Garrison's History of Medicine

This book gives the history of medicine from the earliest ancient and primitive times, on through Egyptian medicine, Sumerian and Oriental medicine, Greek medicine, the Byzantine period; the Mohammedan and Jewish periods, the Mediaeval period, the period of the Renaissance, the revival of learning and the Reformation; the Seventeenth Century (the age of individual scientific endeavor), the Eighteenth Century (the age of theories and systems), the Nineteenth Century (the beginning of organized advancement of science), the Twentieth Century (the beginning of organized preventive medicine.) You get all important facts of medical history. The *modern*

period is exhaustively treated to date, one-half the volume dealing with the Nineteenth and Twentieth Centuries. You get a *biographic dictionary* of the men who have "done things." You get an album of *medical portraits*. You get the *social and cultural phases* of each period. You get a complete *medical chronology*—data on important diseases, drugs, therapeutic procedures, operations, etc. You get *bibliographic notes* for collateral reading, and a series of *test questions* of great value. You get a work that will stimulate your interest in the picturesque aspects of medicine and in the personalities of its great leaders.

Octavo of 763 pages, with many illustrations. By FIELDING H. GARRISON, M.D., Principal Assistant Librarian, Surgeon General's Office, Washington, D. C., and Editor *Index Medicus*.

Cloth, \$6.00 net; Half Morocco, \$7.50 net.

PELLAGRA.

BELL COUNTY NUMBER.

This issue of the JOURNAL is unique in that it is the first issue edited entirely by a county society which does not contain a large city within its borders.

Many of the county societies of Kentucky are doing extraordinary work but none are doing better than that of Bell County. When one thinks that a few years ago there were practically no physicians in this county except at Pineville and Middlesboro, that but little scientific medicine was attempted and sanitation was limited to a greater or less control of the epidemic diseases, one can realize what progress has been made. Pellagra was first diagnosed in this county. We may add that it has been controlled to a larger degree in this county to any other we know in the whole country and the devoted work of Bell County physicians on this subject alone entitles them to the gratitude of the profession everywhere. A larger number of specimens for examination of intestinal parasites has been gathered in this county than in any other. The dispensary campaign conducted by the State Board of Health was a wonderful success because it had the cooperation of practically every physician in the county. They did not merely support it but they actually got out and secured specimens. The results were so interesting and valuable that the magistrates have requested that similar campaign be conducted every year for five years and the people and physicians of Bell County will only be satisfied when they have made it the healthiest county in the United States.

The JOURNAL congratulates the profession of Kentucky that it has a Bell County Medical Society.

The attached editorial in regard to Pellagra was written by Dr. O. P. Nuckols, secretary of the Bell County Medical Society, in the *American Practitioner and News*, in 1908, and is, so far as we are advised, the first appearance of this subject in the medical literature of Kentucky:

"Until recent years pellagra was unknown to American physicians, and the literature on the subject in the English language was very meager and unsatisfactory. There has appeared, however, more or less recently in the Southern States a disease which is possibly true pellagra, and there is some reason to believe that this disease is more prevalent than supposed to be, but overlooked. It is epidemic in character and of a very serious nature, and some knowledge concerning it is becoming more important especially to physicians practicing in the Southern States. Pellagra was first discovered by G. Casel of Spain as early as the year of 1735, he regarding it as a species of leprosy. It was later described under a variety of different names in Spanish literature. It later appeared in Italy and was given its name by an Italian physician from the words, *pella* skin, and *agra* rough, 'rough-skin'. About the year 1810 Margari first called attention to the relation between pellagra and maize, and in 1842 Belardini suggested the theory of its being due to spoiled maize caused by the growth of fungus on the grain.

"In certain parts of Europe the disease has been quite prevalent and has followed the introduction and culture of maize from America. It seems strang, but nevertheless true, that in the original homes of maize, America and Asia, it has not prevailed to any great extent, probably due to more favorable climatic conditions. The pellagra

zone is a small one when compared with the area over which maize is cultivated.

"It is pretty generally accepted by those who have studied the disease that it is a sort of intoxication produced by toxic substances of a chemical nature as a result of a parasitic or fungus growth, developed on the Indian corn. The theory has also been advanced that it is an auto-intoxication produced by a constant and almost exclusive diet of Indian corn. However this may be, it is an established fact that pellagra generally occurs among the poorer classes who subsist largely on corn, and observation has also shown that in pellagrous localities, during epidemics, the corn is of a very poor and unhealthy quality. There seems to be no special predilection for any particular nationality, age or sex, all being equally susceptible. It is neither hereditary nor contagious. The disease seems to be one of great chronicity. Pellagra is both an epidemic and endemic disease which occurs only in those who have been fed on spoiled maize. It is characterized by digestive disturbances, erythema, and great nervousness. Some cases develop grave chaxemia or even insanity. The disease seems to prevail with more virulence in the spring of the year, the symptoms gradually abating during summer and winter, but to reappear the next spring provided, however, the cause has not been removed. It is more or less insidious in its invasion, usually the first symptoms being gastro-intestinal disturbances, soon to be followed by erythema of the skin and in a short time involvement of the nervous system. It is a slowly advancing toxemia with the brunt of the disease falling ultimately on the nervous system. The disease has not prevailed to any extent in this country and opportunity for its study has been very limited, and for the present need not be looked forward to with any great degree of alarm.

"The treatment resolves itself largely into that of prophylaxis and such tonics as iron, quinine, and strychnine with proper sanitary surroundings.

O. P. NUCKOLS."

DR. ARCH DIXON, JR.

In announcing to the profession of the State the death of Dr. Arch Dixon, Jr., in El Paso, Texas, after a prolonged illness, the JOURNAL feels a peculiar regret that this splendidly prepared physician could not have been spared to his people. Bred into the very purple of the profession by a father and ancestry who have shed distinction upon Kentucky's history, he belonged to the type of manhood the profession can ill afford to lose. The following resolution tells of the es-

teem in which he was held by the profession in his adopted home:

"RESOLUTIONS ADOPTED BY THE EL PASO COUNTY MEDICAL SOCIETY ON THE DEATH OF DR. ARCH DIXON, JR.

"Whereas: In the death of Dr. Arch Dixon, Jr., which occurred in this city on November first, after a prolonged illness, the last four years of which this Society was deprived of his help and association which were highly prized in former years, we realize our permanent loss and the loss sustained by this city: therefore,

"Be it Resolved: That we desire to express to his family and friends our sincere appreciation of his splendid life and efforts, and our sorrow, that he, who was so thoroughly equipped by nature and training for great achievements in medicine, should pass from us forever, at the time of life when his usefulness should have been the greatest. In furtherance of these resolutions, the secretary is instructed to send a copy thereof to the family of the deceased, and to spread the same on the records of this society.

S. F. KING,
D. N. DETWILLER,
B. F. STEVENS,
Committee."

THE SOUTHERN MEDICAL.

The sessions of the Southern Medical Association at Lexington were the most profitable from a scientific standpoint that we have ever attended. None of the sections were so large as to be unwieldy and yet the splendid interest in the scientific essays was maintained by the kind of discussion that is rare in large meetings. Entirely devoid of politics, the sessions of the Association were the only things of interest and everybody enjoyed them. We feel satisfied that next year at Richmond, Virginia, there will be a larger delegation from Kentucky to indicate to our Southern brothers how much we enjoyed them and how profitable their meeting was to us.

The profession of Fayette County has again earned the gratitude of the doctors of Kentucky because of their entertainment of our visitors. There was a kind of persuasive hospitality that is always shown in Lexington that can be excelled by the people of no other locality; especially, to Dr. C. C. Garr, who was the active member of the Committee of Arrangements, should credit be given for the perfect entertainment.

THE INDEX.

The index for the JOURNAL for 1913 is published in this issue. We trust the members will preserve it as this will enable them to find subjects or authors easily. It gives us pardonable pride to glance over its columns and see how much scientific work has been done by the profession of Kentucky during the year. The arrangement of the index is a matter of considerable difficulty and we are sure you will feel that it is worth while.

SCIENTIFIC EDITORIALS.

WHAT IS THE ETIOLOGY OF ECZEMA?

While eczema, according to the best authorities, is fully 30 per cent. of all skin diseases; while it is met in all conditions and ages; while its clinical picture is well known to both the specialist and the general practitioner; still its true character and etiology are uncertain. According to the pathologist, it is an inflammatory affection of all the layers of the skin and subsequently divided into many forms. Its etiology has been a stumbling block to all of us. Many theories have been advanced and rejected; revived and rejected again. At the last meeting of the American Dermatological Society held at Washington, the etiology of eczema was taken up and thoroughly discussed. Different dermatoses, resembling eczema, were excluded, such as trade eczemas (which is rather a true dermatitis since we know its real cause) and eczematoids due to staphylococcal origin as reported by Sabouraud, Fordyce, Engman and others. It is the acute and subacute eczema, with its limited and generalized processes, that was taken up and discussed. No definite conclusions were made. Dr. Hartzell reiterated his oft-expressed opinion that during the past century we had not learned a single fact bearing upon the internal cause of eczema.

The most brilliant and scientific data were given in a paper on eczema by Dr. James C. Johnston, who is, by the way, a Kentuckian. Disposing of parasitism, disorders of digestion, elimination, the nervous system, the probable causes of eczema may be narrowed down to derangement of nitrogen metabolism neither anaphylactic nor a defective synthesis of urea, but occurring where for the moment biochemistry cannot demonstrate it. Color is

lent to the theory by the appearance in its course of allergic phenomena and urinary evidence of incomplete desamidation.

Perhaps the fault lies in the favor of protein-splitting in the intestinal wall or the blood stream before the tissues select their store of amino-acid nitrogen. Johnston's paper was widely discussed. The unanimous opinion of the men who discussed the paper was that we did not know much about the etiology of eczema. Zeisler's opinion of the etiology of eczema is rather paradoxical. He expressed himself as follows: When we had a case of eczema of which one knows the cause, then, it was not eczema; and if we had a case of dermatitis and did not know the cause, then, it was eczema. We all must agree with Walker that in eczema we were confronted by disease regarding whose etiology we were absolutely ignorant. Jackson, who has been teaching dermatology for many years, was wont to say that eczema is due to an unknown internal cause plus an external irritant. Pollitzer, unable to get at the true cause of eczema, finds it impossible to get away from the bacterial origin of eczema, while the evidence was all against the possibility of such a theory. Knowles, from numerous cases treated, is of the opinion that microorganisms were apparently not the cause of eczema, but probably played a secondary role in this affection. Grinden is of the opinion that eczema was simply a peculiar type of inflammation due to a wide variety of causes and analogous to catarrh of mucous membranes. He believes that the internal cause of eczema is more important than the external. This we see in eczema of the face in children up to the period of dentition. There is often a cooperation of internal and external causes.

Anaphylaxis has been often mentioned as an important factor bearing upon all the types of eczema. However, the most peculiar feature of eczema is that no pathological changes were found in the so-called sensitized skin after the eczema had disappeared.

The most plausible theory of the real cause of eczema is that of Luithlen, the best known biochemist and dermatologist in Vienna, who paid particular attention to chemistry of the tissues and skin in healthy and diseased condition. He is of the opinion that eczema is due to metabolic disturbances. His observations are the first scientific proof of the old empirical fact that nutrition, diet, and internal treatment are important. They explain in which way diet, mineral waters and health resorts, for instance, Carlsbad, may exert a beneficial influence not only upon the entire system and its metabolism, but also upon the reaction of the skin and some of its affections. These findings show that in the

treatment of eezema we must pay attention to metabolism. They justify regulation of the diet and also internal treatment; they are the proper scientific basis for treatment which many of us have initiated years ago based on clinical observations. They show the road to etiologial therapy upon which we may probably reach more exact indications for treatment with greatest security and success.

M. L. RAVITCH.

SOCIAL SERVICE DEPARTMENT.

The pauperization of our people through the many charities maintained either by private or public means is a real menace to our Republic. To individuals who are absolutely destitute the doors of our Hospitals are thrown open, the coffers of our charitable organizations are placed at their disposal and the services of the large number of physicians, nurses and social workers, etc., are immediately obtained and the independence of spirit which is the birth-right of every one is slowly undermined.

There is a proverb which says, "God helps them that help themselves" and when we see the help that is given to those who do not help themselves, by man or woman, we truly believe that it is God and God only who helps those who help themselves, for certainly man's most strenuous efforts and largest donations are showered upon those who do not attempt to help themselves.

Publish an article in the newspapers describing the destitute condition of an individual, family or community and ask for contributions; go to any man or woman and pour into their ears a story of poverty and dependence about an individual or family and you will not fail to secure donations of every character.

How difficult it is on the other hand to secure real interest and help for those brave individuals who though handicapped either physically or financially, are striving continuously to preserve their independence and yet because of the lack of helping hands, are slowly being dragged down into the cess-pool of pauperism and dependence.

Institutions which are entirely charitable and in which services, etc., are absolutely free, are constantly receiving aid from many sources, but institutions which are requiring persons to pay something for the services rendered eke out a precarious existence.

We must realize that sentimental consideration is not always the best for the persons who are made the recipients of our charities, but that even in our charitable institutions we should make the inmates understand that in return for the services rendered they should

give such return as is possible in money or work. At the same time we should endeavor to enlarge the scope of our energies in endeavoring to discover individuals, families or communities that need assistance and yet who are not willing to be made so-called "objects of charity."

* * * * *

No man or woman can direct their energy along any special line looking to the betterment of a community without finding himself or herself broadened. In this connection it is interesting to note that Mr. J. B. McFerran, who until comparatively recent years has confined his greatest energy to business, has found time lately to endeavor to improve the educational facilities in Kentucky and by exercising those analytical and far-sighted qualities which help him in the world of business, he has come to realize that the word education not only means improvement in our school system but that it also brings within its definition every factor that goes to make up a community's welfare.

He together with other far-sighted men are now endeavoring to bring about a central organization which will conserve time, energy and money in improving conditions whether financial, economic, social or moral throughout our State.

May we hope that more financiers, bankers and business men together with farmers and educators will see the necessity of such a method in order that real results will follow.

* * * * *

The honor system of utilizing prisoners for work on roads bids fair to prove a real advance in our prison system. Colorado, Oregon, Washington, Wisconsin, Florida and Illinois are using it and find that it is a good thing.

It is stated that the departure from Joliet prison in Illinois on the part of the convicts for "Camp Hope" and the work out of doors was most impressive. One convict sat up all night nervous and sleepless over the coming change from four walls to open country and from convict stripes to citizen's clothes. The men travel in suits of Sunday black and work in khaki suits and shirts. The pay which the men receive is sent to their families when they have any or held until they are released.

Kentucky's roads could be improved and her prisoners greatly benefitted if some such system were adopted here, at the same time breaking up the contract system which permits our prisoners to be utilized in manufacturing articles which enter into competition with the free man's labor.

Take off their stripes, let them learn that there is still for them something better than cells and guards. Make them work but pay

them so that their dependent families may not become the wards of our charitable organizations.

* * * * *

Gifford Pinchot who has done so much for forestry conservation has accepted the chairmanship of a special committee on the church and country life to represent the Federal Council of the Churches of Christ in America. Professor Thomas N. Carver of Harvard University is also a member unofficially representing the Rural Organization Service recently created in the department of Agriculture by Secretary Houston.

The Rev. Chas. O'Gill, who together with Mr. Pinchot have published a volume entitled the Country Church, will conduct the work of this special committee. In humiliating contrast to this real sensible forward step is the opposition to the Country Life Department of Home Missions in the Northern Presbyterian Assembly.

* * * * *

From Character, (a Boston business magazine of personality, edited by Thomas Drier) comes the following unusual editorial on loyalty:

In the name of loyalty there is perpetrated upon the world more vile rot than the laws of common sense allow. Oftentimes employers find that talks on loyalty can be given in lieu of salary.

Conversation will not buy the baby Castoria, or fill the cellar with vegetables for the winter, but conversation on loyalty is often given to workmen as if it would purchase for them not only the necessaries but the luxuries of life.

Blind loyalty is asinine. Every employee deserves to know the reason why. It is the divine right of every man to be from Missouri.

Loyalty to employers is a subject upon which the wielders of the whips talk to their wage slaves as they send them out to labor in the sweat of their brow to add to the fame and wealth of those whose tongues are gilded with the germs of loyalty talk.

I believe in loyalty, but I believe infinitely more in the square deal. I know that no institution can be built up unless there is harmony; but I deny that in order to secure harmony the eyes of men must be blinded and they must follow like sheep some leader who uses them only for his own selfish purposes.

It is because of this fetish of loyalty that we have the House of Want and the House of Have. It is because of the blind worship of convention, of precedent, of smug propriety, that men to-day fail to receive what they earn. And they worship blindly these things because they are ignorant and in their ignorance they do not realize their power, nor do

they understand what men mean when they talk of the Square Deal.

Loyalty to self is the greatest loyalty. The man who is truly loyal to himself will give his neighbor a square deal. And it is only when the doctrine of the square deal is practiced that the ailments of society will be cured.

DUNNING S. WILSON.

"DAMAGED GOODS."

I have seen an epoch making play, the like of which has never been produced before, Eugene Brieux's "Les Avaries," or to give it its English title, "Damaged Goods." It is a play intended to convey the biblical statement "that the sins of the father are visited upon the children," a sermon in dialogue, a play of thrilling interest with but few moments of action, a play that holds and attracts even one who is worldly wise and sorrow-worn, who for two decades has been pleading and to whom the story is old and worn.

The theatre was quiet; no music, no tinkling of cymbal, no crash of brass, no gentle reed or string broke its solemnity, for the play and players had come to tell us in a new way, *to the public*, a story centuries old to physicians. The play is adapted from the French by Benjamin Blanchard and upon perusing the program under the title we find: "the object of this play is a study of the disease of syphilis and its bearing on marriage. It contains no scene to provoke scandal or cause disgust nor is there in it any obscene words; and it may be witnessed by every one, unless we must believe that *ignorance and folly* are necessary conditions of *female virtue*." Before the curtain goes up Mr. Richard Bennett, who takes the stellar role, announces from the stage the above quotation and states that the words *mistress, prostitute, prostitution*, etc., will be employed, but in no way to offend; to this they adhere in every sense of the word.

The scene of the first act opens in the consulting room of the Doctor (no name) with George Dupont (Bennett) waiting, evidently having just been examined by the Doctor in adjoining room. The Doctor enters, takes his seat at his desk, prescribes, explains what is necessary for him to do and finally tells him in a kindly way of his disease, its peculiarities, possibilities and dangers. Dupont represents his misfortune, complains and states that he is to be married and announces in extenuation of his position, that he must be married, that everything has been "arranged;" that his match is a "splendid" one, the bonds have been signed and every detail of the notaries complied with. Then follows arguments only too well known

to the medical profession; that syphilis can be controlled (cured?): that he must wait four years; more tears, recriminations, curses upon the "farewell bachelor supper," with its, "wein, weib und gesang," its lewdness and disease, a plea for a more speedy cure and the wholesome, clean, clear cut advice of the Doctor, who makes him fully understand the terrible crime he would commit, not alone against the pure and untarnished girl, but the dangers of having a syphilitic child. We cannot but admire the clearness of the statements made, their freedom from exaggeration and their plain truthfulness,—together with the kindly sympathetic but scientific attitude of the Doctor. When the complaining and whining man at times resents the *dictum* of medicine the Doctor rises in his wrath to teach him the lesson, not only he, but alas! so many others need who have been infected with this terrible malady and its cogener gonorrhoea. The Doctor paints, in strictly honest and truly scientific manner the dangers and results that would fall not alone to the innocent and uninfected woman he is to take for wife, but of the grave risk to the child, should paternity become its lot. The announcement of the cure of syphilis by a persistent and careful course of treatment for four years (Fournier would have said five) leaves to him the hope that he may with honesty, *perhaps*, look to marriage after this time. It is evident from the start that Dupont is not likely to follow the well meaning and, excellently delivered, advice of his physician. No other characters appear upon the stage during this act. After an interval unenlivened by music, the curtain rises upon what should be a happy home. Under the false statement that he was threatened with tuberculosis, Dupont has secured six months stay of proceeding and as the superficial lesions had disappeared he contracted marriage and as a natural sequence has become a father. That he does not realize his perilous position is shown by the marked evidence of his happiness and pleasure in his genuine love for the girl, who he has made wife. But the baby isn't well; it is frail, delicate, has the "snuffles," has some skin lesion of which everyone at the time seems ignorant. The baby is taken to the country and here for the first time the mother-in-law who, like most grandmothers is devotedly and passionately attached to the baby, learns the terrible news; it is a syphilitic baby. She brings the baby back to town and tells the father. It cannot be bottle fed and she has brought a sturdy peasant girl to nurse the baby as foster mother and in her passionate love for the infant is willing to sacrifice this woman to the disease, if the infant may but live. When the nurse finds out the facts, she leaves, presumably

uninfected, but before she leaves she tells the terror-stricken wife the brutal fact that she has gone through the cane-break and picked out a crooked reed, that she has bought goods the warp and woof of which seemed good and durable, but which in reality were damaged. With her horrified shriek to the man to keep his hands off the curtain falls.

In the next act we are back again in the consulting room of the Doctor, who had been called in the previous act to see the infant and who had told the mother and son the vital facts and of the warning that had been given. In this act we have much that can be commended. The wife's father, a deputy of France, comes to the Doctor with the intention of getting at the truth and then "killing the scoundrel." He is to learn a sad lesson for the Doctor truly tells him that it will do no good, that a shooting will but drag his daughter's dishonor and their dirty linen through the press of Paris and accomplish in the end no good. His recommendation is sensible. For they must both learn a sad and terrible lesson, the outcome of the unfortunate cultural conditions of modern life. They must both be treated, they must both take up their life together, they must both learn to devote themselves to one another and try, out of their misfortune to pluck what contentment and happiness is possible. The deputy resents the statement of these facts and names himself as an example of a *moral* husband and *virtuous* father. The Doctor soon takes the starch out of him by showing that *he was not virtuous* as a young man by any means and the fact that he was free from syphilis was due to a species of "*good luck*" and not to any virtuous or well meaning attempt to remain so. The Doctor has brought several people from his clinic. He shows a woman with wrecked life who has gone untreated for years and her plea was "I did not know." A man broken in health, to whom the word happiness had long since passed, plead "I did not know." He then shows a prostitute and in this character traces the frightful course of infection after infection. The girl describes her pure and happy life, her misfortune, her infection, her terrible suffering, her growing hatred of men that trod the "Boulevards," of how she "*made them pay the bill*" how she evened the balance with her seducer, how her beauty and her disease entangled the rich, the poor, the middle aged, youths and even boys until the deputy, sickened beyond belief, cries halt, enough. When the last curtain falls, we find that the star has not been on the stage during this act, that while we have been listening to a large volume of talk, we have in reality been watching a much bigger and more thrilling spectacle of a fight of a man through three acts to

win his beautiful and beloved, and we must be a pretty case hardened sort of a fellow not to just stay awake a little while thinking about this play when we reach home, even though we *have seen* these things for twenty-two years.

And now for the playwright, producer and characters:

Eugene Brieux, a member of the Academy of France, has written some most excellent plays, although the critics say that "*Damaged Goods*" is the least likely the one to have been popular of all of Brieux's plays that have been turned into English. But it has survived the patronage of the curious and morbid and achieved success, a real success on the mere ground of being *worth seeing*. Brieux, we believe is much more of a preacher than a dramatist; he is a tremendous moralist and has written a strong play with a moral to it. He is no prude and while he calls a spade a spade, there was never a word, never a statement and never an idea that could be twisted into the obscene, save by one whose *rationation* is sadly defective. He does not try to write pleasant things concerning the affairs of people and this is certainly not a pleasant subject to look upon, for he shows man and woman suffering, not lightly, but terribly, not because they are bad, not because they have evil intents, but because they are *boldly ignorant and do not know any better*. It is the crime of ignorance and it is this lesson that Monsieur Brieux wishes to convey. God knows it is needed and every true physician wishes this message carried to the uttermost ends of the earth. I cannot agree with Ralph Reed (*Lancet Clinic*, April 26th, 1913) that "*Damaged Goods*" is not a good drama and I think that his statement that "a really great drama must have a theme that finds sympathetic response in every heart. All great dramas do—every one can sympathize with the moral conflict that is the central core of all drama, particularly tragedy." It is our belief that there is here in the last analysis a sympathetic response in every heart for the helpless woman, for the unborn and already born child who has become contaminated with syphilis. But let us not call it a drama. Let us call it a play—the play—"for the play's the thing wherein to catch the conscience of the king" (Hamlet). If we cannot do anything else, we can at least meet on common ground and extend to Monsieur Brieux our sincerest thanks and appreciation of his estimate, not alone of the true physician in his relations to his patients, but in his vocation as a guardian of the morals of the home and the social fabric. All honor to Monsieur Brieux.

Richard Bennett produced this play against opposition, we are told, that was very

pressing. He calls it an educational production which sounds forbidding and one would think would scare away audiences. Puritanical opposition came to his rescue and he has been educating large crowds every week. He has not played to the galleries concerning the sex life of France, but is trying, through this play to teach people the brave business of *facing facts*, of trying to teach legislators how little *they* know, and the absolute need we have of more sensible marriage laws. Mr. Bennett is very effective in his acting, for he has a hard character to play. George Dupont is very mean and despicable, at times; weak and vacillating at others, but never, for one moment does he cease to be very essentially human. We certainly owe Mr. Bennett a debt of gratitude for his production and an appreciation of a part well played.

In many years of theatre going, I have yet to see a piece of character acting to exceed that of the "girl", a *femme du pave*, taken by *Miss Adrienne Morrison*. We have been told that it was difficult to secure a woman to take this part and that the lady who plays it, has sacrificed her feelings, in the belief that her contribution in this play may be of lasting benefit to the human race. The role must naturally be a difficult one, requiring the putting aside of one's personal feelings. Her acting is simply letter perfect; a woman tricked: a prostitute. "*Damaged Goods*." Her acting, true, Oh! so true to life, so full of that subtle truth of acting that makes a character a live, breathing thing. One cannot but feel the heart tighten and the cords of sympathy vibrate to her heart rendering suffering, to her humanity. This is alas too well known to comment upon. We cannot speak too highly of her acting. A difficult part well filled, by a capable actress.

We feel, however, that the *Doctor*, as played by *Louis Bennison*, is undoubtedly the best portrayal we have seen in years upon the stage and we would place him along side of Mr. Albert Brunnings rendition of the character of Dr. Emerson in "*The Case of Becky*." Mr. Bennison *looks* the Doctor; strong, tall, forceful and dignified, who represents all that we would wish for in the physician; truthful, honest, intelligent, scientific in his private work; and who shows to best advantage in the interest he has in the betterment of the social fabric. Oh! how sick and sad and tortured are we through, yea, these many years, so heartily sick of the vaudeville, "mellodramatic" and "movie" picture characterization of "*Doc*" with his perennial whiskers and his little black bag. Angels and ministers of grace, defend us from this continued affliction and may we close this editorial with an expression of

sincerest appreciation from a medical man to Mr. Bennison for his intelligent and scientific rendition of Monsieur Brieux's physician. It is to be hoped that the stage will see more of such men.

"Damaged Goods" pleads with great force for clean living; intellectual and moral honesty and is a courageous fight against hypocrisy. It is never indecent; it never lies; it is *always* frank. We feel that we cannot better conclude in this connection than in publishing the following gem that is decidedly pertinent to the remarks herein made; it is a poem by Ella Wheeler Wilcox.

THE PRICE HE PAID.

I said I would have my fling,
And do what a young man may;
And I didn't believe a thing
That the parsons have to say.
I didn't believe in a God
That gives us blood like fire,
Then flings us into hell because
We answer the call of desire.

And I said: "Religion is rot,
And the laws of the world are nil:
For the bad man is he who is caught
And cannot pay his bill,
And there is no place called hell:
And heaven is only a truth,
When a man has his way with a maid,
In the fresh, keen hour of youth.

And money can buy us grace,
If it rings on the plate of the church
And money can neatly erase,
Each sign of a sinful smirch.
For I saw men everywhere,
Hotfooting the road of vice;
And women and preachers smiled on them
As long as they paid the price.

So I had my joy of life:
I went the pace of the town;
And then I took me a wife,
And started to settle down.
I had gold enough and to spare
For all the simple joys
That belong with a house and a home
And a brood of girls and boys.

I married a girl with health
And virtue and spotless fame,
I gave in exchange my wealth
And a proud old family name.
And I gave her the love of a heart
Grown sated and sick of sin!
My deal with the devil was all cleaned up,
And the last bill handed in.

She was going to bring me a child,
And when in labor she cried.

With love and fear I was wild—
But now I wish she had died.
For the son she bore me was blind
And crippled and weak and sore?
And his mother was left a wreck.
It was so she settled my score.

I said I must have my fling,
And they knew the path I would go;
Yet no one told me a thing
Of what I needed to know.
Folks talk too much of a soul
From heavenly joys debarred—
And not enough of the babes unborn,
By the sins of their fathers scarred.

CURRAN POPE.

ORIGINAL ARTICLES

INSECTS AS TRANSMITTERS OF DISEASE.*

By J. H. HENDREN, Cary.

The subject which has been assigned to me is indeed a broad one, and to do it justice would require a volume instead of a short paper. Possibly the first and most clearly demonstrated case of disease transmitted by insects was the Texas fever of cattle, which was shown to be transmitted by the cattle tick or dog tick. This discovery opened a new field of investigation, and since that time some ten or fifteen of our most important diseases are now known to be dependent either entirely or in a large measure upon insects of some kind for their continuation in the human family.

This subject as a whole is entirely too broad for this paper and I have limited it to "Insects as Transmitters of Disease in Bell County."

Insects which transmit disease may be divided into two great classes:

First, mechanical; second, biological.

To the first class belong those insects which simply act as a carrier of the disease germs from place to place as a man carries mud on his boots in muddy weather. While the second class embraces those insects within whose body the disease germs undergo some transformation necessary to their propagation.

Of the first or mechanical class the most common insect, not only in Bell county but everywhere is the common house fly, *musca domestica*. This insect, so long considered harmless, we now well know to be the cause of much of the typhoid, hookworm, and intestinal summer diarrhoeas of children, so prevalent in this region. It was not known that flies were a causative agent in the pro-

*Read before the Bell County Medical Society.

duction of typhoid fever, until 1898, when typhoid killed more soldiers in the concentration camps of the American army, than the Spaniards did in battle. A typhoid commission was appointed and the charge was made and proven that the house fly was the most active spreading factor.

I believe that a conservative estimate of the cases of typhoid in this county caused by the housefly would be 50 per cent. To tell the truth there is not and can never be any reliable statistics on this point. When we consider that a person may give off active typhoid germs for some time before the disease is seen or recognized by a physician, that some cases run the regular course without ever seeing a doctor; and that some typhoid carriers, though in good health and working every day, give off typhoid germs by the million; statistics in these cases must indeed be meaningless things.

The housefly carries typhoid, not in its body, but on its body. The housefly is abundant in country places, especially near places where horses are kept. The reason for this is that the preferred food of the magot or housefly larvae, is horse manure. Flies breed in incredibly large numbers in horse manure. Ten to twelve days completes the generation, and one adult female will lay from one hundred to one hundred and twenty five eggs every three weeks. In one season the descendants of one fly, under favorable conditions, will number more than one billion.

Stiles in his work on hookworm, seems to think, or at least leaves the impression that all cases of hookworm follow as a result of "ground itch". In my opinion, this is not true. My records show a number of cases of hookworm under one and two years old, with no history of sores of any kind. The infection in these cases I attribute in a large measure to flies carrying the infection to the child's bread and butter, or dropping the eggs or larvae on the floor, which later get directly into the child's alimentary tract, without the formality of going through the skin.

On many farms in this county, where even very intelligent people live, the open type of closet is too common, and I attribute this to a lack of education along sanitary lines. When the physician is called to even a suspected case of typhoid, he should carefully inspect the outhouses, water supply, etc., and give such suggestions to the family as he thinks best. Much good could be done toward better sanitary conditions in the county, as well as to show to the family that he had more at stake than the fee. The only cure for these troubles is to prevent them, and prevention comes only through better sanitation.

Another insect quite common here, is the

little fruit fly, of the genus *Drosophila*. These are much smaller than the house fly and are often spoken of as "gnats." They breed in decayed fruit, and sometimes in human excrement. They may be seen in droves around rotten apples, cider presses, and decayed fruits of any kind. While the danger of infection is not so great as with the house fly, it should be kept in mind. Fruit should be screened when in the home, and over ripe fruit should not be allowed to remain long in the house.

The germs of the cattle disease, anthrax, can be carried by the gad fly or common "horse fly", and when these insects bite man a malignant pustule may result. However they rarely bite the human. The horse fly is common in this county, and while I know of no cases of anthrax, it should be borne in mind.

Another insect which occurs in Bell County is the *simulidae* or minute fly which Sambon claims transmits pellagra. While I have not examined many streams, I have found the larvae of this fly in every stream which I have examined. The adult fly is a small insect, a little larger than the common gnat, while the larvae looks not unlike the common wiggle-tail to the naked eye. The larvae is found on the under side of stones in swift streams, especially at or near rocky fords. They are tender little creatures, and seem easily killed by the waste oils from machinery, and mine waters. They are very hard to hatch into the adult fly, and much trouble and patience is necessary. Personally I have never seen anything to lead me to believe that there was any relation between pellagra and the Sambon fly, but I do believe that pellagra is a germ disease with an intermediate host which has not yet been discovered.

To the second group belong the mosquitoes.

To these insects alone is due the transmission of malarial fever. There are about thirty genera of mosquitoes known and classified but for the purpose of this paper only three need to be mentioned, namely: *Culex*, *Anopheles* and *Stegomyia*, all three of which are found in Bell county. There are many mosquitoes which have not yet proven to carry disease. In fact the majority of them are supposed to be harmless except for the irritating bite. To the harmless mosquitoes belong the genera *Culex* mentioned in this paper for the subject of comparison and not for their disease spreading proclivities.

Of the three species of *Anopheles* mentioned as malarial carriers, *Anopheles maculipennis*, *Anopheles punctipennis* and *Anopheles crucians*, I have found the first two in this county, but never the last. This is rather

odd, as the *anopheles drucians* is said to be widely disseminated over the southern states.

All mosquitoes lay their eggs in water, which hatch in from one to three days. The eggs of the *culex* resemble a minute piece of honey comb, floating with their long axis perpendicular to the surface of the water, while those of the *anopheles* float independently of each other, end to end or side to side as logs in a boom. The larvae of the *culex*, familiar to every one, are found in troughs, rain barrels, tubs, tin cans, in fact still, stagnant water anywhere, and are known as wigglers or wiggletails. The tail is the breathing tube. The larvae come to the surface of the water stick this tube out into the air, and hang heads downward. The breeding places of the *anopheles* are not so varied as the *culex*. They seem to prefer those places that have the soil for a bottom. They are found in the still waters of small streams, swampy pools, ponds, stagnant water in ditches, but seldom in barrels, buckets, etc., where we find the *culex* so abundant.

The food of all mosquito larvae is the green scum or algae of stagnant water. It is a fact of enormous sanitary importance that mosquitoes cannot breed without still and reasonably stagnant water. Adult male mosquitoes usually die soon after copulation while females often live all summer. Only the females bite, and they will attack any warm blooded animal.

In my opinion, malarial fever in Bell county can never amount to very much. In my eight years of residence here I cannot recall more than one or two cases that I felt sure originated here, although I have treated a number of introduced cases, especially from Laurel county and the Phillipines. The reason for this is plain. The smaller streams are swift and rocky, and abundant springs keep the water cool. High mountains prevent the formation of pools on their sides, and the soil of the bottoms is sandy which lets the pools dry up before the water stagnates. Mosquitoes, as a rule, never migrate more than a mile from the place of hatching. High winds might blow them to greater distances under unusual circumstances. They do not rise to very great altitudes, and homes on mountains are free from the pests.

I have also found a few specimens of the adult *stegomyia fasciata*, or yellow fever mosquito, in this section, although I have never found the eggs or larvae. Unless the *stegomyia fasciata* has previously bitten a person suffering from yellow fever, it is as harmless as the *culex*, and we need fear nothing from this source unless some yellow fever refugee should drift into this section. If you have formed the opinion that the yellow fever mos-

quito does not exist here, and that we are free from infection, that is a mistake, for they do exist here, although in very limited numbers.

The stable fly is another insect common in this county which has recently been placed in the list of disease transmitters. This insect differs in size, shape and color from the common housefly. It is noticed most frequently on horses, and is a fierce quick biter. It is yellow in color, with black dots on yellow wings. It is said to transmit the germ of spinal meningitis, but whether it belongs to the first or second group, I am unable to say. An epidemic of infantile paralysis occurred on the left fork of Straight Creek two years ago, but what relation its spread bore to the stable fly I am not able to say.

I would not consider this paper complete if I failed to mention one insect so common to the homes, not only of this county, but elsewhere, the *cimex lectularius* or common bed bug. This insect is too well known to need any description at my hands. So far he has been able to prove an alibi every time an attempt has been made to incriminate as a transmitter of disease. For my part I have never been able to dismiss from my mind the suspicion that there is some relation between the bed bug and pellagra. Every new case that presents itself to me seems to prove a "house infection" and to my mind no insect so fittingly fills the bill in this case as the bed bug.

HYPERTROPHIED TONSILS.*

By EDW. WILSON, Pineville.

Hypertrophied tonsils are one of the most frequent pathological conditions with which the general practitioner has to deal.

They consist of a proliferation of the lymphoid elements with an increase of the connective tissue stroma.

Children may be born with enlarged tonsils or they may develop at any age prior to puberty, and, there is a decided hereditary tendency in certain families. I have done tonsillectomies in as many as six out of a family of eleven. If we find enlarged tonsils in one child of a family we may look for the same in other members of the same family if the family be large.

The clinical symptoms of enlarged tonsils are familiar to us all. The most urgent symptoms calling for tonsillectomy are repeated attacks of tonsillitis or tonsillar abscess and nasal obstruction evidenced by mouth breathing and snoring, also repeated attacks of earache or deafness.

A rheumatic tendency accompanied with

*Read before the Bell County Medical Society.

anemia calls for removal of the tonsils if they are enlarged.

Any or all of the above mentioned symptoms may be produced also by adenoids alone or combined with enlarged tonsils.

Tonsils are best removed under a general anesthetic, preferably ether. After the patient is anesthetized the gag and tongue depressor are placed and held by the anesthetist. The tonsil is seized with a tonsil holding forceps and separated above and in front with a tonsil separator, the wire of the snare is placed around the base and the tonsil is slowly snared off. After the tonsils are removed the adenoids, if present, should be scraped out with an adenoid eurette.

THE DIFFERENTIAL DIAGNOSIS OF
THE DISEASES OF THE EYE AND
EAR MOST COMMONLY MET
WITH BY THE GENERAL
PRACTITIONER.*

By J. P. EDMONDS, Middlesboro.

The diagnosis and proper treatment of diseases of the eye and ear do not receive appropriate attention in the mountain districts, especially, diseased conditions of the ear are overlooked and are never cared for as they should be and the general practitioner having so many other things gives these branches but little thought.

The early detection of disease renders its cure probable and unless we see cases early they cannot be properly treated and many of them we do not see until it becomes chronic, the child with sore eyes goes to school to mix and mingle with others and no doubt transmits it to many others and we do not see the case until the mother tells us, then we see some of the sequelae incident to such cases, partial blindness, ulcers, scars, entropion, all with a profuse discharge and swelling of the lids. In the poor class long treatment is out of the question and they are forced to go through life without help.

It costs about \$15,000,000 annually to care for about three hundred thousand blind people in the United States, most of whom are blind through ignorance and lack of intelligent supervision.

First, taking up the most prevalent diseases of the eye, every case presenting itself and of short duration, is simply called sore eyes and are amenable to mild treatment and usually subside in a short time. Those of long standing or because they are chronic, do not seek a physician until an exacerbation or until the eyes get very sore, in the language of the patient: "I had the sore eyes about six

months ago and Dr. So and So cured them" when if they were examined carefully we would find an entirely different condition. Here in the mountains we see a great deal of trachoma which is very difficult for one that does not see these cases daily to make a differential diagnosis. At Ellis Island, New York, they are held in detention house for several days to make a diagnosis. In the outlying districts, the average physician calls it "granulated lids." These cases are considered dangerous diseases. One had better have smallpox than severe trachoma. It takes a long continuous treatment to cure, then there is danger of recurrence. I have within the past four months, had eight cases come to my office, rather led in, they could not see to walk. I do the scarification and grattage operation then rub them every day and every other day for a period from three to six weeks or until every trachoma body disappears. In all but two cases I have gotten a cure and these two did not come to office as directed. We see them in our schools and in public places where other children are and no steps taken to isolate them. In diagnosing you usually get a history in some that they have had sore eyes all their lives and have been cured several times. In the acute cases the conjunctiva is swollen and a profuse secretion is present and very painful, on examination the conjunctiva of the lids is studded with little bodies resembling millet seeds, these produce so much friction on the cornea that a membrane begins to grow down over the cornea filled with blood vessels. This is called pannus and is always more or less seen in all chronic cases. The vision is lowered and patients protect their eyes by partially closing them from excessive light. The eyelids droop and ptosis develops from a thickened condition of the palpebral conjunctiva and swelling of the tarsal cartilage. Every physician knows or should know from the history of the case just what he is dealing with but in most of the cases, the patient is given an eye wash and the doctor leads himself to believe that a cure will be the result and these cases, if watched carefully, can be eliminated from the milder forms of inflammation.

Then we have some forms of inflammation that will mislead the general practitioner if he does not go thoroughly into the history of the case. A mild attack of iritis is usually called simply sore eyes. These patients usually complain of severe headache at night. Eyes hurt and a great deal of photophobia during the day with but little lachrymation when in conjunctivitis there is profuse discharge and a sensation of sand in the eyes. In looking at the eyes closely we see the conjunctiva very red and congested, in simple

*Read before the Bell County Medical Society.

conjunctivitis the superficial blood vessels are the only ones involved, while in iritis, the deeper blood vessels are the only ones involved and thus we do not have much discharge. There is a pink zone around the iris with pupil contracted showing there is considerable inflammation in the ciliary body. These cases are the hardest for the general practitioner to diagnose and he should be very careful in giving a prognosis. Unrecognized and neglected conditions often become incurable. The early recognition of disease joined with intelligent medical interference will minimize sickness, ignorance and crime.

In taking up the diseased condition of the ear that is commonly met with by the general practitioner, our attention is first directed to a case when told that the child has an earache we should be very careful as to the history, the onset, and number of attacks, or how long the child's ear has given it trouble. The careful and painstaking doctor will examine the child's ear and if pus is found he will clean it out to ascertain the damage done to the tympanic membrane and try to locate the source of the pus and then he will examine the posterior rhino-pharynx for adenoids or epipharyngitis. How many do this? If you would take more pains to see what is the trouble you would treat these cases more conservatively and thereby save the little sufferer from the dangers incident to such conditions. If the infection is due to adenoids they should be removed. If due to epi-pharyngitis, it should receive appropriate treatment. Having removed the cause of tubal infection, that in the tympanum tends to disappear with little or no treatment, however, the infection in the middle ear is attended by pronounced tissue changes that needs additional local treatment. The ear should be examined carefully and if the drum membrane is found to be bulging, it should be incised at once to liberate the pus which is usually found in these cases with a severe pain and a temperature and should not be let alone to wait developments, when these cases are not treated as above, they usually rupture in the course of a few hours and then we have a sloughing perforation in the membrana tympanum. They signify simple infection in the cavum tympani, probably of tubal origin, and you may have a destructive process going on in the middle ear. If the perforation is central, the infection is simple. If you have marginal perforations, this signifies bone necrosis. These are usually of the chronic form, and will result in mastoiditis unless treated energetically.

The general practitioner usually does not carry a mirror and not being conversant with the smaller details does not recognize the very

important lesions. These cases can only be treated by establishing drainage, by keeping the canal clean and if the perforation is small, a myringectomy should be done to enlarge the opening, then pack the canal. Be sure to place the gauze against the drum, then pack it loosely. If you fail to get it in contact with the drum, the gauze will act as a dam and what you want to accomplish will be unsuccessful. Don't treat aural pain and light discharges as if it was a natural consequence. Try to impress on the child's parents the necessity of treatment. Don't allow them to apply poultices. It would be far better that you do nothing. A pain in the ear denotes a blocking up of secretions and some infectious process going on. Find out the trouble, then do something. I wish to recite a case of simple tubal infection of long standing that recently came into my office. Patient was suffering with pain in his ear of two weeks' duration, saying that the doctor had burned it and scraped it out. I found the ear full of sweet oil which had been prescribed by the doctor. I irrigated the ear thoroughly and found the drum bulging and tense. This is a condition hard for the general practitioner to recognize unless he is very familiar with the landmarks of the membrana tympanum. I cocaineized the drum and did a myringectomy opening the drum with a long incision behind the handle of the malleus then I inflated the Eustachian tube and pus came out into the canal very freely. This case was entirely relieved in a few hours as the patient expressed himself that he could hear better than with the good ear.

