became curate of St Stephen's church in Briſtol, and was appointed minor-canon in the cathedral of that city. Here he attracted the notice of Dr Joſeph Butler, then Biſhop of Briſtol, and afterwards of Durham, who appointed Mr Tucker his domeſtic chaplain. By the intereſt of this prelate Mr Tucker obtained a probendal ſtall in the cathedral of Briſtol; and on the death of Mr Catcott, well known by his treatiſe on the Deluge, and a volume of excellent ſermons, he became rector of St Stephen. The inhabitants of that pariſh conſiſt chiefly of merchants and tradeſmen; a circumſtance which greatly aided his natural inclination for commercial and political ſtudies.

When the famous bill was brought into the Houſe of Commons for the naturalization of the Jews, Mr Tucker, conſidering the meaſure rather as a merchant or politician than as a Chriſtian divine, wrote in defence of it with a degree of zeal which, to ſay no more, was at leaſt indecent in a man of his profeſſion. As ſuch it was viewed by his brethren of the clergy, and by his pariſhioners; for, while the former attacked him in pamphlets, newſpapers, and magazines, the latter burnt his effigy dreſſed in canonicals, together with the letters which he had written in defence of the naturalization.

In the year 1753 he publiſhed an able pamphlet on the "Turkey Trade;" in which he demonſtrates the evils that reſult to trade in general from chartered companies. At this period Lord Clare (afterward Earl Nugent) was returned to Parliament for Briſtol; which honour

honour he obtained chiefly through the ftrenuous exertions of Mr Tucker, whofe influence in his large and wealthy parifh was almoft decifive on fuch an occafion. In return for this favour, the Earl procured for him the deanery of Gloucefter, in 1758, at which time he took his degree of doctor in divinity. So great was his reputation for commercial knowledge, that Dr Thomas Hayter, afterwards bifhop of London, who was then tutor to his prefent majefty, applied to Dr Tucker to draw up a differtation on this fubject for the perufal of his royal pupil. It was accordingly done, and gave great fatisfaction. This work, under the title of "The Elements of Commerce," was printed in quarto, but never publifhed.

Dr Warburton, who became bifhop of Gloucefter in the year 1760, thinking very differently from Dr Tucker of the proper ftudies of a clergyman, as well as of the project for naturalizing the Jews, faid once to a perfon who was praifing the Elements of Commerce, that "his Dean's trade was religion, and religion his trade." This farcafm, though not perhaps groundlefs, was certainly too fevere; for fome of the Dean's publications evince him to have devoted part of his time at leaft to the ftudy of theology, and to have been a man of genuine benevolence.

In the year 1771, when a ftrong attempt was made to procure an abolition of fubfcription to the 39 articles, Dr Tucker came forward as an able and moderate advocate of the church of England. About this time he publifhed "Directions for Travellers;" in which he lays down excellent rules, by which gentlemen who vifit foreign countries may not only improve their own minds, but turn their obfervations to the benefit of their native country.

The Dean was an attentive obferver of the American conteft. He examined the affair with a very different eye from that of a party-man, or an interefted merchant; and he difcovered, as he conceived, that both fides would be better off by an abfolute feparation. Mr Burke's language in the Houfe of Commons, in confequence of his publifhing this opinion, was harfh, if not illiberal. In his famous fpeech on the American taxation bill, April the 13th, 1774, he called the Dean of Gloucefter the advocate of the court faction, though it is well known that the court difapproved of the propofal as much as the oppofition. This attack roufed the Dean to refentment; and he publifhed a letter to Mr Burke; in which he not only vindicates the purity of his own principles, but retorts upon his adverfary in very forcible and farcaftic terms. He afterwards fupported Lord Nugent's intereft in Briftol againft that of Mr Burke, and was certainly very inftrumental in making the latter lofe his election.

When the terrors of an invafion were very prevalent in 1779, Dr Tucker circulated, in a variety of periodical publications, fome of the moft fenfible obfervations that were ever made on the fubject, in order to quiet the fears of the people. In 1781 he publifhed, what he had printed long before, "A Treatife on Civil Government;" in which his principal defign is to counteract the doctrines of Locke and his followers. The book made a confiderable noife, and was very fharply attacked by feveral writers on the democratic fide of the queftion, particularly by Dr Towers and Dr Dunbar of Aberdeen. This laft gentleman acted a part which, if not difhonourable, was at leaft uncommon. The Dean had thrown off thirty copies of his work long before he publifhed it; and thefe he fent to different men of eminence, that he might avail himfelf of their animadverfions before he fhould fubmit it to the public at large. Principal Campbell of Aberdeen received one copy for this purpofe; and Dr Dunbar having by him bee[n] favoured with a perufal of it, inftead of fending his o[b]jections privately to the author, publifhed fevere re[mar]ks on it in a work which he had then in the prefs. [Th]is was the anfwer to the Dean of Gloucefter's Tr[eati]fe on Government publifhed before that treatife itfel[f] but Dr Dunbar was no match for Dr Tucker.

In the year 1782 our author clofed his political career with a pamphlet intitled "*Cui Bono?*" in which he balances the profit and lofs of each of the belligerent powers, and recapitulates all his former pofitions on the fubject of war and colonial poffeffions. His publications fince that period confifted of fome tracts on the commercial regulations of Ireland, on the exportation of woollens, and on the iron trade. In 1777 he publifhed feventeen practical fermons, in one volume octavo. In the year 1778, one of his parifhioners, Mifs Pelloquin, a maiden lady of large fortune and moft exemplary piety, bequeathed to the Dean her dwelling houfe in Queen Square, Briftol, with a very handfome legacy, as a teftimony of her great efteem for his worth and talents. In the year 1781 the Dean married a lady of the name of Crowe, who refided at Gloucefter.

It fhould be recorded to his praife, that though enjoying but very moderate preferment (for to a man of no paternal eftate, or other ecclefiaftical dignity, the Deanery of Gloucefter is no very advantageous fituation), he was notwithftanding a liberal benefactor to feveral public inftitutions, and a diftinguifhed patron of merit. The celebrated John Henderfon of Pembroke-college, Oxford, was fent to the univerfity, and fupported there, at the Dean's expence, when he had no means whatever of gratifying his ardent defire for ftudy. We fhall mention another inftance of generofity in this place, which reflects the greateft honour upon the Dean. About the year 1790 he thought of refigning his rectory in Briftol, and without communicating his defign to any other perfon, he applied to the Chancellor, in whofe gift it is, for leave to quit it in favour of his curate, a moft deferving man, with a large family. His Lordfhip was willing enough that he fhould give up the living, but he refufed him the liberty of nominating his fucceffor. On this the Dean refolved to hold the living himfelf till he could find a fit opportunity to fucceed in his object. After weighing the matter more deliberately, he communicated his wifh to his parifhioners, and advifed them to draw up a petition to the Chancellor in favour of the curate. This was accordingly done, and figned by all of them, without any exception, either on the part of the diffenters or others. The Chancellor being touched with this teftimony of love between a clergyman and his people, yielded at laft to the application; in confequence of which the Dean cheerfully refigned the living to a fucceffor well qualified to tread in his fteps. Since that time he refided chiefly at Gloucefter, viewing his approaching diffolution with the placid mind of a Chriftian, confcious of having done his duty both to God and man. He died in November 1799.

Tucker, Tulipomania.

1799. The following we believe to be a tolerably correct lift of his works.

Theological and Controverfial.—1. A Sermon, preached before the Governors of the Infirmary of Briftol, 1745. 2. Letters in behalf of the Naturalization of the Jews. 3. Apology for the Church of England, 1772. 4. Six Sermons, 12mo, 1773. 5. Letter to Dr Kippis on his Vindication of the Proteftant Diffenting minifters. 6. Two Sermons and Four Tracts. 7. View of the Difficulties of the Trinitarian, Arian, and Socinian Syftems, and Seventeen Sermons, 1777.

Political and Commercial.—8. A pamphlet on the Turkey Trade. 9. A brief View of the Advantages and Difadvantages which attend a Trade with France. 10. Reflections on the Expediency of Naturalizing foreign Proteftants, and a Letter to a Friend on the fame Subject. 11. The Pleas and Arguments of the Mother Country and the Colonies ftated. 12. A Letter to Mr Burke. 13. Quere, Whether a Connection with, or Separation from, America, would be for national Advantage? 14. Anfwers to Objections againft the Separation from America. 15. A Treatife on Civil Government. 16. *Cui Bono?* 17. Four Letters on national Subjects. 18. Sequel to Sir William Jones on Government. 19. On the Difpute between Great Britain and Ireland. 20. Several Papers under the Signature of Caffandra, &c. on the Difficulties attendant on an Invafion. 21. A Treatife on Commerce (Mr Coxe, in his Life of Sir Robert Walpole, fays that this was printed, but never publifhed).

Mifcellaneous.—22. Directions for Travellers. 23. Cautions againft the Ufe of Spirituous Liquors. 24. A Tract againft the Diverfions of Cock-fighting, &c.

TULIPOMANIA, the very proper name given to a kind of gambling traffic in *tulip roots*, which prevailed in Holland and the Netherlands during fome part of the 17th century. It was carried on to the greateft extent in Amfterdam, Haerlem, Utrecht, Alkmaar, Leyden, Rotterdam, Hoorn, Enkhuyfen, and Meedenbliek; and rofe to the greateft height in the years 1634, 1635, 1636, and 1637. Munting, who, in 1696, wrote a book of 1000 pages folio on the fubject, has given a few of the moft extravagant prices, of which we fhall prefent the reader with the following. For a root of that fpecies called the *Viceroy*, the after mentioned articles, valued as below, were agreed to be delivered.

	Florins.
2 lafts of wheat	448
4 ditto rye	558
4 fat oxen	480
8 fat fwine	240
12 fat fheep	120
2 hogfheads of wine	70
4 tons beer	32
2 ditto butter	192
1000 pounds of cheefe	120
a complete bed	100
a fuit of clothes	80
a filver beaker	60
Sum	2500

Thefe tulips afterwards were fold according to the weight of the roots. Four hundred perits * of Admiral Liefken coft 4400 florins; 446 ditto of Admiral Von der Eyk, 1620 florins; 106 perits Schilder coft 1615 florins; 200 ditto Semper Auguftus, 5500 florins; 410 ditto Viceroy, 3000 florins, &c. The fpecies Semper Auguftus has been often fold for 2000 florins; and it once happened that there were only two roots of it to be had, the one at Amfterdam and the other at Haerlem. For a root of this fpecies, one agreed to give 4600 florins, together with a new carriage, two grey horfes, and a complete harnefs. Another agreed to give twelve acres of land for a root: for thofe who had not ready money, promifed their moveable and immoveable goods, houfe and lands, cattle and clothes. A man, whofe name Munting once knew, but could not recollect, won by this trade more than 60,000 florins in the courfe of four months. It was followed not only by mercantile people, but alfo by the firft noblemen, citizens of every defcription, mechanics, feamen, farmers, turf-diggers, chimney-fweeps, footmen, maid-fervants, and old clothes-women, &c. At firft, every one won and no one loft. Some of the pooreft people gained in a few months houfes, coaches, and horfes, and figured away like the firft characters in the land. In every town fome tavern was felected which ferved as a change, where high and low traded in flowers, and confirmed their bargains with the moft fumptuous entertainments. They formed laws for themfelves, and had their notaries and clerks.

* A *perit* is a fmall weight lefs than a grain.

To get poffeffion of fine flowers was by no means the real object of this trade, though many have faid that it was, and though we have known fome individuals in Scotland, who, led away by what they thought the fafhion, have given ten guineas for a tulip root. During the time of the tulipomania, a fpeculator often offered and paid large fums for a root which he never received, and never wifhed to receive. Another fold roots which he never poffeffed or delivered. Oft did a nobleman purchafe of a chimney-fweep tulips to the amount of 2000 florins, and fold them at the fame time to a farmer; and neither the nobleman, chimney-fweep, or farmer, had roots in their poffeffion, or wifhed to poffefs them. Before the tulip feafon was over, more roots were fold and purchafed, befpoke, and promifed to be delivered, than in all probability were to be found in the gardens of Holland; and when Semper Auguftus was not to be had, which happened twice, no fpecies perhaps was oftener purchafed and fold. In the fpace of three years, as Munting tells us, more than ten millions were expended in this trade in only one town of Holland.

To underftand this gambling traffic, it may be neceffary to make the following fuppofition. A nobleman befpoke of a merchant a tulip root, to be delivered in fix months, at the price of 1000 florins. During thefe fix months the price of that fpecies of tulip muft have rifen or fallen, or remained as it was. We fhall fuppofe that, at the expiration of that time, the price was 1500 florins; in that cafe, the nobleman did not wifh to have the tulip, and the merchant paid him 500 florins, which the latter loft and the former won. If the price was fallen when the fix months were expired, fo that a root could be purchafed for 800 florins, the nobleman then paid to the merchant 200 florins, which he received as fo much gain; but if the price continued the fame, that is, 1000 florins, neither par-

Tulipomania. ty gained or loſt. In all theſe circumſtances, however, no one ever thought of delivering the roots or of receiving them. Henry Munting, in 1636, ſold to a merchant at Alkmaar, a tulip root for 7000 florins, to be delivered in ſix months; but as the price during that time had fallen, the merchant paid, according to agreement, only 10 *per cent.* "So that my father (ſays the ſon) received 700 florins for nothing; but he would much rather have delivered the root itſelf for 7000." The term of theſe contracts was often much ſhorter, and on that account the trade became briſker. In proportion as more gained by this traffic, more engaged in it; and thoſe who had money to pay to one, had ſoon money to receive of another; as at faro, one loſes upon one card, and at the ſame time wins on another. The tulip dealers often diſcounted ſums alſo, and transferred their debts to one another; ſo that large ſums were paid without caſh, without bills, and without goods, as by the Virements at Lyons. The whole of this trade was a game at hazard, as the Miſſiſſippi trade was afterwards, and as ſtock-jobbing is at preſent. The only difference between the tulip trade and ſtock-jobbing is, that at the end of the contract the price in the latter is determined by the Stock Exchange; whereas in the former it was determined by that at which moſt bargains were made. High and low priced kinds of tulips were procured, in order that both the rich and the poor might gamble with them; and the roots were weighed by perits, that an imagined whole might be divided, and that people might not only have whole, but half and quarter lots. Whoever is ſurpriſed that ſuch a traffic ſhould become general, needs only to reflect upon what is done where lotteries are eſtabliſhed, by which trades are often neglected, and even abandoned, becauſe a ſpeedier mode of getting fortunes is pointed out to the lower claſſes.

At length, however, this trade fell all of a ſudden. Among ſuch a number of contracts many were broken; many had engaged to pay more than they were able; the whole ſtock of the adventurers was conſumed by the extravagance of the winners; new adventurers no more engaged in it; and many becoming ſenſible of the odious traffic in which they had been concerned, returned to their former occupations. By theſe means, as the value of tulips ſtill fell, and never roſe, the ſellers wiſhed to deliver the roots *in natura* to the purchaſers at the prices agreed on; but as the latter had no deſire for tulips at even ſuch a low rate, they refuſed to take them or to pay for them. To end this diſpute, the tulip-dealers of Alkmaar ſent, in the year 1637, deputies to Amſterdam; and a reſolution was paſſed on the 24th of February, that all contracts made prior to the laſt of November 1636 ſhould be null and void; and that, in thoſe made after that date, purchaſers ſhould be free on paying ten *per cent.* to the vender.

The more diſguſted people became with this trade, the more did complaints increaſe to the magiſtrates of the different towns; but as the courts there would take no cognizance of it, the complainants applied to the States of Holland and Weſt Frieſland. Theſe referred the buſineſs to the determination of the provincial council at the Hague; which, on the 27th of April 1637, declared that it would not deliver its opinion on this traffic until it had received more information on the ſubject; that in the mean time every vender ſhould offer his tulips to the purchaſer; and, in caſe he refuſed to receive them, the vender ſhould either keep them, or ſell them to another, and have recourſe on the purchaſer for any loſs he might ſuſtain. It was ordered alſo, that all contracts ſhould remain in force till farther enquiry was made. But as no one could foreſee what judgment would be given reſpecting the validity of each contract, the buyers were more obſtinate in refuſing payment than before; and venders, thinking it much ſafer to accommodate matters amicably, were at length ſatisfied with a ſmall profit inſtead of exorbitant gain: and thus ended this extraordinary traffic, or rather gambling. *Beckmann's Hiſtory of Inventions*, vol. i.

Tulipomania || Turnsol.

TUMAR, in Bengal, rent-roll or aſſeſſment.

TUMBREL, is a kind of carriage with two wheels, uſed either in huſbandry for dung, or in artillery to carry the tools of the pioneers, &c. and ſometimes likewiſe the money of an army.

TUNGSTEN (See CHEMISTRY, n° 178, &c. in this *Suppl.*) when well fuſed, is, according to Guyton *alias* Morveau, of no higher ſpecific gravity than 8.3406. This is very different from the ſpecific gravity which has hitherto been aſſigned to it. The ſame eminent chemiſt concludes, from its extreme brittleneſs and difficulty of fuſion, that it affords little promiſe of utility in the arts, except in metallic alloys, or by virtue of the property which its oxyd poſſeſſes, of affording fixed colours, or giving fixity to the colours of vegetables.

TURNSOL, a dye-ſtuff manufactured in Holland, the preparation of which was long kept a profound ſecret. In order to miſlead foreigners, the Dutch pretended that turnſol was made from rags dyed with the juice of the ſun-flower (*Helianthus*), from which it obtained its name. Since the late revolution, however, in Holland, the true method employed by the Dutch for preparing this colour has been diſcovered, and the proceſs is as follows:—That kind of lichen called orchil (*Lichen-Rocella.* See that article in this *Suppl.*), or, when that cannot be procured, the large oak moſs, after being dried and cleaned, is reduced to powder, and by means of a kind of oil-preſs the powder is forced thro' a braſs ſieve, the holes of which are ſmall. The ſifted powder is then thrown into a trough and mixed with an alkali called *vetas*, which is nothing elſe than the aſhes of wine lees, in the proportion of half a pound of aſhes to one pound of powder. This mixture is moiſtened with a little human urine, for that of other animals contains leſs ammonia, by which a fermentation is produced; and the moiſtneſs is ſtill kept up by the addition of more urine. As ſoon as the mixture aſſumes a red colour, it is poured into another trough; is again moiſtened with urine, and than ſtirred round in order that the fermentation may be renewed. In the courſe of a few days it acquires a bluiſh colour, and is then carefully mixed with a third part of very pure pulveriſed potaſh; after which the mixture is put into wooden pails, three feet in height, and about half a foot broad. When the third fermentation takes place, and the paſte has acquired a conſiderably dark blue colour, it is mixed with chalk or pulveriſed marble, and ſtirred well round that the whole may be completely united. This laſt ſubſtance gives the colour no higher quality, and is intended merely to add to the weight. The blue, prepared in this manner, is poured into oblong ſquare iron moulds;

moulds; and the cakes, when formed, are placed upon fir boards on an airy floor in order to dry, after which they are packed up for sale.

TURPENTINE, a well known fubftance extracted from the pine. Under the article PINUS (*Encycl.*), we have given an account of one procefs by which this extract is made; but the following, which is taken from the 31ft volume of the *Journal de Phyfique*, is very different, and probably better. The pine from which turpentine is extracted, is never fit for this operation till it be thirty years of age. The extraction is begun in February and continued to the end of October. Incifions are made with an hatchet, beginning at the foot of the tree on one fide, and rifing fucceffively: they are repeated once or twice a week, the fize about one finger's breadth acrofs, and three or four inches long. During the four years in which it is continued, the incifions have rifen to about eight or nine feet. Then the incifions are begun on the other fide; and during this time the old ones fill up, and may be again opened after fome years; fo that a tree on a good foil, and well managed, may yield turpentine for a century. At the bottom of the tree, under the incifion, a hole is dug in the ground to receive the refin which flows from the tree. This refin is called *terebinthine brut*, is of a milky colour, and is that which flows during the three fummer months; it requires further purification.

The winter crop is called *barras galipot*, or white refin: it fticks to the bark of the tree, when the heat has not been ftrong enough to let it flow into the trough in the ground. It is fcraped off with iron knives.

Two methods are practifed for purifying thefe refins. That which is followed at Bayonne is to have a copper cauldron which will hold 300lb. of materials fixed over a fire, and the flame circulating at the bottom of the copper. The turpentine is put in, melted with a gentle heat, and, when liquid, it is ftrained through a ftraw-bafket made for the purpofe, and ftretched over a barrel, which receives the ftrained turpentine. This purification gives it a golden colour, and may be performed at all times of the year.

The fecond manner, which is practifed only in the mountain of De Buch, near Bourdeaux, confifts in having a large tub, feven or eight feet fquare, and pierced with fmall holes at the bottom, fet upon another tub to catch the liquor. This is expofed to the hotteft fun for the whole day, filled two thirds with turpentine, which as it melts falls through the holes, and leaves the impurities behind. This pure turpentine is lefs golden-coloured, and is much more efteemed than the other. This procefs can only be done in the fummer.

To make *oil* of turpentine, an alembic, with a worm like what is ufed by the diftillers, is employed here. It generally contains 250lb. of turpentine, which is boiled gently, and kept at the boiling point till no more oil paffes, when the fire is damped. This generally gives 60lb. of oil, and the operation lafts one day.

The boiling turpentine, when it will give no more oil, is tapped off from the ftill and flows into a tub, and from thence into a mold of fand, which it fills, and is fuffered to cool for at leaft two days without difturbing it. This refidue is known under the name of *colophony*. It is of a brown colour, and very dry. It may be made clearer and nearer in colour to that of the refin, by adding hot water to it before it is tapped off the ftill, and ftill boiling and ftirring the water well with it, which is done with a befom of wet ftraw; and it is then fold for rofin, but is little efteemed, as it contains no effential oil.

TUSCULANUM, a villa belonging to Cicero, near Tufculum, where he wrote his *Quæftiones Tufculanæ*, fo named from the place; thus become famous as well for the productions of genius as of nature. Formerly the villa of Sylla: now called *Grotta Ferrata*.—Another *Tufculanum* (infcription), a town of the Tranfpadana, fituated on the weft fide of the Lacus Benatus. Now faid to be called *Tofcolano*, in the territory of Brefcia, fubject to Venice. Here many monuments of antiquity are dug up.

TUSCULUM (anc. geog.), a town of Latium, to the north of Alba; fituated on an eminence, and therefore called *Supernum* (Horace, Strabo). In fight of Rome, at about the diftance of 100 ftadia, or 12 miles. Adorned with plantations and princely edifices: The fpot remarkable for the goodnefs of the foil, and its plenty of water. Built by Telegonus, who flew his father Ulyffes (Ovid, Horace); called the grandfon of Ulyffes in Silius Italicus. A municipium (Cicero); the birth-place of the elder Cato (Nepos, Cicero). Now *Frefcati*, in the Campania of Rome.

TUTENAG, according to Sir George Staunton, is, properly fpeaking, zinc extracted from a rich ore, or calamine. The ore is powdered and mixed with charcoal-duft, and placed in earthen jars over a flow fire, by means of which the metal rifes in the form of vapour, in a common diftilling apparatus, and afterwards is condenfed in water. The calamine from which tutenag is thus extracted, contains very little iron, and no lead or arfenic, fo common in the calamine of Europe (See CALAMINE, *Encycl.*) Hence it is that tutenag is more beautiful than our zinc, and that the white copper of the Chinefe takes fo fine a polifh. See *White Copper*, in this *Supplement*.

TYERS (Thomas), an author both in poetry and profe, the friend of Johnfon, and well known to moft of the eminent characters of the prefent time, was a ftudent of the Temple in 1753. His father intended him for the law, but the young man it feems penned a fonnet when he fhould engrofs. He was an accomplifhed, but not a profound man; and had tafte and elegance of mind, flightly tinged with gleams of genius. He wrote fome paftorals and political tracts, which probably will not furvive the partiality of his particular friends.

TYPOGRAPHY, as the word imports, is the art of printing by types; but it is likewife ufed to fignify the multiplying of copies by any mechanical contrivance. Of the art of printing by types, and the many improvements from time to time either made or attempted in it, a pretty full account will be found in the *Encyclopædia*, under the titles LETTER, LOGOGRAPHY, and PRINTING; and in this *Supplement* under the word PRINTING. Of typography, in the other and larger fenfe, fome account may likewife be found in the *Encyclopædia* under the title *Method of Copying WRITINGS*; but to almoft all thefe articles there is ample room for fome additions here.

The *ftereotype* printing of *Didot* and *Herhan*, being confidered in France as a great improvement, muft not be paffed over wholly without notice. The term *ftereotype*

type is derived from the Greek words στερεος and τυπος, becauſe in this method the types are fixed and immoveable in the form, ſo that none of them can be pulled or diſplaced by the preſſman. We need hardly obſerve, to thoſe who are at all acquainted with the hiſtory of printing, that the project of foldering a whole form together, or of caſting a ſolid form from an impreſſion made by a general ſyſtem of types, or page ready compoſed, is not new. It was realiſed 70 years ago by William Ged, a goldſmith in Edinburgh; for an account of whoſe method we refer the reader to his life in the *Encyclopædia*. Didot now follows nearly the ſame proceſs as Ged. He does not indeed caſt his types in a maſs, but after the form is compoſed and carefully corrected, he cements or ſolders the types together ſo firmly that none of them is liable to be looſened by the action of the preſs or the adheſion of the balls. How far this method of printing is of value with regard to books which are altered and improved in every ſubſequent edition, may, perhaps, be queſtioned; but on a looſe conſideration of the ſubject, it ſeems as if it would, in every caſe, be advantageous to a bookſeller to print a few copies of a work, and keep the types ſtanding to print others as they may be wanted; —we ſay it would be advantageous, if it were not for the immenſe value in types, which would, by that means, be locked up. To form ſome judgment of this, it may be ſtated, that the works of Virgil, printed by Didot, in 18mo, form a beautiful volume of 418 pages, of 35 lines each. The character ranges line for line with that called burgeois, No 2. in Caſlon's book of ſpecimens, the face of the letter being rather ſmaller; and we are told* that the price of the plates of this work is twelve hundred franks, or 50l. ſterling. From this fact ſome judgment may be formed of the commercial queſtion. We have caſually looked at different books printed by Didot, but can ſay nothing of their correctneſs: the page is very pretty.

* *La Decade Philoſophique.*

For multiplying copies of any writing, or of a book of ordinary ſize, Rochon, of the French National Inſtitute, and now Director of the Marine Obſervatory at the port of Breſt, invented, about the year 1781, a machine for engraving, with great celerity and correctneſs, the pages of the book or manuſcript on ſo many plates of copper. It was ſubmitted to the examination of a committee of the Royal Academy of Sciences, whoſe report of its utility was given in the following words:

"This machine appears to us to unite ſeveral advantages. 1*ſt*, Engraved editions of books may be executed, by this means, ſuperior to thoſe which can be made by the hand of the engraver, however ſkilful; and theſe engraved originals will be made with much more ſpeed, and much leſs expence. 2*d*, As this machine is portable, and of no conſiderable bulk, it may become very uſeful in armies, fleets, and public offices, for the impreſſion of orders, inſtructions, &c. 3*d*. It poſſeſſes the advantage which, in a variety of circumſtances, is highly valuable, of being capable of being uſed by any man of intelligence and ſkill, without requiring the aſſiſtance of any profeſſional workman. And, *laſtly*, It affords the facility of waiting for the entire compoſition and engravings of a work before any of the copies are pulled off; the expence of plates, even for a work of conſiderable magnitude, being an object of little charge; and this liberty it affords to authors, may prove highly beneficial in works of which the chief merit conſiſts in the order, method, and connection of ideas."

Rochon's machine conſiſts of two braſs wheels*, placed on the ſame axis above each other, and ſeparated by a number of pillars, each two inches in length. Theſe two wheels, with the interval which ſeparates them, are equivalent to a ſingle wheel about three inches thick. In order therefore to ſimplify the deſcription, they are conſidered as a ſingle wheel which moves freely on its axis.

* See Plate XLVI.

This wheel is perforated near its circumference with a number of ſquare holes, which are the ſheaths or ſockets through which a like number of ſteel punches, of the ſame ſhape, are inſerted, and are capable of moving up and down. They are very well fitted; and from this circumſtance, as well as the thickneſs of the double wheel, they have no ſhake, or ſide motion, independent of the motion of the wheel itſelf. Every punch is urged upwards by a ſeparate ſpring, in ſuch a manner, that the wheel armed with its characters, or ſteel types, (the lower faces of the punches being cut into the figures of the ſeveral letters), may turn freely on its axis; and if it be moved, the ſeveral punches will paſs in ſucceſſion beneath an upright ſcrew, for preſſure. The ſcrew is fixed in a very firm and ſolid frame, attached to the ſupports of the machine; and by this arrangement a copperplate, diſpoſed on the table, or bed of the apparatus, will receive the impreſſion of all the punches in ſucceſſion, as they may be brought beneath the vertical preſſing ſcrew, and ſubjected to its action.

But as the preſs is fixed, it would neceſſarily follow that each ſucceſſive impreſſion would, in part, deſtroy or mutulate the previous impreſſions, unleſs the plate itſelf were moveable. It therefore becomes neceſſary that the plate ſhould be moveable in two directions: the firſt, to determine the interval between the letters and words, and form the lines; and the other motion, which is more ſimple, becauſe its quantity may remain the ſame through the whole of a book, ſerves to give the interval between line and line, and to form the pages.

It will eaſily be conceived that it would be a tedious operation to ſeek, upon the circumference of the wheel, each ſeveral character, as it might be required to come beneath the preſs, becauſe it is neceſſary to repeat this operation as many times as there are characters in a work. The author has conſiderably diminiſhed the time and trouble of this operation, by fixing upon the axis of the great wheel, which carries the punches, another ſmall wheel, about four inches in diameter, the teeth of which act upon a rack, which carries a rule moving between two ſliders. This rule, or ſtraight line, will therefore repreſent the developement, or unfolding of the circumference of the wheel which cauſes it to move, and will ſhew the poſition of the great wheel, which carries the punches. For theſe two wheels being concentric, the developement of the ſmall toothed wheel, of about two inches radius, will exhibit, in a ſmall ſpace (for example, that of a foot), an accurate regiſter of the relative poſitions of the punches with regard to the preſſing-ſcrew. To obtain this effect, nothing more is neceſſary than to place a fixed index oppoſite to the moveable rule, which laſt is divided in the following manner:

The

The punch on which the firſt letter of the alphabet is engraved, muſt be brought under the centre of the preſſing-ſcrew; and a line of diviſion then drawn upon the moveable rule, to which the letter itſelf muſt be added to diſtinguiſh it. The index, already mentioned, being placed oppoſite, and upon this firſt diviſion, will ſerve to place immediately beneath the preſſing-ſcrew the punch, or rather the character, correſponding with the diviſion upon the rule, without its being afterwards neceſſary to inſpect the place either of the punch or the ſcrew, with regard to each other. Conſequently, as ſoon as the diviſions which correſpond with all the punches inſerted in the wheel are engraved upon the ſtraight rule, the fixed index will immediately determine the poſition into which that wheel muſt be brought, in order to place the punches under the preſſing-ſcrew in the order which the work may require.

This regiſter, for this name diſtinguiſhes the rule and its index, has no other function in the machine than to guide the hand of the operator, and to ſhew when the punch is very near its proper poſition beneath the preſſing-ſcrew. When this is the caſe, the required poſition is accurately obtained by means of a detent or catch.

The detent which he uſes for this operation is a lever with two tails, one of which is urged toward the circumference of the wheel by a ſpring. To this extremity of the lever is fixed a piece of hardened ſteel, of the figure of a wedge, which, by means of a ſpring, is preſſed towards the axis of the great wheel, but may be relieved, or drawn back, by preſſure on the oppoſite tail of the lever, ſo as to permit the great wheel to revolve at liberty.

In the next place, it muſt be explained how this detent takes hold of the wheel, ſo as to retain it preciſely in the ſituation neceſſary to cauſe any one of the punches, at pleaſure, to give its impreſſion to the plate. For this purpoſe there are a number of notches cut in the circumference of the wheel, for the purpoſe of receiving the detent. Theſe notches may be about half an inch deep, wider towards the circumference than elſewhere, and it will be of advantage that this outer width ſhould be as great as the circumference of the wheel can conveniently allow. By this contrivance, the wedge will not fail to preſent itſelf oppoſite to one of the notches into which it will fall, and draw the wheel exactly to its due ſituation, even though the index of the regiſter ſhould not be brought preciſely to the line of diviſion appropriated to any particular letter. For if this laſt degree of preciſion were required in working the machine, it would be very prejudicial to the requiſite ſpeed which, above all things, is required in its uſe. When the wedge is therefore left at liberty, it not only enters immediately into its place, and moves the wheel till its two ſides apply fairly to the interior ſurfaces of the notch, but retains the wheel in this ſtate with the neceſſary degree of ſtability.

The method of giving the proper figure to theſe notches is very eaſy. For this purpoſe it is neceſſary, in the firſt place, to impreſs all the characters contained in the wheel on a plate of copper or pewter. The ſupport on which the plate is fixed muſt be moved in a right line, after each ſtroke of the punch, through ſuch a ſpace that the characters may be arranged one after the other without touching. Now, as the perfect linear arrangement (ſuppoſing every other part to be true) muſt depend on the notches, it might ſeem ſufficient to cut theſe according to the method uſed for the wheels of clock work: but as it is very difficult to avoid ſome obliquity on the face of the punch, and perhaps in the hole through which it paſſes, it is in almoſt every caſe neceſſary to retouch the notch itſelf. The requiſite degree of preciſion may be eaſily obtained, when, upon examining with attention the print of the characters engraven upon the plate, the inequalities ſhall have been aſcertained by a very fine line paſſing exactly under the baſe of two ſimilar letters, aſſumed as objects of compariſon: for the irregularity of linear poſition may, by this means, be determined with great exactneſs, and remedied to the moſt extreme nicety. In this operation, the workman muſt file away part of that ſurface of the notch which is oppoſite to the direction of the motion the character requires. Great care muſt be taken to file only a ſmall portion at a time, in order that the inſtant may be ſeized at which the wedge, by entering into the notch, brings the character to its due ſituation.

Theſe details, reſpecting the right-lined arrangement on the characters, muſt not divert our attention from the very great celerity with which any letter is brought to its place under the preſs by means of the regiſter and detent. This celerity is an object of ſo much importance in the engraving of a great work, that every means ought to be purſued which may tend to increaſe it. For this reaſon it is, that inſtead of following the alphabetic order in the arrangement of punches on the ſurface of the wheel, we ought to prefer that in which the ſum of the different motions to be given to the wheel, for engraving an entire work, ſhall be the leaſt poſſible. This tedious enquiry may well be diſpenſed with, by obſerving the order in which printers diſpoſe their caſes of characters, that the letters of the moſt frequent recurrence may be moſt immediately under the hand of the workman.

If all the characters afforded an equal reſiſtance to impreſſion in a plate of metal, a conſtant force would never fail to drive the punches to the ſame depth. But the faces of the letters are very unequal, and conſequently it will be neceſſary to uſe a variable force. Moſt workmen uſe the hammer, and not a ſcrew, as in this machine, for ſtamping. If the hammer had been uſed in this machine, it is evident, that if we ſuppoſed it to have fallen from the ſame height upon every one of the punches, the force of the ſtroke could be rendered variable according to the nature of the characters, by placing a capital, or head, upon each, of an height properly adjuſted to receive the hammer after paſſing through a greater or leſs ſpace. But the heads of our punches are variable at pleaſure, becauſe they are ſcrewed on; and thus it is that, by experimentally adjuſting the heads of all the punches, a ſet of impreſſions are obtained of equal depths from every one of them. When, for example, the letter *i* is placed under the hammer, the upper part of its head is at a ſmall diſtance from the head of the hammer, in order that its fall, which begins always at the ſame place, may ſtrike this letter weakly; but when the letter M is brought under the hammer, the upper part of its head being much leſs elevated than that of the letter *i*, will receive a much ſtronger blow. The impreſſions of the letters M and *i* will therefore always

ROCHON'S MACHINE FOR ENGRAVING METALLIC PLATES

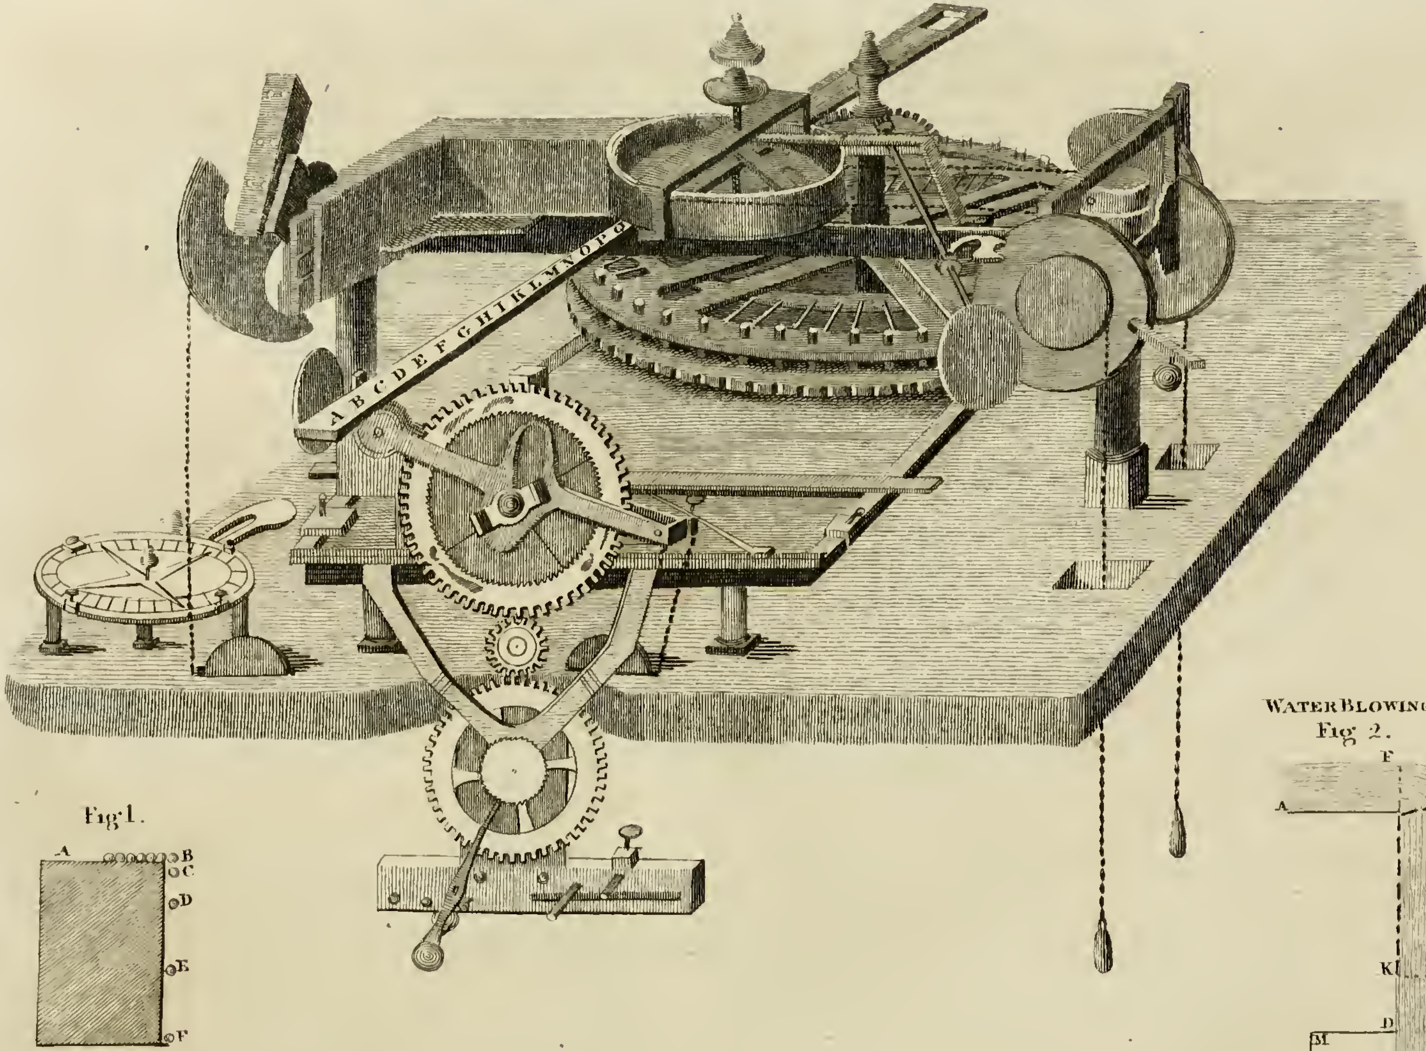


Fig 1.

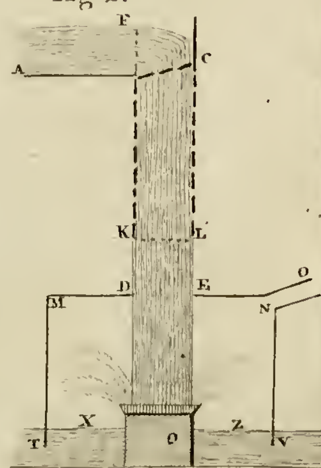
WATER BLOWING
Fig 2.



ways be equally deep, if the heads of the punches be once properly fixed by experiment.

Instead of the stroke of a hammer, however, our author makes use of the pressure of a screw, of which the threads are so inclined that it runs through its female socket, and would fall out merely by its own weight. This construction affords the double advantage of preserving the impressions from the effects of the circular motion, and of affording a fall in the screw of nearly nine lines for each revolution. The head of this screw is solidly fixed in the centre of a brass wheel, of which the position is horizontal. The diameter of this wheel must be sufficiently large, that its motion may not be perceptibly affected by the irregularities of friction in the screw. This considerable diameter is also requisite, because the pressure of the screw depends, not only upon the force which is applied, but the distance of the place of application from the centre of movement.

It is essential that this wheel should have very little shake; for which reason it is advisable that the axis of the screw should be prolonged above the wheel itself, that it may slide in a socket firmly fixed to the frame of the machine. In this situation, the wheel, which is fixed on the prolongation of the screw, will have its plane constantly preserved in a situation parallel to itself, without any libration, notwithstanding the rise and fall of near nine lines, or three quarters of an inch, which it undergoes for each revolution on its axis.

It has been stated, as a requisite condition, that the screw should constantly fall from the same fixed point, or elevation, upon the heads of every one of the punches. To accomplish this essential purpose, a lever is firmly fixed to the support of the screw; which lever resembles the beam of a balance, having one of its extremities armed with a claw, and the other serving to give it motion through a small verticle space. The claw falls into a notch in the upper surface of the wheel attached to the screw, as soon as that wheel has risen to the desired elevation; and the lever itself is so far limited in its motion, that it cannot take hold of the wheel, excepting when it has reached that height. The wheel, therefore, remains confined and immoveable, by means of this detent, and cannot descend until it is delivered by pressure upon the opposite tail of the lever. In this machine, the wheel which has the pressing screw for its axis does not perform an entire revolution. It was with a view that there might never be any fall capable of shaking and disturbing the machine that the author determined to use only two-thirds of a revolution to strike those punches, which afford the strongest resistance. The screw consequently falls only through six lines upon those heads which are least elevated, and about two lines upon those which stand highest. Whence the difference between the extreme heights does not exceed four lines.

It is obvious, that so small a difference is not sufficient to strike all the characters from M to the letter *i*, when the wheel which governs the screw is put in motion by a constant weight, of which the impulse, like that of a hammer, is increased only by the acceleration of its fall. It is evident that this requisite variation of force might be had by changing the weight; but it is equally clear, that the numberless and incessant changes which the engraving of an entire work would demand, would be incompatible with that degree of speed which forms one of the first requisites. He was therefore obliged to render the force of the weight, which turns the screw, variable, by causing it to act upon levers of greater or less lengths, according to the different quantities of impulse required by the several punches. For this purpose he adopted the following construction: He connected by a steel chain to the wheel, which moves the screw, another wheel, having its axis horizontal, so that the two wheels respectively command each other. They are of equal diameter, and the chain is no longer than to make an entire turn round each wheel. This second wheel, or leading pulley, is intended to afford the requisite variations of force, which it does by means of a snail fixed upon its axis. The snail is acted upon by a cord passing over its spiral circumference, or groove, and bearing a weight which is only to be changed when a new set of punches for characters of a different size are put into the great wheel. The spiral is so formed, that when the weight descends only through a small space, the part of the cord, which is unwound, acts at a very short distance from the centre of the pulley; but when the fall is greater, the part of the snail upon which it acts is so far enlarged as to afford a much longer lever, and consequently, to give a proportionally greater effect to the stroke. This construction, therefore, by giving the advantage of a longer lever to a greater fall of the screw, affords all the power which the nature of the work, and the different spaces of the letters demand.

The support on which the plate is fixed must, as has before been remarked, move so as to form strait lines. This motion, which serves to space the different characters with precision, is obtained by means of a screw, the axis of which remains fixed, and carries a female screw or nut. The nut itself is attached to the support of the metallic plate, which receives the letters, and carries it in the right lined direction without any deviation; because it is confined in a groove formed between two pieces of metal. The screw is moved by a lever, which can turn it in one direction only, because it acts by a click upon a ratchet-wheel, which is fixed to the head of the screw. The action of this lever always begins from a fixed stop; but the space through which it moves is variable, according to the respective breadths of the letters. This new consideration induced M. Rochon to fix upon the rule or plate of the register, a number of pins, corresponding with the different divisions which answer to each punch: these pins determine the distance to which the lever can move. It therefore becomes a condition, that its position in the machine should be opposite to the fixed index which determines the character at any time beneath the pressing-screw. The lever and its pin are therefore the sole agents employed to space the characters. If the plate were not moved by the lever, the impressions would fall upon each other; and thus, for example, the letter *i* would be totally obliterated by the impression of the letter *l*.

Whenever, therefore, it is required to dispose the letters *i* and *l* beside each other, the plate must be moved after striking the letter *i* through a space equal to the quantity of the desired operation. Suppose this to be one-fourth of a line, and that the lever should run through an arc of ten degrees to move the plate thro' this quantity; as soon as the pin of the letter *l* shall be adjusted to the necessary length to enable the lever to describe an arc of ten degrees, the operation of spacing the

the two letters *i* and *l* will be reduced to that of placing the laſt letter beneath the fixed index, and moving the plate till the lever ſhall be ſtopped by the pin belonging to the letter *l*. All the other letters will be equally ſpaced, if the diſpoſition of the punches in the wheel be ſuch, that the laſt ſtroke of any letter ſhall confound itſelf with any letter of a ſingle ſtroke, ſuppoſing them to be impreſſed one after the other, without moving the lever between ſtroke and ſtroke. This arrangement deſerves to be very ſeriouſly attended to, becauſe the proceſs could not be performed without it.

Many well-informed perſons are of opinion, that the perfect equality which this machine for engraving affords in the formation of letters and ſigns the moſt difficult to be imitated, may afford a means of remedying the dangers of forgery. It is certain that the performance exhibits a ſimple and ſtriking character of preciſion, which is ſuch, that the leaſt experienced eyes might flatter themſelves, in certain caſes, to diſtinguiſh counterfeits from originals. Lavoiſier, whom the friends of ſcience and the arts will not ceaſe to regret, made ſome experiments of this kind for the *caiſſe de'ſcompte*, which were attended with perfect ſucceſs. Artiſts appointed for that purpoſe endeavoured in vain to imitate a vignette, formed by the ſucceſſive and equal motion of a character of ornament.

TYRTÆUS, an Athenian general and muſician, is celebrated by all antiquity for the compoſition of military ſongs and airs, as well as the performance of them. He was called to the aſſiſtance of the Lacedæmonians in the ſecond war with the Meſſenians, about 685 B. C.; and a memorable victory which they obtained over that people is attributed by the ancient ſcholiaſts upon Horace to the animating ſound of a new military flute or clarion, invented and played upon by Tyrtæus. Plutarch tells us that they gave him the freedom of their city; and that his military airs were conſtantly ſung and played in the Spartan army to the laſt hour of the republic. And Lycurgus the orator, in his oration againſt Leocrates, ſays, "The Spartans made a law, that whenever they were in arms, and going out upon any military expedition, they ſhould all be firſt ſummoned to the king's tent to hear the ſongs of Tyrtæus;" thinking it the beſt means of ſending them forth in a diſpoſition to die with pleaſure for their country. Fragments of his poetry, in elegiac verſe, are preſerved in Stobæus, Lycurgus Orat. in Fulvius Urſinus, at the end of Poems by illuſtrious Women; and in the Oxford edition of *Eleg. & Lyric Frag. & Scholia*, printed 1759. Εκ Συζομενα, &c.

TYTLER (William, Eſq;), ſo well known in the literary world as one of the ableſt, and certainly the moſt gentlemanly, of the defenders of the fame of Mary Queen of Scots, was born at Edinburgh, October 12. 1711. He was the ſon of Mr Alexander Tytler, writer (or attorney) in Edinburgh, by Jane, daughter of Mr William Leſlie, merchant in Aberdeen, and granddaughter of Sir Patrick Leſlie of Idan, provoſt of that city. He received his education at the grammar ſchool (or, as it is there called, the High School) and the univerſity of his native city, and diſtinguiſhed himſelf by an early proficiency in thoſe claſſical ſtudies, which, to the lateſt period of his life, were the occupation of his leiſure hours, and a principal ſource of his mental enjoyments.

In the year 1731, he attended the academical lectures of Mr Alexander Bayne, Profeſſor of municipal law in the univerſity of Edinburgh, a gentleman diſtinguiſhed alike for his profeſſional knowledge, his literary accompliſhments, and the elegance of his taſte. The Profeſſor found in his pupil a congenial ſpirit; and their connection, notwithſtanding the diſparity of their years, was ſoon ripened into all the intimacy of the ſtricteſt friendſhip. So ſtrong indeed became at length that tie of affection, that the worthy Profeſſor, in his latter years, not only made him the companion of his ſtudies, but when at length the victim of a lingering diſeaſe, choſe him as the comforter of thoſe many painful and melancholy hours which preceded his death.

At the age of 31, Mr Tytler was admitted into the Society of Writers to his Majeſty's Signet, and continued the practice of that profeſſion with very good ſucceſs, and with equal reſpect from his clients and the public, till his death, which happened on the 12th of September 1792. He married, in September 1745, Anne Craig, daughter of Mr James Craig of Dalnair, writer to the ſignet, by whom he has left two ſons, Alexander Fraſer Tytler, one of the Lords of Seſſion in Scotland; and Patrick Tytler, Lieutenant-colonel of a regiment of fencible infantry, and Fort-major of the caſtle of Stirling; together with one daughter, Miſs Chriſtina Tytler. His wife died about nine years before him; and, previouſly to that period, he had loſt a ſon and a daughter, both grown to maturity.

The moſt remarkable feature of Mr Tytler's character was an ardour and activity of mind, prompted always by a ſtrong ſenſe of rectitude and honour. He felt with equal warmth the love of virtue and the hatred of vice; he was not apt to diſguiſe either feeling, nor to compromiſe, as ſome men more complying with the world might have done, with the faſhion of the time, or the diſpoſition of thoſe around him. He ſeldom waved an argument on any topic of hiſtory, of politics, or literature; he never retreated from one on any ſubject that touched thoſe more important points on which he had formed a decided opinion. Decided opinions he always formed on ſubjects of importance; for on ſuch ſubjects he formed no opinions raſhly; and what he firmly believed he avowed with confidence, and ſometimes with warmth.

Nor was it in opinion or argument only that this warmth and ardour of mind were conſpicuous. They prompted him equally in action and conduct. His affection to his family, his attachment to his friends and companions, his compaſſion for the unfortunate, were alike warm and active. He was in ſentiment alſo what Johnſon (who felt it ſtrongly in himſelf, and mentions it as the encomium of one of his friends) calls a *good hater*; but his hatred or reſentment went no further than opinion or words, his better affections only roſe into action. In his opinions, or in his expreſſion of them, there was ſometimes a vehemence, an appearance of acrimony, which his friends might regret, and which ſtrangers might cenſure; but he had no aſperity in his mind to influence his actual conduct in life. He indulged oppoſition, not enmity; and the world was juſt to him in return. He had opponents; but two of his biographers, who knew him well, as well as the people with whom he moſt aſſociated, declare their belief that he had not a ſingle enemy. His conteſts were on opinions,

 nions, not on things; his difputes were hiftorical and literary. In converfation, he carried on thefe with uncommon intereft and vivacity; and the fame kind of impulfe which prompted his converfation (as is juftly obferved by an author, who publifhed fome notices of his life and character in the periodical work intitled *The Bee*) induced him to become an author. He wrote not from vanity or vain glory, which Rouffeau holds to be the only inducement to writing; he wrote to open his mind upon paper; to fpeak to the public thofe opinions which he had often fpoken in private; opinions on the truth of which he had firmly made up his own conviction, and was fometimes furprifed that he could not convince others: it was fair to try, if, by a fuller expofition of his arguments, he could convince the world.

With this view, he publifhed, in 1759, his "Inquiry, hiftorical and critical, into the Evidence againft *Mary Queen of Scots*, and an Examination of the Hiftories of Dr Robertfon and Mr Hume with refpect to that Evidence;" in which he warmly efpoufed the caufe of that unfortunate Princefs, attacked with feverity the conduct of her enemies, and expofed the fallacy, in many parts the fabrication, of thofe proofs on which the charges againft her had been founded.

This was a caufe worthy of an advocate who loved truth better than popular applaufe; and Mr Tytler evinced himfelf to be fuch an advocate. The problem of Mary's guilt or innocence, if confidered merely as a detached hiftorical fact, would appear an object which, at this diftance of time, feems hardly to merit that laborious and earneft inveftigation to which it has given rife; though, even in this point of view, the mind is naturally ftimulated to fearch out the truth of a dark myfterious event, difgraceful to human nature; and our feelings of juftice and moral rectitude are interefted to fix the guilt upon its true authors. But when we confider that this queftion involves a difcuffion of the politics of both England and Scotland during one of the moft interefting periods of their hiftory, and touches the characters, not only of the two fovereigns, but of their minifters and ftatefmen, it muft then be regarded in the light of a moft important hiftorical inquiry, without which our knowledge of the hiftory of our own country muft be obfcure, confufed, and unfatisfactory. In addition to thefe motives of inquiry, this queftion has exercifed fome of the ableft heads both of earlier and of later times; and it is no mean pleafure to engage in a conteft of genius and of talents, and to try our ftrength in the decifion of a controverfy which has been maintained on both fides with confummate ability.