If the acute cases are treated energetically from the beginning the cure usually results in a few days. If let alone, the case becomes chronic and the pus continues to flow for two or three weeks, then we know that a destructive process is going on within the middle ear, and all cases with a profuse discharge for two weeks or longer, are considered chronic and need operative interference, but very few have anything done and the case goes on until deafness is well established and the patient goes through life with a discharge from the ear with chronic mastoiditis, which is like a loaded gun. There are many patients that cannot be treated because of insufficient funds and therefore never have anything done.

This is a very large subject and I have only covered a few of the minor points and have not gone into it as deeply as I might have done.

CESAREAN SECTION.*

By E. M. HARRISON, Fork Ridge, Tenn.

Cesarean section, the subject chosen by your committee for me to discuss, has been generally defined as the operation for removing the fetus by opening the abdomen and incising the uterus.

Although this operation was performed hundreds of years ago by ancient surgeons, it has not come into the popularity which should have been accorded it, on account of its life saving proclivities, until during the latter part of the past century, but now, thanks to the almost perfect technique, that goes hand in hand with modern surgery, obstetricians are more and more resorting to its use, abandoning the more crude and unscientific mutilating procedures, which were absolute death to the fetus in every instance and more than likely the death of the mother also.

Among the ancients Cesarean section was only performed immediately after the death of the mother with the idea of saving the life of the child; Cæsar having been among the first to have been delivered in this way, the name Cesarean section was given to this operation. At the present time we more and more perform this operation with the purpose of saving the life of the mother as well as that of the child, with such fortunate results that to-day the rate of mortality in selected cases is much lower than in any other abdominal sections.

While there exists records of this operation having been performed upon the dead mother much earlier, it is not until in the fourteenth century that we find instances of it being performed upon the living subject, it then assumed some degree of popularity but rapidly came into disrepute on account of its high mortality, occasioned by sepsis and hemorrhage, for this reason Pare and Mauriceau, authorities in that day and time, condemned the operation, and so then as it is now when the authorities condemn the rank and file fall in line and no matter how good a thing is it is pushed to the wall and allowed there to cling until some venturesome spirit casts aside the mantle of so-called authority and relying on his own indominate courage brings back into existence some heavenly endowed blessing for mankind, and so with Cesarean section it was practically abandoned until Perre, in 1878 resurrected it, improving the technique of the operation by amputating the uterus and sewing the stump in the abdominal wound. In the first operations the uterine wound was left open, because the belief existed that the alternate contractions and re-

laxations would make the stitches tear out. The wound having been left open and gaping would finally close by adhesive inflammation to the abdominal wall. The scar thus formed was liable to rupture with the formation of hernia. It was not until in the beginning of the present century that uterine suture was advocated and practiced, but notwithstanding the mortality remained excessively high until Perre advocated his idea of amputating the uterus. To Sanger of Leipzig is due the greatest meed of praise for proposing, in 1882, the closure of the uterine wound by multiple sutures, and since the introduction of this operation, craniotomy and the other mutilating operations upon the living child have been practically abandoned by thoroughly up-to-date obstetricians.

Cesarean section should be performed in the interest of mother and child or of either when safe delivery can not be promised by other means, as version or forceps. If the mother is in a dying condition and the safety of the child demands speedy delivery the operation should be performed to save the child.

It is sometimes very hard for us to decide as in the case where it is impossible to save the life of the child in any other way than a Cesarean section, though the mother may be safely delivered by one of the mutilating operations, then the question arises, have we the right to sacrifice the life of the child in the interest of the mother or has she the right to demand it of us, shall we weigh one life against the other; shall we deliberately destroy the life of the child by craniotomy or other similar operations or shall we on the other hand jeopardize the life of the mother by Cesarean section in the hope of saving the child; these are serious questions for us to decide and decision should only be made after consultation with a fellow practitioner and then only after plainly laying open the facts to the mother and her friends and then in advising them let the decision rest with them retaining to ourselves the privilege of retiring from the case should our advice not be accepted. Though we as obstetricians may know that Cesarean section should be performed we are not justified in doing so until consent of mother is obtained whenever her mental condition is clear for her to decide.

As for myself I am thankful that it has never occurred to my lot to deliberately perform craniotomy or any other mutilating operation upon a living child and so has my resolution been laid for the future never to do so believing that no one has the right to take that which he can not give, knowing that there are other means by which this life may be saved and that the added danger to the

*Read before the Bell County Medical Society.

mother's life by Cesarean section is not more than the danger she would incur by prolonged mutilating procedures.

Cesarean section should be performed when it is impossible to deliver the fetus through the natural passages on account of extreme pelvic contraction through arrested development so that the conjugate diameter is 2 1-3 inches and the child is well developed and at full term, or when the lumen of the canal is obstructed by abnormalities due to rickets or osteomalacia, or to bony tumors, also when tumors of the soft parts obstruct the way, as fibroids or cancer. Malpositions of the uterus often constitute an indication for Cesarean section. Very frequently following operations of ventrofixation at following pregnancies it becomes necessary to perform Cesarean section on account of the os pointing towards the sacrum and the strong adhesive bands not permitting the uterus to descend. Placenta previa may be considered an indication for Cesarean section, there are on record numerous cases in which this operation was performed for this cause. Malpresentations that can not be changed to normal presentations by the usual methods constitute an indication for Cesarean section. Eclampsia, where the os is very rigid and early delivery is imperative, can be considered as an indication. Acute nephritis has been considered as an indication. Threatened rupture of the uterus by forceful contractions during labor, as also constitutional diseases, as valvular heart lesions and sclerotic conditions of the blood vessels, are indications for Cesarean section. Malformation of the uterus and birth canal, such as double uterus and vagina have frequently complicated labor so that Cesarean section had to be performed. It may become necessary in the separation of normally implanted placenta where the uterus will not contract to perform Cesarean section and to amputate the uterus. In cases of marked stenosis, and where delivery is complicated by pelvic and abdominal tumors, it may become necessary to perform Cesarean section.

The time to operate in cases of Cesarean section where we have realized that this procedure must be carried out before the actual commencement of labor is very much in dispute, some operators wait until labor has commenced, believing that thereby they have the advantage in the dilated cervix affording free drainage and lessening the danger of hemorrhage; others operate several days before the expected date of labor. The operation before commencement of labor is preferable in that thorough preparation can be had and skilled assistants may be obtained, the fear that lack of contraction of the uterus

may allow severe hemorrhage is unfounded because sufficient contraction does occur whether labor has or has not set up as also the lack of drainage through the undilated cervix can be avoided by forcibly dilating and inserting gauze. Also the membranes may have been ruptured before the operation which is a disadvantage.

The method of operation is elective in most cases; whether we perform the classic Cesarean section or whether some of the modifications should be chosen depends upon the indications; in cases where septic conditions of the uterus exist and where through long continued labor and through repeated examinations and attempts at delivery by forceps it is almost certain that infection will develop, the Porro operation of amputating the uterus should be performed, as also where cancer of the uterus complicates, the entire uterus should be removed.

The classic Cesarean section, where the abdomen is opened by incision in the median line and opening the uterus through the peritoneal cavity delivering the child thereby, has been modified in various ways so that now the elective method of operation may be chosen from among the classic or peritoneal route, the extraperitoneal, the vaginal and the method of amputating the uterus. Whatever method of operation is chosen it is highly imperative that thorough antiseptic and aseptic precautions must be carried out and that sufficient skilled assistance must be obtained so that no hitch in the proceedings may occur as time is an important factor in this operative procedure as in all major operations.

The abdomen and vagina must be thoroughly made as near aseptic as possible by the usual methods of preparation; there must be on hand some preparation of ergot suitable for hypodermic use and a long elastic tourniquet.

The elastic Cesarean section, the one I have employed in the few cases that have been under my care, may be carried out by making a long incision through the median line or to one side from immediately above the symphysis to above the umbilicus and with the patient in the Trendelenburg position after walling off the exposed abdominal skin area by clamping sterile gauze to the peritoneum, the uterus is delivered through the wound and covered by hot sterile towels, the rubber tourniquet is placed around the lower uterine segment tightened and held by an assistant, the abdominal cavity being thoroughly walled off, incision is made in the median line of the uterus commencing just above the lower segment with knife and afterwards extending upward for about five or

six inches with scissors; no matter where the insertion of the placenta may be, or is it necessary to spend time detaching same should it happen to be under the place of incision, the child should be immediately delivered through the opening, umbilical cord clamped by artery forceps and cut, and then handed to an assistant, the membranes and placenta are quickly peeled off and detached, the opening in the uterus is closed by a continuous suture of ten-day catgut, first through the inner muscular coats, care being taken to extend through the decidua lining commencing at the upper angle of the wound and extending to the lower, by tightening this the uterine cavity is shut off, the same ligature is then continued through the balance of the muscular coat, tightened and then the third layer is made by an over and over stitch completely buries the lower two and brings the peritoneal surface together: by this method sinuses are avoided, the lower sutures are completely buried, the separate ligatures are not liable to slip as in interrupted stitch, liability or oozing between the ligatures is avoided, there is no rolling in of the cut surfaces and no eversion of the lips of the wound; some operators prefer the use of silk and of interrupted sutures; when silk is used the stitch becomes encysted and frequently gives trouble later, not being absorbed as is the catgut in a few days.

Some operators prefer not to tighten the tourniquet until after the child is delivered for fear that pressure for any continued time will cause paralysis of the muscular coat and prevent contraction there by causing hemorrhage later; but this fear is not well founded in my opinion for in the cases that I have seen immediate contraction takes place where the tourniquet was applied from the beginning; where the tourniquet was not used the hemorrhage is something fierce and by obstructing the field of operation delays the rapidity of performance on the other hand where the tourniquet was applied and tightened before incising the uterus the loss of blood is in fact nil, not being nearly as much as is lost in normal labor.

The Porro operation is carried out as is the classic one with the addition of amputating the uterus, sewing the stump into the abdominal wound or after covering with peritoneum is allowed to drop into the abdominal cavity.

In both the classic and the Porro operations the abdominal wound is closed by the usual methods in other abdominal sections.

The extraperitoneal operation is performed by making transverse incision through the abdominal walls just above the symphysis from one superior spine to the other down to the sheath of the rectus muscle which is rais-

ed and the muscle separated by handle of knife exposing the transversalis fascia which is penetrated laying bare the peritoneum, this is then separated from the pubis and bladder laying bare the lower uterine segment, this is opened in the vertical direction and the child delivered without much trouble on account of the large lower segment, the uterine wound is closed by interrupted sutures and the abdominal one by the usual methods.

The mortality in early operations was very high, as much as fifty per cent.; by improving the technique the mortality has steadily diminished until now in selected cases the rate is not more than two per cent.

The superiority of Cesarean section over the other methods of delivery, as the mutilating operations, has been proven beyond any conception of doubt, statistics showing that the rate of mortality is much lower.

Rupture of the scar resulting in hernia after Cesarean section, is prevented by securing exact apposition of uterine and abdominal wounds and healing without infection; treatment of hernia is by suturing the tear, the Porro operation or hysterectomy.

TYPHOID FEVER AND ITS PRACTICAL MANAGEMENT.*

By T. T. GIBSON, Middlesboro.

When called to see a case of suspected typhoid fever, we first consider the hygienic management, as it will not detain us long let us briefly consider it here.

It goes without saying that the patient's environment should be made as pleasant and cleanly as possible, as the siege is usually a long and trying one. The room should be light, pleasant and removed as far as possible from all noise. All unnecessary furnishings and hangings, etc, should be removed. A bare floor is best and most easily cleaned. The bed, if possible, should be low and have a reasonably firm mattress, all linen to be changed frequently. The dishes and utensils used by the patient should be kept clean and separate and apart from those used by the rest of the family. A separate thermometer should be used by fever cases. The physician should see that the stools, urine, sputum, and vomitus are promptly disinfected, as this is the chief means of propagation of the disease. As to the means I'll mention the best and most easily obtained in their order of efficiency. Fire, bluestone and fresh slacked lime or white wash. A chart of everything should be kept by a nurse or member of the family. A change of position occasionally should be insisted upon to prevent congestion

*Read before the Bell County Medical Society.

and the formation of bed sores. Generally speaking, the fewer the visitors, the better for the patient. The mouth and tongue should be kept clean throughout the disease, and the body should be kept clean by daily sponges. With this brief hygienic introduction, let us proceed at once with the subject.

The primary or essential conditions necessary to the successful management of a case of typhoid fever are comprised under the following heads:

First, rest in bed.

Second, liquid diet.

Third, intestinal antiseptics.

Fourth, management of special symptoms, should they arise.

Fifth, general supervision during the period of convalescence.

FIRST—REST IN BED.

This factor may be of considerable importance along the line of prognosis. The doctor should insist upon the patient going to bed as soon as he suspects typhoid, even before he makes his diagnosis, as a patient with fever is best off in bed from any cause. It is notoriously true that the individual who in spite of his doctor's advice, persists in remaining up with considerable fever, declaring boastfully, "that he only has a touch of malaria" and that he will soon "wear it out," is usually the type of case that has a hard time. Most always this type is forced to bed with resistance impaired, strength gone and heart threatened, and frequently has a sudden and ugly hemorrhage a few days after taking his bed, at any rate his case is prone to be unusually severe. Occasionally we see them a long distance from home, upon being told of their probable condition they insist upon being bundled up and carried home. With but few exceptions, the physician should always advise strongly against this. They should not even get up to empty the bowels or bladder until some days after the fever subsides and he is put on a semisolid diet, then he may be allowed to sit up at short intervals and then as strength returns he may gradually be allowed to get up and out.

SECOND—A LIQUID DIET.

There are three standard articles which may be obtained anywhere and everywhere, from the slab hut of the mountains to the palatial residence of a large city. They are, in order of their importance, milk, eggs and meat. From these three, either directly or indirectly, may be prepared a dietary sufficiently diverse and nourishing for any and all cases of typhoid fever, milk standing deservedly at the head of the list, as it can be taken longer with greater benefit and less discomfort to the patient than any other single article of diet in quantities of 4, 6 or even 8 ounces

every three or four hours during the day, according to strength and digestive capacity of the patient.

Eggs.—Good, fresh eggs certainly take easily second rank from the standpoint of general utility in the dietary of the typhoid fever patient. They may be prepared in many different ways and one good way is to put the white in a few ounces of cold sweetened water and flavoring with a few drops of fresh lemon juice.

BROTHS AND OTHER DIETARIES.

Broths made from chicken, beef, mutton, veal and squirrels may be added occasionally as a change of diet, care being taken to skim from the top all fat globules and to strain through a muslin cloth to avoid solids, salting to suit the taste. Brandy and whiskey in small amounts, properly used, belong here, as well as in the class of stimulants. Orange juice should be used occasionally.

A patient with typhoid should never use less than one to two pints of pure cold water in the twenty-four hours regardless of other fluids ingested, even if they are delirious and cannot ask for water, usually they will take it if it is put to their lips, which should be done in such cases. No solid food should be used until the temperature has been down to normal for a period of at least ten days, then they should begin with soft milk toast and soft boiled eggs, then gradually work their way out to the full diet of the table. In many instances it is best to aid digestion just at this period.

THIRD—INTESTINAL ANTISEPTICS.

It is absurd to claim that we can take a man in the middle of an attack of typhoid, a man with high temperature, delirium, etc., and bring about a marked and sudden improvement by the use of intestinal antiseptics, and is it not equally absurd to say that intestinal antiseptics are absolutely of no value in any stage of the disease. With all due respect to those who claim they are useless, experience teaches us these general principles: The earlier we get hold of a case and the cleaner we keep the intestinal tract in that same degree and proportion is the attack milder and shorter and freer from complications. But, say our critics, typhoid fever is a systemic not a local disease. True, and we are willing to acknowledge even that a few cases of typhoid fever have been reported by Welch in which there was no enteric lesion at all. These cases were pathological curiosities and not of special clinical interest. In most all cases we know that the intestinal tract is not only the chief point of involvement but it is likewise the point of entry—a gate through which the bacilli must pass to get

into the general system. We do not expect our intestinal antiseptics to get into the systemic circulation and there mounted upon the backs of the leucocytes to go madly chasing in search of typhoid bacilli, and having found them to pounce upon them, and kill them, but we do expect and obtain results with them by rendering the intestines a less habitable place for bacilli in a way controlling decomposition and fermentative changes, preventing the formation and absorption of various toxins and thus do away with a great deal of antioxi-cation which later, if permitted to continue, makes all cases graver.

I shall not in my limited time enter into the relative merits of the various antiseptic drugs. It is sufficient to say that with my limited experience, I have obtained best results with subnitrate of bismuth, salol and urotropine combined.

FOURTH—THE MANAGEMENT OF SPECIAL SYMPTOM, SHOULD THEY ARISE.

It is always our hope, of course, to keep as many of the symptoms from arising as possible, however, they will bob up sometimes perhaps because of us and certainly sometimes in spite of us. I shall mention a few of the more important of them and give the treatment briefly:

(a) *Fever*.—The best and most useful single measure throughout the whole course of the disease for fever is hydrotherapy, either luke warm or cold water as the case demands may be used, and the patient should be sponged every three or four hours when the fever is above 102. High fever in the first stage often responds to free-elimination. High temperature late in the disease means generally systemic toxemia and exhaustion and demands hydrotherapy and brisk stimulation.

(b). *The Heart*.—We seldom see a case of typhoid fever, however mild, where the heart should be permitted to struggle through an illness of from four to eight weeks or more without some support. When to give them should be determined from the patient's condition. Some need them during the second week while some may go well into the third or fourth week. As to the stimulation used, they number many with strychnine and alcohol in the shape of whiskey or brandy at the head of the list.

(c). *Hemorrhage*.—In any form of intestinal hemorrhage, if it is due to the breaking of a blood vessel, and surgical intervention is not applicable, I have long maintained that nature is the chief factor in stopping the hemorrhage, and the good which we can do must be along the line of assisting nature's efforts. We must in a sense let the heart

partially run down, and always resist the inclination to stimulate immediately. I have gotten some mighty nice results with morphine, argotole, adrenalin chloride hypodermatically to quiet the patient and to check a profuse hemorrhage. An ice bag on the abdomen and the foot of the bed elevated is very useful. Give nothing by the mouth that would embarrass the intestines or keep up peristalsis. Never try to obtain a movement from the bowels for at least thirty-six to forty-eight hours or sometimes longer, after a profuse hemorrhage, then use an enema of soap suds. Use only a small amount of pre-digested nutriment.

(d). *Perforation*.—Perforation, the most dreaded and fatal of all complications, demands prompt surgical aid. If this cannot be obtained, then we must perforce follow the expectant plan, viz. opium for pain, heat applied locally and stimulation.

(e). *Tympany* can sometimes be relieved by introducing a tube into the bowels, permitting the gas to escape. Turpentine used internally by mouth or enema with soapsuds or stupes will relieve most of them.

(f). *Constipation*.—Calomel, alone or combined with podophyllin in the beginning and our old friend castor oil gives some mighty happy results with a few drops of turpentine added occasionally. If you have just had or fear intestinal complications it is best to depend upon enema alone. Except in case of hemorrhage or perforation never allow the bowels to go over forty-eight hours without obtaining a movement.

(g). *Diarrhœa* needs no treatment except where there are more than three or four stools a day. If so a little calomel and push other intestinal antiseptics, astringents and bismuth salts.

(h). *Insomnia and Restlessness*.—In many instances can be relieved by sponging. Occasionally a dose of some mild hypnotic may be necessary. Avoid them if possible.

(i). *Delirium*.—Ice cap and sponging and stimulation. Avoid morphine if possible although it is necessary sometimes to give it to enable exhausted nature to pick up the dropped threads and move on again.

(j). *Cystitis*.—My best results have been obtained with urotropine.

(k). *Bed Sores* are more easily prevented than treated by keeping the patient clean, all wrinkles from the bed clothing, and bathing with alcohol, and change of position occasionally.

(l). *Muscular Soreness*.—Sponging, massage and alcohol rubs.

FIFTH—GENERAL SUPERVISION.

During the period of convalescence. At this stage of the disease the typhoid patient is like an individual about to drown near the shore. Usually the doctor leaves about the time the fever does and at best the patient is an emaciated, weakened and threatened individual. The intestine in places is thin and sometimes there may be only a thin layer of peritoneum between life and death; the digestion is crippled, the blood is impoverished, the strength is gone, and he needs a guide, so see your typhoid cases occasionally for a few weeks during convalescence.

In conclusion permit me to say that the mortality of typhoid is lower now than formerly and the clinical picture is as a rule not so severe as it was in olden days. This is due in part to a better understanding of the disease but chiefly to better and more scientific and practical management. Very old text books on typhoid fever speak more of the post-typhoid lesions than they do of the disease itself, that is phlegmasia dolens, spinal trouble, insanity, neuritis, etc. Relatively speaking, we see comparatively little of these now. The change in the clinical picture is brought about by elimination freely, frequently and early, by the use of intestinal antiseptics rendering a less habitable place for bacilli, by diluting the poison so that they do not injure important organs like the kidneys, etc., by the use of water internally, externally, and eternally.

We keep down the fever and obtain rest and supply enough suitable nutrition to replace the waste tissue and then the patient is not permitted to live on himself so to speak. He does not become so emaciated and he is in the majority of instances brought to the shores of convalescence without being wrecked.

Biologic Test for Absorbed Sperma in Female Serum.—The research reported was done on rabbits. It demonstrated the presence in the serum of the female after cohabitation of a ferment that digested testicle tissue; beforehand the test had constantly elicited a negative response. The ferment reaction persisted positive in the gravid animals up to sixteen days after littering. Walstein and Ekler say that these findings indicate that the female organism is materially influenced by substances absorbed from the sperma, causing the production of a ferment hitherto strange to the organism. If these findings apply also to human beings, they would explain certain phenomena in the life of a woman which have hitherto been credited only to psychic processes. Possibly the ninhydrin test for the sperma reaction might prove instructive in certain medicolegal circumstances.

THE DUCTLESS GLANDS AND THEIR RELATION TO DISEASE.*

By O. P. NUCKOLS, Pineville,

In attempting to discuss such a subject as I have laid before me, in what is relatively a new field of investigation, I fully realize that much must yet be regarded, as hypothetical and not fully proven, when we come to deal with the internal secretions, and their relation, and influence on the body metabolism.

While this is true, the many developments of investigation along this line in the last few years in this field of work, has thrown much light on the subject, and we now know that the "ductless glands" furnish to the system internal secretions that play an important part in the normal body functions.

When we speak of the ductless glands, we refer to those glandular bodies, that do not pour their contents into an open channel by means of small ducts, to be carried away with other excretions, but rather to be retained within the glandular structure, and absorbed into the blood current itself.

Their secretions are referred to as internal secretions, because their activities are confined to the glands themselves, and by means of either absorption, or chemical messengers, known as harmones, they exert their influence on other and remote structures.

The comparatively recent theory that the ductless glands, are brought to bear an internal relation on the function of each other, through the medium of harmones, has thrown much light on many subjects that have hitherto been left in darkness. This furnishes at least a theoretical explanation of many of the varied manifestations, in that peculiar tripod of symptoms presented in Graves' disease.

That the ductless glands play an important part in the body metabolism is a matter easy of proof, from the observations of every day life. No doubt the father of organotherapy, that learned Frenchman Brown Sequard when his fertile brain became interested in restoring to man that "elixir of life" that would call a halt on the rapid march toward senility and impotency, he had in mind the buoyant days of his youth when the testicular glands began to surcharge the blood current with their chemie and physiologic force.

That the testicle has an influence on many developmental changes, can be proven both affirmatively and negatively, by the well marked changes of puberty, and the pronounced changes following castration, or disease of the testicle, or the more gradual changes of senility.

*Read before the Bell County Medical Society.

The same marked changes in the female are noted at the age of puberty, and the climacterium. Experimental removal of the ovaries of the female, have been followed by as marked changes as removal of the testicle from the male.

It is with relation to the thyroid gland, and the para-thyroid, that we meet with the most interesting phenomena in connection with the "ductless glands," and the important role they play in the body metabolism. The congenital absence of this gland is followed by that condition known as cretinism, and many and varied are the cretinoid conditions due to this cause.

The hypersecretion of this gland, is soon followed by that tripod of symptoms known as exophthalmic goiter in the majority of cases. The pathology of this disease is somewhat in question, but there can be no reasonable doubt that it is due to the increased internal secretion of this gland, that acts as an intoxication directly upon the central and sympathetic nervous system, or through the means of harmones, and brings into play the many clinical symptoms that characterize this disease. This theory is proven true by the clinical fact, that the removal of a part of the gland, or the ligation of the thyroid artery, thus reducing this secretion in either case, and having relief to follow.

Just to the reverse of this condition, where all the nervous functions are heightened, and the retrograde processes are increased, we have that other side of the picture, produced by the decreased action of the thyroid body, asserting itself in some instances, as simply sluggishness and obesity, and in others as a true myxedema.

It is known that the secretion of the thyroid, contains a considerable per cent. of iodine, which may account for some of the symptoms present in either case. Co-incident with hypersecretion, we have rapid and extreme emaciation, and with sub-secretion we have a tendency toward corpulency, and sluggishness. It is a well known fact that iodine increases the retrograde process, and accounts for the emaciation in hypersecretion, and its absence in the cases of sub-secretion accounts for the tendency to corpulency, and the accumulation of intracellular poison in true cases of myxoedema.

Addison disease is the most familiar disease resulting from failure of the supra-renal bodies, and acromegaly that peculiar abnormal development of the osseous system, has been thought to be due to an adenomatous degeneration of the pituitary gland.

The amylolitic and proteolytic external secretions of the pancreas are well known, but the removal of this viscus is followed by

glycosuria, and it has been discovered by Mering and Minkowski, that this is due to the absence of the internal secretions of the islands of Langerhans, the individual cells of which produce a ferment that maintains the normal degree of glycosuria.

I have cited some of the most familiar, well-marked conditions, that have been reasonably well proven, to show some of the effects of the disturbance of the normal functions of the ductless glands, which tends to show that there is within the body, a force that has much to do with the inter-relationship of the various organs, and their harmonious workings, known as health. Many careful observers have come to regard the force of these internal secretions, as holding the key to the proper and healthful functions of the sympathetic nervous system, and that great teacher, Robert Bartholow, long before the function of the thyroid was known, taught that exophthalmic goitre was a disease of the sympathetic system. There can scarcely be any reasonable doubt that it is through the sympathetic nervous system that many of the symptoms are manifested in this class of diseases.

The question of blood pressure, arteriosclerosis, tachycardia, and no doubt many deviations from the normal, that we cannot as yet account for, may find their true explanation in the study of the internal secretions. Beebe, of New York, advises that in any case of rapid heart that cannot be accounted for by some organic or readily located trouble should direct our attention to the ductless glands.

It is a well established fact that adrenalin, pituitrin, both raise the blood pressure. That thyroid extract increases the heart's action, and raises the blood pressure in the kidney, and is the best treatment for cretinism and myxoedema. That ovarian extract mitigates many of the nervous symptoms of the climacterium, and that pancreatic extract benefits glycosuria. Now, reasoning from effect back to cause, these facts must prove the part these structures must play in controlling many of the body functions, and their relation to the body well being.

The natural result of the study of the ductless glands, has wonderfully developed the use of organic extracts in the treatment of diseases. However, organotherapy in its present form, and in its present scientific manner, is but a revival of some of the crude practices of ancient times, when the priests used the organs of animals as sacrificial offerings. Hippocrates and Celsus made use of various animal organs for the relief of those symptoms in man, which were thought to be due to defective action of the same organ, as the pidgeon or wolf's liver for hepatic diseases, the brain of the hare for the tremors, the lungs

of the fox for dyspnoea, and the remnet for stomach disorders. Pliny advised the use of the testicle of the donkey or stag, as an aphrodisiac, and the following prescription is found in Macbeth:

Filet of a fenny snake,
In the caldron boil and bake;
Eye of newt and toe of frog,
Wool of bat, and tongue of dog,
Adders fork and blind worms sting,
Lizzard's leg and owlet's wing,
For a charm of powerful trouble,
Like a hell-broth boil and bubble.

THE COMPLICATIONS OF TYPHOID FEVER.*

By B. E. GIANNINI, Straight Creek.

From my point of view typhoid fever claims and receives close study. Its wide distribution, insidious beginning, protracted course, debilitating effect, its accidents, complications and sequelae combine to make a clinical picture which though consistent as to outlines, is capable of varying widely as regarding its individual features.

The classical and schematic descriptions of the text books, however detailed and excellent, often fail to adequately represent the comparative frequency of aberrant symptoms. It is proper that our mind should be firmly fixed upon the main features of the disease, so as to secure, by a timely diagnosis advantages both for our patients and ourselves.

The occurrence of unusual symptoms, however, cannot fail to be of peculiar interest to the observant physician, and deserve record in the works of our profession.

There is such a long list of the possible complications of typhoid that to name them would be tiresome, therefore I will only call attention to the more important ones; perforation, haemorrhage, etc.

Perforation occurs in practically 5 to 6 per cent. of all cases of typhoid fever occurring mainly in the small bowel, however, recent investigations show that perforations may occur at remote points of the intestinal tract, a case reported by Lynn of perforation occurring at the junction of the pylorus and duodenum, however he states that it may have been the site of an old duodenal ulcer attacked by the typhoid infection.

Kelly concludes that about 5 per cent of perforative appendicitis is due to a latent typhoid infection plus a mixed infection. The recognition of perforations may be very difficult at times especially if the patient be in the classic typhoid state, dull and apathetic;

but when their condition is bright, about 75 per cent of all perforations are announced by the sudden acute abdominal pain, rapidly develop tenderness and rigidity, an early decline in temperature and an elevation of the pulse with the typical abdominal facies. If the pre-existing tympanities is great and the general symptoms already severe, the occurrence of perforation is very difficult then to determine.

Another of the much dreaded complications of typhoid is hemorrhage, occurs in about 3 to 5 per cent. of all cases and usually occurs during the third or fourth week, terminating fatally in from 30 to 40 per cent. of all cases. If the hemorrhage be very large and profuse death may ensue before its appearance at the rectum, its occurrence being characterized by a sudden fall of temperature with signs of collapse and in a few hours by the voiding of bloody or tarry stools.

Borley reports a case of hemorrhage from the auditory canal which was severe and repeated that gave rise to alarming symptoms, and a case of severe nasal hemorrhage occurred in my own practice that required continual packing.

Of the cerebral complications that arise possibly meningitis is the most frequent, as a large majority of cases have very pronounced cerebral manifestations, various neuritis occur and may be either multiple or single, the typhoid spine that occurs during convalescence is probably a neurosis. A case of ascending paralysis of Landry has been reported by Lyon with a paresis of the muscle of the larynx and pharynx, and a loss of the reflexes. The tender toes of typhoid seen after bathing and usually disappearing after convalescence is a typical neuritis.

Among the rarer nervous complications may be mentioned the typhoid insanity following the more malignant cases, hemiplegia with or without aphasia, and convulsions.

In mentioning the lung complications I should say that lobar pneumonia, hypostatic congestion, and with an associated bronchitis are the most frequent, while pleurisy which is more apt to be an empyema is not uncommon.

Endocarditis, myocarditis and pericarditis follow in the order named, thrombosis and embolism of the veins and arteries are less likely complications that may occur, the left femoral suffering the most likely involvement; a few cases of embolism of the mesentery of the jejunum have been reported with resultant gangrene.

Acute nephritis may usher in the disease, but is most usually seen in a mild form during convalescence; cystitis, pyelitis and perinephritic abscess may also develop. Hyperpyrexia is more a sign of the severity of the

*Read before the Bell County Medical Society.

infection than a danger or a complication. A suppurative parotitis may supervene, usually unilateral and when present is usually a grave and fatal sequelae.

Instances of irregular fever, recurring chilliness or rigours are indicative of an existing septicemia.

In concluding, the earlier the perforation occur in typhoid fever the better the chances the patient has for a recovery if prompt surgical measures are brought to bear on the case, as is shown by Kelly, Murphy and others who give mortality statistics as being not nearly so high with prompt surgery stating that 20 to 30 per cent. of all cases of perforation are recovering from operative measures that is when the patient is not already far advanced in the disease, and *providing* the perforation occurs say in the second to the third week.

APPENDICITIS; OPERABLE AND NON-OPERABLE.*

By TILMAN RAMSEY, Pineville.

Of all the pathological conditions that the country physician is called upon to combat, there is none that gives him more anxiety than appendicitis. Is it operable or not operable? Shall he give opium or purgative and intestinal antiseptics? These are questions of which there is the greatest difference of opinion. So much so that we are left to formulate our treatment of each individual case.

To give opium is to mask all of the symptoms the most important guide we have, and to give to the patient and his friends a sense of security, they feel they are getting better, and often refuse surgical intervention until it is too late.

In the light of the pathological condition we have to deal with, to give purgatives to drain the parts is as rational as it would be to flush a main sewer line to open a blocked service line.

There is no medical treatment for appendicitis.

If all cases of appendicitis could be operated upon during the first twelve hours, the mortality of appendicitis would be nil.

WHEN TO OPERATE.

There is still such a divergence of opinions as to when it is best to operate leads one to the conclusion that we have no reliable index or guide.

The symptoms are a very treacherous guide, as frequently we find that the symptoms and pathologic process are out of all proportions, this disproportion being caused by the different combination of varieties of microorganism

taking part in the inflammatory process as when we have the Butyric acid bacillus and malignant edema bacillus present, we have a rapid and destructive process, accompanied by very mild symptoms.

With the hope of solving the perplexing questions Kohl undertook a study of the leucocyte count and neutrophilic count according to Arnett's system of a large number of patients suffering with appendicitis.

Kohl modifies Arnett's system of classification by counting only the number of neutrophils with a single nuclear segment. He finds this gives him quite as reliable information as the more elaborate method.

His conclusions are as follows: "In order for the leucocyte count or the neutrophilic picture of Arnett to be of much service, they should both be charted in the form of a curve."

"The leukocytes should be counted in every acute case of appendicitis, whether operation is to be performed or not. It is always to be taken into consideration in conjunction with the rest of the clinical picture, but it has fully as much significance as the curve of temperature or pulse. If it clashed with the other clinical symptoms, the curve of the neutrophilic blood picture must be brought to its aid."

"In general, it can be said that the neutrophilic blood picture, according to Arnett, is an expression of the virulence of the infection, whereas, the leukocytosis points on the one side to the degree of peritoneal irritation, and on the other side of the reactive power of the individual."

"Increased leukocytosis in connection with a normal neutrophilic blood picture or one in which the leukocytes with a nucleus of but one segment are but slightly increased, gives a good prognosis; the higher the neutrophilic blood picture goes, the more severe is the infection, and consequently the more unfavorable the prognosis. If the leukocytosis is increased, this is an indication of good powers of resistance, and consequently a favorable prognostic sign; on the other hand, a low leukocytic count, in the presence of a high neutrophilic blood picture, gives an unfavorable aspect to the case."

"A moderate parallel ascent of the curves is of more favorable significance than a sudden, rapid ascent of one curve or the other, or a crossing of the curves." "The most unfavorable cases are those of peritonitis with a very high neutrophilic blood picture, and a normal or subnormal leukocytosis. If after operation on such a case the neutrophile curve sinks and the leukocyte curve rises, the prognosis becomes better, the organism is overcoming the virulence of the infection."

*Read before the Bell County Medical Society.

"After operation there is occasionally observed a rapid ascent of the neutrophile curve, sometimes accompanied with decrease in the leukocytosis, and shortly thereafter a return of the curve to the normal. This postoperative ascent, which is presumably dependant upon the stirring up of a previously encapsulated inflammatory process, is of no significance in regard to the prognosis."

"A gradual steady rise of the neutrophilic blood picture after operation is an indication of great seriousness, as it signifies a progression of the infection."

"Primary or secondary abscesses are indicated by an increase in the leukocytosis while temperature and pulse may remain normal. If the leukocytosis decreases before the abscess is opened, it will in all probability be found encapsulated. With the increase in the leukocytosis there is usually, according to the degree of infection, a more or less marked increase in the neutrophilic picture."

"An early operation for appendicitis is indicated in all cases excepting those in which in addition to a very mild clinical picture, especially slight local tenderness, the leukocytosis and neutrophilic blood picture are either normal or only slightly elevated. In case of recurrence, immediate operation is indicated."

"If in conjunction with slight clinical findings, there is a marked leukocytosis, operation should be undertaken."

As a rule I should say operate in every case as soon as the diagnosis is made, unless the symptoms indicate that inflammatory process is in abeyance.

NORMAL LABOR AND ITS MANAGEMENT.*

By J. G. FOLEY, Pineville.

When I received a program of the Bell County Medical Society, and saw this subject had been assigned to me, it reminded me very much of the boy who had been doing things that he had been repeatedly told not to do, and finally on being asked as to what he himself thought ought to be done with a boy who would continue to do such things, he hesitated, but finally made this answer, "Just let him alone."

Since labor is a physiological act and normal labor has nothing to keep nature from completing that act, then why not give it the boy's treatment, just let it alone? However, it is necessary that a few conditions be looked after in all pregnancies, in order that they may all terminate as nearly as possible in normal labor, as the general condition of the

patient, the breasts and condition of the kidneys.

The patient should have, during the entire period of gestation, a wholesome, nutritious diet, consisting largely of fruits and vegetables; should be clad with loose, comfortable clothing; should have a proper amount of exercise, but not violent; should walk and exercise in the day time and in the sunshine, instead of evenings, as practiced at the present time. The care of the breasts receives but little or no attention at all in a majority of cases, yet this means much to the proper nourishment of the child, and comfort and future welfare of the mother.

Condition of the Kidneys. This, possibly, is one of the most important of all the conditions and cares in pregnancy, and one of the great many people in this country to engage hardest to manage, since it is the custom of a physician and call him into a labor case at the same time. Consequently, he is wholly unarmed, knows nothing of condition of patient at all. Quite often he is ushered into the room and the first thing to see is the patient in an eclamptic convulsion. It is my regular custom to get a specimen of urine from the whole amount passed in at least twelve hours, just as soon as I have been engaged to take care of a labor case, and examine it and keep this up weekly until confinement.

This brings us down to confinement, or active labor. Here it is useless in the present day to say the first thing to do when called to a labor case is to thoroughly clean up. After this is done, make a thorough examination of patient, so as to thoroughly know conditions in hand. If the patient is too nervous and sensitive for this to be done without an anesthetic, give her chloroform and make a thorough examination and make out your position and conditions, then don't examine too often. I know of no other place in the practice of medicine or surgery where the physician should be more in complete possession of all his senses than in a labor case. He should be kind, patient and careful and always keep in mind the fact that he has the responsibility of at least two lives in his hands, instead of one. As to the use of chloroform, personally I prefer to use it and do always use it unless contraindicated. After removing the placenta and seeing that contraction is good, the physician should always look after the cleansing and dressing of the baby and see that everything is alright.

During the confinement period, the physician should give instructions to the nurse as to the care of mother and child. Mother should be well fed on an easily digested, wholesome

*Read before the Bell County Medical Society.

and nutritious diet, and should be seen by physician himself each day, when possible, for a period of ten days, at which time she may be discharged, if conditions are normal.

MALPOSITIONS AND DISEASES OF THE FEMALE PELVIC ORGANS.*

By C. K. BRANTHEAR, Middlesboro.

I find this quite a lengthy subject and will only try to bring out a few points of special interest to the general practitioner.

The most fruitful source of disease and also malpositions is the gonococcus, by its inflammatory action and subsequent adhesions pulling all the pelvic organs out of their normal position and often binding them so tightly that we find their release quite difficult.

Malpositions are of all grades and all positions, forward, backward, up or down or to either side. Caused by, first, lack of support when the pelvic floor is torn or much relaxed from childbirth or some wasting disease, second, by relaxed ligaments, as the round or lateral ligaments, the utero-sacral ligaments, often help in the displacement, third, tumors either pulling or pushing. These tumors may be hard as fibroids, and dermoids, or an enlargement due to pus, blood, or a watery fluid.

Tumors may involve any of the pelvic organs, uterus, tubes, ovaries, broad ligaments or possibly the appendix.

Displacement and diseases depend on each other, the one being caused by the other so that they must be considered together and treated as a combination.

To arrive at a correct diagnosis requires a great deal of careful tact and discrimination as well as a full understanding of the normal, also a knowledge that very often considerable displacement causes no symptoms while again a displacement of much less magnitude causes much suffering. Often a posteriorly displaced uterus may cause no symptoms, but let an ovary be prolapsed and adhesive behind the uterus, may give quite severe pain and nervous symptoms.

Patients come complaining of discharge, pain, missed menstruation (think they have taken cold). Pain may be localized or general in character, covering whole abdomen or in fact many parts of the body. Often a woman who has borne children complains of pain, discharge, pain in back, bearing down feeling, painful menstruation, pain sometimes at defecation, or micturition.

This history always points to laceration of perineum, cervix and prolapse of uterus, which pulls on ligament. Fundus rests on soft structures in front of sacrum, causing trouble with bowels and disturbance of digest-

ion. The cervix against the bladder causes irritation of this organ with frequent, painful micturition.

Discharge from the cervix is thick and glary, can often be removed with difficulty. From the uterus, bloody, purulent or mucopurulent discharge. The bloody flow often coming every two weeks and lasting for several days or at times for weeks, in fact so irregular they cannot tell when to expect the menses. This is a general line of what we have in such cases, some of these symptoms may be lacking while others are most pronounced.

The women who have not borne children seldom give this same line of symptoms. She may have any of those mentioned, but seldom or never all of them.

Her most frequent cause of trouble is gonorrhoea, which after acute symptoms subside, are chronic discharge from the cervix and bloody or purulent of uterus often with periodic discharge from the tubes, and irregular menstruation.

Most of the adhesions in pelvis are caused in this class by the above mentioned germ and these adhesions are, in most cases, the cause of displacements found.

The most important and far-reaching after gonorrhoea is cancer. We can never be too careful in our examination of all cases especially those showing irregular discharge of blood and even in these we are often too late and can only say "if you had attended to this earlier something might have been done."

Cancer is more frequent in old age, but is not so seldom found in those who should be in the prime of life. In my limited experience, I have seen several cases under thirty years of age. The full blooded negro seems almost immune to cancer; I have seen only one case in a "sure enough" black woman and her mother was a mulatto. The only hope of curing our cancer cases is to make the diagnosis at the earliest possible moment and, in my judgment a doctor should never prescribe for a patient who gives suspicious symptoms without a careful examination. For who among us that has not had cases refuse to be examined properly and months later find them in a hopeless condition.

Tumors: Fibroid are found most often in the active childbearing period and especially in the colored race. Symptoms of same are pains from pressure or interference of some function, as the bladder, bowels or circulation. All fibroids of much size or if growing should be removed whether symptoms are urgent or not, as most, if left, will later show degeneration, often of a malignant character.

Pus from pelvic organs should be evacuated, *but beware of opening the abdomen with*

*Read before the Bell County Medical Society.

acute pus tube. If they are large and prolapsed they can be drained through the vagina, but should seldom be attempted through abdominal wall. Put these patients in bed and give nature a little time and most acute cases will subside to a point where an appropriate operation gives promise of success.

Often these chronic cases, when adhesions are not too strong, can be symptomatically cured by using depleting tampons, massaging and stretching adhesions, using electricity and tonics to build up the general system.

Other tumors, such as cysts of ovary are often found. These are seldom serious in themselves unless quite large, but are subject to complications, such as strangulation and adhesions to the surrounding organs. All cysts should be removed if condition of patient will permit. The appendix often becomes a pelvic complication in these cases under discussion and should then be dealt with as such.

I have taken this subject up without order, but such we find them in general practice.

BACTERIAL DISEASES AND THEIR PREVENTION.*

By JACOB SCHULTZ, Logmont.

There is no branch connected with the science of medicine that has made such rapid progress and unravelled so many mysteries as that of bacteriology; by the use of the microscope, the great microscopic world has been revealed and it is proving, with all its mysteries and phenomena, to be uniquely organized and governed by laws as well defined as those governing our universe and the planets which deck the great canopy of the heavens.

It is only the untiring efforts of the bacteriologist, who has made it possible for us to discuss this subject scientifically. Durnig the short time in which he has been exploring what has heretofore been an unknown realm, he has taken the pick and shovel of the mine, and, digging here and blasting there, he has penetrated great barriers which have hidden this great field of science and is now holding up to us pearls of countless value; he has gone to the bottom of a great many of our troubles and has given us facts which are indispensable with the scientific treatment and prevention of disease, we are no longer groping in the dark as to the real cause of disease, but we know beyond all question of doubt the etiology of many of our most prevalent diseases. Among them may be mentioned, tuberculosis, typhoid fever, malarial fever, relapsing fever, epidemic cerebro-spinal fever, Asiatic cholera,

ameboid dysentery, influenza, diphtheria, hookworm disease, syphilis, gonorrhoea, anthrax, tetanus, erysipelas and many others; these are diseases of bacterial origin and are due to the implantation, growth and multiplication of specific micro-organisms.