As we have elfewhere (fee Mary, *Encycl.*) given an abftract of the arguments on both fides of this difputed queftion, it would be altogether improper to repeat them here; but juftice to the fubject of this memoir requires us to fay, that by his manner of difcuffing it he acquired high reputation in the republic of letters. Before the appearance of the Inquiry, fays an ingenious writer, it was the fafhion for literary difputants to attack each other like mifcreants and banditti. The *perfon* was never feparated from the *caufe*; and whatever attached the *one*, was confidered as equally affecting the *other*; fo that fcurrility and abufe blotted the pages even of a Bentley and a Ruddiman. The Hiftorical Inquiry was free from every thing of that fort: and though the higheft name produced not a mitigation of the force of any argument, the meaneft never fuffered the fmalleft abufe. He confidered it as being greatly beneath the dignity of a man contending for truth, to overftretch even an argument in the fmalleft degree, far more to pervert a fact to anfwer his purpofe on any occafion. In the courfe of his argument, he had too often occafion to fhew that this had been done by others; but he difdained to imitate them. His reafoning was forcible and elegant; impartially fevere, but always polite, and becoming the gentleman and the fcholar.

When this book appeared, it was univerfally read in Britain, and very well tranflated into French, under the title of "Recherches Hiftoriques et Critiques fur les Principales Preuves de l'Accufation intentée contre Marie Reine d'Ecoffe." The intereft it excited among literary men may be judged of from the character of thofe by whom it was reviewed on its publication, in the periodical works of the time. Dr Douglas, now Bifhop of Salifbury, Dr Samuel Johnfon, Dr John Campbell, and Dr Smollet—all wrote reviews of Mr Tytler's book, containing very particular accounts of its merits, and elaborate analyfes of the chain of its arguments. As an argument on evidence, no fuffrage could perhaps be more decifive of its merit than that of one of the greateft lawyers, and indeed one of the ableft men that ever fat on the woolfack of England, the late Lord Chancellor Hardwicke, who declared Mr Tytler's Inquiry to be the beft concatenation of circumftantiate proofs brought to bear upon one point that he had ever perufed. What effect that body of evidence, or the arguments deduced from it, ought to have upon the minds of thofe to whom the fubject may become matter of inveftigation, we do not prefume to determine. The opinion of the late Dr Henry, author of the Hiftory of Great Britain on a New Plan, may perhaps be thought neither partial nor confident. He fays, in a letter to Mr Tytler, publifhed in the firft volume of Tranfactions of the Antiquarian Society of Scotland, That he would be a bold man who fhould now publifh an Hiftory of Queen Mary in the fame ftrain with the two hiftorians (Mr Hume and Dr Robertfon), whofe opinions on the fubject the Inquiry had examined and controverted.

The moft exceptionable part of Mary's conduct, which, though it may admit of an apology, cannot be vindicated, is her marriage to Bothwell; and for that marriage Mr Tytler made an apology, founded on facts, which he would be a daring or very bigotted man who would attempt to controvert. See the article already referred to.

Befides the *Hiftorical Inquiry*, and the *Differtation on the Marriage of Queen Mary with the Earl of Bothwell*, our author publifhed feveral other works on hiftorical and literary fubjects; of which the firft was, the *Poetical remains of James I. King of Scotland*, confifting of *the King's Quier*, in fix cantos, and *Chrift's Kirk on the Green*; to which is prefixed a differtation on the Life and Writings of King James, in one volume 8vo, printed at Edinburgh in 1783. This differtation forms a valuable morfel of the literary hiftory of Europe; for James ranked ftill higher in the literary world as a *poet*, than in the political world as a *prince*. Great juftice is done to his memory in both refpects in this differtation: and the two morfels of poetry here refcued from oblivion will be efteemed by men of tafte as long as

Tytler.

as the language in which they are written can be underſtood (A).

2. "A diſſertation on Scottiſh Muſic," firſt ſubjoined to Arnot's hiſtory of Edinburgh. The ſimple melodies of Scotland have been long the delight of the natives, many of which, to them, convey an idea of pathos that can be equalled by none other; and are much admired by every ſtranger of muſical talents who has viſited this country. They have a powerful effect, indeed, when properly introduced, as a relief, into a muſical compoſition of complicated harmony. Theſe are of two kinds, pathetic and humorous. Thoſe who wiſh to receive information concerning this curious ſubject, will derive much ſatisfaction from the peruſal of this diſſertation. There is yet another kind of muſic peculiar to the Highlands of Scotland, of a more wild, irregular, and animating ſtrain, which is but ſlightly treated here, and requires to be ſtill more fully elucidated.

3. "Obſervations on the Viſion, a poem," firſt publiſhed in Ramſay's Evergreen, now alſo printed in the Tranſactions of the Society of Antiquaries of Scotland. This may be conſidered as a part of the literary hiſtory of Scotland.

4. "On the Faſhionable Amuſements in Edinburgh during the laſt century," *ibid.* It is unneceſſary to dwell on the light that ſuch diſſertations as theſe, when judiciouſly executed, throw upon the hiſtory of civil ſociety and the progreſs of manners. Mr Tytler was likewiſe the author of N° 16. of the Lounger, a weekly paper, publiſhed at Edinburgh in the year 1786. His ſubject is the Defects of Modern Female Education in teaching the Duties of a Wife; and he treats that ſubject like a maſter.

On all Mr Tytler's compoſitions the character of the *man* is ſtrongly impreſſed, which never, as in ſome other inſtances, is in the ſmalleſt degree contradicted by, or at variance with, the character of the *author*. He wrote what he felt, on ſubjects which he felt, on ſubjects relating to his native country, to the arts which he loved, to the times which he revered. His heart, indeed, was in every thing which he wrote, or ſaid, or did. He had, as his family and friends could warmly atteſt, all the kindneſs of benevolence: he had its anger too; for benevolence is often the parent of anger. There was nothing neutral or indifferent about Mr Tytler. In philoſophy and in hiſtory, he could not bear the coldneſs, or what ſome might call the temperance of ſcepticiſm; and what he firmly believed, it was his diſpoſition keenly to urge.

His mind was ſtrongly impreſſed by ſentiments of religion. His piety was fervent and habitual. He believed in the doctrine of a particular Providence, ſuperintending all the actions of individuals as well as the great operations of Nature: he had a conſtant impreſſion of the power, the wiſdom, and the benevolence of the Supreme Being; and he embraced, with thorough conviction, the truths of Chriſtianity.

His reading was various and extenſive. There was ſcarcely a ſubject of literature or taſte, and few even of ſcience, that had not at times engaged his attention. In hiſtory he was deeply verſed; and what he had read his ſtrong retentive memory enabled him eaſily to recal. Ancient as well as modern ſtory was familiar to him; and, in particular, the Britiſh hiſtory, which he had read with the moſt minute and critical attention. Of this, beſides what he has given to the public, a great number of notes, which he left in MS. touching many controverted points in Engliſh and Scottiſh hiſtory, afford the moſt ample proof.

In muſic as a ſcience he was uncommonly ſkilled. It was his favourite amuſement; and with that natural partiality which all entertain for their favourite objects, he was apt to aſſign to it a degree of moral importance which ſome might deem a little whimſical. He has often been heard to ſay, that he never knew a good taſte in muſic aſſociated with a malevolent heart: And being aſked, What preſcription he would recommend for attaining an old age as healthful and happy as his own? "My preſcription (ſaid he) is ſimple—ſhort but cheerful meals, muſic, and a good conſcience."

In domeſtic life, Mr Tytler's character was particularly amiable and praiſe worthy. He was one of the kindeſt huſbands and moſt affectionate fathers. At the beginning of this account, we mentioned his having loſt, at an advanced period of life, an excellent wife, and a ſon and a daughter both grown to maturity, who merited and poſſeſſed his warmeſt affections. The temper of mind with which he bore theſe loſſes, he has himſelf expreſſed in a MS. note, written not long before his death; with which, as it conveys a ſentiment equally important in the conſideration of this life, and in the contemplation of that which is to come, we ſhall conclude the preſent memoir: "The lenient hand of time (ſays he) after mentioning the death of his wife and children), the lenient hand of time, the affectionate care of my remaining children, and the duty which calls on my exertions for them, have by degrees reſtored me to myſelf. The memory of thoſe dear objects gone before me, and the ſoothing hope that we ſhall ſoon meet again, is now the ſource of extreme pleaſure to me. In my retired walks in the country I am never alone; thoſe dear ſhades are my conſtant companions! Thus what I looked upon as a bitter calamity, is now become to me the chief pleaſure in life."

U, V.

(A) There is a beautiful hiſtorical picture of this prince playing on the harp, with his queen and a circle of his courtiers liſtening to the muſic, by Graham, in London; one of the moſt eminent artiſts of the age.

U, V.

VACUUM Boyleanum, is the approach to a real vacuum, to which we can arrive by means of the air-pump.

Torricellian Vacuum, is the most complete vacuum which we can make by means of the torricellian tube. See Barometer, and Pneumatics, *Encycl.*

VADE-mecum, the title given to such books as men of particular professions, having frequent occasion to consult, may easily carry about with them. Thus a small volume, published in the beginning of the 18th century, giving an account of the ancient and present church of England, and of the duties, rights, privileges, and hardships of the clergy, is known by the title of *the Clergyman's Vade-mecum.*

VAKEEL, a minister, agent, or ambassador.

VALGUS, *Bow* or *Bandy Legged.* Some children are bow-legged from their birth; others become so from setting them on their feet too early. The tibia of some is crooked; the knees of others are distorted; from a fault in the ankle, the feet of some are turned inwards, these are called *vari;* and in others they turn outwards, these are called *valgi.* The best method of preventing these disorders in weakly children, is to exercise them duly, but not violently; by dancing or tossing them about in one's arms, and not setting them much on their feet, at least not without properly supporting them: if the disorder attends at the birth, or increases after it is begun, apply emollients, then apply boots of strong leather, wood, &c. as required to dispose the crooked legs gradually to a proper form: or other instruments may be used instead of boots, which, when not too costly, are usually to be preferred. Slighter instances of these disorders yield to careful nursing without instruments.

VANDA', the Indian name of a plant of the genus Epidendrum; which see, *Encycl.* The *vandá* is thus described by Sir William Jones.

"Cal. *Spathes* minute, straggling. Cor. *Petals* five, diverging, oval oblong, obtuse, wavy; the two lowest larger; the three highest equal, bent towards the nectary. *Nectary* central, rigid: *Mouth* gaping, oblique: *Upper lip* shorter, three parted, with a polished honey-cup; *under lip* concave in the middle, keeled above, with two smaller cavities below, two processes at the *base*, incurved, hollow, oval pointed, converging, honey-bearing. Stam. *Filaments* very short. *Anthers* round, flattish, margined, covered with a lid, easily deciduous from the *upper lip* of the nectary. Pist. *Germ.* beneath long, ribbed, contorted with curves of opposite flexure. *Style* very short, adhering to the *upper lip*. *Stigma* simple. Per. *Capsule* oblong-conic, wreathed, six-keeled, each with two smaller keels, three-celled, crowned with the dry corol. Seeds innumerable, like fine dust affixed to the *receptacle* with extremely fine hairs, which become thick wool. *Scapes* incurved, solitary, from the cavity of the leaf, at most seven flowered; pedicles alternate. *Petals* milk-white externally, transparent; brown within, yellow-spotted. *Upper lip* of the nectary snow-white; *under lip* rich purple, or light crimson, striated at the base, with a bright yellow gland, as it seems, on each process. The flowers gratefully fragrant, and exquisitely beautiful, looking as if composed of shells, or made of enamel; crisp elastic, viscid internally. *Leaves* sheathing, opposite, equally curved, rather fleshy, sword-form, retuse in two ways at the summit, with one acute point. *Roots* fibrous, smooth, flexible; shooting even from the top of the leaves."

This lovely plant attaches itself chiefly to the highest *Amras* and *Bilvas* (the *Mangifera* and *Crateva* of Lin.); but it is an air-plant, and lives (says the President) in a pot *without earth or water:* its leaves are excavated upwards, to catch and retain dew.

VANDALIA, a duchy of Farther Pomerania, subject to the king of Prussia. Stolpen is the capital.

Vandalia, a country in Germany, in the circle of Lower Saxony and duchy of Mecklenburg. It lies between the bishopric and duchy of Schwerin, the lordships of Stocrock and Stargard, Pomerania, and the marquisate of Brandenburg; and is 75 miles in length and 7 in breadth. It contains several small lakes, and the principal town is Gustrow.

VANDERMONDE, member of the National Institute of Sciences and Arts, was born at Paris in the year 1735. He devoted his youth to self-instruction; and even at the age of thirty was far enough from suspecting that he was destined to instruct others in his turn. Chance brought him near to the celebrated Fontaine. That sexagenary geometrician easily divined the progress which Vandermonde would one day make in the mathematics; in him he anticipated, as it were, a successor to himself; he patronised and caressed him, let him into the secret of his researches, calculations, inventions, of that lively enjoyment which profound speculation gives to an elevated attentive mind; and which, blended with the sweets of tranquillity, the charms of retreat, and the consciousness of success, becomes often a sort of passion, as felicitous as durable. All that time Fontaine, whose attention was again directed to the researches which he had added to those of Jean Bernouili, relative to the then famous question *of the toutocrones*, had the glory to be vanquished only by D'Alembert and La Grange. Vandermonde, a witness to this combat, necessarily illustrious, animated by the honour which he saw annexed to that glorious defeat, enchanted with the sight of Fontaine, as happy, in spite of his age, from his love of geometry, as a youth of twenty could be with a sentiment less tranquil, thought he should insure his happiness for ever, by yielding to a passion which the ice of age could not extinguish; in a word, he devoted himself to geometry.

His labours, however, were for some time secret; and perhaps the public would never have enjoyed the benefit of any of his works, if another geometrician (whose name, says Lacepede, cannot be pronounced, in this place, without a mixture of interest and regret) had not inspired him with a consciousness of his own strength, and courage to display it. Fontaine had already devoted him to geometry; Dusejour exhorted him to penetrate even into its sanctuary. In brief, he presented himself

Vandermonde.

himself to the Academy of Sciences, into which he was admitted in 1771; and in that very year justified the suffrages of his associates, by a paper which he published relative to the resolution of equations.

From the 16th century the method of resolving equations of the four first degrees has been known, and since that time the general theory of equations has received great improvements. In spite, however, of the recent labours of many great geometricians, the solutions of equations of the fifth degree had in vain been attempted. Vandermonde wished to consolidate his labours with those of other illustrious analysts; and he proposed a new theory of equations, in which he seems to have made it particularly his business to simplify the methods of calculation, and to contract the length of the *formulæ*, which he considered as one of the greatest difficulties of the subject.

This work was quickly followed by another on the problems called by geometricians *problems of situation*. It seems to have been the destiny of Vandermonde, as well as of Fontaine, who first initiated him into the mysteries of mathematical science, to labour frequently upon subjects already handled by the greatest master. In his first memoir he had started, so to speak, in competition with La Grange and Euler; in his second, with Euler and Leibnitz. This last was of opinion that the analysis made use of in his time, by the geometricians, was not applicable to all questions in the physical sciences; and that a new geometry should be invented, to calculate the relations of positions of different bodies, in space: this he called *geometry of situation**. Excepting, however, one application, made by Leibnitz himself, to the game of *solitaire*, and which, under the appearance of an object of curiosity, scarcely worthy the sublimity and usefulness of geometry, is an example for solving the most elevated and important questions, Euler was almost the only one who had practised this geometry of situation. He had resorted to it for the solution of a problem called the *cavalier*, which also appeared very familiar at first sight, and was also pregnant with useful and important applications. This problem, with the vulgar, consisted merely in running through all the cases of the chess board, with the *knight* of the game of chess; to the profound geometrician, however, it was a precedent for tracing the route which every body must follow, whose course is submitted to a known law, by conforming to certain required conditions, through all the points disposed over a space in a prescribed order. Vandermonde was chiefly anxious to find in this species of analysis a simple notation, likely to facilitate the making of calculations; and he gave an example of this, in a short and easy solution of the same problem of the cavalier, which Euler had rendered famous.

* See Position, *Suppl.*

His taste for the high conceptions of the speculative sciences, as blended with that which the *amor patriæ* naturally inspires for objects immediately useful to society, had led him to turn his thoughts towards perfecting the arts conversant in weaving, by indicating a manner of noting the points through which are to pass the threads intended to form the lines which terminate the surface of different regular bodies: accordingly a great part of the above memoir is taken up with this subject.

In the year following (1772) he printed a third memoir; in which he traced out a new path for geometers, discovering, by learned analytical researches, *irrational* quantities of a new species, shewing the sequels of which these *irrationals* are the terms or the sum, and pointing out a direct and general method of making in them all the possible reductions.

Vandermonde, Varenius.

In the same year appeared his work on the Elimination of unknown Quantities in Algebra. This elimination is the art of bringing back those equations which include many unknown quantities, to equations which only contain one. The perfection of researches in this art would consist in obtaining a general and particular *formula* of elimination in a form the most concise and convenient, in which the number of equations and their degrees should be designed by indeterminate letters. Vandermonde, while he considered the geometers as very distant from this point, had some glimpse of a possibility of reaching it, and proposed some new methods of approaching nearer it.

In 1778, he presented, in one of the public sittings of the Academy, a new system of harmony, which he detailed more fully in another public sitting of 1780. In this system, Vandermonde reduces the modes of proceeding adopted until his time, to two principal rules, which thus become established on effects admitted by all musicians. These two general rules, one on the succession of according sounds, the other on the arrangement of the parts, depend themselves on a law more elevated, which, according to Vandermonde, ought to rule the whole science of harmony.

By the publication of this work, he satisfactorily attained the end he had proposed to himself, and obtained the suffrages of three great men, representatives, so to speak, of the three great schools of Germany, France, and Italy; Gluck, Philidor, and Piccini.

With these labours, intermingled with frequent researches on the mechanic arts, as well as on objects of political economy, the attention of Vandermonde was taken up; when, July 14. 1789, the voice of liberty resounded over the whole surface of France, and suddenly all the thoughts, as well as all the affections, of Vandermonde, were engaged on the side of what he called liberty.

He became so furious a democrate, so outrageous an enemy to every thing established, that he concurred in the abolition of the Royal Academy, of which he had been so ambitious of becoming a member, and associated himself closely with Robespierre, Marat, and the rest of that atrocious gang of villains, who covered France with ruins, with scaffolds, and with blood. This part of Vandermonde's history is suppressed by his eulogist Lacepede, because, forsooth, discussions on *political opinions* ought not, in his opinion, to be admitted into the sanctuary of the sciences.

In that sanctuary he did not long remain. Soon after his atrocities, he was attacked by a disorder in his lungs, which almost taking away his breath, manifested itself by alarming symptoms, and conducted him by rapid steps to the tomb. He died in the end of the year 1795; a striking instance of the wayward violence of the human mind, which even the love of science could not keep at a distance from tumult and uproar.

VARENIUS (Bernard), a learned Dutch geographer and physician of the 17th century, who was author of the best mathematical treatise on geography, intitled, *Geographia Universalis, in qua affectiones generalis Telluris*

ris explicantur. This excellent work has been tranflated into all languages, and was honoured by an edition, with improvements, by Sir Ifaac Newton, for the ufe of his academical ftudents at Cambridge.

VARIABLE, in geometry and analytics, is a term applied by mathematicians to fuch quantities as are confidered in a variable or changeable ftate, either increafing or decreafing. Thus the abfciffes and ordinates of an ellipfis, or other curve line, are variable quantities; becaufe thefe vary or change their magnitude together, the one at the fame time with the other. But fome quantities may be variable by themfelves alone, or while thofe connected with them are conftant: as the abfciffes of a parallelogram, whofe ordinates may be confidered as all equal, and therefore conftant; alfo the diameter of a circle, and the parameter of a conic fection, are *conftant*, while their abfciffes are *variable*. See FLUXIONS, *Encycl.*

VARIATION OF CURVATURE, in geometry, is ufed for that inequality or change which takes place in the curvature of all curves except the circle, by which their curvature is more or lefs in different parts of them; and this variation conftitutes the quality of the curvature of any line.

1 Variolæ vaccinæ longknown in Gloucefterfhire,

VARIOLÆ VACCINÆ, or *Cow-pox*, is the name commonly, though as fome people think, improperly, given to a very fingular difeafe, which, for two or three years paft, has occupied a great fhare of the attention of medical men. It has been many years prevalent in fome of the great dairy counties in England, particularly Gloucefterfhire; and it has been long underftood by the farmers and others in thefe counties, that it for ever exempts all perfons who have been infected with it from the contagion of fmall-pox.

It is very furprifing that, though they knew this fact, and although no perfon had ever been known to die of the cow-pox, they never thought of having recourfe to a voluntary infection of this kind, in order to free themfelves and their families from the poffibility of being infected with the variolous poifon, which fo often proves mortal. In one cafe, indeed, communicated to Dr Pearfon by Mr Downe of Bridport, the experiment was long ago tried by a farmer upon his own perfon, and with complete fuccefs: But this only makes it the more wonderful that his example fhould not have been followed.

2 And in the duchy of Holftein.

In the town of Kiel, however, in the duchy of Holftein, where the difeafe is faid to be well known, as frequently affecting cows, we are told that children are fometimes inoculated with cow-pox *(Die Finnen)*, with a view to preferve their beauty; but that the people in the country do not like this inoculation, becaufe they pretend that it leaves behind it feveral diforders.

3 Vaccine inoculation introduced by Dr Jenner.

With thefe exceptions, Dr Jenner was the firft perfon who introduced the vaccine inoculation; and to him the public are alfo indebted for the firft careful and accurate inveftigation of this interefting fubject. The following is his account of the origin and hiftory of the difeafe, and of its characteriftic fymptoms.

4 Origin of the difeafe, according to him.

"There is a difeafe to which the horfe, from his ftate of domeftication, is frequently fubject. The farriers have termed it *the greafe*. It is an inflammation and fwelling in the heel, from which iffues matter poffeffing properties of a very peculiar kind, which feems capable of generating a difeafe in the human body (after it has undergone the modification which I fhall prefently fpeak of), which bears fo ftrong a refemblance to the fmall-pox, that I think it highly probable that it may be the fource of that difeafe.

"In this dairy county (Gloucefterfhire), a great number of cows are kept, and the office of milking is performed indifcriminately by men and maid fervants. One of the former having been appointed to apply dreffings to the heels of a horfe affected with *the greafe*, and not paying due attention to cleanlinefs, incautioufly bears his part in milking the cows with fome particles of the infectious matter adhering to his fingers. When this is the cafe, it commonly happens that a difeafe is communicated to the cows, and from the cows to the dairy maids, which fpreads through the farm until moft of the cattle and domeftics feel its unpleafant confequences. This difeafe has obtained the name of the cow-pox. It appears on the nipples of the cows in the form of irregular puftules. At their firft appearance they are commonly of a palifh blue, or rather of a colour fomewhat approaching to livid, and are furrounded by an eryfipelatous inflammation. Thefe puftules, unlefs a timely remedy be applied, frequently degenerate into phagedenic ulcers, which prove extremely troublefome. The animals become indifpofed, and the fecretion of milk is much leffened. Inflamed fpots now begin to appear on different parts of the hands of the domeftics employed in milking, and fometimes on the wrifts, which quickly run on to fuppuration, firft affuming the appearance of the fmall vefications produced by a burn. Moft commonly they appear about the joints of the fingers, and at their extremities; but whatever parts are affected, if the fituation will admit, thefe fuperficial fuppurations put on a circular form, with their edges more elevated than their centre, and of a colour diftantly approaching to blue. Abforptions take place, and tumors appear in each axilla. The fyftem becomes affected, the pulfe is quickened, and fhiverings, with general laffitude, and pains about the loins and limbs, with vomiting, come on. The head is painful, and the patient is now and then even affected with delirium. Thefe fymptoms, varying in their degrees of violence, generally continue from one day to three or four, leaving ulcerated fores about the hands, which, from the fenfibility of the parts, are very troublefome, and commonly heal flowly, frequently becoming phagedenic, like thofe from whence they fprung. The lips, noftrils, eyelids, and other parts of the body, are fometimes affected with fores; but thefe evidently arife from their being needlefsly rubbed or fcratched with the patient's infected fingers. No eruptions of the fkin have followed the decline of the feverifh fymptoms in any inftance that has come under my infpection, one only excepted; and in this cafe a very few appeared on the arms: they were very minute, of a vivid red colour, and foon died away without advancing to maturation: fo that I cannot determine whether they had any connection with the preceding fymptoms.

5 Its appearance on the cow and the perfon who milks her.

"Thus the difeafe makes its progrefs from the horfe to the nipple of the cow, and from the cow to the human fubject.

6 Its fingularity,

"Morbid matter of various kinds, when abforbed into the fyftem, may produce effects in fome degree fimilar; but what renders the cow-pox virus fo extremely fingular, is, that the perfon who has been thus affected

is

Variolæ Vaccinæ.

is for ever after fecure from the infection of the fmall-pox; neither expofure to the variolous effluvia, nor the infertion of the matter into the fkin, producing this diftemper.

7
Though it is fometimes confounded with another difeafe.

"It is neceffary to obferve, that puftulous fores frequently appear fpontaneoufly on the nipples of cows; and inftances have occurred, though very rarely, of the hands of the fervants employed in milking being affected with fores in confequence, and even of their feeling an indifpofition from abforption. Thefe puftules are of a much milder nature than thofe which arife from that contagion which conftitutes the true cow-pox. They are always free from the bluifh or livid tint fo confpicuous in that difeafe. No eryfipelas attends them, nor do they fhew any phagedenic difpofition, as in the other cafe, but quickly terminate in a fcab, without creating any apparent diforder in the cow. This complaint appears at various feafons in the year, but moft commonly in the fpring, when the cows are firft taken from their winter food and fed with grafs. It is very apt to appear alfo when they are fuckling their young. But this difeafe is not to be confidered as fimilar in any refpect to that of which I am treating, as it is incapable of producing any fpecific effects on the human conftitution. However, it is of the greateft confequence to point it out here, left the want of difcrimination fhould occafion an idea of fecurity from the infection of the fmall-pox, which might prove delufive."

Dr Jenner adds, that the active quality of the virus from the horfe's heels is greatly increafed after it has acted on the nipples of the cow, as it rarely happens that the horfe affects his dreffer with fores, and as rarely that a milkmaid efcapes the infection when fhe milks infected cows. It is moft active at the commencement of the difeafe, even before it has acquired a pus-like appearance. Indeed the Doctor is rather induced to think that the matter lofes this property entirely as foon as it is fecreted in the form of pus, and that it is the thin darkifh-looking fluid only, oozing from the newly formed cracks in the heels, fimilar to what fometimes exudes from eryfipelatous blifters, which gives the difeafe. He is led to this opinion, from having often inferted pus taken from old fores in the heels of horfes, into fcratches made with a lancet, on the found nipples of cows, which has produced no other effect than fimple inflammation.

He is uncertain if the nipples of the cow are at all times fufceptible of being acted upon by the virus from the horfe, but rather fufpects that they muft be in a ftate of predifpofition, in order to enfure the effect. But he thinks it is clear that when the cow-pox virus is once generated, the cows, when milked with a hand really infected, cannot refift the contagion, in whatever ftate their nipples may chance to be. He is alfo doubtful whether the matter, either from the cow or the horfe, will affect the found fkin of the human body; but thinks it probable that it will not, except on thofe parts where the cuticle is very thin, as on the lips.

At what period the cow-pox was firft noticed in Gloucefterfhire is not upon record. The oldeft farmers were not unacquainted with it in their earlieft days when it appeared upon their farms, without any deviation from the phenomena which it now exhibits. Its connection with the fmall pox feems to have been unknown to them. Probably the general introduction of inoculation firft occafioned the difcovery. Dr Jenner conjectures that its rife in that neighbourhood may not have been of very remote date, as the practice of milking cows might formerly have been in the hands of women only; and confequently the cows might not in former times have been expofed to the contagious matter brought by the men fervants from the heels of horfes. He adds, that a knowledge of the fource of the infection is new in the minds of moft of the farmers, but has at length produced good confequences; and that it feems probable, from the precautions they are now difpofed to adopt, that the appearance of the cow-pox in that quarter may either be entirely extinguifhed or become extremely rare.

With refpect to the opinion adduced (Dr Jenner obferves), that the fource of the infection is a peculiar morbid matter arifing in the horfe; although I have not (fays he) been able to prove it from actual experiments conducted immediately under my own eye, yet the evidence I have adduced appears to eftablifh it.

"They who are not in the habit of conducting experiments, may not be aware of the coincidence of circumftances, neceffary for their being managed fo as to prove perfectly decifive; nor how often men engaged in profeffional purfuits are liable to interruptions, which difappoint them almoft at the inftant of their being accomplifhed; however, I feel no room for hefitation refpecting the common origin of the difeafe, being well convinced that it never appears among the cows, except it can be traced to a cow introduced among the general herd which has been previoufly infected, or to an infected fervant, unlefs they have been milked by fome one who, at the fame time, has the care of a horfe affected with difeafed heels."

The following cafe, which we alfo quote from Dr Jenner, would feem to fhew that not only the heels of the horfe, but other parts of the body of that animal, are capable of generating the virus which produces the cow-pox.

"An extenfive inflammation of the eryfipelatous kind appeared, without any apparent caufe, upon the upper part of the thigh of a fucking colt, the property of Mr Millet, a farmer at Rockhampton, a village near Berkeley. The inflammation continued feveral weeks, and at length terminated in the formation of three or four fmall abfceffes. The inflamed parts were fomented, and dreffings were applied by fome of the fame perfons who were employed in milking the cows. The number of cows milked was twenty-four, and the whole of them had the cow-pox. The milkers, confifting of the farmer's wife, a man, and a maid fervant, were infected by the cows. The man-fervant had previoufly gone through the fmall-pox, and felt but little of the cow-pox. The fervant maid had fome years before been infected with the cow-pox, and fhe alfo felt it now in a flight degree: but the farmer's wife, who never had gone through either of thefe difeafes, felt its effects very feverely. That the difeafe produced upon the cows by the colt, and from them conveyed to thofe who milked them, was the *true* and not the *fpurious* cow-pox, there can be fcarcely any room for fufpicion; yet it would have been more completely fatisfactory had the effects of variolous matter been afcertained on the farmer's wife; but there was a peculiarity in her fituation which prevented my making the experiment."

Subfequent

Variolæ Vaccinæ.

8 Dr Jenner's opinion of the origin of the disease controverted.

Subsequent authors have not been all disposed to adopt Dr Jenner's opinion that this disease derives its origin from the grease in horses. We have seen the Doctor himself allow that he has not been able to prove it decisively by actual experiments; and to establish a fact so contrary to all analogy, perhaps no weaker evidence ought to be admitted. The only other bestial disorder with which we are acquainted, which is capable of being communicated by contagion to the human species, is hydrophobia: but here the disorder is the same in man as in the animal from which he derives it; and the analogy holds good in the propagation of the vaccine disease from the cow to her milker. But that the discharge from a local disease in the heel of a horse should be capable of producing a general disorder in the constitution of a cow, with symptoms totally different, and that this new disease once produced should be capable of maintaining an uniform character in the cow and in man, seems a much greater departure from the ordinary proceeding of Nature. We are very far from saying that this is impossible; for little indeed do we know of what Nature can or cannot do. All we mean to say is, that a fact so very extraordinary ought not to be hastily admitted.

In Holstein, we are told that the farmers do not know of any relation existing between the grease and the cow-pox, at least a person who resided three years in that country never heard of any. This, however, is certainly no proof. The same communication which contains this remark (a letter from Dr De Carro of Vienna to Dr G. Pearson) adds, "that in great farms men do not milk cows, but that in the smaller ones that happens very often; that a disease of horses, called *mauke* (true German name for *grease*), is known by all those who take care of them; that old horses particularly, attacked with the mauke, are always put in cow's stables, and there are attended by women; and that it is particularly in harvest that men in small farms milk cows." It must be allowed, then, that in this situation, supposing Dr Jenner's opinion well founded, the cow-pox was naturally to be looked for, and here accordingly we find it. The question is certainly of no real utility, and therefore it has very properly been less attended to than other points respecting this disorder which lead to important practical conclusions.

Of all the questions which have arisen relative to the cow-pox, there is none so interesting, and luckily there is none which has received so full a discussion, or so satisfactory an answer, as the one we are now about to consider. Are those persons who have once had the cow-pox effectually and for ever secured against the variolous contagion?

9 A previous attack of this disease renders the body unsusceptible of small-pox.

Dr Jenner, in his first publication, was decidedly of opinion that a previous attack of this disorder rendered the human body for ever unsusceptible of the variolous virus; and besides the universal popular belief in the countries where cow-pox is known, he brought forward a number of cases in support of his assertion. By some of these it appeared that persons who had been affected with the cow-pox above twenty or thirty years before continued secure against infection, either by the effluvia from patients under small-pox, or by inoculation. But along with this opinion he entertained other two, which, to many people, appeared so surprising as to take away all credit from the former. The first was, that a previous attack of small-pox did not prevent a subsequent attack of cow-pox; and the second was perhaps still more wonderful, that the cow-pox virus, although it rendered the constitution unsusceptible of the small-pox, should nevertheless leave it unchanged with respect to its own action, for that the same person is susceptible of repeated attacks of the cow pox.

Variolæ Vaccinæ.

10 Difficulties explained.

These opinions have been submitted to the test of very extensive experience by a variety of intelligent practitioners; and we think there can now be little doubt that the two last are erroneous, while the truth of the first has been established by an immense body of incontrovertible evidence.

The opinions that a person who has had the small-pox may afterwards have the cow-pox, and that the same person may have the cow-pox more than once, probably arose from the distinction between the local effects of the vaccine virus, and the general disorder of the constitution not having been sufficiently attended to. It is generally admitted, that in the inoculated small pox the local affection may go so far as that a pustule shall arise on the part, containing matter capable of communicating the true small-pox to others, and yet, if no general affection of the constitution takes place, the patient is not secure from the disorder. In like manner, there are cases upon record which prove that a person may, after having had the small-pox, have a local affection produced by inoculation, in which true variolous matter shall be formed capable of communicating both the local and constitutional symptoms of small-pox to others; and nurses, when much exposed to variolous contagion, often have an eruption resembling small-pox upon such parts of their skin as have been exposed to the action of the virus, though they have formerly undergone the disease. Yet there is probably no person at this day who will go so far as to assert that the same person can have the specific variolous fever more than once.

The case seems to be precisely the same with respect to cow-pox. Dr Pearson and others have inoculated a number of persons after they have had the small-pox with the vaccine virus, and have produced only the local affection; and by the same test it is ascertained that the same person cannot more than once have the constitutional symptoms of the cow-pox. Dr Woodville indeed tells us that he has seen one case of genuine cow-pox pustule and specific fever in a constitution which had previously suffered the small pox. There can be no higher authority on this subject than that of Dr Woodville; and if he had actually seen his patient in the small-pox as well as the cow-pox, we should have admitted this single case as completely decisive of the question. But the only evidence of this person having had the small-pox, is the assertion of the patient that he had it *when a child*. This we can by no means sustain as conclusive in opposition to the Doctor's own experience, as well as the experience of Dr Pearson.

That the milkers are subject to repeated attacks of the local symptoms of cow-pox, whether they have had the small-pox or not, is certain. In the case of the farmer's servants at Rockhampton, which we have quoted above from Dr Jenner, one of whom had previously undergone the small-pox, and the other the cow-pox, and both of whom were afterwards infected by by the cow-pox *in a ſlight degree*, it ſeems reaſonable to conclude that the local ſymptoms only were preſent in the laſt attack. We may at the ſame time obſerve, that in a caſe of this kind, where a very painful ulcer is produced in a very ſenſible part, this may probably be attended by an increaſed frequency of pulſe; yet if this has not the ſpecific marks of the cow-pox fever, we ſhould not ſay that ſuch a perſon has the diſorder conſtitutionally.

11 Succeſs of vaccine inoculation. With reſpect to the principal propoſition, that the ſpecific fever of cow-pox renders the conſtitution unſuſceptible of the variolous fever, we think no doubt now remains. About 1000 perſons who have undergone the vaccine inoculation have been afterwards inoculated with variolous matter, which has produced no other than local effects. Beſides theſe, there have been a vaſt number inoculated by private practitioners in different parts of the kingdom, the reſult of which has not been reported. But we may ſafely ſuppoſe, that if any one of them had afforded a concluſion oppoſite to the one now generally admitted, it would have been communicated to the public.

We muſt not, however, conceal one ſeemingly well authenticated caſe which has lately occurred, and which, ſo far as it goes, certainly militates againſt this concluſion, and which, we doubt not, will be eagerly caught at by the opponents of the new practice. We quote it from the Medical and Chirurgical Review for September 1800.

12 A ſeemingly well authenticated exception. "Mr Malim, ſurgeon of Carey Street, London, inoculated a child, two years and an half old, with vaccine matter procured from Dr Jenner. On the third day there were ſufficient marks of the action of the virus, and from this time to the end of the diſeaſe the local affection proceeded regularly and without interruption. On the eighth day the child complained of headache and ſickneſs; had a quick pulſe, white tongue, and increaſed heat, with an enlargement and tenderneſs in the axilla. Theſe ſymptoms ſubſided in the courſe of the next day, and the child remained well till the twelfth, when it had a very ſevere attack of fever, ſucceeded, the following day, by an irruption; the appearance, progreſs, and termination of which, left no doubt in the minds of ſeveral eminent practitioners of its being the ſmall-pox. That it was really ſo, has been ſince clearly proved by inoculation. There was a child ill of ſmall-pox in the houſe at the time the above inoculation for cow-pox was performed."

The Reviewers juſtly remark, that the hiſtory is defective, in not deſcribing more minutely the appearances of the inoculated parts at the different ſtages, as well as in not mentioning the length of time that the matter had been taken previous to being uſed. Both theſe points are the more important, as a ſuſpicion naturally ariſes, that the local affection which ſucceeded the vaccine inoculation was not the genuine cow-pox puſtule, but one of the ſpurious kind, which had not the power of deſtroying variolous ſuſceptibility. The matter having been furniſhed by Dr Jenner, no doubt, renders this ſuppoſition the leſs probable; but if it was either long or improperly kept after it came out of his hands, it may have undergone a material change, by putrefaction or otherwiſe. Dr Jenner mentions an inſtance of a practitioner, who had been accuſtomed to preſerve variolous matter in a warm pocket; a ſituation favourable for producing putrefaction in it. This matter, when inſerted, was found to produce inflammation, ſwellings of the axillary glands, fever, and ſometimes eruptions; but not of the true variolous kind, as patients thus inoculated were found ſtill ſuſceptible of the ſmall-pox contagion. It is ſurely a poſſible ſuppoſition, tho' merely a conjecture, that the vaccine matter in Mr Malim's caſe had undergone ſome ſuch change.

The caſe, however, is in ſeveral reſpects an intereſting one. As it has been ſuppoſed that variolous contagion, communicated in the form of exhalation, does not affect the conſtitution in leſs than fourteen or fifteen days, and as the vaccine matter, communicated by inoculation, produces its ſpecific effects ſome days earlier, it has been ſuggeſted, that wherever a perſon has been accidentally expoſed to variolous effluvia, we ſhould endeavour to anticipate the ſmall pox by immediately inoculating with the vaccine virus. But if there be nothing falacious in the above caſe, it appears that this meaſure would not ſtop the progreſs of the ſmall-pox, but that our patient would incur the additional danger of having two diſeaſes inſtead of one.

At all events, it muſt be allowed that this child had been infected by the ſmall-pox before the vaccine matter had begun to produce its ſpecific effects, and probably even before the inoculation. Thus the ſmall-pox may be conſidered as having begun before the cow-pox; and though we ſhould be forced to allow that, matters being thus ſituated, the latter diſorder could not prevent the farther progreſs of the former, it by no means follows, that when the cow-pox has fairly run its courſe, the conſtitution is ſtill ſuſceptible of ſmall-pox. The two diſeaſes muſt have exiſted in this patient at the ſame time, though the one was in a latent ſtate during the active ſtage of the other. 13 Probably accounted for.

This ſolitary caſe, then, is by no means concluſive, and certainly is not ſufficient to outweigh the immenſe maſs of concurring evidence which is oppoſed to it.

We proceed now to another highly important branch of our ſubject—the compariſon of the advantages and diſadvantages of the two diſeaſes, with a view to the practice of inoculation. 14 Advantages of the new practice.

Notwithſtanding the immenſe number of caſes in which the inoculation of the cow-pox has been tried, we are not yet fully qualified to appreciate the value of the new practice; becauſe the diſeaſe has varied very much in ſeverity, and even in its moſt remarkable ſymptoms, and that without any cauſe which has yet been diſcovered.

Dr Jenner's account of the diſeaſe gave us reaſon to think, that the local affection in cow-pox was more ſevere than in the inoculated ſmall-pox; that the fever in this diſeaſe was never attended with dangerous ſymptoms; that thoſe ſymptoms which affect the patient with ſeverity are entirely ſecondary, excited by the irritating proceſſes of inflammation and ulceration; that the diſeaſe was not attended with any eruption reſembling ſmall-pox; and that the ſore produced by the inoculation was apt to degenerate into a very diſtreſſing phagedenic ulcer, which required to be treated with applications of a cauſtic nature, of which he found the unguentum hydrargyri nitrati the moſt uſeful.

Soon after Dr Jenner's publication, the attention of medical men was forcibly drawn to the ſubject; and ſeveral eminent practitioners in London, particularly Dr George

Variolæ Vaccinæ.

George Pearfon, and Dr Woodville phyfician to the fmall-pox and inoculation hofpitals, immediately began to practife the vaccine inoculation. The latter gentleman foon publifhed an accurate and candid account of the effect of this virus upon 200 patients, with a table of the refults of above 500 cafes in which the inoculation was performed.

15 Anomalies in the progrefs of the difeafe.

It is very remarkable, that in none of thefe cafes did the inoculated part ulcerate in the manner defcribed by Dr Jenner, nor did the inflammation ever occafion any inconvenience, excepting in one inftance, in which it was foon fubdued by the aqua lythargyri acetati. The general affection of the conftitution, on the other hand, though in a great majority of cafes it was very flight, yet, in fome inftances, was fevere. An eruption, exactly refembling fmall-pox, was, contrary to expectation, a very common occurrence, and in fome the puftules were not fewer than 1000; and although in thefe cafes the difeafe was ftill unattended with fecondary fever, yet the febrile fymptoms which took place from the commencement were confiderable, and even alarming, as fometimes alfo happens with the inoculated fmall-pox.

Dr Woodville fometimes inoculated with matter from the primary fore in the arm, and fometimes with matter taken from the puftular eruption; and it appears from the table that a much larger proportion of thofe who were inoculated in the latter way had puftules, than of thofe who were inoculated either with matter immediately from the cow, or from the primary fore in the human body. There were 447 patients in all inoculated, either from the cow or from the primary fore; and of thefe 241 had puftules, and 206 had none. Sixty-two perfons, on the other hand, were inoculated with matter from the puftules of ten different patients; and of thefe no fewer than 57 had puftules, and only 5 efcaped without. Nor can it be faid that this difproportion arofe from thefe 10 patients having the difeafe in a more virulent form than ordinary, for matter was alfo taken from the primary fore in 4 of the 10, with which 48 were inoculated; of whom 27 had puftules, and 21 had none: whereas, of 9 perfons who were inoculated with matter from the puftules of thefe fame 4, only 2 efcaped without puftules. This obfervation correfponds alfo with Dr Pearfon's experience.

Although thefe eruptions have been met with by other practitioners, yet they certainly appear very rarely in private practice. Dr Woodville, for this reafon, confiders them, in a more recent publication, as the effect of fome adventitious caufe, independent of the cow-pox: And this he fuppofes to be the variolated atmofphere of the hofpital, which thofe patients were neceffarily obliged to infpire during the progrefs of the cow-pox infection. This opinion, however, does not feem to agree well with his former remark, which, as we have faid, is confirmed by Dr Pearfon, that eruptions rarely took place, if care was taken to avoid matter for inoculation from fuch as had puftules; a fact that cannot be explained on fuch a fuppofition. Neither is this idea reconcileable with what he alfo tells us, that the proportion of cafes in the hofpital attended with puftules has been of late only three or four in a hundred.

This change in the appearances of the difeafe in the hands of different practitioners, and even of the fame practitioner at different times, is one of the moft unaccountable circumftances refpecting this fingular diforder. There is fome curious information on this fubject, contained in a letter from Mr Stromeyer of Hanover to Mr Hannehmann.

"This year (fays he) we have inoculated 40 perfons, as well with the vaccine matter received of Dr Pearfon as with that from Dr Jenner; all of whom underwent the difeafe properly.

"Betwixt the London and Gloucefter vaccine matter, it appears to me there fubfifts an effential difference. The London matter produces frequently an eruption of fmall pimples; but they difappear within a day or two at fartheft. Dr Pearfon calls thefe eruptions *puftules*.—The Gloucefter matter has never produced this effect here; but *frequently occafioned ulcerations of the inoculated part, of a tedious and long duration; which the latter never did*: on account of which I now only make ufe of Dr Pearfon's vaccine matter. The nettle-fever like eruptions I have obferved feveral times, but never that fort of eruption, repeatedly noticed in London, which fo much refembles the fmall-pox."

If thefe obfervations of Mr Stromeyer fhould be confirmed by the experiments of others, they would go far to explain the difference which the London practitioners have found in this difeafe from the account given of it by Dr Jenner, notwithftanding the abfence of the eruption refembling fmall-pox at Hanover. We believe an interchange of vaccine matter has once or twice taken place between London and Gloucefterfhire. Is it fince that period that the eruption has been lefs frequent at London? Dr Pearfon is inclined to fuppofe, that the comparative feverity of the difeafe at London, during the firft winter, arofe rather from the difference in the human conftitution at the different feafons of the year, than from any change in the ftate of the vaccine matter.

16 Mortality for the old practice over-rated by the advocates for the new.

In comparing the degree of danger from the inoculation of cow-pox with that arifing from the inoculated fmall pox, we are convinced that Dr Pearfon greatly over-rates the mortality in the latter diforder. He fuppofes it to be no lefs than one in 200. Dr Mofeley, on the other hand, who is a violent opponent of the vaccine inoculation, afferts, that he has inoculated feveral thoufands with variolous matter, in Europe and the Weft Indies, without ever lofing a patient, and that feveral other perfons, whom he knows, have done the fame, with the fame fuccefs. We are afraid, however, that the experience of other inoculators does not afford fo favourable a refult. We believe that in this country the mortality is often occafioned by improper treatment; and from comparing the accounts which we have received from practitioners of extenfive experience, and undoubted veracity, we believe that, where the treatment is proper from the beginning, the fymptoms very rarely arife to an alarming height, and that the mortality is not fo great as one in 600. And this eftimate nearly correfponds with Dr Woodville's very great experience. It muft be allowed, that patients in an hofpital are fubject to fome difadvantages, which may be avoided in private practice; yet, out of the laft 5000 cafes of variolous inoculation at the inoculation hofpital, prior to the publication of the Doctor's reports, the mortality did not exceed one in 600.

Notwithftanding this ftatement, however, we are happy

Variolæ Vaccinæ. py to say, that the danger in the vaccine disease is still much less. Dr Pearson tells us, that in little more than six months after the new inoculation was introduced into London, which includes the period at which the cow-pox assumed the most unfavourable appearance, 2000 persons at least underwent the operation; of these, one only, an infant at the breast, under the care of Dr Woodville, died. In this solitary fatal case, the local tumor was but very inconsiderable; and the eruptive symptoms took place on the seventh day, when the child was attacked with fits of the spasmodic kind, which recurred at short intervals, with increased violence, and carried it off on the eleventh day after the cow-pox matter had been infected into its arm, and after an eruption of about 80 pustules had appeared.

17 Great success of the new inoculation.

Since that time a much greater number, amounting certainly to several thousands, have been inoculated with cow-pox in different parts of Great Britain and on the continent. Among these, not one fatal instance, that we have heard of, has occurred.

But even if the danger to the individual from the small-pox and from the cow-pox were equal, there is an important advantage to the public attending the latter, which we think would alone be sufficient to intitle it to a preference—It is not capable of being propagated by the effluvia arising from the bodies of persons infected with it. There are many situations in which a prudent surgeon will be restrained from inoculating with small-pox, lest the contagion should spread to other people, who may be either prevented by prejudice from submitting to the operation, or in whom it would be obviously improper, from the circumstances of age, teething, or the presence of some other disease. Here the cow-pox virus may be substituted with great propriety. It is chiefly from this quality that the cow-pox bids fair to extirpate the small-pox entirely.

This valuable property of the vaccine disorder is not, however, to be admitted without some limitation. When it produces numerous pustules on the body, Dr Woodville tells us, that the exhalations they send forth are capable of affecting others, in the same manner as the small-pox. Two instances of casual infection in this way have fallen under his observation. In one, the disease was severe, and the eruption confluent; in the other, the disease was mild, and the pustules few. It has been remarked, that the inoculated cow pox is little, if at all, different from the disease when casually caught. But, strictly speaking, the above are the only two cases in which the disease has been communicated otherwise than by inoculation.

18 Whether the cow-pox and small-pox ought to be considered as different diseases.

The writers upon this subject are divided in opinion, whether the cow-pox and small-pox ought to be considered as different diseases, or whether they are merely varieties of the same disease.

They certainly, notwithstanding the strong analogy which subsists between them, differ from each other in several striking particulars. The cow-pox comes to man from the cow, and is capable of being carried back from him to that animal. Similar attempts with variolous matter have failed: in this respect, then, these two morbid poisons are altogether different.

The local tumor produced by the inoculation of the cow-pox is commonly of a different appearance from that which is the consequence of inoculation with variolous matter: for if the inoculation of the cow-pox be performed by a simple puncture, the consequent tumor, in the proportion of three times out of four, according to Dr Woodville, assumes a form completely circular, and it continues circumscribed, with its edges elevated and well defined, and its surface flat, through every stage of the disease; while that which is produced from the variolous matter, either preserves a peculiar form, or spreads along the skin, and becomes angulated, or irregular, or disfigured by numerous vesiculæ. Another distinction still more decisive and general, is to be drawn from the contents of the cow-pox tumor; for the fluid here formed very rarely becomes puriform; and the scab which succeeds is of a harder texture, exhibits a smoother surface, and differs in its colour from that which is formed by the concretion of pus. The appearances, however, are sometimes so changed, that they can in no respect be distinguished from those which arise from the inoculation of small-pox. We may also mention that the tendency of the sore in the inoculated part to degenerate into a phagedenic ulcer does not occur in small-pox.

On the other hand, the points in which these two diseases resemble each other are very remarkable. When introduced into the body by inoculation, they affect the constitution in nearly the same length of time, and seem to be governed by nearly the same laws. They mutually destroy the susceptibility of the body for the action of each other.

Dr Pearson, who thinks the diseases ought to be considered as distinct species, nevertheless draws the following conclusions, as established by experience.

"That in certain constitutions, or under the circumstances of certain co-operating agents, *the vaccine poison produces a disease resembling the small-pox*; and of course the pustule in the inoculated part is *very different from that of the vaccine pox ordinarily occurring*, and the eruptions *resemble very much, if not exactly, some varieties of the small-pox*: That in some instances these eruptions have occurred, although the inoculated part exhibited the genuine vaccine pustule: That the matter of such eruptive cases, whether taken from the inoculated part, or from other parts, produces universally (A), or at least generally, similar eruptive cases; and has not (he believes) been seen to go back, by passing through different constitutions, to the state in which it produces what is called the *genuine vaccine disease*: That eruptions, of a different appearance from variolous ones, sometimes occur in the true cow-pox."

From these facts we are strongly inclined to think that the vaccine disease and the small-pox ought merely to be considered as varieties of the same disease; and we have little doubt that they both derive their origin from the same source. 19 They are probably only varieties of the same disease.

If Dr Jenner's opinion, that the vaccine disease is derived from *the grease*, were fully established, we should be disposed to offer a conjecture, that the *small-pox*, in coming from the horse to man, may have passed thro' some

(A) We have seen that Dr Woodville's table contains a few exceptions to this rule, though it strongly confirms the general truth of the proposition.

ſome animal different from the cow. and may thus have undergone a modification ſimilar to, but not exactly, the ſame with what takes place in the paſſage of the virus through the conſtitution of the cow.

But without having recourſe to this conjecture, which is perfectly gratuitous, we are of opinion that the variations which have taken place in the cow-pox within the laſt three years are ſufficient to warrant a belief, that the ſmall-pox may have originally been exactly the ſame diſeaſe, even in the human conſtitution, as the cow-pox is now; but that in a ſucceſſion of ages, and from the operation of cauſes wholly unknown to us, it may have been changed to what we now ſee it.

We ſhall now conclude this article with a few practical remarks, which we hope may be of uſe to practitioners who mean to begin the vaccine inoculation.

20 Practical remarks.

It is of the utmoſt conſequence that the matter employed ſhould be the genuine vaccine virus. Dr Jenner points out the following particulars as ſources of a ſpurious cow-pox: 1. That ariſing from puſtules on the nipples or udder of the cow, which puſtules contain no ſpecific virus. 2. From matter, although originally poſſeſſing the ſpecific virus, which has ſuffered a decompoſition, either from putrefaction, or any other cauſe leſs obvious to the ſenſes. 3. From matter taken from an ulcer in an advanced ſtage, though the ulcer aroſe from a true cow-pox. 4. From matter produced on the human ſkin from the contact of ſome peculiar morbid matter generated by a horſe.

Many have remarked that inoculation with the vaccine matter is more apt to fail in communicating the infection than with variolous matter, eſpecially if it be ſuffered to dry upon the lancet before it is uſed. This does not ſeem to depend upon the virus of the former being more volatile, but upon its becoming more hard and indiſſoluble upon exſiccation. Care ſhould therefore be taken to moiſten it a conſiderable time before it is uſed.

We have already noticed the danger that may ariſe from miſtaking the local effects of the vaccine diſeaſe for its effects upon the conſtitution. To guard practitioners againſt this error, Dr Woodville makes the following remarks: "When a conſiderable tumor and an extenſive redneſs take place at the inoculated part, within two or three days after the infectious matter has been applied, the failure of inoculation may be conſidered as certain as where neither redneſs nor tumor is the conſequence. This rapid and premature advancement of the inflammation will always be ſufficient to prevent the inoculator from miſtaking ſuch caſes for thoſe of efficient inoculation. But there are other circumſtances under which I have found the inoculation to be equally ineffectual, and which, as being more likely to deceive the inoculator, require his utmoſt circumſpection and diſcrimination. I here allude to caſes in which it happens that though the local affection does not exhibit much more inflammation than is uſual, yet neither veſicle nor puſtule ſupervenes; and in which, about the ſixth or ſeventh day, it rapidly advances into an irregular ſuppuration, producing a feſtering or cruſtaceous ſore. Care, however, ſhould be taken to diſtinguiſh this caſe from that in which the inoculated part aſſumes a puſtular form, though it continues for one or two days only, when the ſame appearances follow as thoſe above deſcribed; for I have experienced the latter inoculation to be as effectual as where the tumor has proceeded in the moſt regular manner."

"The effloreſcence at the inoculated part, which ſeldom intervenes before the eighth, or later than the eleventh, day, is to be regarded as an indication that the whole ſyſtem is affected; and if the patient has not felt any indiſpoſition on or before its approach, he may be aſſured that there will not be any afterwards. When effloreſcence does not commence till the eleventh day, it is almoſt always attended with more indiſpoſition than when it occurs on the eighth or ninth day. The efflorescence is more frequent in young infants than in children advanced to three or four years of age; and the former have the efflorescence and the diſeaſe more favourably than the latter, inſomuch that by far the greater part of them have no perceptible illneſs, and require no medicines. On the other hand, in adults, the cow-pox frequently produces headache, pain of the limbs, and other febrile ſymptoms, for two or three days, which are greatly relieved by a briſk purgative."