The initiation of these diseases are dependent upon certain conditions and it would be unreasonable to suppose that one typhoid bacillus, when taken into the intestinal canal, would cause a reaction sufficient to produce a case of enteric fever; the same is true of the other diseases of this class, therefore, the excitement of the disease is conditional upon the specific bacteria present, also upon the virulence of their type and the resistive powers of the individual.

The resistive power of the person seems to play an important part in acquiring many of these diseases, while in others, it seems to have but little influence. In typhoid fever, it seems, there is comparatively speaking, no respector of persons as it attacks the young as well as the old, the strong and robust as well as the weak, running its course regardless of any treatment known to our profession; but on the other hand, as in the case of tuberculosis, the resistive power of the patient plays the all important part. According to post-mortem examinations, two-thirds of all the subjects examined have, at some time, been infected with the tubercle bacillus, but, owing to the resistive powers of the patient, in the majority of these cases, the infection had not gained headway but had been completely incapacitated and the infected area walled off from the healthy tissue.

Here we see demonstrated the great protective forces of nature, how wise she is and what a great effort she puts forth to counteract and correct any wrong that is going on in her domains; she is always on her guard and the minutest microbe cannot invade her premises without her instant knowledge of the fact. After the invasion, it is her business to go after the intruder; this she does with all the force and energy at her command, she puts her regulars at work and calls upon her reserves and fights without ceasing until she overcomes or is overcome.

At this stage of the game, we may offer our assistance but this must be done scientifically, lest we hinder rather than help; we must understand, so far as possible, what she is trying to do and the method employed; we must not depress and weaken her forces by trying to overcome the infection by some theory of our own which we do not thoroughly understand. In many cases, it is true, we have a perfect knowledge of what is taking place and we have at our command the forces by which

*Read before the Kentucky State Medical Association, at Bowling Green, Tuesday, September 2, 1913.

we may come to her rescue, clear up the field of battle and gain the victory; this is true in diphtheria, we know that diphtheria anti-toxin contains the very antibodies which the body of the patient is trying to manufacture; here the great man of science has given us the means by which we may come to nature's relief and win battles with her assistance, which, in the past, without our help, have proven too great for her forces.

The great fight which nature puts forth is conclusive evidence that she is struggling with an enemy whose ranks are strong and not lacking in diligence for bacteria are ever present.

For instance a Petri dish, filled with gelatin, and exposed to the air for twenty-four hours and then examined, will show colonies of various strains of bacteria scattered here and there all over the surface; these bacteria, of course, are not all pathogenic and well it is that they are not, but the disease producers are by no means scarce. It is claimed by some that the diplococcus lanceolatus is taken in with each inspiration; this is done with impunity, provided the body of the host is in proper condition, but, when the vitality is lowered by exposure to rain, cold, previous attacks, etc., this bacillus localizes at the *locus minoris resistentiae* and, the condition being suitable, they grow, multiply and cause a reaction on the part of tissue producing lobar pneumonia; of course, the bacillus lanceolatus is not the initiatory of every case of pneumonia as it may be due to various other bacteria but it is, usually, of the lobular type.

Since malaria has been proven to be due to a plasmodium, it has created a world wide interest among bacteriologists and scientists; to my mind, there has never been a greater piece of work done in the history of bacteriology; to trace the course of the plasmodium has attracted the highest powers of the microscope and the keenest eye of the scientist; to trace the tortuous course and the various changes which take place from the time that this plasmodium is drawn from the blood of a patient suffering from malaria by a mosquito—and that particular type known as the anopheles—is almost beyond comprehension.

The great progress that has been made in gaining knowledge of bacterial diseases has made wonderful changes in the treatment and prevention of disease and the fact has revolutionized the whole practice of medicine and surgery.

THE PREVENTION OF BACTERIAL DISEASES.

This is a question of the most vital importance and one in which all are concerned; the medical profession has been trying to educate the people along these lines and show them the

great importance of prophylactic measures; she has sounded the trumpet of alarm and asked the people to join hands with her and wage war against diseases which are depopulating their land and country, but, as strange as it may seem, the people are not awakened to this cry as they should be and their co-operation in the great battle against dreaded foes are lacking.

The medical profession is the only profession on earth that is striving earnestly day and night to tear down her own business; every true doctor feels it his duty to teach the people in every way possible how to live and care for themselves so as to overcome and prevent disease.

The bacterial diseases, if the proper precautions were taken, could be prevented and, in time, wiped out of existence, however, this can not be done by the medical profession alone but, with her leadership and the hearty co-operation of the people, the teeming millions of pathogenic bacteria could be put practically out of reach of most individuals.

The advantages we have to-day over our fathers of yesterday are great in dealing with these questions, the bacteriologist has wrought many wonders and given us a clue and key to the situation; by the discovery of the tubercular bacillus, we know that tuberculosis is due to the implantation, growth and multiplication of this bacillus, that the most frequent way of gaining entrance into the body is through the respiratory tract and that the sputum of tubercular patients is laden with this bacillus which, when dried, is ready to be breathed into the lungs of the first passerby: this gives us the knowledge of how to prevent the spread of tuberculosis and it is astonishing that, after gaining this knowledge, one death out of every seven, according to statistics, should be due to this disease. The medical profession is not to be censured for this condition for she has waged war and sworn vengeance from the beginning, she has organized societies and had laws passed trying to blockade the work of this awful malady.

The great issue in the prevention of tuberculosis is the care of the patient's sputum, it is easy to see how a tubercular patient by expectorating on the street may infect many others—there it remains and dries when the dashing automobile, the street car, the dray wagon, and the whipping of ladies' skirts put it in motion and millions of tubercular bacilli float freely in the air.

Tuberculosis is no longer considered an hereditary disease but, in every case, is due to the introduction of bacteria from without; that is one important fact and those who have a predisposition, a scrofulosis, should especi-

ally be on their guard and should protect themselves, as far as possible. They should sleep, work, and live in the pure air and sunshine which are incompatible to the growth of the tubercular bacillus.

In diphtheria, by the discovery of the Klebs-Loeffler bacillus, we are enabled to take certain precautions and thereby prevent the spread of the disease; first, by the discovery of this bacillus it has made it possible for a certain and early diagnosis; second, by examining the throats of convalescents we are enabled to fix the necessary quarantine term. After the diagnosis has been made, the patient should be isolated, the room which he occupies should not contain more than is necessary for the comfort of the patient, all curtains, pictures, books, etc., should be removed and no one allowed to enter the room except the nurse and the physician and if there are other children of the family they should receive immunizing doses of diphtheritic anti-toxin at once.

In typhoid fever we have a bacterial disease that is easily preventable and it is astonishing to think of the number of cases which occur successively in the same family and community; it is well known that the typhoid bacillus enters the body of the host through the gastro-intestinal canal and its media is most usually in the drinking water but may be contained in the milk or food so the question of prevention is only a problem of cleaning up and cleaning out and of keeping clean, getting on the war path and having a battle tearing down the hog pen which is an incubator for all kinds of germs, boiling the water you drink and thoroughly exterminating the flies.

The early fly is the one to swat. It comes before the weather's hot, and sits around and files its eggs and lays at least ten million eggs, and every egg will bring a fly to drive us crazy by and by. Oh, every fly that skips our swatters will have five million sons and daughters, and countless first and second cousins, and aunts and uncles, scores of dozens, and fifty-seven billion nieces, so knock the blamed thing all to pieces. And every niece and every aunt—unless we swat them so they can't—will lay enough dodgasted eggs to fill up ten five-gallon kegs, and all these eggs ere summer hies, will bring forth twenty trillion flies. And thus it goes, an endless chain, so all our swatting is in vain unless we do that swatting soon, in Maytime and in early June. So men and brothers, let us rise, gird up our loins and swat the flies. And sisters, leave your cozy bowers where you have wasted golden hours; with ardor in your souls and eyes, roll up your sleeves and swat the flies!

Secondly, by the use of typhoid bacterins,

typhoid fever may be and has been cut down wonderfully; this affords us great protection, we can not pick our places to eat and drink every time and we expose ourselves, knowingly, to this disease but we may by the use of the bacterins, establish an immunity which renders us safe against infection.

By the vigorous and untiring efforts of our State Bacteriologist, Dr. Lillian H. South, Chief Sanitary Inspector, Dr. A. T. McCormack, and their co-workers, in their war waged against hookworm disease in every county, town and district in the State, it is possible for the medical profession to obtain better co-operation on the part of the people, besides the many thousands that were cured of the above mentioned disease.

The prevention of bacterial diseases resolves itself into the problem of educating the people; the task imposes itself upon all, the doctor, the preacher, the lawyer, the editor and especially the teachers of our schools, to those who shoulder the burden success will come and bring with it an everlasting blessing to humanity.

THE END RESULTS OF THE HOOKWORM DISPENSARIES.*

By O. P. NUCKOLS, Pineville.

When asked by the Secretary of this Association to present to you a short paper summarizing the end results of the hookworm investigation in the State by the Rockefeller Commission, and your State Board of Health, I felt that it was a task that could have been passed to more competent hands, however, it is by the final results that we judge of all great movements, and designate them as either successes or failures.

In order that we may properly interpret the end results, it becomes necessary, first to present some of the primary conditions, calling for such an investigation. Until a few years back, the many fearful and sad results produced by hookworm infection were unknown and the appalling loss of life, to say nothing of the tremendous loss to the world of business from lowered vitality, and lack of productive energy, would amount to figures that would stagger all of our powers of conception. Thanks be to the investigations of the Rockefeller Commission, that the cause for this tremendous loss of life and power has been made known, and active measures taken to remove the cause. The investigation of hookworm disease in Kentucky, so far, has been largely confined to the eastern part of

*Read before the Kentucky State Medical Association, at Bowling Green, Tuesday, September 2, 1913.

the State, and has been found to prevail, to a marked extent, in the coal fields and rural districts. The per centage of infection has been found to range from as high as seventy-five per cent. in some localities, to as low as fifteen per cent. in others. It has been further found to vary with the higher or lower standards of sanitation, and especially is this true with regard to privy vaults, and the proper care of the excreta.

The end results of the hookworm campaign may be summed up, first, in the effect it has had on those infected; second, the general effect it has had on improved sanitary conditions; and third, the increased respect by the public for the medical profession. Those who have been the direct beneficiaries of the campaign, are, of course, those who were the victims of this dreadful malady. Hundreds have been transformed from invalidism, whose lives were slowly, but surely ebbing away, to active and useful citizens. The pallid cheek of extreme anemia, has been changed to the ruddy glow of health. The listless eye of extreme debility, that looked in the face of death, has been transformed into the sparkling eye of vigor, and peering into a future of hope, happiness and prosperity.

If this were all, the time, labor and money would have been well spent, but the story is told only in part; the thousands that have been rescued before the infection became severe, have still greater reason to be thankful. The prevention of disease in its incipiency, is destined to be the practice of the future, and those who have been relieved of hookworm infection in its incipiency, have not only been fortified against this disease, but against the dangers of other complicating diseases, also. It is a well recognized fact that hookworm disease, paves the way for tuberculosis, and many other serious and rapidly fatal diseases. I made the claim in a paper read before this Association last year, that pellagra was in some way a by-product of hookworm disease, and I feel further justified in this opinion, since there has been a very marked reduction of this disease in the localities where it prevailed, since the hookworm dispensaries have been established. So it seems when you save a patient from the effects of hookworm disease, you in many instances, save him from tuberculosis, pellagra, and many other serious diseases, that so frequently develop in those suffering from the devitalizing effects of hookworm infection.

The effects this investigation has had on public sanitation is too far reaching, to even estimate at this early date. The statistics show by the last report of the Rockefeller Commission, that in Kentucky, approximately twenty-

five thousand persons have been treated for hookworm diseases; over eleven hundred physicians have treated the disease during the last year; about five hundred public lecturers have been given, reaching between eighty and one hundred thousand people. The sanitary privy has become practicable, and is rapidly taking the place of the old open privy, thus reducing to the minimum the dangers from soil pollution. The public has become an active co-operating agency in pushing forward the work.

I may best illustrate the good results of the work upon sanitation by referring to the locality with which I am most familiar, the Straight Creek coal field, and from reports I have, the same results have been accomplished elsewhere. In the years 1910 and 1911, this section of Bell county was made the scene of a most violent outbreak of pellagra, also many cases of typhoid fever, dysentery and the various manifestations of hookworm disease, at that time unknown. These conditions continued through 1910 and 1911 and the early part of 1912. The sanitary conditions were bad. The privy vaults shallow and largely surface, allowing the excreta to become spread in the surface soil, and exposed to flies and other insects; also to be freely washed into the streams, and germs of disease find their way into the drinking water, in many instances. The attention of the State Board of Health was called to these conditions and soon became active in the work. The large coal corporations, and especially the Continental Coal Corporation, which controls most of this field, became active in a crusade for better sanitary conditions. The old privies were torn down, and new sanitary privies with deep vaults, and enclosed, were built in their stead. A campaign of education was inaugurated by the County Board of Health, assisted by the Bell County Medical Society, and the physicians in these localities. In the summer of 1912 the Hookworm Dispensaries were established in the county. A six weeks' campaign under the direct charge of Dr. J. S. Lock, resulted in the finding of about sixty-six per cent. of all those examined, infected with hookworm. It is estimated that from twenty-five to fifty per cent. of those found infected took the treatment, as directed, and were relieved of the disease.

We may ask what has been the end results in this locality? It has been decided and well marked. Pellagra has been reduced to a few scattering cases. Typhoid fever has been very much less, but very few cases during 1912 and up to the present time. Dysenteric troubles have been reduced, and the general health and working capacity improved.

What has been true in this particular locality, has been true elsewhere. The general effects of the campaign, has been educational, and has removed from the public mind many vague ideas and doubts that previously existed. The work has been open and frank, and conducted in the presence of the public. The patients themselves have been permitted to look through the microscope, and see the living, wriggling larvae, also the hook worm ova. The mode of entry into the human system and the normal habitat, have been explained to them, and the way in which they attach themselves to the mucous membrane and live on their life blood, has all been made plain to them, with the result that they see and know and believe. With all this before them, it is easy for them to comprehend how other germ diseases are propagated and spread and the public at once is changed from the attitude of Doubting Thomas, to that of an earnest advocate of all these sanitary measures. Thus it has paved the way for putting into actual practice, many sanitary measures that would have met with serious opposition from the public, and has greatly advanced the work of sanitary science.

Like all new movements, there has been some opposition and criticism by the public, but the ultimate results have been good, and will lead to a higher estimate of the profession by the public in general. Large corporations that employ labor, are quick to note the increase in productive energy, and a larger output for a given amount of time. The prosperity of the country in general is largely fixed by the standard of public health, and public wealth is only the result and natural sequence of public health. So it stands without contradiction that, so far as the medical profession contributes to the public good, it will at least fulfill its higher mission, and receive its proper share of public confidence and respect.

I have in this brief resume endeavored to present a few of the benefits and end results of the hookworm investigation, without going into any details, and I cherish the hope that this good work will go on, until this dreadful malady is no more.

Necessity for School Dental Clinics.—Patrone's article was read at the recent international congress for school hygiene held in Buffalo. He reiterates anew the seriousness of dental caries for the development of the child, the importance of prophylaxis, and the necessity for those realizing this importance to organize, formulate and direct the propaganda for hygiene of the mouth and teeth among school-children as a matter of vital importance for the public health.

GUN SHOT WOUNDS OF THE ABDOMEN.*

By L. L. ROBERTSON, Middlesboro.

The treatment of gun shot wounds of the abdomen by laparotomy is one of the latest developments of modern surgery. Up to 1885, according to Parkes, only six operations for this class of work were recorded. Coley tells us that the first laparotomy for gun shot wound of the abdomen was by Boudens in 1836. He resected eight inches of a small bowel and united the ends by Lembert's sutures. After the death of the patient three days later, an undiscovered wound of the caecum was found. Among the most remarkable laparotomy for gun shot wound was performed by the late Dr. W. T. Bull of New York in 1885 where seven perforations were found and closed, the patient making a complete recovery. This subject was forced into prominence by the interest manifested in connection with the murder of President Garfield by a gun shot wound of the abdomen. The usually hopeless results of these injuries when untreated and the success of certain operations combined with the general improvements in modern abdominal surgery have now resulted in placing the treatment of gun shot wounds of the abdomen among justifiable and beneficial operations. And American surgeons have contributed by far the most important part.

A bullet from any sort of firearm at close range will in most cases cause deep penetration. It is rarely possible to get true information as to the course of the bullet from the position which the wounded person held when the shot was fired. For all practical purposes the size and rapidity of the bullet may be ignored, although a large and nearly spent ball produces more extensive injuries than a small or rapidly moving ball, yet the effects of either are quite serious enough to greatly endanger life and make an urgent claim for operative treatment. It has been truly said that the tendency of gun shot wounds of the abdomen is towards death. In a great majority of cases death is due to a form of peritonitis which is usually described as septic. No doubt the peritonitic fluids are septic but it is doubtful if the death is owing to true blood poisoning rather than to severe shock. In about 90 per cent. of the cases attacked with peritonitis, death takes place within forty-eight hours. It is true that the peritoneum has a limited power of disposing of septic fluids, but this power of the peritoneum has an infinitesimal influence in lessening the death rate from this class of in-

*Read before the Bell County Medical Society.

juries. Even if there has been a moderately perfect plastic closure of the perforation the edges of a bullet wound are so liable to undergo sloughing that a secondary perforation usually takes place. A separated slough cast loose into the cavity has great danger of its own. A slough of the mesentery which cannot fall into the bowel is more dangerous than one on the intestinal wall.

Bleeding is, in itself, rarely fatal unless the bullet should perforate one of the large blood vessels, but the extravasated blood when infected by free visceral fluids produces extreme septic inflammation and so adds to the danger. A few deaths have been caused from loss of blood through perforation of some of the large blood vessels. This is more likely to occur from wounds involving the solid viscera and their vessels than from injuries to the hollow viscera. For instance, presence of blood in the urine indicates, according to the position of the wound, injury to kidney, ureter or bladder, but it is possible you may have injury to any of these organs without the appearance of haematuria. Shot wounds of the kidney are not so dangerous as is generally supposed. According to Edler death most frequently results from pyaemia accompanied with peritonitis and suppuration. Recovery is usually slow on account of the complication of urinary extravasation. Of the uncomplicated shot wounds of the kidney 85 per cent, according to Edler, get well.

Wounds of the omentum are occasionally attended with free bleeding which may form a large haematoma between its layers. In such a case complete amputation of the omentum above the site of injury would be the best treatment. A perforation without bleeding should be excised and the opening closed by continuous suture to prevent gangrene.

Wounds of the liver are by no means necessarily fatal. A good per cent. of these cases will recover. Suppurative inflammation is most frequent cause of death due to foreign bodies in the wounds, particularly to splinters of rib. You should look for foreign bodies and remove them if found. Hemorrhage is the cause of death in some cases. The wound should be cleansed as thoroughly as possible. Bleeding must be checked either by the insertion of deep cat gut sutures or by plugging the wound with gauze. Murphy, in a successful case, employed suture alone.

Wounds from the spleen cause death almost invariably by hemorrhage. Suppuration is rare, and then mostly from the presence of foreign bodies. The checking of hemorrhage is difficult and plugging the wound by gauze is best. Should this fail,

primary removal is indicated. The results of removal for injury are more favorable than for disease.

Wound of the gall bladder is almost certain to cause death from extravasation. Under the best palliative treatment death almost inevitably takes place. In shot wounds of the large intestines the prognosis is more favorable.

Shock is frequently mentioned as an invariable sequence of perforating wounds of the viscera. While in some cases it is an exceedingly variable symptom, frequently it is marked in unimportant cutaneous wounds. I recall a case of a man shot a few years ago. The ball entered on the right side of the abdomen and followed the sheath of the abdominal muscles and was removed on the opposite side of the abdomen. The patient had a profound shock but the bullet never entered the abdominal cavity. In some cases it is simply nerve prostration from terror. In perforation of any of the abdominal viscera a majority of the cases will be followed by shock more or less severe. One of the most important symptoms is a feeling of nausea frequently accompanied with vomiting. This is not common with false shock while in numbers of cases of undoubted perforation it is present in more or less degree. True abdominal shock from extravasation of fluid into the cavity is generally very pronounced and more or less severe.

An important practical question is when is the best time to operate. In a general way it may safely be said that operation should be performed as soon as possible after it has been made sure that there is perforation of peritoneum. Coley reports 39 cases operated on within twelve hours, 18 recovered, while 22 operated on after 12 hours, only 5 recovered. The chance of recovery would seem to be greatly increased by early operation. Symptoms should not be treated for they are often misleading. If there is profound shock the operation may be put off while the patient is watched closely and treated for an improvement which would justify operation. The possibility of the shock being due to hemorrhage must not be overlooked. This, as in many other conditions, must be left to the judgment of the surgeon. It is impossible to provide specific or absolute rules.

Before operation the abdomen should be thoroughly cleansed with soap and water and shaved and painted over with iodine. The instruments are the ordinary ones used for abdominal section, with the addition of four or five intestinal clamps. The incision in the majority of cases should be made in the median line. There is no doubt that it affords more space for a general exploration

of the whole cavity and its contained viscera, while on the other hand there are cases where an incision in the median line is not indicated. What is to be the exact line of incision it is impossible in general terms to indicate.

The length of the incision must be regulated by the thickness of the abdominal wall, but make the incision sufficiently large so you will have room to work. When the abdomen is opened make certain as to the fact of the perforation. Any blood clot which obscures the field of operation is mopped up gently, a systematic examination of all the viscera which lie in or near the track of the ball should be thoroughly made. If there is much hemorrhage the source of it should at once be found before doing anything else and the bleeding point temporarily secured by forceps. While an opening in the bowel that is discharging feces is being closed, no definite order of procedure can be laid down—the most urgent thing attended to first. A survey of the parts is made when the dangerous hemorrhage or abundant extravasation has been checked and the full extent of the injuries is finally ascertained. A moderately severe contusion may be doubled inward and Lembert's suture used or a continuous suture placed in the healthy bowel beyond it so that if it does become gangrenous the slough will be discharged into the lumen of the gut and cannot get into the general cavity. In cases of perforation of the bowel Lembert's sutures will be the best. For a small perforation a continuous suture will be sufficient. A multiple perforation of a small piece of bowel may require a resection. I would like to report a case of a child 14 years of age who was accidentally shot in the abdomen by her brother, playing with a pistol. The bullet entered the abdomen about an inch from the median line. The accident occurred about 7 o'clock in the morning in a neighboring town. The child was sent to me in the afternoon arriving here about 6 o'clock. She was immediately taken to the hospital and upon examination I found her abdomen was very much distended and extremely tight. Pulse very rapid. The child was more or less under the influence of opium given by the nurse with her. An immediate operation was advised and as soon as the operating room was ready she was anaesthetized, an incision made in the median line, the peritoneum opened. We found the abdomen full of blood which was cleaned out as quickly as possible, the bleeding points elamped with forceps and on examination of the intestines we found three perforations of the bowel which were closed by silk sutures. And just here I would like to state that round worms in the bowels were protruding through the opening in the gut.

They of course were removed with pieces of gauze before the perforations were closed. On further inspection we found a multiple perforation of the small bowel which was most impossible to close, so we did a complete resection of about four inches of small intestines, using a Murphy button. The abdomen was cleansed as best we could and closed, leaving two large drainage tubes in the abdomen, the patient removed from the table and placed in bed in the Fowler position, with hot water bottles. The pulse was very bad. She was given transfusion of saline solution at once and continued at intervals for two days. During the first two days her condition was extremely rocky, but from that time on she made a good and complete recovery, leaving the hospital in about four weeks.

EXAMINATION OF THE BLOOD IN DIAGNOSIS AND PROGNOSIS.*

By MASON COMBS, Pineville.

When we consider that the arterial system is the transportation system through which all life-giving and life-sustaining elements are carried to the immense city of cells which constitute the body; and the venous system, the sewerage system through which the system sends to the lungs, liver, kidneys and skin those elements which are used and are no longer fit to remain in the city; that both these systems of transportation are at all times, in health or disease, filled with blood, which is the train used under all conditions, it would seem that being acquainted with the train of the normal body, we should be able to recognize any departure from health by a change in the train or its burden. Surely there is unmistakable evidence in the blood of any and all diseases were we but able to recognize it and the writer predicts that the time will come when its examination will reveal evidence of any diseased process which will be worthy of consideration in its diagnosis. So, at present we are looking into the field of haematology through a crack in the fence and we view its possibilities through a wormhole in the rail. However, notwithstanding our limited knowledge, blood examination to-day plays an important role in diagnosis, and, in this paper the writer shall describe only the most important practical methods of microscopic examination.

To obtain a specimen, the lobe of the ear or the finger tip is cleansed with alcohol and dried with aseptic gauze; the part is then held firmly with the fingers of one hand and with a lancet, a surgeon's cutting needle or a pen point, the half of which has been broken

*Read before the Bell County Medical Society.

off, a quick stroke is made which is followed by a rather free oozing of blood. The first drop is wiped away, as this may be contaminated, and with a glass slide held between the thumb and fingers in each hand, allowing one slide to come in contact with the blood, the other held in readiness to make the smear, which is done by holding its end in contact with the blood just long enough for the blood to flow by capillary attraction across the end it is drawn not pushed slowly until the drop is smeared. If this fails to make the smear even another drop is obtained from the same puncture by allowing the hand to swing back and forth, or by milking the lobe until another drop of blood can be had. For safety three or four specimens are obtained, as one often fails to get a good stain with only one specimen. The smear being made, it is rapidly dried by passing it over an alcohol flame. This is done to prevent changes in the red blood cells which are highly sensitive to air. If the specimen is to be carried to the office, it may now be wrapped in paper, and kept any length of time without undergoing any change. Staining is done, if desired, immediately after the specimen is dried and a good method that is all that is needed to examine for any of the anaemias for malaria or for differential leucocyte count is as follows: Pour on eosine a. l. c. and allow to stand for one minute, wash off with water, then pour on Grubler's alkaline methylene blue and allow to stand for one minute, wash with water and dry with filter paper. To examine, drop one drop of oil of cedar on specimen and place under microscope, when it will be found that eosin has stained the erythrocytes red, the protoplasm of all the leucocytes except the eosinophiles and basophiles light red, which take the basic stain eosin and are bright red. The nuclei of the leucocytes and of the erythrocytes where nucleated, are found to be blue from the methylene blue. In normal blood we notice that the erythrocytes predominate and that ordinarily four or five fields are passed over before observing a leucocyte. Of course, we may see two or three leucocytes in one field, but the average is about one cell in five fields examined. The erythrocytes appear as circular biconcave disks with a semi-transparent center, all having very nearly the same size and shape. The leucocytes, markedly larger, present four types, the most abundant being the polymorphonuclears, representing 65 to 75 per cent. having two or more nuclei. These are sometimes subdivided into polymorphonuclear neutrophiles and basophiles, the former's protoplasm having the same hue as the erythrocytes, light red, while the latter is of brighter hue. However, for purposes of

diagnosis and prognosis, it is not at all necessary to recognize the difference; hence, the writer prefers to speak of them as being polymorphonuclears. The lymphocytes represent 15 to 20 per cent. of the total number and are also represented by two types, the large and small, the former having a large amount of protoplasm, faintly stained blue, and the nucleus dark blue, the latter having the appearance of the former, except smaller and more opaque and exact in outline and structure. The transitionals represent from 2 to 4 per cent. and are identical with the polymorphonuclears, except that the nucleus is horse-shoe shaped. The eosinophiles have usually two, and sometimes more, nuclei; protoplasm is irregularly formed and is composed of large bright red granules. They constitute from 2 to 4 per cent. It is to be understood that the erythrocytes normally have no nucleus. Having acquainted oneself with a normal picture, it is easy to recognize any departure therefrom. Even a leucocytosis may be recognized by observing that instead of passing over four or five fields before seeing one leucocyte, we see an average of one to every two or three fields. This, however, should not be relied upon in all cases, since a total leucocyte count is easily made and is more dependable, usually.

ANAEMIA-SECONDARY.

In this we find that the erythrocytes, or a part of them, have lost their coloring matter and are pale, some of them irregularly shaped, some of them large, some small, some few nucleated and some of them normal in shape and color. Leucocytosis is observed.

PRIMARY-CHLOROSIS.

All the erythrocytes are pale, having lost their haemoglobin, the irregularity in shape and size is more marked than in secondary anaemia, some of them being elongated and of all shapes and sizes, some of them nucleated, and, as in all anaemias, we notice an increase in the leucocytes.

PERNICIOUS ANAEMIA.

Here we notice that the erythrocytes are even redder than in normal blood, but there is a marked diminution in number manifest even to the eye microscopically. They are generally oblong in shape, but we notice large and small, as in the other anaemias, and that some of them are nucleated.

LYMPHATIC LEUKEMIA.

In this condition the most striking change is in the proportionate number of lymphocytes, and in extreme cases we may find that they predominate over the erythrocytes. Of the leucocytes, instead of finding the poly-

morphonuclears, representing 65 to 75 per cent. we find that the lymphocytes are most abundant and may represent even 90 per cent. of the total count.

MYELOGENOUS LEUKEMIA.

In this lesion we meet with a new type of leucocyte, which only appears in diseases of a grave nature, the myelocyte, a larger cell than the large lymphocyte, its protoplasm being granular, whereas the normal large lymphocyte is homogenous and is possessed, as is the normal lymphocyte of a single nucleus. So in any condition where we find this cell, even in small numbers, we know the picture represents a pathological condition of no little consequence. Here we find it outnumbering as a rule the other varieties of leucocytes, and as in the other forms of anaemia, we observe nucleated and irregularly shaped erythrocytes, macrocytes and microcytes.

MALARIA—TERTIAN TYPE.

To examine for malaria, if patient is at the office, it is well to use an unstained specimen, as in it one is able to more easily recognize the parasite by its motility than by the contour in the stained specimen, for which a blood platelet or some other similar thing is liable to be taken; but as a rule convenience does not permit an examination of the fresh unstained specimen so the aforementioned method of staining is a good method to follow in preparing for the search. In the tertian variety the amoeba are seen in variable shapes and sizes in the red blood cells. One or more may be seen in a single cell if they are not fully grown, having the appearance at first of small bluish, from the stain, rings, and as they grow larger the erythrocyte swells until devoured, when sporogenesis takes place, which ushers in a chill. So if the blood is examined immediately prior to the chill, the parasite is seen to be fully grown and to occupy the whole of the cell of the larger than normal neighboring cell, and if examined immediately after a chill, only the small parasite is found, which may be floating in the plasma or in the act of making an attack by clinging onto an erythrocyte.

ESTIVO AUTUMNAL TYPE.

In this type the parasite may very much resemble that of the tertian type, but a particular variety is here found only present in this particular type, namely, the crescent, being oblong, usually curved, and having a dark center, under all conditions, and instead of finding, as the parasite grows that the erythrocyte is larger, it is shrinking and much smaller than its unattacked neighbor.

WIDAL TEST FOR TYPHOID.

For this test, a smear is not made, but a drop of blood is allowed to dry if it is to be carried to the office and when ready to proceed, enough water is added with the platinum needle to give to the blood, when dissolved, a coffee color, when the living typhoid bacilli are taken from a freshly grown agar-culture not more than forty-eight hours old, since they are more active while young, and added to the blood. If typhoid exists the toxins in the blood soon will render the bacilli inactive, and if the test be negative, they will continue active. The time required for this phenomenon is 15 to 20 minutes.

LEUCOCYTOSIS.

As hereinbefore stated, leucocytosis may be recognized by noting that instead of, as the slide is passed over, seeing an average of one in four or five fields, one in every one or two or two or three, according to the degree of leucocytosis is seen. We have, too, even in the presence of a low count, a proportionate increase in the ratio of a particular leucocyte, as for instance instead of the polymorphonuclears representing 65 to 75 per cent. of the total count, they represent 80 to 90 per cent. which is a polymorphonuclear leucocytosis, or we may have an eosinophilia, which is an eosinophile leucocytosis. This is determined only by the differential count, which is made with the stained specimen. But usually when we speak of a leucocytosis, we have reference to an increase in the total number per cubic centimeter of leucocytes. Normal blood contains about seven thousand white blood cells per cubic centimeter, but we may find in healthy persons the count to be as much as ten thousand per cubic centimeter after taking a cold bath, a full meal, or after taking exercise, so under these conditions we would not consider a count of ten thousand a leucocytosis. To make the count, a good equipment is the Thoma-Zeiss blood-counting outfit, which may also be used for counting the reds. A rather free bleeding is required, and when all is in readiness, the pipet is allowed to come in contact with the flowing blood and as soon as the desired reading is reached by the blood which is slowly drawn into the pipet, it is carefully, with a rubber mouth piece, still held so that the blood will not be drawn up nor forced out, inserted into a solution of one-third of one per cent acetic acid which dissolves the erythrocytes and gives the desired solution, usually 1 to 20. After thoroughly shaking, a small amount is placed on the ruled slide and covered with a specially made cover glass. Now, if the specimen is a good one, Newton's rings are observed by holding it so that the light hits it at an angle of about 40 degrees. Now, count the cells in five rows

of crosses at a time until the whole are counted in the four hundred squares, which represent one-tenth of one cubic centimeter. Multiply this by ten and the product by the dilution which gives the number per cubic centimeter. To interpret the meaning of a leucocytosis, speaking now of an increase in the total count, unless it be unusually high, it is necessary to make repeated counts of blood taken at hourly intervals from the patient in order to ascertain whether the number be increasing or diminishing. This is because of the fact that under the same conditions in different individuals the count may vary by reason of the difference in the vitality of the patient.

In appendicitis, the count is not usually more than twenty thousand per cubic centimeter. If from the first count we determine a leucocytosis of twelve thousand, and from a specimen obtained one or two hours later we find that it is increasing, an operation should immediately be performed, since this signifies that the process is overcoming the vitality of the patient, or at least that it is gaining headway. Total leucocyte count speaks nothing comparatively if only one count is made. From the differential count, we learn that if the ratio of polymorphonuclears has increased disproportionately to the total leucocyte count, our prognosis is grave; if it has increased proportionately and is not more than 75 per cent, the count being high, we have a severe infection and a fair body resistance, and in the presence of a low count and a relatively low polymorphonuclear count, mild infection and fair body resistance. If a low count be made and we find that the polymorphonuclear constitute more than 75 per cent, we know that the condition is a grave one, since the infection is severe and the body resistance low. We may observe instead of a leucocytosis a leucopenia, or a less than normal count. This usually denotes poor resistance to disease. The appearance of nucleated reds together with increased leucocytosis means that the body is endeavoring by the manufacture of reds to resist disease and the disappearance of nucleated reds, together with rapid increase in the leucocytosis, signifies oncoming danger; that the body is giving up the fight. Now, a drop in the leucocytosis after the nucleated reds have disappeared, means that the end is near.

Bronchopneumonia. — Treatment. — Creosote carbonate recommended for use in bronchopneumonia and obstinate chronic bronchitis in children. Dosage, 5 drops (0.5 Gm.) three times daily for each year of age in first three years; in fifth and sixth years, 20 drops (2 Gm.)—Hunans.

FRACTURE SUGGESTIONS.*

By GUY P. GRIGSBY, Louisville.

Medicine and surgery have made such rapid strides in other fields that fractures have been allowed to fall into the background as a subject on which our predecessors of years ago had said the last word. There is nothing in the whole field of surgery that is more important than fractures. They are second only in frequency to childbirth. Because of the general advance of surgery and the immunity from disaster afforded by aseptic methods there has been a great advance in the operative surgery of bone.

For surgeons and practitioners who are unable to avail themselves of the operative method, the non-operative procedures are likely to remain (for sometimes yet,) more safe and serviceable. Immaterial what method is adopted it must be efficient from the first. If a surgeon is doubtful as to whether he can successfully treat a fracture by non-operative means, he should consider if he could do better by operating. Don't say if this is not satisfactory we will operate later, for by so doing the opportunity will probably be lost, of getting a good functional result. A fracture man must be a mechanic with a sound knowledge of anatomy, he must be dextrous and have the ability to vary from routine methods, in order to meet special conditions.

MAL-UNION AND NON-UNION.

Both of these conditions are of frequent occurrence. Angulation and improper alignment of the fragments, if one is allowed a free hand should not occur. The sparing or half-hearted application of traction is usually the fault. Reduction should be attempted only under the most favorable conditions. It is needless for me to tell of the importance of an X-ray before and after reduction. The X-ray should be taken in two different planes, otherwise an incorrect reading is liable to occur. Always administer a general anesthetic, unless particularly contraindicated. Produce deep anesthesia. By this you overcome the muscular spasm. Place the patient on a hard flat table, not a sagging bed. A skilled assistant is necessary. Reduction should require as much time as is necessary for its proper performance. Hurry is frequently fatal to a good result. If reduction by the hands is impossible, traction by means of a weight and pulley or an efficient method is a "Buck's extension," attached to several strips of muslin caught over the shoulders of the assistant, who with his back to the pa-

*Read before the Nelson County Medical Society.

tient, can make considerable traction. A sheet around the perineum and tied to the table holds the patient firmly. By this means reduction can be accomplished.

Remember that a correct alignment in conjunction with complete obliteration of shortening must be obtained. A reduction that is impossible during the first anesthesia, by means of traction for twenty-four to forty-eight hours is then easily made. The realization is important; that steady fixed traction or extension will accomplish the desired result while forcible intermittent pulls succeeded by periods of relaxation will only tend towards the exhaustion of the patient and the assistant.

Early reduction before infiltration occurs is desirable, for after it has set in it is often impossible to bring about satisfactory reduction even under ether. In such cases sufficiently heavy weights should be used for not over a week, under careful supervision, for by this time reduction will be easy or obviously impossible by such means. Remember that some few fractures require twice as long to consolidate as others. Do not allow your surgical zeal or impatience to make an ununited fracture out of what would eventually prove a good result. Often the routine practice is to examine the fracture at the end of the fifth week. If it is not united let it alone for two or three weeks longer, it will in all probability unite. Instead of this, an examination is made two or three times a week, a consultant complicates the issue by a thorough manipulation and what chance the dilatory bone has is gone. If there is pain on the site, of an old fracture, particularly when pressed upon, unsound union should be suspected, especially if there is a large callus exudation. In such cases, if there is faulty alignment this should be corrected, *otherwise leave them alone*, providing you correct the systemic condition that is causing it. In cases of non-union without pain upon manipulation of fragments you will not get union, because usually a false joint has been established. An open operation is then indicated with the employment of an autogenous bone graft.

I shall only consider those fractures that seem to offer the most difficulties in their successful handling by mechanical means.

Surgical Neck of the Humerus. The forearm is flexed and held in a sling. A cushion is placed in the axilla for abduction. Adhesive straps are applied from the insertion of the deltoid to 6 inches below the elbow. To these attach a weight of five to ten pounds for one hour. If at the end of that time reduction is accomplished a moulded splint is ap-

plied. Inside splint from axilla to elbow. Outside splint, top of shoulder (shoulder cap) to the wrist. Weight is continued during application of splints. In cases in which reduction is not accomplished, put to bed and apply weight and pulley till fragments are reduced. Massage is begun in ten days; in two or three weeks passive motion is applied every day. Splint is removed at the end of the fifth or sixth week. For fracture of the shaft of the humerus with exception of lower end is similarly treated.

Lower End of the Humerus. The Jones position is the one of choice. Elbow is acutely flexed and the hand is supinated. It is held in this position by means of a plaster splint or adhesive plaster. No change should be made in the position for at least two weeks, then the wrist should be lowered for one inch or more. This should be gradually increased every other day. Passive motion should not begin for at least three weeks. This should be slow and carefully done, the fracture being protected from strain by the hand of the surgeon.

Olecranon. The treatment of this condition would seem operative, but really the difference in the percentage of functional results between it and the mechanical treatment is small, 72 per cent against 75 per cent. You often see quite a fibrous gap with a strong useful arm. In reduction the upper fragment is pressed firmly against the lower and held in this position with crossed pieces of adhesive plaster. The arm is extended and an anterior splint is applied. Operative measures are often indicated in the treatment of these fractures.

Bones of the Forearm. In certain fractures of the shaft of the radius and both bones of the forearm, we encounter some of our greatest difficulties, and often the choice is between operation or some deformity and considerable loss of function. One is surprised what continuous traction extending over a period of three or four days will do in these cases. I recall a case in which two attempts were made under ether without accomplishing reduction of the fracture in the middle of the shaft of the radius. The boy was put to bed, a traction applied for five days. He was then given ether and the reduction was easily accomplished. Operative measures are difficult because of the nearness of the bones to the surface, and a close relation of many important structures. The scar is disfiguring, especially in women. In the sub-periosteal type not much trouble should occur. The angular deformity so often present should be corrected in incomplete supination, with the employment of traction. It is best to fix the elbow especially fractures in the

upper forearm. As a routine practice, the supinated position is safest in all of these fractures. If union is slow, fix elbow in extension, allow patient to swing arm, in order to get the benefit of the congestion. Colles' fracture requires no special mention. The key-note is the thorough reduction of the fragments. The application of a short anterior and a long posterior splint. Use of passive motion at the end of two weeks. The removal of splints and the application of an adhesive plaster dressing.

Femur. Neck. The treatment is divided in two classes: (1) recent fractures; (2) old fractures.

Recent Fractures... As soon as the diagnosis is made, the abduction treatment, as devised by Whitman, should be instituted at once. A general anesthetic is given, preferably ether. The patient is placed upon a box, or pillow, about eight inches high, and large enough to support the head, shoulders and trunk; the pelvis rests upon a pelvic support, and the extended limbs should each be held by an assistant. The sound leg is then abducted to the normal limit, which is usually about forty-five degrees, and the fractured limb is abducted to a degree to correspond to the sound one. Traction is then applied and the outward rotation is overcome by lifting up and supporting upper end of femur and, at the same time, rotating the leg inward. Measurements are then taken to see that all shortening has been overcome by lifting up and supporting upper end of femur and, at the same time, rotating the leg inward. Measurements are then taken to see that all shortening has been overcome, and if it is still present a greater amount of traction is applied until the two limbs are of equal length. A plaster spica is then applied, from the toes to the costal margin, during the application of which the assistants should maintain their respective positions and use the utmost care not to disturb the fragments. The spica is worn usually for eight to ten weeks, followed (perhaps) by a short spica for three or four weeks. After removal of the plaster, there is usually a tendency to adduction deformity, and this is overcome by daily stretching of limb.

This treatment is used for the aged as well as the young, and I would condemn the almost universal practice of treating these cases by "Buck's extension" and sand-bags, because of the almost uniform bad results that follow this line of treatment. So long as a patient is able to take an anesthetic for twenty or thirty minutes, this is by far the most rational and satisfactory treatment. Several cases have been reported of good functional cures in very old patients where this treatment has been used. I am sure it is quite

needless for me to recount to you the advantages of this treatment; results speak for themselves, and the results from this treatment during the past four or five years have proven conclusively that in this condition it gives the best hope for a functionally active hip.

Old Fractures, should be treated unreservedly by operation. Unless they are impacted and the functional result is satisfactory.

Femur. Fracture of Shaft. Under ether traction as previously described with manipulation until reduction is accomplished. The limb is then straightened until the anterior, superior spine, midpatella and the middle of the ankle are in the same alignment as the opposite limb. Under continuous traction a plaster spica is applied in moderate abduction. Be sure to measure and overcome all shortening. Plaster is worn for eight or ten weeks, is removed and reapplied if union is not firm. Through the course of treatment it is necessary to be positive of four things:

(a) Absence of shortening; (b) prevention of outward bowing of thigh; (c) prevention of outward rotation of the leg and lower thigh below seat of fracture; (d) sagging backward of the thigh.

Fracture of Leg. In fracture of tibia and fibula immediate reduction under ether is indicated. Traction is made on foot and counter traction by sheet over the body and under the perineum. Then by manipulation the fragments are approximated. The subcutaneous line of tibial crest should be brought in alignment. The molded cast of splint is then applied including the knee and foot. If cast is used, cut gutter over tibial crest. In order to observe any change in the line of the crest. In three or four weeks cut casts and allow movement in knee. A Potts' fracture should be reduced immediately notwithstanding swelling or effusion. Results of delay are serious. To reduce fracture the knee is well bent, and it may be helpful at first to increase the deformity in order to disentangle the end. With foot slightly flexed, the heel is well pulled forward, and the tibia pressed backward until the dislocation of the ankle is corrected. Enough force should be used to slightly overcorrect the valgus deformity. Once reduced there is little tendency to recurrence. Remember that inversion of the foot should be maintained, even after the patient begins to walk. I make it a practice to slightly raise inside the inside heel and sole of the shoe, and compel them to walk in moderate varus.

Patella. Mechanical treatment will at times give good results, but I would consider that the operative correction is the wise and safe procedure. Operation so shortens the time of disability two to three months by

operation, ten to twelve by non-operative means, that the small chance of complication that may follow operation are out-weighed. The mechanical treatment—reduction is not attempted until the joint is free of effusion and swelling. After reduction the fragments are held by cross-adhesive strapping, and the limb is placed in a cast in complete extension. This is worn for four weeks. After this a posterior splint is applied and the patient allowed to walk with crutches. The use of passive motion is desirable at this time. Some form of retentive dressing should be worn for at least eight to twelve months while patient is bearing his weight.

Compound Fractures. In dealing with the individual case first aim is to decide whether the limb can be saved without sacrificing the life of the patient. Second, whether the active treatment is preferable to the expectant treatment. The least handling of the parts is desirable. Hemorrhage should be stopped, and the next danger is from infection. Do not lather the parts with soap and scrub them with a brush, until they appear to the layman or the surgical tyro clean. During this manipulation you have only enhanced the danger of infection. The parts which have only apparently been dirty by clinging particles of mud are now thoroughly rubbed in with microorganisms. No matter how much gauze has been put on top of the wound, how much cotton, and how carefully it has been wrapped up, fever and other symptoms of sepsis will soon appear. The most satisfactory method of initial treatment is to seal the parts which are exposed to contamination after removing mechanically and carefully all the particles from the surface of damaged parts which can be easily removed. Paint the skin with iodine thoroughly, also the wound. Remove what parts that have been so badly damaged that they will not recover life by their own circulation or by adhering to parts still living. Open all recesses that may harbor infection. Drain them, and wait for nature to throw up her defenses. It is frequently advisable to give a prophylactic injection of antitetanic serum. If the consideration of life requires an amputation it should be done, but not too rashly, since it is surprising what nature will do toward the repair of damaged tissue. Wait until your period of initial infection is passed, then treat as a simple fracture. It is needless to say that all these cases are best treated in a hospital by a competent surgeon.

HOOKWORM.*

By J. S. FITZHUGH, Island.

On the 10th day of last January a gentleman brought his son into my office for treatment for chronic leg ulcer. He said he had been trying for twelve months to get the ulcers healed. Part of the time he had been

MINSEY FAMILY

MINSEY BOY AT TIME OF TREATMENT

*Read before the McLean County Medical Society.

under the care of a physician and part of the time he had been treated with domestic remedies.

MINSEY TWO MONTHS AFTER TREATMENT

He was given a simple ointment and directed to keep the foot elevated. He returned one week later slightly improved. I had noticed in the bulletins of the State Board of Health that patients with these leg ulcers were often infected with hookworm, this and the boy's anemic, run-down condition and a stare from his eyes, hard to describe on paper, prompted me to make a diagnosis of hookworm. This diagnosis was later confirmed by the State Bacteriologist.

The boy is eighteen years old. After the usual preliminary preparations he was given 45 grains of thymol. The treatment was successful and the boy cured. He has been well ever since, except for malaria. This boy was a red pepper fiend, ate it when ever he could get it.

The leg ulcer had healed before I could get a picture of it. But the dark spot near the

ankle shows the large ulcer and two smaller ones are seen near the knee. The leg has given the boy no more trouble.

The picture of the boy standing by his home was made at the time of treatment. The one in which he is standing by a tree is two months later. There is a marked difference.

The boy is brighter and says he feels better than he ever remembers feeling before. He weighs more, notwithstanding he was doing heavy work in new ground and it was at the time for him to weight less.

The family group shows by the X the ones that have had specimens examined and the hookworm found to be present.

The father did not bring specimens of the ones I told him to bring. There are others in the group more typical. For example, the small boy and girl toward the left and at the bottom of the group, must be heavily infected. The object of this report is not to go into the symptoms, treatment and prophylaxis which have been gone over so thoroughly by the

State Board of Health, but merely to call attention to the broad strip of Kentucky extending from Meade county in a south-westerly direction, in which the hookworm has not been found, and in which the worm is probably very common.

These cases are four miles below Island, in McLean county, and on Green river.

DIAGNOSIS AND TREATMENT OF KNEE LESIONS IN THE ADULT.*

By V. P. GIBNEY, New York.

The President of the Association, soon after his election, was good enough to invite me to attend this meeting, and to prepare a paper for your discussion. An intimacy extending over a period of forty years induced me to accept this invitation, and I can assure you, gentlemen, that the honor of meeting the members of the Kentucky Medical Association is one that is deeply appreciated by one born and reared in old Kentucky.

I recall a meeting in Danville many years ago where it was my distinction to be seated upon the platform when that eloquent Kentuckian, the late Richard O. Cowling, presented to that giant in surgery, Samuel D. Gross, the door-knocker that had hung on the front-door of the father of ovariectomy, Ephraim McDowell.

The profession of this State has always occupied an exalted position in the medical world, and it has always been a subject for self-congratulation that my medical education was begun in the Medical Department of the University of Louisville.

In selecting a topic which I thought would at least elicit a discussion, I have had in mind the one idea—something practical. The topic I have chosen is one dear to my heart, obtruding itself on all occasions, and when easting about for something which might interest my friends in Kentucky, I had quite forgotten a vacation incident in the early part of the century. Indeed, I had already chosen my title and sent it to my friend and pupil, Dr. McCormack, and had written the introductory, while enjoying my vacation on the shores of Long Island Sound, when my secretary sent me a lot of reprints of papers on the knee. I found one with this title, "Diagnosis and Management of Some of the More Common Lesions of the Adult Knee," extracted from Washington Medical Annals, 1902.

In February of that year, while enjoying a rest at the New Willard in Washington, a delegation from the Medical Society of the District of Columbia invited me to present a paper on any topic I might select.

In reading that old paper, I find that I have become a little bolder in treatment and a little more confident in diagnosis.

The temptation was very strong to treat you as many of the circuit riders in my early Kentucky days treated their congregations, viz.: fish out an old sermon and "let it go at that," on the ground that the faithful follow-

ers of the Meek and Lowly never tired of the old, old story.

You may rest assured, my brethren, that I am presenting "a brand new sermon."

The knee-joint is as important a joint as any one in the human mechanism, and demands recognition in every period of life. If a babe in arms is poorly fed and scorbutus results, the subperiosteal hemorrhages frequently involve the periosteum bordering on the knee, and alarming symptoms and signs call for prompt measures of relief, lest the functions of the joint be holelessly impaired. When the little one begins to walk and the second summer is passed, the bacilli of tuberculosis of the bovine type in their migratory wanderings prefer to colonize often in the distal femoral epiphysis or the proximal tibial epiphysis when these cancellous structures become hyperemic because of trivial traumata and a tuberculous knee, formerly known as scrofulous, or, a tumor albus, develops, most insidiously making alarming headway, while the family physician is casting about for a diagnosis.

During the period of adolescence in this commendable athletic age, traumata on the tennis court, on the diamond, on the football field or in the mountain passes, bring about the various forms of internal derangement of the knee; and errors in diagnosis contribute not infrequently to a crippling condition, extending well into adult life.

Later still, when adolescence has passed and when a vocation has been chosen, long hours at a desk in ill-ventilated quarters, with irregularity of meals, efforts at keeping up social requirements, induce changes in the alveolar processes and impairment of the digestion, with static disturbances in the pedal extremities, we come face to face with the many forms of infections and the knee often is obliged to bear the brunt of the invasion of the pathological cocci with which the research laboratory has made us so well acquainted.

Lesions of the knee in adult life have always interested me quite as much as have those in childhood. Hospitals have been founded in all parts of the world for the crippled child, while few have opened wards for the adult cripple. The reason therefor is simple enough. The helplessness of childhood appeals to the public, and the maternal instinct predominates.

No argument is needed to convince this Association of the importance of an early recognition of the exact lesion which bids fair to cripple the wage-earner or his helpmeet in the struggle for existence.

Diagnosis presupposes an intimate knowl-

*Read before the Kentucky State Medical Association, at Bowling Green, Tuesday, September 2, 1913.

edge of the anatomy of the joint, deep as well as superficial. One needs to recall the outline of the lower end of the femur and the spines in the centre of the upper end of the tibia. These articular surfaces are admirably adapted one to the other for the ginglymoid action of the knee. The location and function of the semi-lunar cartilages and their relationship to the ligamentum alara need to be remembered, as injury to these, either by trauma or infection, induces a good deal of internal derangement. It is essential that one should bear in mind the spines of the tibia and their relationship to the crucial ligaments, for I am convinced that a diagnosis is not often made of a fracture of one or both of these spines which we see standing out so prominently in all of our X-ray plates. One should study the normal size and outline of these spines and become thoroughly familiar with their function, so that any blurring in the plate or any markings suggestive of a partial or complete fracture can be easily recognized. It should be remembered, too, that the attachments of the crucial ligaments close to the bases of the spines could easily be detached by avulsion or fracture. Given then an ability to recognize these anatomical disturbances, a closer investigation as to the nature of the trauma and the functions of the joint soon following the trauma, is demanded, and a diagnosis ought to be made with reasonable accuracy.

While my own histories record comparatively few lesions of the crucial ligaments or tibial spines, I am reminded now, in the preparation of this paper of my failure to diagnose many cases which have puzzled me in times past and have been relegated to that class of internal derangements, by a most interesting paper sent me by my good friend, Mr. Robert Jones, the title of which is, "On Rupture of the Crucial Ligaments of the Knee, and on Fracture of the Spine of the Tibia," by Robert Jones, of Liverpool, and S. Alwyn Smith, of Winnipeg, and published in the *British Journal of Surgery*, Vol. 1, No. 1, 1913. Did time permit I would like to quote extensively from this illuminating contribution, but I must content myself with advising all interested in this subject to study the plates, the cases, and the text of the paper.

Among my records I have a case; I (No. 4437) of rupture of the crucial ligaments I made out in 1898. The patient was a distinguished laryngologist, 52 years of age, who injured the ligaments by fancy riding in the ring, a few months before he came under my observation. There was a laxity of the joint presenting a subluxation laterally in full extension as well as in partial flexion. By limiting these movements in the lateral direction with an apparatus, relief was obtained.

In studying the cases in the paper to which allusion is made, one cannot help arriving at the same conclusion they do, viz.:

"In a case of recent rupture of one or both crucials, fixation of the knee for a period of from three to six months offers the best chance of recovery, and that immediate operation should not be resorted to."

And that

"The rupture of any of the ligaments of the knee should be treated by absolute rest until healing is complete. This of course applies with the greatest force to rupture of the crucial ligament."

If the practitioner fails to recall the instruction received in the anatomical rooms, his trusty "anatomy" is at hand, and there is no excuse for a failure to get knowledge of fundamental points in arriving at a diagnosis.

The history of the case is the next important factor. The exact date when lameness or disability was first observed requires a little cross-examination to bring out a probable trauma as the exciting cause. My own routine method in conducting this cross-examination enables me to locate pretty accurately—

1. The initial lameness.
2. Whether pain is present when the patient is standing or walking only.
3. Just where the pain is felt; and
4. Whether the pain or distress persists after use and into the night.

These points being fully established, a search for other factors in the etiology follows quite naturally; such as excessive weight and the strain on the muscles of the leg that would be induced by a falling arch or a poorly balanced shoe.

Should no information be obtained by the above investigation, a source of infection should be diligently sought, and with the many instruments of precision at hand one can soon determine a clue worth following.

Without trespassing on your time with a didactic essay, I am sure I can convey the lessons I have to impart by illustrating points in diagnosis, in treatment and in prognosis by a selection of clinical records taken from my history sheets, and very little reference will therefore be made to bibliography.

In illustration of lesions periarticular, let me cite the case of a strain complicated by weak foot, in the person of a personal friend, a distinguished author of a work on surgery.

Case II (No. 11039). Male, aged 60, consulted me November 11, 1911, for a lameness involving the left knee, while the history elicited, was that he had always been temperate in eating and drinking, and had, prior to the summer of 1911, never had any signs or symptoms of gout or rheumatism. A medical

friend of high repute as an internist had for several weeks been treating him for a gouty knee, depriving him of his after-dinner cigar, of articles of diet of which he was especially fond, and of all alcoholic drinks. I knew that he lived many months in the year on a farm in the northern part of Connecticut—the Berkshire Hills. I soon learned that he had been superintending the digging of a pond, and had been wearing rubber boots, sinking often deep into the mud, requiring quite a pull to extricate the foot. He recalled a pain in his knee after one or two of these efforts. Toward the close of the summer he found his knee tender about the head of the tibia and was convinced that these frequent traumata were responsible for his lameness. An examination failed to discover any actual joint lesion. The tenderness and pain were confined to the internal lateral ligament and about the origin of the tibialis anticus. There was some thickening and tenderness at the metatarsopharyngeal joint—great toe, and while he had a good arch, this gave way as he stood and walked.

The diagnosis was made in accordance with the above findings; the knee was strapped with rubber adhesive plaster, and a shoe built to fit the under surface of the foot in repose.

November 15th, practically cured and happy over a return of his former mode of living.

December 11th, discharged cured.

In the winter of 1912 and of 1913, I saw him in Augusta, Ga., and there had been no return of symptoms.

Case III (No. 11079). A gentleman, aged 26, came under my care, December 10th, 1911, and a diagnosis of acute synovitis with periarthritis, traumatic, was easily made after obtaining the following history and findings:

On stepping from a subway train to the platform, December 6th, he fell into an open space, striking the lower part of the shin and knee left side. The former was "barked" and the latter bruised a little, but not enough to prevent him walking up the steps and to his hotel, and dancing all that evening, the discomfort being trifling. Next day he consulted his doctor, who dressed the shin and strapped the knee. Swelling naturally followed, and pain increased. On the fourth day I found the strapping had given no relief; he was lame, the contour of knee was far from normal, there was a moderate amount of fluid in joint, the range of motion was very nearly normal, and the points of tenderness were at the insertion of the quadriceps tendon into the patella and over the tubercle of the tibia. These parts, it seemed to be, had been strained in his efforts at pulling his foot out of the space between the car and platform. As he

was soon to sail for a position in the Embassy at Rome, I decided to rest the joint at once; so applied a plaster of Paris bandage over a skin-fitting stockinette, with knee in slight flexion, permitting him to use the limb moderately in walking.

Next day I cut a window from the upper border of the patella to the tibial tubercle, as I had not taken the precaution to pad these sensitive points, when running on the plaster of Paris.

December 18th, seven days after his first visit, he was so much improved that I removed the plaster of Paris, making it into a splint for night use. The knee was strapped with adhesive plaster, and on the 26th he was discharged cured and all treatment discontinued. He sailed next on his foreign mission.

April 25th, 1912. His mother tells me that he has had no recurrence of any symptoms and is attending all the social functions connected with the Embassy.

Report has recently—this summer—come to me that there has been no relapse.

These two cases just reported in detail presented no difficult points in diagnosis, according to my way of thinking, and the indications for treatment were perfectly clear, the results justifying the method adopted.

Let me call your attention to an injury done the subpatellary bursa—many coming under my observation and when recognized early—say, a few days after—the trauma responded promptly to treatment.

Case IV (No. 11044A). A boy, 12 years of age, was seen at his home, November 14th, 1911. While playing tennis, September 14th, he fell on the right knee and was obliged to discontinue playing. The rest gave so much relief that he played next day and the following; but swelling and pain resulting, a doctor was called; the knee was strapped, and at the end of the week he was so far relieved that he resumed his tennis without the doctor's consent. The exercise served but to add additional trauma, and he was obliged to take to bed. I found a moderate enlargement of the popliteal bursa with decided enlargement under the ligamentum patella and thickening with tenderness around the tubercle of the tibia. There was no fluid in the joint and the range of motion was very good, if carefully made. My diagnosis was traumatic periostitis and subpatellary bursitis.

A strapping with adhesive plaster secundum artum soon afforded relief, and by the 24th he was so far advanced toward a cure that he was allowed to go to school. There has been no relapse.

One sees quite frequently cases of traumatic synovitis where simple measures afford

relief; but these measures are not continued long enough to effect a cure, and recurring traumata induce a chronic arthritis requiring more persistent protection. Take as illustration the following:

Case V (No. 4537). A gentleman from Texas, age 25 years, came under my observation, April 29th, 1898, with this history: A year ago sprained the right knee alighting from a buggy and was laid up for at least a month. Plaster of Paris was employed at the outset, and on its removal a month later nothing was done to restore the tone of the muscles protecting the joint. He was simply put on crutches, and continued their use up to the date of his appearance at my office, although a leather splint had been worn night and day, keeping the movements out of commission all the time. Even thus protected he injured the joint twice during the year. He complained on attempts at using. There was very little change in contour and the comparative measurements showed no difference in the thighs—one inch increase directly over the knee and three-quarters of an inch atrophy of the calf, patella freely movable, flexion not beyond a right angle without pain, extension to the normal limit. I could detect no lesion of the semi-lunars.

The indications seemed clear enough, and I soon had him fitted up with a brace known as the Campbell brace, which protected him from lateral strain, distributed the strain in walking throughout the entire limb, and allowed a range of motion equal to his own. This brace was attached to the shank of the shoe, and care was taken to avoid any pressure on thigh or calf muscles. The important feature, however, in the management of the case was daily massage with active and resistive movements. The improvement was quite apparent from the start, and by the twenty-first of May—less than a month—the crutches had been abandoned, the pain was no longer present and the range of motion had increased nearly to the normal. A week later he was so well advanced toward recovery that I allowed him to return to Texas with instructions to continue the brace until all traces of the trouble had disappeared.

Quite recently, August 14th, 1913, fifteen years later, he called at my office socially, but really to express his gratitude, and to tell me that the cure was established within a few months after his return home in May, 1898, and the knee had remained well for fifteen years. Then he bruised it one day last spring, but within a week all was well again, and there had been no further trouble.

In illustration of this same point, let me cite another case requiring more vigorous treatment.

Case VI (No. 11036). A gentleman, 40 years of age, from New Orleans, consulted me, November 9th, 1911, and my diagnosis was subacute synovitis, traumatic. He came soon after the injury two weeks previously, playing golf. The presumption was he played in poor form different from that of our presiding officer. The wrench was pretty severe, but next day he played again and twenty-four hours thereafter he had a well marked hydrops articuli, which persisted up to the date of his visit to my office. The measurements were: right knee, 13 3-4, 13 3-4, 12 3-4; left knee (affected one), 16, 16, 14 1-2. Flexion to 90 degrees was resisted and painful, while extension was normal.

The Paquelin cautery light touches, followed at once by criss-cross strapping of rubber adhesive plaster, leaving free the popliteal space, was the treatment adopted, and he was encouraged to use the limb in moderation.

The fluid was perceptibly less within a week; but at the end of another week, while the fluid was still present, he complained of pain on use and was not much encouraged.

The aspirator was used, quite emptying the joint cavity, and a skin-fitting plaster of Paris was applied. The fluid was sent to the laboratory, and the report was that a serous exudate with a few blood corpuscles was all that the specimen revealed. No pus, no bacteria, and no tubercle bacilli.

At the end of a week I substituted for the plaster of Paris a Campbell brace, and with the joint thus partially protected he returned to New Orleans, where Dr. Hatch continued the treatment begun in New York.

On November 28th, 1912, a year later, I had an opportunity of examining, and made the following note:

“Quite well for at least three months; wore brace two months, and then for the rest of the spring the knee was strapped; in summer playing golf without pain. Knee same size as its fellow; joint function good and painless.”

Lest the records already presented may give the impression that a diagnosis of an acute or a chronic synovitis is always easy, I beg to present an illustration of how one with a very large experience can easily make an incorrect diagnosis.

Case VII (No. 5133). A young lady, about 18 years of age, was referred to me by the late Dr. Francis Markoe, October 23, 1899, and I made out a “subacute chronic arthritis left knee with very little impairment of function;” because the history obtained was, that five years ago, while bathing, was conscious of a strain from a bruise of the knee, was lame for a day or two, but a rubbing brought about prompt relief and for three months no sign or

symptom was noted. Without any more injury she began to favor the limb in use, and this disability has continued without interruption to the date of my first observation. Once or twice during the five years she has complained of pain in one or the other elbow, and the case was regarded as "rheumatism," although the measures usually adopted for such cases, such as douches, medication and a course at Richfield Springs failed to afford relief.

The day she walked into my office there was a distinct lameness, but the range of motion was unimpaired. On flexing and extending I could feel a rice body-like crepitation; but there was nothing present in the other knee. The comparative measurements were practically identical. The quadriceps femoris was weaker on the left side. Because of the long standing of the lameness, I provided her with an apparatus to diminish the strain in walking and proceeded to strengthen the quadriceps.

By the latter part of November, while she walked with more ease, she was distinctly more fatigued after moderate walking. Potassium iodide was prescribed; but she could not get beyond ten grain doses without physiological effects. Massage was continued without interruption. A medical man, the late Dr. Kinnicut, helped me out in antirheumatic medication. She attended regularly, and yet at the end of eighteen months she had made very little progress; in fact, we were disappointed, and, as she suffered very little and was able to keep up with her social duties, we practically relied on time as about the best factor in therapeutics.

In January, 1901, she married and moved to Boston; where she consulted Dr. Goldthwaite, who, after a very careful examination, wrote me that, on finding a marked spasticity in her flexor muscles, especially the gastrocnemius, he made out a "lateral sclerosis," and no real true lesion whatever. He had his diagnosis confirmed by Dr. Walton of Boston.

In April I had an opportunity of going over the case again and noted the signs Dr. Goldthwaite had observed. The treatment advised by him was approved, viz.: a pair of plates in the shoe to give a better balance.

In due time she became a mother, and nothing active in the way of treatment was done until after confinement.

In February, 1903, I had another opportunity of examining the patient, finding the same crepitation in both knees, the same fatigue after walking. Curiously enough, however, she told me that while in the mountains the summer preceding she walked five miles without any fatigue. I had Dr. C. L. Dana see the case with me, and he made out a myopathy or

dystrophy after finding exaggerated reflexes both sides, a Babinski reflex with no reaction of regeneration. His prognosis was that it could be arrested by mild massage and avoidance of strain or fatigue.

This case, therefore, started with an apparent knee lesion induced by trauma, and proved most instructive, because of my good fortune in being able to follow it through all of the phases of the neurosis.

Among the odd things happening to a knee as a result of trauma, one finds occasionally a steno-synovitis of the hamstrings and not infrequently a rupture of the tendon of the quadriceps, as the following briefly reported will illustrate.

Case VIII (No. 11244). A gentleman, age 32, was referred to me by Dr. DeWolf of Providence, R. I., April 13, 1912, with a history of an injury to the left knee from a fall with joint in sharp flexion at which time the doctor found extreme tenderness over the external hamstring near its insertion, the joint apparently not involved. Under bandaging he got no relief and five or six weeks later underwent a course of baking in super-heated air. A month afterward distinct crepitation with swelling over the hamstrings and limitation of full movements were prominent features. An orthopedic surgeon in Boston confirmed Dr. DeWolf's diagnosis and advised a week's rest followed by douches, massage and electricity. After six or seven weeks' treatment, and pain on use persisting, the surgeon advised an arthrotoomy, under the impression that a lipoma arborescence had developed. All of this antedated his visit to me in April, when I found swelling in popliteal space on extension to 170 degrees, and lameness and fatigue easily induced. There was a moderate degree of atrophy of thigh, knee and calf. I was unable to detect anything within the joint by palpation. My advice was massage with full extension, as all acute symptoms had disappeared. Three weeks under this treatment proved beneficial, and I found range of motion perfect, thighs and calves same size and cure about complete.

A letter from the patient, November 15th, 1912, contained the following:

"Your diagnosis was correct, the treatment you prescribed successful; my knee is now entirely well."

As a rule, swelling in popliteal space is suggestive of a hydrods articuli because the popliteal bursa often communicates with the synovial sac, but when the sac can be found quite free of any effusion a bursitis of the popliteal may exist independently of any synovitis. The teno-synovitis in the case just reported easily explained the bursitis.

The following is hardly pertinent to the present discussion, but because of the slight flexion deformity and the lameness referable to the knee, to say nothing of the relief afforded by operation, prompts me to make a brief abstract.

Case IX (No. 5520). An elderly gentleman, age 70, in 1898 had a partial separation of the tendon of the quadriceps from the patella. Enough of the tendon was left to enable him to get about with a limb only. This was on the right side and he had to exercise great care to keep from falling. He took a tumble a few days before I saw him, September 20th 1900, completely separating the tendon of the quadriceps from the left patella, and his gait was awkward, indeed. The transverse depression just above the patella was so marked and the history was so clear that a diagnosis was easily made, and on my advice he entered my private hospital. Two days later when under ether through a longitudinal incision the torn fibres were exposed, revealing a laceration of the capsule. Part of this was removed, the rent sutured, and the ends of the tendons sutured to the patella with kangaroo tendons. The joint was dressed posteriorly and limb secured in plaster of Paris. The dressing was removed on the sixth day, healing about complete, the case acting to a wish.

On November 28th, two and a half months from date of operation, full active extension and flexion was made easily; he walked well; could get on and off a car without any trouble, and the cure was fully established.

The lesions of the knee calling for an arthrotomy are varied—loose bodies, torn semilunar cartilages, lipomata arborescences or fatty fringes—do not, as a rule, respond to anything short of operation. Because of the old dread of opening a joint, especially the knee joint, the older surgeons have advised against this procedure; but within the past decade there has been a decided change in sentiment, current literature being full of successful cases, and one hardly feels like reporting unless he can count his operations into the hundreds.

Take, for example, a discussion on injuries to the knee-joint other than fractures and dislocations, at the recent meeting of the British Medical Association at Brighton, in July. Dr. A. M. Martin of Newcastle-on-Tyne, presented a series of 509 operations on the semilunar cartilage. In this series he found the external semilunar was torn in only 38 cases. The common type of injury was a split from before backward. He contended that the cartilage could not be torn from its attachments when the knee was extended, and his cases so

carefully studied proved the point he tried to establish.

Whitlock of Oxford was just as positive that lesions of the semilunar cartilages were always caused in partial flexion of the knee combined with external irritation. But his experience was by no means as great as that of Martin.

In this discussion, which was reported in abstract (*Medical Record* for August 6th, 1913, page 314); the concensus of opinion was that complete removal of the injured cartilage gave far better results than any attempt at suturing.

While my own experience has extended over a number of years, I have failed to collect my cases for statistical study, yet I am convinced that the opinion expressed by the English surgeons is the correct one.

My method of handling these internal derangements is about as follows:

An attempt is made to reduce the cartilage, if it be subluxated, hold it in place with adhesive strips and reinforced with plaster of Paris for a few weeks; then apply a Campbell brace, limiting the range of motion commensurate with ordinary use of the limb, the brace preventing the trauma of use, or lateral displacement. In a certain number of cases this treatment is quite efficient. Take as illustration the following:

Case X (No. 2047). A young man, 18 years of age, came under my care on the 7th of March, 1892, and I immediately diagnosed the case as internal derangement of the knee interpreted as occasional subluxation of the internal semilunar cartilage and resulting synovitis. Eight or nine months previously, while turning a somersault, he missed his footing as he came over, the left knee was abducted rather sharply, and he felt something slip. He remembers this very accurately, and puts his finger upon the spot which is directly over the internal semilunar cartilage. He found some difficulty in extending the limb, but did so very quickly, while something slipped into place. He paid no further attention to it, played tennis all the afternoon, but a half dozen times since then, if he started quickly to run, or if he arose quickly from a sitting posture, he would experience a sensation of something slipping. The pain caused thereby would last only an instant, something would slide into place, and he would be all right again. Two weeks before he came under my observation, while catching a ball, the slipping recurred, and he did not recover from this as quickly as before; in fact, he had not recovered up to the time of his visit to my office.

This injury was followed by a good deal of

effusion into the joint—a sign of synovitis. The limb was put up in a water-glass bandage by the local physician, after adjusting a posterior splint, but the cartilage was not reduced. He was able to extend the limb only to an angle of 150 degrees; there was distinct swelling over the internal semilunar, but there seemed to be no complete subluxation. The limbs were practically the same in size. By the pressure of my thumb over the cartilage and a sharp flexion, followed by extension and some further manipulation, I seemed to get the cartilage into place. The treatment by adhesive plaster of Paris bandage was applied immediately, and this was changed from time to time until July 11th, when he was apparently well. There was no lameness, no disability. I saw him again in the fall and there was no relapse. He was attending to his athletics in college.

On December 7th, 1902, I had a report that he was entirely well.

What I have found as a sequence of a number of cases of this kind is a certain apprehension lest something may happen to the knee; but where a good course of massage can be followed, the muscles regain their tone and nothing further happens. In the majority, however, things do not go on so well, and I have found it necessary to remove the cartilage, making a pretty thorough arthrotomy. If the lesion has persisted for a long while, and if recurring attacks of synovitis have been the rule, I not infrequently find great thickening of the alar ligaments, requiring removal of these as well as fatty masses throughout the joint. In at least half a dozen operations, in the present year, I have found fatty tumors within the joint. I could illustrate this point by a recital of many from my records, but they would add nothing to the statements already made. With us the all-important question with patients is the subsequent function of the limb. All have an impression that the full range of motion will not be restored, and I find it necessary to employ passive motion from two to three or four times under anesthetic, following this always with immediate massage. They often object to any further anesthesia, but I am obliged to insist on more vigorous passive movements at the hands of the masseur, and these patients, as a rule, prefer this to any further operative measures.

One of the most obstinate, I am sure, will be of enough interest to report in detail:

Case XI (No. 8158). A lady, 51 years of age, came under treatment, April 11th, 1906. My diagnosis was chronic arthritis of the right knee, traumatic, with lipomata and enlarge fringes. The history she gave me was the following:

In July, 1904, she fell on the sidewalk and apparently tore one of the semilunars. There seemed to have been a pretty sharp arthritis requiring plaster of Paris and a rest in bed for a period of five months. All efforts at relief were unsatisfactory, and with this history I had no hesitation in advising an arthrotomy at once. To this she objected so strenuously that I proceeded to treat in the usual way, giving her a Campbell brace, but the operation was done within two or three months afterwards and I found fatty masses about the size of one's thumb and thickening of the fringe, cartilages remaining intact. The return of motion was tedious, on account of the pain induced; so I was obliged to move the knee half a dozen times in the next few months under anesthesia employing massage immediately after each brisenent force. She finally wearied of remaining in the hospital and I allowed her to return to her home in the northern part of the state, giving her full instructions about active and passive movements. She learned to strap the knee very well, and continued so to do until all thickening had disappeared. When I last saw her, in January, 1909, she walked without a limp, going up and downstairs naturally, with full extension and flexion to an acute angle. The limb is well developed. I have heard from time to time of this patient through mutual friends, and I am quite sure that there has been no relapse.

While preparing this paper, I recall a few where it was necessary to do an arthrotomy two or three times, as I had failed to remove completely all offending material from the joint cavity. In my later series, however, I have had no such ill luck, because I have been most careful to explore the joint carefully and remove every tissue that might be of any annoyance.

One of the most obstinate cases of this type that I have had to deal with—one in which both knees were subjected to operation, not by myself, however—is the following:

Case XII (No. 10418). A gentleman, 35 years of age, referred to me by a patient on whom I had done an arthrotomy with brilliant results, came under my treatment on the 11th of August, 1910, for a double chronic hydro-s-articuli. He gave a history; that five years prior to this date, without provocation the right knee began to trouble him; had no treatment other than elastic knee cap; got some relief from using arch supporters but in January, 1910, seemed to have developed a lesion in both knees and was operated upon by a prominent homeopathic surgeon in New York; and in July—a month before I saw him—a second operation was done by the same surgeon.

I found fluid in the right knee, the fringes apparently a little enlarged; and in the left knee, while the contents in the synovial sac were not so thick, there was decided evidence of water in both knees. The popliteal bursa on both sides were enlarged.

The treatment adopted was the cautery and tapping both knees. This was continued for several months with at least half a dozen tapings. He would get apparently better, and then relapse; and in 1912, early in January, I aspirated both knees and injected two and a half ounces of a two per cent. solution of carbolic acid, repeating this on the right knee a week later, and within three or four days the fluid had recurred, the result being most unsatisfactory. On the 12th of January I drew off the left about an ounce of fluid and injected the same amount of a two per cent. solution of formalin and glycerin. The pain was most excessive—excruciating as he termed it—and required morphia for a day or two to give any relief. This was repeated in March, and while one knee seemed to improve the other was not any better. When I saw him last on the 25th of June, 1912, he was decidedly crippled, both knees were painful, and he held both moderate flexion; he employed a cane, and was so much discouraged that we decided to give up further active treatment. Recently, during the present summer, my masseuse saw him on the boardwalk at Atlantic City, and she reported that he was using crutches when not in the wheel-chair.

The only comment I have to make upon a case of this kind is that the arthrotomies were not sufficiently thorough, and I reproach myself for not having undertaken these operations myself instead of subjecting him to such long and expensive treatment.

Remarks on diagnosis would be incomplete without a reference to sarcoma in the neighborhood of the joint. Let me illustrate by the following:

Case XIII (No 8289). A gentleman, 35 years of age, consulted me June 26th, 1906, and I made the diagnosis, subacute arthritis of the left knee, probably infectious. He told me that seven or eight months previously he had had an acute attack of rheumatism in the left arm and knee, but was not confined to bed. In February he went to Mount Clemens and took the baths, and returned somewhat relieved. Soon after his return, while standing in a trolley car, the car suddenly stopped and jarred the knee, so that it felt wobbly; but he got off and walked to his doctor's office. Since that time the knee has been stiffish and sensitive. The knee could be extended to an angle of 175 degrees with a little force, and flexed to 90 degrees only. The measurements which I have reeorded show

that there was no marked difference in size; but I thought I could detect enlarged fringes beneath the ligamentum patella.

I subjected him to the usual treatment, employing a brace, and in addition to this a skin fitting plaster of Paris because of the atrocious pain about the head of the tibia. As he got no relief, I secured an X-ray in August; and this showed a suspicious spot in the lower end of the femur. The pain at this time was so great that he required narcotics by day and by night. Two or three days later we thrust a scalpel into the same thickened tissue of the femur, and sent the specimen to the pathologist for report, which was a sarcoma. The physician who had referred the patient to me felt quite sure that the pathologist was wrong, especially as he had treated him for a chancre nine or ten years ago. So an anti-syphilitic treatment was adopted without any result at the end of a month.

On further study of the X-ray plate I was positive that this suspicious spot in the lower end of the femur was a sarcoma because of its markings; and after conclusion with Doctors Coley and Erdman, both confirming my interpretation, it was decided to do an exploratory operation with an amputation if the tumor was found. This was done on the 5th of September, and the broken-down mass was found in the lower end of the femur, the pathologist reporting later that it was true giant cell sarcoma. The amputation had been made the upper third of the thigh. Dr. Coley undertook the antitoxin treatment with highly gratifying results.

My last report from the patient, on the 25th of July, 1911, was that he was very healthy and there had been no sign of recurrence.

In the *American Journal of Surgery*, May, 1913, Dr. Walter M. Brickner, of New York, has published a paper the title of which is the following: "The Differential Diagnosis of Syphilis, Tuberculosis, Tumors and Osteomyelitis of the Long Bones." It is illustrated by X-ray prints, which correspond very closely with a large number of plates in my possession.

The text of Dr. Brickner's paper is quite as instructive as the prints, and did time permit I should be glad to quote extensively from this valuable contribution to bone literature. I am reminded, however, gentlemen, that my paper is already too long for an audience in mid-summer, but I must be allowed to detain you a while longer with a reference at least to tuberculous knees in the adult, and a recital of cases, did time permit. Suffice it to say, however, that at the present time a radical treatment, such as excision, is about the best for men and women who are obliged to earn a living. I have in mind a number of

instances where excision has served a useful purpose, but the patients have belonged to a better class, have not been obliged to work, and can afford to live in parts of the country where the best air and hygienic measures prevail. It is quite true that cases diagnosticated as tuberculosis are diagnosticated on what is known as circumstantial evidence. The knees themselves present very few signs, but because there is a history of pulmonary hemorrhage and signs pointing toward invasion of the lung, the tubercular test is regarded by of my colleagues as a valuable aid in diagnosis; but I have refrained from employing this, because I have feared a transfer of the lesion to other parts of the body, what is known as activation of a latent focus. I could quote instances where the test has been made by myself and colleagues where other joints were subsequently involved, and inasmuch as the tests made by the average practitioner are not always reliable, I find myself unwilling to employ the same. There are examples a plenty where excision of a knee in a tubercular subject has seemed to arrest the disease, especially where the patient has had the benefit of good climate and an outdoor life. Take as illustration the following, which, I am sure, would interest the members of this Association, as the patient herself spent the early years of her life in Bardstown, Kentucky.

Case XIV (No 4049). On April 29th, 1897, a young lady, 18 years of age, sought my advice for a deformity of the left knee dependent upon the tubercular osteitis. When ten years of age she had the first sign of trouble of the knee. Symptoms were slow in developing, obscure. Without going into detail the history is that which we find in the large majority. She was fairly comfortable one the knee was held fixed in an angle of about 150 degrees. There was a little puffiness on the outer side of the ligamentum patella. She had been through the usual treatment of braces, plaster of Paris, etc., and had become thoroughly discouraged.

I did an excision on the 3rd of May, 1897, placing the limb in slight hyper-extension, as she was short in stature, and I thought that she would be able to walk better. The wounds healed without any suppuration, and on removing the plaster a brace was applied to ensure a better fixation and give her more confidence in the use of the limb.

The further history of the case may be summed up in this way: She became a wage-earner, a year or two later serving as reporter on the *New York World*; had a hemorrhage of the lung, and was sent by this newspaper to Arizona, where she spent many months in the saddle, gaining rapidly in flesh and becoming

quite active. As she was returning home in 1901, the early part of the year, she attended a dance in Denver, and danced so well that a distinguished surgeon, her partner in the dance, was amazed at her ability to get about so well, not recognizing any lameness whatever. Shortly after this she returned to the city, and I could find no lameness. She has continued well up to the present time. Early in June, 1904, she was married, and has since given birth to a healthy child, and has never regretted the operation of excision.

In closing, I beg to say that in eleven cases of old tuberculous knees, long since healed, in which I did an arthroplasty, after Dr. Murphy's method, I have been disappointed in the results. In no single instance has there been enough motion given the patient to use the limb without apprehension. Dr. Baer of Johns-Hopkins, and you know, has had some excellent results in an operation which consists in the insertion of a chromicized pig's bladder between the ends of the bone securing it with interrupted sutures. Many of us have done this operation, but our results have not been equal to those reported by Dr. Baer. I do not wish to be understood as criticising; on the contrary, I believe these procedures are perfectly justifiable. Ankylosed joints will ultimately be restored to motion, and we shall all be indebted to the pioneer work of these eminent surgeons.

COUNTY SOCIETY REPORTS

Adair—The Adair County Medical Society met at Dr. Cartwright's office on Thursday, October 9th, with the following members present: S. P. Miller, President; U. L. Taylor, Secretary; W. J. Flowers, B. J. Bolin, W. R. Grissom, C. M. Russell, Garland, Grssom, W. F. Cartwright, and S. J. Simmons. The minutes of the last meeting were read and approved.

B. J. Bolin was first on the program for the day and read a paper on the financial problem, or how can doctors make their business more profitable. The paper was a good one, and was discussed and endorsed by nearly every member present.

After this the meeting was interrupted by the announcement of the death of Dr. W. H. Wathen, of Louisville, Ky. The society was immediately adjourned, and a committee appointed to draft some suitable resolutions expressing the feelings of this society on the great calamity to the society, and the medical profession generally. All the members present were appointed on that committee, with U. L. Taylor as chairman. The committee was directed to report at the next meeting. The following is the report:

Whereas, the sad news has come to us, that Dr. W. H. Wathen, under whose teaching every member of this society has sat, and whom every

one has learned to love and every one has been made sad by his untimely taking off; therefore be it

Resolved, That in the death of Prof. Wathen the United States, the State of Kentucky, the city of Louisville, and every county society has sustained an irreparable loss.

And Whereas, the medical profession in all the land has lost an able councillor, every young physician a loyal friend, his widow a loving husband, his son a noble father, the community in which he lived a loss that cannot be repaired.

Resolved, That a copy of these proceedings be sent to the family of the deceased, a copy be furnished to the JOURNAL, and a copy be spread upon the minutes of this society.

U. L. TAYLOR, Chairman,
W. F. CARTWRIGHT,
W. J. FLOWERS,
C M. RUSSELL,
W. R. GRISSOM,
S. J. SIMMONS,
B. J. BOLIN,
S. P. MILLER,
GARLAND GRISSOM,

Committee.

Bell—The regular meeting of the Bell County Medical Society, was held at Middlesboro on the evening of December 12th, at the Middlesboro Hotel. The business session was called to order by the President, Dr. Jacob Schultz, and the minutes of the previous meeting were read by the Secretary and approved as read. This being the last meeting of the year, the scientific papers were dispensed with in order to get through with the election of officers for the ensuing year, and to discuss some other matters that were to come before the meeting. The name of Dr. Price Martin was presented for membership in the society, which was referred to the Board of Censors to be reported on at our next meeting.

County Attorney Chas. I. Dawson, was presented to the society, and in a very impressive way, laid before the society some of the deplorable conditions that exist in the county, in regard to the reckless spread of venereal diseases and asked the co-operation of the Bell County Medical Society in coping with the situation, and furthering legislation along this line. As usual in all things that stand for better social and hygienic conditions, he found the society ready and willing to render every aid possible, and the society promptly passed resolutions endorsing the passage of a bill by the next legislature, requiring all physicians to keep a record of all venereal cases treated by them, that shall be open to the officers of the law, when necessary to refer to these records in the prosecution of any case.

The election of officers was then taken up and the election resulted in the election of the following officers for the year 1914:

President, Edward Wilson, Pineville; Vice-

President, W. K. Evans, Middlesboro; Secretary and Treasurer, O. P. Nuckols, Pineville. H. C. Chance was elected Censor for the years 1914, 1915, and 1916.

The retiring President, Jacob Schultz, entertained the members of the society for the balance of the evening in his usual charming way, and at this juncture invited those present to repair to the large dining room of the Middlesboro Hotel, where a most excellent dinner awaited them. It goes without saying that all good doctors enjoy a good dinner, and this was no exception to the rule.

Jacob Schultz acted as toastmaster and the following toasts were responded to:

“The Family Doctor,” J. Harry Hendren.
“The Doctor and Society,” L. L. Robinson.
“The Specialist,” J. P. Edmonds.
“The Booster and the Dinner,” H. C. Chance.
“The Ladies,” U. G. Brummett.
“Scientific Medicine,” Fred D. Haston.
“The Signs of the Times,” J. G. Moss.
“The Bell County Bunch,” O. P. Nuckols.

After a late hour, the dinner and all the speech making being over, the society rose to their feet in a vote of thanks to Dr. Schultz, and a renewal of their zeal for the Bell County Medical Society and for the incoming year to be the best in its history.

O. P. NUCKOLS, Secretary.

Christian—At 1:30 P. M., Tuesday, August 19th, the Christian County Medical Society was called to order by the President, Dr. Stites.

After reading and approving the minutes of the last meeting the following members answered to roll call: Rozzell, Barnes, Gaither, Caudle, Lackey, Keith, Barker, Watts, Bell, Perkins, Lacy, Sargeant, Rudd, Harned, Thomas, Stites, Durham and Sandbach. We had with us Dr. A. T. McCormack and Dr. Curry of the State Tuberculosis Commission

Austin Bell presented a case of “Addison’s Disease.” This case had been before the society before and all were glad to see it again. Dr. McCormack advised arsenic in some form. Dr. Sargeant advised tonic treatment in absence of acute symptoms. Dr. Bell read from Osler in discussing the case.

J. G. Gaither reported a case of heart trouble. Dr. McCormack thinks it aneurysm but does not know of what. There is an insufficiency and roughening of all four of the valves. Most remarkable case he had ever seen.

B. A. Caudle reported a case of “Carbolic Acid Poisoning,” with recovery.

W. S. Sandbach reported a case of “Concentrated Lye Poisoning,” with death as result.

W. A. Lackey spoke on a proposition for establishing a tuberculosis hospital, followed by Drs. McCormack and Curry. A motion was made by Dr. Sandbach and passed for the President to appoint the committee of three to go before

the fiscal court asking that the county be declared a district for establishing a tuberculosis hospital. The President appointed Drs. Barker, Barnes and Sandbach to be assisted by the county and city health officers.

No further business, we adjourned to meet the third Tuesday in September.

W. S. SANDBACH, Secretary.

Christian—The Christian County Medical Society met in regular session in the Avalon, Tuesday, September 16th, with President Stites presiding.

The minutes of the last meeting were read and approved.

Those present were P. M. Stites, Perkins, Woosley, Gaither, Donnelly, Bell, Keith, Gates, Rudd, Rozzell, Lacy, Sargeant, Harned, Harris, and Sandbach.

Austin Bell, Gaither, Rozzell and **Sandbach** all reported cases and each case was freely discussed.

J. G. Gaither read a paper on "Primary Dressings for Compound Fractures, and exhibited a case with perfect results illustrating his paper.

W. W. Rozzell read a paper on "Preventive Blindness." He also exhibited a case showing his method of treatment and good results.