We would, upon the whole, recommend the vaccine inoculation to our medical readers as being an effectual preventative againſt the ſmall pox, and ſafer to the individual, while it is more advantageous to the public at large, in being leſs capable of propagation by contagion.

VECTOR, or Radius Vector, in aſtronomy, is a line ſuppoſed to be drawn from any planet, moving round a centre, or the focus of an ellipſe, to that centre or focus. It is ſo called, becauſe it is that line by which the planet ſeems to be carried round its centre; and with which it deſcribes areas proportional to the times.

VEGETABLES. } See *Vegetable Substances* in
VEGETATION. } this *Suppl.*

VENTILATION of Ships is a matter of ſo great importance, that we would rather hazard the ſtating of an idle project for this purpoſe, than omit any thing which may be uſeful. We hazard nothing, however, in ſtating the following plan by Mr Abernethy, who candidly acknowledges that it is built upon the principles which we, together with the learned editor of Chambers's Cyclopædia, have borrowed from Dr Hailes. This plan conſiſts merely in cauſing two tubes to deſcend from above the deck to the bottom of a veſſel, or as low as ventilation is required; and which ſhould communicate by ſmaller pipes (open at their extremities) with thoſe places deſigned to be ventilated. There ſhould be a contrivance for ſtopping theſe communicating pipes, ſo that ventilation may be occaſionally prevented from taking place, or confined to any particular part of the veſſel.

One of the principal air tubes ſhould deſcend as near to the ſtern of the veſſel as convenient, and the other as near to the ſtem.

Through that tube which is in the head, the foul air is to be extracted; and through that which is in the ſtern, the freſh air is to deſcend to the different decks and other apartments of the veſſel.

The extraction of the air is eaſily effected in the following manner: Let a tranſverſe tube be fitted to that which deſcends in the head of the veſſel; it may be ſunk within the level of the deck, ſo as to cauſe no inequality of ſurface. Let it be continued till it comes beneath

neath the fire-place, then afcend in a perpendicular direction through the fire, and open a little above it; or it may be made to communicate with the chimney. It would be more convenient if the fire was near the place where the tube rifes through the deck; but the experiment muft equally fucceed, if the tube be made to defcend again till it is beneath the common fire-place. The effect that will refult from this contrivance is obvious; when the tube which paffes through the fire is heated, the air will afcend with a force proportionable to its levity, and the afcending column can only be fupplied from below, confequently it muft come from all thofe parts of the fhip with which the main tube communicates.

When the ports are open, the quantity of air thus exhaufted from the fhip will be fupplied from all quarters; but if they were all fhut, and the hatchways and other openings completely clofed, the renewal of frefh air is made certain by means of the tube which defcends in the ftern. The main air tube, where it rifes above the deck in the ftern, fhould have an horizontal one fitted to it, which might be made to traverfe, fo that it could be turned to windward; it might alfo expand at its extremity like the mouth of a trumpet; and thus perfectly frefh air muft enter, and the force of the gale would tend to impel it into the veffel.

When that part of the tube which paffes through the fire is red hot, the draught which would be thus occafioned might perhaps be too great, and the open pipes which communicate with the decks might emit and imbibe the frefh air in fo direct a ftream, that it might be injurious to thofe perfons within the current.

Mr Abernethy therefore thinks it would be better if thofe fmaller pipes which lead from the main tubes were made to run along the decks, and communicate with them by numerous orifices. Two pipes opening into the main exhaufting tube might be extended along the tops of the deck, in the angle formed between the fides and the cieling: and thus the air would be extracted equally from all parts, and in a manner not likely to occafion injurious currents. Some divifion of the ftream of air which enters from the ftern might alfo be made, if it were thought neceffary.

Thus a very complete, and in no way injurious, ventilation may be obtained: the air in the veffel would be perfectly changed when the fire was ftrong, without expence or trouble; and a gradual and falubrious alteration of it might at all times be made, by a very little additional quantity of fuel. The air tubes fhould confift of feparate joints, fo that occafionally they might be taken to pieces; and to prevent their being injured or put out of order by rough ufage, the copper pipes fhould be made of confiderable ftrength, placed againft the fides of the veffel, and even incafed in wood.

In the Letters and Papers of the Bath Society, &c. we have the following defcription of a ventilator for preferving corn on fhip-board, by Thomas South, Efq;

Plate XLVII. Fig. 1. is a cylindrical air-veffel, or forcing pump, of lead, tin, or other cheap metal; its internal diameter being ten inches, and its length three feet; having a crutch-handled pifton to work with, and an iron nofle, *viz.* a hollow inverted cone, two feet long, to condenfe the air, and increafe its power in its paffage downwards. This cylinder fhould be rivetted or fcrewed, by means of an iron collar or ftraps, to the deck it paffes through, both above and below, as at *a a*; and fhould be farther fecured by fome holdfaft near *b*, to keep it fteady in working.

Fig. 2. is a bottom of wood, four inches and a half thick, with a projecting rim at its bafe, for the metal cylinder to reft on when cemented and fcrewed to the wood. The centre of this bottom is excavated, for the reception of the crown of the nofle. In the fame figure the nofle is reprefented with its crown like a bowl difh, to condenfe the air gradually, without refiftance, in its advance to the more contracted bafe of the inverted cone, *i. e.* the top or entrance of the nofle. About two-thirds down this nofle may be fixed a male fcrew, as *c c*, for the purpofe hereafter mentioned.

N. B. The forcing-pump fhould be cafed in wood, to protect it from outward bruifes, which would prevent the working of the pifton, and ruin its effects. The leather round the embolus fhould be greafed when ufed.

Fig. 3. is a crutch-handle, faftened to the embolus A by its iron legs B, B. A is a cylinder of wood, cafed with leather, fo as to fit well, but glide fmoothly, in the metal cylinder; having an opening as large as its ftrength will permit, for the free accefs of atmofpheric air. C is a valve well leathered on its top, and yielding downwards to the preffure of the air when the pifton is raifed up. D is a crofs bar of iron, to confine the valve, fo that it may clofe inftantly on the return of the pifton downwards.

Fig. 4. is a tin pipe or tube, of lefs than four inches diameter, and of fuch length as, when fixed to the bafe of the cylinder, fig. 1. fhall admit the nofle *d*, fig. 2. to within half an inch of the valve E, at the bottom of the wooden cylinder F, in fig. 4; which valve E will then yield to the preffure of air condenfed in its paffage through the nofle, and deliver it into the pipes below. This valve muft be well leathered on its upper furface, and faftened with an hinge of leather to the cylinder it is meant to clofe: affixed to its bottom is the fpindle G, paffing through a fpiral fpring H, which, being compreffed on the defcent of the valve, will, by its elafticity, caufe it to rife again, clofe the aperture above, and retain the air delivered beneath it. On connecting this cylinder with the upper end of the nofle, at *e e*, fig. 2. we muft carefully prevent any lapfe of air that way, by a bandage of oakum fmeared with wax, on which to fcrew the cylinder, like the joints of a flute air-tight. I is a bar of iron, having a rifing in its centre, wide enough for the fpindle to play through but at the fame time fufficiently contracted to prevent the paffage of the fpiral fpring.

Fig. 5. is an affemblage of tin pipes, of any lengths, fhaped fuitably and conveniently to their fituation in the fhip. to the form of which, when fhut into one another, they muft be adapted; obferving only, that the neck be ftraight for a length fufficient to admit the lower end of the cylinder, fig. 4. as high as the letter F, or higher.

Fig. 6. To the middle pipe, which runs along the bottom, fhould be fixed a perpendicular one, fully perforated, to convey the air more readily into the centre of the heap; and this may have a conical top, as reprefented in the Plate, perforated with a fmaller punch to prevent the air from efcaping too haftily. In large cargoes, two or three of thefe perpendiculars may be neceffary;

necessary; and each should be well secured by an iron bar *g*, screwed down to prevent their being injured by the shifting of the cargo in stormy weather or a rolling sea. The top of the conical cap of these pipes may reach two-thirds up the cargo.

Fig. 7. is a valve of the same construction as that represented in fig. 4. but inclosed in a tube of brass, having a female screw at *ff*, adapted to the male screw *cc*, on the nosle fig 2. and may then be inserted into the head of the pipe fig. 5. This will add to the expence; but in a large apparatus is to be preferred, as a more certain security from lapse of air, than the junction of the tube fig. 4. to the neck *ee* in fig. 2.

N. B. *ee* is a neck of wood, making a part of the bottom fig. 2. whereon to secure the tube fig. 4. when applied to the nosle. The joints of the pipes, when put together for use, should be made air-tight, by means of bees wax or some stronger cement, till they reach the bottom of the vessel, when there is no farther need of this precaution. The horizontal pipes should run by the side of the kelson the whole length of the hold. The tin plates of which K is made, should be punched in holes, like the rose of a watering-pot, in two or three lines only at most, and then formed into a tube, with the rough side outwards. L may have four or five lines of the like perforations. M, and the rest, should gradually increase in their number as they advance towards the middle of the hold, and continue fully perforated to the last pipe, which should be closed at its end to prevent the ingress of the corn. It is the centre of the cargo which most requires ventilating, yet air should pervade the whole. Like the trade winds, it will direct its course to the part most heated, and, having effected its salutary purpose there, will disperse itself to refresh the mass.

Where the hatches are close-caulked, to prevent the influx of water, vent-holes may be bored in convenient parts of the deck, to be bunged up, and opened occasionally, from whence the state of the corn may be known by the effluvia which ascend when the ventilator is working.

The power of the ventilator is determined by the square of its diameter multiplied into the length of the stroke, and that again by the number of strokes in any given time.

The air-vessel or forcing pump, with the rest of the apparatus here described, is adapted to a vessel of 120 tons burden; but by lengthening the air-vessel, extending its diameter to 14 inches, and adding 10 inches more to the length of the stroke, a power may be obtained of ventilating a cargo of 400 tons within the hour. If this machine be properly wrought for one hour every day, or even every two days, beginning the operations immediately when the corn is put on board, the cargo may be preserved from taint or injury of every kind during the longest voyage.

VERDEN, a duchy of Germany, in the circle of Lower Saxony. It is bounded on the east and south by that of Lunenburg; on the west, by the Weser and the duchy of Bremen; and on the north, by the duchies of Bremen and Lunenburg; extending both in length and breadth about 28 miles. It consists chiefly of heaths and high dry lands; but there are good marshes on the rivers Weser and Aller. In 1712, the Danes wrested this duchy from Sweden, and, in 1715, ceded it to the king of Great Britain, as elector of Hanover; which cession, in 1718, was confirmed by the Swedes. The inhabitants are Lutherans.

VERDIGRIS, or Acetite of Copper. See that article, *Encycl.* where an account is given of the process by which verdigris was long manufactured. A different, and more economical process, however, has for some years been practised in Montpellier, which is worthy of notice, because it may be adopted in this country by substituting the husks of gooseberries or currants for those of grapes

In the manufacture of verdigris, the materials are copper and the husks of grapes after the last pressing. The copper is formed into round plates, half a line in thickness, and from twenty to twenty five inches in diameter. Each plate, at Montpellier, is divided into twenty-five laminæ, forming almost all oblong squares of from four to six inches in length, three in breadth, and weighing about four ounces. They are beat separately with the hammer on an anvil to smooth their surfaces, and to give the copper the necessary consistence. Without this precaution it would exfoliate, and it would be more difficult to scrape the surface in order to detach the oxydated crust. Besides this, scales of pure metal would be taken off, which would hasten the consumption of the copper.

The husks, which should not be too much pressed, are first made to ferment by being put into close vats, and the fermentation is generally completed in three or four days. The time, however, must vary according to the temperature in which they are kept, and other circumstances. Whilst the husks are fermenting, a preliminary preparation is given to the copper plates. This consists in dissolving verdigris in water in an earthen vessel, and rubbing over each plate with a piece of coarse linen dipped in this solution. The plates are then immediately placed close to each other, and left in that manner to dry. Sometimes the plates are only laid on the top of the fermented husks, or placed under those which have been already used for causing the copper to oxydate. It has been observed, that when this operation has not been employed, the plates grow black at the first operation, instead of becoming green. It is not, however, necessary to those which have been once used, and are to be used again.

When the plates are thus prepared, and the husks have been brought to ferment, the workmen try whether the latter are proper for the process, by placing under them a plate of copper, and leaving it buried there for twenty-four hours. If the plate, after this period, is found covered with a smooth green crust, in such a manner that none of the metal appears, they are then thought fit for being disposed in layers with the copper. On the other hand, if drops of water are observed on the surface of the plates, the plates are said to *sweat*, and it is concluded that the heat of the husks has not sufficiently subsided. They consequently defer making another trial till the next day. When they are assured that the husks are in a proper state, they form them into layers in the following manner:

The plates are all put into a box, which, instead of having a bottom, is divided in the middle by a wooden grate. The plates disposed on this grate are so strongly heated by a chaffing-dish placed under them, that the woman employed in this labour is sometimes obliged

to

to take them up with a cloth, in order that ſhe may not burn her hands. As ſoon as they have acquired that heat, they are put into jars in layers with the huſks. Each jar is then cloſed with a covering of ſtraw, and left to oxydate. Thirty or forty pounds of copper, more or leſs according to the thickneſs of the plates, are put into each jar. At the end of ten, twelve, fifteen, or twenty days, the jar is opened; and if the huſks are white, it is time to take out the plates. The cryſtals are then ſeen detached, and of a ſilky appearance on their ſurface. The huſks are thrown back, and the plates are put in what is called *relai*. For that purpoſe they are immediately depoſited in a corner of the cellar on ſticks ranged on the floor. They are placed in an upright poſition, one leaning againſt the other; and at the end of two or three days they are moiſtened, by taking them up in handfuls and immerſing them in water in earthen pans. They are depoſited quite wet in their former poſition, and left there for ſeven or eight days; after which they are once or twice immerſed again. This immerſion and drying are renewed ſix or eight times every ſeven or eight days. As the plates were formerly put into wine, theſe immerſions were called *one wine*, *two wines*, *three wines*, according to the number of times. By this proceſs the plates ſwell up, the green is nouriſhed, and a coat of verdigris is formed on all their ſurfaces, which may be eaſily detached by ſcraping them with a knife.

This verdigris, which is called *freſh* verdigris, *moiſt* verdigris, is ſold by the manufacturers to people who dry it for foreign exportation. In this firſt ſtate it is only a paſte, which is carefully pounded in large wooden troughs, and then put into bags of white leather, a foot in height and ten inches in diameter. Theſe bags are expoſed to the air or the ſun, and are left in that ſtate till the verdigris has acquired the proper degree of dryneſs. By this operation it decreaſes about 50 *per cent.* more or leſs according to its primitive ſtate. It is ſaid to ſtand proof by the knife, when the point of that inſtrument puſhed againſt a cake of verdigris through the ſkin cannot penetrate it. White lead may be made by a ſimilar proceſs.

Cryſtallized VERDIGRIS is manufactured at Montpellier in the following manner: A vinegar, prepared by the diſtillation of ſour wine, is put into a kettle, and boiled on the common verdigris. After ſaturation the ſolution is left to clarify, and then poured into another kettle of copper, where it is evaporated till a pellicle forms on the ſurface. Sticks are then immerſed into it, and by means of ſome packthread are tied to ſome wooden bars that reſt on the edge of the kettle. Theſe ſticks are about a foot long, and are ſplit croſs-wiſe nearly two inches at the end, ſo that they open into four branches, kept at about the diſtance of an inch from each other by ſmall bags. The cryſtals adhere to theſe ſticks and cover them entirely, forming themſelves into groups or cluſters, of a dark blue colour, and a rhomboidal ſhape. Each cluſter weighs from five to ſix pounds. Three pounds of moiſt verdigris are required for one pound of the cryſtals; the undiſſolved reſiduum is thrown away.

VERDUN, an ancient, ſtrong, and conſiderable town of France, in the department of Meuſe, and late province of Lorrain, with a biſhop's ſee, and a ſtrong citadel. Its fortifications were conſtructed by the Chevalier de Ville and Marſhal de Vauban. The latter was a native of this place. In 175[illegible], great part of the cathedral was deſtroyed by lightning. Verdun was taken by the Pruſſians in 1792, but retaken by the French ſoon after. The inhabitants are noted for the fine ſweetmeats they make. It is ſeated on the river Maeſe, which runs through the middle, 42 miles ſouth-weſt of Luxemburg, and 150 eaſt of Paris E. Lon. 5° 28′ N. Lat. 45° 9.

VERMIFUGE, a medicine which expels worms from the inteſtines. Of theſe medicines numbers are daily advertiſed in the newſpapers as infallible, though the ingredients of which they are compoſed are carefully kept ſecret. We think it our duty therefore to aſſure our readers, that the medicines vended by quacks are generally the very ſame that would be preſcribed by a regular phyſician for the diſeaſe in which they are pretended to be ſpecifics, with this only difference, that the unſeen and unprincipled quack generally preſcribes them in more powerful doſes than the regular phyſician deems ſafe for his patient. Thus Ching's famous worm medicine, which has been ſo ſtrenuouſly recommended, is nothing more than mercury given in the very ſame form in which it is given by every phyſician; but Ching gives it in doſes, which, though they have not injured the children of a biſhop and a judge, we have *known* to *ſalivate* other children to the great hazard of their lives. It is indeed wonderful that parents ſhould truſt the health and the lives of their children to men whom they never ſaw, and whom they know to be not oppreſſed with an over delicate ſenſe of honour, in preference to a man of ſcience who has a character to ſupport, and who is probably their friend, and almoſt always their acquaintance.

Of the different vermifuges, however, it muſt be confeſſed that the greater number are liable occaſionally to fail. One of the moſt powerful which we have mentioned in the article MEDICINE, *Encycl.* is compoſed of the ſpiculæ of the *cowhage* or *cow-itch*; and ſince that article was publiſhed, it has come more into uſe, chiefly through the recommendation of Mr Chamberlaine ſurgeon. He ſays that a tea-ſpoonful of the electuary (See MEDICINE, *Encycl.* p. 342.) may be ſafely given to a young child, and one or even two table ſpoonfuls to adults. The medicine is to be taken in the morning faſting; and the doſe to be repeated for two or three mornings, after which a gentle purge completes the cure. This medicine, however, Mr Chamberlaine prohibits in every caſe where there is a tendency to inflammation in any part of the inteſtinal canal, or where the mucus has been carried off or greatly diminiſhed by dyſentery or any other cauſe.

Dr Haemmerlin of Ulm has lately recommended as a very powerful and ſafe vermifuge the coraline of Corſica, and ſays that it has been ſo uſed in that iſland with complete ſucceſs from time immemorial. It is a fucus adhering to the rocks waſhed by the ſea, and ſometimes to the ſtones and ſhells thrown upon the ſhore. It is found in little tufts. It is generally of a yellow colour, with a reddiſh tincture. When dried, as it appears when offered for ſale, it contains a ſtrong ſmell of the ſea. It conſiſts of little cartilaginous ſtalks, with full threads, gradually cylindrical and tubulated. Its taſte is ſalt and unpleaſant. In the ſyſtem of plants of Linnæus, it belongs to the claſs *cryptogamia*. Its moſt common

mon names are, fea-rock mofs; the Grecian herb; lemithochorton; and the coraline of Corfica. It is the *conferva helminthortos* of Schwendimann, and the *fucus helminthocorton* of Latourette. There is reafon to think that all thofe fpecies of fucus whofe texture is foft and fpungy, might be applied to the fame medicinal ufes. There is a fort of red coraline found in Sweden which, according to fome writers, is a greater deftroyer of worms than any other known fubftance; being not too ftrong for the ftomach either of infants or of adults. Schwendimann afferts that the *conferva dichotoma* of Linnæus, which is found in the ditches in England, bears a ftrong analogy to the coraline of Corfica. Might not this conferva be tried as a vermifuge? The Corfican coraline is in great eftimation in the pharmacopœias of the Continent, efpecially in that of Geneva, in which is given a recipe for preparing a fyrup of it.

VERMONT, one of the United States of North America, bounded on the north by Canada; on the eaft, by the river Connecticut, which divides it from New Hampfhire; on the fouth, by Maffachufets; and on the weft, by New York. It is about 155 miles long, and 60 broad, and is divided into 7 counties. A chain of high mountains, running north and fouth, divides this ftate nearly in the centre, between the river Connecticut and lake Champlain. The height of land is generally from 20 to 30 miles from the river, and about the fame diftance from the New York line. The natural growth upon this mountain is hemlock, pine, fpruce, and other evergreens: hence it has always a green appearance, and, on this account, has obtained the defcriptive name of Vermont, from the French *Verd Mont*, Green Mountain. On fome high parts of this mountain, fnow lies till May, and fometimes till July. The country is generally hilly, but not rocky. It is finely watered, the foil is very fertile, and there is not a better climate in the world. The inhabitants have very lately been eftimated at 100,000. The bulk of them are emigrants from Connecticut and Maffachufets. The principal town is Bennington, but the affembly generally hold their feffions at Windfor.

VESPA (See *Encycl.*). A new fpecies of this genus of infects has been lately defcribed by *Cuvier*, in a note read before the Philomathic Society of Paris. It has fome refemblance to the *vefpa nidulans* of Fabricius, which, as is generally known, is a native of certain parts of America. The nefts of the vefpa nidulans are conftructed of a very fine web, of a very folid and pretty white pafte. Their form is that of a bell clofed upon all fides, excepting a narrow hole at the bottom; and they are fufpended from the branches of trees.

The *vefpa* defcribed by Cuvier, which is a native of Cayenne in America, has in general more volume than the preceding fpecies, and its pafte is grey, coarfer, lefs homogeneous, and lefs folid. The bottom of its neft alfo, in lieu of being fhaped funnel-like, is flat, and the orifice appears at one of the fides of the bottom part, and not in the middle. In the country where it is found, this fpecies of wafp is called the *tatou fly* (*mouche tatou*). It differs greatly in form from that which Fabricius has defcribed; it is all entirely of a fhining black; the firft articulation, or joint of its abdomen, is narrow, and in form of a pear; the fecond, larger than the others, is in form of a bell: the wings are brown. The following is the character affigned to it by Cuvier:

Vefpatatua, Nigra, Nitida, Alis fufcis, abdomine pedicellato.

VESPERTILIO (fee *Encycl.*) has been fubjected to fome cruel, but curious experiments, by the Abbé Spallanzani and M. de Jurine. The former of thefe philofophers having let loofe feveral bats in a chamber perfectly dark, found that they flew about in it without any impediment, neither rufhing againft any thing in the apartment, nor touching the walls with their wings. This furprifed him; but imagining that they were conducted by fome glimpfe of light which he did not perceive, he blindfolded them with a fmall and very clofe hood. They then ceafed to fly; but he obferved, at the fame time, that this did not proceed from any deprivation of light, but rather from the conftraint thence occafioned, efpecially when a hood of a very light texture was attended with the fame effect.

He then conceived the idea of pafting up the eyes of the bats with a few drops of fize or gum; but they ftill flew about in the fame manner as if their eyes had been open. As this, however, was not fufficient, he pafted up the eyes of thefe animals with round bits of leather; and this even did not impede them in their flight.

That he might at length be certain of his object, he blinded them entirely, either by burning the cornea with a red hot wire, or by pulling out the pupil with a pair of fmall pincers, and fcooping out the eye entirely. Not contented even with this precaution, he covered the wounds with pieces of leather, that the light might have no influence whatever on the remains of the organs which had been deftroyed. The animals feemed to fuffer very much by this cruel operation; but when they were compelled to ufe their wings, either by day or by night, and even in an apartment totally dark, they flew perfectly well, and with great caution, towards the walls, in order to fufpend themfelves when they wifhed to reft. They avoided every impediment, great or fmall, and flew from one apartment to another, backwards and forwards, through the door by which they were connected, without touching the frame with their wings. In a word, they fhewed themfelves as bold and lively in their flight as any other animals of the fame fpecies which enjoy the ufe of their eye-fight.

Thefe experiments were repeated by M. Jurine, and with the fame refults. Spallanzani had fuppofed that the bat poffeffed fome organ or fenfe which is wanting in the human fpecies, and which fupplies to thefe animals the place of vifion; and Jurine determined to afcertain the truth or falfehood of this hypothefis by anatomical refearches. During the courfe of thefe, he found the organ of hearing very great in proportion to that of other animals, and a confiderable nervous apparatus affigned to that part. The upper jaw alfo is furnifhed with very large nerves, which are expanded in a tiffue on the muzzle.

M. Jurine then extended his experiments to the organ of hearing and that of fmell. Having put a fmall hood on a long-eared bat, it immediately pulled it off, and flew. He ftopped up its ears with cotton; but it freed itfelf in the like manner from that inconvenience. He then put into its ears a maftic of turpentine and wax. During the operation the animal fhewed a great deal of impatience, and flew afterwards very imperfectly.

A long-eared bat, the ears of which had been bound up, flew very badly: but this did not arife from any pain

pain occasioned by the ligature; for when its ears were sewed up, it flew exceedingly well. In all probability the animal would have preferred having its ears bound up to having them sewed. Sometimes it flew towards the cieling, extending its muzzle before it settled.

M. Jurine poured liquid pomatum into the ears of a bat which enjoyed the use of its sight. It appeared to be much affected by this operation; but when the substance was removed it took flight. Its ears were again filled, and its eyes were taken out; but it flew then only in an irregular manner, without any certain or fixed direction.

The ears of a horse-shoe bat, which had the use of its sight, were filled with tinder mixed with water. It was uneasy under the operation, and appeared afterwards restless and stunned; but it conducted itself tolerably well. On being blinded, it rushed with its head against the cieling, and made the air resound with strokes which it gave itself on the muzzle. This experiment was repeated on other bats with the like effects.

The tympanum of a large horse-shoe bat was pierced with a pin (*trois quart*). The animal appeared to suffer much from the operation, and fell down in a perpendicular direction when thrown into the air. It died next morning. The same effect was produced on piercing the tympanum of a long-eared bat with a needle.

The author then made very accurate researches on the difference between the organisation of the brain of these two kinds of bats; and, after a careful dissection, found that the eye of the long-eared bat is much larger than that of the horse-shoe bat, but that the optic nerve is proportioned to it. The outer part of the ear of the former is much larger than that of the latter, but the interior part is smaller.

The horse-shoe bat is indemnified for this difference by a greater extension of the organ of smell, as evidently appears when the external elevations and irregularities of its muzzle are examined. When it is about to take flight, it agitates its nose much more than the long-eared bat.

From these experiments, the author concludes: *First*, That the eyes of the bat are not indispensably necessary to it for finding its way; *secondly*, That the organ of hearing appears to supply that of sight in the discovery of bodies, and to furnish these animals with different sensations to direct their flight, and enable them to avoid those obstacles which may present themselves.

VIBRATION Figures, are certain figures, formed by sand or very dry saw-dust, on a vibrating surface, which is connected with the sensation of sound in our organs of hearing. If the surface, on which the figures are to be formed, be strewed over with bodies easily put in motion, these, during the vibration, remain on the parts at rest, and are thrown from the parts in motion. The form of the parts at rest, which will be shewn by the sand that remains unmoved, and which, in general, is symmetric, is called a *vibration figure*. To produce such a figure, nothing is necessary but to know the method of bringing that part of the surface which you wish not to vibrate into a state of rest, and of putting in motion that which you wish to vibrate. On this depends the whole expertness of producing vibration figures.

Thus take a square piece of glass, pretty thin, and very smooth, such as that used for windows, about four or five inches over, or even more. Smooth it at the edges on a grinding-stone; strew a little saw-dust over its surface, and lay hold of it gently with the thumb and forefinger of the left hand. Holding it thus by the middle, with the right hand rub a violin bow softly against one of its edges, drawing the bow either up or down in a direction almost perpendicular to the surface of the glass, and you will see a tremulous movement, and the whole dust leap about. If the bow be exactly in the middle of one of the sides, the dust will arrange itself almost in the direction of the two diagonals, dividing the square into four isosceles triangles. If the bow be applied at a quarter only of the distance of the one corner from the other, the dust will arrange itself in such a manner as to be found in the two diameters of the square, dividing it into four equal squares. At other times, when the bow diviates a little, the dust forms a figure like a double C, when the two letters are joined back to back. If the square be held by the two extremities of the diameter, opposite to that against which the bow is applied, the dust will form a kind of oval, one of the axes of which will be the same diameter. If the glass be of a circular figure, and be held by the middle, the dust will arrange itself in such a manner as to form the six radii of a regular hexagon. These discoveries were made by Dr Chladni, about the time that he invented the musical instrument, to which he gave the name of EUPHON (see that article, *Suppl.*); and as he found the vibration figures to vary in form with the various tones produced by the vibrating substances, a prosecution of his experiments may probably contribute to throw new light on the philosophy of musical sounds. We shall therefore give, from the 3d volume of *Neues Journal der Physik*, by professor Gren, a few directions for making such experiments.

Any sort of glass may be employed, provided its surface be smooth; and when the plate has acquired the proper vibration, it should be kept in that state for some seconds, by continuing to rub it with the bow. The figures will thus be accurately formed.

Such plates should be procured as are pretty equal in thickness. It may be said, in general, that a plate the thinner it is will be so much the fitter for these experiments, though in this respect there is a certain minimum. In small plates, such as those that are circular, and not above six inches in diameter, the observation is general; but in larger plates too great thinness is prejudicial. Besides, it will be found that very thin glass is commonly very uneven, and must therefore be unfit for the experiments.

In practising the experiments, it will be proper to have plates of different sizes; and the sand employed should not be too fine. In other words, it must be of such a nature that when you incline the glass-plate it may readily roll off; because, in that case, it will be easily thrown from the vibrating parts. It will be of advantage that it be mixed with fine dust, which shews peculiar phenomena during the experiments, as it collects itself at one place of the vibrating part.

The plate must be equally bestrewed with sand, and not too thick, as the lines will then be exceedingly fine, and the figures will acquire a better defined appearance.

VIETA (Francis), a very celebrated French mathematician, was born in 1540 at Fontenai, or Fontenai-le-Comté, in Lower Poitou, a province of France. He

Hutton's Mathematical Dictionary.

Vieta.

He was Master of requests at Paris, where he died in 1603, being the 63d year of his age. Among other branches of learning in which he excelled, he was one of the most respectable mathematicians of the 16th century, or indeed of any age. His writings abound with marks of great originality, and the finest genius, as well as intense application. His application was such, that he has sometimes remained in his study for three days together without eating or sleeping. His inventions and improvements in all parts of the mathematics were very considerable. He was in a manner the inventor and introducer of Specious Algebra, in which letters are used instead of numbers, as well as of many beautiful theorems in that science. He made also considerable improvements in geometry and trigonometry. His angular sections are a very ingenious and masterly performance: by these he was enabled to resolve the problem of Adrian Romanus, proposed to all mathematicians, amounting to an equation of the 45th degree. Romanus was so struck with his sagacity, that he immediately quitted his residence of Wirtzbourg in Franconia, and came to France to visit him, and solicit his friendship. His Apollonius Gallus, being a restoration of Apollonius's tract on Tangencies, and many other geometrical pieces to be found in his works, shew the finest taste and genius for true geometrical speculations.—He gave some masterly tracts on Trigonometry, both plane and spherical, which may be found in the collection of his works, published at Leyden in 1646, by Schooten, besides another large and separate volume in folio, published in the author's life-time, at Paris, in 1579, containing extensive trigonometrical tables, with the construction and use of the same, which are particularly described in the introduction to Dr Hutton's Logarithms, p. 4. &c. To this complete treatise on trigonometry, plane and spherical, are subjoined several miscellaneous problems and observations; such as, the quadrature of the circle, the duplication of the cube, &c. Computations are here given of the ratio of the diameter of a circle to the circumference, and of the length of the sine of 1 minute, both to a great many places of figures; by which he found that the sine of 1 minute is

between 2908881959
and 2908882056;

also the diameter of a circle being 1000, &c. that the perimeter of the inscribed and circumscribed polygon of 393216 sides will be as follows, viz. the

perim. of the inscribed polygon - 31415926535
perim. of the circumscribed polygon 31415926537

and that therefore the circumference of the circle lies between those two numbers.

Vieta having observed that there were many faults in the Gregorian Kalendar, as it then existed, composed a new form of it, to which he added perpetual canons, and an explication of it, with remarks and objections against Clavius, whom he accused of having deformed the true Lelian reformation, by not rightly understanding it.

Besides these, it seems a work, greatly esteemed, and the loss of which cannot be sufficiently deplored, was his *Harmonicon Cœleste*, which, being communicated to father Mersenne, was, by some perfidious acquaintance of that honest-minded person, surreptitiously taken from him and irrecoverably lost, or suppressed, to the great detriment of the learned world. There were also, it is said, other works of an astronomical kind, that have been buried in the ruins of time.

Vintain || Vision

Vieta was also a profound decipherer, an accomplishment that proved very useful to his country. As the different parts of the Spanish monarchy lay very distant from one another, when they had occasion to communicate any secret designs, they wrote them in ciphers and unknown characters during the disorders of the league. The cipher was composed of more than 500 different characters, which yielded their hidden contents to the penetrating genius of Vieta alone. His skill so disconcerted the Spanish councils for two years, that they published it at Rome, and other parts of Europe, that the French king had only discovered their ciphers by means of magic.

VINTAIN, a town, situated about two miles up a creek on the southern side of the river Gambia. It is much resorted to by Europeans, on account of the great quantities of bees-wax which are brought hither for sale. The wax is collected in the woods by the Feloops, a wild and unsociable race of people. Their country, which is of considerable extent, abounds in rice; and the natives supply the traders, both on the Gambia and Cassamansa rivers, with that article, and also with goats and poultry, on very reasonable terms. The honey which they collect is chiefly used by themselves in making a strong intoxicating liquor, much the same as the mead which is produced from honey in Great Britain.

In their traffic with Europeans, the Feloops generally employ a factor, or agent, of the Mandingo nation, who speaks a little English, and is acquainted with the trade of the river. This broker makes the bargain; and, with the connivance of the European, receives a certain part only of the payment; which he gives to his employer as the whole; the remainder (which is very truly called the *cheating money*) he receives when the Feloop is gone, and appropriates to himself as a reward for his trouble. Vintain, according to Mr Park, from whose valuable travels this account of the Feloops is taken, is situated in 13° 9′ North Lat. and 15° 56′ Long. West from Greenwich.

VIRGINITY, the test or criterion of a virgin; or that which intitles her to the denomination. See HYMEN, *Encycl.*

VISION. In the article OPTICS, n° 154. (*Encycl.*), it is said, that as we have a power of contracting or relaxing the *ligamenta ciliaria*, and thereby altering the form of the crystalline humour of the eye, we hence see objects distinctly at different distances. It appears, however, from some experiments made by Mr Everard Home and Mr Ramsden, in the year 1794, that this power of contracting and relaxing the ligamenta ciliaria is not alone sufficient to account for the phenomenon. Conversing with Mr Home on the different uses of the chrystalline humour, Mr Ramsden said, that as that humour "consists of a substance of different densities, the central parts being the most compact, and from thence diminishing in density gradually in every direction, approaching the vitreous humour on one side, and the aqueous humour on the other, its refractive power becomes nearly the same with that of the two contiguous substances. That some philosophers have stated the use of the crystalline humour to be, for accommodating

commodating the eye to see objects at different distances: but the firmness of the central part, and the very small difference between its refractive power near the circumference and that of the vitreous or the aqueous humour, seemed to render it unfit for that purpose; its principal use rather appearing to be for correcting the aberration arising from the spherical figure of the cornea, where the principal part of the refraction takes place, producing the same effect that, in an achromatic object-glass, we obtain in a less perfect manner by proportioning the radii of curvature of the different lenses. In the eye the correction seems perfect, which in the object-glass can only be an approximation; the contrary aberrations of the lenses not having the same ratio: so that, if this aberration be perfectly corrected, at any given distance from the centre, in every other it must be in some degree imperfect.

"Pursuing the same comparison: In the achromatic object glass we may conceive how much an object must appear fainter from the great quantity of light lost by reflection at the surfaces of the different lenses, there being as many primary reflections as there are surfaces; and it would be fortunate if this reflected light was totally lost. Part of it is again reflected towards the eye by the interior surfaces of the lenses; which, by diluting the image formed in the focus of the object-glass, makes that image appear far less bright than it would otherwise have done, producing that milky appearance so often complained of in viewing lucid objects through this sort of telescope.

"In the eye, the same properties that obviate this defect, serve also to correct the errors from the spherical figure, by a regular diminution of density, from the centre of the crystalline outward. Every appearance shews the crystalline to consist of laminæ of different densities; and if we examine the junction of different media, having a very small difference of refraction, we shall find that we may have a sensible refraction without reflection. Now, if the difference between the contiguous media in the eye, or the laminæ in the crystalline, be very small, we shall have refraction without having reflection: and this appears to be the state of the eye; for although we have two surfaces of the aqueous, two of the crystalline, and two of the vitreous humour, yet we have only one reflected image; and that being from the anterior surface of the cornea, there can be no surface to reflect it back, and dilute an image on the retina.

"This hypothesis may be put to the test whenever accident shall furnish us with a subject having the crystalline extracted from one eye, the other remaining perfect in its natural state; at the same time we may ascertain whether or no the crystalline is that part of the organ which serves for viewing objects at different distances distinctly. Seeing no reflection at the surface of the crystalline, might lead some persons to infer that its refractive power is very inconsiderable; but many circumstances shew the contrary: yet what it really is may be readily ascertained by having the focal length and distance of a lens from the operated eye, that enables it to see objects the most distinctly; also the focal length of a lens, and its distance from the perfect eye, that enables it to see objects at the same distance as the imperfect eye: these data will be sufficient whereby to calculate the refractive power of the crystalline with considerable precision.

"Again, having the spherical aberration of the different humours of the eye, and having ascertained the refractive power of the crystalline, we have data from whence to determine the proportional increase of its density as it approaches the central part, on a supposition that this property corrects the aberration.

"An opportunity presented itself for bringing the observations of Mr Ramsden, respecting the use of the crystalline lens, to the proof. A young man came into St George's Hospital with a cataract in the right eye. The crystalline lens was readily extracted, and the union of the wound in the cornea took place unattended by inflammation; so that the eye suffered the smallest degree of injury that can attend so severe an operation. The man himself was in health, 21 years of age, intelligent, and his left eye perfect: the other had been an uncommonly short time in a diseased state, and 27 days after the operation appeared to be free from every other defect but the loss of the crystalline lens.

"A number of experiments were made on the imperfect eye, assisted by a lens, and compared with the perfect eye. The aim of these trials, which were judiciously varied, was to ascertain whether the eye which had been deprived of the crystalline lens was capable of adjusting itself to distinct vision at different distances. Among other results, the perfect eye, with a glass of $6\frac{1}{2}$ inches focus, had distinct vision at 3 inches; the near limit was $1\frac{7}{8}$ inch, the distant limit less than 7 inches. The imperfect eye, with a glass $2\frac{2}{10}$ inches focus, with an aperture $\frac{1}{10}$ths of an inch, had distinct vision at $2\frac{7}{8}$ inches, the near limit $1\frac{7}{8}$ inch, and the distant limit 7 inches. The accuracy with which the eye was brought to the same point, on repeating the experiment, proved it to be uncommonly correct; and as he did not himself see the scale used for admeasurement, there could be no source of fallacy. From the result of this experiment, it appears that the range of adjustment of the imperfect eye, when the two eyes were made to see at nearly the same focal distance, exceeded that of the perfect eye. Mr Ramsden suggested a reason why the point of distinct vision of the imperfect eye might appear to the man himself nearer than it was in reality; namely, that from the imperfection of this organ he might find it easier to read the letters when they subtended a greater angle than at his real point of distinct vision. The experiments, however, appear to shew that the internal power of the eye, by which it is adjusted to see at different distances, does not reside in the crystalline lens, at least not altogether; and that if any agency in this respect can be proved to reside in the crystalline, the other powers, whatever they may be, are capable of exertion beyond their usual limits, so as to perform its office in this respect.

"From these considerations, and in consequence of other reflections tending to shew that an elongation of the optical axis is not probably the means of adjustment, these philosophers directed their enquiries to ascertain how far the curvature of the cornea might be subject to change. They found by trial that this part of the organ possesses a degree of elasticity which is very considerable, both for its perfection and its range; and by anatomical

anatomical diffection it was found that the four ftraight mufcles of the eye do in effect terminate in the cornea at their tendinous extremities; that the whole external lamina of the cornea could by gentle force be feparated, by means of thefe mufcles, from the eye; fo that the tendons feem loft in the cornea, and this laft has the appearance of a central tendon. It was alfo feen that the central part of the cornea is the thickeft and the moft elaftic.

"Thefe were confiderable advances towards eftablifhing the hypothefis of adjuftment by the external curve of the eye. It remained to be fhewn, by experiments on the living fubject, that this curve does really vary in the due direction, when the mind perceives the diftinct vifible fenfation of objects at different diftances. For this purpofe Mr Ramfden provided an apparatus, confifting of a thick board fteadily fixed, in which was a fquare hole large enough to admit a perfon's face; the forehead and chin refting againft the upper and lower bars, and the cheek againft either of the fides; fo that when the face was protruded, the head was fteadily fixed by refting on three fides; and in this pofition the left eye projected beyond the outer furface of the board. A microfcope, properly mounted, fo as with eafe to be fet in every requifite pofition, was applied to view the cornea with a magnifying power of thirty times. In this fituation, the perfon whofe eye was the object of experiment was defired to look at the corner of a chimney, at the diftance of 235 yards, through a fmall hole in a brafs plate, fixed for that purpofe, and afterwards to look at the edge of the hole itfelf, which was only fix inches diftant. After fome management and caution, which the delicate nature of thefe experiments requires, the motion of the cornea, which was immediately perceptible, became very diftinct and certain. The circular fection of its furface remained in a line with the wire in the field of the microfcope, when the eye was adjufted to the diftant object, but projected confiderably beyond it when adapted to the near one. When the diftant object was only 90 feet from the obferver, and the near object fix inches, the difference in the prominence of the cornea was eftimated at 1-800th of an inch. Thefe experiments were repeated and varied at different times and on different fubjects. The obferver at the microfcope found no difficulty in determining, from the appearance of the cornea, whether the eye was fixed on the remote or the near object.

"From thefe different experiments Mr Home confiders the following facts to have been afcertained:

"1. That the eye has a power of adjufting itfelf to different diftances when deprived of the cryftalline lens; and therefore the fibrous and laminated ftructure of that lens is not intended to alter its form, but to prevent reflections in the paffage of the rays through the furfaces of media of different denfities, and to correct fpherical aberration.

"2 That the cornea is made up of laminæ; that it is elaftic, and when ftretched is capable of being elongated 1-11th part of its diameter, contracting to its former length immediately upon being left to itfelf.

"3. That the tendons of the four ftraight mufcles of the eye are continued on to the edge of the cornea, and terminate, or are inferted, in its external laminæ: their action will therefore extend to the edge of the cornea.

"4. That in changing the focus of the eye from feeing with parallel rays to a near diftance, there is a vifible alteration produced in the figure of the cornea, rendering it more convex; and when the eye is again adapted to parallel rays, the alteration by which the cornea is brought back to its former ftate is equally vifible."

Mr Home made many other experiments with a view to throw light upon this curious fubject; and the refult of the whole appears to be, that the adjuftment of the eye is produced by three different changes in that organ; an increafe of curvature in the cornea, an elongation of the axis of vifion, and a motion of the cryftalline lens. Thefe changes, in a great meafure, depend upon the contraction of the four ftraight mufcles of the eye. Mr Ramfden, from computations grounded on the principles of optics and general ftate of the facts, eftimates that the increafe of curvature of the cornea may be capable of producing one-third of the effect, and that the change of place of the lens, and elongation of the axis of vifion, fufficiently account for the other two-thirds of the quantity of adjuftment neceffary to make up the whole.

VITALITY, the power of fubfifting in life, which the fafhionable philofophers of the French and German fchools attribute to *chemiftry*. For a confutation of their abfurd and impious jargon on this fubject, we refer our readers, with fome degree of confidence, to the articles PHYSIOLOGY (*Encycl.*), and *Animal* SUBSTANCES (*Suppl.*)

VIVERRA (fee *Encycl.*) A new fpecies of this genus of animals was difcovered by Vaillant during his laft travels in Africa; at leaft he ranks under the generic name *Viverra*, the animal of which he gives the following defcription. Its body was of the fize of that of a kitten fix months old: it had a very large nofe, the upper jaw exceeding the lower near two-thirds of an inch in length, and forming a fort of moveable fnout refembling that of the *coati* of Guiana. The fore feet were armed with four large claws, very fharp and curved; the hind ones have each five, but they are fhort and blunt. All the fur on the upper part of the body is marked with crofs bands of a deep brown colour, on a ground of light brown with which many white hairs are intermixed. The lower part of the body and infides of the legs are of a reddifh white. The tail, which is very flefhy, and more than two thirds longer than the body, is black at the tip, and the reft brown, intermixed with white hairs.

This animal employs its fore paws to dig very deep holes in the earth, in which it remains concealed during the day, not going out till fun-fet in queft of food.

The Hottentots who accompanied our traveller called it *muys-hond* (a moufe dog); a general name among the inhabitants of the Cape for all the fmaller carnivorous quadrupeds.

VIVES (Ludovicus), the contemporary and friend of Erafmus, was a native of Valentia in Spain. Though well trained in all the fubtleties of the fcholaftic philofophy at Paris, he had the good fenfe to difcover its futility, and diligently applied himfelf to more ufeful ftudies. At Louvain he undertook the office of a preceptor, and exerted himfelf with great ability and fuccefs in correcting barbarifm, chaftifing the corrupters of learning, and reviving a tafte for true fcience and elegant letters. Erafmus, with whom he lived upon the

Vives, Ultramarine.

footing of intimate friendſhip, ſpeaking of Vives when he was only 26 years of age, ſays, that there was no part of philoſophy in which he did not excel; and that he had made ſuch proficiency in learning, and in the arts of ſpeaking and writing, that he ſcarcely knew his equal. He wrote a commentary upon Auguſtine's treatiſe *De Civitate Dei*, which diſcovers an extenſive acquaintance with ancient philoſophy. Henry VIII. of England, to whom he dedicated this work, was ſo pleaſed with it, that he invited the author to his court, and made him preceptor to his daughter Mary. Though he diſcharged his office with great fidelity, yet in conſequence of his oppoſition to the king's divorce, he fell under his diſpleaſure; and it was not without difficulty that he eſcaped to Bruges, where he devoted the remainder of his days to ſtudy. He died in the year 1537, or, according to Thuanus, in 1541. With Eraſmus and Buddæus he formed a triumvirate of literature which did honour to the age. He wrote *De Prima Philoſophia*, "On the Firſt Philoſophy;" *De Explanatione Eſſentiarum*, "On the Explanation of Eſſences;" *De Cenſura Veri*, "On the Teſt of Truth;" *De Initiis, Sectis, et Laudibus Philoſophiæ*, "On the Origin, Sects, and Praiſes of Philoſophy;" and *De Corruptis Artibus et Tradendis Diſciplinis*, "On the Corruption of Science, and on Education." Theſe writings, of which the two laſt are the moſt valuable, diſcover great ſtrength of judgment, an extenſive knowledge of philoſophy, much enlargement of conception, uncommon ſagacity in detecting the errors of ancient and modern philoſophers, particularly of Ariſtotle and his followers, and, in fine, a mind capable of attempting things beyond the ſtandard of the age in which he lived. To all this he added great perſpicuity and elegance of ſtyle, not unworthy of the friend of Eraſmus.

ULTRAMARINE is a very fine blue powder, almoſt of the colour of the corn-flower or blue-bottle, which has this uncommon property, that, when expoſed to the air or a moderate heat, it neither fades nor becomes tarniſhed. On this account it is uſed in painting; but it was employed formerly for that purpoſe much more than at preſent, as ſmalt, a far cheaper article, was not then known. (See COBALT, in this *Suppl.*) Ultramarine is made of the blue parts of the lapis lazuli, by ſeparating them as much as poſſible from the other coloured particles with which they are mixed, and reducing them to a fine powder. The real lapis lazuli is found in the mountains of that part of Tartary called Bucharia, which extends eaſtwards from the Caſpian ſea, and particularly at Kalab and Budukſchu. It is ſent thence to the Eaſt Indies, and from the Eaſt Indies to Europe. Good ultramarine muſt be of a beautiful dark colour, and free from ſand as well as every other mixture. It muſt unite readily with oil; it muſt not become tarniſhed on a red-hot tile or plate of iron, and it ought to diſſolve in ſtrong acids, almoſt like the zeolite, without cauſing an efferveſcence. In the year 1763, an ounce of it at Paris coſt four pounds ſterling, and an ounce of *cendre d'outremer*, which is the refuſe, two pounds. The baſis of this colour was long ſuſpected to be copper, but the experiments of Margraff ſhewed that it was iron, in ſome unknown ſtate of combination. New light has been thrown on this ſubject by Morveau, who has diſcovered that ſelenite loaded with iron, when decompoſed by carbonaceous matter, yields a blue ſulphuret of iron of equal permanency with the true ultramarine.

Unicorn, Vortices.

At preſent, ſmalt of a good colour is often purchaſed at a dear rate and ſubſtituted for ultramarine: and it is found that the colour of this preparation of cobalt is more durable in the fire than even that of the lapis lazuli. For the analyſis of lapis lazuli, ſee MINERALOGY, n° 69. *Suppl.*

UNICORN, the ſcriptural name of an animal, which was undoubtedly the one horned rhinoceros. Ariſtotle, however, deſcribes a unicorn of a different kind; and, from his deſcription, ſeems to have been derived the idea of that figure, which is one of the ſupporters of the royal arms of Great Britain, and is generally ſuppoſed to repreſent a fictitious animal, or creature of the imagination. But this ſuppoſition, if not groundleſs, ſeems to be carried by much too far. Under the word UNICORN (*Encycl.*) we have recorded the teſtimony of Sparman and Labo, to the exiſtence of a unicorn ſhaped like a beautiful horſe; and their teſtimony has lately been ſtrongly corroborated by Mr Barrow, (A) a man of unqueſtionable veracity, who held a high office under government when the Cape of Good Hope was in the poſſeſſion of the Engliſh. He actually ſaw figures of the unicorn, ſuch as deſcribed by Labo, drawn with thoſe of the elephants and other animals on the ſmooth rocks in the interior of the country; and he very naturally infers that ſuch figures would not have been conceived by ſavages, who had not ſeen the living animal. The Boſhmen or Bojeſmans, were ſurpriſed at his expreſſing any doubt of its exiſtence; and the Dutch coloniſts take it for granted that ſuch an animal is to be found beyond the limits of the colony. Some of the Bojeſmans ſeemed ready to undertake an expedition to the north ſide of the great range of mountains, and for a proper reward to bring to the author a real unicorn; but what prevented the expedition we are not told. It may be performed, and is ſurely as well worthy of the amateurs of natural hiſtory as a journey into the heart of Africa in queſt of birds, flowers, or ſerpents. Till very lately the MAMMOTH (ſee *Encycl.*) was confounded with the elephant, and ſtrange inferences were thence drawn reſpecting the change of the poles of the earth. But now (1802) the ſkeleton of a *Mammoth* is exhibiting in London, whence it appears that the two animals, though nearly the ſame ſize, are quite diſtinct, and that the one may have lived in countries, where the bones of the mammoth are indeed generally found, of ſuch a temperature, that the elephant could not exiſt in them five months. Now, indeed, the mammoth ſeems to be extinct, and ſo may the unicorn be; but it appears unqueſtionable that both have once exiſted; and it is probable that the latter ſtill exiſts.

VORTICES of Des Cartes are now juſtly exploded; but being the fiction of a very ſuperior mind, they are ſtill an object of curioſity, as being the foundation of a great philoſophical romance. According to the author of that romance, the whole of infinite ſpace was full

(A) See his *Travels into the Interior of Southern Africa, in the years* 1797, 1798.

Vortices. full of matter; for with him matter and extenfion were the fame, and confequently there could be no void. This immenfity of matter he fuppofed to be divided into an infinite number of very fmall cubes; all of which, being whirled about upon their own centres, neceffarily gave occafion to the production of two different elements. The firft confifted of thofe angular parts which, having been neceffarily rubbed off, and grinded yet fmaller by their mutual friction, conftituted the moft fubtle and moveable part of matter. The fecond confifted of thofe little globules that were formed by the rubbing off of the firft. The interftices betwixt thefe globules of the fecond element were filled up by the particles of the firft. But in the infinite collifions, which muft occur in an infinite fpace filled with matter, and all in motion, it muft neceffarily happen that many of the globules of the fecond element fhould be broken and grinded down into the firft. The quantity of the firft element having thus been increafed beyond what was fufficient to fill up the interftices of the fecond, it muft, in many places, have been heaped up together, without any mixture of the fecond along with it. Such, according to Des Cartes, was the original divifion of matter. Upon this infinitude of matter thus divided a certain quantity of motion was originally impreffed by the Creator of all things, and the laws of motion were fo adjufted as always to preferve the fame quantity in it, without increafe, and without diminution. Whatever motion was loft by one part of matter, was communicated to fome other; and whatever was acquired by one part of matter, was derived from fome other: and thus, through an eternal revolution from reft to motion, and from motion to reft, in every part of the univerfe, the quantity of motion in the whole was always the fame.

But as there was no void, no one part of matter could be moved without thrufting fome other out of its place, nor that without thrufting fome other, and fo on. To avoid, therefore, an infinite progrefs, he fuppofed that the matter which any body pufhed before it rolled immediately backwards to fupply the place of that matter which flowed in behind it; as we may obferve in the fwimming of a fifh, that the water which it pufhes before it immediately rolls backwards to fupply the place of what flows in behind it, and thus forms a fmall circle or vortex round the body of the fifh. It was in the fame manner that the motion originally impreffed by the Creator upon the infinitude of matter neceffarily produced in it an infinity of greater and fmaller vortices, or circular ftreams: and the law of motion being fo adjufted as always to preferve the fame quantity of motion in the univerfe, thofe vortices either continued for ever, or by their diffolution gave birth to others of the fame kind. There was thus at all times an infinite number of greater and fmaller vortices, or circular ftreams, revolving in the univerfe.

But whatever moves in a circle is conftantly endeavouring to fly off from the centre of its revolution. For the natural motion of all bodies is in a ftraight line. All the particles of matter therefore, in each of thofe greater vortices, were continually preffing from the centre to the circumference, with more or lefs force, according to the different degrees of their bulk and folidity. The larger and more folid globules of the fecond element forced themfelves upwards to the circumference, while the fmaller, more yielding, and more active particles of the firft, which could flow even through the interftices of the fecond, were forced downwards to the centre. They were forced downwards to the centre notwithftanding their natural tendency was upwards to the circumference; for the fame reafon that a piece of wood, when plunged in water, is forced upwards to the furface, notwithftanding its natural tendency is downwards to the bottom; becaufe its tendency downwards is lefs ftrong than that of the particles of water, which, therefore, if one may fay fo, prefs in before it, and thus force it upwards. But there being a greater quantity of the firft element than what was neceffary to fill up the interftices of the fecond, it was neceffarily accumulated in the centre of each of thefe great circular ftreams, and formed there the fiery and active fubftance of the fun. For, according to that philofopher, the folar fyftems were infinite in number, each fixed ftar being the centre of one; and he is among the firft of the moderns who thus took away the boundaries of the univerfe: even Copernicus and Kepler, themfelves, have confined it within what they fuppofed the vault of the firmament.