Both papers were discussed by nearly every one present and we adjourned to meet again the third Tuesday in October.

W. S. SANDBACH, Secretary.

Franklin—The Franklin County Medical Society met in the office of Drs. Williams & Mastin, December 1st, at 2 P. M. Present, J. T. Minnisi, Budd, Heilman, Dawson, Darnell, Wilson, Mastin, Keller, Coleman, Garrett, Patterson, Stewart, Montfort, Hill and Williams.

D. S. Wilson, Councillor of Louisville district, was present, and discussed the aims and needs of the county society in a most entertaining manner with many useful suggestions which were discussed exhaustively by the members present and resulted in a reorganization of the society, after which it was moved and carried that the next meeting shall be on the first Monday in January, at which time a social feature shall be inaugurated. In pursuance of which a committee on entertainment, composed of U. V. Williams, Budd and Montfort, were directed to prepare a suitable entertainment. It was facetiously suggested that the road to success of this society and the awakening of enthusiasm might be reached by stimulation of the gastronomic diversion.

G. A. Budd and **Garrett** were appointed and accepted to prepare papers for the meeting.

Being the date for the annual election of officers, G. A. Budd was elected President; H. S. Keller, Vice-President; U. V. Williams, Secretary

and Treasurer; J. W. Hill, Delegate; U. V. Williams, Patterson and Hill, Board of Censors.

Meeting adjourned

U. V. WILLIAMS, Secretary.

Taylor—The Taylor County Medical Society met in the office of the Secretary. Present, Drs. Heistand, Reesor, Sanders, Gowdy, S. H. Kelsay, and Atkinson.

C. V. Heistand reported the following cases:

(1) Further report on case of "Hemophilia," recovered, having treated it with ergot and lime water.

(2) Case of triplets delivered at seven months, two placentae.

(3) Child five weeks old, convulsive movements toward right side. This is the fourth child of same mother, all of whom are dead except the last, which he thinks will die.

(4) Reported six cases of typhoid fever in one family this summer and autumn.

(5) Reported a series of cases of diphtheria, several of which had an eruption. Cases probably diphtheria complicated with scarlet fever.

Reports of some of the members on some anomalous cases of conditions of children at birth evoked a discussion on "Maternal Impressions."

J. L. Atkinson reported a case of erysipelas in a child one year old to which he administered 5 c.c. antistreptococcic serum, repeating the dose in eight hours. Prompt recovery.

C. V. Heistand says he uses lotion of zinc oxide and water for erysipelas, with satisfactory results.

E. L. Gowdy read a paper on "Buttermilk as a Therapeutic Agent." A splendid paper which is enclosed for the JOURNAL.

Next meeting, December 4th, to be held at the Merchant's Hotel to be followed by a banquet.

J. L. ATKINSON, Secretary.

Benzol in Leukemia.—Fossati's patient was a young woman with severe splenomedullary leukemia, not imminent when a course of benzol treatment was given and prompt improvement followed. The young woman was not able to bear the large doses of benzol that have been advocated, so the dosage was only from 20 to 60 drops in capsules, suspending the treatment for a day or so occasionally. The temperature returned to normal and by the end of two months the general condition was better than it had been since the first symptoms had been observed a year before. The blood-count at various dates is tabulated showing the increase in the reds and the drop in the whites from 360,000 to 56,000 in three months, the hemoglobin increasing from 35 to 50 per cent.

SEX HYGIENE SYMPOSIUM

I.

VARIOUS ASPECTS OF THE SOCIAL EVIL.

By H. A. DAVIDSON, Louisville.

When the social evil or prostitution is mentioned in public in this enlightened age the people throw up their hands in horror and speaking metaphorically, run from it as they would from a leper.

This evil with all its attendant evils, constitutes the greatest problem ever undertaken by the human race to solve. The medical profession in the past have been prone to keep their hands off when they, above all others because of their greater knowledge, should be the leaders in a fight against the forces which cause more disease and suffering among men, women and children of our country than nearly all other diseases combined.

The tuberculosis problem in the beginning was considered insurmountable, but already we are beginning to see the results of the campaign of education which has been so intelligently waged by our profession and many public spirited laymen. A campaign conducted along similar lines will do much to ameliorate the condition represented by the mountainous mass of disease and corruption which is the direct result of the social evil.

It has been estimated from reliable statistics that there are 300,000 public prostitutes in the United States. This does not take into

account the clandestine or occasional prostitutes who come from fairly respectable families and work in our department stores and factories. Here in Louisville paid investigators revealed the fact that we have twenty times as many houses of assignation as there are public houses of ill-fame. These assignation houses represent a greater evil than the public houses because the women and men who frequent them do not take the same precautions. It has been estimated that the life of a prostitute will average seven to ten years; this is a conservative estimate; some reliable investigators place it as low as four years. This fearful mortality means that there must be a constant supply of young girls and women to fill the ranks and meet the great demand, therefore, 50,000 new recruits enter the ranks of prostitution every year.

Why do so many of our girls become prostitutes?

In the first place many of them are seduced by some boy or man. We cannot get away from the fact that the source of the most of this evil originates with the male portion of society, or as one has said the male factor is the chief malefactor.

A woman's love of fine clothes and entertainment is the cause of her downfall in many cases. Bad home surroundings and alcoholism are contributing causes. In some of our department stores the girls are paid such low wages that it is impossible for them to live upon the amount paid. The employer of these girls must know that they make on the side the extra money necessary to supply them with proper clothes and amusement. No doubt the chief contributing cause is that false social code of morals which readily con-

done in the man what it unsparingly condemns in the woman. Doubtless there are some women who are fated to prostitution through their inherited tendencies to vice. In the words of Prince Morrow, "The woman in most instances becomes a prostitute not from deliberate choice or from inherited tendencies, but because her ruin has been accomplished by seduction, fraud or force; she remains a prostitute because men pay her to do so; she sells her body because society does not permit her other means of livelihood."

It is in the role of transmitter of syphilis, gonorrhoea and chaneroid that the prostitute becomes the greatest menace to the human race. Reliable authorities have established the fact by means of the Wasserman test that 80 to 90 per cent of the prostitutes are infected with syphilis, practically 100 per cent. of all prostitutes have had gonorrhoea. Investigations have proven the fact that practically no woman can practice prostitution more than a few weeks without becoming infected with one of the venereal diseases.

With the above information before us we are prepared to understand that 75 to 80 per cent. of all the male population have had gonorrhoea and many of these cases are uncured, although not apparently active. Because so many of these cases are not completely cured 1,500,000 innocent wives are infected in this country to-day. Another natural sequel is the 10 to 20 per cent. of blindness in children due to gonorrhoea. While syphilis is not as prevalent as gonorrhoea we have millions of cases in this country, the estimates of various authorities ranging from 5 to 18 per cent of the population. Nearly 70 per cent. of all syphilitic infections in married women are traced to contamination by the husbands. Neisser and Noeggerath state that from 45 to 50 per cent. of all sterility in women is due to gonorrhoea; 75 to 80 per cent of abdominal operations on women are due to gonorrhoea. Price, of Philadelphia, says that in a series of 1,000 abdominal operations, 95 per cent. were the result of conditions due to gonorrhoea. Lydston states that gonorrhoea cripples one in one hundred of the population and kill one in two hundred.

When we think of the large number of defenseless wives and innocent children infected by syphilis and gonorrhoea transmitted by the prostitute through the husband and father, then it is we realize the magnitude of the danger and the great necessity of remedial measures. What can be done to remedy the evil? Reglementation, which has for its object the hygienizing of prostitution by eliminating all sources of disease in the woman engaged in it, has been tried in most European countries and has been a failure. Hamburg is prob-

ably the only city where it is still practiced. Reglementation only affects the public prostitute and the clandestine prostitute is left to spread infection broadcast. One reason it has failed is because it does not take into account the male source of infection. A woman might be given a certificate of good health and within ten minutes be infected with gonorrhoea by a male carrier. It has not been popular in this country, in fact has been introduced only in one state, Missouri, and there it was in operation for only a brief period (about one year), when the law was swept from the statute books by an avalanche of protests from the citizens of the state.

In certain cities at various times there have been outbursts of indignation because of the brazen character of the evil and attempts have been made to run them out of certain districts. The result of such attempts has been the scattering of prostitutes over the city and later after the outburst of the citizens has subsided they settle back in their old haunts as before. Recently a new law has been passed in Iowa known as the Iowa Injunction Law, which if properly enforced will do some good. It places a penalty upon the property used for purposes of prostitution and such property may be held vacant for one year, no tenant being allowed to rent same, if any citizen prove before the Court that such property is used for immoral purposes. Such a law will close up the house of prostitution very quickly and it has been a success in a few western cities. This law has been declared constitutional by the U. S. Supreme Court.

The medical profession can do much to help in the fight against prostitution and its attendant evils. They above all others should educate the men, women and children in regard to the great dangers of prostitution. The venereal diseases if shown up in their proper light will deter many a boy and young man from having intercourse with prostitutes. It is not sufficient for the medical profession to teach methods of prevention alone, that is very good but it does not go far enough; they should teach young boys and men to be more continent. At the Brussels International Congress the specialists declare that "continence is not prejudicial to health, but on the contrary, is to be recommended from a purely hygienic point of view." Now if we as members of the medical profession believe that, why shouldn't we grasp every opportunity to make it known to the boys and men who need this information. While there are many hot blooded young fellows who will not heed your advice, there are others who will be and have been prevented from sexual excess by such information. The tendency of modern medicine to-day is toward prevention of dis-

ease and the teaching of continence is pre-eminently prevention. I would like to see the medical profession of Kentucky endorse a bill before the State legislature which would make it a penal offense for any man to knowingly infect his wife and children with a venereal disease. Such a law would assist the physician in preventing a man from marrying who is infected with syphilis or gonorrhoea in an active stage and who would be certain to contaminate his wife and children.

The medical profession should teach young men and young women who are under their care to require certificates from their family physicians before marrying. While in some states, a law with this in view has been passed, it has not always been successful in practice, but it could be made the custom before marriage to require a clean bill of health from each of the participants. Education and time could bring about this state of affairs, and the medical profession should be the chief factor in establishing this custom. Such a custom would have a tremendous influence upon the social evil. Prostitution will never be eliminated entirely until all the causative factors have been removed, such as low wages for women, alcoholism, cadet system, bad home surroundings, the double standard for men and women and most important of all the insatiable sexual appetite of man.

IS THERE A VENEREAL MENACE?

By H. J. FARBACH, Louisville.

Gentlemen, I consider it a waste of time to argue the affirmative side of this question by quoting the army and navy reports of various countries concerning the venereal diseases, by recapitulating the histories obtained in institutions for the insane, and feeble-minded asylums. Statistics in most instances are tiresome and why go so far from home for argument. There isn't a man present who has been engaged in the active practice of medicine for one year, who can not argue my question from the affirmative side from personal experience. So rather than waste time airing my point of view that is already conceded, let us consider the causes that make a venereal menace possible.

Question nine out of ten of the victims of venereal diseases and you will find that one of the main factors in their becoming infected is ignorance. Ignorance of liability of infection and ignorance of venereal prophylaxis. It is astonishing how little, even highly educated and cultured people outside of the medical profession, know of sexuality. Its proper anatomical and physiological elements and its fundamental physice influence. In public and private schools is taught the basic principles,

function and care of the eyes, teeth, voice and a general idea is obtained of the body as a whole, with the exception of the generative organs. By this ignorance of the subject, it was expected and hoped to not attract the attention of the growing mind. But the absurdity of this assumption is manifest on every hand. Sexual instincts and functions are recognized by the child before any other body function, hunger and thirst being excepted, and all of our training of children tends to direct their attention to the generative organs rather than to detract. What is one of, if not the first willful control of body functions, that is taught the child? That of defecation and urination. And is he or she not taught this control in the majority of instances through shame? So at the very beginning of life, the child is taught and instilled with the feeling that that portion of its body between its umbilicus and its knees is something that it must be ashamed of, must be hidden away and spoken of only in the illusive sense. Parents, ostrich like, have tried to evade their duty in the early life of the child, by telling themselves and those interested that their child was too young to think of anything sexual. Deep down in their hearts they own this is not true, but rather than accept the responsibility, they compromise in hoping and wishing that the child will be what they would like it to be. But the sexual instinct is present in every child, and a great deal earlier than parents like to admit. They in most instances hope to curb this instinct by ignoring it, and when it does crop out in spite of evasion, they meet the question of the child with falsehoods or with the declaration that the discussion of this subject is not within propriety. As an indication of the early development of sexual instincts in the child is the desire for knowledge of things sexual. The inquiry of a child as to the source of babies is not an idle fleeting question, it is one of the earliest and analytical actions of the rapidly growing brain. The question is asked as a rule of the mother, and is asked with the same sweet, wholesome innocence that the young seek knowledge of all things. Here is the pliant, supple clay for the parent to mould. And how do they do it? Instead of answering the question they tell some fairy-tale of Santa Claus, of the stork or the doctor's satchel. These parents must realize that sooner or later, this child, the pride of their hearts, must learn the true source of babies. But they would rather that this knowledge come from some vicious or ignorant source rather than from them, so right here at the beginning, the mother loses two great influences from her child: one that it cannot believe, as is its inherent desire to believe the truthfulness of the parent; and the other is that it must seek

elsewhere for knowledge of the thing that is most potent for much good or for much harm. So the boy gets his sexual education in the back alley and the girl from vicious companions or servants. Why do parents allow this state of affairs to continue? A few perhaps can argue ignorance on their part, but this is not true in most instances. They know from their own experiences, what the child must go through, and the one thing above all others that restrains them from saving their child so much anguish and even pain is prudery. The subject is a delicate one, one to be discussed by servants behind doors and a besmearing thing that no refined person would acknowledge. So prudery is born of and based on a distorted idea that sex is evil. But this is not true. Sex is not evil, unless we make it evil. It is true that a small percentage of the population make it evil, but have not these same people debauched, and debased everything they came in contact with? Because a parody on a masterpiece is written, does not lessen the value of or render less sweet, the songs of the great composers. And because sex has been prostituted is no criterion that it is evil.

The generative organs and the generative track were and are sacred to primitive people. But as luxury and indolence grow they give rise to the debasement of sex. This is as true to-day as it was two thousand years ago. How this is brought about and why, does not lie within this discussion, but this we must heed. America to-day, by virtue of her natural resources and by the genius of the minds of her great men, is giving our people of every class more than any other civilization has or is. The so-called poor or lower class of people in this country to-day enjoy more rights and privileges and physical comfort than do some of the privileged class of other countries. The child of the poor man is not only offered but is forced to take an education. Influence and a derth of natural resources have placed within the reach of all, the comedy and drama and the music of the world. People have been taught to think and to dream things that in the past have been for the chosen few are now the property of every one, and with this stimulant of mind and imagery, must of an necessity come the stimulant of sexuality. This is but natural and right, but it is not right to develop sexuality without developing also hand to hand with it the power to control it. In the history of civilized country or nation when the fathers of that nation become rakes and the mothers prostitutes, that nation soon ceases to exist. This is simply an ultimate result of a natural law that man cannot change. So with the general development and improvement of our race, we must not lose sight of the necessity of the development of the con-

trol of things sexual. The folly of municipal control of the adult can be seen on every hand. The regulation and segregation of prostitution does not regulate or segregate. The attempt to abolish it entirely from any large community is followed by the mushroom appearance of numerous places where illicit intercourse can be held. What then, if the law and the public cannot awe or control this will give the individual such power? Education. Man has conquered the sea. How? By solving the mysteries of the waves and wind.

In the railroad, the automobile, and the airship, the advances were made by first reducing what seemed to be a mysterious superhuman thing to cold fact and figures. And so it is with sex, as long as sexology is hidden behind a cloak of mystery, it will remain uncontrollable. Perhaps a hundred years ago, there would have been some excuse for this attitude of mysteriousness, because at that time the production of life was unknown. But that excuse is gone and it is time for sex education. Grant you, you say this is true. How are you going to do it? This is a big question, but the most important factor in its solution is the removal of mysteriousness that has been thrown around it. We are told that in doing this we will simply stimulate licentiousness. If you do it with that end in view, I agree it will. But if sexuality is taught as it should be, sensuality will lessen rather than increase. Sensuality is an attribute given to sex by prostitution only. There are a few instances in the life of the individual at which time the institutions of church and society have emphasized the sacredness of things sexual. Two of these are birth and marriage. Now if these public demonstrations of the beginning of sexual life and the results of such life do not stimulate sensuality and licentiousness, why should a full enlightenment of sexuality do so, if it too is taught in a sacred way, and at the proper time of life? It is time the world at large was discarding the attitude of the prostitute and the rakes and adopt the natural and proper because sexuality is naturally sacred. Teach the child the anatomy and physiology of the generative organs, not late, but early in life as other things are taught. Every child is born a savage. He drags a kitten or puppy around by the tail until it is dead and still in his manhood he lives and protects animals. It is just as easy to teach him that sex stands for the best as it has been to infer that it stands for evil.

I have not made much mention of the percentage of gonorrhoea and syphilis. We all know how prevalent and rapidly increasing they are, and we realize about how futile the regulation and the segregation of prostitution is, as a means to lessening these.

The successful control of a venereal men-

ace lies in the education of the individual. The subject is a delicate one, I know, especially from the female side, and sometimes I feel that we could ignore the female side just now. Teach the fathers and the sons they are the genetic centers. Explain to a boy at the stage of puberty, when the sexual instinct, due to his manner of education, is stronger than his will power, the dangers of gonorrhoea and syphilis. Teach him by clear distinctive argument that the controlling of his sexual desire trains and develops his mind and will power more than anything else could. Have him obtain his knowledge of sexuality from the proper sources, his father or the physician, and you will cut the percentage of venereal diseases in half in the first generation.

So what are the things that make a venereal menace possible? First, and by far the greatest, if not the only cause is ignorance. This ignorance is the result of years of prudery, and this prudery is due to the misconception that sex is evil. This conception is not a natural one, for the inherent natural feeling is that sex is sacred.

HEREDITY AND ITS SOCIAL BEARINGS.

By JOHN D. TRAWICK, Louisville.

Child culture within the last few years has come to be so vital a topic for serious discussion, that we are finding ourselves actually a generation ahead of the results sought.

There can be no doubt entertained, that from the standpoint of race improvement, the most compelling subject before the medical profession to-day is the conservation of the child life of the nation.

Specialists in every phase of child welfare are giving most serious thought to the keeping of the child already born, to the preparation of the environment in which the new life is to be moulded, and pre-eminently to the problem of securing a generation of well born children.

It is recognized that parenthood and race culture are inevitably related. But the problems involved in the study of parenthood in relation to the social body have been for so long confused in the minds of students that, little progress was made until the discovery of enlightening laws of heredity whereby a biologic basis has been established for the claim that fit parents are necessary to the production of fit progeny. As applied to the human individual, some enthusiasts who have given superficial thought to the problems involved have been bold enough to make claims which serious students of the science are not yet ready to substantiate in particular. A few of

the fundamental facts of heredity must be remembered.

The gametes or producing cells carry within their nucleus the unit characters for traits which are destined ultimately to appear in the new individual.

The unit characters are fixed by determiners within the chromosomes.

Whatever trait appears in the matured individual has been potential in the inheritance and is present in the individual by virtue of the determiner for that trait.

The absence of the determiner in the gamete (producing cells) means that the trait for which that determiner stood will be lacking in the new being produced. The persistence of the germ protoplasm must be borne in mind. The carriers of inheritance continue through the generations, determining the same trait with unflinching persistency, and are apparently unchangeable.

The child of two deaf-mute parents, each of whom have sprung from a line of deaf-mutism is reasonably sure to be afflicted as were its parents, because the conditions which determine deaf-mutism have undoubtedly been present in the producing cells from which that child sprang.

One parent of neurotic, neurasthenic type mated to another possessing tendencies to alcoholism will almost certainly produce children who are neurotic, or possibly epileptic or criminally tended.

Such studies by careful students as "The Hill Folk" "The Kallikak Family," "The Pineys," "The Nam Family," are but convincing documents in the overwhelming mass of evidence that the feeble-minded, the pauper, the criminal, the prostitute, the chronic alcoholic, the sex pervert, all tend to produce like traits in their ever increasing offspring. And furthermore, the progeny of such individuals not only possess potentialities for little culture, but actually perpetuate the strain by intermarriage and illicit reproduction until the economic burden becomes frightful to contemplate.

The chiefest advances in the study of heredity in relation to the social order have been made along the line of the anti-social or anti-eugenic traits of human beings. With fixed certainty it can be shown that the higher attainments of genius, poetical ability, scholarship, inventiveness, etc., are heritable, and in given cases practically Mendelian proportions can be deduced in the study of long strains of families of worth. But it is too soon to claim to be able to predict what will be the characteristics of progeny of a given union, from the standpoint of the reproduction of children of higher attainment. The reverse of this proposition however, is more clearly understood, because the unfor-

tunate victims of heritable defects have been clearly defined in their relationship to the community, even kept apart in institutions long enough to give sometime for definite research. This research is at best only in its very beginning, and as stated only untaught enthusiasts are making insupportable claims.

The manner in which study of disease has been taken up during the last decade and particularly within the last few years, points to a definite awakening of the medical eugenic conscience, to the importance of studying disease not merely as a condition to be immediately cured, but to consider its deeper influence upon the race. Consequently disease expressions are being more clearly classified, and preventive medicine is bringing to bear its strongest resistance against those diseases which threaten the integrity of the race.

It will be necessary to determine what diseases definitely affect the germ plasm, before we are able to pronounce upon the hereditary quality of a disease, for only those influences which touch the germ plasm, find their expression through heredity upon the matured product.

At the present moment the diseases arising from the violations of well defined laws of society are being named as most deadly agents working to the detriment of the race. It is a startling fact that society is being menaced by a misuse of the function, which society has safeguarded for its own perpetuation. The community is finding that the function of procreation is the very means whereby the stronghold of the community is being attacked, and there are being introduced into the purity of the home, all the defilements of illicit commerce in that which was created to keep the home pure. The anti-social qualities of the disease resulting from this violation of society's laws must be shown to exist before they can be classified as deadly to race integrity.

If children are born healthy and without taint into the community it is at least reasonable to presume (things being equal in their environment) that they will in due time be able to produce healthy beings, and the nation will then be that much the gainer by every healthy strain perpetuated. But if children are born with constitutions already crippled, already injured in the very process of their origin, how can there be a healthy perpetuation of the race? Gonorrhoea becomes then more than a disease or a local manifestation to be treated more or less lightly or even to be considered alone in the light of its passing manifestations. If this disease acts at all as an agent to prevent the bringing into the world, of healthy, whole children, it must be classified as a racial menace, and be dealt with in the light of this larger relation-

ship to society. The carriers of the disease then become not merely "immoral men," but more, and if possible of more deadly significance they become directly responsible for the lives menace. Whether or not, syphilitic disease can be classed as a distinctly heritable disease, in the light of the newer laws of inheritance, it can be clearly shown that the vitiation of constitution which marks the offspring of the syphilitic is as clearly a racial menace as though the spirocheta had definitely injured the germ plasm.

It matters not whether directly or indirectly these disease expressions are hurting the children or society. They must be dealt with as any other menace, whether of the epileptic, feeble-minded, or criminal type. The springs of the nation must run pure and free from taint that a goodly heritage may be the nation's portion.

MEDICAL ETHICS AND SOCIAL HYGIENE

(AN ADDRESS.)

By J. M. MATHEWS, Louisville.

It has been a long time since I have seen you, but it has not been altogether my fault. Most of the time I have been so far away that I could not get here, but I want to assure you that, wherever I have been, I have thought of you. The reason I am back here now is because of the love I have for my friends, especially among the medical profession.

I have not written an essay for to-night; I wanted to hear the other gentlemen read theirs and get my points from them.

The phase of the subject that has been allotted to me is a very practical one and concerns every individual member of the medical profession. What are the ethics, if any, by which the doctor shall be guided in dealing with patients afflicted with venereal diseases? That is the question we want to decide. From time immemorial the medical profession has prided itself—and honestly so—upon the secrecy it has maintained with respect to the relationship between the doctor and his patient. That is, as a rule a very honorable position to assume, but there are conditions and circumstances under which we labor at the present time which justify a different attitude to that which we maintained even so recently as twenty years ago. We did not then know, as a profession, the alarming truths that have been told us here to-night. It has never been impressed upon our minds that so many cases of gonorrhoea and syphilis existed in this country, nor were we ever impressed with the magnitude of the effect which these two

diseases have upon the human race. It has only been within the past twenty years that this subject has been taken up and discussed, and practically forced upon the attention of the medical profession. Assuming the accuracy of Dr. Davidson's statement that there are, in the United States, millions of cases of syphilis, and more cases of gonorrhoea, and also assuming the accuracy of the statements of the other gentlemen as to the effect of these two diseases when transmitted to the wives of those afflicted with them, it is manifest that we are not justified in screening with the veil of professional secrecy those who come to us to be treated for these terrible diseases, even though they may be numbered among our dearest friends. Suppose that a friend of yours were to come to you and say, "Doctor, I know I can trust you as a friend; I intend to kill a man to-night at twelve o'clock. If you are my friend you will say nothing about it." Do you believe there is a man in this room who, under such circumstances, would permit his love for his friend to prevent him from immediately notifying the proper authorities that this man intended to commit a murder? Therefore, we will suppose that a man who is your friend (and I presume we can take it for granted that any man who puts himself under our guidance and direction may be considered a friend) comes to you and says: "Doctor, I have gonorrhoea (or syphilis); I know I can trust you to treat me and say nothing about it to any one." Of course, under such circumstances we can keep his secret with propriety. The law at the present time does not require us to report cases of gonorrhoea or syphilis that come under our observation, although in the near future it may do so. Therefore, we are not called upon to tell any one that this man has gonorrhoea or syphilis. But, suppose, after a while, this man tells you that he intends to marry. You say, "Not now," and he replies, "Yes, the date has been announced—but remember, doctor, I am your friend and your patient, and you must not tell anybody that you have been treating me for this disease." Now what are you to do, bearing in mind what these gentlemen have told us to-night; that if he marries the probability is that he will infect his wife, possibly giving rise to a condition that may necessitate an abdominal section, and ultimately lead to her death; or, if the disease is syphilis, not only will the wife be infected, but the disease will probably be transmitted to the children. Can you conscientiously maintain an attitude of secrecy for the sake of friendship? Not at all. Then what are you going to do? You are up against it. Of course, you want to act fairly and squarely with your friend and patient, but staring you in the face is a thing almost as horrible as if

the man had said that he intended to commit murder. What are you going to do? Permit me to cite just three instances of this nature.

A number of years ago a physician of this city said to me: "I had a peculiar experience this morning. A carriage drove up in front of my office, and there emerged a lady, apparently a person of wealth. She came in and, after inquiring my name, she said: 'Doctor, I want to ask you a question and I want you to give me an honest answer. Do you know of any reason why I should not marry Mr. _____, whom I understand you are treating?'" He said that at first he did not know what to reply, but his manhood came to the rescue and he said: "Yes, I do know of a reason why you should not marry him." She said, "Doctor, I thank you." The marriage did not take place.

Several years ago a young gentleman came to me suffering from some irritation of the prostate and, believing that he had rectal trouble, I examined him. During the course of the examination, he said, "Doctor, I am going to marry. I am being treated for gonorrhoea, and while I am not quite well I will be in a few days." I asked him if he had told his doctor that he was going to marry, and he said he had not. I told him to go back and tell the doctor; that by all means he should not marry at that time. He said: "Doctor, it has been announced; I simply have to marry." I tried to persuade him not to and gave him my reasons, but soon after that I read an announcement of the marriage in the paper. Less than a year after that, in the halls of one of our infirmaries, I met this young gentleman and he was seemingly in great distress. I asked him what was wrong, and he replied that his wife was on the operating table undergoing an abdominal section. It was unnecessary for me to inquire any further particulars.

Another young man consulted me, and during the course of my examination I discovered that he had gonorrhoea. He remarked that he intended to marry, and I told him he could not think of it for some time to come. He insisted that he had to, as it had already been announced. I went to his family physician and asked him if he would help me prevent the marriage. He said he would, and suggested that he would tell the facts to the young lady's sister-in-law, which he did, but, nevertheless, the marriage took place.

A member of this society told me, a short time ago, that he was treating for gonorrhoea a young man who was engaged to be married to a certain young lady of this city. After unsuccessfully endeavoring to persuade the young man not to marry, he went directly to a sister of the young lady, and told her the

state of affairs, but still the marriage took place.

It is very often a vexing problem to know just what to do under such circumstances. You owe a duty to the patient and a duty to the public. However, I believe that, with the knowledge that a man is not fit to marry, if you do not take steps to prevent the marriage, you make yourself a party to the crime if it may be so termed. I do not believe any doctor is bound to secrecy in a case of this kind simply because the patient happens to be his friend.

The relationship between the doctor and his patient has been compared with that of the confessional, but they are not the same thing. In the confessional the individual is required to make restitution for his sins, but when a patient with gonorrhoea or syphilis comes to the doctor, all that he can require is that he will not communicate the disease to others. Dr. Joseph Price, who has been quoted here to-night, once said in a public address, that, in his opinion, every man who has gonorrhoea should be confined in prison until he recovers, because he is a menace to the public. Assuming that this is true, are you called upon to acquaint the public with every case of gonorrhoea you treat? Not all all. There may come a time when you will be required by law to report every case of gonorrhoea to the proper authorities, but until then you cannot violate the confidence of your patient. It would do no good.

There is another question of ethics that confronts practically every general practitioner. It is this: If a married woman contracts gonorrhoea or syphilis from her husband, should she be informed on the nature of the disease? So distinguished an authority as Dr. Cabot says positively, that we should so inform the wife, but I differ with him in this respect. What good could possibly be accomplished by telling her that her husband had given her gonorrhoea or syphilis? On the other hand you may disrupt a comparatively happy family and bring about a separation.

Now, what is the remedy for the conditions we have been discussing to-night? In my opinion there is but one. Dr. Cabot says he has come to the conclusion that a certificate of health from a physician is worthless, because the majority of doctors are not experts along this line and their opinions are worth very little. A far better plan is to enact a law requiring every man who desires to get married to be examined by a commission of experts. For instance, we could easily select from among the members of this society three men who would be competent to say whether any individual was in a marriageable condition. My idea would be to have a commission appointed by the Governor, consisting of three

reputable *experts* in these diseases, and to require every man (I will not say every woman, though some go that far) to secure from them a certificate of health before permitting him to marry.

In conclusion, I believe the only way to secure a remedy for the conditions spoken of here to-night is to educate the public. Just a few months ago I lectured to more than a thousand women on the subject of gonorrhoea and syphilis, and without mincing words I told them straightforward facts. A few years ago the newspapers would not publish anything that contained the words "gonorrhoea" or "syphilis"; now they publish such articles every day. Therefore, by means of public lectures, symposiums like this, and by demonstrations in museums and other places, illustrating the effects of these diseases, we may hope to eventually educate the public along this line. An old gentleman, 70 years of age, told me the other day that, when a young man, he had visited a museum in Chicago where the effects of syphilis were illustrated, and from that day to this he said he had never *experimented*. Therefore, I believe the thing to do is to educate the public with respect to gonorrhoea and syphilis just as we do about tuberculosis and other infectious diseases.

DISCUSSION.

J. A. Stucky, Lexington: Any scheme which ignores the sexual instinct as the basic cause of the social evil is bound to fail. Education, segregation, suppression, regulation, and medical inspection have all been tried, and all have failed. They have failed because you can not eliminate a primal instinct by education. Segregation failed because only a small proportion of prostitutes declared themselves, and segregation—no difference how perfect it may be—does not eliminate the social evil, but simply concentrates it within certain boundaries.

Suppression failed because it does not suppress, but scatters and multiplies the centers of infection.

Regulation failed because it was a compromise, and because it placed an instrument in the hands of officials that was used for purposes of extortion and blackmail, and that led to the debauching of public officials.

Medical inspection, the only method which gives any reason to hope that the evils resulting may be mitigated, has failed or succeeded according to the individual point of view. As carried on in this city by some private physicians, it not only contributes to moral delinquency but actually increases the number of cases of venereal diseases. A sanitary inspection was recently made in this city of about one-third of the inmates of known houses of prostitution. Twenty per cent. of the inmates were found diseased and

were working under certificates of health dated within a week of the inspection and, in most instances, within from twenty-four to forty-eight hours of the inspection. In a number of cases the diseased prostitute was under treatment for venereal disease by the man signing the certificate of health in which he stated over his signature that she was free from venereal disease. This is not medical inspection, but one way of securing money by false pretenses, and leaves no one in doubt as to which is the worse prostitute the woman or the physician signing the certificate.

Some people see a solution in a minimum wage law. Granting the constitutionality of such a law, how are employers of labor to be forced to employ people whose services are worth less than the minimum wage? On the present standard of wages a great army of women are living respectably and comfortably, although not luxuriously. What is to become of these if a minimum wage law makes it impossible for them to work? They must eat, have clothing, and places of shelter! Isn't there a very grave probability that the method employed, instead of protecting them from lives of prostitution, will throw them into it as the only source of livelihood? Dr. Watson has said that in investigation of the reasons for leading lives of prostitution disclosed the fact that only ten per cent. of these women are in houses of prostitution because of failure to make a living in other walks of life. Would a minimum wage law, even if possible of universal enforcement, remove the basic cause of the social evil? The numerous scandals in families rich in this world's goods have no possible connection with low wages, and give the lie to those who would lay the whole blame on the poor.

Others find a solution in a single standard of purity. Back of everything that exists lie definite causes, and the double standard of purity exists because of a variety of reasons. Society condones man's moral lapse. If a woman falls, she is eternally damned. Society merely elevates its eyebrows when a man goes wrong. He is the victim of a designing woman. When the woman comes up for judgment, it is a case of thumbs down. The father of the race may be a past master in debauchery, but society demands that the mother be without taint or blemish of immorality. These are some of the reasons why the double standard of purity exists.

CONCLUSIONS.

First. Segregation fails to segregate.

Second. Segregation means graft in any administration.

The principal argument of the proponents of segregation is that by such means it is possible to enforce proper health regulations. From many years' observation in the former "crib" district, however, I maintain that under the old system here, there was practically as much evil scattered throughout the city as at the present time.

Quack doctors thrived then as now, and I can not see that the youth can be "saved" by putting the civic stamp of approval and protection upon prostitution.

Before venturing to prescribe a method of dealing with this problem, I desire to make my position absolutely clear on several points without retracting in any way what has already been said.

1. I believe in a single standard of purity based on continence, not on incontinence.

2. I believe in working for a system of education on sex relations which will acquaint developing youths and maidens with a knowledge of the pathological results due to immoral practices.

3. I believe in working for the complete eradication of the social evil whether it be conducted openly in known houses of prostitution or secretly in assignation houses and private flats or in places disguised as tobacco or soft drink shops.

4. I believe in working for the correction of social and economic conditions which are partially responsible for conditions as they exist to-day.

5. Realizing, as we all must, that the ideal conditions outlined are difficult to bring about and that years must pass before they are obtained, I believe that the health problem created by the social evil should receive the same careful attention from the medical profession that is accorded other health problems.

Prophylaxis is not only the watchword in modern medicine, but its pride and glory. The debt owed our profession is not because of those we have cured, but because of those we have kept well; not because of emergencies met, but because of emergencies avoided.

Up to the present time, the deadly effects of gonorrhoea and syphilis have been overshadowed by the moral side of the question. Illegitimate sexual congress with its deadly train of complications had not been considered a subject fit for discussion or one upon which the general public should be enlightened. Would it not be better to bring it forth from the shadows, and place it naked before the world where the spotlight of publicity can beat upon it? While it is not to be expected that any plan will entirely remove the social evil, there is strong reason for believing that many of its evil consequences can be avoided by education and prophylactic methods.

The fact that all of its evil results can not be eliminated is no reason why an attempt should not be made to minimize them. The fact that venereal disease is contracted through an act of immorality is no reason why the innocent victim of that immoral act should not be protected from the consequences of it. The cause and method of transmission of venereal diseases is known. Norfolk, Va., the army and navy have demonstrated the method of prevention to those exposed. Shall we sit quietly and dream of the millenium, or shall we accept man as he is and protect him

and his future wife and children from the evil consequences of his immorality?

Medical inspection of prostitutes and the use of prophylactic means to avoid infection after contact will not prove to be a popular subject for discussion. It will not eliminate prostitution, but it does offer a partial remedy against its evil results. It is in harmony with what is being done to solve other infectious disease problems. Until the time arrives when man shall be the master of his sexual instinct instead of its slave, our duty as sanitarians is as binding to protect him from the evil consequences of this slavery as it is to safeguard his food and water supplies; our moral responsibility to protect his wife and children, as great as if he exposed them to the plague.

While divers opinions paralyze efforts directed to a sane solution of this problem, degeneracy is gaining a firmer hold on future generations. While we question one another's honesty of purpose, when our opinions differ as to what shall be done, the pit for our descendents is being made deeper and wider. What shall be do, act or theorize? Do the best we can with man as he is, or dream of ideal conditions impossible of attainment on this side of the grave?

Shall we build more hospitals, more insane asylums, more blind asylums and more penal institutions in which to house the victims of this problem, while the seeds of moral suasion are being sown, cultivated and brought to full fruition in the dim future, or shall we apply the same sanitary principles which have stayed the plague, eliminated yellow fever, stopped the spread of cholera, and rendered smallpox less deadly than measles?

Shall we handle a sanitary problem by established sanitary methods or by a series of wheries and a ringing resolution?

Shall science be given a free hand, or shall the future be sacrificed to well-intentioned emotionism and hysteria?

Which shall it be?

Leon L. Solomon: The papers which have been read to-night are surely deserving of commendation. As was aptly stated in a recent magazine article, the world is considering, not the time of day, but, as the writer puts it, "sex o'clock."

I cannot agree with much that has been said to-night with respect to the education of the young, along lines sexological. I wondered at the attitude of one of the speakers, who is inclined to look askance at museums, but at the same time heralds as educational a play called "Damaged Goods." If the presentation of such a word picture as this play to the young is accomplishing so much good, then I confess I am at a loss to understand why a study of the actual life picture by medical men and students has been productive of so little good. When, thousands of years ago, the great Jehovah handed down from Mt. Sinai his inspired message, the Ten Com-

mandments, among them, "Thou shalt not commit adultery," it must have been foremost in the Great Maker's mind that man would often be guilty of this great sin. I have a most vivid recollection of the presentation to medical students of case after case, showing the horrible effects of syphilis. These young men say, not a word picture but actual life picture—the man with his penis destroyed; the woman upon whom a laparotomy was done in the class-room for gonorrhoeal salpingitis, the child with hereditary syphilis; and I must confess that, so far as I am aware, it did not deter a single one of these men from practicing illicit sexual intercourse. I have known medical students to make engagements with prostitutes who came to the gynecological ward for treatment.

I went to see "Damaged Goods" because I was invited to do so by ladies and gentlemen representing the Purity League, and what I have to say must not be construed as in any wise derogatory to them.

The plot of the play deals with a young man who is fearful of acquiring syphilis, and in order to avoid it he chooses as his companion the wife of his best friend, knowing that this friend also had a horror of the disease and feeling that he was not likely to contract it through intercourse with the wife of such a man. If word pictures of this sort are the means of any good end, I must confess my inability to understand it. No man of to-day would contend that such a play as this would be proper to bring before a medical student who proposed to seriously study medicine, and if it is not fit for a medical student, it is surely not fit to bring before the average young man and woman. In my humble judgment, gentlemen, we are not ready for this sort of instruction.

I wonder how many single men among us to-night, who have reached the age of 28 or 30, can say that they have kept themselves pure? I venture the assertion that there are not many. Again, how many married men can say that since their marriage they have kept themselves pure?

The question is wholly a moral one and we cannot get away from it. I agree with you that we must educate the public, and let the education be as broad as we can properly make it, but let us not forget that man was commanded to increase and multiply, and sometimes the sexual part of man overwhelms him.

Only a few days ago a kindergarten teacher told me of an incident which had come under her observation. She had a class composed of boys and girls four and five years of age, among whom is a little boy of five, who is exceedingly bad, and two very beautiful little girls, and she has found it necessary to keep this boy away from the girls because one of the little girls told her that he had attempted to take liberties with her person.

I have always maintained that a man, when he faces the bridal altar, should be just as pure as

he expects the woman to be; that no man has a right to expect more of his wife, mother, or sister than they have a right to expect of him.

As Dr. Mathews has said, the question is one of moral education, and the medical profession must do it, but it is a mistake to believe that it can be accomplished by the exhibition of such vile, abominable plays as "Damaged Goods."

J. T. Windell: One of the speakers has estimated there are about three hundred thousand prostitutes in this country, and his figures are probably about correct, but I will venture the assertion that, if all of these women were to die to-night, within thirty days there would be three hundred thousand more to take their places. That prostitution cannot be eliminated has been demonstrated in practically every country in the world.

In regard to the relationship between the doctor and his patient, not only with respect to venereal disease, but any other disease, the moment a man becomes your patient you form a partnership with him, as it were, and anything connected with that partnership is sacred. I do not believe we have the right to violate that partnership if it will in any way interfere with the treatment and cure of the patient. I have had several cases in which I was tempted to inform women who were about to enter matrimony with patients under my care, of the condition of the prospective husband, but I have refrained from doing so.

There are two sides to every question. I know of one case in particular where a doctor went to the family of the bride-to-be, and told her that the young man she was about to marry had venereal disease. It happened that, at the time, the young man had no evidence of the disease that was manifest to a layman. He immediately consulted an attorney who instituted suit against the doctor and was able to secure two physicians to testify that there was nothing wrong with the young man. Such a thing is liable to happen to any of us.

Irvin Lindenberger: I would like to mention a case that came under my observation recently, illustrating another phase of this subject. This patient, a girl 17 years of age, was referred to me about two weeks ago with a suspicious looking sore on the vulva, which she said had been there for three or four weeks. From the history of the case I believed it to be syphilitic. She came to me again yesterday, and upon examination I found a marked efflorescence all over the body. I referred her to the City Hospital and told her I would see her there this morning. When I went to the hospital this morning I found that she had not been admitted for the reason that she had been in Louisville only a month.

Those of you who have read the report of the Chicago Vice Commission will recall that it contained a memorandum of the houses of prostitution in Chicago, the names of the girls and the number of times they had intercourse with men

in one night. I recall that in one case it was stated that one girl had intercourse forty-five times in one night. In the case I mentioned, this girl may infect anywhere from one to one hundred men, and yet there is no place where she can be taken care of and prevented from disseminating the infection.

In this connection, I cannot help but recall an incident that occurred in the administration of Mayor McClelland of Cincinnati, who was elected on a reform ticket many years ago. A mother brought to him her boy, 17 years old, who had lost the sight of one eye from gonorrhoeal ophthalmia, and asked him what he was going to do about it. He said he would try to do something, and started a system of examinations of inmates of houses of prostitution. If a girl was found to be new at the business, an attempt was made to persuade her to return home, and transportation was secured for her. Those cases of gonorrhoea and syphilis found were quarantined in the City Hospital in a special ward. That this does a great deal of good cannot be denied. If this girl I spoke of had been taken into the City Hospital yesterday, it would undoubtedly have been the means of preventing her from spreading the infection. While this plan is said to have been a failure by some in Hamburg, Berlin, and Vienna, those of you who have lived abroad know that it is considered safer to have intercourse with a girl who has been examined than one who has not. It is but logical to assume that if these cases are kept in quarantine, it will decrease the percentage of cases of venereal disease, and I believe the statistics in Cincinnati while the above plan was in operation will prove the truth of this statement.

Carl Weidner, Sr.: The subject has been so thoroughly discussed that there is very little left to be said.

I shall speak to only one phase of the subject; namely the ethics that should govern the doctor in his relationship with his patients. It will be a long time before that question is settled in a satisfactory manner. The medical profession must uphold, to some extent, the sacredness of the relationship between doctor and patient; but, as Dr. Mathews has said, conditions have changed somewhat. There was a time when we observed secrecy with respect to tuberculosis, typhoid fever and other infectious diseases. We are now compelled by law to report these diseases to the health authorities. However, I believe it will be a long time before we are required to report venereal diseases.

Dr. Mathews' remarks reminded me of the story written about a Paris physician, who had a patient whom he was treating for syphilis or gonorrhoea, and who intended to marry the daughter of one of the physician's most intimate friends. He told the young man he could not marry, to which he replied that he would marry, and defied the physician to prevent it. The doc-

tor could think of no other means except to knock the man down on his way to church, which he did, thereby creating a scandal and preventing the marriage.

During the past year I treated a young girl during the active stage of syphilis, and a short time later I discovered her in one of our hospitals as a nurse. I consulted with my friends. What should I do? I did not like to expose this girl publicly. Finally one of my friends suggested that he would take care of the matter, and I presume the girl was discharged shortly after that because I did not see her at the hospital any more. I hope I did right. I would not like for any of my patients, medical or surgical, to be exposed to contamination by such a nurse.

I agree with Dr. Windell that prostitution cannot be prevented, but I do believe that we can do a great deal of good by educating the young. When is this education to begin? In some children it should begin earlier than in others, in proportion to their ability to understand.

The medical profession has a very important duty to perform. Let the preachers and school teachers do their part, but the most practical part of the work is bound to fall upon the medical profession. In the past three years I have had under my care six children, under six years of age, with gonorrhoea. In our practice in the homes we should endeavor to teach the fathers and mothers the danger of the transmission of these diseases by means of dirty towels and napkins, common wash-bowls, etc. Twenty-five per cent. of blindness is due to gonorrhoea. By teaching our patients the necessity of proper sanitary precautions, we can do a great deal to prevent the transmission of these diseases.

In regard to Dr. Lindenberger's case, I must say there is "something rotten in Denmark" when such cases as this cannot be taken care of somewhere as a measure of protection to the public.

Louis Frank: I have listened with much pleasure to this symposium and also to the discussion. It seems, however, that my own opinions in connection with certain phases of this subject are greatly at variance with those of the other speakers. There are two questions to be considered. One is the question of sex, which is inherent in the human being, is impossible of eradication, but may be repressed within limits, just as the appetite for food and drink may be repressed. The other is a medical question, pure and simple. That the two are so closely correlated that they cannot be separated, I do not believe. It has been shown that syphilis may be contracted in many ways other than by sexual intercourse. Possibly our attention had best be directed to a study of the medical side of the question. As to the education of the young, Dr. Solomon has expressed pretty nearly my own views. The sexual instinct is the strongest of any in the human being; perhaps even stronger than the instinct of

self-preservation. The strongest emotion of the human mind is probably that of fear. Every unlawful desire of the human race is controlled by the fear we have of the penalty for gratification of that desire. For instance, many men are deterred from killing another man solely because of the law on our statute books which fixes a heavy penalty for murder. In the same way, it appears to me that fear of the law might induce repression of the sexual instinct to a certain extent. But, will repression of the sexual instinct tend to eradicate syphilis and gonorrhoea? I must confess that I have been somewhat astounded by the statements of the dire results produced by gonorrhoea that have been made here tonight, insofar as the life and future usefulness of the individual are concerned. Personally, I am convinced that in gonorrhoea in the male, just as in the female, a stage is reached when the germs are no longer transmissible. Furthermore, we know that after a certain period of time, syphilis is not communicable. Let us be honest with ourselves. Recently a great furor has been raised, and the whole country is engaged in the discussion of eugenic and sociologic questions, I think it has gone a step too far and that it is time to put an end to it.

Jno. W. Price, Jr.: This subject appeals to me very strongly. One point which it appears to me should be emphasized more than any other, is prophylaxis. One way of teaching prophylaxis would be for the State to pass a law requiring every man contemplating marriage to secure a certificate of health from a physician. Of course this in itself would not prevent disease. It simply teaches the public to guard against it; it makes the prospective husband who has been so fortunate as to escape venereal disease up to the time he contemplates marriage, very careful to avoid contamination during the few months immediately preceding his marriage, because he knows he will have to pass an examination.

As to prostitution, it is an established thing and we must accept it. One means of avoiding the spread of syphilis and gonorrhoea through this source would be for the City to furnish each house of prostitution with an outfit similar to those used in the United States Army and Navy, containing argyrol, mercury, etc., with printed instructions as to their use, and require the girls to supply this to the men who visit the house. A great many men will neglect such precautions unless it is made easy for them. The records of the Army and Navy show that the percentage of cases of venereal disease has been greatly reduced under this method. Men visiting houses of prostitution would soon become acquainted with the contents of these packages, and would probably supply themselves with a similar package when contemplating clandestine intercourse.

CERVICAL LACERATIONS AND THEIR RELATIONS TO NERVOUS MANIFESTATIONS.

By C. C. ENGLISH, Louisville.

There was a time until comparatively recent that when the average physician or surgeon was consulted by a woman suffering with what was apparently a nervous exhaustion, that, if the woman had borne children, the first and almost only thought was, "Here is a case of neurasthenia from cervical laceration." A vaginal examination would reveal the fact that there did exist a cervical tear. Here the examination of the patient, and study of the case oftentimes would end. It was a case for surgical treatment, and the patient would be told that she must undergo an operation, otherwise she could have no hope for a recovery; that the operation was all that was necessary, and that it would give her complete relief. This was found not to be true in many cases; quite a few submitting to an operation were not benefited. They were not benefited because other important factors had not been sought and considered, and proper medicinal treatment instituted in conjunction with the operation.

To-day these cases are studied more carefully and handled more conservatively. But even now the profession is too prone to assume that when a woman has attacks of headache, backache, etc., that she must have some diseased condition of her pelvic organs as an underlying cause.

The presence of a cervical tear, of even a major degree, does not cause nervous manifestations in every instance; and there are so many conditions that produce symptoms that so closely assimilate the symptoms of neuroses from cervical laceration, such as astigmatism, obscure syphilis, beginning goitre, faulty elimination, autointoxication, etc.; that one has to be constantly on his guard. We should not too frequently arrive at conclusions—just because a woman has a cervical tear. We should be certain of our diagnosis; and even then slow to promise a cure by surgical measures alone. To illustrate this point let me cite two cases in my own experience, both of which had been promised recovery by operative interference.

Case I.—Mrs. M., age 34; married eight years; had had two children; first delivery by forceps; youngest child four years old. Complained of extreme nervousness, irritability, severe headache and backache, and unable to sleep until early morning. Vaginal examination revealed the existence of bilateral cervical laceration of moderate degree; uterus slightly sub-involuted, tubes and ovaries

slightly tender and a moderate degree of pelvic discomfort.

This seemed to me a case of neurasthenia induced by a cervical tear. Operation advised and cervical laceration repaired with perfect union; but patient was not relieved. Finally, growing suspicious of the sleeplessness in the early part of the night, I questioned her closely and found that her headache, backache, in fact all her symptoms exaggerated at night. I then made diagnosis of obscure syphilis, put her on mercury and iodode of potash. Her symptoms immediately subsided, she was completely relieved, and made a decided gain in weight. Operation probably not necessary.

Case II.—Mrs. R., widow, age 40. Had had three children, youngest child ten years old. Had had cervical laceration repaired with good union as a result, but without relief, four months previous to consulting me. Complained of insomnia, nervousness, headache, backache, bloating, numbness of limbs, palpation of heart or, as she put it, "sinking spells" in which she thought that she was going to die," frequently remained in bed most of the day. After careful and persistent questioning it was found that she was constipated; she ate too much nitrogenous food; the whole fluid intake in twenty-four hours was practically nil; her liver and kidneys were inactive; she was suffering from reabsorption of effete material. It was a case of autointoxication. Her mode of living was regulated; she was taught the necessity of keeping her liver and kidneys active, and given a good tonic. She made a complete recovery.

Others of you, I dare say, have had the same experience; and in the light of these experiences is it any wonder that so many refuse operation; wander into the realms of patent medicine and are benefited, or finally fall into the hands of some careful diagnosis and are promptly relieved.

There are a class of cases in which nervous disturbances will not be pronounced until after some acute sickness, then symptoms will appear and remain until relieved by trachelorrhaphy followed by constitutional treatment. We will often encounter a case with a rather severe cervical laceration of eight or ten years standing, who has had no nervous symptoms until very recently. This is very puzzling, but the torn cervix is often the prime cause of the nervous condition, and is explained by the fact that so long as a woman has prime health the cervical tear will cause nervous manifestations; but let her have an attack of typhoid fever, lagrippe, or have some worry or anxiety over family or financial affairs, or in fact anything that lowers her state of health, then the tear plays

a very important role in the production of symptoms. This should be explained to the patient for they often ask the question, "Why has the 'torn womb' caused me no trouble before?" In some cases, too, it is probable that the contraction of the cicatrix may become so great as to compress the nerve filaments and produce symptoms which in the earlier stage of the scar were not present. In these cases dense cicatricial tissue will be found filling up the angles of the tear.

In the more severe grades the diagnosis is comparatively easy. In these cases there exists a dull, heavy weight and dragging in the pelvis, oftentimes associated with a burning sensation in the vagina. Without any acute sickness as an assignable cause the general health is usually more or less bad. If the tear has set up an interstitial inflammation, accompanied by cystic degeneration in the cervix, then the reflex nervous phenomena are especially marked. Here the headache is almost constant, the patient is very nervous, emotional, and even hysterical.

In those cases also where the laceration is extensive, extending into and almost through the vaginal attachment, the reflex nervous disturbances are very pronounced. The irregularity of menstruation or its increase in duration and amount as a result of the subinvolution of the uterus, and chronic congestion, and perhaps inflammation of the endometrium is constantly wearing and and exhausting nervous energy. Neuralgia may occur in any part of the body, however, it is usually situated in the pelvis, extending to the groin and down the thigh. There may appear reflex nausea and vomiting, cataleptic convulsions, hysteria, the constant fear of some impending danger, numbness in the limbs, insomnia, irritability, constant headache, and backache, etc., in other words the woman is a confirmed neurasthenic.

In the treatment inexhaustible patience and careful study of the individual and careful study of the individual case is necessary. They have often, in search of relief, gone from one physician or surgeon to another. Too much or too quick relief is often promised, and in expecting too much they become dissatisfied. They should be told that they can be benefited and probably relieved, but that it will take time—probably several months.

Failure to obtain relief for the patient is often encountered because—as I stated in the beginning of this paper proper medical treatment is not instituted in conjunction with the operation. Rest and tonic treatment is necessary to improve the lowered vitality. Another very frequent cause of failure to obtain a good result lies in neglecting to carry

out local treatment for a sufficient length of time. If trachelorrhaphy is performed within a few months after the reception of the laceration—before sclerotic, cystic, and erosional changes have appeared—there is usually required but little preparatory treatment. When, however, there is a marked and widespread erosion, and the cervix is hard and sclerotic from inflammatory exudate, it is necessary to devote from two to six weeks to preparation of the cervix for operation. Many failures in the operation of trachelorrhaphy are due to neglect of such preparatory treatment. The hard cystic or eroded cervix may unite but imperfectly, if at all, after operation; or if good union is obtained, the sclerotic cystic condition of the cervix, and perhaps subinvolution of the uterus, will often persist, and symptoms continue as pronounced as before the operation.

Preparatory treatment consists in the administration of vaginal douches, regulation of the bowels by saline purgatives, and such local applications to the cervix uteri as are indicated in each individual case. The local treatment should be continued until there is no longer any leucorrhoea, and the erosion and cysts have disappeared. However, if the inflammatory changes secondary to the laceration have become so deeply seated that they do not show improvement after five or six weeks careful local treatment, it is not a case for trachelorrhaphy, but amputation of the cervix is necessary.

Often after local and constitutional treatment for five or six weeks the cervix will take on a much healthier appearance, and the general symptoms will be so much improved that the patient will sometimes want to defer the operation. This should not be countenanced as the symptoms will return with cessation of treatment, and the return of the patient to her multifarious duties; besides these are just the cases in which trachelorrhaphy gives most brilliant results.

DISCUSSION.

Jno. J. Moren: This excellent paper should not be permitted to go without discussion.

Nervousness is attributed to all sorts of conditions. We oftentimes have these patients tell us that some doctor said if they would have a baby they would get well, or if they would have the uterus removed they would get well, and frequently both are failures. I was very glad indeed to hear Dr. English take the position that these patients should have proper and exhaustive medical treatment before surgery is resorted to. My observation has been that, in many instances where operation does not produce results, the surgeon is apt to ascribe it to some malnutrition or nervous exhaustion that prevents the proper recovery of the patient. The longer I handle

these cases the more I believe in iron. If we would give Blaud's mass more frequently before operations, we would get better results from surgery.

Curran Pope: This paper is a most excellent one and the subject is timely at all times. I think it teaches us a paramount lesson, which is this: An essential, fundamental necessity before attempting to do anything, is to know what we are going to do. Then the presumption is that we know how to do it. Therefore, one cannot spend too much time, too much care, or too much thought upon his diagnosis. When he has gotten all of his factors together, when he knows, as far as it is possible to know, the secretory state of his patient, the condition of the urine, the blood and the blood serum, the gastric condition and wherever these may lead him, even though it leads to a careful conscientious X-ray examination of the entire gastro-intestinal tract—then, with all these facts, and his physical diagnosis lying before him, he should be able to establish the relationship that one thing found bears to another, and when all this is done he is certainly in a better position to pass upon the condition of his patient than he would be if they had been left undone. Many of these individuals, as the essayist has pointed out, are well in spite of a cervical laceration; their nervous systems are in such poise that they are able to carry the burden without difficulty. It is only when they begin to fall below par generally that local manifestations make their appearance. I maintain that the relation of the surgeon to the neuroses and the psycho-neuroses is this: Surgery when necessary, should be done—just as it should be done as a fundamental factor in any condition where it is necessary—but it should not be looked upon as a curative measure in any sense of the words. It is only one of a number of measures to be carried out in order to place the patient in the state that we call health.

The doctor's paper finds me in the midst of the collection of data for a paper on the end results of surgery in the neuroses and psycho-neuroses; therefore, it is a subject that is of great interest to me.

I would like to take exceptions to one statement in the doctor's most excellent paper. It is this: Hysteria is a psychosis. It is a dissociation of the personality. It is a common cause of ocular, uterine and cardiac conditions. But it is a psychic condition pure and simple—a psychic dissociation, that has a different psychic cause in each case. Therefore, every case is a law unto itself and can be best reached by modern psycho-analytic methods. This is the advanced teaching and thought of the day. We can very frequently tell whether a localized condition, such as a lacerated cervix, is causing symptoms by the following measures: Put the woman to bed for a few days and get her alimentary tract thorough-

ly cleaned out. Introduce into the vagina an electrode properly prepared. Place a large pad upon the abdomen and pass the galvanic current, in large doses, through the cervix, the negative pole being in the vagina. If we have to deal with symptoms that are reflected from the uterus, we will find that they become very pronounced in from four to six hours after the application. Of course the patient must not be told what is the object of the test.

Jno. K. Freeman: Those of us who do considerable obstetrical practice know that six out of every ten women who have borne babies have laceration of the cervix to some extent, but we also know what will cause symptoms in one woman may not in another. When a surgeon gets a case of this kind that has been through the hands of a general practitioner whom he knows has carefully analyzed it, and has perhaps been under the observation of a neurologist of note who has also carefully studied the case, and if, when the patient is put upon the table, the only abnormal condition that can be found is a lacerated cervix, then it is clearly the duty of the surgeon to insist upon the patient going to the hospital and having the laceration repaired. We must trust such men as have spoken here tonight. When they have studied the case thoroughly and have exhausted every measure other than surgery without relieving the patient, then it is our duty to correct whatever surgical condition may be found to exist.

It must be confessed that, unfortunately, in some of these cases, the surgical procedure is not followed up by careful and scientific medical treatment, as has been very beautifully brought out by Dr. English. I have always said that every surgeon should be a good doctor, and I am glad that the essayist has emphasized this fact.

F. T. Fort: It is this class of patients that gives the internist and the neurologist the greatest amount of trouble, and from which the Christian Scientist and the osteopath reap their harvest. I believe the failure to cure many of these patients is due, in part, to a lack of proper appreciation by the surgeon of the medical and neurological aspects of the case, as well as to an unwillingness on the part of the internist and the neurologist to recommend surgery for fear they may lose the patient. These are the cases in which the most hearty co-operation between the internist, the neurologist and the surgeon should be the rule. As Dr. English has brought out, these conditions may be due to toxemias of intestinal origin, to cervical tears, or to kidney or bladder dyscrasias, and we should endeavor to get at the bottom of the trouble in every case, whether it requires one examination or half a dozen. If we are unable to accomplish this single-handed, we should call in the other side of the house, as it were, and when the cause has finally been determined, whether it be surgical, medical or neurological, it should be corrected. If we will

get together in these cases trace out the cause of the trouble and correct it, we will be able to prevent many of these patients from going to osteopaths and Christian Scientists, as so many of them do.

Leo Bloch: I believe that statistics show that cancer of the uterus occurs most frequently in women who have borne children. Therefore, for this reason if no other, I think any appreciable tear in the cervix should be repaired.

C. W. Hibbitt: I have always been of the opinion that nervous manifestations in the presence of cervical laceration cannot always be attributed to the laceration itself, particularly when we consider what usually follows lacerations such as subinvolution, endometritis, or endocervicitis and retrodisplacements. These conditions I believe are responsible more frequently for the nervous manifestations following extensive lacerations than the laceration itself. While it is true that scar tissue developing in the torn area or angle may probably give rise in some degree to a nervous disturbance, still I do not believe we can attribute the amount of nervous disturbance seen in many of these cases to this plug of scar tissue. Many of these cases of slight laceration will get along very well without surgical interference. In cases where surgery is necessary, where the laceration is exhaustive, and where the cervix is sclerotic, or cystic degeneration has taken place, what can we hope to accomplish by repairing the cervix? Practically nothing. In such cases we must do an amputation of the cervix and in addition care for and relieve the other conditions which usually follow extensive laceration (as I have named above) in order to afford the patient relief from the nervous symptoms and effect a cure.

Simrall Anderson: I think the most brilliant results obtained in gynecological surgery have been from trachelorrhaphy; or, in cases where it is necessary, amputation of the cervix. A great many things are accomplished in doing this operation. In the first place it is usually preceded by a curettment. Again, when we do a trachelorrhaphy or an amputation of the cervix, we invariably have a shrinkage of the uterus. If there is a chronic endometritis, that is relieved. Subinvolution will take place, the uterus will shrink up away from the pelvis and the patient will be entirely relieved. In the presence of an uterus that is enlarged, with retroflexion or retroversion, if we will do a trachelorrhaphy, or if necessary amputation of the cervix, we will entirely relieve the condition and the bladder symptoms will disappear.

I wish to go on record as making the assertion that there is no operation in gynecological surgery that promises such brilliant results as trachelorrhaphy, or, where indicated, amputation of the cervix.

Fritz C. Askenstedt: I fully agree with Dr. Hibbitt in regard to the local irritation resulting

from scar tissue itself. It appears to me, viewing it from a pathological standpoint, that this can only occur to a minimum degree. After the tear is made, there is a formation of granulation tissue, which grows upon the muscular tissue bridging the gap, and forms scar tissue, but is not supplied with any nerves whatever. As there is no nervous tissue in this scar, there are no nerves to be impinged upon. It is true that, as it contracts, it does slightly compress the muscular tissue at its margin, but we know that the nerve ending subject to constant pressure atrophy and cease to functionate. I cannot conceive of any good reason why a scar of that kind should give rise to nervous symptoms. We are not familiar with anything of that kind elsewhere in the body, and why should it be true here? I am not now considering an interstitial inflammation.

I think that a great deal of the benefit that is attributed to trachelorrhaphy is in a large measure due to the curettment which precedes the operation, to the fact that the uterus is restored to its normal position, and to other work done upon the uterus itself. As far as the operation of trachelorrhaphy itself is concerned, I think it is greatly over-estimated.

C. C. English, (Closing): Referring to Dr. Askenstedt's remarks, it is in the rarest instances where we encounter a torn cervix with any great amount of cicatricial tissues, that we do not have marked sub-involution of the uterus, with a chronic inflammation in the tubes and ovaries, and by taking out the scar tissue we reduce the size of the uterus, relieve the weight and dragging in the pelvis, and also relieve the inflammation in the tubes and ovaries. It is probably not the tear itself that gives rise to nervous manifestations, but sub-involution of the uterus, and the inflammation of the ovaries and tubes as a result of the tear, and the scar tissue must be removed and the tear repaired before the pelvic organs will return to their normal condition.

Dermoid Cyst Interfering with Delivery.—In the case described the cyst was punctured and the contents withdrawn through a wide trocar after which the child was safely delivered. Three months later the cyst was removed by the vagina; it weighed then 100 gm. Analysis of the literature on the subject shows that removal by laparotomy of a cyst interfering with delivery has frequently entailed serious complications for mother or child or both, while vaginal removal is simple and harmless if preceded by puncture and evacuation of the contents of the cyst. This permits natural delivery and normal puerperium. The cases on record are summarized to show the advantage of this technic over the abdominal technic or colpotomy.

CLINICAL CASES

TABES DORSALIS.

(REPORT OF TWO CASES.)

By HARRY C. WEBER, Louisville.

February 21st of the present year case No. 1 appeared for consultation. Male, white, age 36 years, weight 150 pounds, married, occupation auditor. Until one year ago healthy, strong and athletic, weight 180 pounds. Contracted a case of syphilis ten years previous which gave him very little trouble. Took mercury and the iodides per mouth almost constantly for six years. Thinking he was completely cured, he married and during the next four years his wife gave birth to two healthy children who have remained so to date.

One year ago began this creeping disease, Tabes dorsalis or locomotor ataxia, with the following symptoms: Loss of knee jerks, incoordination of the muscles of locomotion, producing that peculiar ataxic gait. Eye symptoms not very pronounced. Lightning pains in different parts of the body. Romberg's sign or swaying of the body with the eyes closed. Bladder irritated at times, then sluggish and would not empty. Wasserman very positive.

I told him we had a new remedy I thought would benefit him and he related to me a great many disastrous results he had heard of "606" and would not submit to any physician injecting a quart of solution in his veins. I was not very anxious to give him an intravenous injection, so I explained the intramuscular method, and as I previously had some experience with eye cases and paralytics, I did not fear this method would injure him.

February 22nd, gave nine grains of salvarsan intramuscular, saturated solution of iodide of potash up to tolerance and 21 hypodermic injections of 1-6 grain each of the oxycyanate of mercury and 1-4 grain of the protoiodide per mouth, three times a day during the next month. March 24th gave another injection of "606" and the following month 21 mercurial injections, and 3 to 4 drops of Fowler's solution three times a day after meals.

During the first two weeks his locomotion was very much worse and the shooting pains very severe. I attributed most of the increased symptoms to soreness of the muscles produced by the salvarsan. At the end of two weeks case improved, and when I gave the second injection of "606" on March 24th, case again appeared worse for about ten days, then gradually improved until bladder symptoms disappeared and pains ceased in differ-

ent parts. Romberg's sign improved and the art of walking was returning and he was regaining confidence in himself. Left for his home in Illinois about the last of April.

I advised a month's rest from treatment then a Wasserman. Received a letter in June saying Wasserman slightly positive. "Am feeling so well, believe I could help the Louisville Base Ball Club win the pennant." I immediately advised another course of salvarsan and mercurial treatment, but heard nothing more of the case.

Case No. 2., was just the opposite in many respects. Male, age 40 years, weight 130 pounds, single, occupation lawyer. No desire for athletics. Very anaemic and drank more or less all the time. Specific fifteen years, had but little treatment. Slight symptoms of locomotor ataxia for eight years. Last two years all of the symptoms of case No. 1 very pronounced. Would not venture on the street without an escort for fear of running into some one or falling through a plate glass window. Would not leave the house on a rainy day thinking he could not walk on wet pavements.

May 18th to June 2nd a mercurial injection was given each day and the iodides to physiological effect. June 2nd I gave him an intramuscular injection of "606" which was accompanied by no local pain or soreness whatever. Two weeks of the mercurial injections and the iodides per mouth, then two weeks of Fowler's solution as a tonic and on July 1st, a blood test was positive. July 8th, "606", no pain or soreness. This was followed by intramuscular injections of mercury to July 25th, then another injection of salvarsan and a month of liquor potassii arsenitis.

July 25th case appeared slightly improved when he left for his home in a neighboring town. On October 8th patient came to my office unassisted, had gained 12 pounds and could walk along a crowded street with confidence.

DISCUSSION.

Geo. H. Day: It is in this class of cases that we are oftentimes at a loss what to do? We see many patients who have been well treated, so far as anti-syphilitic measures are concerned, who suddenly develop these cerebral conditions, which is very discouraging to the practitioner.

Swith has recently advanced some new ideas in regard to the treatment of these conditions which have met with considerable success in his hands, and which I believe hold out more hope for these patients than anything we have yet tried. It consists in giving an intravenous injection of salvarsan, and one hour later 40 c.c. of blood is withdrawn, allowed to coagulate and centrifugalized. The following day, 12 c.c. of serum is pipetted off, diluted with 18 c.c. of normal saline

solution, and heated for half an hour at 56 degrees C. A sufficient quantity of the cerebrospinal fluid is then withdrawn, and the diluted blood serum introduced into the spinal cord. Swith has reported a number of cases in which this has been carried out and, while he has not followed them up a sufficient length of time to enable him to draw any definite conclusions, he believes that his method will prove to be of great benefit to these patients.

I do not believe we should rely upon the Wasserman test for the diagnosis of this condition. We would get better results by establishing the diagnosis from the spinal fluid itself, and then carrying out the treatment recommended by Swith.

Jno. J. Moren: I have had an opportunity of seeing two or three cases treated by the method of Swith, and in each instance the patient showed very marked physical improvement, but the knee-jerk, Argyle-Robinson pupil and headache persisted. These symptoms will resist in spite of all the mercury, "606", or iodide that we may give. Personally, I have been able to secure better results by building up the physical condition of these patients, then putting them on the Franklin exercises, which is really a system of re-education, teaching them to use their legs although a number of the essential fibres are gone; "driving the horse without the bridle" so to speak.

Curran Pope: The tendency of the modern neurologist is to get away from the designation "locomotor ataxia," which merely describes one of the symptoms, and to use the older term *tabes dorsalis*, which embraces a wider symptom complex.

I believe there are always two factors in the production of *tabes dorsalis*; one syphilitic and the other nutritional. The former is to be combated with arsenical or mercurial preparations. Personally, I have more faith in mercury than in arsenic. However, I do not believe permanently good results are ever obtained in these cases by medication *per orem*; hypodermic injection is the method of choice. To-day the consensus of opinion among the French and German neurologists, as well as the majority of those in this country, is that iodide of potash, nor any iodide, has ever done a particle of good in *tabes dorsalis*, but, on the contrary, has done an immense amount of harm. I never use iodides in the treatment of syphilitic conditions, and it is with great pleasure that I again refer to the fact that, in 1896, I clinically took the stand that the iodides are injurious in locomotor ataxia and should never be used. Personally I have not used them since 1894.

I always tell these patients that they should have recurring courses of treatment. It makes no difference whether the patient considers himself sick or well; he should be treated every year of his life until he is put in the grave. This is a

safe plan, and in my opinion, if it was carried out more frequently, we would have fewer so-called para-syphilitics which, as we know, is nothing more than another manifestation of syphilis.

Dr. Weber pointed out the fact that the mild cases exhibit very few symptoms. It has been my experience that the mild cases are the most treacherous ones and the most likely to be followed by nerve involvement. We are dealing, not with a meta-syphilitic or a para-syphilitic condition, but with a straight syphilitic trouble in which, as has been demonstrated by Noguchi and others, the specific micro-organism of syphilis is present.

H. C. Weber, (Closing): I have been treating syphilis for fifteen years, and have always depended upon mercury up to the time that salvarsan was introduced. We have never considered that the iodides were curative and only gave them in cases where there was pain. After beginning the use of salvarsan, it appeared to me to have a better effect when given in conjunction with iodide, and also when the patient was thoroughly saturated with mercury. I am inclined to believe that we have secured a specific in the two drugs combined.

SARCOMA OF THE UNDESCENDED TESTICLE.

By C. B. SPALDING, Louisville.

Mr. C. L., white, age 22, was referred to me by Dr. Katzmann, for examination, on the 25th of October, 1911.

The family history shows that, on the paternal side there were four brothers and sisters; a sister, and the mother died of supposed cancer, also one of the father's brothers died of cancer. The maternal side shows that the parents, maternal grandfather and two of his brothers died of tuberculosis. The patient has one sister and one brother, both well and healthy.

The personal history shows, that the parent had diphtheria twice, measles, chicken pox, typhoid fever, and was a frequent sufferer from abscesses in the ears from the age of six months to fourteen years. His feet have been deformed since he was three years old.

Patient has had several attacks of appendicitis during the past two years. For one year, undescended testicle on the left side, had given some pain, but for three weeks previous to examination the testicle had enlarged rapidly and was very tender and painful.

We advised the mother of our suspicions of a malignancy and the probable outcome.

On October 25th, 1911, the appendix was removed and then the testicle. There was no perceptible infiltration about the adjacent structures, and the recovery was uneventful, and rapid. A pathological examination of

the testicle, by Dr. Baldauf, of the University, showed a few suspicious looking cells, but nothing definite enough to make a positive diagnosis of sarcoma. The family was warned, and urged to report to Dr. Katzmann at the first sign of any recurrence.

On the first day of June, 1912, Dr. Katzmann again returned the patient to me. A mass, the size of an egg, and resembling the former testicle in size and location, had appeared. This mass seemed not only adherent to the skin but fixed at its base. On June 3, 1912, this mass and the underlying fascia and inguinal glands were removed. The wound healed very nicely, except for an abscess appearing below Poupart's ligament, after he went home, which Dr. Katzmann opened and treated.

The specimen was submitted to Dr. Baldauf and he reported positively a mixed spindle and small round cell sarcoma.

The mother was informed of the probabilities of an early recurrence, and the ultimate outcome. It has now been over two years since the first operation, and one year and about six months since the last operation, and there is no evidence of any recurrence. The patient has gained greatly in weight and general health, and seems absolutely well. I report this case, because of the frequency of malignancy in the undescended testicle, and the rarity of a final cure.

DISCUSSION.

Jno. W. Price, Jr.: I am glad to have heard Dr. Spalding's excellent report. I think the fact that this patient had been wearing a truss for some time was a factor in the production of the malignant growth.

The result of the operation is very favorable for an ultimate cure, but sad experience has taught me not to consider such a case out of the woods until several years have elapsed.

E. S. Allen: Tumors of the testicle are most interesting from an embryological standpoint. We know that in these structures we have the remains of the Wolffian body, and that frequently as is true in many instances of embryonic remains, they are on the border line of development, so to speak, and it does not take much irritation to start their growth. Although in Dr. Spalding's case the tumor is a sarcoma, and sarcomata, as a rule develop in the body of the testes or in the connective tissue proper, still it has not been definitely settled whether the Wolffian body is of isodermic or mesodermic origin; some authorities claim that it is both, and that any kind of a tumor may develop here. Embryonic tissue being present in greater or less quantity, irritation of any kind may stimulate the nutrition of these cells, and we know that embryonic remains once stimulated and started to growing, soon get beyond the control of the govern-

mental force that directs development, and the growth reverts back to the embryonic type. The more rapidly it grows, the further it reverts back to the embryonic type and the more malignant it becomes. The fact that this patient had an undescended testicle indicates a lack of developmental capacity, and the truss he wore probably irritated the embryonic remains and started their growth.

I think Dr. Spalding was very wise in warning the parents of this patient not to be too hopeful, because it has been the experience of the most operators that, in cases of this kind, there is usually very rapid and extensive metastasis. However, in view of the time that has elapsed since the second operation, I think Dr. Spalding is justified in feeling a little more hopeful about the case.

W. C. Dugan: The lesson to be learned from this report is that we should endeavor to do more work in the way of replacing these undescended testicles in the scrotum before they undergo atrophy and other changes which lead to the formation of tumors. I do not believe there is any doubt that the proportion of tumors in the undescended testicle is much greater than in the normally located testicle. Those cases in which the testicle is in the canal are the ones in which sarcomata develop—not the testicle that is suprapitoneally located. In the latter cases we rarely see a malignant growth. Some authority in London, whose name I do not recall, just now, has done a great deal of work along this line, and he has found that, when the case is seen early and the testicle placed in the scrotum, it develops in a normal manner. Therefore, I think we should encourage operation for placing the testicle in its normal location before the development of such conditions as existed in Dr. Spalding's case.

J. Hunter Peak: I have had the good (or bad) fortune to have seen quite a number of cases of undescended testicle before any tumor had developed. In some instances I have tried to place the testicle in its normal location, and it was certainly one of the hardest jobs I have ever tackled. Sometimes it cannot be done, and in such cases I usually advise the family that the testicle should be removed. I have seen cases in which one testicle was in the canal and the other in the abdomen, and in such cases the question arises: should we deal with both of them at the same time? This is a question that the patient should decide for himself. Some prefer not to disturb the one in the abdomen, because it does not run so much risk of injury. However, it is more or less liable to growths, particularly malignant growths.

Wearing a truss is not the only source of irritation in these cases. By reason of its location, the testicle is liable to be injured by falls, and other accidents incident to the life of the average man, and such injuries are frequently followed by the development of a malignant growth. For

this reason these patients should be carefully watched and the testicle removed whenever a growth develops whether it is malignant or not.

C. B. Spalding, (Closing): I wish to thank the gentlemen for their discussion. In regard to the source of irritation in undescended testicle, I think this condition is always accompanied by a partial hernia, and the hernial contents slipping in and out of the sac is a constant source of irritation. In the few cases in which I have placed the testicle in its normal location there has been no subsequent trouble. One factor that tends to make this operation a difficult one is the fact that the blood supply comes from the outer side, along the brim of the ilium, instead of in the median line, and in pulling the testicle down we are apt to injure this blood supply. However, in the majority of cases it can be accomplished without any great difficulty.

MEDICAL PROGRESS

PELLAGRA.

(REPORT OF CASE.)

By I. A. ARNOLD, Louisville.

Mrs. M., widow, forty-six years of age, mother of three children; has had all the diseases relative to childhood, a blonde and of slender build; hygienic surroundings fairly good. She had good health until about six years ago, when at the birth of her youngest child she said she was sick five or six months; just following the birth of her child she had convulsions which from her history were probably uremic. She gradually improved but not up to former standard of health. About November 1st, 1912, she began to be very nervous, she had considerable trouble with her stomach, constipated, kidneys acting freely, and symptoms rapidly becoming worse when her family called me to see her on January 1st, 1913, they were apprehensive of her losing her mind. I found her in a very weakened condition, mind weak, not particularly off on any one subject, but more like a child's mind easily moved either to tears or laughter. She was unable to walk—general tremor on one occasion. I noticed that she cried because she was unable to hold a glass of water. She complained of a peculiar disagreeable odor which she was unable to intelligently describe. Vision and hearing poor, reflexes exaggerated—complained of a burning in nose and throat, also extreme pain in chest, arms and back; also complained of a burning on the surface of the fore-arms to such a degree, that made it necessary to use an opiate to relieve her. She was nauseated and unable to eat, and complained of being unable to breathe good at night. She was much emaciated.

Upon examination I found the heart rapid and weak, the tongue red, in fact, the entire buccal cavity fiery red; a slight rise in temperature, also an macular eruption on the fore-arms of a bright red hue, the spots about 1-4 to 1-2 inch in diameter, resembling sun-burn.

The symptoms above described gradually became worse until about March, 1913, when her condition seemed so intensified that there were grave fears of her death. The emaciation was extreme, equal to that we see in the third stage of tuberculosis. She was unable to sit up in bed, neither could she sleep for the severe pain and burning sensation of the skin.

Menstruation, which had been coming on every three weeks, ceased, but returned July 1st, 1913, but not much stress can be put on this symptom because of her age. March 1st, 1913, her mind gave signs of great mental weakening. The eruption which was confined to the dorsal surfaces of the hands, the feet, and the back of the neck and shoulders, began to spread over the arms, the face, particularly over the nose and forehead and continued until the entire body, except the abdomen, was more or less covered. The temperature, which at first showed a slight rise, became subnormal and remained so to this date. Pulse got faster and weaker, running to about 130 or 140. Examination of urine at first showed slight trace of albumen, but after two weeks there was no trace of any. She remained in this condition until about April 1st, when she began to improve gradually, being able to retain some nourishment. Constipation was relieved by drugs, and at this date she is able to walk a distance of four or five blocks. How long she will thus continue I am unable to say, but it is my opinion that it is only temporary relief.

I have not given the family my opinion of the case, but I am about convinced that it is a case of pellagra.

DISCUSSION.

W. E. Gardner: From the description of this case I think it was undoubtedly one of pellagra. The skin lesion described is very characteristic of the disease. The symmetrical dermatitis on the backs of both hands is not easily mistaken for any other condition by one who has seen many of these cases. I would like for the doctor to tell us, in closing, whether this patient gave a history of mental or nervous disturbance during the year or two prior to the appearance of the local symptoms.

I. A. Arnold: Yes, sir; this patient gave such a history.

W. E. Gardner: From a study of these cases during the past two or three years, I am very much inclined to believe that the appearance of the dermatitis indicates the approach of the end of the disease, which may have existed for

some two or three years prior to this time. When we recall a muscular weakness, loss of flesh, gastric discomfort and a certain amount of mental hebetude or confusion, that have existed for a year or two previous to the appearance of the dermatitis I believe the dermatitis is due to certain trophic changes which take place in the skin, due to a general lack of nutrition, and that this, along with the intestinal symptoms, are the sequelae of more serious structural changes which may have been going on in the brain and cord for months or years before the local manifestations become apparent.

Curran Pope: I have seen very little of pellagra and possibly I care to see even less. Among the most hopeful signs of professional activity along this line is a recent article by Niles, in which he reviews some of his experiences in the treatment of pellagra, and particularly the almost wonderful benefit he has obtained from the use of hydrotherapy. He has given these cases quite extensive courses of treatment and in his latest report, which he sent me about a month ago, he holds out promise of a great deal of relief to be obtained from hydrotherapy, with the possibility of a cure in some early cases of pellagra. I was interested in the report from a purely academic standpoint, and not from the standpoint of treating these cases myself. Undoubtedly, however, the great value of hydrotherapy in overcoming vasomotor and trophic conditions would certainly indicate its use in this particular class of cases. I think this report indicates a decided progression in the study of pellagra.

A. J. Davidson: The essayist stated that his patient had no temperature. In the cases I have seen where there was temperature, we have hardly given any treatment at all; that is, for the temperature alone. As to the secretions, they are always very plentiful.

As to the urine, we do not find anything characteristic. Almost all of these cases, no matter what we do for them, will die, and I do not know whether hydrotherapy or anything else is going to help them very much. In three cases that I have seen in the past nine months, the alum baths recommended by Niles, have been used.

One of the speakers referred to the probability of the mental condition having existed for several months prior to the manifestation of the local symptoms in nearly all asylum cases, as well as those reported outside of asylums, there is a history of these symptoms, as well as some mental aberration.

The symptoms enumerated by the essayist have been present in nearly all the cases I have seen. The dermatitis is very similar to pustular eczema; in some cases the skin sloughs off in large masses. In most cases it appears first on the palmar and dorsal surfaces, appearing later on the lips, back and neck; sometimes on the feet, but not often.

As to the mental condition, there is usually ir-

ritability with a tendency to complain, but the patient does not seem to appreciate the gravity of the situation; there is little inclination to exertion of any sort.

Some persons have undoubtedly had pellagra and either recovered from it, or there has been a remission period of over a year and a half. I know some cases that have presented all of these symptoms that we are accustomed to ascribe to pellagra, but have recovered from them and are still alive. I know of at least two such instances.

Bernard J. O'Connor: I believe one of the most interesting points has been overlooked by the reporter; that is, the etiology of pellagra: I would be glad if he would tell us the previous residence of this patient, and also the probable cause of the disease.

Curran Pope: I would like to correct a misapprehension which may arise in connection with my remarks and those of the speaker who followed me. My remarks concerning the work of Dr. Niles did not refer to mineral baths, but rather to ordinary hydrotherapy. In the article I mentioned he does not refer to the alum baths, which I understand has practically been discarded.

I. A. Arnold, (Closing): In answer to Dr. O'Connor's question, I will say that I intended to write to Dr. Carpenter, who treated this patient in Winchester, regarding the surroundings of the patient there, but from what she has told me they must have been very similar to the conditions here. Her present environments are fairly good. She lives in a cottage in the west end of the city. She said that Dr. Carpenter reported her case to a medical society once before, but whether it was the same condition or not, I do not know.

I had never seen a case of pellagra until this patient came under my observation, and I simply treated her along the line of general tonics, giving her plenty of such foods as lettuce, greens, etc. For the constipation of the bowels I gave her cascara. For a while I did not know what I was treating, except that it was something I had never seen before, until finally I made the diagnosis of pellagra.

Constipation.—Treatment—Stubborn constipation in infants is relieved by giving 1 dram (4 c.c.) of olive oil once or twice daily. Constipation in neurasthenics is also benefitted.—Bram.

Carcinoma, Esophageal.—Treatment. — Hydrogen dioxide, 1 dessertspoonful of 1 to 3 per cent. solution every hour, found to be valuable palliative measure where stenosis apparently complete. Within twenty-four hours stenosis is overcome, and later purees and even solid food can be swallowed. Subjective symptoms disappear and patients gain in weight. Measure of little use, however, in scirrhus form of cancer.—Fradiss.

THE SENSIBILITY OF THE ALIMENTARY CANAL IN HEALTH AND DISEASE.

Hertz, *Lancet*, 1911, in the Goulstonian lectures, records his observations on the sensibility of the gastro-intestinal tract to various stimuli. The mucous membrane of the whole canal was found insensitive to tactile stimuli: insensitive to thermal, the esophagus and rectum being sensitive. The esophagus and stomach are quite insensitive to dilute hydrochloric acid even as high as 5 per cent, a concentration never found in health or disease. Glycerin effects the anal canal and alcohol generally produces a feeling of warmth. The feeling of fullness in stomach and intestines is due to a slow increase in the tension exerted on the muscular fibres of their coat. The volume of contents necessary to produce this tension varies with the tone of the organ, that is a small quantity will cause a sensation of fullness in a tonically or organically contracted stomach, while it would be unnoticed in the dilated.

In the rectum this special sensation of fullness is a call to defecation. This call should be answered at once; for the passing off of the desire is not due to a return of the feces to the pelvic colon, but to a gradual relaxation of the rectal wall. A new desire means only one thing—that more feces have come to the rectum and to prevent progressive dilatation it should be evacuated at once. The feeling of hunger is one of general malaise associated with the periodical muscular activity of the stomach when empty and the nerves hypersensitive. This causes local pressure symptoms analagous to those to be described in pain. Hunger can be allayed by the taking of water or of any non digestible substance like earth. It is, however, with especial reference to abdominal pain that his observations are most interesting. He has described how he found the stomach insensitive to hydrochloric acid, even when ulcerated, and believes that abdominal pain, is, in part, truly visceral and has one cause—tension produced upon the muscular coat of the viscus. This tension must be induced rapidly; if slowly the sensation of fulness results, and the pain returns when more pressure is added. Gastric pain associated with ulcer he describes as due to the pressure caused by (1) pyloric spasm either organic or due to the passage of too acid chyme into the duodenum, together with (2) increased peristalsis of the pyloric

end of the stomach. This rapidly raises pressure locally, and the pain is severe. The peristalsis may be more active from direct stimulation of their nerves of the open ulcer, or it may be due to plain hyperacidity. If the ulcer is in the cardia the peristalsis is evidently greatly increased, reaching a region of the stomach where it normally does not belong. The late pain of duodenal ulceration he explains by the fact that the first chyme to pass the pylorus has hydrochloric acid bound with the protein, and that there is no excess to cause pyloric spasm. As the secretion of hydrochloric acid arises, the spasm increases and peristalsis causes the increase in pressure. Relief by soda bicarbonate is explained by the reduction of acidity and consequently of the pyloric spasm, thus permitting extension of chyme. Similarly, vomiting results in emptying the stomach with lack of pressure owing to their being nothing for the stomach to contract upon. The pain of chronic appendicitis and cholelithiasis is most probably due to reflex inhibition of the pyloric relaxation. That of colic is due to increase of pressure caused by excessive peristalsis and spasm of the next lowest colonic segment. Local tenderness may be due to two things—hyperalgesia of the skin, subcutaneous tissues and muscles, together with a local rise in tension, caused by the pressure of the hand. That it is not due to pressure on the ulcer is evident from the fact that exploratory laparotomies often show the ulcer remote from the tender spot.

INFLUENCE OF THE DIET ON THE RESISTING POWER OF INFECTIONS.

In the *Medicine Clinic*, Berlin, 1913, Czerney's article is another illustration of the way in which practical experience leads the way and science follows along possibly far behind, with the explanation of phenomena observed. With the explanation in hand he says we can now go systematically to work to protect children against infections, when before it was a matter of haphazard empiricism. He shows how important is the natural immunity possessed by the individual in respect to infection, and how it is possible to enhance or reduce this by the diet. The natural immunity of the human organism is its most precious possession, he declares, and it is one of the highest tasks of the medical profession to protect and cultivate further this natural immunity. Conditions in this respect are most easily studied in infants. A healthy infant does not develop thrush even if its mouth is inoculated with oidium, but if digestive disturbances arise, the oidium starts up the

thrush at once. Let the digestive disturbance be corrected and the thrush subsides without any local measures. As the infant grows older, the natural immunity increases and the oidium does not induce thrush except in debilitated children. The saying that "the food is responsible for the infants being sick but that it dies from infection" must be modified. Czerny insists, by the additional statement that this occurs only with a constitutional inferiority, and that the latter is a factor in the development of the infection by its depressing influence on the natural immunity. He discusses the different elements of the food in relation to natural immunity, the fat, carbohydrates, etc., and emphasizes that the water content of the body has extreme importance for natural immunity. Bacteria flourished in culture mediums more luxuriantly in direct proportion to the measure in which the water content of the medium surpasses the average water content of the body of an adult.