The centre of each vortex being thus occupied by the moft active and moveable parts of matter, there was neceffarily among them a more violent agitation than in any other part of the vortex, and this violent agitation of the centre cherifhed and fupported the movement of the whole. But among the particles of the firft element, which fill up the interftices of the fecond, there are many, which, from the preffure of the globules on all fides of them, neceffarily receive an angular form, and thus conftitute a third element of particles lefs fit for motion than thofe of the other two. As the particles, however, of this third element were formed in the interftices of the fecond, they are neceffarily fmaller than thofe of the fecond, and are therefore, along with thofe of the firft, urged down towards the centre, where, when a number of them happen to take hold of one another, they form fuch fpots upon the furface of the accumulated particles of the firft element, as are often difcovered by telefcopes upon the face of that fun which enlightens and animates our particular fyftem. Thofe fpots are often broken and difpelled by the violent agitation of the particles of the firft element, as has hitherto happily been the cafe with thofe which have fucceffively been formed upon the face of our fun. Sometimes, however, they encruft the whole furface of that fire which is accumulated in the centre; and the communication betwixt the moft active and the moft inert parts of the vortex being thus interrupted, the rapidity of its motion immediately begins to languifh, and can no longer defend it from being fwallowed up and carried away by the fuperior violence of fome other like circular ftream; and, in this manner, what was once a fun becomes a planet. Thus the time was, according to the fyftem, when the moon was a body of the fame kind with the fun, the fiery centre of a circular ftream of ether, which flowed continually round her; but her face having been crufted over by a congeries of angular particles, the motion of this circular ftream began to languifh, and could no longer defend itfelf from being abforbed by the more violent vortex of the earth, which was then, too, a fun, and which chanced to be placed in its neighbourhood. The moon therefore became a planet, and revolved round the earth. In procefs of time,

time, the fame fortune, which had thus befallen the moon, befel alfo the earth; its face was encrufted by a grofs and inactive fubftance; the motion of its vortex began to languifh, and it was abforbed by the greater vortex of the fun: but though the vortex of the earth had thus become languid, it ftill had force enough to occafion both the diurnal revolution of the earth, and the monthly motion of the moon. For a fmall circular ftream may eafily be conceived as flowing round the body of the earth, at the fame time that it is carried along by that great ocean of ether which is continually revolving round the fun; in the fame manner as, in a great whirpool of water, one may often fee feveral fmall whirpools, which revolve round centres of their own, and at the fame time are carried round the centre of the great one. Such was the caufe of the original formation and confequent motions of the planetary fyftem. When a folid body is turned round its centre, thofe parts of it which are neareft, and thofe which are remoteft from the centre, complete their revolutions in one and the fame time. But it is otherwife with the revolutions of a fluid: the parts of it which are neareft the centre complete their revolutions in a fhorter time than thofe which are remoter. The planets, therefore, all floating in that immenfe tide of æther which is continually fetting in from weft to eaft round the body of the fun, complete their revolutions in a longer or a fhorter time, according to their nearnefs or diftance from him.

This bold fyftem was eminently fitted to captivate the imagination; and though fraught with contradictions and impoffibilities, attempts have been made to revive it, even in this country, under different names. All thofe fyftems which reprefent the motions of the heavenly bodies as being the effect of the phyfical agency of æthers, of air, of fire, and of light, of which the univerfe is conceived to be full, labour under the fame difficulties with the Cartefian hypothefis; and very few of them, if any, are fo neatly put together. It is furely fufficient, however, to demolifh this goodly fabric, barely to afk how an abfolute infinity of matter can be divided into cubes, or any thing elfe? how there can poffibly be interftices in a perfect plenum? or how in fuch a plenum any portion of matter can be thruft from its place?

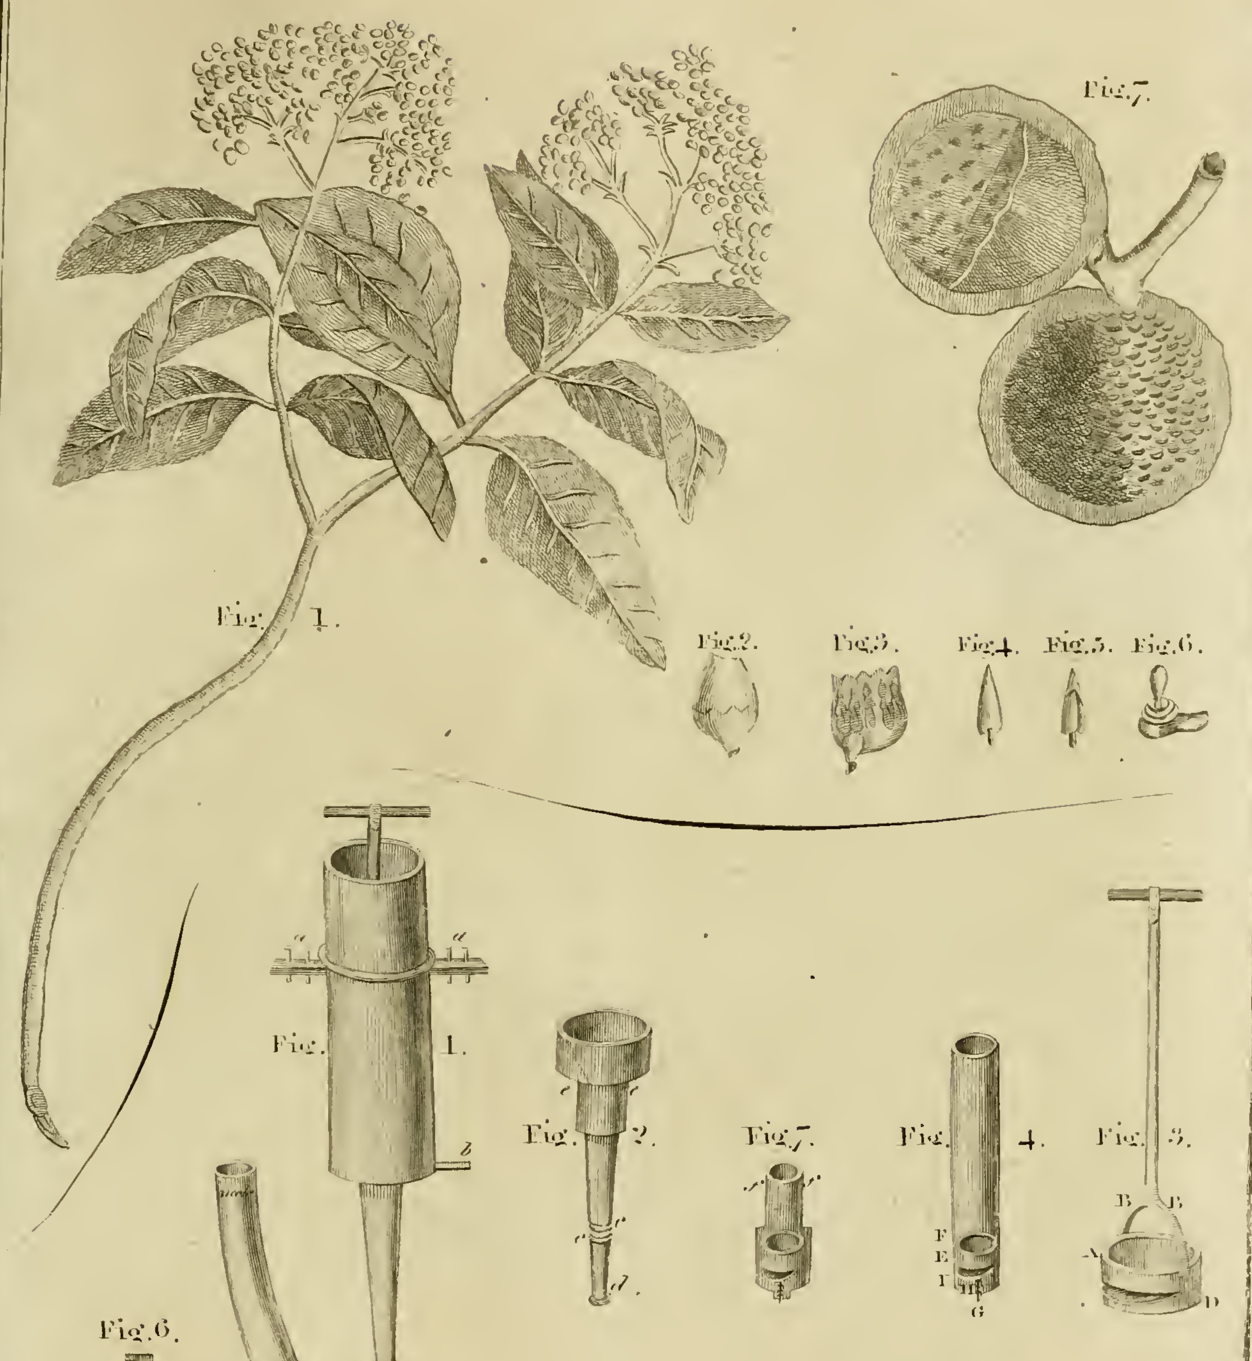
URALIAN Cossacs, a people that inhabit the Ruffian province of Orenburg in Afia, on the fouth fide of the river Ural. Thefe Coffacs are defcended from thofe of the Don: they are a very valiant race. They profefs the Greek religion; but there is a kind of diffenters from the eftablifhed religion, whom the Ruffians called *Rofkolniki*, or Separatifts, and who ftyle themfelves *Staroverfki*, or Old Believers. They confider the fervice of the eftablifhed church as profane and facrilegious, and have their own priefts and ceremonies. The Uralian Coffacs are all enthufiafts for the ancient ritual, and prize their beards almoft equal to their lives. A Ruffian officer having ordered a number of Coffac recruits to be publicly fhaved in the town of Yaitfk, in 1771, this wanton infult excited an infurrection, which was fuppreffed for a time; but, in 1773, that daring impoftor, Pugatchef, having affumed the name and perfon of Peter III. appeared among them, and taking advantage of this circumftance, and of their religious prejudices, roufed them once more into open rebellion. This being at laft effectually fuppreffed by the defeat and execution of the impoftor (See Suworow, *Suppl.*), in order to extinguifh all remembrance of this rebellion, the river Yaik was called *Ural*; the Yaik Coffacs were denominated *Uralian Coffacs*; and the town of Yaitfk, *Uralfk*. The Uralian Coffacs enjoy the right of fifhing on the coaft of the Cafpian Sea, for 47 miles on each fide of the river Ural. Their principal fifhery is for fturgeons and beluga, whofe roe fupplies large quantities of caviare; and the fifh, which are chiefly falted and dried, afford a confiderable article of confumption in the Ruffian empire. In confequence of thefe fifheries, thefe Coffacs are very rich.

URBINO, a town of Italy, in the territory of the Pope, and capital of the duchy of Urbino, with an old citadel, an archbifhop's fee, and a handfome palace, where the dukes formerly refided. The houfes are well built, and great quantities of fine earthen ware are made here. It is feated on a mountain, between the rivers Metro and Foglia, 18 miles fouth of Rimini, 58 eaft of Florence, and 120 north-eaft of Rome. E. Lon. 12. 40. N. lat. 43. 46.

Urbino, a duchy of Italy, in the territory of the church, bounded on the north by the gulph of Venice; on the fouth, by Perugino and Umbria; on the eaft, by the marquifate of Ancona; and on the weft, by Tufcany and Romagna. It is about 55 miles in length, and 45 in breadth. Here is great plenty of game and fifh; but the air is not very wholefome, nor is the foil fertile. Urbino is the capital.

URCEOLA, a lately difcovered genus of the *pentandria* clafs, and *monogynia* order of plants, ranking immediately after Tabernæ montana (fee *Encycl.*), and confequently belonging to the 30th natural order or clafs called *Contortæ* by Linnæus in his natural method of arrangement. One of the qualities of the plants of this order is their yielding, on being cut, a juice which is generally milky, and for the moft part deemed of a poifonous nature. The genus is thus characterifed by Dr Roxburgh: *Calyx* beneath five-toothed; corol one petaled, pitcher fhaped, with its contracted mouth five-toothed: nectary entire, furrounding the germs; follicles two, round, drupacious; feeds numerous, immerfed in pulp. There is but one known fpecies, which is thus defcribed by the fame eminent botanift;

Urceola elastica: Shrubby, twining, leaves oppofite, oblong, panicles terminal, is a native of Sumatra, Prince of Wales's Ifland, &c. Malay countries. *Stem* woody, climbing over trees, &c. to a very great extent, young fhoots twining, and a little hairy, bark of the old woody parts thick, dark coloured, confiderably uneven, a little fcabrous, on which are found feveral fpecies of mofs, particularly large patches of lichen; the wood is white, light, and porous. *Leaves* oppofite, fhort-petioled, horizontal, ovate, oblong, pointed, entire, a little fcabrous, with a few fcattered white hairs on the under fide. *Stipulus* none. *Panicles* terminal, brachiate, very ramus. *Flowers* numerous, minute, of a dull greenifh colour, and hairy on the outfide. *Bracts* lanceolate, one at each divifion and fubdivifion of the panicle. *Calyx* perianth, one-leaved, five-toothed, permanent. *Corol* one petaled, pitcher-fhaped, hairy, mouth much contracted, five-toothed, divifions erect, acute, nectary entire, cylindric, embracing the lower two-thirds of the germs. *Stamens*, filaments five, very fhort from the bafe of the corol. Anthers arrow-fhaped, converging,



D. Lizars sculp.

Urceola. verging, bearing their pollen in two grooves on the infide, near the apex; between thefe grooves and the infertions of the filaments they are covered with white foft hairs. *Piftil*, germs two; above the nectary they are very hairy round the margins of their truncated tops. Style fingle, fhorter than the ftamens. Stigma ovate, with a circular band, dividing it into two portions of different colours. *Per.* Follicles two, round, laterally compreffed into the fhape of a turnip, wrinkled, leathery, about three inches in their greateft diameters—one celled, two valved. *Seeds* very numerous, reniform, immerfed in firm flefhy pulp.

See Plate XLVII. where fig. 1. is a branchlet in flower of the natural fize. 2. A flower magnified. 3. The fame laid open, which expofes to view the fituation of the ftamens inferted into the bottom of the corol, the nectarium furrounding the lower half of the two germs, their upper half with hairy margins, the ftyle and ovate party coloured; ftigma appearing above the nectary. 4. Outfide of one of the ftamens; and, 5. Infide of the fame, both much magnified. 6. The nectarium laid open, expofing to view the whole of the piftil. 7. The two feed veffels (called by Linnæus *follicles*), natural fize; half of one of them is removed, to fhew the feed immerfed in pulp. A portion thereof is alfo cut away, which more clearly fhews the fituation and fhape of the feed.

From wounds made in the bark of this plant there oozes a milky fluid, which on expofure to the open air feparates into an elaftic coagulum, and watery liquid apparently of no ufe, after the feparation takes place. This coagulum is not only like the American caoutchouc or Indian rubber, but poffeffes the fame properties; for which, fee CAOUTCHOUC, both in the *Encycl.* and *Suppl.*

The chemical properties of this vegetable milk, while frefh, were found by Mr Howifon, late furgeon on Prince of Wales's Ifland, furprifingly to refemble thofe of animal milk. From its decompofition, in confequence of fpontaneous fermentation, or by the addition of acids, a feparation takes place between its cafeous and ferous parts, both of which are very fimilar to thofe produced by the fame proceffes from animal milk. An oily or butyrous matter is alfo one of its component parts, which appears upon the furface of the gum fo foon as the latter has attained its folid form. He endeavoured to form an extract of this milk fo as to approach to the confiftence of new butter, by which he hoped to retard its fermentative ftage, without depriving it of its ufeful qualities; but as he had no apparatus for diftilling, the furface of the milk, that was expofed to the air, inftantly formed into a folid coat, by which the evaporation was in a great degree prevented. He, however, learned, by collecting the thickened milk from the infide of the coats, and depofiting it in a jelly pot, that, if excluded from the air, it might be preferved in this ftate for a confiderable length of time; and even without any preparation be kept in bottles, tolerably good, upwards of twelve months.

Urinary, Urtica. URINARY, CONCRETIONS. See *Animal Substances*, Suppl.

URTICA. See *Encycl.* where it is obferved that the common nettle, though it has a place in the *materia medica*, is now very little ufed. It has lately been recommended, however, by *Zannetini*, a phyfician who attended the French army in Italy, as a good fubftitute in fevers for cinchona. The fuccefs of fome experiments, which he made with it in tertian and quartain malignant fevers, furpaffed, he fays, his moft fanguine expectation. The nettle often produces a fpeedier effect than bark; for it heats in a great degree, and when the dofe is pretty ftrong, occafions a lethargic fleep. The dofe muft never exceed a dram, and is given in wine two or three times in the courfe of 24 hours. Zannetini found this medicine of great fervice to guard againft that total exhauftion which forms the principal character of malignant fevers; and he recommends a flight infufion of it in wine as an excellent prefervative for thofe who refide in marfhy and infalubrious diftricts. In employing the nettle in fever, Zannetini gives the fame caution as ought to be obferved in regard to cinchona, that is, that it muft not be employed where there is an inclination to inflammation, or where a continued fever, arifing from obftructions, exifts. This difcovery is not unworthy the attention of phyficians, and deferves at leaft to be farther inveftigated, as a great deal would be faved if cinchona could be entirely difpenfed with.

W.

Wales. WALES, New South, is a country which muft be interefting on account of the fingular colony which was fettled there in the year 1788. Under the title *New Holland* (*Encycl.*) fome account has been given of that fettlement, as well as of the climate and the foil about Port Jackfon; but it will probably gratify the curiofity of our readers, if we give a fhort hiftory of thofe European fettlers, of whom it is to be hoped that they carried not with them, to that diftant fhore,

"Minds not to be changed by time or place."

This hiftory we fhall take from the accurate *Account of the Englifh Colony in New South Wales*, by David Collins, Efq; who went out with Governor Phillip, and continued to execute the offices of Judge-advocate and Secretary

Wales. Secretary till the close of the year 1796; and we shall begin our narrative from the disembarkation of the first colonists, when his Majesty's commission to the governor, and the letters patent, establishing courts of criminal and civil judicature in the territory, were read.

The criminal court was constituted a court of record, and was to consist of the judge-advocate and such six officers of the sea and land service as the governor shall, by precept issued under his hand and seal, require to assemble for that purpose This court has power to inquire of, hear, determine, and punish all treasons, misprisions of treasons, murders, felonies, forgeries, perjuries, trespasses, and other crimes whatsoever that may be committed in the colony; the punishment for such offences to be inflicted according to the laws of England as nearly as may be, considering and allowing for the circumstances and situation of the settlement and its inhabitants. The charge against any offender is to be reduced into writing, and exhibited by the judge-advocate: witnesses are to be examined upon oath, as well for as against the prisoner; and the court is to adjudge whether he is guilty or not guilty by the opinion of the major part of the court. If guilty, and the offence is capital, they are to pronounce judgment of death, in like manner as if the prisoner had been convicted by the verdict of a jury in England, or of such corporal punishment as the court, or of the major part of it, shall deem meet. And in cases not capital, they are to adjudge such corporal punishment as the majority of the court shall determine. But no offender is to suffer death unless five members of the court shall concur in adjudging him to be guilty, until the proceedings shall have been transmitted to England, and the king's pleasure signified thereupon. The provost-marshal is to cause the judgement of the court to be executed according to the governor's warrant under his hand and seal.

Beside this court for the trial of criminal offenders, there is a civil court, consisting of the judge-advocate and two inhabitants of the settlement, who are to be appointed by the governor; which court has full power to hear and determine in a summary way all pleas of lands, houses, debts, contracts, and all personal pleas whatsoever.

From this court, on either party, plaintiff or defendant, finding himself or themselves aggrieved by the judgment or decree, an appeal lies to the governor, and from him, where the debt or thing in demand shall exceed the value of L. 300, to the king in council.

A vice-admiralty court was also appointed, for the trial of offences on the high seas; and the governor, lieutenant-governor, and judge-advocate, were by patent made justices of the peace, with a power in the governor to appoint other justices.

The situation which Governor Phillip had selected for his residence, and for the principal settlement, was the east side of a cove in Port Jackson, which he called *Sydney Cove*. Its latitude was found to be 33° 52′ 30″ south, and its longitude 152° 19′ 30″ east. This situation was chosen without due examination; for it soon appeared that the head or upper part of the cove wore a much more favourable appearance than the ground immediately about the settlement. From the natives, the new settlers met no opposition: during the first six weeks they received only one visit from them, two men strolling one evening into the camp, and remaining in it for about half an hour. They appeared to admire whatever they saw; and after receiving a hatchet (of the use of which the eldest instantly and curiously shewed his knowledge, by turning up his foot and sharpening a piece of wood on the sole with the hatchet) took their leave, apparently well pleased with their reception. The fishing boats also frequently reported their having been visited by many of these people when hauling the seine; at which labour they often assisted with cheerfulness, and in return were generall rewarded with a part of the fish taken.

The first labour in which the convicts were employed was that of building huts; and for this purpose it was found necessary to divide them into gangs, and to appoint an overseer to each, who should see that the proper quantity of work was performed. The provisions were distributed by a weekly ration, and to each man were allowed 7lb. of biscuit, 1lb. of flour, 7lb. of beef or 4lb. of pork, 3 pints of pease, and 6 ounces of butter. To the female convicts two thirds of this ration were allowed. This was the full ration, which, in many instances, it became necessary to reduce; and once, in consequence of the delay of transports with a supply, the convicts were put on an allowance of which flesh meat constituted no part.

The temporary huts in which the colonists lived, for some time after their arrival, were formed principally of the cabbage-tree. With this the sides and ends were filled; the posts and plates being made of the pine; and the whole was plastered with clay. The roofs were generally thatched with the grass of the gumrush; though some were covered with clay; but several of these failed, the weight of the clay and rain soon destroying them. In a short time they applied themselves to the burning of bricks; by which their habitations soon became much more lasting and comfortable. The progress of the colony, however, towards that degree of convenience which was within its reach, was greatly impeded by the incorrigible vices of those who principally composed it. Drunkenness, theft, robbery, and unconquerable laziness, continued to mark the character of the great body of the convicts. Though to fly from the colony, and venture into the interior of the country, was inevitable death in the form of famine or of murder, yet such was the invincible antipathy to labour manifested by some of those people, that they often fled to the woods, from which they seldom returned; some dying of hunger, and some being sacrificed by the natives. Disinclination to labour produced here, as elsewhere, its natural effect—robbery.

In the month of May 1788, a lad of 17 years of age was tried, convicted, and executed, for breaking open a tent belonging to one of the transport ships; several others were taken into custody in that month for various thefts and burglaries, and two were afterward tried and executed. One of these had absconded, and lived in the woods for 19 days, subsisting by what he was able to procure by nocturnal depredations among the huts and stock of individuals. His visits for this purpose were so frequent and daring, that it became absolutely necessary to proclaim him an outlaw. By the negligence of one of those fellows who had been entrusted with the care of the cattle, the bull and four cows were lost: he left them in the fields, and returned to his hut to dine; and in the mean time they either strayed away or were

Wales. were driven off by the natives Five years elapfed before thefe cattle were difcovered wild, at a confiderable diftance up tbe country, and greatly multiplied.

The perpetration of crimes, chiefly theft and robbery, had become fo prevalent before twenty months had paffed fince the colony was eftablifhed, that it was neceffary to think of a fyftem of police. A plan was prefented to the governor by a *convict*, which with fome improvements was adopted on the 8th of Auguft 1789. The following are the heads of the arrangement.

The fettlement was divided into four diftricts, over each of which was placed a watch confifting of three perfons, one principal and two fubordinate watchmen. Thefe being felected from among thofe convicts whofe conduct and character had been unexceptionable fince their landing, were vefted with authority to patrole at all hours in the night, to vifit fuch places as might be deemed requifite for the difcovery of any felony, trefpafs or mifdemeanor, and to fecure for examination all perfons that might appear to be concerned therein; for which purpofe they were directed to enter any fufpected hut or dwelling, or to ufe any other means that might appear expedient. They were required to detain and give information to the neareft guardhoufe of any foldier or feaman who fhould be found ftraggling after the tattoo had been beat. They were to ufe their utmoft endeavours to trace out offenders on receiving accounts of any depredation; and in addition to their night-duty, they were directed to take cognizance of fuch convicts as gamed, or fold or bartered their flops or provifions, and report them for punifhment. A return of all occurrences during the night was to be made to the judge-advocate; and the military were required to furnifh the watch with any affiftance they might be in need of, beyond what the civil power could give them. They were provided each with a fhort ftaff, to diftinguifh them during the night, and to denote their office in the colony; and were inftructed not to receive any ftipulated encouragement or reward from any individual for the conviction of offenders, but to expect that negligence or mifconduct in the execution of their truft would be punifhed with the utmoft rigour. It was to have been wifhed, fays Mr Collins, that a watch eftablifhed for the prefervation of public and private property had been formed of free people, and that neceffity had not compelled us, in felecting the firft members of our little police, to appoint them from a body of men, in whofe eyes, it could not be denied, the property of individuals had never before been facred. But there was not any choice: The military had their line of duty marked out for them, and between them and the convict there was no defcription of people from whom overfeers or watchmen could be provided. It might, however, be fuppofed, that among the convicts there muft be many who would feel a pride in being diftinguifhed from their fellows, and a pride that might give birth to a returning principle of honefty. It was hoped that the convicts whom we had chofen were of this defcription; fome effort had become neceffary to detect the various offenders who were prowling about with fecurity under cover of the night; and the convicts who had any property were themfelves interefted in defeating fuch practices. They promifed fidelity and diligence, from which the fcorn of their fellow-prifoners fhould not induce them to fwerve, and began with a confidence of fuccefs the duty which they had themfelves offered to undertake.

A fpecies of difturber now infefted the colony, againft which the vigilance of a police could not guard. Rats, in immenfe numbers, had attacked the provifion ftores, and could be counteracted only by removing the provifions from one ftore to another. When their ravages were firft difcovered, it was found that eight cafks of flour were already deftroyed by thefe vermin. Such of thefe animals as efcaped the dogs, which were fet upon them, flew to the gardens of individuals, where they rioted on the Indian corn that was growing, and did confiderable mifchief.

Our author gives the moft melancholy account of the extreme fufferings of the early colonifts from want of provifions, and of the difeafes imported into the country by newcomers, who had either caught them on the voyage or brought them from England The fettlers on Norfolk-*Ifland* (fee *Encycl.*), to which New South Wales was a mother country, muft have been much more liable than that colony to fuffer from famine, had they not fometimes obtained a temporary fupply from a fource which was unknown at Sydney Cove. On a mountain in the ifland, to which had been given the name of *Mount Pitt*, they were fortunate enough to obtain, in an abundance almoft incredible, a fpecies of aquatic birds, anfwering the defcription of that known by the name of the *puffin*. Thefe birds came in from the fea every evening, in clouds literally darkening the air, and defcending on Mount Pitt, depofited their eggs in deep holes made by themfelves in the ground, generally quitting them in the morning, and returning to feek their fubfiftence in the fea. From two to three thoufand of thefe birds were often taken in a night. Their feeking their food in the ocean left no doubt of their own flefh partaking of the quality of that upon which they fed; but to people circumftanced as were the inhabitants on Norfolk Ifland, this leffened not their importance; and while any Mount Pitt birds (fuch being the name given them) were to be had, they were eagerly fought.

The firft fettler in New South Wales, who declared himfelf able to live on the produce of his farm, without any affiftance from the ftores, was James Rufe; who in April 1790 relinquifhed his claim to any farther fhare of the public provifion. As a reward, the governor immediately put him in poffeffion of an allotment of 30 acres

In the July of the fame year, the convicts whofe terms of tranfportation had expired were now collected, and by the authority of the governor informed, that fuch of them as wifhed to become fettlers in this country fhould receive every encouragement; that thofe who did not, were to labour for their provifions, ftipulating to work for 12 or 18 months certain; and that in the way of fuch as preferred returning to England no obftacles would be thrown, provided they could procure paffages from the mafters of fuch fhips as might arrive; but that they were not to expect any affiftance on the part of government to that end. The wifh to return to their friends appeared to be the prevailing idea, a few only giving in their names as fettlers, and none engaging to work for a certain time.

That the wifh to return home was ftrong indeed, and paramount to all other feelings, was evinced in a very

Wales.

melancholy inftance fome time before. A convict, an elderly man, was found dead in the woods, near the fettlement; who, on being opened, it appeared, had died from want of nourifhment; and it was found that he was accuftomed to deny himfelf even what was abfolutely neceffary to his exiftence, abftaining from his provifions, and felling them for money, which he was referving, and had fomewhere concealed, in order to purchafe his paffage to England when his time fhould terminate!

Of fome convicts whofe terms of tranfportation had expired, the governor eftablifhed a new fettlement in Auguft 1791, at a place which he called *Profpect Hill*, about twenty miles diftant from Sydney Cove; and another refidence was formed at the Ponds within three or four miles of the former. This made the fourth fettlement in the colony, exclufively of that at Norfolk Ifland.

About this time the governor received from England a public feal for the colony: on the obverfe of which were the king's arms and royal titles; and on the reverfe, emblematic figures fuited to the fituation of the people for whofe ufe it was defigned. The motto was "*Sic fortis Etruria crevit;*" and in the margin were the words "*Sigillum Nov. Camb. Auft.*" A commiffion alfo arrived, empowering him to remit abfolutely, or conditionally, the whole or any part of the term for which the felons fent to the colony might be tranfported. By this power he was enabled to beftow on fuperior honefty and induftry the moft valuable reward which, in fuch circumftances, they could receive.

In addition to the calamities under which the fettlement had fo often laboured from being reduced to very fhort allowance of provifions, and the frequency of the ordinary difeafes which were to be expected among a people fo fituated, a new malady of a very alarming nature was perceived about April 1792. Several convicts were feized with infanity; and as the major part of thofe who were vifited by this calamity were females, who, on account of their fex, were not haraffed with hard labour, and who in general fhared largely of fuch little comforts as were to be procured in the fettlement, it was difficult to affign a caufe for this diforder. It feems, however, to have been of fhort duration; for we hear not of it again during the period that Mr Collins's narrative comprehends.

About this time (1792) the colony had affumed fomething of an eftablifhed form. Brick huts were in hand for the convicts in room of the miferable hovels occupied by many, which had been put up at their firft landing, and in room of others which, from having been erected on fuch ground as was then cleared, were now found to interfere with the direction of the ftreets which the governor was laying out. People were alfo employed in cutting paling for fencing in their gardens. At a place called Paramatta, about 16 miles from Sydney Cove, fituated on a fmall river which runs into Port Jackfon, the people were employed, during the greateft part of the month of May, in getting in the maize and fowing wheat. A foundation for an hofpital was laid, a houfe built for the mafter carpenter, and roofs prepared for the different huts either building or to be built in future.

In December 1792, when Captain Phillip refigned the government, nearly five years from the foundation of the colony, there were in cultivation at the different fettlements 1429 acres, of which 417 belonged to fettlers; that is, 67 fettlers, for there was no more, cultivated nearly half as much ground as was cultivated by the public labour of all the convicts; a ftriking proof of the fuperior zeal and diligence with which men exert themfelves when they have an intereft in their labour. Of free fettlers, whofe exertions promifed fo fairly to promote the interefts of the colony, feveral arrived from England in January 1793, and fixed themfelves in a fituation which they called *Liberty Plains.* To one of thefe, Thomas Rofe, a farmer from Dorfetfhire, and his family of a wife and four children, 120 acres were allotted. The conditions under which thefe people agreed to fettle were, "to have their paffage provided by government (A); an affortment of tools and implements to be given to them out of the ftores; that they fhould be fupplied with two years provifions; that their lands fhould be granted free of expence; the fervice of convicts alfo to be affigned to them free of expence; and that thofe convicts fhould be fupplied with two years rations and one year's clothing."

Among the great difficulties with which this infant eftablifhment had to ftruggle, not the leaft was that of procuring cattle. Of thofe which were embarked in England and other places for the colony, a very fmall proportion only arrived; for of 15 bulls and 119 cows, which had been embarked for Botany Bay, only 3 bulls and 28 cows were landed at the fettlement. It was not until the arrival of the Endeavour, Captain Bampton, in 1795, that the mode of conveying cattle to the colony without material lofs was difcovered. In that veffel, out of 130 head which he embarked at Bombay, one cow only died on the paffage, and that too on the day before his arrival.

The fcarcity of cattle naturally raifed their price. Even after this laft importation, an Englifh cow in calf fold for L.80.

Notwithftanding the various obftacles which induftry had met in the cultivation of this fettlement, it yet made confiderable advances; for in October 1793, the value of land had fo rifen, that one fettler fold his allotment of 30 acres for as many pounds; and one farm, with the houfe, &c. fold for L.100. The value of ground, indeed, was confiderably enhanced by government agreeing to purchafe the redundance of the produce of the fettlers at fixed prices. Wheat properly dried and cleanfed was received from the fettlers at Sydney, by the commiffary, at 10s. per bufhel. Some cultivators, however, had devifed another mode of difpofing of their corn. One of them, whofe fituation was near Paramatta, having obtained a fmall ftill from England, found it more advantageous to draw an ardent diabolical fpirit from his wheat, than to fend it to the ftores. From one bufhel of wheat he obtained nearly five quarts of fpirit, which he fold or paid in exchange for labour, at the rate of five or fix fhillings per quart.

(A) Government paid for the paffage of each perfon above ten years of age L.8, 8s. and one fhilling per day for victualling them.

Wales.

quart. A better ufe was made of grain by another fettler; who, having a mill, ground it, and procured 44lb. of good flour, from a bufhel of wheat taken at 59lb. This flour he fold at 4d. per lb.

By a return of the number of perfons in New South Wales and Norfolk Ifland in April 1794, it appeared that there were in all 4414, including women and children; the annual expence of whom, to the mother-country, Mr Collins eftimates at L. 161,101. Rapid ftrides, however, were at that time making towards independence, if not towards an ability of repaying to England a part of what the fettlement had coft her. Already the colony lived on grain of its own growth, and an increafe of live ftock was become almoft certain. There were now 4665 acres of ground cleared for cultivation; more than half of which had been effected by thofe who had become fettlers in the courfe of fifteen months.

To this fpirit of improvement fuch a check was given in September 1794, that not more than a third of government ground, and a fifth of ground belonging to individuals, was in cultivation in 1795. As this event has been mifreprefented, we fufpect purpofely, by fome of our journalifts, we fhall give the true account of it in the words of Mr Collins himfelf.

"The Francis fchooner (fays he) returned from Norfolk, having been abfent about eight weeks and three days. From Mr King, who commanded in that ifland, we learned that his harveft had been prodigioufly productive. He had purchafed from the firft crops, which the fettlers had brought to market, upwards of 11,000 bufhels of maize; and bills for the amount were drawn by him in favour of the refpective fettlers; but requiring the fanction of the Lieutenant governor, they were now fent to Port Jackfon. Mr King had been partly induced to make this provifional kind of purchafe, under an idea, that the corn would be acceptable at Port-Jackfon, and alfo in compliance with the conditions on which the fettlers had received their refpective allotments under the regulations of Governor Phillip; that is to fay, that their overplus grain fhould be purchafed at a fair market price. Being, however, well ftocked with that article already, the Lieutenant governor did not think himfelf juftifiable in putting the crown to fo great an expence (nearly L.3000 Sterling), and declined accepting the bills." This naturally excited fome difcontents in Norfolk Ifland, and one or two fettlers gave up their farms; but immediately on the arrival of Governor Hunter, he paid for the corn, and tranquillity was reftored to the ifland."

Though feveral quarrels had occurred between the natives and individuals among the colonifts, yet it was fuppofed that our people were in general the aggreffors. The governor had taken much pains to infpire the natives with confidence, and had in a great meafure fucceeded. To theft they were naturally and irrefiftibly inclined: but, like other favages, they feemed unconfcious of the crime, and were feldom deterred by detection from mixing with the colonifts. At a fettlement which had early been formed at a river called the *Hawkefbury* (and at which, cultivation having gone on well, there was, in courfe, much grain to ftimulate to depredation), the natives affumed a more formidable appearance.

"At that fettlement (fays Mr Collins) an open war feemed about this time to have commenced between the natives and the fettlers; and word was received overland, that two people were killed by them; one a fettler of the name of Wilfon, and the other a freeman, one William Thorp, who had hired himfelf to this Wilfon as a labourer. The natives appeared in large bodies, men, women, and children, provided with blankets and nets to carry off the corn, of which they appeared as fond as the natives who lived among us, and feemed determined to take it whenever and wherever they could meet with opportunities. In their attacks they conducted themfelves with much art; but where that failed they had recourfe to force; and on the leaft appearance of refiftance made ufe of their fpears or clubs. To check at once, if poffible, thefe dangerous depredators. Captain Paterfon directed a party of the corps to be fent from Paramatta, with inftructions to deftroy as many as they could meet with of the wood tribe (Bè-diagal); and, in the hope of ftriking terror, to erect gibbets in different places, whereon the bodies of all they might kill were to be hung. It was reported that feveral of thefe people were killed in confequence of this order; but none of their bodies being found (perhaps if any were killed they were carried off by their companions), the number could not be afcertained. Some prifoners, however, were taken, and fent to Sydney; one man (apparently a cripple), five women, and fome children. One of the women, with a child at her breaft, had been fhot through the fhoulder, and the fame fhot had wounded the babe. They were immediately placed in a hut near our hofpital, and every care taken of them that humanity fuggefted. The man was faid, inftead of being a cripple, to have been very active about the farms, and inftrumental in fome of the murders which had been committed. In a fhort time he found means to efcape, and by fwimming reached the north fhore in fafety; whence, no doubt, he got back to his friends. Captain Paterfon hoped, by detaining the prifoners and treating them well, that fome good effect might refult; but finding, after fome time, that coercion, not attention, was more likely to anfwer his ends, he fent the women back. While they were with us, the wounded child died, and one of the women was delivered of a boy, which died immediately. On our withdrawing the party, the natives attacked a farm nearly oppofite Richmond Hill, belonging to one William Rowe, and put him and a very fine child to death; the wife, after receiving feveral wounds, crawled down the bank, and concealed herfelf among fome reeds half immerfed in the river, where fhe remained a confiderable time without affiftance: being at length found, this poor creature, after having feen her hufband and her child flaughtered before her eyes, was brought into the hofpital at Paramatta, where fhe recovered, though flowly, of her wounds."

By the vigorous meafures which were adopted, the colony, towards the clofe of 1796, had acquired a degree of ftrength which feemed to enfure its future profperity. Not only the neceffary edifices were raifed for the habitations of its people, but fome for the purpofes of religion, amufement, &c. A playhoufe had been erected at the expence of fome perfons who performed in it for their own emolument, and who admitted auditors at one fhilling each. A convenient church had been built, a printing prefs had been fet up, the civil court

court was open for the recovery of debts by action and for proving wills, licences had been issued to regulate the sale of spirits, and passage-boats were established for the convenience of communication between the different settlements. In the houses of individuals were to be found most of the comforts, and not a few of the luxuries, of life; and, in a word, the former years of famine, toil, and difficulty, were now exchanged for those of plenty, ease, and pleasure.

The quantity of ground at this time in cultivation was 5419 acres; of which 2547 were occupied by settlers. The number of persons in New South Wales and its dependencies amounted to 4848. The price of labour, however, compared with the prices of provision, (as given in Mr Collins's Tables), does not appear so high as to enable the workman to live very comfortably. He who receives but three shillings for his day's work, and gives two shillings for a pound of mutton, fifteen pence for a pound of pork, and half of that sum for a pound of flour, will scarcely derive from his mere labour the support necessary for a family.

That many things are yet wanted to give full effect to the advantages which the colony now enjoys, Mr Collins declares in the following paragraph, with which he concludes his account:

"The want at this time of several public buildings in the settlement has already been mentioned. To this want must be added, as absolutely necessary to the well-being and comfort of the settlers, and the prosperity of the colony in general, that of a public store, to be opened on a plan, though not exactly the same, yet as liberal as that of the Island of St Helena, where the East India Company issue to their own servants European and Indian goods at 10 *per cent.* advance on the prime cost. Considering our immense distance from England a greater advance would be necessary; and the settlers and others would be well satisfied, and think it equally liberal, to pay 50 *per cent.* on the prime cost of all goods brought from England; for at present they pay never less than 100, and frequently 1000, *per cent.* on what they have occasion to purchase. It may be supposed that government would not choose to open an account, and be concerned in the retail of goods; but any individual would find it to his interest to do this, particularly if assisted by government in the freight; and the inhabitants would gladly prefer the manufactures of their own country to the sweepings of the Indian bazars.

"The great want of men in the colony must be supplied as soon as a peace shall take place; but the want of respectable settlers may, perhaps, be longer felt; by these are meant men of property, with whom the gentlemen of the colony could associate, and who should be thoroughly experienced in the business of agriculture. Should such men ever arrive, the administration of justice might assume a less military appearance, and the trial by jury, ever dear and most congenial to Englishmen, be seen in New South Wales."

There is, however, one serious difficulty which the colony has not yet overcome, and which, until it be overcome, will certainly prevent such men from settling in New South Wales. Till some staple commodity can be raised for exportation, industrious free settlers will never be tempted to emigrate from Europe to a country where their industry cannot procure the comforts as well as the necessaries of life. The American colonies, in their infancy, did not labour under this disadvantage. Tobacco soon became, and still continues to be, an article of such importance, that its cultivation afforded the trans-atlantic farmer a ready exchange for European commodities; whilst in New South Wales there seems to be no vegetable production of much value, except New Zealand hemp, which is produced indeed in great abundance in Norfolk Island, and which Captain Cook long ago pointed out as an article of great importance to the British navy. This is indeed a valuable plant, and grows in all the cliffs of the island, where nothing else will grow, in sufficient abundance to give constant employment to 500 people; yet when Mr Collins left the settlement, there was no more than one loom on the island, and the slay or reed was designed for coarse canvas; nor did they possess a single tool required by flax-dressers or weavers beyond the poor substitutes which they were obliged to fabricate for themselves. In this defect of necessaries for the manufacture, only 18 people could be employed in it; and of these the united labour in a week produced 16 yards of canvas, of the size called N° 7.

Besides a useful manufactory of this plant, which certainly might be established, the colony appears to possess several important advantages. From Mr Collins's narrative, it appears probable that a seal and perhaps a whale fishery might be established with a fair prospect of success; good rich earth is found near Sydney Cove; there are immense strata of coal in the southern part of New Holland; Norfolk Island abounds with lime; and vast quantities of shells, which answer the same purpose, have been found on the main-land. Though the wood in general be not of a durable kind, it appears that there is some good timber near the Hawkesbury river; and at Norfolk Island and New-Zealand it is remarkably fine.

WALPOLE (Horace, Earl of Orford), was the youngest son of the celebrated Sir Robert Walpole, afterwards Earl of Orford, by his first wife, Catharine, daughter of Robert Shorter, Esq. of Bybrook in Kent. He was born 1716; and was educated, first at Eton school, and afterwards at Cambridge. At Eton he formed an intimate acquaintance with the celebrated poet Gray; and they went together on the tour of Europe, in the years 1739, 1740, and 1741. Unhappily they had a dispute in the course of their travels, which produced a separation.

Mr Walpole was able to make a splendid figure during the remainder of his destined course; but poor Gray, after the separation, was obliged to observe a very severe economy. "This difference arose from the difference of their tempers: the latter being, from his earliest years, curious, pensive, and philosophical; the former, gay, lively, and inconsiderate. This, therefore, occasioned their separation at Reggio. Mr Gray went before him to Venice; and staying there till he could find means of returning to England, he made the best of his way home, repassing the Alps, and following almost the same rout, through France, which he had before gone to Italy. In justice to the memory of so respectable a friend, Mr Walpole (says Mr Mason, Life of Gray, 4to, p. 41.) enjoins me to charge him with the chief blame in their quarrel, confessing that more attention, complaisance, and deference, to a warm friendship, Walpole. ſhip, and ſuperior judgment and prudence, might have prevented a rupture that gave much uneaſineſs to them both, and a laſting concern to the ſurvivor; though in the year 1744 a reconciliation was affected between them, by a lady who wiſhed well to both parties."— This event took place after their return to England; but the *wound* in their friendſhip left a *ſcar* that never was totally effaced.

We do not, indeed, think that Horace Walpole and Mr Gray were formed, either by nature or by habits, to continue long in a ſtate of intimate friendſhip. Gray appears to have been a man of the pureſt moral principles, a friend to religion, penſive, and at leaſt ſufficiently conſcious of his intellectual powers and intellectual attainments. Walpole's morality was certainly of a looſer kind; he ſeems to have had no religion; he was often unſeaſonably gay; and to an equal ſhare of intellectual pride, though without equal reaſon, he added the pride of birth. It can therefore excite no ſurpriſe that a man of Gray's independent ſpirit could not bear the ſupercilious freaks of ſuch a character.

Mr Walpole was nominated to repreſent the city of Norwich, when his father viſited it July 3d, 1733, having acquired conſequence, not only as the ſon of the miniſter, but as having attended the Prince of Orange to England in that year. He was choſen member for Collington, in Cornwall, in the parliament which met June 25th, 1741; was a ſecond time in parliament as repreſentative for Caſtle-Riſing, in Norfolk, in 1747; and for King's Lynn in 1754 and 1761; and, at the expiration of that parliament, he finally retired from the ſtage of politics, and confined himſelf wholly to literary purſuits. He held to his death the office of uſher of his Majeſty's exchequer, comptroller of the pipe, and clerk of the eſtreats. Upon the death of his nephew, George, third Earl of Orford, 1791, he ſucceeded to the title and eſtates; but that event made ſo little alteration in his mode of living, that we know not whether he ever took his ſeat in the houſe of peers. During almoſt the whole courſe of his life he was the victim of the gout, which at laſt reduced him to a cripple: but it never impaired his faculties; and, to the very moment of death, his underſtanding ſeemed to bid defiance to the ſhock of Nature. He died at his houſe in Berkeſley Square, in 1796, having juſt entered his 80th year; and was interred in the family vault at Houghton, in a private manner, agreeably to his particular directions.

Horace, Lord Orford, was never married, and, by one of his biographers, his chief miſtreſs through life is ſaid to have been the muſe It is certain that he devoted the greater part of his life to belles lettres and virtú, though he ridiculouſly affected, in his letters to his friends, to deſpiſe learning and learned men, for which he was very properly reprimanded both by Gray and Hume. It was an affectation peculiarly abſurd in him, who was conſtantly publiſhing ſomething, and who wrote with uncommon acrimony againſt all who preſumed to call in queſtion the fidelity of the picture which he had drawn of Richard III. or indeed to controvert any of his opinions. Hence his antipathy to Johnſon, becauſe he was a tory, a Chriſtian, and a rigid moraliſt; whilſt he himſelf was a whig, an infidel, and ſuch a moraliſt as could retail, without bluſhing, all the ſcandalous anecdotes, whether true or falſe, of that auguſt family, from whom he acknowledged his whole fortune to be derived. He had, indeed, another reaſon for diſliking Johnſon. Lord Orford ſhone in converſation, and ſurpaſſed all his contemporaries in that kind of talk which, without dazzling by its wit, always delighted; while Johnſon, when rouſed, knocked down, as by a flaſh of lightning, his Lordſhip, and every one elſe who had the confidence before him to talk profanely. Johnſon's wit was original; Lord Orford's conſiſted of ludicrous ſtories and of literary and political anecdotes. His works, of which by far the moſt valuable part has long been in the hands of the public, were collected in 1798, and publiſhed in five volumes 4to. They reſemble his converſation, being rather amuſing than profound or inſtructive.

Waring. WARING (Edward, M. D.), Lucaſian Profeſſor of Mathematics in the univerſity of Cambridge, was the ſon of a wealthy farmer, of the Old Heath, near Shrewſbury. The early part of his education he received at the free-ſchool in Shrewſbury; whence he removed to Cambridge, and was admitted on the 24th of March 1753 a member of Magdalen college. Here his talents for abſtruſe calculation ſoon developed themſelves, and, at the time of taking his degree, he was conſidered as a prodigy in thoſe ſciences which make the ſubject of the bachelor's examination. The name of Senior Wrangler, or the firſt of the year, was thought ſcarcely a ſufficient honour to diſtinguiſh one who ſo far outſhone his contemporaries; and the merits of John Jebb were ſufficiently acknowledged, by being the ſecond in the liſt. Waring took his firſt, or bachelor's degree, in 1757, and the Lucaſian Profeſſorſhip became vacant before he was of ſufficient ſtanding for the next, or maſter's degree, which is a neceſſary qualification for that office. This defect was ſupplied by a royal mandate, through which he became maſter of arts in 1760; and ſhortly after his admiſſion to this degree, the Lucaſian Profeſſor.

The royal mandate is too frequently a ſcreen for indolence; and it is now become almoſt a cuſtom, that heads of colleges, who ought to ſet the example in diſcipline to others, are the chief violaters of it, by making their office a pretext for taking their doctor's degree in divinity, without performing thoſe exerciſes which were deſigned as proofs of their qualifications. Such indolence cannot be imputed to Waring; yet ſeveral circumſtances, previous to his election into the profeſſorial chair, diſcovered that there was, at leaſt, one perſon in the univerſity who diſapproved of the anticipation of degrees by external influence.—Waring, before his election, gave a ſmall ſpecimen of his abilities, as proof of his qualification for the office which he was then ſoliciting; and a controverſy on his merits enſued: Dr Powell, the maſter of St John's College, attacking, in two pamphlets, the Profeſſor; and his friend, afterwards Judge Wilſon, defending. The attack was ſcarcely warranted by the errors in the ſpecimen; and the abundant proofs of talents in the exerciſe of the profeſſorial office are the beſt anſwers to the ſarcaſms which the learned divine amuſed himſelf in caſting on riſing merit. An office held by a Barrow, a Newton, a Whiſton, a Cotes, and a Sanderſon, muſt excite an ingenuous mind to the greateſt exertions; and the new Profeſſor, whatever may have been his ſucceſs, did not fall

behind

behind any of his predeceffors, in either zeal for the fcience, or application of the powers of his mind, to extend its bounderies. In 1762, he publifhed his Mifcellanea Analytica; one of the moft abftrufe books written on the abftrufeft parts of algebra. This work extended his fame over all Europe. He was elected, without folicitation on his part, member of the focieties of Bononia and Gottingen; and received flattering marks of efteem from the moft eminent mathematicians at home and abroad. The difficulty of this work may be prefumed from the writer's own words, "I cannot fay that I know any one who thought it worth while to read through the whole, and perhaps not the half of it."

Mathematics did not, however, engrofs the whole of his attention. He could dedicate fome time to the ftudy of his future profeffion; and in 1767, he was admitted to the degree of doctor of phyfic; but, whether from the incapacity of uniting together the employments of active life with abftrufe fpeculation, or from the natural diffidence of his temper, for which he was moft peculiarly remarkable; the degree which gave him the right of exercifing his talents in medicine was to him merely a barren title. Indeed he was fo embarraffed in his manners before ftrangers, that he could not have made his way in a profeffion in which fo much is done by addrefs; and it was fortunate that the cafe of his circumftances permitted him to devote the whole of his time to his favourite purfuit. His life paffed on, marked out by difcoveries, chiefly in abftract fcience; and by the publication of them in the Philofophical Tranfactions, or in feparate volumes, under his own infpection. He lived fome years after taking his doctor's degree, at St Ives, in Huntingdonfhire. While at Cambridge he married—quitted Cambridge with a view of living at Shrewfbury; but the air or fmoke of the town being injurious to Mrs Waring's health, he removed to his own eftate at Plaifley, about 8 miles from Shrewfbury, where he died in 1797, univerfally efteemed for inflexible integrity, modefty, plainnefs, and fimplicity of manners. They who knew the greatnefs of his mind from his writings looked up to him with reverence everywhere; but he enjoyed himfelf in domeftic circles with thofe chiefly among whom his purfuits could not be the object either of admiration or envy. The outward pomp which is affected frequently in the higher departments in academic life, was no gratification to one whofe habits were of a very oppofite nature; and he was too much occupied in fcience to attend to the intrigues of the univerfity. There, in all queftions of fcience, his word was the law; and at the annual examination of the candidates for the prize inftituted by Dr Smith, he appeared to the greateft advantage. The candidates were generally three or four of the beft proficients in the mathematics at the previous annual examination for the bachelor's degree, who were employed from nine o'clock in the morning to ten at night, with the exception of two hours for dinner, and twenty minutes for tea, in anfwering, *viva voce*, or writing down anfwers to the profeffor's queftions, from the firft rudiments of philofophy to the deepeft parts of his own and Sir Ifaac Newton's works. Perhaps no part of Europe affords an inftance of fo fevere a procefs; and there was never any ground for fufpecting the Profeffor of partiality. The zeal and judgment with which he performed this part of his office cannot be obliterated from the memory of thofe who paffed through his fiery ordeal.

Wifhing to do ample juftice to the talents and virtue of the Profeffor, we feel ourfelves fomewhat at a lofs in fpeaking of the writings by which alone he will be known to pofterity. He is the difcoverer, according to his own account, of nearly 400 propofitions in the analytics. This may appear a vain glorious boaft, efpecially as the greater part of thofe difcoveries are likely to fink into oblivion; but he was, in a manner, compelled to make it by the infolence of Lalande, who, in his life of Condorcet, afferts that, in 1764, there was no firft-rate analyft in England. In reply to this affertion, the Profeffor, in a letter to Dr Mafkelyne, firft mentions, with proper refpect, the inventions and writings of Harriot, Briggs, Napier, Wallis, Halley, Brunker, Wren, Pell, Barrow, Mercator, Newton, De Moivre, Maclaurin, Cotes, Stirling, Taylor, Simpfon, Emerfon, Landen, and others; of whom Emerfon and Landen were living in 1764. He then gives a fair and full detail of his own inventions, of which many were publifhed anterior to 1764; and concludes his letter in thefe words.