With a water content merely equal to this average or below, no colonies of the bacteria develop. The higher the water content of the body, the less the resisting power to infection, he reiterates.

Carbohydrates in the diet tend to increase the water content of the tissues; the amount of increase depends on individual conditions, so that some infants and older children have to have the intake of carbohydrates more strictly regulated than others. The embryo and new-born infant have a larger water content than older children and adults, and the experiences with those illustrate forcibly the special danger of this high water content. They not only contract infections with exceptional facility, but the infection rapidly spreads from a local to a generalized process.

Tubercle bacilli in young infants almost invariably a generalized active disease while infection as the child grows older is usually a local process.

Another factor of importance for natural immunity is the swelling of the colloid substances in the tissues: under normal conditions the calcium salts have an inhibiting and regulating influence on this swelling. If the absorption of the calcium salts from the food is prevented by too much fat in the food, then they are thrown off in the form of soaps in the stools and the infant suffers from the lack of necessary calcium salts. This is most liable to occur on a cow's milk diet, both in infants and in older children fed too long on milk. The loss of the alkalies in this way leads to acid intoxication, the more readily the younger the child. The natural immunity is lower on a cow's milk diet than on any other food.

With the exudative diathesis, in particular,

the exceptionally low natural immunity can be enhanced to a practically normal phase by simply modifying the diet, reducing milk after the first year of life to the proportion of milk usually taken by adults. His twenty years' study of the subject has shown that it is possible to control the exudative diathesis effectually by a proper diet, and thus to control the tendency to infection, so that the children very rarely contract scarlet fever, and when it occurs it is in an alternated form. He even affirms that the frequency of the occurrence of scarlet fever and the seriousness of the disease are generally speaking, a mirror to reflect the condition as to the suitable or unsuitable diet given children.

The exudative diathesis, he reiterates, is a sharply defined condition of certain exudative and consecutive infectious processes in the skin and mucous membrane, which are directly dependent on the diet and can be controlled at will by modifying the food, reducing the intake of milk and of fluids in general to the amounts generally taken by adults, and giving the children in their diet certain substances which they need. Experience has shown that these latter substances can be supplied to infants in maltose and to older children in meat. The recent research on beriberi has demonstrated that even minimal amounts of certain substances in the food have a wonderful effect on the general health. In conclusion Czerny urges that some of the research now being devoted to active and passive immunization should be diverted to study of the factors governing natural immunity, especially the alimentary factors.

J. A. K.

The Treatment of Syphilitic Affections of the Central Nervous System with Especial Reference to the Use of Intraspinous Injections.—Swith and Ellis, (Archives of Internal Medicine, Sept. 15, 1913.)

They report their work done at the Hospital of the Rockefeller Institute for Medical Research.

Syphilis of the central nervous system is caused by a known parasite—the treponema pallidum—against which we have at least two specific therapeutic agents. It is therefore amenable to treatment. In the first place it is necessary to recognize the nature of the disease in the nervous system before irreparable damage has been done to important structures and, secondly, to determine the most efficient method of application of the curative agents.

It has been demonstrated that in parasymphilitic diseases there is an active syphilis of the nervous system. The cerebrospinal fluid shows an increased globulin content, and pleocytosis, increased cell content; these indicate

a chronic inflammatory process in the cerebrospinal axis and a positive Wasserman in the cerebrospinal fluid indicates its syphilitic nature. In late syphilis and tabes the spirochetes have established themselves in the lymph spaces of the central nervous system and are difficult to reach with drugs given in the ordinary manner, as there is very little excretion of drugs from the blood into the cerebrospinal fluid. Flexner has shown that it is necessary to inject the antimeningococcal serum into the subarachnoid space to have a curative effect.

Mercury and iodides have very slight effect on the abnormal constituents of the spinal fluid. Salvarsan intravenously has more effect, but does not cause the globulin to disappear or change the positive Wasserman in the fluid.

Salvarsan and neosalvarsan, when injected intraspinaly produce symptoms too severe to permit of their use in this manner, however, serum can be injected repeatedly without apparent injury to the nervous tissue. The authors have used serum from the patient after the administration an hour previously of from 0.2 to 0.5 gr. salvarsan.

Their method which they give in detail is practically as follows:

One hour after the intravenous injection of salvarsan 40 c.c. of blood is withdrawn directly into bottle-shaped centrifuge tubes and allowed to coagulate, after which it is centrifugalized. The following day 12 c.c. of serum is pipetted off and diluted with 18 c.c. of normal saline. This 40 per cent. serum is then heated at 56 C. for one-half hour. After lumbar puncture the cerebrospinal fluid is withdrawn until the pressure is reduced to 30 mm. cerebrospinal fluid pressure. The diluted serum is then introduced by gravity in order not to suddenly increase the intraspinal pressure. Frequently there is a certain amount of pain in the legs commencing a few hours after the injection.

Ten cases are reported where this treatment was given, and the result shown in tables—giving the treatment, the Wassermann reaction in the blood and a quantitative Wassermann for the cerebrospinal fluid, the cell count and globulin in the fluid.

Eight were cases of tabes dorsalis the other two of different types of cerebrospinal syphilis. These cases all showed improvement with disappearance of pain and arrest of the progress of the disease. In several of them the improvement had lasted for over a year. In two cases the serum was taken from other persons to whom salvarsan had been given.

The number of injections given vary from 5 to 15 with an average of 9. The interval between injections being from a week to several weeks or a month.

The cases reported are examples of groups of cases they have had under treatment.

These observers point out that the successful treatment of syphilis of the central nervous system is not two or four or any number of injections of salvarsan or certain amounts of mercury or iodides, but only when the spinal fluid has become normal are we justified in discontinuing treatment.

They do not offer the intraspinal injection as a substitute for other accepted forms of treatment, but as an aid in attacking severe cases as a rapidly advancing tabes or paresis.

This interesting work appears to offer some hope at least in those cases of parasyphilis—all too common, and by the ordinary methods practically hopeless to treatment. However, these are severe measures, and should not be undertaken except by those having at hand opportunity for careful observations of the changes occurring in the cerebrospinal fluid. That this is not a task for a tyro one can see by looking over the charts presented with their article.

J. R. M.

IV.

In these days of delving into the very minutiae of things with high hopes for even ultra microscopic views, it seems rather unique, but altogether wholesome that quite a few prominent observers have hearkened back and shown the necessity of the study of anatomy in its relation to some of the more complex diseases.

Dr. Charles F. Painter in an article entitled the "Influence of Skeletal Defects, Congenital and Acquired, Upon the Body in Health and Disease, (*American Journal of the Medical Sciences*, October, 1913), discusses this subject in a very interesting manner. Commenting on the valuable work done in this line by Lane, Goldthwait, Preiser and F. H. Martin.

It is becoming more and more apparent that many disease processes cannot be attributed to infection, so earnest search has been made by many for their real origin, and much valuable information has been found by these observers to be in skeletal defects, frequently congenital.

Many defects are attributed to the human animal having to walk on two feet instead of four as his ancient ancestors did. There can be no doubt that much strain has been put on certain parts of the body by assuming the upright position, and that in many instances the skeleton has not been able to meet this with absolute success.

Painter says, "We are disposed to assume that the body is so endowed with energy and is so infinitely adaptable to changing conditions that its functions may be continued in

a normal manner to permit of healthful existence and the output of a volume of energy proportioned to the capacity of the machine. It is true that in the human mechanism there is a wider latitude than there is in any other known mechanism for loss of force and for the performance of function under conditions which are, to say the least, adverse. What we do not realize, and have taken few steps to understand, is (1) to what extent anatomic defect influences the proper functional uses of the body; (2) to what degree and in what way these anatomic peculiarities may influence physiologic function; (3) to what kind of abnormal anatomic changes these perversions of function may give rise."

Probably the earliest part of the medical profession to recognize this effect of strain was the ophthalmologist—by correcting unbalanced eye muscles and relieving eye strain many headaches and general nervous disorders were overcome.

Many valuable lessons are to be found in the relief offered the general health and well being of individuals by recognizing and correcting weak and pronated feet and flat foot. We also owe much to orthopedic surgeons, especially Goldthwait for directing attention to the fact that many cases of sciatica, lumbago, etc, were strains and displacements of the vertebra and sacro-iliac joints and therefore amenable to treatment by relieving the true cause.

For the past few years, universal interest has been manifested in visceral ptosis and its resultant alimentary toxemia. Following the brilliant work of Arbuthnot Lane on this subject, showing its anatomical origin and that it was frequently congenital, many most valuable papers have been written on this subject especially those of F. H. Martin of Chicago, Coffey of Seattle, and Richard R. Smith of Grand Rapids.

Most of these men are surgeons and too many of us are prone to think that the only relief offered in this condition is by surgery—this one would believe to be the case from the writings of some of these gentlemen, but no doubt this extreme view is moderating a great deal, as Coffey says in his article (*Surgery, Gynecology and Obstetrics*, Vol. XV, 1912-) that most of these cases can be relieved without operation and are amenable to treatment by diet, fattening, exercise and general regulation of the patient's habits.

It therefore appears that these cases of skeletal defect and resultant strain should be of much interest to medical men in general, not only to surgeons and specialists for the general practitioner sees these cases first and if he train himself to be able to detect these defects he will not lose valuable time in trying every sensible means of overcoming them as

early as possible and one can see the great advantage to be gained in these conditions in beginning in youth.

Painter says, "These problems comprise much of the work that those who are becoming interested in chronic medicine have lain out for themselves. A new and attractive field for investigation exists. Light is being shed upon many questions which have puzzled all branches of the profession of medicine. The need for a correlation of the knowledge which has been accumulated through the activities of workers in various special lines of research is becoming more and more evident. We are getting past the period when within the narrow limits of our particular spheres of activity we can assume a position of authority and say that this or that ailment can be treated properly only by this or that specialist. It can be properly treated only by the one who has the best conception of the anatomic-physiologic relations of the condition before him, and is broad enough to act on that knowledge. A better conception of the functional anatomic relations of the human being, not merely the ability to recognize and call by name its structural components, is what is necessary in medicine and surgery. When the profession recognizes this and bases its treatment upon such knowledge, some at least of our present-day problems are certain to become easier of solution, and mankind at large will be the gainer. J. R. M.

MINUTES OF ANNUAL MEETING OF THE JEFFERSON COUNTY MEDICAL SOCIETY, DECEMBER 22ND, 1913.

The 235th Stated Meeting (Annual Business Meeting) of the Jefferson County Medical Society was called to order by the President, Dr. Dunning S. Wilson, on Monday evening, December 22nd, 1913.

Minutes of the previous meeting were read and approved.

UNFINISHED BUSINESS.

Dr. Doherty, Charman of Committee to draft resolutions concerning the death of Dr. John G. Cecil, made a report submitting the following resolution.

By an inscrutable decree of an All-wise Providence death has again invaded our society and Dr. John Giles Cecil in the zenith of his career of usefulness, and in the prime of intellectual life, has been called to his reward.

Resolved, That in the death of Dr. Cecil this society has lost an accomplished, thorough and sound medical scholar, an earnest and zealous colleague for the advancement of our profession, and a pre-eminent and worthy exemplar of honor and integrity.

Resolved, That in the loss of this able physician

possessed of great judgment and skill, and a medical teacher of surpassing merit, the community, in common with ourselves, has experienced a profound bereavement.

Resolved, That his example of earnest and faithful labor in his profession, his nobility and integrity of purpose that characterized all his actions, his Christian home ties and domestic relations, are memories to be cherished, and worthy the admiration and emulation of his survivors.

Resolved, That we tender to his family our condolences in the grief that has overtaken them; that a copy of these resolutions be presented to his family and published in the Kentucky State Medical Journal.

WM. B. DOHERTY,
Chairman.

J. M. RAY,

CLAUDE G. HOFFMAN.

Upon motion duly seconded and carried the report was received and the resolution adopted by the society.

NEW BUSINESS.

Dr. H. E. Tuley asked endorsement by the society of a bill proposed to be introduced at the next session of the legislature, providing that the management of the new City Hospital, when completed, shall be taken out of the hands of the Board of Public Safety, and put in the hands of a permanent Hospital Commission to be appointed by the Mayor. Seconded. Moved by Dr. W. F. Boggess that motion made by Dr. Tuley be tabled until a draft of the proposed bill has been written and its exact contents can be ascertained by the society.

Dr. Virgil E. Simpson announced his resignation of the office of Business Manager of the Jefferson County Number of the Journal, and stated that the co-operative plan of obtaining advertising necessary for the continuance of the Journal would be resumed.

REPORTS OF OFFICERS.

REPORT OF SECRETARY.

Mr. President, Fellow Officers and Members of the Jefferson County Medical Society:

Before making this report your secretary in retiring from office wishes to first thank the society for the honor so bestowed and trusts that his record has merited your confidence, further he wishes to thank the officers and members both collectively and individually for their hearty cooperation and support.

In making this report your secretary points with pride to the present condition of the society. There has been a considerable increase in membership, an increase in balance in the treasury, an increased interest, an increase in attendance, perfect harmony prevailing and still brighter prospects for the future.

Scientific Work.

The programs as furnished by your Program Committee have always been of the highest type and with very few exceptions those upon said programs have responded when their names were called. We desire to thank the Program Committee for its excellent work—and by the way this is one of the most important committees of the society, as the attractiveness of the program has all to do with the attendance.

Before leaving the scientific work we must mention the Jefferson County Number of the Kentucky Medical Journal, of which the society should feel very proud. The members should rally to its support and patronize its advertisers, as it exists through its advertisements. Dr. V. E. Simpson, its business editor, to whom the society is greatly indebted for his untiring efforts, should have the help of every member of this society in keeping the Journal going.

Financial and Business.

The financial affairs of the society were never in better condition. They have been well taken care of by your most efficient Treasurer and by Mr. H. S. Smith, who has looked after the renting of the hall.

In connection with the management of the society's business affairs we wish to thank both Mr. Smith and Miss Goff, the Librarian for their faithful and untiring efforts in discharging their respective duties.

Library.

During the past year quite a number of journals were bound. The circulating branch has materially increased and is very popular. The cataloguing has been nearly completed. We desire to thank the Library Board, especially Dr. Lindenberger, its Chairman for his great interest in the library, also to thank Miss Goff for the faithful discharge of her duties as Librarian.

Public Policies.

During the year there has been very little action taken by the society out of the ordinary in regard to public affairs, a few of which follow:

A local Red Cross Committee was appointed to cooperate with the Committee on Red Cross work of the A. M. A., said committee to be called upon to render medical aid during any great public disaster.

The society voted as favoring the adoption of one telephone. Nothing definite has as yet been accomplished.

Resolutions were adopted by the society in an effort to secure admission of surgical instruments duty free, copy of same sent to the congressman from this district and a request made that other societies take up the same cause.

A committee appointed to cooperate with a like committee from the Louisville Board of Trade, looking towards ways and means of preventing so many unjust damage suits.

A Committee was appointed to look into the feasibility of drafting and having presented to the next legislature, providing that in the future alleged insane persons shall be passed upon by a commission of medical men and not by jury.

Recommendations.

Your secretary desires to make the following recommendations:

First. That a larger membership committee be appointed and that they be instructed to hold a meeting at least once a month and discuss ways and means of increasing membership and review names of non-members who are eligible and desirable.

Second. In selecting committees, the proposed ones be consulted with and his duties be made known, and promise exacted that he will discharge said duties to the best of his ability. When efforts have ceased to do so, he automatically ceases to be a member of said committee.

Third. That more adequate means be provided

for keeping the records and correspondence of the society.

Respectfully submitted,
A. C. L. PERCEFULL, Secretary.

Moved and seconded that the report be received and adopted and a vote of thanks tendered the Secretary for his efficient service. So ordered.

REPORT OF TREASURER.

Jefferson County Medical Society.
December 22nd, 1913.

Receipts.

Dues	\$3119.00
Hall Rent	471.00
Interest	14.49
Balance 1912	159.29
<hr/>	
	\$3763.78

Disbursements.

Rent	\$1332.60
Salaries, Stenographer and Librarian...	960.00
State Dues	797.50
Printing	64.10
Piano Rent	60.00
Miscellaneous	190.91
<hr/>	
	\$3405.11
Total Receipts	\$3763.78
Total Expenditures	3405.11
<hr/>	
	\$358.67

<hr/>	
	\$385.17

In a comparison of the disbursements for the year 1913 with those of the preceding year, it should be borne in mind that during 1913 dues for the State Society and Medical Defense were raised from \$2.50 to \$3.00, necessitating the payment to the State Society of \$.50 per member more than was paid in the preceding year, making a total of \$797.50.

Ky. State Medical Ent. Fund.....	\$180.32
Balance 1913	358.17
<hr/>	

Total on hand

E. L. HENDERSON, Treasurer.

Moved and seconded that the report be received and adopted and a vote of thanks tendered the treasurer for his efficient service. So ordered.

REPORT OF THE EXECUTIVE COMMITTEE.

Gentlemen:

In making this, the second and last report, we wish to state that the work of this Committee has been pleasant and harmonious since our election two years ago. At no time has there been dissection in our committee. It has been of great aid to the committee in having one member who was particularly adapted to "Forsee" the future

effect of any question which might arise.

Several questions, all important, that had much to do with the success and usefulness of the society, have been brought before your committee. We have kept no record of such questions, and cannot give a detailed report, however, we can say that all questions were decided according to what we thought best for the society.

The fact that only one question which was recommended did not prevail, showed that we were not dictatorial, or in any way offensive to the will of the society. We recommended that the society remain in the Atherton Building, however, new phases as to the possibilities at the City Hospital developed the fact that suitable quarters could be secured there, and was so accepted by the society.

As far as we can recall this is the only instance where our recommendations were turned down. We hope that the new committee will be as successful, and work as harmoniously as your retiring committee.

Recommendations.

Some weeks ago the proposed Nurses' Bill was handed to us for our advice. After a conference with all of the Committeemen, we recommended that the County Society approve of this bill, as printed and recommended by the Kentucky State Medical Association.

As to the future policies of the society, your committee unanimously concur in the belief that some step should be taken concerning the criticism of the Medical Expert Witness. From the personal observation of a member of your Committee, we know that many of the doctors are being hounded and persecuted, and we are all subject to the same evil by the liability to be sued for malpractice. We have absolutely no recourse. Unscrupulous parties can enter suits against us and all we can do is to fight, and if we win we often have to pay the court costs on account of the plaintiff's having no means.

The Committee feels that if the supposed criticism of the medical witness could be removed, and show to the legal profession that we, as a society, want to do right, and fight for what we think is fair, we can in turn expect them to do the same by us. In plain words say to the legal profession "We have stopped the abuse of the medical testimony, you stop the unscrupulous attacks upon us."

We recommend the following amendment to the Constitution and By-Laws and ask a due and thoughtful consideration of same:

Witness Committee.

Whereas, we the members of the Jefferson County Medical Society, realizing the increasing skeptical attitude of the general public towards the testimony of alienist and other medical experts as given in the various courts of our Commonwealth and desiring to aid in so far as

lies within our power to save our profession from unjust criticism as well as to aid in the administration of justice to all litigants and to the general public, do hereby adopt the following resolutions as a portion of the Constitution and By-Laws of this society:

Be it Resolved, First, That at the annual meeting of this society the President shall appoint a committee of not less than three and no more than seven whose duty it shall be to select from the members of this Society such of its members as make a specialty of the various branches of the profession of medicine and surgery, such selection not to exceed in number fifty, to act as expert witnesses in the various courts of Jefferson County, Kentucky, the selection of such committee to be recommended to the society at the first monthly meeting succeeding the annual meeting for the approval and indorsement of the society, such approval and indorsement to be indicated by ballot;

Second, That any member of this society shall have the privilege of voting for any other member of this society not placed in nomination by the committee provided for in the section immediately preceding this section, and that the fifty members of this society receiving the highest vote shall constitute a committee of fifty physicians and surgeons to be recommended to the courts of this county and to the member of the Jefferson Bar Association as experts particularly qualified to testify in such cases as involve facts pertaining to the various branches of medicine and surgery.

Third, That this society does hereby express its condemnation and disapproval of the prevailing practice of physicians testifying without consultation with each other in suits at law, and we do hereby recommend that in future, at least, so far as members of this society are concerned, that no physician or surgeon shall testify as an expert witness in any suit in the Court of Jefferson County until he has had a consultation with the physician or surgeon representing the opposing litigants, or until he has exhausted every means to hold such consultations; and that in the event the physicians and surgeons representing the opposing litigants cannot agree a third physician or surgeon be called into consultation, this recommendation of course, it is not intended to influence any physician or surgeon to express any opinion other than that he may conscientiously hold after the consultation which has been recommended, and is in no wise to be construed as an effort to influence the violation of any oath administered in a court of justice;

Fourth, That such fees as shall be paid physicians and surgeons who are members of this society in such cases as they may be called upon to testify in, shall be fixed by the presiding judge, and no fee or fees for expert testimony shall be accepted from litigants other than fees fixed by

the presiding judge of the court in which is tried the case they testify n;

Fifth, That such physician and surgeon who is a member of the committee of fifty receiving a fee as an expert witness shall pay to this society or library 20 per cent of such fee;

Sixth, That this resolution shall take effect on the 1st day of February, 1914; and;

Seventh, That copies of this resolution be furnished the Judges of the various trial courts and Courts of Chancery in Jefferson County and to the Jefferson County Bar Association.

We of the Executive Committee endorse and recommend the above amendment to our constitution.

JOHN J. MOREN, chairman,
C. G. FORSEE,
WALTER F. BOGGESS.

It was moved by Irvin Abell that the recommendation of the Executive Committee to endorse the proposed bill for the "Regulation for Trained Nursing in Kentucky" be adopted by the society. Seconded and so ordered.

The president said that without objection the consideration and vote upon the proposed amendment of the constitution as recommended by the Executive Committee would be set for the first regular meeting in February and the secretary instructed to give all members constitutional notice of same.

REPORT OF MEMBERSHIP COMMITTEE.

Jefferson County Medical Society, December 22nd, 1913.

The membership of the Jefferson County Medical Society for 1911 was 200; for 1912 it was 242, and for 1913 is 265.

Comparing these figures, it shows that the society has gained for 1912 in membership, 42, in 1913, 23. While we were not able to obtain as many members this year as we gained in 1912, yet the membership has substantially increased, —the increase coming mainly from the younger members of the profession.

This has been encouraged by the Membership Committee, and yet an effort to increase the membership from the older physicians of the county has not been overlooked. After a great deal of personal canvassing among the members of the profession, the following letter was sent to a hundred doctors in the county, who were not members of the society:

"My Dear Doctor:—As Chairman of the Membership Committee of the Jefferson County Medical Society I am making this appeal to you, in order to secure as many members of the profession as possible for the Jefferson County Medical Society before the year expires.

"The dues are \$12.00 per annum. This entitles you to membership in the society, and carries with it, not only the Jefferson County Number of the State Journal, but also the Kentucky

State Journal in addition. It also entitles you to a paid membership card in the State Society and the benefits of the Medical Defense organization of that society, which protects you against damage suits for malpractice.

"We are anxious to have you join us and feel certain that we can help you, as well as you help us. The scientific programs are splendid. The clinical reports of cases and the essays are all arranged from the membership list in alphabetical order. If all this does not appeal to you sufficiently we invite you to attend some of the meetings, which take place in the meeting room of the society, 700 Atherton Building, every Monday evening, at 7:45 P. M."

Your Committee would recommend early in coming year a field day canvass similar to the effort of some time ago.

C. H. HARRIS,
Chairman Membership Committee.

Moved and seconded that the report be received and adopted and a vote of thanks tendered the Membership Committee for its efficient service. So ordered.

REPORT OF PROGRAM COMMITTEE.

To the President and Members of the Jefferson County Medical Society:

Your Program Committee feels that through the monthly programs, regularly mailed to all members it has kept even those irregular in attendance informed of what it has done toward securing interesting and profitable subject matter for your weekly sessions. In arranging these programs the customary rule of alphabetical rotation has been adhered to as far as practical. It has not been always easy to complete them and if at times they have been tardily received by you the Committee has not been wholly at fault. In many instances the difficulty arising out of eleventh hour withdrawals has been overcome by the readiness of certain accommodating members to fill the breach upon short notice; their material help is gratefully acknowledged by the Committee.

It desires also to give full credit to Dr. Keith of the Clinical Report Committee for his dependable co-operation.

Respectfully submitted,
LEE KAHN, Chairman,
S. SCOTT PRATHER,
J. ALLEN KIRK,

It was moved and seconded that the report be received and adopted and a vote of thanks tendered the Chairman of the Program Committee. So ordered.

REPORT OF THE LIBRARY BOARD.

Of the Jefferson County Medical Society for the Year 1913.

To the President and Members of the Jefferson County Medical Society:

The Library Board wishes to submit this, our

report of the management of the Library this past year:

In April, of this year, there being no money in the treasury of the Library Board, there was donated by the society the sum of \$100. This money was spent mostly in the binding of journals, many of these journals not having been bound for several years. There was a total of 85 volumes. In the latter half of the year, namely after July 1st, there were 12 volumes bound. The total cost of this binding amounted to \$87.90. This work was given out after various bids had been taken, the bid of John P. Morton Company being much the lowest.

There has been purchased for the Library four volumes. This expenditure bringing up the total expenditure of \$100, the sum donated.

Considering the fact that the society as a whole is to move, the Library of course going with it, we have no especial recommendations to make, except to say that there will be an expense in moving, and probably more so if the Library is to be properly installed. This expense in moving probably will not be so light as the time and trouble incurred will necessitate the use of intelligent handlers.

There may be some names overlooked regarding the donors to the Library, the past year, but we wish to thank especially Dr. H. E. Tuley, who has supplied us with very many of the current journals. Dr. Louis Frank, Dr. M. L. Ravitch Dr. Jno. J. Moren, Dr. Cuthbert Thompson, Dr. Jno. R. Wathen, Dr. R. B. Gilbert, Dr. Lewis McMurtry, and Dr. W. T. Hayes.

It is known to the Library Board that there are some present members of the society who in their wills have donated at their death their libraries to the Jefferson County Medical Society. As these libraries after death bring so little in a financial return to an estate, this suggestion is made with the hope that it may be followed out by those who are now members or irrespective of the fact.

Books.

Number of Volumes in the Library in	
1912	7,000
Number of Volumes Donated in 1913	200
Total	7,200

Between 4,00 and 5,00 of these books are catalogued.

Journals.

There are 105 current journals on the shelves, bound up to July 1st, 1913.

The total attendance in the Library during the year was 879, or a daily attendance of 3.

Especial thanks is due Miss Annie Goff, our

efficient Librarian and stenographer for the work accomplished by her during the past year.

Respectfully submitted,
IRVIN LINDENBERGER, Chm.
J. A. O. BRENNAN,
DAVID C. MORTON,
B. W. BAYLESS,

Library Board.

REPORT OF THE MILK COMMISSION.

To the President and Members of the Jefferson County Medical Society:

Gentlemen:

Your Committee wishes to make its Seventh Annual report. The original work outlined for this Commission was that it should arrange for a clean, pure milk supply free from the germs of tuberculosis or any other infectious disease. For the first year this milk was used principally for infant feeding, but as time wore on, certified milk began to be used in many homes exclusively until at the present time about twenty times as much is being supplied now, as was used to the end of the first year. Not only has quantity of certified milk increased, but we are delighted to report that we have had very little trouble in keeping it up to the standard set by the American Commission of Certified Milk. The tuberculin test is applied yearly to our Certified Herds. Last year we found only one cow reacting in our entire herds of 450 cows, this proves that tuberculosis can be eradicated from herds by careful examinations. During the last year we have had very few complaints either from doctors or from the users of Certified Milk. Whenever we do get such a complaint we immediately take steps to find out the cause of the trouble. We are also pleased to find that dairies producing certified milk have served to educate dairy men in their neighborhood how clean milk can be produced, and in this way the standard for market milk has been greatly improved in this city.

We regret to record the loss our Commission has sustained in the death of Dr. Cecil, one of the original members of our Commission. Although he was not able to devote much time to this work, still his advice was always sought, and much appreciated by the members.

CUTHBERT THOMPSON, Chm.
BEN CARLOS FRAZER, Secy.,
J. ROWAN MORRISON,
HENY ENOS TULEY.

ELECTION OF OFFICERS.

President directed the Secretary to call the roll. Moved by W. F. Boggess that roll call be dispensed with. Seconded and duly carried.

Nominations for President were then called for and the following names were placed in nomination. Carl Weidner, Sr., nominated C. H. Harris. Seconded by Ap Morgan Vance and E. S. Allen. Dr. Grant nominated Harry J. Phillips. Seconded by W. F. Boggess. President appointed

Drs Keith, Yeatts, Hall and Trawick as tellers. After balloting the tellers announced that C. H. Harris had received a majority of votes cast.

Moved by Dr. Grant that the election of Dr. Harris be made unanimous. Seconded and so ordered. President appointed Harry J. Phillips and D. Y. Keith to escort the new president to the chair.

Nominations for First Vice-President were then called for, and the following nominations were made:

Dr. Dunning S. Wilson nominated Claude G. Hoffman. Seconded. Irvin Abell nominated A. W. Nickell. E. S. Allen nominated E. F. Katzman.

Dr. Hoffman received the majority of votes cast and was declared elected First Vice-President.

Nominations for Second Vice-President: E. L. Henderson nominated D. Y. Keith. It was moved and seconded that the nominations be closed and the secretary instructed to cast one ballot for Dr. Keith for Second Vice-President. So ordered.

Nominations for Secretary: Dr. W. B. Gossett nominated E. L. Henderson. It was moved and seconded that the nominations be closed and the secretary instructed to cast one ballot for Dr. Henderson. So ordered.

Nominations for Treasurer: Jno. J. Moren nominated A. C. L. Percefull. It was moved and seconded that the nominations be closed and the secretary instructed to cast one ballot for Dr. Percefull as Treasurer. So ordered.

Nominations for Judicial Council: W. F. Boggess nominated Geo. S. Coon. Sam P. Meyers nominated W. Barnett Owen. Virgil E. Simpson nominated S. C. McCoy and E. L. Henderson nominated Barnard Asman. It was moved and seconded that the three names receiving the highest number of votes on the first ballot be declared elected. After balloting, the tellers announced the following elections: W. Barnett Owen, S. C. McCoy, Barnard Asman.

Drs. Owen and McCoy having received the highest number of votes, respectively, were declared elected for the full term of two years each, and Dr. Barnard Asman was declared elected to fill the unexpired term of W. T. Bruner.

Nominations for Executive Committee: E. Y. Roberts nominated Robt. T. Pirtle, J. Rowan Morrison nominated David C. Morton, Jno. J. Moren nominated J. Garland Sherrill, E. W. Stokes nominated W. C. White, Virgil E. Simpson nominated Harry J. Phillips.

Moved and seconded that the number of names receiving the highest number of votes on the first ballot be declared elected in like order.

Drs. Phillips, Morton and Sherrill, having received the highest number of votes cast were declared elected members of the Executive Committee for the period of two years.

The society then adjourned.

A. C. L. PERCEFULL, Secretary.

COUNTY SOCIETY REPORTS

Carlisle—The Carlisle County Medical Society met in the office of Dr. Geo. W. Payne, Bardwell, Ky., December 2nd, 1913, at 10 A. M., with the following members present: Drs. W. Z. Jackson, J. F. Dunn, and R. F. Hocker, of Arlington; G. W. Payne and T. J. Marshall, of Bardwell. We had the pleasure of entertaining the Rev. Bro. Hutton, of Arlington.

In the absence of both the President and Vice President, W. Z. Jackson was elected president pro tem.

J. F. Dunn read a paper on the "First State of Labor."

T. J. Marshall read a paper on the "Second and Third Stages of Labor." All present entered into the discussion.

The society then adjourned to the Richardson Hotel for dinner, and reconvened at 1 P. M.

R. T. Hocker read a paper on "Puerperal Fever," which was discussed by Payne and Marshall.

The following officers were elected for the year 1914: President J. F. Dunn, Arlington; Vice President, H. A. Gilliam, Milburn; Secretary, T. J. Marshall, Bardwell; Treasurer G. W. Payne, Bardwell; Censor R. T. Hocker, Arlington.

Motion made and carried that the society adopt resolutions expressing our sympathy to H. T. Crouch and W. L. Mosby, they both being confined to their rooms on account of illness.

The society adjourned to meet in Arlington the first Tuesday in March.

T. J. MARSHALL, Secretary.

Christian—The Christian County Medical Society met in regular session in the Avalon, Hopkinsville, Tuesday, December 16th, at 1:30 P. M., with President Stites presiding. The members present were F. M. Stites, J. W. Harned, Austin Bell, T. D. Rudd, M. H. Rozzell, J. E. Johnson, Andrew Sargeant, J. H. Donnelly, E. L. Gates, F. H. Bassett, G. W. Lovin, O. L. Barnes, J. H. Rice, S. H. Williams, W. A. Lackey, D. H. Erkiletain, B. A. Caudle, J. L. Barker, J. A. Southall, W. E. Reynolds, H. C. Beazley, H. W. Watts, and W. S. Sandbach.

As this was the annual meeting for the election of officers after the reading and adoption of the minutes of the last meeting the President called the election.

J. L. Barker moved and it passed that the election be made by nominations. Drs. Gates, Watts and Bassett were nominated for president, and only after the third ballot that Dr. Watts was elected over Dr. Gates, by two votes. The rest of the officers were elected by acclamation and resulted as follows:

President, H. W. Watts; Vice President, E. L. Gates; Secretary-Treasurer, W. S. Sandbach;

Censor, J. H. Rice; Delegate, F. M. Stites and W. S. Sandbach.

As a compliment to W. S. Sandbach for his services as Secretary, Dr. Barker moved and it was passed unanimously that the society pay Dr. Sandbachs railroad fare and hotel bill while he attends the State Meeting at Newport.

The President appointed a Committee composed of Drs. Erkiletian, Rice and Williams to draw resolutions on the death of L. J. Harris.

B. A. Caudle and **E. L. Gates** presented an exceedingly interesting clinical case of inherited syphilis.

As we had no program for this meeting we adjourned, everyone feeling good with a unanimous support of the officers and the prospects better for a larger and better society than ever before.

W. S. SANDBACH, Secretary.

Daviess—The Daviess County Medical Society held its greatest December meeting on the 16th. Forty-seven members were present.

In looking over the hall we saw that venerable and honored member, C. H. Todd, who was assistant surgeon with Lee at Gettysburg, and who was elected president of the Kentucky State Medical Association at Frankfort in 1878 and presided at Danville in 1879 when the monument to McDowell was unveiled. That other ex-President of the State Society, the handsome and genial D. M. Griffith, who is able to speak for himself. Also the President-Elect J. W. Ellis, from whom I withhold comment till you hear him at Newport next October. If you are not proud of him then I shall be surprised. Another member was present, of whom we are very proud, S. J. Harris, the silver-tongued orator of Philpot. He followed Pickett in his famous charge at Gettysburg. Has practiced medicine at Philpot, this county, for over forty years; was county physician for twenty years; served one term as president of our society, but has always been too busy to hold an office in the State Society.

J. W. Ellis read a paper on medical ethics which we will send in for I am sure everyone will read it with pleasure and profit.

J. H. Thorpe late of Beech Grove, McLean County, was elected to membership.

R. C. Foster, who recently came from Oklahoma, made application for membership.

The annual election of officers then took place with the following result.

President, J. M. Stuart; Vice President, Z. H. Shultz; Secretary-Treasurer, J. J. Rodman; Delegate, J. T. Dixon; Censor, J. L. Carter.

The society then adjourned to the dining room of the Methodist Memorial Church and did justice to a dinner which the ladies had prepared at the suggestion of the city society.

At the afternoon session some interesting cases were discussed.

J. J. RODMAN, Secretary.

Franklin—The Franklin County Medical Society met in the office of Drs. Williams & Mastin, Frankfort, Ky., Jan. 5th, 1914 at 11 A. M. in social session. Present: G. A. Budd, G. H. Heilman, N. M. Garrett, Curtis Austin, of Bagdad; E. E. Hunne, Johns Hopkins, F. W. Mastin, U. V. Williams, J. W. Hill, L. T. Minnish, W. Montfort, Jno. Patterson, A. Stewart, J. S. Wilson.

U. V. Williams presented a case of bronchopneumonia in an infant of nine months with history and treatment, discussed by all the doctors present.

N. M. Garrett presented a paper on "Management of Labor in Contracted Pelves," in which he reviewed the history from over a thousand cases, in which the subject was elaborately presented, discussed exhaustively by all the members present. After which a vote of thanks was presented to Dr. Garrett for his excellent paper.

G. A. Budd and **A. Stewart** were appointed to prepare papers for the next meeting, which will convene on February 2nd, 1914, at the same place. After which the society repaired to the Manhattan Cafe where an elegant buffet luncheon was served, which was as ably discussed and as fully enjoyed as were the intellectual proceedings.

The society then adjourned.

U. V. WILLIAMS, Secretary.

Harrison—The Harrison County Medical Society met November 3rd, as guests of M. McDowell. The meeting was called to order by President M. McDowell. Minutes of last meeting read and approved. Members present: Rees, Wood, Givens, Smizer, Martin, N. W. Moore, Wells, Midden, Best, W. B. Moore, Lail, McIntire, Mussleman and I. A. Shirley, of Winchester.

Committee of three appointed to arrange for a banquet at the December meeting.

N. W. Moore reported fatal case of poisoning by wood alcohol.

R. W. Wood presented a man 47 years of age with chronic suppurating sinus in lower third of femur of twenty years duration, patient also had large amount of albumin in urine. This case was discussed freely.

M. M. McDowell read a paper on "Treatment of Infected Wounds." Discussed by J. E. Wells, J. M. Rees, N. W. Moore, Mussleman and Givens.

J. Martin, J. M. Rees and **W. B. Moore** made talks on "Anaphylaxis."

I. A. Shirley gave us a splendid talk on "Hookworm," and heartily thanked the members for the support given him during the campaign in this county.

The society adjourned to Dr. McDowell's dining room, where an elegant supper was enjoyed by all present.

W. B. MOORE, Secretary.

Harrison—The Harrison County Medical Society held its December meeting at Elks' Home, December 1st. After the banquet, the society

was called to order by President M. McDowell. Members present: H. T. Smizer, Wells, Boyd, Mussleman, Givens, Wood, Patterson, Lail, Yyles, Phillips, Swinford, Vanderin, Petty, Carr, Martin, Rees, Best, N. W. Moore, Midden, McDowell, W. B. Moore, J. W. Pryor, of Lexington.

On motion the chair appointed a committee to petition the next legislature to pass the bill regulating the practice of nursing in this state.

The election of officers for 1914 resulted: H. T. Smizer, President; B. B. Petty, Vice-President; W. B. Moore, Secretary; W. F. Phillips, Treasurer; Dr Carr, Censor, and L. S. Givens, Delegate to State Meeting.

The officers for 1914 having been chosen J. W. Pryor gave a stereopticon lecture on the development of bones which was very instructive and showed the doctor had done a great deal of original work on the subject.

Meeting adjourned to meet January 5, 1914.

The society has accomplished much during the year. We can and will do better in 1914. Three members failed to pay their dues this year but we hope they have seen the error and will return to the fold.

W. B. MOORE, Secretary.

Henderson—The Henderson County Medical Society held its annual banquet on the evening of December 30th. The banquet was an unqualified success.

Several visitors were present, as invited guests, and every one said that it was one of the most enjoyable affairs the society has ever held. Although the night was very inclement, there were quite a number of the physicians in from the country. Dr. Graham acted as toastmaster, instead of "roastmaster" as is frequently the case, and he seemed to have something good to say about everyone. In calling upon Dr. Albert S. Denton of the country, the toastmaster spoke very feelingly about the trials, merits and pleasures of the "Country Doctor," and recited a few lines from Will Carleton's celebrated poem of that name:

"He has learned that Death is master both of
Science and of Art;
He has done his duty fairly, and has acted out
his part,
And the strong old country doctor,
And the weak old country doctor,
Is entitled to a furlough for his brain and for his
heart."

Then giving Dr. Denton as a toast "The Need of a Furlough," to which the doctor responded in a very interesting talk.

Another very interesting talk was made by the Rev. Dr. Adams of the Methodist church in responding to the toast, "The Installment Plan."

This is my first meeting with this society in their annual banquet, since I have been located in Kentucky, and I think it one of the best ways to bring the doctors together, and in social meet-

ings forget their differences, their trials and worries in the pleasant jest and story of an annual feast.

I enclose you a copy of our annual programme.

Hoping this this year will be the best in the history of Kentucky medicine.

B. J. NEARY, Secretary.

Knox—The annual election of officers of Knox County Medical Society was held December 28th. Officers for 1914 are as follows: S. C. Jones, Barbourville, President; Geo. T. Corum, Wilton, Vice President; C. L. Heath, Lindsay, Secretary-Treasurer.

We will have program for the entire year, will send it in as soon as completed.

C. L. HEATH, Secretary.

Todd—The Todd County Medical Society met at Elkton, December 3rd, 1913. It being the regular annual business meeting. Election of officers: President, C. M. Givens, of Trenton; Vice President, J. M. Robinson, of Guthrie; Secretary-Treasurer L. P. Trabue; Delegate to State Meeting, R. W. Fry, of Trenton; Alternate, W. E. Bartlett; E. T. Riley, of Trenton, to Board of Censors.

L. P. TRABUE, Secretary.

Laurel—At the annual meeting of the Laurel County Medical Society, December 17, 1913, the following officers were elected for the ensuing year:

President, J. W. Crook; Vice President, H. V. Pennington; Secretary and Treasurer, Oscar D. Brock; Censor, H. S. Pitman; Delegates, P. E. Bryant and H. V. Pennington.

O. D. BROCK, Secretary.

Muldraugh Hill—The Muldraugh Hill Medical Society called to order at 11:30 A. M. by Secretary in the courthouse at Mumfordsville, twenty-two members being present.

The Secretary called attention to the fact that no President or Vice-President being present, the first business at hand would be the election of a temporary chairman. R. C. McChord, of Lebanon was chosen by acclamation.

The Secretary read a financial statement the minutes being passed.

Hon. W. H. Strange, of Mumfordsville, delivered an address of welcome to the society in a masterful manner.

Curran Pope responded in his inimitable style. Adjournment for dinner.

After dinner the society reconvened for the election of officers. Curran Pope was elected President unanimously. G. C. Hall was re-elected Secretary.

On motion of R. C. McChord a Committee composed of Drs. Pope, Riggs, and Hall was appointed to redraft the constitution and by-laws together with the readjustment of the geographical

outline of the Society. Carried. Report to be made in April.

A letter from Dr. W. A. Ligon was read by the Secretary requesting his withdrawal from the society on account of ill health. On motion by the Secretary, the society voted Dr. W. A. Ligon an honorary member of the society and wrote him a letter of condolence.

Scientific Program.

C. T. Riggs reported a case of "Cystic Fibroma of the Neck," lying under the sheath of sterno cleido mastoid muscle.

H. E. Tuley being absent Dr. Trawick opened the symposium on Social Hygiene by making a statement defining the limits of social hygiene, its scope and the hopes of its adherents after which he read a paper on "Heredity and Child Welfare."

H. J. Farbach read a paper on the "Problem of Sex Education."

Curran Pope delivered an address on "Social and Sex Development in its relation to the Neuroses and Psycho-Neuroses."

H. J. Farbach opened the discussion and spoke upon the difficulty of getting a discussion on such subjects, and the erroneous instincts that repressed it. We should proceed slowly among the general public but there should be no hesitation among lawyers, ministers, doctors, or professional men discussing such subjects. Advocated sane sex education and health certificates at time of marriage.

R. C. McChord complimented the symposium and the authors of the papers. Thought it was a most important subject and one often neglected. Thought sex education should be begun early and treated tactfully. Thought more deaths caused by gonorrhoea and syphilis. Discussion of subject should be open and there should be but one standard of morals. Thought women partly to blame as they allow immoral men to be received in their houses and marry them.

H. P. Honaker thought that early sex education was the solution of the difficulty; that the mother was the proper teacher but some one must teach the mother. It will take more than a generation to accomplish the task. Parents should be the confidential advisers and friends of the children.

The medical profession have a duty to perform in instructing the laity along sex matters and should take this task with them in their daily rounds. We should do right for right's sake and put aside fear of law or consequences.

B. J. Bolin complimented the presentation of the subject. Thought heredity and environment cast the whole of our lives. Spoke of the incidence of heredity in institutions of feeble minded and insane due chiefly to syphilis and alcohol. Spoke of the curse of licentiousness and thought that if people were as continent as animals a greater race of people would be brought forth.

Broad educational principles should underlie our treatment of our people in our educational campaign.