"I know that Mr Lalande is a firft-rate aftronomer, and writer of aftronomy; but I never heard that he was much converfant in the deeper parts of mathematics; for which reafon I take the liberty to afk him the following queftions:

"Has he ever read or underftood the writings of the Englifh mathematicians: and, as the queftion comes from me, I fubjoin, particularly of mine? If the anfwer be in the negative, as it is my opinion, if his anfwer be the truth, that it will, then there is an end of all further controverfy;—but if he afferts that he has, which is more than Condorcet did by his own acknowledgment, then he may know, from the enumeration of inventions made in the prefaces, with fome fubfequent ones added, that they are faid to amount to more than 400 of one kind or other. Let him try to reduce thofe to as low a number as he can, with the leaft appearance of candour and truth; and then let him compare the number with the number of inventions of any French mathematician or mathematicians, either in the prefent or paft times, and there will refult a comparifon (if I miftake not) not much to his liking; and, further, let him compare fome of the firft inventions of the French mathematicians with fome of the firft contained in my works, both as to utility, generality, novelty, difficulty, and elegance, but wifely as to utility, there is little contained in the deep parts of any fcience; he will find their difficulty and novelty from his difficulty of underftanding them, and his never having read any thing fimilar before; their generality, by the application of them; principles of elegance will differ in different perfons.—I muft fay, that he will probably not find the difference expected. After or before this inquiry is inftituted for mine, let him perform the fame for the other Englifh mathematicians; and when he has completed fuch inquiries, and not before, he will become a judge of the juftice of his affertion; but I am afraid that he is not a fufficient adept in thefe ftudies to inftitute fuch inquiries; and if he was, fuch inquiries are invidious, troublefome, and of fmall utility."

By mathematical readers this account, which was not publifhed publiſhed by the Profeſſor himſelf, is allowed to be very little, if at all, exaggerated. Yet if, according to his own confeſſion, "few thought it worth their while to read even half of his works," there muſt be ſome grounds for this neglect, either from the difficulty of the ſubject, the unimportance of the diſcoveries, or a defect in the communication of them to the public. The ſubjects are certainly of a difficult nature, the calculations are abſtruſe; yet Europe contained many perſons not to be deterred by the moſt intricate theorems. Shall we ſay, then, that the diſcoveries were unimportant? If this were really the caſe, the want of utility would be a very ſmall diſparagement among thoſe who cultivate ſcience with a view chiefly to entertainment and the exerciſe of their rational powers. We are compelled, then, to attribute much of this neglect to a perplexity in ſtyle, manner, and language; the reader is ſtopped at every inſtant, firſt to make out the writer's meaning, then to fill up the chaſm in the demonſtration. He muſt invent anew every invention; for, after the enunciation of the theorem or problem, and the mention of a few ſteps, little aſſiſtance is derived from the Profeſſor's powers of explanation. Indeed, an anonymous writer, certainly of very conſiderable abilities, has aptly compared the works of Waring to the heavy appendages of a Gothic building, which add little of either beauty or ſtability to the ſtructure.

A great part of the diſcoveries relate to an aſſumption in algebra, that equations may be generated by multiplying together others of inferior dimenſions. The roots of theſe latter equations are frequently terms called *negative* or *impoſſible;* and the relation of theſe terms to the coefficients of the principal equation is a great object of inquiry. In this art the profeſſor was very ſucceſsful, though little aſſiſtance is to be derived from his writings in looking for the real roots. We ſhall not, perhaps, be deemed to depreciate his merits, if we place the ſeries for the ſum of the powers of the roots of any equation among the moſt ingenious of his diſcoveries; yet we cannot add, that it has very uſefully enlarged the bounds of ſcience, or that the algebraiſt will ever find occaſion to introduce it into practice. We may ſay the ſame on many ingenious transformations of equations, on the diſcovery of impoſſible roots, and ſimilar exertions of undoubtedly great talents. They have carried the aſſumption to its utmoſt limits; and the difficulty attending the ſpeculation has rendered perſons more anxious to aſcertain its real utility; yet they who reject it may occaſionally receive uſeful hints from the Miſcellanea Analytica.

The firſt time of Waring's appearing in public as an author was, we believe, in the latter end of the year 1759, when he publiſhed the firſt chapter of the Miſcellanea Analytica, as a ſpecimen of his qualifications for the profeſſorſhip; and this chapter he defended, in a reply to a pamphlet, intitled, "Obſervations on the Firſt Chapter of a book called Miſcellanea Analytica." Here the Profeſſor was ſtrangely puzzled with the common paradox, that nothing divided by nothing may be equal to various finite quantities, and has recourſe to unqueſtionable authorities in proof of this poſition. The names of Maclaurin, Sanderſon, De Moivre, Bernoulli, Monmort, are ranged in favour of his opinion: But Dr Powell was not ſo eaſily convinced, and returns to the charge in defence of the Obſervations; to which the Profeſſor replied in a letter to the Rev. Dr Powell, Fellow of St John's college, Cambridge, in anſwer to his obſervations, &c. In this controverſy, it is certain that the Profeſſor gave evident proofs of his abilities; though it is equally certain that he followed too implicitly the deciſions of his predeceſſors. No apparent advantage, no authority whatever, ſhould induce mathematicians to ſwerve from the principles of right reaſoning, on which their ſcience is ſuppoſed to be peculiarly founded. According to Maclaurin, Dr Waring, and others, If $P = \frac{a-x}{a^2-x^2}$, then, when $x = a$, P is equal to $\frac{1}{2a}$; for, ſay they, $\frac{a-x}{a^2-x^2}$ is equal to $\frac{a-x}{a-x} \times \frac{1}{a+x}$; that is, when x is equal to a, $P = \frac{1}{a+x}$, or $\frac{1}{2a}$. But when x is equal to a, the numerator and denominator of the fraction $\frac{a-x}{a^2-x^2}$ are both, in their language, equal to nothing. Therefore, nothing divided by nothing is equal to $\frac{1}{2a}$. In the ſame manner, $\frac{a-x}{a^3-x^3} = \frac{1}{a^2+ax+x^2} \times \frac{a-x}{a-x}$, which, when x is equal to a, becomes $\frac{1}{3a^2}$. Therefore, nothing divided by nothing is equal to $\frac{1}{3a^2}$, or $\frac{1}{3a^2} = \frac{1}{2a}$; that is, $\frac{1}{3a} = \frac{1}{2}$; which is abſurd. But we need only trace back our ſteps to ſee the fallacy in this mode of reaſoning. For P is equal to ſome number multipled into $\frac{a-x}{a-x}$; that is, when x is equal to a, P is equal to ſome number multiplied into nothing, and divided by nothing; that is, P is, in that caſe, no number at all. For $a - a$ cannot be divided by $a - x$ when x is equal to a, ſince, in that caſe, $a - x$ is no number at all.

If, in the beginning of his career, the Profeſſor could admit ſuch paralogiſms into his ſpeculations, and the writings of the mathematicians, for nearly a century before him, may plead in his excuſe, we are not to be ſurpriſed that his diſcoveries ſhould be built rather on the aſſumptions of others than on any new principles of his own. Acquieſcing in the ſtrange notion, that nothing could be divided by nothing, and produce a variety of numbers, he as eaſily adopted the poſition, that an equation has as many roots as it has dimenſions.— Thus 2 and — 4 are ſaid to be roots of the equation $x^2 - 2x = 8$, though 4 can be the root only of the equation; $x^2 - 2x = 8$, which differs ſo materially from the preceding, that in one caſe $2x$ is added, in the other caſe it is ſubtracted from x^2.

Allowances being made for this error in the principles, the deductions are, in general, legitimately made; and any one, who can give himſelf the trouble of demonſtrating the propoſitions, may find ſufficient employment in the Profeſſor's analytics. Perhaps it will be ſufficient for a ſtudent to devote his time to the ſimpleſt caſe $x^n + 1 = 0$; and when he has found a few thouſand roots of + 1 and — 1, the publication of them may afford to poſterity a ſtrong proof of the ingenuity

ingenuity of their predeceffors, and the application of the powers of their mind to ufeful and important truths In this exercife may be confulted the method given by the Profeffor, of finding a quantity, which, multiplied into a given irrational quantity, will produce a rational product, or confequently exterminate irrational quantities out of a given equation ; but if an irrational quantity cannot come into an equation, the utility of this invention will not be admitted without hefitation.

The "Proprietates Algebraicarum Curvarum," publifhed in 1772, neceffarily labour under the fame defects with the Mifcellanea Analytica, the Meditationes Algebraicæ, publifhed in 1770, and the Meditationes Analyticæ, which were in the prefs during the years 1773, 1774, 1775, 1776. Thefe were the chief and the moft laborious works edited by the Profeffor; and in the Philofophical Tranfactions is to be found a variety of papers, which alone would be fufficient to place him in the firft rank in the mathematical world. The nature of them may be feen from the following catalogue.

Vol. LIII. p. 294, Mathematical Problems.—LIV. 193. New properties in Conics.—LV. 143. Two Theorems in Mathematics.—LXIX. Problems concerning Interpolations.—86. A General Refolution of Algebraical Equations.—LXXVI. 81. On Infinite Series. LXXVII. 71. On Finding the Values of Algebraical Quantities by Converging Seriefes, and Demonftrating and Extending Propofitions given by Pappus and others.—LXXVIII. 67. On Centripetal Forces. *Ib.* 588. On fome Properties of the Sum of the Divifion of Numbers.—LXXIX. 166. On the method of Correfpondent Values, &c.—*Ib.* 185. On the Refolution of Attractive Powers.—LXXXI. 146. On Infinite Seriefes.—LXXXIV. 385—415. On the Summation of thofe Seriefes whofe general term is a determinate function of z, the diftance of the term of the Series.

For thefe papers, the Profeffor was, in 1784, defervedly honoured by the Royal Society with Sir Godfrey Copley's medal ; and moft of them afford very ftrong proofs of the powers of his mind, both in abftract fcience, and the application of it to philofophy ; though they labour, in common with his other works, under the difadvantage of being clothed in a very unattractive form. The mathematician, who has refolution to go through them, will not only add much to his own knowledge, but be ufefully employed in dilating on thofe articles for the benefit of the more general reader. We might add in this place, a work written on morals and metaphyfics in the Englifh language ; but as a few copies only were prefented to his friends, and it was the Profeffor's wifh that they fhould not have a more extenfive circulation, we fhall not here enlarge upon its contents.

In the mathematical world, the life of Waring may be confidered as a diftinguifhed æra. The ftrictnefs of demonftration required by the ancients had gradually fallen into difufe, and a more commodious, though almoft mechanical mode by algebra and fluxions took its place, and was carried to the utmoft limit by the Profeffor. Hence many new demonftrations may be attributed to him, but 400 difcoveries can fcarcely fall to the lot of a human being. If we examine thoroughly thofe which our Profeffor would diftinguifh by fuch names, we fhall find many to be mere deductions, others, as in the folution of biquadratics, anticipated by former writers. But if we cannot allow to him the merit of fo inventive a genius, we muft applaud his affiduity ; and, diftinguifhed as he was in the fcientific world, the purity of his life, the fimplicity of his manners, and the zeal which he always manifefted for the truths of the Gofpel, will intitle him to the refpect of all who do not efteem the good qualities of the heart inferior to thofe of the head.

WARTON (Jofeph, D. D.) was born either towards the end of the year 1721, or in the beginning of the year 1722. He was the eldeft fon of Thomas Warton, B. D. who had been fellow of Magdalen College, Oxford ; poetry profeffor from the year 1718 to 1728, and vicar of Bafingftoke in Hampfhire, and of Cobham in Surrey. Where the fubject of this memoir was born we have not learned, though, were we to hazard a conjecture, we would fay that it was in Oxford, as his father probably refided in that city during his profefforfhip.

Our knowledge of the private hiftory of Dr Warton is indeed extremely limited. We do not even know at what fchool, or in what college, he was educated ; tho' it was probably at Winchefter fchool, and certainly in fome of the colleges in the univerfity of Oxford. For many years, he was fucceffively under and upper mafter of Winchefter college ; but refigned the laft of thefe offices when he found the infirmities of age coming upon him ; and was fucceeded by Dr Goddard the prefent excellent mafter. He was likewife prebendary of the cathedral church of Winchefter, and rector of Wickham in Hampfhire, where he died, aged 78.

His publications are few, but valuable. A fmall collection of poems, without a name, was the firft of them, and contained the Ode to Fancy, which has been fo much and fo defervedly admired. They were all of them afterwards printed in Dodfley's collection. He was alfo a confiderable contributor to the Adventurer, publifhed by Dr Hawkefworth ; and all the papers which contain criticifms on Shakefpeare were written by him and his brother Thomas Warton, the fubject of the next article.

The firft volume of his Effay on the Life and Writings of Pope was publifhed, had paffed through feveral editions, and an interval of between 20 and 30 years had elapfed, before he gave a fecond volume of that elegant and inftructive work to the world. He had not only meditated, but had collected materials for a literary hiftory of the age of Leo X. ; and propofals were actually in circulation for a work of that kind ; but it is probable that the duties of his ftation did not leave him the neceffary leifure for an undertaking which required years of feclufion and independence. His laft and late work, which he undertook for the bookfellers at a very advanced age, was an edition of Pope's Works, that has not altogether fatisfied the public expectation. He retained, with great propriety indeed, many of the notes of Warburton ; but is feverely reprehended by the author of the Purfuits of Literature for fuppreffing the name of that prelate on his title-page, or including it only, as fubordinate to his own, in the general expreffion *others*.

Dr Warton was cheerful in his temper, convivial in his difpofition, of an elegant tafte and lively imagination, with a large portion of fcholarfhip, and a very general

Warton. general knowledge of the Belles Lettres of Europe; it may be presumed that Dr Warton possessed, beyond most men, the power of enlivening Classical Society. He was the intimate friend of Dr Johnson; was seen at the parties of Mrs Montague, as well as at the table of Sir Joshua Reynolds, and was an original member of the Literary Club. He possessed a liberal mind, a generous disposition, and a benevolent heart. He was not only admired for his talents and his knowledge, but was beloved for those qualities which are the best gifts of this imperfect state.

WARTON (Thomas) the brother of the preceding, was born in the year 1728. He received, as we have reason to believe, the first part of his education at Winchester; and at the age of 16 was entered a commoner *Biog. Dict.* of Trinity College, Oxford, under the tuition of Mr Geering.

He began his poetical career at an early age. In 1745, he published five pastoral eclogues, in which are beautifully described the miseries of war to which the shepherds of Germany were exposed. Not long after, in the year 1748, he had full scope afforded for the exertion of his genius. It is well known that Jacobite principles were suspected to prevail in the university of Oxford about the time of the rebellion in the year 1745. Soon after its suppression, the drunkenness and folly of some young men gave offence to the court, in consequence of which a prosecution was instituted in the court of King's Bench, and a stigma was fixed on the vice chancellor and some other heads of colleges in Oxford. Whilst this affair was the general subject of conversation, Mr Mason published his "Isis," an elegy, in which he adverts to the above-mentioned circumstances. In answer to this poem, Mr Warton, encouraged by Dr Huddesford, the president of his college, published, in 1749, "The Triumph of Isis," which excelled more in manly expostulation and dignity than the poem that produced it did in neatness and elegance. With great poetical warmth, and a judicious selection of circumstances, he characterises the eminent men who had been educated in Oxford, and draws a striking and animated portrait of Dr King, the celebrated public orator of that time. The whole poem shews the early maturity of his genius, and is finished with happy diligence.

In the year 1751, he succeeded to a fellowship of his college, and was thus placed in a situation easy and independent, and particularly congenial with his habits of retirement and study. In 1753, appeared his observations on "The Faery Queen of Spencer," in 8vo, a work which he corrected, enlarged, and republished, in two volumes crown octavo, in the year 1762. He sent a copy of the first edition to Dr Johnson, who, in a letter to him upon the subject, expressed this handsome compliment: "I now pay you a very honest acknowledgment for the advancement of the literature of our native country: you have shewn to all, who shall hereafter attempt the study of ancient authors, the way to success, by directing them to the perusal of the books which these authors had read."

In 1754, Dr Johnson visited Oxford for the first time after he had quitted residence there. Much of his time was spent with Mr Warton; and there appeared to have been a considerable degree of confidential intercourse between them upon literary subjects, and particularly on their own works. A pleasing account of Warton this visit was communicated by Mr Warton to Mr Boswell, who has inserted it in his life of Johnson.

In 1755, Mr Warton exerted himself to procure for his friend the degree of master of arts by diploma from the university of Oxford; an honour which Johnson esteemed of great importance to grace the title page of his dictionary which he was about to publish. In 1756, Mr Warton was elected professor of poetry, which office he held for the usual term of ten years. His lectures were remarkable for elegance of diction and justness of observation. One of them, on the subject of pastoral poetry, was afterwards prefixed to his edition of Theocritus. In 1758, he contributed to assist Dr Johnson in the subscription to his edition of Shakespeare, and furnished him with some valuable notes. The Doctor remarks, in a letter to him, when soliciting his farther aid, "It will be reputable to my work, and suitable to your professorship, to have something of yours in my notes."

From the Clarendon press, in the year 1766, he published "Anthologiæ Græcæ, a Constantino Cephalâ conditæ, Libri tres," in 2 vols, 12mo. He concludes the learned and classical preface to this work, which is replete with accurate remarks on the Greek epigram, in the following words, which mark this publication for his own: "Vereor ut hactenus in plexendis florum corollis otium nimis longum pertraxerim. Proximè sequetur, cui nunc omnes operas et vires intendo, Theocritus. Interea quasi promulsidem convivii Lectoribus meis elegantias hasce vetustatis eruditæ propino.

In the year 1770, he conferred a similar honour upon the academical press by his edition of Theocritus, in 2 vols, 8vo. He undertook this work by the advice of Judge Blackstone, then fellow of All Souls College, and an ardent promoter of every publication that was likely to do credit to the Clarendon press. This elaborate publication reflects no small credit on the learning, diligence, and taste of the editor.

In 1771, he was elected a fellow of the Antiquarian Society, and was presented by the Earl of Litchfield to the small living of Kiddington in Oxfordshire, which he held till his death. He likewise in this year published an improved account of "The Life of Sir Thomas Pope, founder of Trinity College, Oxford. In composing these memoirs, he bestowed much labour and research, and shewed great judgment in the arrangement of his materials. But possibly, in his ardour to pay a debt of gratitude, he has not sufficiently considered what was due to his own fame. The same strength of description and vigour of remark would have better suited the life of some eminently distinguished character, and extended the reputation of the author as a biographer beyond the circle of those academical readers who are influenced by the same feelings of veneration, respect, and gratitude which prompted Mr Warton to compose this work. The preface contains some excellent remarks on biographical writing.

The plan for a history of English poetry was laid by Pope, enlarged by Gray: but to bring an original plan nearly to a completion was reserved for the perseverance of Warton. In 1744 appeared his first volume; in 1778, the second and third; which brings the narrative down to the commencement of the reign of Elizabeth in

Warton.

in 1581. This work difplays the moft fingular combination of extraordinary talents and attainments. It unites the deep and minute refearches of the antiquary with the elegance of the claffical fcholar and the fkill of the practifed writer. The ftyle is vigorous and manly; the obfervations acute and juft; and the views of the fubject are extenfive and accurate.

In 1777, he collected his poems into an octavo volume, containing mifcellaneous pieces, odes, and fonnets. This publication may be confidered in fome meafure original; there being only feven pieces that had before appeared, and near three times that number which were then printed for the firft time.

In vindication of the opinion he had given in his fecond volume of "The Hiftory of Poetry," relative to the ingenious attempt of Chatterton to impofe upon the public, he produced, in 1782, "An Inquiry into the Authenticity of the Poems attributed to Rowley." In this excellent pamphlet the principles of true criticifm are laid down, an appeal is properly made to the internal evidence of the poems; and upon thefe grounds it is proved, in the moft fatisfactory manner, that they could not have been written by a monk of the fourteenth century.

The year 1785 brought him thofe diftinctions which were no lefs honourable to thofe who conferred than to him who received them. He was appointed poet-laureat on the death of Whitehead, and elected Camden profeffor of ancient hiftory on the refignation of Dr Scott. His inauguration lecture was delivered in a clear and impreffive manner from the profefforial chair. It contained excellent obfervations on the Latin hiftorians, and was written in a ftrong, perfpicuous, and claffical ftyle. In his odes, the vigour and brilliancy of his fancy were not proftituted to an infipid train of courtly complements: each prefents an elegant fpecimen of defcriptive poetry, and as all of them have only a flight relation to the particular occafion on which they were written, and have always a view to fome particular and interefting fubject, they will be perufed with pleafure as long as this fpecies of compofition is admired.

He made occafional journeys to London to attend the literary club, of which he was fome years a member; and to vifit his friends, particularly Sir Jofhua Reynolds. At his houfe he was fure to meet perfons remarkable for fafhion, elegance, and tafte.

His laft publication, except his official odes, confifted of Milton's fmaller poems. A quarto edition appeared in 1790, with corrections and additions. The great object of thefe notes is to explain the allufions of Milton, to trace his imitations, and to illuftrate his beauties.

Until he reached his fixty fecond year, he continued to enjoy vigorous and uninterrupted health. On being feized with the gout, he went to Bath, and flattered himfelf, on his return to college, that he was in a fair way of recovery. But the change that had taken place in his conftitution was vifible to his friends. On Thurfday, May 20, 1790, he paffed the evening in the common room, and was for fome time more cheerful than ufual. Between ten and eleven o'clock he was ftruck with the palfy, and continued infenfible till his death, which happened the next day at two o'clock. On the 27th, his remains were interred in the college chapel with the moft diftinguifhed academical honours. The infcription upon the flat ftone which is placed over his grave contains only an enumeration of his preferments.

Such was the general conduct and behaviour of Mr Warton as to render him truly amiable and refpectable. By his friends he was beloved for his open and eafy manners; and by the members of the univerfity at large he was refpected for his conftant refidence, ftrong attachment to Alma Mater, his ftudious purfuits, and high literary character. In all parties where the company accorded with his inclination, his converfation was eafy and gay, enlivened with humour, enriched with anecdote, and pointed with wit. Among his peculiarities it may be mentioned that he was fond of all military fights. He was averfe to ftrangers, particularly to thofe of a literary turn; and yet he took a great pleafure in encouraging the efforts of rifing genius, and affifting the ftudious with his advice; as many of the young men of his college, who fhared his affability and honoured his talents, could teftify. He was bred in the fchool of punfters; and made as many good ones as Barton and Leigh, the celebrated word-hunters of his day. Under the mafk of indolence, no man was more bufy; his mind was ever on the wing in fearch of fome literary prey. Although, at the accuftomed hours of Oxford ftudy, he was often feen fauntering about, and converfing with any friend he chanced to meet; yet, when others were wafting their mornings in fleep, he was indulging his meditations in his favourite walks, and courting the Mufes. His fituation in Oxford was perfectly congenial with his difpofition, whether he indulged his fallies of pleafantry in the common room, retired to his own ftudy, or to the Bodleian library; fauntered on the banks of his favourite Cherwell, or furveyed, with the enthufiaftic eye of tafte, the ancient gateway of Magdalen College, and other fpecimens of Gothic architecture.

The following is a lift of Mr Warton's works: 1. "Five Paftoral Eclogues," 4to, 1745. Reprinted in Pearch's Collection of Poems. 2. "The Pleafures of Melancholy," written in 1745; firft printed in Dodfley's Collection, and afterwards in the Collection of Mr Warton's Poems. 3. "Progrefs of Difcontent," written in 1746. Firft printed in the "Student," a periodical paper. 4. "The Triumph of Ifis, a Poem," 4to, 1750. 5. "Newmarket, a Satire," folio, 1751. 6. "Ode for Mufic," performed at the theatre in Oxford 1751. 7. "Obfervations on the Faerie Queen of Spenfer," 8vo, 1754. 8. "Infcriptionum Metricarum Delectus," 4to, 1758. 9. "A Defcription of the City, College, and Cathedral, of Winchefter," 8vo, no date. 10. "The Life of Sir Thomas Pope," in the 5th volume of the Biographia Britannica," republifhed in 1772. 11. "The Life and literary Remains of Ralph Bathurft, M. D. Dean of Wells, and Prefident of Trinity College in Oxford," 1761. 12. "A Companion to the Guide, and a Guide to the Companion," 12mo, 1762. 13. "The Oxford Saufage," in which are feveral Poems by Warton. 14. "Anthologiæ Græcæ a Conftantino Cephalâ conditæ Libri tres," 2 tom. 1766. 15. "Theocritis Syracufii quæ fuperfunt, cum Scholiis Græcis," &c. 2 tom. 4to, 1770. 16. "Hiftory of Englifh Poetry, from the Clofe of the 11th to the Commencement of the 18th Century," 4to, Vol. I. 1774. Vol. II. 1778. Vol. III. 1781. 17. "Poems," 8vo, 1777. 18. "Specimen of a

Hiftory

Hiſtory of Oxfordſhire," 1783. 19. "An Enquiry into the Authenticity of the Poems attributed to Thomas Rowley," 8vo, 1782. 20. Verſes on Sir J. Reynolds's painted Window in New College Chapel, 4to," 1782. 21. "Poems on ſeveral Occaſions, by John Milton, with Notes critical and explanatory," 8vo, 1785.

WASHINGTON (George), whoſe name is likely to live as long as that of any modern, was born on the 11th of February 1732, in the pariſh of Waſhington, Virginia. He was deſcended from an ancient family in Cheſhire, of which a branch had been eſtabliſhed in Virginia about the middle of the 17th century. We are not acquainted with any remarkable circumſtances of his education or his early youth; and we ſhould not indeed expect any marks of that diſorderly prematureneſs of talent, which is ſo often fallacious, in a character whoſe diſtinguiſhing praiſe was to be regular and natural. His claſſical inſtruction was probably ſmall, ſuch as the private tutor of a Virginian country gentleman could at that period have imparted; and if his opportunities of information had been more favourable, the time was too ſhort to profit by them (A). Before he was twenty he was appointed a major in the colonial militia, and he had very early occaſion to diſplay thoſe political and military talents, of which the exertions on a greater theatre have ſince made his name ſo famous throughout the world.

The plenipotentiaries who framed the treaty of Aix la Chapelle, by leaving the boundaries of the Britiſh and French territories in North America unfixed, had ſown the ſeeds of a new war, at the moment when they concluded a peace.—The limits of Canada and Louiſiana, negligently deſcribed in vague language by the treaties of Utrecht and Aix la Chapelle, becauſe the greater part of theſe vaſt countries was then an impenetrable wilderneſs, furniſhed a motive, or a pretext, for one of the moſt ſucceſsful, but one of the moſt bloody and waſteful wars in which Great Britain had ever been engaged. See BRITAIN, *Encycl.*

In the diſputes which aroſe between the French and Engliſh officers on this ſubject, Major Waſhington was employed by the governor of Virginia, in a negociation with the French governor of Fort du Queſne (now Pitſburgh); who threatened the Engliſh frontiers with a body of French and their Indian allies. He ſucceeded in averting the invaſion; but hoſtilities becoming inevitable, he was in the next year appointed lieutenant colonel of a regiment raiſed by the colony for its own defence; to the command of which he ſoon after ſucceeded. The expedition of Braddock followed in the year 1755; of which the fatal iſſue is too well known to require being deſcribed by us. Colonel Waſhington ſerved in that expedition only as a volunteer; but ſuch was the general confidence in his talents, that he may be ſaid to have conducted the retreat. Several Britiſh officers are ſtill alive who remember the calmneſs and intrepidity which he ſhewed in that difficult ſituation, and the voluntary obedience which was ſo cheerfully paid by the whole army to his ſuperior mind. After having acted a diſtinguiſhed part in a ſubſequent and more ſucceſsful expedition to the Ohio, he was obliged by ill health, in the year 1758, to reſign his military ſituation. The ſixteen years which followed of the life of Waſhington ſupply few materials for the biographer. Having married Mrs Cuſtis, a Virginian lady of amiable character and reſpectable connections, he ſettled at his beautiful ſeat of Mount Vernon, of which we have had ſo many deſcriptions; where, with the exception of ſuch attendance as was required by his duties as a magiſtrate and a member of the aſſembly, his time was occupied by his domeſtic enjoyments, and the cultivation of his eſtate, in a manner well ſuited to the tranquillity of his pure and unambitious mind. At the end of this period he was called by the voice of his country from this ſtate of calm and ſecure though unoſtentatious happineſs.

For almoſt half a century ſymptoms of diſaffection to the mother-country had been ſo viſible in the New England provinces, that ſo early as 1734 the celebrated Biſhop Berkeley had predicted a total ſeparation of North America from Great Britain. That prelate, when a private clergyman, had lived three years in Rhode Iſland, and was an attentive and ſagacious obſerver of the manners and principles of the people, among whom he perceived the old leaven of their forefathers fermenting even then with great violence. The middle and ſouthern provinces, however, were more loyal, and their influence, together with perpetual dread of the French before the peace of 1763, put off the ſeparation to a more diſtant day than that at which, we have reaſon to believe, the Biſhop expected it to take place. Virginia, the moſt loyal of all the colonies, had long been in the habit of calling itſelf, with a kind of proud pre-eminence, *his Majeſty's ancient dominion*; and it was with ſome difficulty that the demagogues of New England could gain over that province when the time arrived for effecting their long meditated revolt. At laſt, however, they ſucceeded; and we find Mr Waſhington as a delegate from Virginia in the Congreſs which met at Philadelphia on the 26th of October 1774. (See AMERICA, n° 174. *Encycl.*) As no American united in ſo high a degree as he did, military experience with reſpectability of character, he was appointed to the command of the army which had aſſembled in the New England provinces, to hold in check the Britiſh army which was then encamped under General Gage at Boſton.

At this period there is ſome reaſon to believe that neither Mr Waſhington nor his conſtituents entered heartily into the views of the New Englanders; but afraid leſt the army of thoſe rebellious fanatics, after ſhaking off the yoke of Great Britain, might give law to the continent, he took upon himſelf the command of that army in the

 month

(A) Several accounts of the life of Waſhington have ſtated that he ſerved as a midſhipman on board a Britiſh frigate. This is a miſtake. His elder brother, who died young, ſerved in that capacity in Vernon's expedition againſt Carthagena; whence the family ſeat was called Mount Vernon. Waſhington himſelf never left the United States, except in one ſhort voyage to a Weſt India iſland, when he was very young.

Washington.

month of July 1775 (B). To detail his conduct in the years which followed, would be to relate the history of the American war, which we have already related in the article AMERICA (*Encycl.*). Within a very short period after the declaration of independence, the affairs of America were in a condition so desperate, that perhaps nothing but the *peculiar* character of Washington's genius could have retrieved them. Activity was the policy of invaders. In the field of battle the superiority of a disciplined army is displayed. But delay was the wisdom of a country defended by undisciplined soldiers against an enemy who must be more exhausted by time than he could be weakened by defeat. It required the consummate prudence, the calm wisdom, the inflexible firmness, the moderate and well balanced temper of Washington to embrace such a plan of policy, and to persevere in it: to resist the temptations of enterprize; to fix the confidence of his soldiers without the attraction of victory; to support the spirit of the army and the people amidst those slow and cautious plans of defensive warfare which are more dispiriting than defeat itself; to contain his own ambition and the impetuosity of his troops; to endure temporary obscurity for the salvation of his country, and for the attainment of solid and immortal glory; and to suffer even temporary reproach and obloquy, supported by the approbation of his own conscience and the applause of that small number of wise men, whose praise is an earnest of the admiration and gratitude of posterity. Victorious generals easily acquire the confidence of their army. Theirs, however, is a confidence in the *fortune* of their general. That of Washington's army was a confidence in his *wisdom*. Victory gives spirit to cowards, and even the agitations of defeat sometimes impart a courage of despair. Courage is inspired by success, and it may be stimulated to desperate exertion even by calamity; but it is generally palsied by inactivity.—A system of cautious defence is the severest trial of human fortitude; and by this test the firmness of Washington was tried. It must not, however, be concealed, that some of the British commanders gave him advantages, which he surely did not expect; for more than once, as it appears to us, they had it in their power to annihilate his army, merely by following up their victories. The issue of the contest is known.

Much has been said by the British and American democrates of the magnanimity of Washington during the ravages of a civil war, in which he acted so conspicuous a part; and we feel not ourselves inclined to refuse him the praise which he may have merited on this or on any other account. But granting that duty required him to execute as a spy the accomplished *Andre*, true magnanimity would have prevented him from insultingly erecting, in the view of that unfortunate officer, the gallows on which he was to be hung, several days before his execution! When Earl Cornwallis was overpowered by numbers, and obliged at York-town to surrender to the united armies of America and France, a magnanimous conqueror would not have maliciously claimed, contrary to the usage of civilized war, the sword from the hands of that gallant nobleman. On these two occasions, and on some others, the conduct of Washington agreed so ill with his general character, that we are inclined to believe that he must have been influenced by the leaders of the French army Rochembeau and Fayette. One thing is certain, that he was so little pleased either with his own conduct on particular occasions, or with the general principle of the American revolution, that he never could be forced to talk on the subject. An Italian nobleman, who visited him after the peace, had often attempted, in vain, to turn the conversation to the events of the war. At length he thought he had found a favourable opportunity of effecting his purpose; they were riding together over the scene of an action where Washington's conduct had been the subject of no small animadversion. Count ——— said to him, "Your conduct, Sir, in this action has been criticised." Washington made no answer, but clapped spurs to his horse; after they had passed the field, he turned to the Italian and said, "Count ———, I observe that you wish me to speak of the war; it is a conversation which I always avoid. I rejoice at the establishment of the liberties of America. But the time of the struggle was a horrible period, in which the best men were compelled to do many things repugnant to their nature." This, we think, is the language of a good man not altogether satisfied with the part which he had been compelled to act, and who though he rejoiced at the establishment of the *liberties* of America, probably foresaw that she would reap no benefit from her favourite *independence*.

The conclusion of the American war permitted Washington to return to those domestic scenes, from which no views of ambition seem to have had the power to draw him. But he was not allowed long to enjoy this privacy. The supreme government of the United States, hastily thrown up, in a moment of turbulence and danger, as a temporary fortification against anarchy, proved utterly inadequate to the preservation of general tranquillity and permanent security. The confusions of civil war had given a taint to the morality of the people, which rendered the restraints of a just and vigorous government more indispensably necessary. Confiscation and paper money, the two greatest schools of rapacity and dishonesty in the world, had widely spread their poison among the Americans. One of their own writers tells us, that the whole system of paper money was a system of public and private frauds. In this state of things, which threatened the dissolution of morality and government, good men saw the necessity of concentrating and invigorating the supreme authority. Under the influence of this conviction, a convention of delegates was assembled at Philadelphia, which strengthened the bands of the Federal Union, and bestowed on Congress those powers which were necessary for the purposes of good government. Washington was the president of this convention, as he, in three years after, was elected president of the United States of America, under what was called "The New Constitution," tho' it ought to have been called a *reform* of the republican government,

(B) That such were the motives of his conduct on this occasion, is rendered in the highest degree probable in the preface to *A View of the Causes and Consequences of the American Revolution, in thirteen Discourses, Preached in North America, between the years* 1763 and 1775; by Jonathan Boucher, A. M. and F. A. S. Vicar of Epsom in the County of Surrey.

Washington. government, as that republican government itself was only a *reform* of the ancient colonial constitution under the British crown. None of these changes extended so far as an attempt to new-model the whole social and political system.

Events occurred during his chief magistracy which convulsed the whole political world, and which tried most severely his moderation and prudence. The French revolution took place; Washington, who had experienced the evils of one revolution, augured, from the beginning, no good from the daring speculations of inexperienced visionaries; and the progress of the revolution was not calculated to cure his distrust. When, in the year 1793, France, then groaning under the most intolerable and hideous tyranny, became engaged in war with almost all the governments of the civilized world, it is said to have been a matter of deliberation with the President of the United States, whether the republican envoy, or the agent of the French princes, should be received in America as the diplomatic representative of France. But whatever might be his private feelings of repugnance and horror, his public conduct was influenced only by his public duties. As a virtuous man he must have abhorred the system of crimes which was established in France. But as the first magistrate of the American commonwealth, he was bound only to consider how far the interest and safety of the people whom he governed were affected by the conduct of France. He saw that it was wise and necessary for America to preserve a good understanding and a beneficial intercourse with that great country, in whatever manner she was governed, as long as she abstained from committing injury against the United States. Guided by this just and simple principle, uninfluenced by the abhorrence of crimes which he felt, and which others affected, he received Mr Genet, the minister of the French Republic. The history of the outrages which that minister committed, or instigated, or countenanced, against the American government, must be fresh in the memory of all our readers. The conduct of Washington was a model of firm and dignified moderation. Insults were offered to his authority in official papers, in anonymous libels, by incendiary declaimers, and by tumultuous meetings. The law of nations was trampled under foot. His confidential ministers were seduced to betray him, and the deluded populace were so inflamed by the arts of their enemies, that they broke out into insurrection. No vexation, however galling, could disturb the tranquillity of his mind, or make him deviate from the policy which his situation prescribed. With a more confirmed authority, and at the head of a longer established government, he might perhaps have thought greater vigour justifiable. But in his circumstances, he was sensible that the nerves of authority were not strong enough to bear being strained. Persuasion, always the most desirable instrument of government, was in his case the safest. Yet he never overpassed the line which separates concession from meanness. He reached the utmost limits of moderation, without being betrayed into pusillanimity. He preserved external and internal peace by a system of mildness, without any of those virtual confessions of weakness, which so much dishonour and enfeeble supreme authority. During the whole of that arduous struggle, his personal character gave that strength to a *new magistracy* which in other countries arises from ancient habits of obedience and respect. The authority of his virtue was more efficacious for the preservation of America than the legal powers of his office.

During this turbulent period, he was re-elected to the office of the Presidency of the United States, which he held from April 1789 till September 1796. Probably no magistrate of any commonwealth, ancient or modern, ever occupied a place so painful and perilous. Certainly no man was ever called upon so often to sacrifice his virtuous feelings (he had no other sacrifices to make) to his public duty. Two circumstances of this sort deserve to be particularly noticed. In the spring of 1794, he sent an ambassador to Paris with credentials, addressed to his "Dear friends the citizens composing the Committee of Public Safety of the French Republic," whom he prays God "to take under his holy protection." Fortunately the American ambassador was spared the humiliation of presenting his credentials to these bloody tyrants. Their power was subverted, and a few of them had suffered the punishment of their crimes, which no punishment could expiate, before his arrival at Paris. Readily as we admit the purity of the motives which induced him to send this embassy to Paris, we cannot possibly approve of his conduct in deviating so far from the usual diplomatic style, as to call Robespierre his friend; but he was beset by an absurd, though formidable, faction at home.

He had another struggle of feeling and duty to encounter, when he was compelled to suppress the insurrection in the western counties of Pennsylvania by force of arms. But here he had a consolation. The exercise of mercy consoled his mind for the necessity of having recourse to arms. Never was there a revolt quelled with so little blood. Scarcely ever was the basest dastard so tender of his own life, as this virtuous man was of the lives of his follow-citizens. The value of his clemency is enhanced by recollecting that he was neither without provocations to severity, nor without pretexts for it. His character and his office had been reviled in a manner almost unexampled among civilized nations. His authority had been insulted.—His safety had been threatened. Of his personal and political enemies some might, perhaps, have been suspected of having instigated the insurrection; a greater number were thought to wish well to it; and very few shewed much zeal to suppress it. *Is habitus animorum fuit, ut pessimum facinus auderent pauci, plures vellent, omnes paterentur.* But neither resentment, nor fear, nor even policy itself, could extinguish the humanity of Washington. This seems to have been the only sacrifice which he was incapable of making to the interest of his country.

Throughout the whole course of his second Presidency, the danger of America was great and imminent almost beyond example. The spirit of change, indeed, at that period, shook all nations. But in other countries it had to encounter ancient and solidly established power; it had to tear up by the roots long habits of attachment in some nations for their government; of awe in others; of acquiescence and submission in all.—But in America the government was new and weak. The people had scarce time to recover from the ideas and feelings of a recent civil war. In other countries the volcanic force must be of power to blow up the mountains, and to convulse the continents that held it down,

down, before it could escape from the deep caverns in which it was imprisoned :—in America it was covered only by the ashes of a late convulsion, or at most by a little thin soil, the produce of a few years quiet.

The government of America had none of those salutary prejudices to employ, which in every other country were used with success to open the eyes of the people to the enormities of the French revolution. They had, on the contrary, to contend with the prejudices of their people in the most moderate precautions against internal confusion, in the most measured and guarded resistance to the unparalleled insults and enormous encroachments of France. Without zealous support from the people, the American government was impotent. It required a considerable time, and it cost an arduous and dubious struggle, to direct the popular spirit against a sister republic, established among a people to whose aid the Americans ascribed the establishment of their independence. It is probable, indeed, that no policy could have produced this effect, unless it had been powerfully aided by the crimes of the French government, which have proved the strongest allies of all established governments; which have produced such a general disposition to submit to any *known* tyranny, rather than rush into all the unknown and undefinable evils of civil confusion, with the horrible train of new and monstrous *tyrannies* of which it is usually the forerunner. But of these circumstances Washington availed himself with uncommon address. He employed the horror excited by the atrocities of the French revolution for the most honest and praise-worthy purposes; to preserve the internal quiet of his country; to assert the dignity, and to maintain the rights, of the commonwealth which he governed, against foreign enemies. He avoided war without incurring the imputation of pusillanimity. He cherished the detestation of Americans for anarchy, without weakening the spirit of liberty ; and he maintained, and even consolidated, the authority of government, without abridging the privileges of the people.

The resignation of Washington in 1796 was certainly a measure of prudence, and we doubt not of patriotism; but the conduct of his successor has been such as to give the Americans reason to regret that the reins of government were thrown up by the only hand, perhaps, that was fit to guide them during so unsettled a state of public affairs. When he retired, he published a valedictory address to his countrymen, as he had before done when he quitted the command of the army in 1783. In these compositions, the whole heart and soul of Washington are laid open. Other state papers have, doubtless, shewn more spirit and dignity, more eloquence, greater force of genius, and a more enlarged comprehension of mind ; but none ever displayed more simplicity and ingenuousness, more moderation and sobriety, more good sense, more prudence, more honesty, more earnest affection for his country and for mankind, more profound reverence for virtue and religion; more ardent wishes for the happiness of his fellow-creatures, and more just and rational views of the means which alone can effectually promote that happiness.

From his resignation till the month of July 1798, he lived in retirement at Mount Vernon. At this latter period, it became necessary for the United States to arm. They had endured with a patience, of which there is no example in the history of states, all the contumely and wrong which successive administrations in France had heaped upon them. Their ships were everywhere captured, their ministers were detained in a sort of imprisonment at Paris ; while incendiareis, clothed in the sacred character of ambassadors, scattered over their peaceful provinces the fire brands of sedition and civil war. An offer was made to terminate this long course of injustice, for a bribe to the French ministers. This offer was made by persons who *appeared* to be in the confidence of M. Talleyrand, who *professed* to act by his authority ; who have been since, indeed, disavowed by him ; but who never will be believed not to have been his agents, till he convict them of imposture by legal evidence, and procure them to be punished for so abominable a fraud.

The United States resolved to arm by land and sea. The command of the army was bestowed on General Washington ; which he accepted, because he was convinced that " every thing we hold dear and sacred was seriously threatened* ;" though he had flattered himself " that he had quitted for ever the boundless field of public action, incessant trouble and high responsibility, in which he had long acted so conspicuous a part." In this office he continued during the short period of his life which still remained.—On Thursday the 12th December 1799, he was seized with an inflammation in his throat, which became considerably worse the next day ; and of which, notwithstanding the efforts of his physicians, he died on Saturday the 14th of December 1799, in the 68th year of his age, and in the 23d year of the independence of the United States, of which he may be considered as the founder. The same calmness, simplicity, and regularity, which had uniformly marked his demeanor, did not forsake him in his dying moments. He saw the approaches of death without fear: —he met them without parade.—Even the perfectly well-ordered state of the most minute particulars of his private business, bore the stamp of that constant authority of prudence and practical reason over his actions, which was a distinguishing feature of his character. He died with those sentiments of piety which had given vigour and consistency to his virtue, and adorned every part of his illustrious life.

* See his *Letter of Acceptance.*

WATCHWORK. Our intention in this article does not extend to the manual practice of this art, nor even to all the parts of the machine. We mean to consider the most important and difficult part of the construction, namely, the method of applying the maintaining power of the wheels to the regulator of the motion, so as not to hurt its power of regulation. Our observations would have come with more propriety under the title SCAPEMENT, that being the name given by our artists to this part of the construction. Indeed they were intended for that article, which had been unaccountably omitted in the body of the Dictionary under the words CLOCK and WATCH. But the bad health and occupations of the person who had engaged to write the article, have obliged us to defer it to the last opportunity which the alphabetical arrangement affords us ; and, even now, the same causes unfortunately prevent the author from treating the subject in the manner he intended, and which it well deserves. But we trust that, from the account which is here given, the reader, who is conversant in mathematical philosophy, will perceive the justness of the conclusions, and that an intelligent

Watch-work.

gent artist will have no hesitation in acceding to the propriety of the maxims of construction deduced from them.

The regulator of a clock or watch is a pendulum or a balance. Without this check to the motion of the wheels, impelled by a weight or a spring, the machine would run down with a motion rapidly accelerating, till friction and the resistance of the air induced a sort of uniformity, as they do in a kitchen jack. But if a pendulum be so put in the way of this motion, that only one tooth of a wheel can pass it at each vibration, the revolution of the wheels will depend on the vibration of the pendulum. This has long been observed to have a certain constancy, insomuch that the astronomers of the East employed pendulums in measuring the times of their observations, patiently counting their vibrations during the phases of an eclipse or the transits of the stars, and renewing them by a little push with the finger when they became too small. Gassendi, Riccioli, and others, in more recent times, followed this example. The celebrated physician Sanctorius is the first person who is mentioned as having applied them as regulators of clock movements. Machines, however, called *clocks*, with a train of toothed wheels, leading round an index of hours, had been contrived long before. The earliest of which we have any account is that of Richard of Wallingford, Abbot of St Alban's, in 1326 (A). It appears to have been regulated by a fly like a kitchen jack*. Not long after this Giacomo Dondi made one at Padua, which had a *motus succussorius*, a hobbling or trotting motion; from which expression it seems probable that it was regulated by some alternate movement. We cannot think that this was a pendulum, because, once it was introduced, it never could have been supplanted by a balance. The alternate motion of a pendulum, and its seeming uniformity, are among the most familiar observations of common life; and it is surprising that they were not more early thought of for regulating time measurers. The alternate motions of the old balance is one of the most far-fetched means that can be imagined, and might pass for the invention of a very reflecting mind, while a pendulum only requires to be drawn aside from the plumb-line, to make it vibrate with regularity. The balance must be put in motion by the clock, and that motion must be stopped, and the contrary motion induced; and we must know that the same force and the same checks will produce uniform oscillations. All this must be previously known before we can think of it as a regulator; yet so it is that clocks, regulated by a balance, were long used, and very common through Europe, before Galileo proposed the pendulum, about the year 1600. Pendulum clocks then came into general use, and were found to be greatly preferable to balance clocks as accurate measurers of time. Mathematicians saw that their vibrations had some regular dependance on uniform gravity, and in their writings we meet with many attempts to determine the time and demonstrate the isochronism of the vibrations. It is amusing to read these attempts. We wonder at the awkwardness and insufficiency of the explanation given of the motions of pendulums, even by men of acknowledged eminence. Mersennus carried on a most useful correspondence with all the mathematicians of Europe, and was the means of making them acquainted with each other; nay, he was himself well conversant in the science; yet one cannot but smile at his reasonings on this subject. Standing on the shoulders of our predecessors, we look around us, in great satisfaction with our own powers of observation, not thinking how we are raised up, or that we are trading with the stock left us by the diligent and sagacious philosophers of the 17th century (B). Riccioli, Gassendus, and Galileo, made similar attempts to explain the motion of pendulums; but without success. This honour was reserved for Mr Huyghens, the most elegant of modern geometers. He had succeeded in 1656 or 1657 in adapting the machinery of a clock to the maintaining of the vibrations of a pendulum. Charmed with the accuracy of its performance, he began to investigate with scrupulous attention the theory of its motion. By the most ingenious and elegant application of geometry to mechanical problems, he demonstrated that the wider vibrations of a pendulum employed more time than the narrower, and that the time of a semicircular vibration is to that of a very small one nearly as 34 to 29; and, aided by a new department of geometrical science invented by himself, namely, the evolution of curves, he shewed how to make a pendulum swing in a cycloid, and that its vibrations in this curve are all performed in equal times, whatever be their extent.

* Conradi Gesneri Epitome, p. 604.

But before this time, Dr Hooke, the most ingenious and inventive mechanician of his age, had discovered the great accuracy of pendulum clocks, having found that the manner in which they had been employed had obscured their real merit. They had been made to vibrate in very large arches, the only motion that could be given them by the contrivances then known; and in 1656 he invented another method, and made a clock which moved with astonishing regularity. Using a heavy pendulum, and making it swing in very small arches, the clocks so constructed were found to excel Mr Huyghens's cycloidal pendulums; and those who were unfriendly to Huyghens had a sort of triumph on the occasion. But this was the result of ignorance. Mr Huyghens had shewn, that the error of $\frac{1}{100}$ of an inch, in the formation of the parts which produced the cycloidal motion, caused a greater irregularity of vibration than a circular vibration could do, although it should extend five or six degrees on each side of the perpendicular. It has been found that the unavoidable inaccuracies,

(A) Professor Beckmann, in the first volume of his *History of Inventions*, expresses a belief that clocks of this kind were used in some monasteries so early as the 11th century, and that they were derived to the monks from the Saracens. His authorities, however, are discordant, and seem not completely satisfactory even to himself.

(B) We are provoked to make this observation, by observing at this moment, in a literary journal, a pert and petulant upstart speaking of Newton's optical discoveries in terms of ridicule and abuse, employing these very discoveries to diminish his authority. Is it not thus that Christianity is now slighted by those who enjoy the fruits of the pure morality which it introduced?

Watch-work.

inaccuracies, even of the beſt artiſts, in the cycloidal conſtruction, make the performance much inferior to that of a common pendulum vibrating in arches which do not exceed three or four degrees from the perpendicular. Such clocks alone are now made, and they exceed all expectation.

We have ſaid that a pendulum needed only to be removed from the perpendicular, and then let go, in order to vibrate and meaſure time. Hence it might ſeem, that nothing is wanted but a machinery ſo connected with the pendulum as to keep a regiſter, as it were, of the vibration. It could not be difficult to contrive a method of doing this; but more is wanted. The air muſt be diſplaced by the pendulum. This requires ſome force, and muſt therefore employ ſome part of the momentum of the pendulum. The pivot on which it ſwings occaſions friction—the thread, or thin piece of metal by which it is hung, in order to avoid this friction, occaſions ſome expenditure of force by its want of perfect flexibility or elaſticity. Theſe, and other cauſes, make the vibrations grow more and more narrow by degrees, till at laſt the pendulum is brought to reſt. We muſt therefore have a contrivance in the wheelwork which will reſtore to the pendulum the ſmall portion of force which it loſes in every vibration. The action of the wheels therefore may be called a *maintaining power*, becauſe it keeps up the vibrations.

But we now ſee that this may affect the regularity of vibration. If it be ſuppoſed that the action of gravity renders all the vibrations iſochronous, we muſt grant that the additional impulſion by the wheels will deſtroy that iſochroniſm, unleſs it be ſo applied that the ſum-total of this impulſion and the force of gravity may vary ſo with the ſituation of the pendulum, as ſtill to give a ſeries of forces, or a law of variation, perfectly ſimilar to that of gravity. This cannot be effected, unleſs we know both the law which regulates the action of gravity, producing iſochroniſm of vibration, and the intenſity of the force to be derived from the wheels in every ſituation of the pendulum.

The neceſſary requiſite for the iſochronous motion of the pendulum is, that the force which urges it toward the perpendicular, be proportional to its diſtance from it (ſee DYNAMICS, nº 103. Cor. 7. *Suppl.*); and therefore, ſince pendulums ſwinging in ſmall circular arches are ſenſibly iſochronous, we muſt infer that ſuch is the law by which the accelerating action of gravity on them is really accommodated to every ſituation in thoſe arches.

It will greatly conduce to the better underſtanding of the effect of the maintaining power, if the reader keep in continual view the chief circumſtances of a motion of this kind. Therefore let AC a (fig. 1.) repre-
Plate XLVIII.
ſent the arch paſſed over by the pendulum, ſtretched out into a ſtraight line. Let C be its middle point, when the pendulum hangs perpendicular, and A and a be the extremities of the oſcillation. Let AD be drawn perpendicular to AC, to repreſent the accelerating action of gravity on the pendulum when it is at A. Draw the ſtraight line DC d, and $a\,d$, perpendicular to A a. About C, as a centre, deſcribe the ſemicircle AFH a. Through any points B, K, k, b, &c. of A a, draw the perpendiculars BFE, KLM, &c. cutting both the ſtraight line and the ſemicircle. Then,

1. The actions of gravity on the pendulum, when in the ſituations B, K, &c. by which it is urged toward C, are proportional to, and may be repreſented by, the ordinates BE, KL, $b\,e$, $k\,l$, &c. to the ſtraight line DC d.

2. The velocities acquired at B, K, &c. by the acceleration along AB, AK, &c. are proportional to the ordinates BF, KM, &c. to the ſemicircle AH a; and, therefore, the velocity with which the pendulum paſſes through the middle point C, is to its velocity in any other point B, as CH to BF.

3. The times of deſcribing the parts AB, BK, KC, &c. of the whole arch of oſcillation, are proportional to, and may be repreſented by, the arches AF, FM, MH, &c. of the ſemicircle.

4. If one pendulum deſcribe the arch repreſented by AC a, and another deſcribe the arch KC k, they will deſcribe them in equal times, and their maximum velocities (viz. their velocities in the middle point), are proportional to AC and KC; that is, the velocities in the middle point are proportional to the width of the oſcillations.

The ſame proportions are true with reſpect to the motions outwards from C. That is, when the pendulum deſcribes CA, with the initial velocity CH, its velocity at K is reduced to KM by the retarding action of gravity. It is reduced to BF at B, and to nothing at A; and the times of deſcribing CK, KB, BA, CA, are as HM, HF, HA. Another pendulum ſetting out from C, with the initial velocity CO, reaches only to K, CK being = CO. Alſo the times are equal.—If we conſider the whole oſcillation as performed in the direction A a, the forces AD, BE, KL accelerate the pendulum, and the ſimilar forces $a\,d$, $b\,e$, $k\,l$, on the other ſide, retard it. The contrary happens in the next oſcillation aCA.

5. The areas DABE, DAKL, &c. are proportional to the ſquares of the velocities acquired by moving along AB, AK, &c. or to the diminution of the ſquares of the velocities ſuſtained by moving outwards along BA or KA, &c.

The conſideration of this figure will enable the reader (even though not a mathematician) to form ſome notion of the effect of any propoſed application of a maintaining power by means of wheelwork: For, knowing the weight of the pendulum, we know the accelerating action of that weight in any particular ſituation A of the pendulum. We alſo know what addition or ſubtraction we produce on the pendulum in that ſituation by the wheel-work. Suppoſe it is an addition of preſſure equal to a certain number of grains. We can make AD to D δ as the firſt to the laſt; and then A δ will be the whole force urging the pendulum toward C. Doing the ſame for every point of AC, we obtain a line $\delta\,\iota\,\lambda\,c$, which is a new ſcale of forces, and the ſpace DC δ, comprehended between the two ſcales CD and C δ, will expreſs the addition made to the ſquare of the velocity in paſſing along AC by the joint action of gravity and the maintaining power. Alſo, by drawing a line $\kappa\,\pi$ perpendicular to AC, making the ſpace C $\pi\,\kappa$ equal to CAD, the point π will be the limit of the oſcillation outward from C, where the initial velocity HC is extinguiſhed. If the line $\kappa\,\pi$ cut the ſame circle in ϑ, one-half the arch ϑ A will nearly expreſs the contraction made in the time of the outward oſcillation by the maintaining power. An accurate determination

Watch-work. termination of this laſt circumſtance is operoſe, and even difficult; but this ſolution is not far from the truth, and will greatly aſſiſt our judgment of the effect of any propoſal, even though $\kappa \pi$ be drawn only by the judgement of the eye, making the area left out as nearly equal to the area taken in as we can eſtimate by inſpection. This is ſaid from experience.

Since the motion of a pendulum or balance is alternate, while the preſſure of the wheels is conſtantly in one direction, it is plain that ſome art muſt be uſed to accommodate the one to the other. When a tooth of the wheel has given the balance a motion in one direction, it muſt quit it, that it may get an impulſion in the oppoſite direction. The balance or pendulum thus eſcaping from the tooth of the wheel, or the tooth eſcaping from the balance, has given to the general contrivance the name of SCAPEMENT among our artiſts, from the French word *echappement*. We proceed, therefore, to conſider this ſubject more particularly, firſt conſidering the ſcapements which are peculiarly ſuited to the ſmall vibrations of pendulums, and then thoſe which muſt produce much wider vibrations in balances. This, with ſome other circumſtances, render the ſcapements for pendulums and balances very different.

I. *Of the Action of a Wheel and Pallet.*

THE ſcapement which has been in uſe for clocks and watches ever ſince their firſt appearance in Europe, is extremely ſimple, and its mode of operation is too obvious to need much explanation. In fig. 2. XY repreſents a horizontal axis, to which the pendulum P is attached by a ſlender rod, or otherwiſe. This axis has two leaves C and D attached to it, one near each end, and not in the ſame plane, but ſo that when the pendulum hangs perpendicularly, and at reſt, the piece C ſpreads a few degrees to the right hand, and D as much to the left. They commonly make an angle of 70, 80, or 90 degrees. Theſe two pieces are called PALLETS. AFB repreſents a wheel, turning round on a perpendicular axis EO, in the order of the letters AFEB. The teeth of this wheel are cut into the form of the teeth of a ſaw, leaning forward, in the direction of the motion of the rim. As they ſomewhat reſemble the points of an old-faſhioned royal diadem, this wheel has got the name of the CROWN WHEEL. In watches it is often called the *balance wheel*. The number of teeth is generally odd; ſo that when one of them B is preſſing on a pallet D, the oppoſite pallet C is in the ſpace between two teeth A and I. The figure repreſents the pendulum at the extremity of its excurſion to the right hand, the tooth A having juſt eſcaped from the pallet C, and the tooth B having juſt dropped on the pallet D. It is plain, that as the pendulum now moves over to the left, in the arch PG, the tooth B *continues* to preſs on the pallet D, and thus accelerates the pendulum, both during its deſcent along the arch PH, and its aſcent along the arch HG. It is no leſs evident, that when the pallet D, by turning round the axis XY, raiſes its point above the plane of the wheel, the tooth B eſcapes from it, and I drops on the pallet C, which is now nearly perpendicular. I preſſes C to the right, and accelerates the motion of the pendulum along the arch GP. Nothing can be more obvious than this action of the wheel in maintaining the vibrations of the pendulum. We can eaſily perceive, alſo, that when the pendulum is hanging perpendicularly in the line XH, the tooth B, by preſſing on the pallet D, will force the pendulum a little way to the left of the perpendicular, and will force it ſo much the farther as the pendulum is lighter; and, if it be ſufficiently light, it will be forced ſo far from the perpendicular that the tooth B will eſcape, and then I will catch on C, and force the pendulum back to P, where the whole operation will be repeated. The ſame effect will be produced in a more remarkable degree, if the rod of the pendulum be continued through the axis XY, and a ball Q put on the other end to balance P. And, indeed, this is the contrivance which was firſt applied to clocks all over Europe, before the application of the pendulum. They were balance clocks. The force of the wheel was of a certain magnitude, and therefore able, during its action on a pallet, to communicate a certain quantity of motion and velocity to the balls of the balance. When the tooth B eſcapes from the pallet D, the balls are then moving with a certain velocity and momentum. In this condition, the balance is checked by the tooth I catching on the pallet C. But it is not inſtantly ſtopped. It continues its motion a little to the left, and the pallet C forces the tooth I a little backward. But it *cannot* force it ſo far as to eſcape over the top of the tooth I; becauſe all the momentum of the balance was generated by the force of the tooth B; and the tooth I is equally powerful. Beſides, when I catches on C, and C continues its motion to the left, its lower point applies to the face of the tooth I, which now acts on the balance by a long and powerful lever, and ſoon ſtops its farther motion in that direction, and now, continuing to preſs on C, it urges the balance in the oppoſite direction.

Thus we ſee that in a ſcapement of this kind, the motion of the wheel muſt be very hobbling and unequal, making a great ſtep forward, and a ſhort ſtep backward, at every beat. This has occaſioned the contrivance to get the name of the RECOILING SCAPEMENT, the recoiling pallets. This hobbling motion is very obſervable in the wheel of an alarm.

Thus have we obtained two principles of regulation. The firſt and moſt obvious, as well as the moſt perfect, is the natural iſochronous vibration of a pendulum. The only uſe of the wheelwork here, beſides regiſtering the vibrations, is to give a gentle impulſion to the pendulum, by means of the pallet, in order to compenſate friction, &c. and thus maintain the vibrations in their primitive magnitude. But there is no ſuch native motion in a balance, to which the motion of the wheels muſt accommodate itſelf. The wheels, urged by a determined preſſure, and acting through a determined ſpace (the face of the pallet), muſt generate a certain determined velocity in the balance; and therefore the time of the oſcillation is alſo determined, both during the progreſſive and the retrograde motion of the wheel. The actions being ſimilar, and through equal ſpaces, in every oſcillation, they muſt employ the ſame time. Therefore a balance, moved in this manner, muſt be iſochronous, and a regulator for a time-keeper.

By thus employing a balance, the horizontal poſition of the axis XY is unneceſſary. Accordingly, the old clocks had this axis perpendicular, by which means the whole

whole weight of the balance refted on the point of the pivot Y or X, according as the balance PQ was placed above or below. By making the fupporting pivot of hard fteel, and very fharp, friction was greatly diminifhed. Nay, it was entirely removed from this part of the machine by fufpending the balance by a thread at the end X, inftead of allowing it to reft on the point of the pivot Y.

As the balance regulator of the motion admits of every pofition of the machine, thofe clocks were made in an infinite variety of fanciful forms, efpecially in Germany, a country famous for mechanical contrivances. They were made of all fizes, from that of a great fteeple clock, to that of an ornament for a lady's toilet. The fubftitution of a fpring in place of a weight, as a firft mover of the wheel-work, was a moft ingenious thought. It was very gradual. We have feen, in the Emperor's mufeum at Bruffels, an old (perhaps the firft) fpring clock, the fpring of which was an old fword blade, from the point of which a catgut was wound round the barrel of the firft wheel. Some ingenious German fubftituted the fpiral fpring, which both took lefs room, and produced more revolutions of the firft wheel.

When clocks had been reduced to fuch fmall fizes, the wifh to make them portable was very natural; and the means of accomplifhing this were obvious, namely, a farther reduction of their fize. This was accomplifhed very early; and thus we obtained pocket watches, moved by a fpiral fpring, and regulated by a balance with the recoiling fcapement, which is ftill in ufe for common watches. The hobbling motion of the crown wheel is very eafily feen in all of them.

It is very uncertain who firft fubftituted a pendulum in place of the balance (Clock, *Encycl.*) Huyghens, as we have already obferved, was the firft who inveftigated the motions of pendulums with fuccefs, and his book *De Horologio Ofcillatorio* may be confidered as the elements of refined mechanics, and the fource of all the improvements that have been made in the conftruction of fcapements. But it is certain that Dr Hooke had employed a pendulum for the regulation of a clock many years before the publication of the abovementioned treatife, and he claims the merit of the invention of the *only proper* method of employing it. We imagine therefore that Dr Hooke's invention was nothing more than a fcapement for a pendulum making fmall vibrations, without making ufe of the oppofite motions of the two fides of the crown wheel. Dr Hooke had contrived fome fcapement more proper for pendulums than the recoiling pallets, becaufe certainly thofe might be employed, and are actually employed as a fcapement for pendulum clocks to this day, although they are indeed very ill adapted to the purpofe. He had not only remarked the great fuperiority of fuch pendulum clocks as were made before Huyghens's publication of the cycloidal pendulum over the balance clocks, but had alfo feen their defects, arifing from the light pendulums and wide arches of vibration, and invented a fcapement of the nature of thofe now employed. The pendulum clock which he made in 1658 for Dr Wilkins, afterwards Bifhop of Chefter, is mentioned by the inventor as peculiarly fuited to the moderate fwing of a pendulum; and he oppofes this circumftance to a general practice of wide vibrations and trifling pendulums. The French are not in the practice of afcribing to us any thing that they can claim as their own; yet Lepaute fays that the *Echappement à l'Ancre* came from England about the year 1665. It is alfo admitted by him that clock-making flourifhed in England at that time, and that the French artifts went to London to improve in it. Putting thefe and other circumftances together, we think it highly probable that we are indebted to Dr Hooke for the fcapement now in ufe. The principle of this is altogether different from the fimple pallets and direct impulfe already defcribed; and is fo far from being obvious, that the manner of action has been mifunderftood, even by men of fcience, and writers of fyftems of mechanics.

In this fcapement we employ thofe teeth of the wheel which are moving in one direction; whereas in the former fcapement, oppofite teeth were employed moving in contrary directions. Yet even here we muft communicate an alternate motion to the axis of the pallets. The contrivance, in general, was as follows: On the axis A (See fig. 3.) of the pendulum or balance is fixed a piece of metal BAC, called the crutch by our artifts, and the anchor by the French. It terminates in two faces B *b* C *c* of tempered fteel, or of fome hard ftone. Thefe are called the pallets, and it is on them that the teeth of the wheel act. The faces B *b* C *c* are fet in fuch pofitions that the teeth pufh them out of the way. Thus B pufhes the pallet to the left, and C pufhes its pallet to the right. Both pufh their pallets fidewife outward from the centre of the wheel. The pallet B is ufually called the *leading*, and C the *driving* pallet by the artifts, although it appears to us that thefe names fhould be reverfed, becaufe B *drives* the pallet out of the way, and C *pulls* or leads it out of the way. They might be called the *firft* and *fecond* pallet, in the order in which they are acted on by the wheel. We fhall ufe either denomination. The figure is accommodated to the inactive or refting pofition of the pendulum. Suppofe the pendulum drawn afide to the right at Q, and then let go. It is plain that the tooth B, preffing on the face of the pallet β B *b* all the way from β to *b*, thrufts it afide outwards, and thus, by the connection of the crutch with the pendulum rod, aids the pendulum's motion along the arch QPR. When the pendulum reaches R, the point of the tooth B has reached the angle *b* of the pallet, and efcapes from it. The wheel preffing forward, another tooth C drops on the pallet face C *c*, and, by preffing this pallet outward, evidently aids the pendulum in its motion from R to P. The tooth C efcapes from this pallet at the angle *c*, and now a tooth B′ drops on the firft pallet, and again aids the pendulum; and this operation is repeated continually.

The mechanifm of this communication of motion is thus explained by feveral writers of elements. The tooth B (fig. 2.) is urged forward in the direction BD, perpendicular to the radius MB of the swing wheel. It therefore preffes on the pallet, which is moveable only in the direction BE, perpendicular to BA the radius of the pallet. Therefore the force BD muft be refolved into two, *viz.* BE, in the direction in which alone the pallet can move, and ED, or BF, perpendicular to that direction. The laft of thefe only preffes the pallet and crutch againft the pivot hole A.

BE

BE is the only useful force, or the force communicated to the pallet, enabling it to maintain the pendulum's motion, by restoring the momentum lost by friction and other causes.

But this is a very erroneous account of the *modus operandi*, as may be seen at once, by supposing the radius of the pallets to be a tangent to the wheel. This is a position most frequently given to them, and is the very position in fig. 3. In this case MB is perpendicular to BA, and therefore BD will coincide with BA, and there will be no such force as BE to move the pendulum. It is a truth, deducible from what we know of the mechanical constitution of solid bodies, and confirmed by numberless observations, that when two solid bodies press on each other, either in impulsion or in dead pressure, the direction in which the mutual pressure is exerted is always perpendicular to the touching surfaces, whatever has been the direction of the impelling body (See Impulsion, *Suppl.* n° 66. Machinery, *Suppl.* n° 35. and several other parts of this Work.) Moreover this pressure is mutual, equal, and opposite. Whatever be the shapes of the faces of the tooth and pallet, we can draw a plane BN, which is the common tangent to both surfaces, and a line HBI through the point of contact perpendicular to BN. It is farther demonstrated in the article Machinery, *Suppl.* n° 35, &c. that the action of the wheel on the pendulum is the same as if the whole crutch were annihilated, and in its stead there were two rigid lines AH, MI, from the centres of the crutch and wheel, perpendicular to HI, and connected by a third rigid line or rod HI, touching the two in H and I.

For if a weight V be hung at v, the extremity of the horizontal radius M v of the wheel, it will act on the lever v MI, pressing its point I upwards in the direction IH perpendicular to MI; the upper end of this rod IH will, in like manner, press the extremity H of the rod HA, and this will urge the pendulum from P toward R. To withstand this, the pendulum rod AP may be withheld by a weight z, hanging by a thread on the extremity of the horizontal lever A z, equal to M v, and connected with the crutch and pendulum. The weights V and z may be so proportioned to each other that, by acting perpendicularly on the crooked levers v MI, and z AH, the pressures at H and I shall be equal, and just balance each other by the intervention of the rod HI. When this is the case, we have put things into the same mechanical state, in respect of mutual action, as is effected by the crutch, pallets, and wheel, which, in like manner, produce equal pressures at B the point of contact, in the direction BH and BI. The weight V may be such as produces the very same effect at B that is produced by the previous train of wheel-work. The weight z therefore must be just equal to the force produced by the wheel-work on the point z of the pendulum rod, because by acting in the opposite direction it just balances it. Let us see therefore what force is communicated to the pendulum by the wheels.

Let x be the upward pressure excited at I, and y the equal opposite pressure excited at H. Then, by the property of the lever, we have $\text{MI} : \text{M}v = \text{V} : x$, and $x \times \text{MI} = \text{V} \times \text{M}v$. In like manner $y \times \text{AH} = \text{Z} \times \text{A}z$. Therefore, because $x = y$, and $\text{A}z = \text{M}v$, we have $\text{V} : \text{Z} = \text{MI} : \text{AH}$. That is, the force exerted by the tooth of the wheel in the direction of its motion is to the force impressed on the pendulum rod at a distance equal to the radius of the wheel as MI to AH. The force impressed on the ball of the pendulum is less than this in the proportion of AP to A z, or M v.

Cor. 1. If the perpendiculars MN, AV, be drawn on the tangent plane, the forces at B and z will be as BN to BO. For these lines are respectively equal to MI and AH.

Cor. 2. If HI meet the line of the centres AC in S, the forces will be as SM to SA; that is, $\text{V} : \text{Z} = \text{SM} : \text{SA}$.

Cor. 3. If the face β B b of the pallet be the evolutrix of a circle described with the radius AH, and the face of the tooth be the evolutrix of a circle described with the radius MI, the force impressed on the pendulum by the wheels will be constant during the whole vibration (Machinery, n° 36.) But these are not the only forms which produce this constancy. The forms of teeth described by different authors, such as De la Hire, Camus, &c. for producing a constant force in trains of wheel work, will have the same effect here. It is also easy to see that the force impressed on the pendulum may be varied according to any law, by making these faces of a proper form. Therefore the face, from B outwards, may be so formed that the force communicated to the pendulum by the wheels, during its descent from Q to P, may be in one constant proportion to the acceleration of gravity, and then the sum of the forces will be such as produce isochronous vibrations. If the inner part B b of the face be formed on the same principle, the difference of the forces will have the same law of variation. If the face βb be the evolutrix of a circle, and the tooth B terminate in a point gently rounded, or quite angular, the force on the pendulum will continually increase as the tooth slides from β to b. For the line AH continues of the same magnitude, and MI diminishes. The contrary will happen, if the pallet be a point, either sharp or rounded, and if the face of the tooth be the evolutrix now mentioned; for MI will remain the same, while AH diminishes. If the tooth be pointed, and βb be a straight line, the force communicated to the pendulum will diminish, while the tooth slides from β to b. For in this case AH diminishes and MI increases.

Cor. 4. In general, the force on the pendulum is greater as the angle MB b increases, and as AB b diminishes.

Cor. 5. The angular velocity of the wheel is to that of the pendulum, in any part of its vibration, as AH to MI. This is evident, because the rod IH moving (in the moment under consideration) in its own direction, the points H and I move through equal spaces, and therefore the angles at A and M must be inversely as the radii.

All that has now been said of the first pallet AB may be applied to the second pallet AC.

If the perpendiculars C s be drawn to the touching plane o C n, cutting AM in s, we shall have $\text{V} : z = s\text{M} : s\text{A}$, as in Cor. 2. And if the perpendiculars Mi, Ah, be drawn on C s, we have $\text{V} : \text{Z} = \text{M}i : \text{A}h$, as in the general theorem. The only difference between the action on the two pallets is, that if the faces of both are plain, the force on the pendulum increases during the whole of the action on the pallet C, whereas it dimi-

 nishes

nifhes during the progrefs of the tooth along the other pallet.

The reader will doubtlefs remark that each tooth of the wheel acts on both pallets in fucceffion ; and that, during its action on either of them, the pendulum makes one vibration. Therefore the number of vibrations during one turn of the wheel is double the number of the teeth : confequently, while the tooth flides along one of the pallets, it advances half the fpace between two fucceffive teeth ; and when it efcapes from the pallet, the other tooth *may* be juft in contact with the other pallet. We fay it *may* be fo ; in which cafe there will be no dropping of the teeth from pallet to pallet. This, however, requires very nice workmanfhip, and that every tooth be at precifely the fame diftance from its neighbour. Should the tooth which is juft going to apply to a pallet chance to be a little too far advanced on the wheel, it would touch the pallet before the other had efcaped. Thus, fuppofe that before B efcapes from the point b of the pallet, the tooth C is in contact with the pallet CG, B cannot efcape. Therefore when the pendulum returns from R towards Q, the pallet βb, returning along with it, will pufh back the tooth B of the wheel. It does this in oppofition to the force of the wheel. Therefore, whatever motion the wheel had communicated to the pendulum, during its fwing from P to Q, will now be taken from it again. The pendulum will not reach Q, becaufe it had been aided in its motion from Q, and had proceeded further than it would have done without this help. Its motion toward Q is further diminifhed by the friction of the pallet. Therefore it will now return again from fome nearer point q, and will not go fo far as in the laft vibration, but will return through a ftill fhorter arch : And this will be ftill more contracted in the next vibration, &c. &c. Thus it appears that if a tooth chances to touch the pallet before the efcape of the other, the wheel will advance no farther, and foon after the pendulum will be brought to reft.

For fuch reafons it is neceffary to allow one tooth to efcape *a little before* the other reaches the pallet on which it is to act, and to allow a fmall drop of the teeth from pallet to pallet. But it is accounted bad workmanfhip to let the drop be confiderable, and *clofe fcapement* is accounted a mark of care and of good workmanfhip. It is evidently an advantage, becaufe it gives a longer time of action on each pallet. This freeing the fcapement cannot be accomplifhed by filing fomething from the face of the tooth ; becaufe this being done to all, the diftance between them is diminifhed rather than augmented. The pallets muft be firft fcaped as clofe as poffible. This obliges the workman to be careful in making the teeth equidiftant. Then a fmall matter is taken from the point of each pallet, by filing off the back $b\,r$ of the pallet. The tooth will now efcape before it has moved through half a fpace.

From all that has been faid on this particular, it appears that the interval between the pallets muft comprehend a certain number of teeth, and half a fpace more.

The firft circumftance to be confidered in contriving a fcapement is the angular motion that is intended to be given to the pendulum during the action of the wheel. This is ufually called the *angle of fcapement*, or the *angle of action*. Having fixed on an angle a that we think proper, we muft fecure it by the pofition and form of the face of the pallets. Knowing the number of teeth in the fwing-wheel, divide 180° by this number, and the quotient is the angle b of the wheel's motion during one vibration of the pendulum. In the line AM, joining the centres of the crutch and wheel, make SM to SA, and sM to sA, as the angle a to the angle b; and then, having determined how many teeth fhall be comprehended between the pallets, call this number n. Multiply the angle b by $n + 1$, and take the half of the product. Set off this half in the circumference of the wheel (at the points of the teeth) on each fide of the line joining the centres of the crutch and wheel, as at TB and TC. Through S and s draw SB and sC, and through B draw βBb perpendicular to SB, for the medium pofition of the face of the firft pallet ; that is, for its pofition when the pendulum hangs perpendicular. In like manner, drawing oCn perpendicular to sC, we have the medium pofition of the fecond pallet. The demonftration of this conftruction is very evident from what has been faid.

We have hitherto fuppofed that the pendulum finifhes its vibration at the inftant that a tooth of the wheel efcapes from a pallet, and another tooth drops on the other pallet. But this is never, or fhould never be, the cafe. The pendulum is made to fwing fomewhat beyond the angle of fcapement : for if it do not when the clock is clean and in good order, but ftop precifely at the drop of a tooth, then, when it grows foul, and the vibration diminifhes, the teeth will not efcape at all, and the clock will immediately ftop. Therefore the force communicated by the wheels during the vibration within the limits of fcapement, muft be increafed fo as to make the pendulum *throw* (as the artifts term it) farther out; and a clock is more valued when it throws out confiderably beyond the angle of fcapement. There are good reafons for this. The momentum of the pendulum, and its power to regulate the clock (which Mr Harrifon fignificantly called its *dominion*), is proportional to the width of its vibrations very nearly.

This circumftance of exceeding the angle of fcapement has a very great influence on the performance of the clock, or greatly affects the dominion of the pendulum. It is eafy to fee that, when the face βb of the leading pallet is a plane, if the pendulum continue its motion to the right, from P toward Q, after the tooth B has dropped on it, the pallet will pufh the wheel back again, while the tooth flides outward on the pallet toward β. Such pallets therefore will make a *recoiling fcapement*, refembling, in this circumftance, the old pallet employed with the crown wheel, and will have the properties attached to this circumftance. One confequence of this is, that it is much affected by any inequalities of the maintaining power. It is a matter of the moft familiar obfervation, that a common watch goes flower when within a quarter of an hour of being down, when the action of the fpring is very weak, in confequence of its not pulling by a radius of the fufee. We obferve the fame thing in the beating of an alarum clock. Alfo if we at any time prefs forward the wheelwork of a common watch with the key, we obferve its beats accelerate immediately. The reafon of this is pretty plain. The balance, in confequence of the acceleration in the angle of fcapement, would have gone much farther, employing a confiderable time in the

Watch-work.

the excurſion. This is checked abruptly, which both ſhortens the vibration and the time employed in it. In the return of the pendulum, the motion is accelerated the whole way, along an arch which is ſhorter than what correſponds to its velocity in the middle point; for it is again checked on the other ſide, and does not make its full excurſion. Moreover, all this irregularity of force, or the great deviation from a reſiſtance to the excurſion proportional to the diſtance from the middle point, is exerted on the pendulum when it is near the end of the excurſion, where the velocity being ſmall, this irregular force acts long upon it, at the very time that it has little force wherewith to reſiſt it. All temporary inequalities of force, therefore, will be more felt in this ſituation of the balance than if they had been exerted in the middle of its motion. And although the regulating power of a pendulum greatly exceeds that of the light balances uſed in pocket watches, ſomething of the ſame kind may be expected even in pendulum clocks. Accordingly this appears by a ſeries of experiments made by Mr Berthoud, a celebrated watchmaker of Paris. A clock, with a half ſecond pendulum weighing five drams, was furniſhed with a recoiling ſcapement, whoſe pallets were planes. The angle of ſcapement was $5\frac{1}{2}$ degrees. When actuated with a weight of two pounds, it ſwung 8°, and loſt 15′ per hour; with four pounds, it ſwung 10°, and loſt 6′. Thus it appears that by doubling the maintaining power, although the vibration was increaſed in conſequence of the greater impulſe, the time was leſſened 9″ per hour, viz. about $\frac{1}{400}$. It is plain, from what was ſaid when we deſcribed the firſt ſcapement, that an increaſe of maintaining power muſt render the vibration more frequent. We ſaw, on that occaſion, that, even when the gravity of the pendulum is balanced by a weight on the other end of the rod, the force of the wheels will produce a vibratory motion, and that an augmentation of this force will increaſe it, or make the vibrations more rapid. The preciſe effect of any particular form of teeth can be learned only by computing the force on the pendulum in every poſition, and then conſtructing the curve ʃ ε λ C of fig. 1. The rapid increaſe of the ordinates beyond thoſe of the triangle ADC, forms a conſiderable area DA π o, to compenſate the area π o C, and thus makes a conſiderable contraction A π of the vibration, and a ſenſible contraction $\frac{A\theta}{2}$ of the time.

Mr George Graham, the celebrated watchmaker in London, was alſo a good mathematician, and well qualified to conſider this ſubject ſcientifically. He contrived a ſcapement, which he hoped would leave the pendulum almoſt in its natural ſtate. The acting face of the pallet *a b c* (fig. 4.) is a plane. The tooth drops on *a*, and eſcapes from *c*, and is on the middle point *b* when the pendulum is perpendicular. Beyond *a*, the face of the pallet is an arch *a d*, whoſe centre is A, the centre of the crutch. The maintaining power is made ſo great as to produce a much greater vibration than the angle of active ſcapement *a* A *c*. The conſequence of this is that, when the tooth drops on the angle *a*, the pendulum, continuing its motion, carries the crutch along with it, and the tooth paſſes on the arch *a d*, in a direction paſſing through the centre of the crutch. This preſſure can neither accelerate nor retard the motion of the crutch and pendulum. As the pendulum was accelerated after it paſſed the perpendicular, by the other pallet, it will (if quite unobſtructed) throw out farther than what correſponds to the velocity which it had in the middle point of its vibration; perhaps till the tooth paſſes from *a* to *e* on the circular arch of the pallet. But although it ſuſtains no contrary action from the wheels during this excurſion beyond the angle of ſcapement, it will not proceed ſo far, but will ſtop when the tooth reaches *d*; becauſe there muſt be ſome reſiſtance ariſing from the friction of the tooth along the arch *a d*, and from the clammineſs of the oil employed to lubricate it: but this reſiſtance is exceedingly minute, not amounting to $\frac{1}{8}$th of the preſſure on the arch. Nay, we think that it appears from the experiments of Mr Coulomb that, in the caſe of ſuch minute preſſures on a ſurface covered with oil, there is no ſenſible retardation analogous to that produced by friction, and that what retardation we obſerve ariſes entirely from the clammineſs of the oil. We are ſo imperfectly acquainted with the manner in which friction and viſcidity obſtruct the motions of bodies, that we cannot pronounce deciſively what will be their effect in the preſent caſe. Friction does not increaſe much, if at all, by an increaſe of velocity, and appears like a fixed quantity when the preſſure is given. This makes all motions which are obſtructed by friction terminate abruptly. This will ſhorten both the length and the time of the outward excurſion of the pendulum. The viſcidity of the oil reſiſts differently, and more nearly in the proportion of the velocities. The diminution of motion will not be in this proportion, becauſe in the greater velocities it acts for a ſhorter time. Were this accurately the caſe, the reſiſtance of viſcidity would alſo be nearly conſtant, and it would operate as friction does. But it does not ſtop a motion abruptly, and the motions are extinguiſhed gradually. Therefore, although viſcidity muſt always diminiſh the extent of the excurſion, it may ſo vary as not to diminiſh the time. We apprehend, however, that it generally does. But whatever happens in the excurſion, the return will certainly be ſlower, and employ more time than if it had not been obſtructed, becauſe the velocity in every point is leſs than if perfectly free. The whole arch, conſiſting of a returning arch and an excurſion on the other ſide, may be either ſlower or quicker, according as the compenſation is complete or not, or is even overdone.

All theſe reflections occurred to Mr Graham; and he was perſuaded that the time of the tooth's remaining on the arch *a d*, both aſcending and deſcending, would differ very little from that of the deſcription of the ſame arch by a free pendulum. The great cauſes of irregularity ſeemed to be removed, viz. the inequalities in the action of the wheels in the vicinity of the extremity of the vibration, where the pendulum having little momentum is, long in the ſame little ſpace, expoſed to their action. The derangement produced by any force depends on the time of its action, and therefore muſt be greateſt when the motion is ſloweſt. The pendulum gets its impulſe in the very middle of its vibration, where its velocity is the greateſt; and therefore the inequalities of the maintaining power act on it only for a ſhort time, and make a very trifling alteration in the time of its deſcribing the arch of ſcapement. Beyond this, it is nearly in the ſtate of a free pendulum;

lum ; nay, even though it be affected by an inequality of the maintaining power, and it be accelerated beyond its usual rate in that arch, the chief effect of this will be to cause it to describe a larger arch of excursion. The shortening of the time of this description by the friction will be the same as before, happening at the very end of the excursion ; but the return will be more retarded by the friction on a longer arch. And, by this, a compensation may be made for the trifling contraction of the time of describing the arch of scapement.

This circumstance of giving the impulse in the middle of the vibration. where its time of action is the smallest possible, and whereby the pendulum is so long left free from the action of the wheels, is of the very first importance in all scapements, and should ever be in the mind of the mechanician. When this is adhered to, the form of the face *a b c* is scarcely of any moment. Much has been written on this form, and many attempts have been made to make it such that the action of the wheels shall be proportional to the action of gravity. To do this is absolutely impossible. Mr Graham made them planes, not only because of easiest execution, but because a plane really conspires pretty well with the change of gravity. While the pendulum moves from Q to P (fig. 3.), the force of gravity, acting in the direction QP, is continually diminishing. So is the accelerating power of the pallet from *a* to *b*. When the pendulum rises from P to R, a force in the opposite direction RP continually increases. This is analogous to the continual diminution of a force in the direction PR. Now we have such a diminution of such a force, in the action of the pallet from *b* to *c*, and such an augmentation in the action of the other pallet.

For all these reasons, this construction of a scapement appeared very promising. Mr Graham put it in practice, and it answered his most sanguine expectation, and is now universally adopted in all nice clocks. Mr Graham, however, did not think it prudent to cause a tooth to drop on the very angle *a* of the pallet. He made it drop on a point *f* of the arch of excursion. This has also the advantage of diminishing the angle of action, which we have proved to be of service. It requires, indeed, a greater maintaining power ; but this can easily be procured, and is less affected by the changes to which it is liable by the effect of heat and cold on the oil. Our observations on the effects of friction and viscidity in the arch *a d* seem to be confirmed by the observations of several artists, who agree in saying that a great increase of maintaining power increases the vibrations, but makes them perceptibly slower. When they wrote, much oil was applied to diminish the friction on the arch of repose ; but, since that time, the rubbing parts were made such as required no oil, and this retardation disappeared. In the clock of the transit room of the Royal Observatory, the angle of action seldom exceeds one-third of the swing of the pendulum. The pallets are of oriental ruby, and the wheel is of steel tempered to the utmost degree of hardness. This clock never varies a whole second from equable motion in the course of five days.

This contrivance is known by the name of the DEAD BEAT, the DEAD SCAPEMENT; because the seconds index stands still after each drop, whereas the index of a clock with a recoiling scapement is always in motion, hobbling backward and forward.

These scapements, both recoiling and dead beat, have been made in a thousand forms ; but any person tolerably acquainted with mechanics, will see that they are all on the same principles, and differ only in shape or some equally unimportant circumstance. Perhaps the most convenient of any is that represented in fig. 5. where the shaded part is the crutch, made of brass or iron, and A and B are two pieces of agate, flint, or other hard stone, cut into the proper shape for a pallet of either kind, and firmly fixed in proper sockets. They project half an inch, or thereabouts, in front of the crutch, so that the swing wheel is also before the crutch, distant about $\frac{1}{10}$th of an inch or so. Pallets of ruby, driven by a hard steel swing wheel, need no oil, but merely to be once rubbed clean with an oily cloth.

Sometimes the wheel has pins instead of teeth. They are ranged round the rim of the wheel, perpendicular to its plane, and both pallets are on one side of the wheel, standing perpendicular to its plane. One of these pins drops from the first to the second pallet at once. The pallets are placed on two arms, as in fig. 6. in which case the pins are alternately on different sides of the wheel ; or on one, as in fig. 7. By the motion of the pendulum to the right, the pin (in fig. 7.), after resting on the concave arch *d a*, acts on the face *a c*, and drops from *c* on the other concave arch *i g*, which continues to move a little way to the right. It then returns, and the pin slides and acts on the pallet *i h*, and escapes at *h* ; and the next pin is then on the arch of repose *d a*.

It being evident that the recoiling scapement accelerates the vibrations beyond the rate of a free pendulum, and it also appearing to many of the first artists that the dead scapement retards them, they have attempted to form a scapement which shall avoid both of these defects, by forming the arches *a d*, *i g*, so as to produce a very small recoil. Mr Berthoud does this in a very simple manner, by placing the centre of *a d* at a small distance from that of the crutch, so as to make the rise of the pallet above the concentric arch about one-third of the arch itself. Applying such a crutch to the light pendulum mentioned in a former paragraph, he found that doubling, and even trebling the maintaining power, produced no change in the time of vibration, though it increased the width from 8° to 12° and 14°. We have no doubt of the efficacy of this contrivance, and think it very proper for all clocks which require much oil, such as turret clocks, &c. But we apprehend that no rule can be given for the angle that the recoiling arch should make with the concentric one. We imagine that this depends entirely on the share which friction and oil have in producing the retardation of the dead beat.

Other artists have endeavoured to avoid the inconveniences of friction and oil on the arch of repose in another way. Instead of allowing the tooth of the wheel to drop on the back of the pallet, which we called the *arch of excursion*, and others call the *arch of repose*, it drops on a detent *o t a* (fig. 8.), of which the part *t a* is part of an arch whose centre is A, the centre of the crutch, and the part *t o* is in the direction of the radius. This piece does not adhere to the pallet, but is on the end of an arm *o* A, which turns round the axis A of the crutch on fine pivots : it is made to apply itself to the back of the pallet by means of a slender spring A*p*, attached to the pallet, and pressing inward on a pin *p*, fixed

fixed in the arm of the detent. When fo applied, its arch *t a* makes the repofe, and its point *a* makes a fmall portion of the face *a c* of the pallet.

The action of this apparatus is very eafily underftood. When a tooth efcapes from the fecond pallet, by the motion of the pendulum from the left to the right, another tooth drops on this pallet (which the figure fhews to be the firft or leading pallet) at the angle *t*, and refts on the fmall portion *t a* of an arch of repofe. But the crutch, continuing its motion to the right, immediately quits the arm *o A*, carrying the pallet *a c r* along with it, and leaving the wheel locked on the detent *o t a*. By and bye the pendulum finifhes its excurfion to the right, and returns. When it enters the arch of action, the pallet has applied itfelf to the detent *o t a*, and withdraws it from the tooth. The tooth immediately acts on the face *a c* of the pallet, and reftores the motion loft during the laft vibration. The ufe of the fpring is merely to keep the detent applied to the pallet without fhaking. It is a little bent during their feparation, and adds fomething of an oppofing force to the afcent of the pendulum on the other fide of the wheel, and accelerates its return. A fimilar detent on the back of the fecond pallet performs a fimilar office, fupporting the wheel while the pendulum is beyond the arch of fcapement, and quitting it when the pendulum enters that arch.

We do not know who firft practifed this very ingenious and promifing invention. Mr Mudge certainly did fo as early as 1753 or 1754. Mr Berthoud fpeaks obfcurely of contrivances of the fame nature. So does Le Roy, and (we think) Le Paute. We fay that it is very promifing. Friction is almoft annihilated by transferring it to the pivots at A; fo that, in the excurfion beyond the angle of fcapement, the pendulum feems almoft free. Indeed fome artifts of our acquaintance have even avoided the friction of the pivots at A, by making the arm of the detent a fpring of confiderable thicknefs, except very near to A, where it is made very thin and broad. But we do not find that this conftruction, though eafily executed, and fufceptible of great precifion and fteadinefs of action, is much practifed. We prefume that the performance has not anfwered expectations. It has not been fuperior to the incomparably more fimple dead fcapement of Graham. Indeed we think that it cannot. A part of the friction ftill remains, which cannot be removed; namely, while the arch *t a* is drawn from between the tooth and pallet. Nay, we apprehend that fomething more than friction muft be overcome here. The tooth is apt to force the detent outward, unlefs the part *t a* be a little elevated at its point *a* like a claw, above the concentric arch, and the face of the tooth be made to incline forward, fo as to fit this fhape of the detent. This will confume fome force, when the momentum of the pendulum is by no means at its maximum. Should the clock be foul, and the excurfions beyond fcapement be very fmall, this difturbance muft be exceedingly pernicious. But we have a much greater objection. During the whole excurfion beyond fcapement, there is a new force of a fpring acting on the pendulum, which deviates confiderably from the proportions of the accelerating power of gravity. It does not commence its action till the detent feparates from the arm of the crutch. Then the fpring of the detent acts as a retarding force againft the excurfion of the pendulum, now on the other fide, bringing it fooner to reft, and then accelerating it in its way back to the beginning of the arch of fcapement. In fhort, this conftruction fhould have the properties of a recoiling fcapement. We got a clock-maker to make fome experiments on one which he had made for an amateur, which fully confirmed our conjecture. When the detent fpring was ftrong, an increafe of maintaining power made the vibrations both wider and more rapid. The artift reduced the ftrength of the fpring till this effect was rendered very fmall. It might perhaps be quite removed by means of a ftill weaker fpring: But the fpring was already fo weak that a hard ftep on the floor of the room did fometimes difengage the detent from the wheel. It appears, therefore, that nothing can be reafonably expected from this conftruction that is not as well performed by the dead fcapement of Mr Graham, of much eafier execution, and more certain performance.

Very fimilar to this conftruction (at leaft in the excurfion beyond the angle of fcapement) is the conftruction of Mr Cumming, and it has the fame defects. His pallets are carried, as in the one defcribed, by the crutch. The detents prefs on them behind by their weight only: therefore, when the tooth is locked on the detent of one pallet, its weight is taken off from the pendulum on that fide, and the weight of the detent on the other fide oppofes the afcent, and accelerates the defcent of the pendulum.

Mr Cumming executed another fcapement, confifting, like thofe, of a pallet and detent. But the manner of applying the maintaining power is extremely different in principle from any yet defcribed. It is exceedingly ingenious, and feems to do all that is poffible for removing every fource of irregularity in the maintaining power, and every obftruction to free motion arifing from friction and oil in the fcapement. For this reafon we fhall give fuch an account of its effential circumftances as may fuffice to give a clear conception of its manner of acting, and its good properties and defects; but referring the inquifitive reader to Mr Cumming's Elements of Clock and Watch Work, publifhed in 1766, for a more full account.

In the fcapements laft defcribed, the pallets were fixed to the crutch and pendulum, and the maintaining power, during its action, was applied to the pendulum by means of the pallets, in the fame way as in ordinary fcapements. The detents were unconnected with the pendulum, and it was free during the whole excurfion. In the prefent fcapement both the pallets and detents are detached from the pendulum, except in the moment of unlocking the wheel; fo that the pendulum may be faid to be free during its whole vibration, except during this fhort moment.

ABC (fig. 9.) reprefents a portion of the fwing wheel, of which O is the centre, and A one of the teeth; Z is the centre of the crutch, pallets, and pendulum. The crutch or detents is reprefented of a form refembling the letter A, having in the circular crofs piece a flit *i k*, alfo circular, Z being the centre. This form is very different from Mr Cumming's, and inferior to his, but was adopted here in order to avoid a long defcription. The arm ZF forms the firft detent, and the tooth A is reprefented as locked on it at F. D is the firft pallet on the end of the arm Z *d* moveable round

round the fame centre with the detents, but moveable independently of them. The arm *d e*, to which the pallet D is attached, lies altogether behind the arm ZF of the detent, being fixed to a round piece of brafs *e f g*, which has pivots turning concentric with the verge or axis of the pendulum. To the fame round piece of brafs is fixed the horizontal arm *e* H, carrying at its extremity the ball H, of fuch fize, that the action of the tooth A on the pallet D is juft able (but without any rifk of failing) to raife it up to the pofition here drawn. ZP*p* reprefents the fork, or the pendulum rod, behind both detent and pallet. A pin *p* projects forward, coming through the flit *i k*, without touching the upper or under margin of it. There is alfo attached to the fork the arm *m n* (and a fimilar one on the other fide), of fuch length that, when the pendulum rod is perpendicular, as is reprefented here, the angular diftance of *n q* from the rod *e q* H is precifely equal to the angular diftance of the left fide of the pin *p* from the left end *i* of the flit *i k*.

The mode of action on this apparatus is abundantly fimple. The natural pofition of the pallet D is at *s*, reprefented by the dotted lines, refting on the back of the detent F. It is naturally brought into this pofition by its own weight, and ftill more by the weight of the ball H. The pallet D, being fet on the fore fide of the arm at Z, comes into the fame plane with the detent F and the fwing-wheel. It is drawn, however, in the figure in another pofition. The tooth C of the wheel is fuppofed to have efcaped from the fecond pallet, on which the tooth A immediately engages with the pallet D, fituated at *s*, forces it out, and then refts on the detent F, the pallet D leaning on the tip of the tooth. F is brought into this fituation in a way that will appear prefently. After the efcape of C, the pendulum, moving down the arch of femivibration, is reprefented as having attained the vertical pofition. Proceeding ftill to the left, the pin *p* reaches the extremity *i* of the flit *i k*; and, at the fame inftant, the arm *n* touches the rod *e* H in *q*. The pendulum proceeding a hair's breadth further, withdraws the detent F from the tooth, which now even pufhes off the detent, by acting on the flant face of it. The wheel being now unlocked, the tooth following C on the other fide acts on its pallet, pufhes it off, and refts on its detent, which has been rapidly brought into a proper pofition by the action of A on the flant face of F. It was a fimilar action of C on its detent, in the moment of efcape, which brought F into a fit pofition for locking the wheel by the tooth A. The pendulum ftill going on, the arm *m n* carries the weight of the ball H, and the pallet connected with it, and it comes to reft before the pin *p* again reaches the end of the flit, which had been fuddenly withdrawn from it by the action of A on the flant face of F. The pendulum now returns towards the right, loaded on the left with the ball H, which reftores the motion which it had loft during the laft vibration. When, by its motion to the right, the pin *p* reaches the end *k* of the flit *i k*, it unlocks the wheel on the right fide. At the fame inftant the weight H ceafes to act on the pendulum, being now raifed up from it by the action of a tooth like B on the pallet D.

Let us now confider the mechanifm of thefe motions. The prominent feature of the contrivance is the almoft complete difengagement of the regulator from the wheels. The wheels, indeed, act on the pallets; but the pallets are then detached from the pendulum. The fole ufe of the wheel is to raife the little weights while the pendulum is on the other fide, in order to have them in readinefs at the arrival of the pendulum. They are then laid on the pendulum, and fupply an accelerating force, which reftores to the pendulum the momentum loft during the preceding vibration. Therefore no inequalities in the action of the wheel on the pallets, whether arifing from friction or oil, has any effect on the maintaining power. It remains always the fame, namely, the rotative momentum of the two weights. The only circumftance, in which the irregularity of the action of the wheels can affect the pendulum is at the moment of unlocking. Here indeed the regulator may be affected; but this moment is fo fhort, in comparifon with other fcapements, that it muft be confidered as a real improvement.

It is very uncandid to refufe the author a claim to the character of an ingenious artift on account of this contrivance, as has been done by a very ingenious univerfity Profeffor, who taxes Mr Cumming with ignorance of the *firft elements of mechanics*, and fays that the beft thing in his book is his advice to fufpend the pendulum from a great block of marble, firmly fixed in the wall*. This is certainly a good advice, and we doubt not but that the Profeffor's clock would have performed ftill better if he had condefcended to follow it. It is ftill lefs candid to queftion the originality of the invention. We know for certain that it was invented at a time and place where the author *could* not know what had been done by others. It would have been more like the urbanity of a well-educated man to have acknowledged the genius, which, without fimilar advantages, had done fo much.

* See *Ludlam's Effay*.

But, while we thus pay the tribute of juftice to Mr Cumming, we do not adopt all his opinions. The clock has the fame defects of the former in refpect of the laws of the force which accelerates the pendulum. The fudden addition of the fmall weight, and this almoft at the extremity of the vibration, would derange it very much, if the addition were fufceptible of any fenfible variation. The irregularity of the action of the wheels *may* fenfibly affect the motion during the unlocking, when the clock is foul, and the pendulum *juft* able to unlock; for any difturbance at the extremity of the vibration greatly affects the time. We acknowledge that the parts which we here fuppofe to be foul may not be fo in the courfe of twenty years, thefe parts being only the pivots of the fcapement. The great defect of the fcapement is its liablenefs to unlock by any jolt. It is more fubject to this than the others already mentioned. This rifk is much increafed by the flender make of the parts, in Mr Cumming's drawings, and in the only clock of the kind we have feen; but this is not neceffary: and it fhould be avoided for another reafon; the interpofing fo many flender and crooked parts between the moving power and the pendulum weakens the communication of power, and requires a much more powerful wheelwork.

All thefe, however, are flight defects, and only the laft can be called a fault. The clocks made on this principle have gone remarkably well, as may be feen by the regifters of his majefty's private obfervatory. But the greateft objection is, that they do not perform better

Watch-work.

ter than a well-made dead ſcapement; and they are vaſtly more troubleſome to make and to manage. This is ſtrictly true, and is a ſerious objection. The fact is, that the dominion of a heavy pendulum is ſo great, that if *any one* of the ſcapements now deſcribed be well executed with pallets of agate, and a wheel of hard ſteel, and if the pendulum be ſuſpended agreeably to Mr Cumming's advice, there is hardly any difference to be obſerved in their performance. We ſhall content ourſelves with a ſingle proof of this from fact. The clock invented by the celebrated Harriſon is *at leaſt equal* in its performance to any other. Friction is almoſt annihilated, and no oil is required. It went fourteen years without being touched, and during that time did not vary one complete ſecond from one day to another, nor ever deviated half a minute by accumulation from equable motion: Yet the ſcapement, in ſo far as it reſpects the law of the accelerating force, deviates more from the proportion of the ſpaces than the moſt recoiling ſcapement that ever was put to a good clock. It is ſo different from all hitherto deſcribed, both in form and principle, that we muſt not omit ſome account of it, and with it we ſhall conclude our ſcapements for clocks.

Let GDO repreſent the ſwing-wheel, of which M is the centre. A is the verge or axis of the pendulum. It has two very ſhort arms AB, AE. A ſlender rod BC turns on fine pivots in the joint B, and has at its extremity C a hook or claw, which takes hold of a tooth D of the ſwing-wheel when the pendulum moves from the right ſide to the left. This claw, when at liberty, ſtands at right angles, or, at leaſt, in a certain determinate angle, with regard to the arm AB; and when drawn a little from that poſition, it is brought back to it again by a very ſlender ſpring. The arm AE is furniſhed with a detent EF, which alſo, when at liberty, maintains its poſition on the arm by means of a very ſlender ſpring.

Let us now ſuppoſe that the tooth D is preſſing on the claw C, while the pendulum is moving to the right. The joint B yields, by its motion round A, to the preſſure of the tooth on the claw. By this yielding, the angle ABC opens a little. In the mean time, the ſame motion round A cauſes the point F of the detent on the other ſide to approach the circumference of the wheel in the arch of a circle, and the tooth G at the ſame time advances. They meet, and the point of G is lodged in the notch under the projecting heel *f*. When this takes place, it is evident that any farther motion of the point E round A muſt puſh the tooth G a little backward, by means of the detent EF. It cannot come any nearer to the wheel, becauſe the point of the tooth ſtops the heel *f*. The inſtant that F puſhes G back, the tooth D is withdrawn from the claw C, and C flies out, by the action of its ſpring, and reſumes its poſition at right angles to BA; and the wheel is now free from the claw, but is puſhing at the detent F (c). The pendulum, having finiſhed its excurſion to the right (in which it cauſes the wheel to recoil by means of the detent F), returns toward the left. The wheel now advances again, and, by preſſing on F, aids the pendulum through the whole angle of ſcapement. By this motion the claw C deſcribes an arch of a circle round A, and approaches the wheel, till it take hold of another tooth, namely, the one following D, and pulls it back a little. This immediately frees the detent F from the preſſure of the tooth G, and it flies out a little from the wheel, reſuming its natural poſition by means of its ſpring. Soon after, the motion of the pendulum to the left ceaſes, and the pendulum returns; D pulling forward the hook C to aid the pendulum, and the former operation is repeated, &c. &c.

Such is the operation of the pallets of Harriſon and Hindley. Friction is almoſt totally avoided, and oil entirely (D). The motion is given to the pendulum by a fair pull or puſh, and the teeth of the wheel only apply themſelves to the detents without rubbing. There is no drop, and the ſcapement makes no noiſe, and is what the artiſts call *a ſilent ſcapement*. The mechanician will readily perceive, that by properly diſpoſing the arms AB, AE, and diſpoſing the pallets on the circumference of the wheel, the law, by which the action of the wheel on the pendulum is regulated, may be greatly varied, ſo as to harmonize, as far as the nature of ſcapement, alternately puſhing and pulling, will admit, with the action of gravity.

But this is evidently a recoiling ſcapement, and one of the worſt kind; for the recoil is made at the very confines of the vibration, where every diſturbance of the regular cycloidal vibration occaſions the greateſt diſturbance to the motion. Yet this clock kept time with moſt unexampled preciſion, far excelling all that had been made before, and equal to any that have been made ſince. This is entirely owing to the immenſe ſuperiority of the momentum of the pendulum over the maintaining power.

(c) The reader may here remark the manner in which the preſſure of the tooth G on the detent is transferred to the joint E by the intervention of the ſhank FE, and from the joint E to the pendulum rod, by the intervention of the arm EA. This communication of preſſure is preciſely the ſame that we made uſe of in explaining the common ſcapement. MG, FE, and EA, in this fig. 10. are performing the offices which we then gave to the lines MB, B !, and HA, in fig. 3. Harrriſon's pallet realiſes the abſtract theory.

(D) Mr Harriſon was at firſt by profeſſion a carpenter in a country place. Being extremely ingenious and inventive, he had made a variety of curious wooden clocks. He made one, in particular, for a turret in a gentleman's houſe. Its expoſure made it waſte oil very faſt, and the maker was often obliged to walk two or three miles to renew it, and got nothing for his trouble. In trudging home, not in very good humour, he pondered with himſelf how to make a clock go without oil. He changed all his pinion leaves into rollers; which anſwered very well But the pallets required it more than any other part. After various other projects, he contrived thoſe now repreſented, where there was no friction, and no oil is wanted. The turret clock continued to go without being touched till Mr Harriſon left the country.

II. *Of Scapements for a Watch.*

The execution of a proper ſcapement for watches is a far more delicate and difficult problem than the foregoing, on account of the ſmall ſize, which requires much more accurate workmanſhip, becauſe the error of the hundredth part of an inch has as great a proportion to the dimenſions of the regulator as an inch in a common houſe clock. It is much more difficult on another account. We have no ſuch means of accumulating ſuch a dominion (to uſe Mr Harriſon's expreſſive term) over the wheel-work in the regulator of a watch as in that of a clock. The heavieſt balance that we can employ, without the certainty of ſnapping its pivots by every ſlight jolt, is a mere trifle, in compariſon with the pendulum of the moſt ordinary clock. A dozen or twenty grains is the utmoſt weight of the balance, even of a very large pocket watch. The only way that we can accumulate any notable quantity of regulating power in ſuch a ſmall pittance of matter is by giving it a very great velocity. This we do by accumulating all its weight in the rim, by giving it very wide vibrations, and by making them extremely frequent. The balance-rim of a middling good watch ſhould paſs through at leaſt ten inches in every ſecond. Now, when we reflect on the ſmall momentum of this regulator, the inevitable inequalities of the maintaining power, and the great arch of vibration on which theſe inequalities will operate, and the comparative magnitude even of an almoſt inſenſible friction or clammineſs, it appears almoſt chimerical to expect any thing near to equability in the vibrations, and incredible that a watch can be made which will not vary more than one beat in 86400. Yet ſuch have been made. They muſt be conſidered as the moſt maſterly exertions of human art. The performance of a reflecting teleſcope is a great wonder: the worſt that can find a market muſt have its mirrors executed without an error of the ten-thouſandth part of an inch; but we now know that this accuracy is attained almoſt in ſpite of us, and that we ſcarcely *can* make them of a worſe figure. But the caſe is far otherwiſe in watch work. Here all thoſe wonderful approaches to perfection are the reſults of rational diſcuſſion, by means of ſound principles of ſcience; and, unleſs the artiſt who puts theſe principles into practice be more than a mere copyiſt, unleſs the principles themſelves are perceived by him, and actually direct his hand, the watch may ſtill be good for nothing. Surely, then, this is a liberal art, and far above a manual knack. The ſtudy of the means by which ſuch wonders are ſteadily effected, is therefore the ſtudy of a gentleman.

In the account given above of the ſcapements for pendulums, we aſſumed as one leading principle that *the natural vibrations of a pendulum are performed in equal times, whether wide or narrow.* This is ſo nearly true, when the arches on each ſide of the perpendicular do not exceed four degrees, that the retardation of the wider arches within that limit will not become ſenſible, though accumulated for a long time. The common ſcapement with a plane face of the pallet, helps to correct even this ſmall inequality much better than the niceſt form of the cycloidal cheeks propoſed by Huyghens.

In watch-work we aſſume a ſimilar principle, namely, that *the oſcillations of a balance, urged by its ſpring, and undiſturbed by all foreign forces, are performed in equal times, whether they be wide or narrow.* This principle was aſſumed by the celebrated mechanician Dr Robert Hooke, on the authority of many experiments which he had made on the bending and unbending of ſprings. He found that the force neceſſary for retaining a ſpring in any conſtrained poſition was proportional to its tenſion, or deflection from its natural form. He expreſſed this in an anagram, which he publiſhed about the year 1660, in order to eſtabliſh his claim to the diſcovery, and yet conceal it, till he had made ſome important application of it. When the anagram was explained ſome years afterwards, it was, "*Ut tenſio, ſic vis.*" Dr Hooke thought of applying this diſcovery to the regulation of watch movements. For, if a ſlender ſpring be *properly* applied to the axis of a watch balance, it will put that balance in a certain determinate poſition. If the balance be turned aſide from this poſition, it ſeems to follow that it will be urged back toward it by a force proportional to its diſtance from it. He immediately made the application to an old watch, which he afterward gave to Dr Wilkins, Biſhop of Cheſter. This was in 1658. Its motion was ſo amazingly improved, that Hooke was perſuaded of the perfection of his principle, and thought that nothing was now wanting for making a watch of this kind a perfect chronometer but the hand of a good workman. For his watch ſeemed almoſt perfect, though made in a ſmall country town, in a very coarſe manner. Mr Huyghens alſo claims this diſcovery. He publiſhed his claim about the year 1675, and propoſed to make watches for diſcovering the longitude of a ſhip at ſea. But there is the moſt unqueſtionable evidence of Dr Hooke's priority by fifteen years, and of his having made ſeveral watches of this kind. One of them was in the poſſeſſion of his majeſty king Charles II. Dr Hooke's firſt balance ſpring was ſtraight, and acted on the balance in a very imperfect manner. But he ſoon ſaw the imperfections, and made ſeveral ſucceſſive alterations; and, among others, he employed the cylindrical ſpiral now employed by Mr Arnold; but he gave it up for the flat ſpiral: and the king's watch had one of this kind before Mr Huyghens publiſhed his invention. His project of longitude watches had been carried on along with Lord Brouncker and Sir Robert Moray, and they had quarrelled ſome years before that publication. See Watch, *Encycl.*

But both Dr Hooke and Mr Huyghens were too ſanguine in their expectations. We, by no means, have the evidence for the truth of this principle that we have for the accelerating action of the gravity on a pendulum. It reſts on the nicety and the propriety of the experiments; and long experience has ſhewn that it is ſenſibly true only within certain limits. The demonſtrations by which Bernoulli ſupports the unqualified principle of Mr Huyghens, proceed on hypothetical doctrines concerning the nature of elaſticity. And even theſe ſhew that the law of elaſticity which he aſſumed was ſelected, not becauſe founded on ſimpler principles than any other, but becauſe it was conſiſtent with the experiments of Hooke and Huyghens. Beſides, although this ſhould be the true law of a ſpring, it does not follow that this ſpring, applied in *any way* to the axis of a balance, will urge that balance agreeably to the ſame law: and if it did, it ſtill does not follow that the oſcillations

Watch-work.

tions of the balance will be isochronous; for the force has to move not only the balance but also the spring. Part of the restoring force of the spring is employed in restoring it rapidly to its quiescent shape, and thus enabling it to *follow and still impel* the yielding balance. It is therefore only the surplus which is employed in actually moving the balance, and it is uncertain whether this surplus varies according to the same law, being always the same proportion of the whole force of the spring. We find it an extremely difficult problem to determine the law of variation of this surplus, even in the simplest form of the spring; nay, it is by no means an easy problem to determine the law of oscillation of a spring, unloaded with any balance; and we can easily shew that there are such forms of a spring, that although the velocity with which the different parts approach to their quiescent position be exactly as their excursion from it, this is by no means the law of velocity which this spring will produce in a balance. The matter of fact is, that when the spring is a simple straight steel wire, suspending the balance in the direction of its axis, the motions of it, if not immoderate, are precisely agreeable to Huyghens's and Hooke's rule; and that the motion of a balance urged by a spring wound up into a flat, or a cylindrical spiral, as in common watches, and those of Arnold, deviates sensibly from it, unless a certain analogy be preserved between the length and the elasticity of the spring. If the spring be immoderately long, the wide vibrations are slower than the narrow ones; and the contrary is observed when the spring is immoderately short. A certain taper, or gradual diminution of the spring, is also found to have an effect in equalizing the wide and narrow vibrations. There is also a great difference between the force with which a part of the spring unbends itself, and the action of that force in urging the balance round its axis; and the performance of many watches, good in other respects, is often faulty from the manner in which this unbending force is employed.

But, since these corrections are in our power in a considerable degree, we may suppose them applied, and the true motion (which we shall call the cycloidal) attained; and we may then adapt the construction of the scapement to the preserving this motion undisturbed. And here we must see at once that the problem is incomparably more delicate than in the case of pendulums. The vibrations must be very wide, and the angular motion rapid, that it may be little affected by external motions. The smallest inequalities of maintaining power acting through so great a space, must bear a considerable proportion to the very minute momentum of a watch balance. Oil is as clammy on the pallets of a watch as on those of a clock; a viscidity which would never be felt by a pendulum of 20 pounds weight will stop a balance of 20 grains altogether. For the same reason, it is evident that any impropriety in the form of the pallet must be incomparably more pernicious than in the case of a pendulum; the deviation which this may occasion from a force proportional to the angular distance from the middle point, must bear a great proportion to the whole force.

The common recoiling scapement of the old clocks still holds its place in the ordinary pocket watches, and answers all the common purposes of a watch very well. A well finished watch, with a recoiling scapement, will keep time within a minute in the day. This is enough for the ordinary affairs of life. But such watches are subject to great variation in their rate of going, by any change in the power of the wheels. This is evident; for if the watch be held back, or pressed forward, by the key applied to the fusee square, we hear the beating greatly retarded or accelerated. The maintaining power, in the best of such watches, is never less than one-fifth of the regulating power of the spring. For, if we take off the balance spring, and allow the balance to vibrate by the impulse of the wheels alone, we shall find the minute hand to go forward from 25 to 30 minutes per hour. Suppose it 30. Then, since the wheels act through equal spaces with or without a spring, the forces are as the squares of the acquired velocities. (DYNAMICS, *Suppl.* n° 95.) The velocity in this case is double; therefore the accelerating force is quadruple, and the force of the spring is three times that of the wheels. If the hand goes forward 25 minutes, the force of the wheels is about one-fifth of that of the spring. This great proportion is necessary, as already observed, that the watch may go as soon as unstopped.

We have but little to say on this scapement; its principle and manner of action, and its good and bad qualities, being the same with those of the similar scapement for pendulums. It is evident that the maintaining power being applied in the most direct manner, and during the whole of the vibration, it will have the greatest possible influence to move the balance. A given mainspring and train will keep in motion a heavier balance by means of this scapement than by any other. But, on the other hand, and for the same reason, the balance has less dominion over the wheel-work, and its vibrations are more affected by any irregularities of the wheel-work. Moreover, the chief action of the wheel being at the very extremities of the vibrations, and being very abrupt, the variations in its force are most hurtful to the isochronism of the vibrations.

Although this scapement is extremely simple, it is susceptible of more degrees of goodness or imperfection than almost any other, by the variation of the few particulars of its construction. We shall therefore briefly describe that construction which long experience has sanctioned as approaching near to the best performance that can be obtained from the common scapement. Fig. 11. represents it in what are thought its best proportions, as it appears when looking straight down on the end of the balance arbor. C is the centre of the balance and verge. CA and CB are the two pallets; CA being the upper pallet, or the one next to the balance, and CB being the lower one. F and D are two teeth of the crown wheel, moving from left to right; and E, G, are two teeth on the lower part of the circumference, moving from right to left. The tooth D is represented as just escaped from the point of CA, and the lower tooth E as just come in contact with the lower pallet. The scapement should not, however, be quite so close, because an inequality on the teeth might prevent D from escaping at all. For if E touch the pallet CB before D has quitted CA, all will stand still. This fault will be corrected by withdrawing the wheel a little from the verge, or by shortening the pallets.

The proportions are as follow. The distance between the front of the teeth (that is, of G, F, E, D,) and

 the

the axis C of the balance is one-fifth of FA, the diftance between the points of the teeth. The length CA, CB of the pallets is three-fifths of the fame diftance. The pallets make an angle ACB of 95 degrees, and the front DH or FK of the teeth make an angle of 25° with the axis of the crown wheel. The floping fide of the tooth muft be of an epicycloidal form, fuited to the relative motion of the tooth and pallet.

From thefe proportions it appears that the pallet A can *throw out*, by the action of the tooth D, till it reaches *a*, 120 degrees from CL, the line of the crown-wheel axis. For it can throw out till the pallet B ftrike againft the front of E, which is inclined 25° to CL. To this add BCA, = 95°, and we have LC *a* = 120. In like manner B will throw out as far on the other fide. From 240°, the fum of thefe angles, take the angle of the pallets 95°, and there remains 145° for the greateft vibration which the balance can make without ftriking the front of the teeth. This extent of vibration fuppofes the teeth to terminate in points, and the acting furfaces of the pallets to be planes directed to the very axis of the verge. But the points of the teeth muft be rounded off a little for ftrength, and to diminifh friction on the face of the pallets. This diminifhes the angle of fcapement very confiderably, by fhortening the teeth. Moreover, we muft by no means allow the point of the pallet to bank or ftrike on the forefide of a tooth. This would greatly derange the vibration by the violence and abruptnefs of the check which the wheel would give to the pallet. This circumftance makes it improper to continue the vibrations much beyond the angle of fcapement. One-third of a circle, or 120°, is therefore reckoned a very proper vibration for a fcapement made in thefe proportions. The impulfe of the wheels, or the angle of fcapement, may be increafed by making the face of the pallets a little concave (preferving the fame angle at the centre). The vibration may alfo be widened by pufhing the wheel nearer to the verge. This would alfo diminifh the recoil. Indeed this may be entirely removed by bringing the front of the wheel up to C, and making the face of the pallet not a radius, but parallel to a radius and behind it, *i. e.* by placing the pallet CA fo that its acting face may be where its back is juft now. In this cafe, the tooth D would drop on it at the centre, and lie there at reft, while the balance completes its vibration. But this would make the banking (as the ftroke is called) on the teeth almoft unavoidable. In fhort, after varying every circumftance in every poffible manner, the beft makers have fettled on a fcapement very nearly fuch as we have defcribed. Precife rules can fcarcely be given; becaufe the law by which the force acting on the pallets varies in its intenfity, deviates fo widely from the action of the balance fpring, efpecially near the limits of the excurfions.

The difcoveries of Huyghens and Newton in rational mechanics engaged all the mathematical philofophers of Europe in the folution of mechanical problems, about the end of the laft century. The vibrations of elaftic plates or wires, and their influence on watch balances, became familiar to every body. The great requifites for producing ifochronous vibrations were well underftood, and the artifts were prompted by the fpeculatifts to attempt conftructions of fcapements proper for this purpofe. It appeared clearly, that the moft effectual means for this purpofe was to leave the balance unconnected with the wheels, efpecially near the extremities of the vibration, where the motion is languid, and where every inequality of maintaining power muft act for a longer time, and therefore have a great effect on the whole duration of the vibrations. The maxim of conftruction that naturally arifes from thefe reflections is to *confine*, if poffible, *the action of the wheels to the middle of the vibration*, where the motion is rapid, and where the chief effect of an increafe or diminution of the maintaining power will be to enlarge or contract the angular motions, but will make little change on their duration; becaufe the greateft part of the motion will be effected by the balance fpring alone. This maxim was inculcated in exprefs terms by John Bernoulli, in his *Recherches Mechaniques et Phyfiques*; but it had been fuggefted by common fenfe to feveral unlettered artifts before that time. About the beginning of this century watches were made in London, where the verge had a portion *e d b* (fig. 12.) of a fmall cylinder, having its centre *c* in the axis, and a radial pallet *b a* proceeding from it. Suppofe a tooth juft efcaped from the point of the pallet, moving in the direction *b d e*, the cylindrical part was fo fituated that the next tooth dropped on it at a fmall diftance from its termination. While the verge continues turning in the direction *b d e*, the tooth continues refting on the cylinder, and the balance fuftains no *action* from the wheels, and has only to overcome the minute frictions on the polifhed furface of a hard fteel cylinder. This motion may perhaps continue till the pallet acquires the pofition *f*, almoft touching the tooth. It then ftops, its motion being extinguifhed by the increafing force of the fpring. It now returns, moving in the direction *e d b*; and when the pallet has acquired the pofition *c i*, the tooth *g* quits the circumference of the cylinder, and drops in on the pallet at the very centre. The crooked form of the tooth allows the pallet to proceed ftill farther, before there is any danger of banking on the tooth. This vibration being alfo ended, the balance refumes its firft direction, and the tooth now acts on the face of the pallet, and reftores to the balance all the motion which it had loft by friction, &c. during the two preceding vibrations.

It is evident that this conftruction obviates all the objections to the former recoiling fcapement, and that, by fufficiently diminifhing the diameter of the cylindrical part, the friction may be reduced to a very fmall quantity, and the balance be made to move by the action of the fpring during the whole of the excurfion, and of the returning vibration. Yet this conftruction does not feem to have come much into ufe, owing, in all probability, to the great difficulty of making the drop fo accurate in all the teeth. The fmalleft inequality in the length of a tooth would occafion it to drop fooner or later; and if the cylinder was made very fmall, to diminifh friction, the formation of the notch was almoft a microfcopical operation, and the fmalleft fhake in the axis of the verge or the balance-wheel would make the tooth flip paft the cylinder, and the watch run down amain.

About the fame time, a French artift in London (then the fchool of this art) formed another fcapement, with the fame views. We have not any diftinct account of it, but are only informed (in the 7th volume of the *Machines approuvées par l'Acad. des Sciences*) that the tooth

Watch-work.

tooth refted on the furface of a hollow cylinder, and then efcaped by acting on the inclined edge of it. But we may prefume that it had merit, being there told that Sir Ifaac Newton wore a watch of this kind.

A much fuperior fcapement, on the fame principle, was invented by Mr Geo. Graham, at the fame time that he changed the recoiling fcapement for pendulums into the dead beat. Indeed it is the fame fcapement, accommodated to the large vibrations of a balance. In fig. 13. DE reprefents part of the rim of the balance-wheel. A and C are two of its teeth, having their faces *b e* formed into planes, inclined to the circumference of the wheel, in an angle of about 15 degrees; fo that the length *b e* of the face is nearly quadruple of its height *e m*. Suppofe a circular arch ABC defcribed round the centre of the wheel, and through the middle of the faces of the teeth. The axis of the balance paffes thro' fome point B of this arch, and we may fay that the mean circumference of the teeth paffes through the centre of the verge. On this axis is fixed a portion of a thin hollow cylinder *b c d*, made of hard tempered fteel, or of fome hard and tough ftone, fuch as ruby or fapphire. Agates, though very hard, are brittle. Chalcedony and cornelian are tough, but inferior in hardnefs. This cylinder is fo placed on the verge, that when the balance is in its quiefcent pofition, the two edges *b* and *d* are in the circumference which paffes through the points of the teeth. By this conftruction the portion of the cylinder will occupy 210° of the circumference, or 30° more than a femicircle. The edge *b*, to which the tooth approaches from without, is rounded off on both angles. The other edge *d* is formed into a plane, inclined to the radius about 30°.

Now, fuppofe the wheel preffed forward in the direction AC. The point *b* of the tooth, touching the rounded edge, will pufh it outwards, turning the balance round in the direction *b c d*. The heel *e* of the tooth will efcape from this edge when it is in the pofition *h*, and *e* is in the pofition *f*. The point *b* of the tooth is now at *d*, but the edge of the cylinder has now got to *i*. The tooth, therefore, refts on the infide of the cylinder, while the balance continues its vibration a little way, in confequence of the fhove which it has received from the action of the inclined plane pufhing it out of the way, as the mould board of a plough fhoves a ftone afide. When this vibration is ended, by the oppofition of the balance-fpring, the balance returns, the tooth (now in the pofition B) rubbing all the while on the infide of the cylinder. The balance comes back into its natural pofition *b c d*, with an accelerated motion, by the action of its fpring, and would, of itfelf, vibrate as far, at leaft, on the other fide. But it is aided again by the tooth, which, preffing on the edge *d*, pufhes it afide, till it come into the pofition *k*, when the tooth efcapes from the cylinder altogether. At this moment the other edge of the cylinder is in the pofition *l*, and therefore is in the way of the next tooth, now in the pofition A. The balance continues its vibration, the tooth all the while refting, and rubbing on the outfide of the cylinder. When this vibration, in the direction *d c b*, is finifhed, the balance refumes its firft motion *b c d*, by the action of the fpring, and the tooth begins to act on the firft edge *b*, as foon as the balance gets into its natural pofition, fhoves it afide, efcapes from it, and drops on the infide of the cylinder. In this manner are the vibrations produced, gradually increafed to their maximum, and maintained in that ftate. Every fucceeding tooth of the wheel acts firft on the edge *b*, and then on the edge *d*; refting firft on the outfide, and then on the infide of the cylinder. The balance is under the influence of the wheels while the edge *b* paffes to *h*, and while *d* paffes to *k*; and the reft of the vibration is performed without any *action* on the part of the wheels, but is a little obftructed by friction, and by the clamminefs of the oil. In the conftruction now defcribed, the arch of action or fcapement is evidently 30°, being twice the angle which the face of a tooth makes with the circumference.

The reader will perceive, that when this fcapement is executed in fuch a manner that the fucceeding tooth is in contact with the cylinder at the inftant that the preceding one efcapes from it, the face of the tooth muft be equal to the infide diameter of the cylinder, and that the diftance between the heel of one tooth and the point of the following one muft be equal to the outfide diameter. When the fcapement is fo clofe there is no drop. A good artift approaches as near to this adjuftment as poffible; becaufe, while a tooth is dropping, but not yet in contact, it is not acting on the balance, and fome force is loft. The execution is accounted very good, if the diftance between the centres of two teeth is twice the external diameter of the cylinder. This allows a drop equal to the thicknefs of the cylinder, which is about $\frac{1}{25}$th of its diameter.

We muft alfo explain how this cylinder is fo connected with the verge as to make fuch a great revolution round the tooth of the wheel. The triangular tooth *e b m* is placed on the top of a little pillar or pin fixed into the extremity of the piece of brafs *m* D formed on the rim of the wheel. Thus the wedge-tooth has its plane parallel to the plane of the wheel, but at a fmall diftance above it. Fig. B reprefents the verge, a long hollow cylinder of hard fteel. A great portion of the metal is cut out. If it were fpread out flat, it would have the fhape of fig. C. Suppofe this rolled up till the edges GH and G'H' are joined, and we have the exact form. The part acted on by the point of the tooth is the dotted line *b d*. The part DIFE' ferves to connect the two ends. Thus it appears to be a very flender and delicate piece; but being of tempered fteel, it is ftrong enough to refift moderate jolts. The ruby cylinders are much more delicate.

Such is the cylinder fcapement of Mr Graham, called alfo the HORIZONTAL SCAPEMENT, becaufe the balance wheel is parallel to the others. Let us fee how far it may be expected to anfwer the intended purpofes. If the excurfions of the balance beyond the angle of impulfion were made altogether unconnected with the wheels, the *whole vibration* would be quicker than one of the fame extent, made by the action of the balance-fpring alone, becaufe the middle part of it is accelerated by the wheels. But the excurfions are obftructed by friction and the clamminefs of oil. The effect of this in *obftructing* the motion is very confiderable. Mr Le Roy placed the balance fo, that it refted when the point of the tooth was on the middle of the cylindric furface. When the wheel was allowed to prefs on it, and it was drawn 80° from this pofition, it vibrated only during $4\frac{1}{2}$ feconds. When the wheel was not allowed to touch the cylinder, it vibrated 90 feconds, or 20 times as long;

Watch-work.

long; so much did the friction on the cylinder exceed that of the pivots. We are not sufficiently acquainted with the laws of either of these obstructions to pronounce decidedly whether they will increase or diminish the *time* of the whole vibrations. We observe distinctly, in motions with considerable friction, that it does not increase nearly so fast as the velocity of the motion; nay, it is often less when the velocity is very great. In all cases it is observed to terminate motions abruptly. The friction requires a certain force to overcome it, and if the body has any less it will stop. Now this will not only contract the excursion of the balance, but will shorten the time. But the return to the angle of impulsion will undoubtedly be of longer duration than the excursion; for the arch of return, from the extremity of the excursion to its beginning, where the angle of impulsion ends, is the same with the arch of excursion. The velocity which the balance has in any point of the return is less than what it had in the same point of the excursion; because, in the excursion, it had velocity enough to carry it to the extremity, and also to overcome the friction. In the return, it could, even without friction, only have the velocity which would have carried it to the extremity; and this smaller velocity is diminished by friction during the return. The velocity being less through the whole return than during the excursion, the time must be greater. It may therefore happen that this retardation of the return may compensate the contraction of the excursion and the diminution of its duration. In this case the vibration will occupy the same time as if the balance had been free from the wheels. But it may more than compensate, and the vibrations will then be slower; or it may not fully compensate, and they will be quicker. We cannot therefore say, *à priori*, which of the two will happen: but we may venture to say that an increase of the force of the wheels will make the watch go slower: for this will exert a greater pressure, give a greater impulsion, produce a wider excursion, and increase the friction during that greater excursion, making the wide vibrations slower than the narrow ones; because the angle of impulsion remaining the same, the pressures exerted must be quadrupled, in order to double the excursion (See DYNAMICS, n° 95. *Suppl.*), and therefore the friction will be increased in a greater proportion than the momentum which is to overcome it. But, with respect to the obstruction arising from the viscidity of the oil, we know that it follows a very different law. It bears a manifest relation to the velocity, and is nearly proportional to it. But still it is difficult to say how this will affect the whole vibration. The duration of the excursion will not be so much contracted as by an equal obstruction from friction, because it will not terminate the motion abruptly. There are therefore more chances of the increased duration of the return exceeding the diminution of it in the excursion. All that we can say, therefore, is, that there will be a compensation in both cases. The time of excursion will be contracted, and that of return augmented.

Now, as the friction may be greatly diminished by fine polish, fine oil, and a small diameter of the cylinder, we may reasonably expect that the vibrations of such a balance will not vary nearly so much from isochronism as with a recoiling scapement, and will be little affected by changes in the force of the wheels. Accordingly, Graham's cylindrical scapement supplanted all others as soon as it was generally known. We cannot compare the vibrations with those of a free balance, because we have no way of making a free balance vibrate for some hours. But we find that doubling or trebling the force of the wheels makes very little alteration in the rate of the watch, though it greatly enlarges the angular motion. Any one may perceive the immense superiority of this scapement over the common recoiling scapement, by pressing forward the movement of a horizontal watch with the key, or by keeping it back. No great change can be observed in the frequency of the beats, however hard we press. But a more careful examination shews that an increase of the power of the wheels generally causes the watch to go slower; and that this is more remarkable as the watch has been long going without being cleaned. This shews that the cause is to be ascribed to the friction and oil operating on the wide arches of excursion. But when this scapement is well executed, in the best proportions of the parts, the performance is extremely good. We know such watches, which have continued for several weeks without ever varying more than 7′ in one day from equable motion. We have seen one whose cylinder was not concentric with the balance, but so placed on the verge that the axis of the verge was at *o* (fig. 13.), between the centre B of the cylinder and the entering edge *b*, and B*e* was equal to the thickness of the cylinder. The watch was made by Emery of London, and was said to go with astonishing regularity, so as to equal any time-piece while the temperature of the air did not vary; and when clean, was said to be less affected by the temperature than a watch with a free scapement, but unprovided with a compensation piece. It is evident that this watch must have a minute recoil. This was said to be the aim of the artist, in order to compensate for the obstruction caused by friction during the return of the balance from its excursions. It indeed promises to have this effect; but we should fear that it subjects the excursions to the influence of the wheels. We suspect that the indifferent performance of cylinder watches may often arise from the cylinder being off the centre in some disadvantageous manner.

The watch from which the proportions here stated were taken, is a very fine one made by Graham for Archibald Duke of Argyle, which has kept time with the regularity now mentioned. We believe that there are but few watches which have so large a portion of the cylinder: few indeed have more than one half, or 180° of the circumference. But this is too little. The tooth of the wheel does not begin to act on the resting cylinder till its middle point A or B touch one of the edges. To obtain the same angle of scapement, the inclination of the face of the tooth must be increased (it must be doubled); and this requires the maintaining power to be increased in the same proportion. Besides, in such a scapement it may happen that the tooth will never rest on the cylinder; because the instant that it quits one edge it falls on the other, and pushes it aside, so that the balance acquires no wider vibration than the angle of scapement, and is continually under the influence of the wheels. The scapement is in its best state when the portion of the cylinder exceeds 180° by twice the inclination of the teeth to the circumference of the wheel.

It

It would employ volumes to defcribe all the fcapements which have been contrived by different artifts, aiming at the fame points which Graham had in view. We fhall only take notice of fuch as have fome effential difference in principle.

Fig. 14. reprefents a fcapement invented in France, and called the *Echappement à Virgule*, becaufe the pallet refembles a comma. The teeth A, B, C, of the balance wheel are fet very oblique to the radius, and there is formed on the point of each a pin, ftanding up perpendicular to the plane of the wheel. This greatly refembles the wheel of Graham's fcapement, when the triangular wedge is cut off from the top of the pin on which it ftands. The axis *c* of the verge is placed in the circumference paffing through the pins. The pallet is a plate of hard fteel *a e f d b*, having its plane parallel to the plane of the wheel. The inner edge of this plate is formed into a concave cylindrical furface between *o* and *b*, whofe axis *c* coincides with the axis of the verge. Adjoining to this is the acting face *b d* of the pallet. This is either a ftraight line *b d*, making an angle of nearly 30° with a line *c b g* drawn from the centre, or it is more generally curved, according to the noftrum of the artift. The back of the pallet *a e f* is alfo a cylindrical furface (convex) concentric with the other. This extends about 100° from *a* to *f*. The part between *f* and *d* may have any fhape. The interval *a o* is formed into a convex furface, in fuch a manner as to be everywhere interfected by the radius in an angle of 30° nearly; *i. e.* it is a portion of an equiangular fpiral. The whole of this is connected with the verge by a crank, which paffes perpendicularly through it between *f* and *e*; and the plate is fet at fuch height on the crank or verge, that it can turn round clear of the wheel, but not clear of the pins. The teeth of the wheel are fet fo obliquely, and made fo flender, that the verge may turn almoft quite round without the crank's banking on the teeth. The part *f d b*, called the horn, is of fuch a length, that when one pin B refts on the outfide cylinder at *a*, the point *d* is juft clear of the next pin A.

When the wheel is not acting, and the balance-fpring is in equilibrio, the pofition of the balance is fuch that the point *d* of the horn is near *i*, about 30° from *d*. The figure reprefents it in the pofition which it has when the tooth A has juft efcaped from the point *d* of the horn. In this pofition the next tooth B is applied to the convex cylinder, a very little way (about 5°) from its extremity *a*. This defcription will enable the reader to underftand the operation of the virgule fcapement.

Now fuppofe the pin A juft efcaped from the horn. The fucceeding pin B is now in contact with the back of the cylinder; and the balance, having got an impulfe by the action of A along the concave pallet *b d*, continues its motion in the direction *d g h*, till its force is fpent, the point of the horn arriving perhaps at *h*, more than 90° from *d*. All this while the following tooth B is refting on the back *e f* of the cylinder. The balance now returns, by the action of its fpring; and when the horn is at *i*, the pin gets over the edge *a o*, and drops on the oppofite fide of the concave cylinder, where it refts, while the horn moves from *i* to *k*, where it ftops, the force of the balance being again fpent. The balance then returns; and when the horn comes within 30° of *d*, the pin gets out of the hollow cylinder, fhoves the horn out of its way, and efcapes at *d*. Befides the impulfe which the balance receives by the action of the wheel on the horn *b d*, there is another, though fmaller, action in the contrary direction, while the point of B paffes over the furface *a o*; for this furface being inclined to the radius, the preffure on it urges the balance round in the direction *h d i*.

The chief difference of this fcapement from the former is, that the inclined plane is taken from the teeth of the wheel, and placed on the verge. This alone is a confiderable improvement; for it is difficult to fhape all the teeth alike; whereas the horn *b d* is invariable. Moreover, the refting parts, although they be drawn large in this figure for the fake of diftinctnefs, may be made vaftly fmaller than Graham's cylinder, which muft be big enough to hold a tooth within it. By this change, the friction, during the repofe of the wheel, that is, during the excurfions of the balance, may be vaftly diminifhed. The infide cylinder need be no bigger than to receive the pin. But although the performance of thefe fcapements is excellent, they have not come into general ufe in this country. The caufe feems to be the great nicety requifite in making the pins of the wheel pafs exactly through the axis of the verge. The leaft fhake in the pivots of the balance and balance wheel muft greatly change the action. A very minute increafe of diftance between the pivots will caufe the pin B to flide from the edge *a* to the horn, without refting at all on the infide cylinder; and when it does fo, it will ftop the balance at once, and, immediately after, the watch will run down. The fame irregularities will happen if all the pins be not at precifely the fame diftance from the axis of the wheel.

This fcapement was greatly improved, and, in appearance, totally changed, by Mr Lepaute of Paris in 1753. By placing the pins alternately on the two fides of the rim of the balance-wheel, he avoided the ufe of the outfide cylinder altogether. The fcapement is of fuch a fingular form, that it is not eafy to reprefent it by any drawing. We fhall endeavour, however, to defcribe it in fuch a manner as that our readers, who are not artifts, will underftand its manner of acting. Artifts by profeffion will eafily comprehend how the parts may be united which we reprefent as feparate.

Let ABC (fig. 15.) reprefent part of the rim of the balance-wheel, having the pins 1, 2, 3, 4, 5, &c. projecting from its faces; the pins 1, 3, 5, being on the fide next the eye, but the pins 2 and 4 on the farther fide. D is the centre of the balance and verge, and the fmall circle round D reprefents its thicknefs. But the verge in this place is crooked, like a crank, that the rim of the wheel may not be interrupted by it. This will be more particularly defcribed by and bye. There is attached to it a piece of hard tempered fteel *a b c d*, of which the part *a b c* is a concave arch of a circle, having D for its centre. It wants about 30° of a femicircle. The reft of it *c d* is alfo an arch of a circle, having the fame radius with the balance-wheel. The natural pofition of the balance is fuch, that a line drawn from D, through the middle of the face *c d*, is a tangent to the circumference of the wheel. But, fuppofe the balance turned round till the point *d* of the horn comes to *d'*, and the point *c* comes to 2, in the circumference in which the pins are placed. Then the pin,

pin, preſſing on the beginning of the horn or pallet, puſhes it aſide, ſlides along it, and eſcapes at *d*, after having generated a certain velocity in the balance. So far this ſcapement is like the virgule ſcapement deſcribed already. But now let another pallet, ſimilar to the one now deſcribed, be placed on the other ſide of the wheel, but in a contrary poſition, with the acting face of the pallet turned away from the centre of the wheel. Let it be ſo placed at E, that the moment that the pin 1, on the upper ſide of the wheel, eſcapes from the pallet *c d*, the pin 4, on the under ſide of the wheel, falls on the end of the circular arch *e f g* of the other pallet. Let the two pallets be connected by means of equal pulleys G and F on the axis of each, and a thread round both, ſo that they ſhall turn one way. The balance on the axis D, having gotten an impulſe from the action of the pin 1, will continue its motion from A towards *i*, and will carry the other pallet with a ſimilar motion round the centre E from *h* towards *k*. The pin 4 will therefore reſt on the concave arch *g f e* as the pallet turns round. When the force of the balance is ſpent, the pallet *c d* returns towards its firſt poſition. The pallet *g h* turns along with it; and when the point of the firſt has arrived at *d*, the beginning *g* of the other arrives at the pin 4; and, proceeding a little farther, this pin eſcapes from the concave arch *e f g*, and ſlides along the pallet *g h*, puſhing it aſide, and therefore urging the pallet round the centre E, and conſequently (by means of the connection of the pulleys) urging the balance on the axis D round at the ſame time, and in the ſame direction. The pin 4 eſcapes from the pallet *g h*, when *h* arrives at 3; but in the time that the pin 4 was ſliding along the yielding pallet *g h*, the pin 3 is moving in the circumference BDA; and the inſtant that the pin 4 eſcapes from *h* at 3, the pin 3 arrives at 2, and finds the beginning *c* of the concave arch *c b a* ready to receive it. It therefore reſts on this arch, while the balance continues its motion. This perhaps continues till the point *b* of the arch comes to 2. The balance now ſtops, its force being ſpent, and then returns; and the pin 3 eſcapes from the circle at *c*, ſlides along the yielding pallet *c d*, and when it eſcapes at 1, another pin on the under ſide of the wheel arrives at 4, and finds the arch *g f e* ready to receive it. And in this manner will the vibration of the balance be continued.

This deſcription of the mode of action at the ſame time points out the dimenſions which muſt be given to the parts of the pallet. The length of the pallet *c d* or *g h* muſt be equal to the interval between two ſucceeding pins, and the diſtance of the centres D and E muſt be double of this. The radius D*e* or E *g* may be as ſmall as we pleaſe. The concave arches *c b a* and *g f e* muſt be continued far enough to keep a pin reſting on them during the whole excurſion to the balance. The angle of ſcapement, in which the balance is under the influence of the wheels, is had by drawing D *c* and D *d*. This angle *c* D *d* is about 30°, but may be made greater or leſs.

Fig. B will give ſome notion how the two pallets may be combined on one verge. KL repreſents the verge with a pivot at each end It is bent into a crank MNO, to admit the balance wheel between its branches. BC repreſents this wheel, ſeen edgewiſe, with its pins, alternately on different ſides. The pallets are alſo repreſented edgewiſe by *b c d* and *h g f*, fixed to the inſide of the branches of the crank, fronting each other. The poſition of their acting faces may be ſeen in the preceding figure, on the verge D, where the pallet *g h* is repreſented by the dotted line 2 *i*, as being ſituated behind the pallet *c d*. The remote pallet 2 *i* is placed ſo, that when the point *d* of the near pallet is juſt quitted by a pin 1 on the upper ſide of the wheel, the angle formed by the face and the arch of reſt of the other pallet is juſt ready to receive the next pin 2, which lies on the under ſide of the rim. A little attention will make it plain, that the action will be preciſely the ſame as when the pallets were on ſeparate axes. The pin 1 eſcapes from *d*, and the pin 2 is received on the arch of reſt, and locks the wheel while the balance is continuing its motion. When it returns, 2 gets off the arch of reſt, puſhes aſide the pallet 2 *i*, eſcapes from it when *i* gets to 1, and then the pin 3 finds the point *c* ready to receive it, &c. The vibrations may be increaſed by giving a ſufficient impulſe through the angle of ſcapement. But they cannot be more than a certain quantity, otherwiſe the top N of the crank will ſtrike the rim of the wheel. By placing the pins at the very edge of the wheel, the vibrations may eaſily be increaſed to a ſemicircle. By placing them at the points of long teeth, the crank may get in between them, and the vibrations extended ſtill farther, perhaps to 240°.

This ſcapement is unqueſtionably a very good one; and when equally well executed, ſhould excel Graham's both by having but two acting faces to form (and theſe of hard ſteel or of ſtone), and by allowing us to make the circle of reſt exceedingly ſmall without diminiſhing the acting face of the pallet. This will greatly diminiſh the friction and the influence of oil. But, on the other hand, we apprehend that it is of very difficult execution. The figure of the pallets, in a manner that ſhall be ſuſceptible of adjuſtment and removal for repair, and yet ſufficiently accurate and ſteady, ſeems to us a very delicate job.

Mr Cumming, in his Elements of Clock and Watch-work, deſcribes (ſlightly) pallets of the very ſame conſtruction, making what he conceives to be conſiderable improvements in the form of the acting faces and the curves of reſt. He has alſo made ſome watches with this ſcapement; but they were ſo difficult, that few workmen can be found fit for the taſk; and they are exceedingly delicate, and apt to be put out of order. The connection of the pallets with each other, and with the verge, makes the whole ſuch a contorted figure, that it is eaſily bent and twiſted by any jolt or unſkilful handling.

There remains another ſcapement of this kind, having the tooth of the balance-wheel reſting on a cylindrical ſurface on the axis of the verge during the excurſion, of the balance beyond the angle of ſcapement, and which differs ſomewhat in the application of the maintaining power from all thoſe already deſcribed.

This is known by the name of *Dupleix's ſcapement*, and is as follows: Fig. 16. repreſents the eſſential parts greatly magnified. AD is a portion of the balance-wheel, having teeth *f*, *b*, *g*, at the circumference. Theſe teeth are entirely for producing the *reſt* of the wheel, while the balance is making excurſions beyond the ſcapement. This is effected by means of an agate cylinder *o p q*, on the verge. This cylinder has a notch *o*. When the cylinder turns round in the direction *o p q*, the notch eaſily paſſes the tooth B which is reſting on the cylindric ſurface; but when it returns in the direction *q p o*, the tooth B gets into the notch, and follows it, preſſing on one ſide of it till the notch comes into the poſition *o*. The tooth being then in the poſition *b*, eſcapes from the notch, and another tooth drops on the convex ſurface of the cylinder at B.

The balance-wheel is alſo furniſhed with a ſet of ſtout flat ſided pins, ſtanding upright on its rim, as repreſented by *a*, D. There is alſo fixed on the verge a larger cylinder GFC above the ſmaller one *o p q*, with its under ſurface clear of the wheel, and having a pallet C, of ruby or ſapphire, firmly indented into it, and projecting ſo far as juſt to keep clear of the pins on the wheel. The poſition of this cylinder, with reſpect to the ſmaller one below it, is ſuch that, when the tooth *b* is eſcaped from the notch, the pallet C has juſt paſſed the pin *a*, which was at A while B reſted on the ſmall cylinder; but it moved from A to *a*, while B moved to *b*. The wheel being now at liberty, the pin *a* exerts its preſſure on the pallet C in the moſt direct and advantageous manner, and gives it a ſtrong impulſion, following and accelerating it till another tooth ſtops on the little cylinder. The angle of ſcapement depends partly on the projection of the pallet, and partly on the diameter of the ſmall cylinder and the advance of the tooth B into the notch. Independent of the action on the ſmall cylinder, the angle of ſcapement would be the whole arch of the large cylinder between C and *x*. But *a* ſtops before it is clear of the pallet, and the arch of impulſion is ſhortened by all the ſpace that is deſcribed by the pin while a tooth moves from B to *b*. It ſtops at *a'*.

We are informed by the beſt artiſts, that this ſcapement gives great ſatisfaction, and equals, if it do not excel, Graham's cylindrical ſcapement. It is eaſier made, and requires very little oil on the ſmall cylinder, and none at all on the pallet. They ſay that it is the beſt for pocket watches, and is coming every day more into repute. Theory ſeems to accord with this character. The reſting cylinder may be made very ſmall, and the direct impulſe on the pallet gives it a great ſuperiority over all thoſe already deſcribed, where the action on the pallet is oblique, and therefore much force is loſt by the influence of oil. But we fear that much force is loſt by the tooth B ſhifting its place, and thus ſhortening the arch of impulſion; for we cannot reckon much on the action of B on the ſide of the notch, becauſe the lever is ſo extremely ſhort. Accordingly, all the watches which we have ſeen of this kind have a very ſtrong main ſpring in proportion to the ſize and vibration of the balance. If we leſſen this diminution of the angle of impulſion, by leſſening the cylinder *o p q*, and by not allowing B to penetrate far into the notch, the ſmalleſt inequality of the teeth, or ſhake in the pivots of the balance or wheel, will cauſe irregularity, and even uncertainties in the locking and unlocking the wheel by this cylinder.

A ſcapement exceedingly like this was applied long ago by Dutertre, a French artiſt, to a pendulum. The only difference is, that in the pendulum ſcapement the ſmall cylinder is cut through to the centre, half of it only being left; but the pendulum ſcapement gives a more effective employment of the maintaining power, becauſe the wheel acts on the pallet during the *whole* of the aſſiſted vibration. In a balance ſcapement, if we attempt to diminiſh the inefficient motion of the pin from A to *a*, by leſſening the diameter of the ſmall cylinder, the hold given to the tooth in the notch will be ſo trifling, that the tooth will be thrown out by the ſmalleſt play in the pivot holes, or inequality in the length of the teeth.

With this we conclude our account of ſcapements, where the action of the maintaining power on the balance is ſuſpended during the excurſion beyond the angle of impulſion, by making a tooth reſt on the ſurface of a ſmall concentric cylinder. In ſuch ſcapements, the balance, during its excurſions, is almoſt free from any connection with the wheels, and its iſochroniſm is diſturbed by nothing but the friction on this ſurface.—We come now to ſcapements of more artful conſtruction, in which the balance is really and completely free during the whole of its excurſion, being altogether diſengaged from the wheelwork. Theſe are called DETACHED SCAPEMENTS. They are of more recent date. We believe that Mr Le Roi was the firſt inventor of them, about the year 1748. In the Memoirs of the Academy of Paris for that year, and in the Collection of approved Machines and Inventions, we have deſcriptions of the contrivance. The balance wheel reſts on a detent, while the balance is vibrating in perfect freedom. It has a pallet ſtanding out from the centre, which, in the courſe of vibration, paſſes cloſe by the point of a tooth of the wheel. At that inſtant a pin, connected with this pallet, withdraws the detent from the wheel, and the tooth juſt now mentioned follows the pallet with rapidity, and gives it a ſmart puſh forward. Immediately after, another tooth of the wheel meets the other claw of the detent, and the wheel is again locked. When the balance returns, the pin puſhes the detent back into its former place, where it again locks the wheel. Then the balance, reſuming its firſt direction, unlocks the wheel, and receives another impulſion from it. Thus the balance is unconnected with the wheels, except while it gets the impulſion, and at the moments of unlocking the wheels.

This contrivance has been reduced to the greateſt poſſible ſimplicity by the Britiſh artiſts, and ſeems ſcarcely capable of farther improvement. The following is one of the moſt approved conſtructions. In fig. 17. *a b c* repreſents the pallet, which is a cylinder of hard ſteel or ſtone, having a notch *a b*. A portion of the balance wheel is repreſented by A B. It is placed ſo near to the cylinder that the cylinder is no more than clear of *two adjoining* teeth. DE is a long ſpring, ſo fixed to the watch-plate at E, as to preſs very gently on the ſtop pin G. A ſmall ſtud F is fixed to that ſide of the ſpring that is next to the wheel. The tooth of the wheel reſts on this ſtud, in ſuch a manner that the tooth *a* is juſt about to touch the cylinder, and the tooth *f* is juſt clear of it. Another ſpring, extremely ſlender, is attached to the ſpring DE, on the ſide next the balance wheel, and claps cloſe to it, but keeping clear of the ſtud F, and having its point *o* projecting about $\frac{1}{10}$th of an inch beyond its extremity. When the point *o* is preſſed towards the wheel, it yields moſt readily; but, when preſſed in the oppoſite direction, it carries the ſpring DE along with it. The cylinder being ſo placed on the verge that the edge *a* of the notch is

Watch-work.

is close by the tooth a, a hole is drilled at i, close by the projecting point of the slender spring, and a small pin is driven into this hole. This is the whole apparatus; and this situation of the parts corresponds to the quiescent position of the balance.

Now, let the balance be turned out of this position 80 or 90 degrees, in the direction $a\,b\,c$. When it is let go, it returns to this position with an accelerated motion. The pin i strikes on the projecting point of the slender spring, and, pressing the strong spring DE outward from the wheel, withdraws the stud F from the tooth; and thus unlocks the wheel. The tooth a engages in the notch, and urges round the balance. The pin i quits the slender spring before the tooth quits the notch; so that when it is clear of the pallet, the wheel is locked again on the stud F, and another tooth g is now in the place of a, ready to act in the same manner. When the force of the balance is spent, it stops, and then returns toward its quiescent position with a motion continually accelerated. The pin i arrives at the point o of the slender spring, raises it from the strong spring without disturbing the latter, and almost without *being* disturbed by this trifling obstacle; and it goes on, turning in the direction $a\,b\,c$, till its force is again spent; it stops, returns, again unlocks the wheel, and gets a new impulsion. And in this manner the vibrations are continued. Thus we see a vibration, almost free, maintained in a manner even more simple than the common crutch scapement. The impulse is given direct, without any decomposition by oblique action, and it is continued through the *whole* motion of the wheel. No part of this motion is lost, as in Dupleix's scapement, by the *gradual* approach of the tooth to its active position. Very little force is required for unlocking the wheel, because the spring DFE is made slender at the remote end E, so that it turns round E almost like a lever turning on pivots. A sudden twitch of the watch, in the direction $b\,a$, might chance to unlock the wheel. But this will only derange one vibration, and even that not considerably, because the teeth are so close to the cylinder that the wheel cannot advance till the notch comes round to the place of scapement. A tooth will continue pressing on the cylinder, and by its friction will change a little the extent and duration of a single vibration. The greatest derangement will happen if the wheel should thus unlock by a jolt, while the notch passes through the arch of scapement in the returning vibration. Even this will not greatly derange it, when the watch is clean and vibrating wide; because, in this position, the balance has its greatest momentum, and the direction of the only jolt that can unlock the wheel tends to increase this momentum relatively. In short, considering it theoretically, it seems an almost perfect scapement; and the performance of many of these watches abundantly confirms that opinion. They are known to keep time for many days together, without varying one second from day to day; and this even under considerable variations of the maintaining power. Other detached scapements may equal this, but we scarcely expect any to exceed it; and its simplicity is so much superior to any that we have seen, that, on this account, we are disposed to give it the preference. We do not mean to say that it is the best for a pocket watch. Perhaps the scapement of Dupleix or Graham may be preferable, as being susceptible of greater strength, and more able to withstand jolts. Yet it is a fact that some of the watches made in this form by Arnold and others have kept time in the wonderful manner abovementioned while carried about in the pocket.

Mr Mudge of London invented, about the year 1763, another detached scapement, of a still more ingenious construction. It is a counterpart of Mr Cumming's scapement for pendulums. The contrivance is to this effect. In fig. 18. $a\,b\,c$ represents the balance. Its axis is bent into a large crank EFGHIK, sufficiently roomy to admit within it two other axes M and L, with the proper cocks for receiving their pivots. The three axes form one straight line. About these smaller axes are coiled two auxiliary springs, in opposite directions, having their outer extremities fixed in the studs A and B. The balance has its spring also, as usual, and the three springs are so disposed that each of them alone would keep the balance at rest in the same position, which we may suppose to be that represented in the figure. The auxiliary springs A and B are connected with the balance only occasionally, by means of the arms m and n projecting from their respective axes. These arms are catched on opposite sides by the pins o, p, in the branches of the crank; so that when the balance turns round, it carries one or other of those arms round with it, and, during this motion, it is affected by the auxiliary spring connected with the arm so carried round by it.

Let us suppose that the balance vibrates 120° on each side of its quiescent position $a\,b\,c$, so that the radius Ea acquires, alternately, the positions Eb and Ec. The auxiliary springs are connected with the wheels by a common dead-beat pendulum scapement, so that each can be separately wound up about 30°, and retained in that position. Let us also suppose that the spring A has been wound up 30° in the direction $a\,b$, by the wheel-work, and that the point a of the rim of the balance, having come from c, is passing through a with its greatest velocity. When the radius Ea has passed a 30° in its course toward b, the pin o finds the arm m in its way, and carries it along with it till a gets to b. But, by carrying away the arm m, it has unlocked the wheel-work, and the spring B is now wound up 30° in the other direction, but has no connection with the balance during this operation. Thus the balance finishes its semivibration $a\,b$ of 120°, opposed by its own spring the whole way, and by the auxiliary spring A through an angle of 90°. It returns to the position Ea, aided by A and by the balance-spring, through an angle of 120°. In like manner, when Ea has moved 30° toward the position Ec, the pin p meets with the arm n, and carries it along with it through an angle of 90°, opposed by the spring B, and then returns to the position Ea, assisted by the same spring through an arch of 120°.

Thus it appears that the balance is opposed by each auxiliary spring through an angle of 90°, and assisted through an angle of 120°. This difference of action maintains the vibrations, and the necessary winding up of the auxiliary springs is performed by the wheel-work, at a time when they are totally disengaged from the balance. No irregularity of the wheel-work can have any influence on the force of the auxiliary springs, and therefore the balance is completely disengaged from all

all these irregularities, except in the short moment of unlocking the wheel that winds up the springs.

This is a most ingenious construction, and the nearest approach to a free vibration that has yet been thought of. It deserves particular remark that, during the whole of the returning or accelerated semivibration, the united force of the springs is proportional to the distance from the quiescent position. The same may be said of the retarded excursion beyond the angle of impulse: therefore the only deviation of the forces from the law of cycloidal vibration is during the motion from the quiescent position to the meeting with the auxiliary spring. Therefore, as the forces, on both sides, beyond this angle, are in their due proportion, and the balance always makes such excursions, there seems nothing to disturb the isochronism, whether the vibrations are wide or narrow. Accordingly, the performance of this scapement, under the severest trials, equalled any that were compared with it, in as far as it depended on scapement alone. But it is evident that the execution of this scapement, though most simple in principle, must always be vastly more difficult than the one described before. There is so little room, that the parts must be exceedingly small, requiring the most accurate workmanship. We think that it may be greatly simplified, preserving all its advantages, and that the parts may be made of more than twice their present size, with even less load on the balance from the inertia of matter. This improvement is now carrying into effect by a friend.

Still, however, we do not see that this scapement is, theoretically, superior to the last. The irregularities of maintaining power affect that scapement only in the arch of impulsion, where the velocity is great, and the time of action very small. Moreover, the chief effect of the irregularities is only to enlarge the excursions; and in these the wheels have no concern.

Mr Mudge has also given another detached scapement, which he recommends for pocket watches, and executed entirely to his satisfaction in one made for the Queen. A dead beat pendulum scapement is interposed, as in the last, between the wheels and the balance. The crutch EDF (fig. 19.) has a third arm DG, standing outwards from the meeting of the other two, and of twice their length. This arm terminates in a fork AGB. The verge V has a pallet C, which, when all is at rest, would stand between the points A, B of the fork. But the wheel, by its action on the pallet E, forces the fork into the position B g b, the point A of the fork being now where B was before, just touching the cylindrical surface of the verge. The scapement of the crutch EDF is not accurately a dead beat scapement, but has a very small recoil beyond the angle of impulsion. By this circumstance the branch A (now at B) is made to press most gently on the cylinder, and keeps the wheel locked, while the balance is going round in the direction BHA. The point A gets moving from A to B by means of a notch in the cylinder, which turns round at the same time by the action of the branch AG on the pallet C; but A does not touch the cylinder during this motion, the notch leaving free room for its passage. When the balance returns from its excursion, the pallet C strikes on the branch A (still at B), and unlocks the wheel. This now acting on the crutch pallet F, causes the branch b of the fork to follow the pallet C, and give it a strong impulse in the direction in which it is then moving, causing the balance to make a semivibration in the direction AHB. The fork is now in the situation A g a, similar to B g b, and the wheel is again locked on the crutch pallet E.

The intelligent reader will admit this to be a very steady and effective scapement. The lockage of the wheel is procured in a very ingenious manner; and the friction on the cylinder, necessary for effecting this, may be made as small as we please, notwithstanding a very strong action of the wheel: For the pressure of the fork on the cylinder depends entirely on the degree of recoil that is formed on the pallets E and F. *Pressure* on the cylinder is not *indispensably* necessary, and the crutch scapement might be a real dead beat. But a small recoil, by keeping the fork in contact with the cylinder, gives the most perfect steadiness to the motion. The ingenious inventor, a man of approved integrity and judgment, declares that her Majesty's watch was the best pocket watch he had ever seen. We are not disposed to question its excellency. We saw an experiment watch of this construction, made by a country artist, having a balance so heavy as to vibrate only twice in a second. Every vibration was sensibly beyond a turn and a half, or 540°. The artist assured us, that when its proper balance was in, vibrating somewhat more than five times in a second, the vibrations even exceeded this. He had procured it this great mobility by substituting a roller with fine pivots in place of the simple pallet of Mudge. This great extent of detached vibration is an unquestionable excellence, and is peculiar to those two scapements of this ingenious artist.

Very ingenious scapements have been made by Ernshaw, Howel, Hayley, and other British artists; and many by the artists of Paris and Geneva. But we must conclude the article, having described all that have any difference in principle.

The scapement having been brought to this degree of perfection, we have an opportunity of making experiments on the law of action of springs, which has been too readily assumed. We think it easy to demonstrate, that the figure of a spring, which must have a great extent of rapid motion, will have a considerable influence on the force which it impresses on a balance *in actual motion*. The accurate determination of this influence is not very difficult in some simple cases. It is the greatest of all in the plane spiral, and the least in the cylindrical; and, in this last form, it is so much less as the diameter is less, the length of the spring being the same. By employing many turns, in order to have the same ultimate force at the extremity of the excursion, this influence is increased. A particular length of spring, therefore, will make it equal to a given quantity; and it may thus compensate for a particular magnitude of friction, and other obstructions. This accounts for the observation of Le Roy, who found that every spring, *when applied to a movement*, had a certain length, which made the wide and narrow vibrations isochronous. His method of trial was so judicious, that there can be no doubt of the justness of his conclusion. His time keeper had no fuzee; and when the last revolution of the main wheel was going on, the vibrations were but of half the extent of those made during the first revolution. Without minding the real rate of going, he only compared the

Water.

the duration of the firſt and laſt revolution of the minute hand. An artiſt of our acquaintance repeated theſe experiments, and with the ſame reſult: But, unfortunately, could derive little benefit from them; becauſe in one ſtate of the oil, or with one balance, he found the lengths of the ſame ſpring, which produced iſochronous vibrations, were different from thoſe which had this effect in another ſtate of the oil, or with another balance. He alſo obſerved another difference in the rate, ariſing from a difference of poſition, according as XII, VI, III, or IX, was uppermoſt; which difference plainly ariſes from the ſwagging of the ſpring by its weight, and, in that ſtate, acting as a pendulum. This unluckily put a ſtop to his attempts to leſſen this hurtful influence by employing a cylindrical ſpiral of ſmall diameter and great length.

WATER-Blowing Machine, called in French *Soufflet d'eau* or *trompe*, is a machine which, by the action of falling water, ſupplies air to a blaſt furnace. It conſiſts of an upright pipe, through which a ſhower of water is made to fall; and this ſhower carries down with it a maſs of air, which is received beneath in a kind of tub, and conducted to the furnace by means of a pipe. The firſt idea of ſuch a machine was doubtleſs ſuggeſted by thoſe local winds, which are always produced by natural falls of water over precipices, and in the mountains (ſee page 277 of this Volume); but perhaps we are indebted for the firſt accurate theory of it to Profeſſor Venturi.

That philoſopher, in his experimental reſearches concerning the lateral communication of motion in fluids, proves that the water-blowing machine affords air to the furnace, by the accelerating force of gravity and the lateral communication of motion combined together. He begins with an idea, which, he candidly acknowledges, did not eſcape the penetration of Leonardo Da Vinci. Suppoſe a number of equal balls to move in contact with each other along the horizontal line AB (Plate XLVI. fig. 1.). Imagine them to paſs with an uniform motion, at the rate of four balls in a ſecond. Let us take BF, equal to 16 feet Engliſh. During each ſecond four balls will fall from B to F, and their reſpective diſtances in falling will be nearly BC = 1, CD = 3, DE = 5, EF = 7. We have here a very evident repreſentation of the ſeparation, and ſucceſſive elongation, which the accelerating force of gravity produces between bodies which fall after each other.

The rain water flows out of gutters by a continued current; but during its fall it ſeparates into portions in the vertical direction, and ſtrikes the pavement with diſtinct blows. The water likewiſe divides, and is ſcattered in the horizontal direction. The ſtream which iſſues out of the gutter may be one inch in diameter, and ſtrike the pavement over the ſpace of one foot. The air which exiſts between the vertical and horizontal ſeparations of the water which falls, is impelled and carried downwards. Other air ſucceeds laterally; and in this manner a current of air or wind is produced round the place ſtruck by the water. Hence the following idea of a water-blowing maching:

Let BCDE (fig. 2.) repreſent a pipe, through which the water of a canal AB falls into the lower receiver, MN. The ſides of the tube have openings all round, through which the air freely enters to ſupply what the water carries down in its fall. This mixture of water and air proceeds to ſtrike a maſs of ſtone Q; whence rebounding through the whole width of the receiver MN, the water ſeparates from the air, and falls to the bottom at XZ, whence it is diſcharged into the lower channel or drain, by one or more openings TV. The air being leſs heavy than the water, occupies the upper part of the receiver; whence being urged through the upper pipe O, it is conveyed to the forge.

It has been ſuppoſed by ſome eminent chemiſts, that the air which paſſes through the pipe O is furniſhed by the decompoſition of water. To aſcertain whether this be the caſe or not, our author formed a water-blowing engine of a ſmall ſize. The pipe BD was two inches in diameter, and four feet in height. When the water accurately filled the ſection BC, and all the lateral openings of the pipe BDEC were cloſed, the pipe O no longer offered any wind. It is therefore evident, that in the open pipes the whole of the wind comes from the atmoſphere, and no portion is afforded by the decompoſition of water. It remains, therefore, to determine the circumſtances proper to drive into the receiver MN the greateſt quantity of air, and to meaſure that quantity.

1. To obtain the greateſt effect from the acceleration of gravity, it is neceſſary that the water ſhould begin to fall at BC, (fig. 2.) with the leaſt poſſible velocity; and that the height of the water FB ſhould be no more than is neceſſary to fill the ſection BC. Our author ſuppoſes the vertical velocity of this ſection to be produced by an height or head equal to BC.

2. We do not yet know, by direct experiment, the diſtance to which the lateral communication of motion between water and air can extend itſelf; but we may admit with confidence, that it can take place in a ſection double that of the original ſection with which the water enters the pipe. Let us ſuppoſe the ſection of the pipe BDEC to be double the ſection of the water at BC; and, in order that the ſtream of fluid may extend and divide itſelf through the whole double ſection of the pipe, ſome bars, or a grate, are placed in BC, to diſtribute and ſcatter the water through the whole internal part of the pipe.

3. Since the air is required to move in the pipe O with a certain velocity, it muſt be compreſſed in the receiver. This compreſſion will be proportioned to the ſum of the accelerations, which ſhall have been deſtroyed in the inferior part KD of the pipe. Taking KD = 1,5 feet, we ſhall have a preſſure ſufficient to give the requiſite velocity in the pipe O. The ſides of the portion KD, as well as thoſe of the receiver MN, muſt be exactly cloſed in every part.

4. The lateral openings in the remaining part of the pipe BK may be ſo diſpoſed and multiplied, particularly at the upper part, that the air may have free acceſs within the tube. We will ſuppoſe them to be ſuch that 0,1 foot height of water might be ſufficient to give the neceſſary velocity to the air at its introduction through the apertures.

All theſe conditions being attended to, and ſuppoſing the pipe BD to be cylindrical, it is required to determine the quantity of air which paſſes in a given time through the circular ſection KL. Let us take in feet KB = 1,5; BC = BF = a; BD = b. By the common theory of falling bodies, the velocity in KL will be $7{,}76 \sqrt{(a+b-1{,}4)}$; the circular ſection KL = 0,785

Water, Weaving. Weaving

$0{,}785\,a^2$. Admitting the air in KL to have acquired the fame velocity as the water, the quantity of the mixture of the water and air which paffes in a fecond through KL is $= 6,\ 1\,a^2 \sqrt{(a + b - 1{,}4)}$. We muft deduct from the quantity $(a + b - 1{,}4)$ that height which anfwers to the velocity the water muft lofe by that portion of velocity which it communicates to the air laterally introduced; but this quantity is fo fmall that it may be neglected in the calculation. The water which paffes in the fame time of one fecond thro' BC is $= 0{,}4\,a^2 \sqrt{(a + 0{,}1)}$. Confequently, the quantity of air which paffes in one fecond through KL, will be $= 6,\ 1\,a^2 \sqrt{(a + b - 1{,}4)} - 0{,}4\,a^2 \sqrt{(a + 0{,}1)}$, taking the air itfelf, even in its ordinary ftate of compreffion, under the weight of the atmofphere. It will be proper, in practical applications, to deduct one-fourth from this quantity; 1. On account of the fhocks which the fcattered water fuftains againft the inferior part of the tube, which deprive it of part of its motion; and, 2. Becaufe it muft happen that the air in LK will not, in all its parts, have acquired the fame velocity as the water.

If the pipe O do not difcharge the whole quantity of air afforded by the fall, the water will defcend at XZ; the point K will rife in the pipe, the afflux of air will diminifh, and part of the wind will iffue out of the lower lateral apertures of the pipe BK.

We fhall not here examine the greater or lefs degree of perfection of the different forms of water-blowing machines which are ufed at various iron forges; fuch as thofe of the Catalans, and elfewhere. Thefe points may be eafily determined from the principles here laid down, compared with thofe eftablifhed in the articles *Resistance of Fluids (Encycl.)*, and Dynamics (*Supplement*.).

WEAVING (fee *Encycl.*) is an operation which, by means of a well-known inftrument called the *weaving-loom*, has hitherto been performed by bodily labour. That labour is pretty fevere; and Mr Robert Millar, an ingenious calico printer in the county of Dumbarton, Scotland, wifhing to leffen it, invented, fome years ago, a weaving-loom, which may be wrought by water, fteam, horfes, or any other power. For his invention he received a patent, dated June 26th 1796; and though truth compels us to fay, that we do not think it likely to emulate the fpinning machine of Arkwright, it is fufficiently ingenious to deferve notice in a Work of this kind. The following is his own defcription of his patent weaving-loom:

Fig. 1. (Plate L.) reprefents a fide view of the loom, AA, BB, CC, DD, being the frame. *a* is an axis (which we fhall call the fpindle) acrofs the frame. On this axis is a fheeve *b*, two inches thick, having a groove round it, two inches deep, and half an inch wide. The bottom of this groove is circular, except in one part *c*, where it is filled up to the top; a lever *d* refts on the bottom of this groove, and is lifted up by it when the elevation *c* comes round to the fituation reprefented in the figure. By this motion, the lever *d* acts on the ratchet-wheel *e* by the catch *t*, and draws it forward one tooth, each revolution of the fheeve. This ratchet wheel is in an iron frame *gg*, which alfo properly carries the two catches *t* and *u*, which are connected with it at *v*. The catch *u* holds the ratchet-wheel in its pofition, while the lever *d*, and the catch *t*, are moved by the groove *c* in the fheeve. On the arbor of the ratchet is a fmall pinion *h*, working in the wheel *f*; this wheel is fixed on the end of the roller *e* of fig. 3. On the fide of the fheeve *b* is fixed a wiper *k*, which lifts the treadle *l*. This treadle turns on its joints in the fheeve E, which is fixed to the fide of the frame A and D; it is kept preffing on the bottom of the groove in the fheeve by a fpring *m*, fixed to the frame fide A, and having a flender rod *n* from its extremity, joining it with the treadle at *l*. From the point of the treadle there goes a belt *o*, which paffes over the pulley *p*, which is feen edgewife in this figure, and is joined to the top of the fly pin *q*, of fig. 2. At the end of the frame A is the fhort poft F; on this refts the yarn-beam *j*, having a fheeve *r*, over which paffes a cord, having a weight *s* fufpended to it. The other end of this cord is faftened to the fpring *v*; the weight caufes the yarn-beam to ftretch the web from the ratchet wheel *e*, with its catch *u*; and the fpring *v* allows the rope to flide on the fheeve as the ratchet is drawn round during the working.

Fig. 2. is a front view of the loom. *a a* is the fpindle which carries the fheeve *b*, and the wipers *d* and *d*, which move the treadles *w*, *w*, of fig. 1. Thefe ufe the treadles of the headles, with which they are connected by cords from the fhafts of the headles *s*, *s*. From the upper fhaft there go two leathern belts *f*, *f*, to the roller *y*, furnifhed each with a buckle, for tightening them at pleafure. The two wipers *c*, *c*, on the fhaft *a*, which ferve for taking back the lay, have the two treadles *x*, *x*, in fig. 3. with a belt from each paffing over the roller *b* 2 of fig. 1. and fixed to the fword of the lay. From the fwords of the lay forward is fixed a belt to each end of the roller *i*; from this roller there goes a cord to the fpring *j*, which ferves for taking forward the lay which is hinged on the rocking tree *t*. The ftar-wheel *b* of fig. 3. and the fheeve *b* of fig. 1. are fixed to the oppofite ends of the fpindle *a* without the frame; and both the wheel and fheeve have a wiper *k* fixed to them for moving the treadles. In order to drive the fhuttle, the belts *o*, *o*, go from the points of the treadles, over the pulleys *p*, *p*. to the top of the fly-pin *q*: This turns on a pin-joint in a rail *r*, which goes acrofs the loom. From its lower end there go two fmall cords to the fhuttle drivers *g*, *g*, which flide on the iron rods *n*, *n*. A long iron rod *v* goes acrofs the lay, and is hung on two centres at the ends. In this rod *v* are fixed two fmall crooked wires *w*, *w*, which are more diftinctly marked in the little figure *w* above, which reprefents a fection of the lay. The dot at the lower end of the wire *w*, in this figure, is the fection of the rod *v*. The fhuttle paffes between thefe wires and the lay every fhot, and lifts them up, caufing the rod *v* to turn round a little. But if the fhuttle fhould not pafs thefe wires, nor lift them, it would be drawn home by the lay, and deftroy the web. To prevent this, there is fixed on one end of the rod *v* a ftout crooked wire *z*, having a broad or flat head, which naturally refts on a plate of iron, marked and fixed to the back of the lay. This plate has a flit in its middle about an inch deep. In this flit refts the rod *a* 2 of fig. 3. on which is a fhort ftud. which is caught by the wire *z* when the wire *w* is not lifted back by the paffing fhuttle. This will ftop the lay from coming home, and will fet off the loom.

Fig. 3. is another fide-view of the loom oppofite

fite to fig. 1. On the fpindle *a* is the ftar wheel *b*, on the outfide of the loom frame, on the arms of which wheel is fixed the wiper *k*, as the fimilar wiper is fixed to the fheeves on the other end of the fpindle. The wipers which drive the fhuttles are fixed on oppofite fquares of the fpindle, and work alternately. Below the ftar-wheel is a pinion *e*, which is on a round fpindle, turned by the water-wheel, by means of a wheel on this fpindle. In a wheel on this fpindle are two ftuds, on which the pinion *c* flides off and on as the loom is fet off and on by the lever *d*. At the farther end of this lever is the weight *s*, hanging by a cord which paffes over a pulley *t*, fixed at the outer end of the fpring-catch on which the lever *d* refts; and thus the loom is drawn in at the upper end of the lever *d*. But when the fhuttle does not lift the wire *z*, it catches on the ftud on the rod *a* 2, which is conneĉted with the fpring-catch, and the lever *d* flies off with the weight *s*, and the loom ftops working. On the head of the poft F is the yarn-beam. The rollers *e* and *f* are cylinders, preffed together by a fcrew lever, and take away the cloth between them at a proper rate. In the roller *f* is a groove for a band for driving the roller *g*, on which the cloth winds itfelf as it is wrought. Wherever fprings are mentioned to be ufed in the above defcription, weights may be ufed in their ftead, and to the fame effeĉt, and more efpecially upon the treadle of fig. 1. for driving the fhuttle.

WEIGHTS AND MEASURES, in commerce, are fo various, not only in different countries, but even in different provinces of the fame country, and this variation is the fource of fo much inconveniency in trade, that writers on polical and commercial economy have propofed various methods for fixing an univerfal and immoveable ftandard of weights and meafures for all ages and nations. Sir James Stewart Denham's fpeculations on this fubjeĉt have been noticed in his life publifhed in this *Supplement*; Mr Whithurft's ingenious contrivance for eftablifhing a ftandard of weights and meafures has been mentioned under the title MEASURE (*Encycl.*); and the new table of weights and meafures, which the French republicans wifh to impofe upon all Europe, is given (*Encycl.*) under the title REVOLUTION, n° 183.

As thefe meafures occur frequently, even in Englifh tranflations of French books of value, we fhall here give fuch an account of them as may enable the reader to reduce them with eafe to the Englifh ftandards. They are of five kinds; *meafures of length, of capacity, of weight, of fuperficies for land, and of wood for fuel.* For every kind, there are many meafures of different fizes, one of which has been taken as the bafis of all the reft, and its name affumed as the root of their names. Thus METRE is called the principal meafure of length; LITRE, of capacity; GRAMME, of weight; ARE, of fuperficies of land; and STERE, of wood for fuel. Thefe words being the radical terms of the names of other meafures of length, capacity, &c. a relation is hereby preferved between the names.

The meafures of length above the *metre*, are ten times, a hundred times, a thoufand times, ten thoufand times, greater than the metre. The meafures of length below the metre, are ten times, a hundred times, a thoufand times, lefs. To form the names of thefe meafures, other words which indicate the relations of *ten times*, a *hundred times*, greater; and of *ten times*, a *hundred times*, lefs, &c. are placed before the word *metre*. The fame annexes have been ufed to form the names of meafures, greater or lefs, than the *litre*, the *gramme*, &c. It is neceffary, therefore, to ftate in this place the Englifh equivalents of only the *metre*, the *litre*, the *gramme*, the *are*, and the *ftere*.

The METRE = 3.28084 feet Englifh.

The LITRE = 61.0243 cubic inches, or $1\frac{101}{141}$ pint ale meafure.

The GRAMME, or cubic *centi metre* of water, at the freezing point, = $\frac{1}{454}$ lb. averd. or $\frac{1}{28}$ of an ounce, or $\frac{26}{45}$ of a dram nearly.

The ARE = $1076\frac{2}{5}$ fquare feet, or $119\frac{3}{5}$ fquare yards, or $\frac{1}{40}$ of an acre nearly.

The STERE, or cubic metre = 35.31467 cubic feet.

The better part of our countrymen, not choofing to adopt the weights and meafures prefcribed to them by the French Convention and the National Inftitute, Sir George Shuckburgh Evelyn, Bart. turned his attention to this fubjeĉt, and publifhed, in the Philofophical Tranfaĉtions for 1798, an account of fome endeavours to afcertain a ftandard of weights and meafures. The principles upon which he proceeded are the fame with Mr Whitehurft's; but he has carried his experiments much farther than his predeceffor, and feems to have conduĉted them with greater accuracy. His memoir is hardly fufceptible of abridgment; and our limits do not permit us to infert it entire. This is indeed unneceffary, if it be true, as another ingenious gentleman alleges *, that we are in the aĉtual poffeffion, and the conftant ufe, of a ftandard both for weight and meafure, as invariable as that now ufed in France. This ftandard he finds in the foot meafure, and in the avoirdupoife, or, as he thinks it ought to be called, the *decade* ounce weight.

* H. Goodwin, Efq. in *Nicholfon's Journal*, vol. iv. p. 163, &c.

The decade ounce weight of pure rain, or diftilled water, at 60° of heat, is generally allowed to be equal in bulk to the one-thoufandth part of the cubic foot. Were 44.3511 parts out of 10000, or about $\frac{1}{225}$th part added to the prefent Winchefter bufhel, that bufhel would then contain exaĉtly 10 cubic feet or 10000 oz. of diftilled water, at 60° of heat.

Our author then gives comparative tables between this fyftem and that which is now eftablifhed in France. Taking the metre at 3 French feet, and 11.296 lines †, and the French foot to be to the Englifh as 1 : 1.065752004 ‡, one French foot will be equal to 10.65752004 Englifh decades, or tenths of an Englifh foot: hence he calculates the following

† *Journal de Phyf.* vol. v. p. 460.

‡ *Phil. Tranf.* 1768, p. 326, and *Connoiffance des Temps*, 1795.

COMPARATIVE TABLES, Englifh with French.

LONG MEASURE.

Long decade.	Metre.	Metre.	Long decades.
1 =	0.03047983 fere	1 =	32.808583358, &c. or inches 39.3703.

SQUARE MEASURE.

Square decades.	Ares,	Ares,	Square decades.
1 =	0.0000092902 fere	1 =	107640.3142, or fqr. inch. 155002.052448

CUBE MEASURE.

Cube decades.	Litres.	Litre.	Cube decades.
1 =	0.02831637 fere	1 =	35.3152622, &c. or cub.inch. 61.0247727

WEIGHTS.

WEIGHTS.

Avoird. or decade oz.	Grammes	Gramme.	Decade oz.
1	= 28.31637 fere	1 =	0.03531526, &c. or grains, 15.45042625

Long, Square, or Cube, decades are reduced to Long, Square, or Cube, English inches by multiplying by 1.2, 1.44, 1.728; and decade ounces are reduced to grains, containing 7000, or 5760, to the lb. Avoird. Troy, by multiplying the ounce by $437.5 =$ the number of grains in an avoirdupoise ounce.

Our author, who feems to have paid much attention to weights and meafures, obferves, that a ftandard meafure for the purpofes of trade, in particular, as well as for others, that would uniformly give an accurate refult, and could be eafily made, examined, and afcertained, by common mechanics, which neither our prefent liquid nor dry meafures evidently can, would furely be an acquifition of great value. Such an one, he prefumes, would be the following: A fquare pyramid, whofe perpendicular height is exactly thrice the length of the fide of the bafe: for fuch an one, and every fection of it, made by a plane parallel to its bafe, would, in the firft inftance, poffefs, and, in every fubdivifion, retain thefe remarkable properties.

1ft, Similar comparative dimenfions to thofe above given, for the original pyramid, *i. e.* every fmaller pyramid, formed by the above-mentioned parallel fection, would have its perpendicular height thrice the length of the fide of its bafe; and,

2dly, The length of the fide of each bafe will always indicate, or equal the cube root of the folid content of the pyramid; *e. g.* If the length of the fide of the bafe be 3, the folid content will be the cube of 3, *viz.* $3 \times 3 \times 3 = 27$.

We do not perceive very clearly the great value of this ftandard; but Mr Goodwyn fays, that he has been many years in the habit of ufing a pyramid meafure to examine corn; and is perfectly convinced that fuch a one will indicate a far more accurate refult than can arife from the manner in which corn is meafured by the bufhel. This we are bound to believe; for it is abfurd to oppofe theories to a fact afcertained by experience.

WESTRINGIA, a new genus of plants defcribed by J. E. Smith, M. D. prefident of the Linnæan Society of London. It was firft difcovered in New Holland by Dr Solander, who called it *Cunila Fruticofa*, though it is totally different from the CUNILA (fee that article, *Encycl.*), and more refembles rofemary, from which, however, it is likewife different. Its peculiar character is: *Calyx femiquinquefidus, pentagonus; corolla refupinata, limbo quadrifido, lobo longiore erecto, bipartito: Stamina diftantia, duo breviora (inferiora) abortiva.* Dr Smith affigns it rather to the *didynamia-angiofpermia*, placing it immediately after the *Teucrium*, than to the *diandria* clafs of plants.

WHEAT (fee TRITICUM, *Encycl.*) has for fome years paft been at fo very high a price, that every hint for increafing its quantity or improving its quality is intitled to notice. In the Leicefter Journal for the 6th of December 1799, there is an ingenious paper on the fubject of tranfplanting wheat, as a means of providing againft the expected fcarcity of that neceffary of life. It is recommended "to fow, in dry land, at the ufual feafon, as much corn as may be deemed neceffary to plant in the fpring any number of acres which may be occupied with that article in the following year. When the foil is prepared, a furrow is to be made with a very fmall plough and one horfe, in the centre of the ridge or land, returning back in the fame track (this time only of every ridge); then turn towards the left hand, and plough another furrow, about eight or nine inches from the firft furrow, turning always to the left hand, till the whole ridge is finifhed; it will then be formed into trenches, in parallel lines, of about eight or nine inches afunder, and imitate what gardeners term drawing of drills. In thefe furrows the plants are to be laid." Mr John Ainfworth of Glen, the experienced author of this communication, fays he has practifed this method with the moft complete fuccefs.

It has been likewife practifed, on a fmall fcale, with equal fuccefs, but we know not in what county. About the end of Auguft 1783, that gentleman threw a fmall quantity of wheat, which near two years before had been fteeped and limed (fee WHEAT, *Encycl.*) into an unmanured corner of his garden. In the beginning of February following he had a piece of ground (alfo unmanured) dug in an open part of his orchard, and he tranfplanted it on beds of fix rows wide, at nine inches afunder every way. It tillered, and fpread over the ground fo completely, as to prevent even a weed growing among it. It produced admirable corn, and at the rate of near four quarters per acre.

From accurate calculations which he then made, he found that an acre, fuppofing the feed to be very good, and the plants fet at the diftance above mentioned, would require only *half a peck* of feed.

Befides the faving of the feed, there are two other material advantages which attend fuch a method; one is, that fome fuitable crop may be on the ground all the winter for ufe; and the other is, that ploughing the ground fo late as February, will effectually bury and deftroy thofe weeds which were beginning to vegetate; and before others can fpring up, the corn plants have taken to the ground, and fo fpread over it that the weeds cannot rife, by which means there is a very clean crop, and all the cuftomary expence for weeding is faved.

This author feems to think that wheat will thrive as well, and produce as full a crop, when fown in the fpring, as if it had been committed to the ground in the preceding autumn. In the fouthern counties of England we doubt not but it may; but the cafe is otherwife in Scotland, where the fpring is not fo early, and where, from the narrownefs of the ifland, the froft is feldom fo fevere. We agree, however, with Dr Pike, in thinking it a pity that the way of fetting wheat (as done in Norfolk and Suffolk) is not every where more general. The procefs is indeed tedious and troublefome; and we have often wondered that, among the numberlefs machines lately contrived to leffen manual labour, none has been invented for dibbling wheat expeditioufly and accurately. We are therefore pleafed to learn, that Dr Pike himfelf has turned his attention to the fubject, and hopes in the courfe of this year (1800) to prefent the public with a *method of fetting wheat*

wheat at PERFECTLY EXACT *distances through a whole field, and as* EXPEDITIOUSLY *as the common broadcast sowing, which can therefore be applied to forms of any magnitude*; and when a peck of seed is found to be sufficient for an acre (and in some land much less), the saving on a large farm must be immense. We trust to the liberality of his profession, that he will not take out a patent for his invention.

Though we have elsewhere given the usual recipes for preventing smut in wheat, it would be improper to conclude this article without mentioning the very simple one which Mr Wagstaffe of Norwich has uniformly found attended with complete success. This consists in nothing more than immersing the seed in pure water, and repeatedly scouring it therein, just before it is sown or dibbled in the soil. Whether well, spring, or river water be used, is indifferent; but repeated stirring and change of water is essential to remove the particles of infection that may have imperceptibly adhered to the seeds thus purified The subsequent crop will be perfect in itself, and its seeds, he says, successively so likewise, if there are no adjacent fields from whence this contamination may be wafted. He recommends the same washing, and for the same reason, of barley and oats before they be sown.

WILKIE (William, D. D.), the author of an heroic poem, intitled the *Epigoniad*, was born in the parish of Dalmeny, in the county of West-Lothian, on the 5th of October 1721. He was descended of an ancient family in that county, though his father rented only a small farm, and was poor and unfortunate through life. He was able, however, to give his son a liberal education; and that son, it is said, discovered so early a propensity to the study of poetry, that he began to write verses in his tenth year.

As this wonderful prematurity of genius was never heard of during Wilkie's life, it will probably be considered as a story fabricated to raise the Scottish poet to the same eminence with Pope, whose versification he is allowed to have imitated with success. We have no doubt but that Wilkie wrote in early life the description of a storm, which is published in the 9th volume of the Statistical Account of Scotland; but that he wrote it in his tenth year is not proved, and is highly improbable. The poem displays a notion—a confused notion indeed—of the laws of electricity, which a boy in his tenth year, and at a period when electricity was little understood, could not have acquired.

Having learned the rudiments of the Latin tongue at the parish-school of Dalmeny, young Wilkie was, at the age of thirteen, sent to the university of Edinburgh, where he was soon distinguished by his originality of thought, and by his rapid progress in erudition and science. Among his fellow-students he was most closely associated with Dr Robertson the historian, Mr John Home the poet, Dr M'Ghie(A), who afterwards obtained the friendship of Johnson, and became a member of the Ivy-lane Club; and a Mr Cleghorn, who promised be an ornament to the university, in which he was afterwards a professor, but died before he had time to realize the fond hopes of his friends. During the course of his education, Wilkie became acquainted with the celebrated David Hume and Dr Ferguson, and at a later period with Dr Adam Smith, the far-famed author of "The Wealth of Nations." Of all those men he regarded Dr Ferguson with the greatest affection, and Dr Smith with the greatest admiration. This last writer he considered as equal to Robertson and Hume in erudition, and vastly their superior in originality and invention; and this opinion he cherished to the day of his death.

Before he had completed his education, his father died, leaving him no other inheritance than the stock and unexpired lease of his farm, and the care of his three sisters. Wilkie, therefore, turned much of his attention to agriculture, in which he became eminent, not merely as a theorist, but as a practical farmer. He had too much science to be the slave of ancient prejudice, and too much judgment to be hurried into hazardous experiments by the charms of untried speculation. One of his sisters being married to a skilful, though unlettered farmer, he availed himself of his brother's experience; and upon the facts and maxims derived from him built a system of practical farming, which fully answered his own expectation, and obtained the applause of all his neighbours.

He still prosecuted his studies in the university, and without ceasing to be a farmer became a preacher in the church of Scotland. For some years this made no alteration in the mode of his living. He preached occasionally for the ministers in his neighbourhood; cultivated his farm; read the classics; and, enamoured of the simple sublimity of Homer, projected an epic poem on the Homeric model. The subject of his intended poem he drew from the fourth book of the *Iliad*, where Sthenelus gives Agamemnon a short account of the sacking of Thebes; and as that city was taken by the sons of those who had fallen before it, Wilkie gave to his poem the quaint title of *Epigoniad*, from the Greek word επιγονοι which signifies *descendants*. It is not our business to write a criticism upon this poem. The subject was ill-chosen; for the learned reader has enough of the heroic ages in the immortal poems of Homer and Virgil, and in those ages the unlearned reader can feel no interest. The Epigoniad, therefore, though composed in smooth and elegant verse, with due attention to ancient manners, and constructed on the most regular plan, has fallen into neglect, from which no critic or biographer will ever rescue it.

In the year 1753, Mr Wilkie was ordained minister of Ratho, in consequence of a presentation from the Earl of Lauderdale, who knew his worth and admired his genius. Without neglecting his favourite amusements of husbandry, or the study of the belles lettres, he discharged with fidelity the duties of a Christian pastor, was famed for his original and impressive mode of preaching,

(A) According to Sir John Hawkins, this man bore arms on the side of government at the battle of Falkirk 1745. After which, taking a degree in physic, he went to London in hopes of employment through the interest of his countrymen, and perhaps in return for his loyalty. He was a learned, ingenious, and modest man; but so little successful in his profession, that he died of a broken heart, and was buried by a contribution of his friends.

Wilkie.

preaching, and soon came to be loved as well as esteemed by his rural flock.

In the year 1757 the Epigoniad was published, the result of fourteen years study and application, which might surely have been more usefully employed on some other work; and in 1759 a second edition was called for, to which he added *A Dream in the manner of Spenser*. He was, the same year, chosen professor of natural philosophy in the university of St Andrew's; an office for which it is difficult to conceive how he could have been fitted by the study of epic poetry, and close attention to the cultivation of his farm. He was, however, a man of a vigorous mind, and we never heard that he disgraced his electors.

When he removed to St Andrew's, his whole fortune exceeded not L. 200 Sterling; a proof that his Epigoniad had not enriched him. With this sum he purchased a few acres of land in the neighbourhood of the city, carried his two unmarried sisters with him, and continued to live in the university exactly as he had lived at Ratho. In his professorial career there was nothing remarkable. He patronised genius, especially poetical genius, in the young men who attended his lectures, and by them was, of course, loved and esteemed: (See FERGUSSON in this *Suppl.*) In the year 1768 he published a volume of fables of no great value, previous to which the university conferred upon him the degree of D. D.; and he died, after a lingering illness, on the 10th of October 1772.

The manners of Dr Wilkie were singular, and in some respects disgusting. He has been severely blamed for his penuriousness, but, in our opinion, unjustly. His father had left him in debt, with nothing but the profits which he might make of a small farm to discharge that debt, and to support himself and three sisters. In him, therefore, rigid economy was, for many years, a virtue; and he knows little of human nature, who can blame a man for not breaking habits which it had been the duty, as well as the business, of a great part of his life to form. Amidst his most rigid and offensive economy, he was liberal in his donations to the poor.

He had been seized, while minister of Ratho, with an unformed ague, of which he never got entirely rid. For this complaint he thought an extraordinary perspiration necessary, and generally slept, in winter, under twenty-four blankets. He had an utter aversion from clean linen, and has been known to bargain, when he staid a night from home, not only for the proper quantity of blankets to his bed, but also for sheets, which had been used by some other person, and rendered sufficiently dirty to please his feeling. It will easily be conceived that such a man was, to the last degree, slovenly in his dress.

Suspicions have been thrown out by his latest, and we believe his only, biographer, that Dr Wilkie's belief of the Christian religion was neither orthodox nor steady. Not having had the pleasure of his acquaintance, we cannot positively say that these suspicions are groundless; but the writer of this article has conversed much about the author of the Epigoniad with a clergyman who knew him well, and who would have been glad to accuse him of infidelity, if he could have preferred such an accusation with truth. He was a very absent man, apt to forget what he was about even when discharging the most solemn parts of his clerical duty, and used to say of himself that he never could conduct a sacrament. From this absence of mind, and those confessions of it, may have arisen the suspicion that he was not a firm believer; but no such suspicion was ever thrown out to this writer by the clergyman already referred to.

He had one very extraordinary defect in a poet: He could not read aloud the smoothest verses, so as to preserve either the measure or the sense of them. Of this Dr Anderson has produced very complete proof in his life of Wilkie, prefixed to his poetical works in the Edinburgh edition of the British Poets. With all his defects, however, and all his foibles, he was unquestionably a genius, and, we are inclined to believe, a good man.

Wines, Wood-cuts.

WINES (see that article, *Encycl.* and *Vegetable Substances, Suppl.*) are so often adulterated with minerals prejudicial to the health, that various methods have been devised for detecting the adulteration. The property which liver of sulphur (alkaline sulphures) and hepatic air (sulphurated hydrogen) possess of precipitating lead in a black form, has been long ago made public; and this property has been employed to determine the quality of wines by means of the *liquor probatorius Wirtembergensis*, or Wirtemberg proving liquor. But in trying wines supposed to have been adulterated, this proof does more hurt than service, because it precipitates iron of the same colour as the pernicious lead. Many wine-merchants, therefore, of the greatest respectability, rendered by these means suspected, have been ruined.

The following is recommended by M. Hanhemann as a better test of sound wines than the proving liquor of Wirtemberg. Mix equal parts of oyster shells and crude sulphur in a fine powder, and put the mixture into a crucible. Heat it in a wind furnace, and increase the fire suddenly, so as to bring the crucible to a white heat, for the space of 15 minutes. Pulverise the mass when it is cool, and preserve it in a bottle closely stopped.

To prepare the liquor, put 120 grains of this powder, and 120 grains of cream of tartar (acidulous tartarite of potash), into a strong bottle; fill the bottle with common water, which boil for an hour, and then let it cool; close the bottle immediately, and shake it for some time: after it has remained at rest to settle, decant the pure liquor, and pour it into small phials capable of holding about an ounce each, first putting into each of them 20 drops of muriatic acid. They must be stopped very closely with a piece of wax, in which there is a small mixture of turpentine.

One part of this liquor, mixed with three parts of suspected wine, will discover, by a very sensible black precipitate, the least traces of lead, copper, &c. but will produce no effect upon iron, if it contains any of that metal. When the precipitate has fallen down, it may still be discovered whether the wine contains iron, by saturating the decanted liquor with a little salt of tartar (tartareous acidulum of potash), by which the liquor will immediately become black. Pure wines remain clear and bright after this liquor has been added to them.

WOOD-CUTS are engravings on wood, commonly on

Wood-cuts. on box, which, in many cafes, are ufed with advantage inftead of copper-plates. The art of cutting or engraving on wood is undoubtedly of high antiquity; for Chinefe printing is a fpecimen of it. (See CHINA, n° 127 *Encycl.*) Even in Europe, if credit be due to Papillon, this art was practifed at a period confiderably remote; for he mentions eight engravings on wood, entitled, "A reprefentation of the warlike actions of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, prefented, and humbly offered, to the moft holy father, Pope Honorius IV. by us Alexander Alberic Cunio Chevalier, and Ifabella Cunio, &c." This anecdote, if true, carries the art of cutting in wood back to 1284 or 1285; for Honorius occupied the papal throne only during thefe two years. Even this is not the remoteft period to which fome have carried the art in Europe; for the ufe of feals or fignets being of very high antiquity, they imagine that the invention of wood-cuts muft be coeval with them. The fuppofition is certainly plaufible, but it is not fupported by proof. The earlieft impreffion of a wooden-cut, of which we have any certain account, is that of St Chriftopher carrying an infant Jefus through the fea, in which a hermit is feen holding up a lantern to fhew him the way; and a peafant, with a fack on his back, climbing a hill, is exhibited in the back ground. The date of this impreffion is 1423.

In the year 1430 was printed at Haarlem, "The hiftory of St John the evangelift and his revelation, reprefented in 48 figures in wood, by Lowrent Janfon Cofter;" and, in 1448, Jorg Schappf of Augfburg cut in wood the hiftory of the Apocalypfe, and what was called *The poor man's bible*. (See ENGRAVING, *Encycl.* page 668.)

A folio chronicle, publifhed 1493 by Schedal, was adorned with a vaft number of wood-cuts by William Plydenwurf and Michael Wolgemut, whofe engravings were greatly fuperior to any thing of the kind which had appeared before them. Wolgemut was the preceptor of Albert Durer, whofe admirable performances in this department of art are juftly held in the higheft efteem even at the prefent day.

About this period it became the practice of almoft all the German engravers on copper to engrave likewife on wood; and many of their wood cuts furpafs in beauty the impreffion of their copper-plates. Such are the wood-cuts of Albet Aldtorfer, Hifbel Pen, Virgil Soles, Lucas van Cranach, and Lucas van Lyden, the friend and imitator of Albert Durer, with feveral others.

It appears that the Germans carried this art to a great degree of perfection. Hans or John Holbien, who flourifhed in 1500, engraved the *Dance of Death*, in a feries of wooden-cuts, which, for the freedom and delicacy of execution, has hardly been equalled, and never furpaffed.

Italy, France, and Holland, have produced many capital artifts of this kind. Joan Tornæfium printed a bible at Lyden, in 1554 (a copy of which we have feen), with wooden-cuts of excellent workmanfhip. Chriftopher Jegher of Antwerp, from his eminence in the art, was employed by Rubens to work under his infpection, and he executed feveral pieces which are held in much eftimation; the character of thefe is boldnefs and fpirit.

The next attempt at improvement in this art was by Hugo da Carpi, to whom is attributed the invention of the *chiara fcuro*. Carpi was an Italian, and of the 16th century; but the Germans claim the invention alfo, and produce in evidence feveral engravings by Mair, a difciple of Martin Shoen, of date 1499. His mode of performing this was very fimple. He firft engraved the fubject upon copper, and finifhed it as much as the artifts of his time ufually did. He then prepared a block of wood, upon which he cut out the extreme lights, and then impreffed it upon the print; by which means a faint tint was added to all the reft of the piece, excepting only in thofe parts where the lights were meant to predominate, which appear on the fpecimens extant to be whitened with white paint. The drawings for this fpecies of engraving were made on tinted paper with a pen, and the lights were drawn upon the paper with white paint.

There is, however, a material difference between the *chiaro fcuros* of the old German mafters and thofe of the Italians. Mair and Cranach engraved the outlines and deep fhadows upon copper. The impreffion taken in this ftate was tinted over by means of a fingle block of wood, with thofe parts hollowed out which were defigned to be left white upon the print. On the contrary, the mode of engraving by Hugo da Carpi was, to cut the outline on one block of wood, the dark fhadows upon a fecond, and the light fhadows, or half tint, upon a third. The firft being impreffed upon the paper, the outlines only appeared: this block being taken away, the fecond was put in its place, and being alfo impreffed on the paper, the dark fhadows were added to the outlines; and the third block being put in the fame place upon the removal of the fecond, and alfo impreffed upon the paper, made the dim tints, when the print was completed. In fome inftances, the number of blocks were increafed, but the operation was ftill the fame, the print receiving an impreffion from every block.

In 1698, John Baptift Michel Pappillon practifed engraving on wood with much fuccefs, particularly in ornamental foliage and flowers, fhells, &c. In the opinion, however, of fome of the moft eminent artifts, his performances are ftiff and cramped. From that period the art of engraving on wood gradually degenerated, and may be faid to have been wholly loft, when it was lately re-invented by Mr Bewick of Newcaftle.

This eminent artift was apprentice to Mr Bielby, an engraver on metal of the very loweft order, who was feldom employed in any thing more difficult than the cutting of the face of a clock. Application having been made to this man for a wood-cut or two of the moft trifling defcription, the job was given to Thomas Bewick; by whom it was executed in fuch a manner, that Mr Bielby, who was accuftomed to employ his apprentices in fuch work, advifed him to profecute engraving in that line. The advice was followed; and young Bewick inventing tools, even making them with his own hands, and fawing the wood on which he was to work into the requifite thicknefs, proceeded to improve upon his own difcoveries, without affiftance or inftruction of any kind. When his apprenticefhip expired, he went to London, where the obfcure wood-engravers of the time wifhed to avail themfelves of his abilities, while they were determined to give him no infight

into

into their art. He remained ſome years in London; and during that time, if we miſtake not, received from the *Society for the Encouragement of Arts, &c.* a premium of conſiderable value for the beſt engraving in wood. Returning to Newcaſtle, he entered into copartnerſhip with his old maſter; and eſtabliſhed his reputation as an artiſt by the publication of his admirable Hiſtory of Quadrupeds. This was followed by his Hiſtory of Birds, of which only one volume has yet (1800) appeared.

John Bewick, brother to Thomas, learned the art of him, and practiſed it for ſeveral years in London with great applauſe. His abilities, however, though reſpectable, were not, by the beſt judges, deemed ſo brilliant as his brother's; and owing to bad health, and the nature of his connection with the bookſellers and others, he ſeems not to have advanced the art beyond the ſtage at which he received it. He died, three or four years ago, at Newcaſtle.

Mr Neſbit, who executed the admirable Hudibras publiſhed by Vernor and Hood (A), and Mr Anderſon, whoſe beautiful cuts adorn the poem entitled *Grove Hill*, were the next, and hitherto have been the laſt of Thomas Bewick's pupils, who have appeared before the public as artiſts. By theſe gentlemen we are authoriſed to ſay, that the method practiſed by the ancient engravers on wood, whoſe works are ſtill admired, muſt have been different from that of Bewick and his pupils. What that method was ſeems to be altogether unknown. Papillon, who writes the beſt hiſtory extant of the art, gueſſes indeed in what manner the old engravers proceeded ſo as to give their works the ſpirit and freedom for which they are famed; but that his gueſſes are erroneous ſeems evident from the ſtiffneſs of his own works. The principal characteriſtic in the mechanical department of the productions of the ancient maſters is the croſſing of the black lines, which Papillon has attempted with the greateſt awkwardneſs, though it ſeems to have been accompliſhed by them with ſo much eaſe, that they introduced it at random, even where it could add nothing to the beauty of the piece. In Bewick's method of working, this croſs hatching is ſo difficult and unnatural, that it may be conſidered as impracticable (B).

The engravers of Bewick's ſchool work on the end of the wood which is cut acroſs the trunk of the tree, in pieces of the proper thickneſs. As wood-cuts are generally employed in the printer's preſs amidſt a form of types, this thickneſs muſt be regulated by the height of the types with which they are to be uſed. The tools employed are nearly the ſame with thoſe uſed in copperplate engraving, being only a little more deep, or lozenge, as engravers call it. They muſt have points of various degrees of fineneſs for the different purpoſes to which they are applied, ſome of them being ſo much rounded off at the bottom as to approach to the nature of a goodge, whilſt others are in fact little chiſſels of various ſizes. Theſe chiſſels and goodges, to which every artiſt gives the ſhape which he deems moſt convenient, are held in the hand in a manner ſomewhat different from the tool of the engraver on copper, it being neceſſary to have the power of lifting the chips upwards with eaſe. To attempt a deſcription of this in writing would be in vain; but it is eaſily acquired, we are told, by practice.

The pupils of the ſchool of Bewick conſider it as quite improper to ſpeak of his invention as a revival of the ancient art. Some old prints, it is true, have the appearance of being executed in the ſame way with his; but others have certainly been done by a method very different. It is therefore not fair to appreciate the preſent art by what has been done, but by what may be done; and that remains yet to be ſhewn. The art is in its infancy; and thoſe who are diſpoſed to compare it with the art of engraving on copper, ought to look back to the period when the copperplate engraving was of ſo recent invention as Bewick's method of engraving on wood. Marc Antonio, who engraved under the direction of the great painter Raphael, thought it no mean proof of his proficiency in his art, that he was able to imitate on copper-plates the wood-cuts of Albert Durer; and Papillon is highly indignant that there ſhould have been perſons ſo very blind as to miſtake the copies for the originals. If copper has its advantages over wood in point of delicacy and minuteneſs, wood has, in its turn, advantages not inferior in regard to ſtrength and richneſs. Thoſe prints which were executed under the auſpices of Titian and Rubens, will always remain a monument of the ſpirit and vigour natural to wood engraving; and if there be not found in them all the attention to *chiaro ſcuro*, which the preſent age demands, it muſt not be attributed either to defect in the art, or to want of abilities in the artiſts, but to the taſte of the times when *chiaro ſcuro* was little underſtood. It remains for ſome enterpriſing artiſt to ſhew that the vigour of the ancient art may be attained by the preſent one, and at the ſame time to add to that vigour thoſe gradations of ſhade which are ſo much admired in good copperplates. As there ſeems to be a more perfect, or at leaſt a more pleaſant black produced by a wood than by copperplate printing, and certainly a more perfect white (C), who will ſay that any intermediate ſhade whatever may not be produced by wood-cuts? To attempt this on a ſmall ſcale would indeed be vain, becauſe the ſlighteſt variation, produced by a little more or leſs ink, or a harder preſſure in printing, bears ſuch a proportion to a very ſhort line, as muſt neceſſarily render the attempt abortive.

Wood-engraving, therefore, muſt always appear to diſadvantage while it is confined to ſmall ſubjects, and will never reach its ſtation *as a fine art*, till thoſe who are engaged in its cultivation improve upon the diſcoveries of one another, and apply to ſubjects to which it is properly adapted. As an *economical art* for illuſtra-

 ting

(A) The deſigns were by Thornton; and the cuts from them have been compared to Holbein's far-famed Dance of Death.

(B) Mr Neſbit has indeed introduced ſomething of it into two or three of his pieces, merely to ſhew that he *could* do it; but ſo great was the labour, and ſo little the advantage of this improvement, if ſuch it can be called, that probably it will not be attempted again.

(C) The parts of the print intended to be white are not even touched by the wood-block.

Wool-combing. ting mechanics and other ſubjects of ſcience, it is too little employed even in its preſent ſtate.

The works of Bewick and his pupils, which have hitherto been publiſhed, are not numerous. Beſides his quadrupeds and birds, the Hudibras by Neſbit, and the Grove Hill by Anderſon, which have been already noticed, we are acquainted with none but the following :—Goldſmith's *Traveller* and *Deſerted Village* with elegant plates, all by Thomas Bewick, except one or two which were executed by John ; Somerville's *Chace* by the ſame artiſts, executed in a ſtyle of elegance which perhaps has never been ſurpaſſed ; a View of St Nicholas's Church, Newcaſtle, 15 inches long, by Mr Neſbit, who received for it a ſilver medal from the Society for the Encouragement of Arts, and an honorary letter from the Society of Antiquaries.

WOOL-COMBING, a well known operation, which, when performed by the hand, is laborious, tedious, and expenſive. The expence of it through all England has been calculated at no leſs a ſum than L. 800,000 ; and to leſſen this expence, the Rev. Edmund Cartwright of Doncaſter in Yorkſhire bethought himſelf, ſome years ago, of carding wool by machinery. After repeated attempts and improvements, for which he took out three patents, he found that wool can be combed in perfection by machinery, of which he gives the following deſcription :

Plate L. Fig. 1. Is the crank laſher. A is a tube through which the material, being formed into a ſliver, and ſlightly twiſted, is drawn forward by the delivering rollers. B, a wheel faſt upon the croſs-bar of the crank. C, a wheel, on the oppoſite end of whoſe axis is a pinion working in a wheel upon the axis of one of the delivering rollers.

Note, When two or more ſlivers are required, the cans or baſkets, in which they are contained, are placed upon a table under the laſher (as repreſented at D), which, by having a ſlow motion, twiſts them together as they go up.

Fig. 2. Is the circular clearing comb, for giving work in the head, carried in a frame by two cranks. Fig. 3. The comb-table, having the teeth pointed towards the centre, moved by cogs upon the rim, and carried round upon trucks, like the head of a windmill. *a*, *b*, the drawing rollers. *c*, *d*, callender, or conducting rollers.

Note, Underneath the table is another pair of rollers, for drawing out the backings.

In the above ſpecification, we have omitted the frame in which the machine ſtands, the wheels, ſhafts, &c. Had theſe been introduced, the drawing would have been crowded and confuſed ; beſides, as matters of information, they would have been unneceſſary, every mechanic, when he knows the principles of a machine, being competent to apply the movements to it.

The wool, if for particular nice work, goes through three operations, otherwiſe two are ſufficient : the firſt operation opens the wool, and makes it connect together into a rough ſliver, but does not clear it. The clearing is performed by the ſecond, and, if neceſſary, a third operation. A ſet of machinery, conſiſting of three machines, will require the attendance of an overlooker and ten children, and will comb a pack, or 240 lb. in twelve hours. As neither fire nor oil is neceſſary for machine-combing, the ſaving of thoſe articles, even the fire alone, will, in general, pay the wages of the overlooker and children ; ſo that the actual ſaving to the manufacturer is the *whole* of what the combing coſts, by the old imperfect mode of hand-combing. Machine-combed wool is better, eſpecially for machine-ſpinning, by at leaſt 12 *per cent.* being all equally mixed, and the ſlivers uniform, and of any required length.

Y.

Yeaſt. YEAST, is ſometimes a deſideratum, when it cannot eaſily be found. By pouring on a ſmall tea-cupful of ſplit peas a pint of boiling water, and ſetting the veſſel containing the peas and water for a night on the hearth or any warm place, a froth will in the morning be found on the top of the water, which, we are aſſured, will anſwer all the purpoſes of yeaſt.

Z.

Zaminy. ZAMINY, in the language of Bengal, ſecurity.

Zemindars. ZEMINDARS, the great landholders of Bengal. This is the original ſenſe of the word ; but it is now more ſtrictly applicable to thoſe who have their title conſtituted or confirmed by a patent or charter from government, by which they hold their lands or Zemindaries upon certain conditions. As far as can be aſcertained from the narrations of hiſtory, it appears that, in times prior to the irruptions of the Mahomedans, the Rajahs who held their reſidence at Delhy, and poſſeſſed the ſovereignty of Hindoſtan, deputed officers to collect their revenues (Kherâje), who were called in the Indian language

WOOL-COMBING

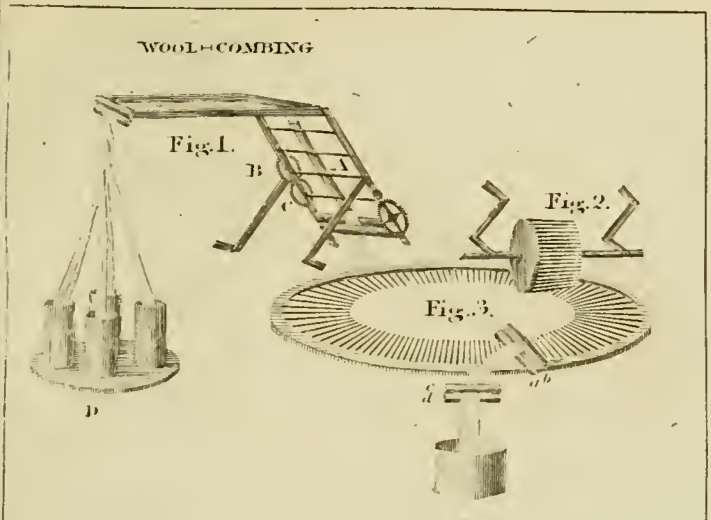

Fig.3.

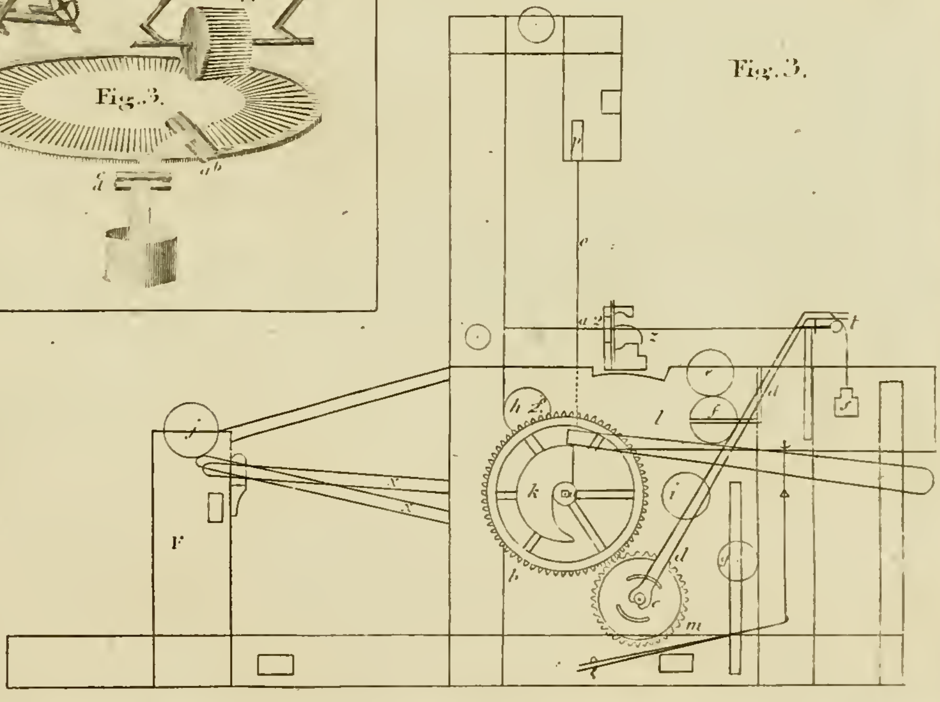

Zemindars. language *Choudheries*. The word *Zemindar* is Persian, and that language can have had no currency in the countries of India, until it was introduced by the people of Persia. When the Emperor Shehâb-ul-Dien Ghory conquered the empire of Hindostan (A), he left Sultan Cutub-ul-Dien to be his viceroy at Delhy, and administer the government of Hindostan. From that time the customs and practices of the Mahomedans began gradually to be established in India: their armies were sent into the countries of the reduced Rajahs, under the command of Omrahs, in order to preserve the conquest; and lands were allotted to them to defray the expence. From hence arose the system of Jaghiredarry in Hindostan. But when these Omrah Jaghiredars had established their own strength, several of them rebelled against the imperial authority, and aspired at the crown. Thus circumstanced, the emperors, in order to obviate these mischiefs, thought it would be more politic to commit the management of the country to the native Hindoos, who had most distinguished themselves by the readiness and constancy of their obedience to the sovereign power.

In pursuance of this plan, districts were allotted to numbers of them under a reasonable revenue (Jummah Monâsib), which they were required to pay in money to the governors of the provinces, deputed from the Emperor. And in case any one of the Omrahs or provincial governors should swerve from his allegiance, the Zemindars of that country were to exert themselves in such a manner as should check rebellion, and restore good government. For this purpose, grants of Zemindary were severally conferred upon such of the Hindoos as were obedient; describing their apportionment of the country; and every person who had received a grant under the authority of the crown was thereby fully invested with the functions of Zemindar.

The functions of a Zemindar are, 1st, The preservation and defence of their respective boundaries from traitors and insurgents; 2dly, The tranquillity of the subjects, the abundance of cultivators, and increase of his revenue; 3dly, The punishment of thieves and robbers, the prevention of crimes, and the destruction of highwaymen. The accomplishment of these objects is considered in the royal grant as the discharge of office to the sovereign; and on that account the word *office* (Khidmut) is employed in the Dewanny Sunnud for a Zemindary.

It was a rule in the times of the ancient emperors, that when any of the Zemindars died, their effects and property were sequestrated by the government. After which, in consideration of the rights of long service, which is incumbent on sovereigns, and elevates the dignity of the employer, Sunnuds for the office of Zemindary were granted to the children of the deceased Zemindar; and no other person was accepted, because the inhabitants could never feel for any stranger the attachment and affection which they naturally entertain for the family of their Zemindar, and would have been afflicted if any other had been put over them. For this reason, the emperors, considering it as a means of conciliating the minds of the people, graciously fixed and confirmed the children of the deceased Zemindar in the office of their fathers and grandfathers, by issuing new Sunnuds to transfer the possession to them. By degrees Zemindaries became truly heritable property, which, however, could be transferred by gift or sale from one family to another. They could likewise be forfeited to the sovereign, by the Zemindar's deviating from his allegiance, neglecting to pay his tribute, or to discharge the duties of his station.

It is universally known, says Sir Charles Rouse Boughton, that, when the three provinces of Bengal, Bahar, and Orissa, were ceded to the British East India Company, the country was distributed among the Zemindars and Talookdars (see that article in this Vol.), who paid a stipulated revenue, by twelve instalments, to the sovereign power or its delegates. They assembled at the capital in the beginning of every Bengal year (commencing in April), in order to complete their final payments, and make up their annual accounts; to settle the discount to be charged upon their several remittances in various coins for the purpose of reducing them to one standard, or adjust their concerns with their bankers; to petition for remissions on account of storms, drought, inundation, disturbances, and such like; to make their representations of the state, and occurrences of their districts: after all which they entered upon the collections of the new year; of which, however, they were not permitted to begin receiving the rents from their own farmers, till they had completely closed the accounts of the preceding year, so that they might not encroach upon the new rents, to make up the deficiency of the past. Our author proves, we think completely, the right of the Zemindars to transfer their possessions, either by inheritance to their children, or, with the consent of the sovereign, to other families; and he argues strenuously and successfully against the bad policy, as well as injustice, of interfering with those rights, as long as the Zemindars discharge the duties of their several stations.

(A) This event took place towards the close of the 12th century. N. B. *Kheräje* signified specifically the tribute paid by a conquered country.