J. J. Mudd complimented the readers of the papers. Thought that the medical profession might reach some people but there were certain classes that no one could reach. Thought that alcohol was responsible directly for the cause of much crime and venereal disease.

S. F. Richardson called attention to the fact that woman's education prompts her to look up to men in her home life and makes her trustful towards all men. Was surprised at the tender age in which the child seeks enlightenment.

J. D. Trawick thought eugenic conscience of profession was awakening. Must take study of child through parents. Thought matter of woman's dress over estimated. Has nothing to do with education of small child in sex matters. This dress question applies only to adult males. Thought hypogenetic tendencies that crop out in children due to characters or potentialities in ancestors. Must teach more than simple truth in sex education but must teach also morality and refinement.

Curran Pope in closing said we inherit only tendencies or trends. Spoke of difficulty that people have in giving instruction in sex matters. Quoted St. Ignatius Loyola as to importance of early education up to age of seven. Don't be a liar to the children because it lays up trouble for parent; causes disrespect. Thought it a good sign that such plays as "Damaged Goods" could be presented to the public in serious manner.

J. B. Shacklette read a paper, "Is the Demand for the Services of the General Practitioner Growing Less?"

G. C. Hall, opening the discussion, referred to refraction work done by the general practitioner. Should not be attempted unless thoroughly done by use of drops and retinoscopy which was easy to learn and required no expensive apparatus. In cases of foreign bodies in oesophagus or air passages the general practitioner was often tempted into injudicious treatment under the idea that something must be done. In cases of great cyanosis or impending suffocation low tracheotomy should be done at once and patient rushed to hospital. In cases with no urgent symptoms the patient should be sent to one versed in bronchoscopy and X-ray plate made to locate the offending substance and extraction done through natural passages. Blind passage of sounds, probangs, etc was condemned unreservedly.

J. D. Trawick enjoyed the paper. His own father was a general practitioner. The general practitioner's work should not be growing less. The field is broader now than it ever was. General education among physicians is better. Physicians are becoming interested in social problems and improvement of general physical

well being of community. Rural physician is greatest factor for uplift of his community.

C. T. Riggs spoke of the arduous labors of the old time practitioner. Thought that the general man should not dabble in special lines. Had tried refraction but given it up.

C. C. Carroll thought that doctors should not complain. As a class they they were well fed. Must not degrade the profession by putting it on a money basis for they were humanitarians primarily and should be proud of such a calling.

Curran Pope thought that if we eliminated the quack, charlatan, etc., there would be much less reason for the general practitioner to complain. There are no secrets among specialists.

J. B. Shacklette disclaimed in closing any reference to secret specialists and referred to them as irregulars. Thought no one should attempt work they can not successfully treat. Thanked the gentlemen for their discussion.

R. C. McChord closed the program by reading a paper on "The Treatment of the 'So-called' Inoperable Cases of Cancer of the Cervix."

Discussion opened by Dr. Farback, who complimented the doctor on the simple and direct manner in which he presented the results of his researches. Dr. Farback spoke of the efficiency of the vulcan soldering iron and the necessity of watching the temperature of the surrounding tissues.

J. J. Mudd reported several interesting cases of cancer of the cervix.

C. T. Riggs moved to extend to the Hart County Medical Society a vote of thanks for their kind hospitality. Carried.

R. C. McChord in closing discussion thanked the members for the interest and said that it was surprising how much good was accomplished by this method of treatment. He cited several cases of his own that had been so treated with great improvement.

No farther business coming before the society the meeting was declared adjourned to meet again in April at Elizabethtown.

It was a matter of regret that more of the members in the other counties did not attend. Several well beloved and familiar faces were absent. We hope to see them at our next meeting.

GAYLORD C. HALL, Secretary.

Pendleton—The Pendleton County Medical Society met at Butler, Ky., on Wednesday, October 8, 1913, with the following members present: Drs. Blackerby, Brown, Clark, Daugherty, Hopkins, Woolery, John E. Wilson, Yelton, Caldwell, J. A., from Newport, and Dr. Eckler, who has recently moved into the county from Harrison county.

The meeting was called to order by President O. W. Brown. After reading journal of last meeting and roll call, we proceeded to business.

J. N. Blackerby made a motion that the secretary write the State Secretary and find out what action has been taken in regard to the Anti-Narcotic Law that is pending in the U. S. Senate. Motion carried.

We then had a splendid report of clinical cases by **J. A. Caldwell** and others present.

Afternoon Session.

First on the program for the afternoon session were papers by Dr. Ellis and Dr. Nichols, but neither being present nor ready, John E. Wilson read a paper on "Preventive medicine."

O. W. Brown read a paper on the same subject, the serum side of it. He rendered a splendid account of himself as he always does.

This closing the business of the day, we adjourned to meet on the second Wednesday in November.

W. A. McKENNEY, Secretary.

Pendleton—The Pendleton County Medical Society met at the office of John E. Wilson in Butler, on Wednesday, November 12, 1913, with the following members present: Beckett, Blackerby, Brown, Clark, Ellis, Kendall, McKinney, John E. Wilson, W. H. Yelton. Meeting was called to order with the President in the chair. After roll call and a reading of the journal we proceeded to the business of the day.

On motion of W. H. Yelton, that the chair appoint a committee of three to draught suitable resolutions of respect to V. E. Smith, whose death occurred since our last meeting. Motion carried.

The next thing in order was the nomination of officers of the society for next year, to be voted for at our next meeting. The following were placed in nomination: J. Ed Wilson for President; J. F. Daugherty for Vice-President; W. A. McKenney for Secretary and Treasurer; Dr. Woolery for Assistant Secretary; H. C. Clark for Delegate to State Meeting, after which nominations were closed. The Program Committee was instructed to have our programs ready to distribute at our next meeting. We then had a few reports of clinical cases.

O. W. Brown read a paper on "Atypical Pneumonia," which was discussed pretty thoroughly.

J. N. Blackerby read a paper on "Fracture of Long Bones, which elicited some discussion.

We then adjourned to meet December 10, 1913.

W. A. McKENNEY, Secretary.

Pendleton—The Pendleton County Medical Society met at the office of John E. Wilson in Butler, with the following members present: Drs. Beckett, Blackerby, J. M. Blydes, Brown, Clark, Cram Daugherty, Ellis, Hopkins, C. H. Kendall, McKinney, Nichols, John E. Wilson, J. Ed Wilson, W. H. Yelton.

The meeting was called to order by President

Brown, and after reading of the minutes and roll call we proceeded to the business of the day.

A resolution of respect to the memory of Dr. V. E. Smith was read, and ordered spread upon the minutes of the meeting and a copy sent to the Journal.

The officers nominated at our last meeting were elected to serve for the incoming year 1914.

After hearing some good reports of clinical cases and the reading of two good papers, we wound up the old year with a splendid attendance and a jolly good feeling of a kind fraternal spirit to all the members of the society. Thus closed a very profitable year to most of us. We then adjourned to meet the second Wednesday in January, 1914.

W. A. McKENNEY, Secretary.

Scott—The Scott County Medical Society met in regular session at the City Hall, December 18, at 10 A. M., J. E. Pack, President, presiding. Those present were Drs. Knox, Pack, Downs, Barlow, Johnson, Heath, Porter and allphine.

The following officers were elected for 1914: L. F. Heath, President; Wm. Mason, Vice President; E. C. Barlow, Secretary and Treasurer; L. F. Heath 3rd year Censor; H. V. Johnson, 2nd year Censor; J. E. Pack, 1st year Censor; W. B. Salin, Delegate; L. F. Heath, Alternate; R. W. Porter, Referee.

The society decided to meet quarterly on the first Thursday. Also to have program for meetings printed in advance.

E. C. BARLOW, Secretary.

Taylor—The Taylor County Medical Society met in the parlors of the New Merchant's Hotel, Campbellsville, on December 4, 1913, at 5 P. M. Present: Drs. Heistand, Reesor, Gowdy, O. M. Kelsay, S. H. Kelsay Black Buchanan and Atkinson.

The pre-prandial hours were spent in social converse, report of cases and reminiscences, serious, humorous, entertaining and instructive.

At 7:30 we adjourned to the dining room to discuss quail furnished by Dr. Heistand and the trimmings prepared by mine host Mr. Hoskins, of the New Merchant's Hotel, but the appearance of the table indicated that Mrs. Hoskins was the presiding genius in its preparation.

Following the feast the society adjourned to the parlors and engaged in a social session, the memory of which will linger with us long.

Officers were elected for the year 1914 as follows: President, O. M. Kelsay; Vice President, O. R. Reesor; Secretary-Treasurer, J. L. Atkinson; Delegate, E. L. Gowdy.

The reading of the papers prepared for this meeting was postponed till the next regular session, January 8, 1914.

J. L. ATKINSON, Secretary.

Whitley—The meeting of the Whitley County Medical Society was called to order and C. G. Ellison was elected temporary chairman in the absence of our president.

C. A. Moss read a paper on the use of salvarsan in the treatment of syphilis with histories of twenty-six cases. The paper was discussed by all doctors present.

A. W. Alsip delivered a talk on "Pellagra and Its Causes," and said paper was discussed by the doctors present.

The following officers were elected for the year 1914:

C. G. Ellison, Williamsburg, President; W. H. Parker, Williamsburg, Vice-President; C. A. Moss, Williamsburg, Secretary and Treasurer; L. B. Croley, Williamsburg, Delegate; S. S. Brown, Mt. Ash, Alternate; S. S. Brown, Mt. Ash, B. J. Edwards, Corbin, and J. H. Parker, Corbin, Board of Censors.

J. D. Adkins passing by stopped and greeted the members of the society.

The members were disappointed as they had expected to have Dr. Miller, of Knoxville, present to deliver a paper, but he was unable to attend.

There being no further business, the meeting was adjourned to the next regular meeting at Corbin, Ky., the first Thursday in February, 1914.

C. A. MOSS, Secretary.

Warren—The Warren County Medical Society met in regular session, September 17th, at 1:50 P. M.

In the absence of the president and secretary, Dr. Arnold was chosen as temporary chairman, and J. W. Lewis as secretary.

J. H. Blackburn made a report as Chairman of the Finance Committee for the entertainment of Kentucky State Medical Association. The members of the Warren County Medical Society contributed \$380.00; the business men of Bowling Green, \$22.50, making a total of \$602.50. The total amount expended for entertainment was \$394.28, which left a balance of \$208.28.

Dr. Stone moved that a purse of \$25.00 be given to Mr. Will Sumpter for his services in the management of the barbecue, which motion was seconded and carried by a unanimous vote.

The society unanimously voted to pro rata the remainder of the money on hand, and return to the business men who had contributed.

Drs. Blackburn and **Martin** reported a case of "Acute Hemorrhagic Pancreatitis," which was discussed by several members of the society.

After which the meeting adjourned till next regular time of meeting.

J. W. LEWIS, Secretary Pro Tem.

EDITORIAL

ALL ABOARD FOR NEWPORT.

Happening to have a few hours to spare while sojourning in the muddy city of Cincinnati a few days ago, I concluded to take a run over to Newport to see the boys with whom it has been my pleasure to mingle once a year for a long, long time during the meetings of the K. S. M. A. I first found brother Anderson from whom I inquired for that famous hotel that he spoke of in such highly and gilt edged language at Bowling Green when inviting the doctors to visit Newport this fall; you remember don't you, Mr. Secretary, that he said it soared high up into the clouds, that the mountain on which it was situated rivaled the highest peak in the Alps; and that he said in addition that Mount McKinley was not a circumstance to it when it came to cloud climbing? Well he just would not let me go to that famous hostelry until I had broken bread with him: to have done otherwise would not have been W. W. Anderson, so he kindly took me in and gave me a splendid dinner presided over by his accomplished sister. After the meal was over he hustled me into an auto and seated with him and my good brother Stine after a hearty hand shake from another of the same kind of the best of men, Dr. Phythian, we almost flew to the place of refuge for the Kentucky State Medical Association next fall. There we found an ideal summer resort, almost if not really equal to the famous Adirondaeks or the points of the world wide Virginia and West Virginia mountain watering places to which the elite are prone to wander when the Sun gets perpendicular over our heads. The "Blue Grass Inn" is in the midst of the mountains minus the brush—hilly as hilly can well be while at the same time it is surrounded with blue grass and a beautiful woodland: a great treat

to the city doctor where he can be wafted to quiet slumber by the music of the hooting owl and nightingale untouched by misquitoes and flies. To the country physician it will be an entire change of scenery and he will escape the hum and hustle of the city with its ever rattling street cars and many other things to chase dame sleep away. The house is grand, a beautiful structure with capacious halls, porches and three or four dining rooms: if you don't like the looks of one you can take another: in fact if you don't care for any on the first floor or the Grill room in the basement you can take one up in the tree for we actually saw a table, a sure enough table with legs and body made of plank resting quietly on the limbs of a stately oak quite a distance from the ground. No noise there to disturb the quiet of discussion or other distractions where even the clarion and lion-like laugh of a "Herman" can not long remain on account of the rolling, frolicking incline of the voice in this beautiful mountain land. But ten minutes street car run to Cincinnati if you like but from what I saw you need not leave the ground for something to cut the dust or cobwebbs from your throat or so much as to fight an imaginary snake (for all that have ever been known there are but imaginary ones) for ample provision has been made for all such contingencies. From what I saw that dismal winter day I can't imagine a more appropriate or ideal spot within the confines of our beloved Commonwealth at which we could possibly assemble for our annual pow wow next fall. So boys let your only thought be "On to Newport with our wives, sweethearts and selves" when the time comes for the meeting and my word for it all will be well so far as the place of meeting goes.

Yours truly,

I. A. SHIRLEY.

TUBERCULOSIS.

A few months ago the Campbell-Kenton Medical Society offered a prize to the scholar of the High School for the best paper on tuberculosis. The first prize was awarded to Walter Binder, of the Junior Class. It is so good that we reproduce it here:

"My arm is most mighty.
I spare none, rich and poor, young and old,
 alike they fall in my path.
My fingers are small put powerful.
The flies and mosquitoes are my helpers.
I thrive in filth and unclean places.
I live in exposed milk and food.
I float in the water of rivers.
I fly in the air.
I am unseen but terrible.
I am a fiend, torturing my victims slowly to death.
I attack the weakest first.
I besiege the lungs and throat.
I am in the food you eat, in the water you drink, in the dust you breathe.
I hate the sunlight.
Fresh air is my deadliest enemy.
Doctors are my ruin.
Pure water is poison to me.
If these are not used, I will glory,
I will regain my former strength,
I will conquer the earth,
I am TUBERCULOSIS.

SCIENTIFIC EDITORIALS.

TELEPATHY.

Can the soul or the mind or the body travel through the limitless spaces of the air and the earth and produce in a far distant human being these peculiar feelings, or experiencings of sensations, that we call Mental Telepathy? Where telepathy is spoken of in the unscientific manner, and often with undue levity, the speaker does not seem to realize that in the true meaning of the Greek word, *tele*, a far off, and *pathos*, in sympathy with, but suffering conveys an entirely different idea from that generally understood by the average layman. Is there such a thing as Mental Telepathy? Weighed in the cold scales of science and measured by the world of materialistic manifestations, we would be compelled to come to the conclusion that no such thing really exists as mental telepathy.

"Horatio says, tis but our phantasy
And will not let belief take hold of him
Touching this dreaded sight twice seen by us."
—(Hamlet, Act I, Scene I.)

There have appeared within the recent year a number of articles upon this subject and others touching more or less upon it, but probably the most interesting discussion that has

taken place in a long time concerning thought-transference appeared in *Bedrock* (London, September) under the title "The Truth About Telepathy." In this a "business man" contributed his experience in connection with an offer he had made of \$5,000 for satisfactory proofs of mental telepathy. The "juicy peach" remains still unclaimed and is likely, in the opinion of the reviewer, to remain securely out of reach of even such distinguished investigators as those that comprise the "Society for Psychical Research." We quote from the *Literary Digest* the following interesting discussion between Sir Oliver Lodge, Principal of Manchester University and the "Business Man."

"I do not know what evidence there may be of 'wagers'; but let me ask, in all seriousness, what are the reasons for making the defamatory statements which I have put into italics? They certainly are not true, if intended to refer to a ease I have in mind; and they are unworthy of the Man or Science to whom, in all good faith, liberal payment was offered for particulars supposed to be available, but which he failed to supply. He had often declared that, to him, telepathy is 'perfectly clear and certain'; and nobody ought to doubt the sincerity of Sir Oliver Lodge's belief; but, requiring facts and not beliefs, I waded through volumes of 'records' to which he had referred me, and worked back to his first experiment with a square and a cross, as described by him in a letter to the editor of *Nature*, dated June 12, 1884. Being unable to find anything but statements that would not bear to be looked into carefully, or accounts of phenomena that had occurred under conditions in which trickery was always possible, I prest Sir Oliver Lodge for definite information, and finally got from him this gem:

"I am surprised that you imagine that incontrovertible evidence can be obtained at all in an inductive problem."

"After writing to many others, I caused the following advertisement to be inserted in *The Times* for several days in August, 1911:

"TELEPATHY"

"The sum of £1,000 has, during the past six months, been offered privately to the leading authorities and writers of repute on this subject for satisfactory proofs of so-called thought-transference, but not one single case could be found; and it has now been decided to advertise publicly for the particulars required. Persons applying to the undersigned are requested to name their own terms for evidence that will stand cross-examination, and to state whether or not their communications are to be treated as confidential, MATTHEW JARVIS, Solicitor, 4, Finsbury Square, E. C."

"There is no suggestion of 'wagers in the

above—only a plain statement of fact and a request that persons shall name their own terms; but, though the replies were too numerous to acknowledge the receipt of separately no evidence could be obtained. The advertisement was copied into many foreign and colonial newspapers, so that dupes all over the world were put on their guard against believing something that might not be true.

“Remembering that Sir. Oliver Lodge had specially vouched for the movements of a chair in the moonlight, on one occasion when he had tried to control a female medium for hours at a stretch, I next proceeded to arrange for the payment of £5,000 to any one who could perform or prove a case of levitation; and, on my informing Sir Oliver Lodge of this, he wrote: ‘To me these offers of money seem quite preposterous and never likely to obtain anything at all.’” So I took this as an indication that he was again unable to produce any proof. But, supposing I offered him a large fee for writing a book on some mental incursion into the realms of the unverifiable, would there be, in such an offer, anything objectionable to which a deaf and contemptuous ear should be ever turned; or would it be readily accepted by the Man of Science acting for the time being as a business man?

“It now appears strange to me that present-day members of the S. P. R. should attach any importance whatever to opinions and expressions of belief, instead of trying to prove facts. Perhaps they do not consider that there is any credit in believing what is merely true—because any fool can do that—and they find comfort in the Bergson-Lodge philosophy which has become fashionable because it is so ‘scientific’! You start by accepting something which may or may not be true, but which is highly improbable and has not been proved; and, on such a want of basis, you build up your system—making everything as obscure as possible in order that it may seem profound.

“I can give an amusing instance of how some members of the S. P. R. can be brought ‘to heel,’ for when I approached Sir W. F. Barrett (whom I take this opportunity of again thanking for his kind promise of help), he was very keen to assist me in finding a case of telepathy; and he was good enough to offer to call upon me the next time he came over to England from Dublin. He made no objection to being paid £1,000 for proofs, and his letters show that he was genuinely anxious to be of use in the matter; but, after seeing Sir Oliver Lodge in London, Sir. W. F. Barrett wrote to me:

“‘I could not undertake to prove the re-

sults of a long and difficult investigation to order or for a pecuniary offer.’

“My reply was to point out that I had not asked for any long investigation, but that I merely wanted one single case of telepathy, which he, as its father or discoverer, thirty or more years ago, ought to have no difficulty in finding for me. I never got one, however, nor did I have any better luck with Sir William Crookes, who was too busy with other scientific work to help me.

“I have no desire to advertise myself; and my name need not appear, though it is known to Sir William Crookes, Sir Oliver Lodge, and many others who are interested in this matter; but I shall be happy to place at their disposal all the information I have collected and to assist, as a business man, in getting at the facts. These, so far as they go, certainly confirm the statement of Sir Ray Lankester, on page 66 of the April number of *Bedrocks* ‘I say that Sir Oliver Lodge and his associates have not (in answer to the question “Does telepathy exist?”) given any demonstration of its existence nor even any evidence which makes its existence probable.’”

To the thoughtful and reflecting individual and without the slightest reflection upon the interesting work that is being done along these lines, the reviewer is constrained to believe that the “business man” is the “better bet.” Personally we have heard of some extremely interesting incidents connected with what was supposed to be thought-transference, but were never able to satisfy our somewhat materialistic attitude with the proofs that were adduced. To those, who have been most deeply concerned in these beliefs, we are inclined when they become angry at the request for proof to refer them to the well known lines, to express their feelings:

“We do it wrong, being so majestical,
To offer it the show of violence;
For it is, as the air, invulnerable
And our vain blows, malicious mockery.”

—(Hamlet, Act I, Scene I.)

Nor do we believe that in this materialistic world of ours, thoughts and sensations arising from a materialistic or non-materialistic body can enter space and like some pale ghost traverse almost limitless space and make definite endo-sensory impressions upon another individual. It is indeed unreal, unpractical, ghost like and makes us exclaim:

“What may this mean
That thou, dead corpse, again in complete
steel

Re-visits thus, the glimpses of the moon
Making night hideous and we fools of nature
So horrible to shake our disposition
With thoughts beyond the reaches of our
souls.”

—(Hamlet, Act I, Scene IV.)

Perhaps our position is rank heresy, but still weighed in the balance, the record lacks convincing materialistic proof of something that is absolutely against all known scientific laws. We will admit that it does not necessarily fail, because it does not conform to present known scientific laws, but there is no special evidence to justify our acceptance of mental telepathy as an established fact.

We are well wishers to all investigators. Perhaps it is early yet to expect results. What we want is not doctrine, theory or belief but facts. In the absence of facts, *demonstrable* facts, we believe that scientific skepticism is justifiable and that the attitude to be assumed is only of cordial well wishing to the investigators and a receptive state of mind for any real demonstrable results. From our standpoint we are inclined to believe that as yet the pole is not long enough to reach that \$5,000 persimmon.

The latest position assumed by our most estimable contemporary, Sir Oliver Lodge does not, and we say this with the most profound and unqualified respect, seem to us to clear the field by any means. We quote from the *Mobile Times* as follows:

"The possible existence of consciousness apart from brain (however obviously consciousness requires brain to manifest itself here and now) is not a phenomenon at all, but a hypothesis—one that I spoke of as eminently debatable, though I admitted that it was the working hypothesis to which I have been myself led by long continued study of a considerable range of obscure psychical facts. Such a hypothesis does not rest solely on the occurrence of simple telepathy, on which the present discussion hinges; it is sustained by a good deal more.

"The experimentally observed fact immediately under consideration is the transference of thought or mental impression between a few living people, i. e., between such as have the faculty sufficiently developed, without the use of their normal sense organs, the conditions of transfer being not yet known. But what the explanation of this fact may be is an open question. It may possibly be due to brain waves, or some kind of syntonic material or ethereal connection between brains; for, though I think that unlikely, it is what some people have suggested and provisionally hold, finding in it an obvious analogy with wireless telegraphy; and if that can be proved to be the explanation no question of consciousness apart from brain need arise, i. e., no such hypothesis would in that case be necessary to account for ample telepathy.

"The process would then take its place as an extension of, or addition to the already known methods of transmitting thought—speech,

writing, gesture, code signalling, etc. Some of these methods would seem mysterious to a savage, just as we are unacquainted with the mechanism of the process. On anything beyond affirming the bare fact I have been careful not to dogmatize, though I myself am inclined to maintain that telepathy is not a physical process, *pari passu* with the other or long known methods of communication, but is a sign or incipient outcome of a faculty and a method essentially different.

"But whether incipiently widespread or not, and however it be explained, the faculty of telepathic receptivity certainly exists in a few people, though even in them it is by no means always and under all circumstances available. In that respect it differs from an inorganic property like radio-activity—though that, too, appears limited to a few substances and is not conspicuous or widespread.

"It is sometimes said—Sir Bryan Dakin either says or clearly implies—that the existence of telepathy would contradict established knowledge. If that were true, it would indeed be an absurdity, but telepathy does nothing of the kind; it enlarges and expands, it opens up a new chapter, but it does not contradict. By psychical research our knowledge of fact is supplemented, but in no other way changed. The unwelcome facts will fit into the coherent scheme of science in due course, and will displace nothing already there, though they will remove some mistaken accretions—the beginnings of a premature fence or boundary.

"To sum up. Any one who limits his range of inquiry to the general categories of already acquired knowledge has a sufficiently rich and extensive field, and, by surrounding himself with a definite boundary, is in a very strong position. Entrenched in such a fortress, Sir Ray Lankester and those who think with him look with pitying eyes on us, who, after some exploration inside, have ventured outside the walls, and they regard with contempt any assertions as to what lies beyond the pale. They are like the orthodox mariners of old who limited themselves to the shores of the Mediterranean, cruising round its coasts and gradually becoming familiar with every port. The world as known to the ancients was their domain, and it was impious to sail out through the Pillars of Hercules into the ocean beyond. Venturesome explorers who transgressed those limits and from time to time returned with legends of times and other unusual phenomena were doubtless received with disapprobation and incredulity, still more so if they ventured to deduce the possible existence of a new continent, which as yet confessedly they had not reached, from evidences derived from drifting logs and a Sargasso Sea.

"Meanwhile, we are accused of lying, of

megalomania, of folly and of madness. Let it be so. I for one am in no hurry. I am not sorry that the present state of ignorance and prejudice surrounding this subject in the minds of a large number of scientific men in the year 1913 should be put on record, lamentable though it be, else posterity, familiar with a mass of developed knowledge, will hardly credit the curious obstruction which pioneers in this domain still have to encounter. Secure in the progress of the human race, we shall bide our time, cultivate our gardens and pass on before any wealth of fruits can be gathered in."

CURRAN POPE.

THE RESPIRATORY TRACT IN LEUCEMIA.

Dr. J. Safranel assistant to Prof. Onodi, of Budapest, has recently published an exhaustive article dealing with the pathological changes occurring in the upper respiratory tract in cases of leucaemia. He had occasion to examine 32 cases of leucemia all but one of which had applied to the medical clinic for general treatment, the one case having applied for throat treatment to the laryngological clinic. All forms of leucemia were seen, ten cases representing the lymphatic variety and twenty-two the myeloid form. He also observed several cases of pseudoleucemia.

The most pronounced changes in the upper respiratory tract were observed in the lymphatic cases in which the blood picture showed a great increase in the lymphocytes and lymphoblasts, and in which there was considerable enlargement of the lymphatic glands and the spleen.

Although the typical hyperplasia of high degree was most pronounced in the lymphoid tissue it was frequently observed in organs and tissues which normally contained no lymphoid cells. In the respiratory tract the cell invasion was most pronounced in the lymphatic tissue of the mouth and pharynx, viz: the pharyngeal, faucial and lingual tonsils, and in the uvula, the epiglottis and posterior wall of the pharynx. Histologically the lymphoid infiltration appears as closely crowded lymphoid cells, which displace the normal structures. The cells reach the capillaries but often leave the veins by passing through their walls to invade the epithelial tissue, the submucous layers and even the deeper structures, as the fatty and muscular tissues.

In the tonsils they pass through the fibrous capsule into the surrounding muscle and fatty structures. They have even been found invading cartilage of the larynx by passing through the perichonrium.

In the myeloid variety the blood contains many myeloid cells most polymorphonuclear neutrophile cells, myelocytes and myeloblast.

Eosinophiles and basophile cells are constantly increased in this form of leucemia. The bone marrow always shows characteristic changes, and the spleen, liver and lymphatic glands nearly always show considerable enlargement.

Clinically the cases were all characterized by progressively increasing anemia, emaciation, dyspnoea, digestive derangement, etc., indicating circulatory disturbances.

The symptoms referable to the upper respiratory tract were epistaxis, dyspnea, enlargement of the glands of neck and axilla.

Epistaxis should be classed with the cardinal symptoms of leucemia. It may occur at any stage of the disease and is often the first symptom to call attention to the disease. The point of bleeding is usually the nasal septum, where reddish or greyish yellow areas of infiltration are frequently visible. In some cases such areas are not visible, the entire nasal mucous membrane appearing very pale and waxy. In the cases presenting areas of infiltration necrotic and ulceration is not infrequent. Conditions similar to those occurring in the nose are also seen in the mucous membrane of the throat.

However the most characteristic change in the throat seen in leucemia is the lymphatic hyperplasia of the structures of Waldeyer's ring—especially in the faucial tonsils. The tonsils at times take on large dimensions, so that cases have been seen where the two glands overlap each other and impede respiration. In some cases the tonsils may be smaller and the faucial pillars, the uvula and the mucous membrane of the posterior pharyngeal wall become so infiltrated with cells that they reach several times their normal thickness.

The lingual tonsil may also become much enlarged. The enlarged lymphatic structures are all pale, of a yellowish gray color. Although leucemia occurs principally after middle age, it does occur in children, and it may readily be understood how the lymphatic enlargement of leucemia may be mistaken for a simple hypertrophy of the faucial and pharyngeal tonsil.

Zarmike, Burges and others have reported cases of mistaken identity where the children were subjected to operation and in whom death resulted from inability to stop the bleeding.

The enlargement of the submaxillary cervical glands, the pale waxy mucous membrane and the pallor of the skin should always be looked upon with suspicion and should at least lead to a blood examination before resorting to removal of tonsils.

In some cases the lymphatic hyperplasia is not limited to the lymphatic structures, but appears as a diffuse infiltration of the entire mucous membrane of the upper respiratory

tract—bringing about dysphasia and dyspnoea.

The lymphocytes become so crowded in the submucous tissue that they finally infiltrate the epithelial covering of the mucous membrane. This becomes thinner, and thinner and finally breaks. At such points as well as at mechanically abraded areas infection takes place and ulceration follows. Similar infiltration of the larynx may give rise to serious symptoms, as any portion of it can be involved in the process. It occurs there either in small circumscribed raised areas (nodules) or as a diffuse swelling of the membrane which may become so pronounced that it covers the false cords and epiglottis and interferes considerably with breathing.

Fortunately ulceration is less frequent in the larynx than in the pharynx and mouth. Hoarseness may result from the infiltration interfering with muscular contraction and proper approximation of the cords. It may also result from pressure of enlarged peritracheal mediastinal and peribronchial glands on the trachea causing stenosis. This stenosis has been so pronounced that tracheotomy had to be resorted to to prevent asphyxiation.

Stenosis of the trachea also occurs in anemia at times from the infiltration of the mucous membrane.

Although the changes in the mucous membrane of the upper respiratory tract are most pronounced in the lymphatic form of leucemia the myeloid form of the disease frequently presents similar conditions. The waxy pallor of the mucous membrane is nearly always noted. Swelling of the mucous membrane is less frequent. Hemorrhages are quite common in the myeloid form, due to cell growth in the blood vessels and destruction of their walls. The hemorrhages occur mostly from the nasal mucous membrane and have frequently led to a diagnosis of leucemia that had not been suspected. Later in the course of the disease the spleen and the lymphatic glands enlarge.

Regarding the cases of pseudo-leucemia, under which head the author places Hodgkin's disease, a leucemic lymphadenosis and lympho-sarcoma, it is pointed out that though they may present similar enlargement of the lymphatic structure as do the cases of leucemia, but that they can be differentiated by the blood picture, the blood in pseudoleucemia showing a normal blood count.

ADOLPH O. PFINGST.

HYPERTHYROIDISM.

As a result of the advances in our knowledge of the causation, and treatment of disease, surgery has made tremendous inroads upon the practice of medicine. Many of the most serious of diseases formerly considered medical have been transferred to the surgical side.

One of the most recent to be so transferred is that group represented by changes in the thyroid gland. This gland is the most accessible of the ductless glands, and is unquestionably the most important and interesting. Its importance is abundantly attested by its tremendous blood supply for such a small organ. This supply is equal to, and derived from, the same sources as the circle of Willis which supplies the brain. This fact alone is sufficient to indicate that this small gland, weighing one to two ounces, has a most important function in the animal economy. Furthermore, if this gland is absent at birth, or is completely removed afterward, development both mental and physical is retarded, and death finally results.

Interest has centered around the thyroid secretion and the questions, What is it? How does it leave the gland? and What function has it? are only partially answered. These partial answers are that it is a combination of iodine with globulin called iodothyron. That there are short lymph spaces in the thyroid that empty into the veins, and through these the iodothyron probably reaches the circulation. Its function is intimately connected with the function of the sex glands. In the female the thyroid undergoes physiologic enlargement at puberty, and during menstruation and pregnancy, and in some of the lower forms of animal life it is connected with the genital tract by a distinct duct. Certain of the toxæmias of pregnancy are thought to be due to a lack of thyroid secretion and have been treated, especially vomiting of pregnancy, by the administration of thyroid extract. Iodothyron is a vaso dilator and seems to occupy an antagonistic position to adrenalin, the action of the one counteracting in the organism that of the other.

Up to the latter part of the last century exophthalmic goitre was looked upon as a medical disease, except in rare instances. The conception of its etiology was very vague. Disease of the central nervous system; of the vasomotor nerves; of the sympathetic nerves, especially of the lower cervical ganglia; and a general neurosis, were some of the theories brought forward to explain the three cardinal symptoms of tachycardia, exophthalmos and enlargement of the thyroid gland.

Moebius in 1886 was the pioneer of our present views of the causation of this disease. He maintained that the normal amount of thy-

roid secretion was essential to the proper physical and mental development of the individual. A reduced amount, or hypothyroidism resulted in imbecility, cretinism and myxoedema. A much increased amount, or hyperthyroidism, caused the disease known as exophthalmic goitre, (Graves's or Basedow's disease). That the absorption of an abnormal amount of thyroid secretion acted as an irritant poison, likened to alcohol. That this poison caused rapid action of the heart; dilated the peripheral blood vessels causing flushing of the skin and sweating; dilated the bloodvessels back of the eye and caused an increased production of fat in that locality thus producing the exophthalmos. The increased number of thyroid cells plus dilatation of the blood vessels of the thyroid gland resulted in the goitre.

The prolonged action of this poison resulted in degeneration of the liver, kidneys and heart muscle.

Wilson of the Mayo Clinic has been able to trace a direct connection between the severity of symptoms in hyperthyroidism and the increase in the number of functioning cells of the thyroid gland. In fact he has been able in 85 per cent. of cases, to take a pathological specimen of thyroid gland and state with a marked degree of accuracy, the symptomatology of the case.

The surgical treatment of this disease is based upon Moebius theory, the object being to reduce the amount of thyroid secretion absorbed into the system of the patient. Injection of boiling water into the gland, ligation of part of blood supply, and resection of a portion of the gland are the three surgical procedures resorted to.

Injection of boiling water and ligation of one or both superior thyroid arteries and veins are valuable procedures in cases with severe intoxication in which a thyroidectomy would be very dangerous. Either can be done under local anaesthesia. C. H. Mayo, who has had an enormous experience in the treatment of these cases, states that ligation almost uniformly results in marked improvement in these severe cases. The average gain in weight in a series of cases was 22 pounds in four months, at which time they became favorable cases for thyroidectomy. Thyroidectomy is the operation of choice, and shows a mortality of 1 to 2 per cent in skilled hands. The end results are 75 per cent. of cures with improvement in the others who survive. One lobe and the isthmus is usually removed, though the exact amount is a matter of judgment with the operating surgeon. A certain percentage of these cases later develop renewed symptoms of hyperthyroidism, due either to the removal of too little of the

gland or to subsequent hypertrophy of the remaining portion. These cases should be reoperated and more gland removed.

F. H. MONTGOMERY.

WHAT IS THE ETIOLOGY OF PSORIASIS?

In the research studies on the cause of psoriasis under the direction of J. F. Schamberg, at the dermatological research laboratories of the Philadelphia Polyclinic and College for Graduates of Medicine, Auspitz's remark was quoted as final "was psoriasis ist, weiss bis heute noch kein Mensch"—what psoriasis is, no man at present knows.

In the final report the research committee had to acknowledge, that though the symptomatology, histopathology, diagnosis and course are known, yet the cause is unknown, as it was two thousand years ago.

The research for the etiology of psoriasis was made from two standpoints: (1) bacteriological, (2) metabolic.

From the bacteriological standpoint of view several possibilities were considered: If parasitic, (a) the disease may be due to the implantation upon the skin of an exogenous parasite, as is observed in ringworm, favus and tinea versicolor. Such an organism has hitherto not been found, but might be discoverable by the use of the ultramicroscope or by some new technique. (b) The disease might be caused by one of the common facultative organisms belonging to the group of cocci, so readily cultivable from the skin, in individuals in whom the soil is rendered favorable by some special condition. (c) The disease might be the result of the circulation in the fluids of the body and deposition in the skin of a microparasite, analogous to what is observed in syphilis and variola.

With all the methods, new and old, no special parasite was found and the results were inconclusive.

Theories which hold disturbances of metabolism responsible for psoriasis were investigated. The following conclusions were made by the investigators:

- (1) That these patients possess a strong tendency to store nitrogen.
- (2) That the nitrogen is stored with great ease.
- (3) That on a low protein diet the patients may eliminate extraordinarily small quantities of nitrogen in their urine.
- (4) That a low protein diet has a distinct and a remarkably beneficial influence on the course of the psoriasis.
- (5) That very large quantities of nitrogen may be lost through the skin in the form of scales.

(6) That on a high protein diet, tremendous quantities of nitrogen may be retained in the system.

(7) That a high protein diet, although it did not bring about a relapse in a case where the active process had been checked, did stimulate very considerably the course of the existing psoriasis in active form.

(8) That the retention of nitrogen is not always associated with a corresponding gain in body weight.

These metabolic conclusions were made from the historical characteristics of psoriasis, in the rapid growth and proliferation of the epithelial cells of the skin. For their growth and life, these cells require building material which can be obtained only from one source—the blood and lymph streams. The principal building material required by these cells is protein. A high protein diet therefore stimulates their growth, because it provides all the necessary components of the epithelial cells. By keeping the patient on a low protein diet, we bring about a condition in which no extra protein can be supplied to the rapidly multiplying cells of the skin, and this condition therefore would retard the progress of the disease.

Though no criticism can be offered on the result of such good work as has been done under the directorship of Schamberg, yet, no definite results as to the real etiology of psoriasis could be found, neither from bacteriological nor metabolic standpoints. We are today just as ignorant as to the real etiology of psoriasis as we were years ago; but let us not get discouraged, but go investigating until we do find the cause.

To my mind, the etiology of psoriasis is due to incomplete metabolism causing the symptom-complex known as psoriasis. Careful, rational and patient treatment does cause amelioration of the most apparent phases of this disease.

M. L. RAVITCH.

Exophthalmic Goiter.—Stern gives an interesting review of the experience to date with the serum of thyroidectomized animals in exophthalmic goiter and relates its successful application, supplemented by a Naureim course of carbonated baths, in three cases, two very severe. The patients were women of 29 and 51, and the exophthalmic goiter had resisted all other treatment. In the oldest patient a course of baths the year before had been ineffectual, but this year, supplemented by the serotherapy, remarkable improvement was realized. The much dilated left ventricle subsided to normal size in all the cases. The circumference of the neck grew smaller by 1.5, 2 and 2.5 cm. By commencing with small doses it is possible to improve without by-effects.

SYMPOSIUM ON DISEASES OF THE NASAL ACCESSORY SINUSES

DISEASES AND PATHOLOGY OF NASAL ACCESSORY SINUSES.*

By ERNEST RAU, Bowling Green.

I don't believe that the inflammations and infections of the nasal accessory sinuses very often get the recognition and treatment that they deserve. Especially is this true of the frontal sinuses. In the fall and winter of 1909 there was more grippe and so-called bad colds than common, and a good deal of frontal sinus infection followed. On account of there being no pus present or symptoms referable to the nose a great many of these cases were treated as neuralgia, etc. On inspecting the nares the middle turbinate would be found swollen, and tender, completely blocking off the frontal sinus. The pain being due not so much to the infection, as to interference with circulation of air causing a negative pressure within the sinus, with consequent swelling of mucous membrane, and congestion of blood vessels, and irritation of nerves.

A great many theories have been advanced as to why we should have the accessory sinuses at all. Most all seem to agree that they have to do with olfaction. It seems that certain of the lower animals with keen sense of smell have accessory olfactory ridges situated in the frontal, sphenoid, and maxillary sinuses. That by evenly distributing the inspired air in the olfactory region they aid in that sense.

It has also been advanced that by lightening the bones of the skull that proper balance is maintained, also as an adjunct to respiration, moistening the inspired air. From their location it would seem that they would be continually infected, and yet as a matter of fact it is comparatively rare, when you consider that at every inspiration bacteria are carried into them. At first thought it would seem as though, especially in the case of the maxillary sinus, that the construction for drainage was not up-to-date, the ostium being considerably higher than the floor. However it has been demonstrated at autopsy several times that subjects with normal sinuses that had not been dead over two hours, that the frontal and the maxillary sinuses were without exception sterile. This is not because bacteria do not get into them, for the nasal sinuses are aërated during every respiration, but because they are protected against such an invasion by ciliated

*Read before the Kentucky State Medical Association, at Bowling Green, Wednesday, September 3, 1913.

epithelium, the cilia constantly escorting the bacteria towards the ostia, and the mucous glands of these sinuses have a secretion that is germicidal in power. The diseases of the sinuses are the same as those which may attack the mucous membrane of the nose. But especially regarding the maxillary sinus, it is more prone to chronic inflammation and formation of cheesy masses, etc., on account of the location of its ostium.

Of the bacteria most often found as a causative factor, it has been claimed that the influenza bacillus holds first rank, the pneumococcus next, staphylococcus pyogenes aureus and albus, and the streptococcus pyogenes. It is doubtful whether a pure culture will be found except in the beginning, for after the defenses are broken down it is only a matter of a short while until it is a mixed infection. It has been claimed by some authors that in every case of influenza that the sinuses become infected some time during its course.

Whether they enter directly through the nasal passages and ostia of sinuses or whether they find their way through the blood stream has not fully been determined. Some also are of the opinion that the sinus infection is a sequelae rather than a complication.

It would seem that there is no longer any question that in the acute diseases of the inferior air passages that the nasal sinuses become infected. In croupous pneumonia bacteriological examination of sinuses of those dying of this disease have always shown cultures of the pneumococcus. In diphtheria examination of the sinuses show the presence of Klebs-Loeffler bacillus. Pearce demonstrated inflammatory sinus changes in 25 out of 39 post-mortems, and in the maxillary sinus especially he found the bacillus on both sides in all but three cases. There seems little doubt also but that in erysipelas that the sinuses are very often affected. The sinus affections in these four diseases takes the character of the primary disease, while in the other infectious diseases that are followed by sinus affections, are principally due to other bacteria than those causing the original trouble.

The pathological changes that take place in these cases of infections and inflammations of the sinuses depend upon several conditions, viz: virulence of attacking germs; the length of time that the disease has been present; the amount of resistance the sinus has to inflammation, and the condition of drainage system.

The maxillary sinus, on account of the location of its ostium, shows the greatest pathological changes, as the mucous membrane at the lowest point is constantly bathed in purulent secretion. This will account for the

presence of cheesy, fetid pus that is so frequently found in these old chronic cases of the maxillary sinus, regardless of cause. For matters of description it is best that these conditions be considered under a general head of acute and chronic.

On the mucous membrane becoming infected, there results an intense hyperaemia and swelling due to an outpouring of serum into the sub-mucous connective tissue, which may be of sufficient quantity to completely close the lumen of the sinus.

This swelling naturally crowds the cilia together and interferes with their motion, and may become so great as to stop their motion altogether. No secretion is formed at this stage, because the lining membrane has not been penetrated by the exudate. Oedema follows this stage on account of pressure upon the blood vessels. Owing to the cilia having become motionless the mucosa is no longer able to throw off the secretion forming in the glands. This inflammatory exudate is composed of serum, mucus, leucocytes and exfoliated epithelium. Bacteria may or may not be present. Resolution may set in at this time with lessening of hyperaemia and oedematous swelling. The cilia gradually regain their motion, and the secretion may cease entirely or assume a mucoid or serous muco-purulent character, then watery, gradually returning to normal. The inflammation, however, may continue and become chronic.

Chronic sinus inflammation presents two distinct types, viz: Hyperplastic and ulcerative. In the hyperplastic type the mucous membrane is of a whitish-grayish color, more or less loosened from the bone, often wrinkled and papillomatous. Hyperaemia may be present, but not so prominent as in the acute stages.

The connective tissue is considerably thickened and retention cysts often occur from constriction of the necks of the glands. Small areas of metamorphosis of ciliated epithelium pavement occur. The ulcerative type is claimed by some to be just an ulceration in the hyperplastic. Owing to the fact that the third layer of the mucosa is so intimately blended with the periosteum, the bone very often becomes affected, and were it not for the collateral circulation through the sinus walls this would happen much more frequently.

The Blood-Pressure and the Cholesterin Content.—Cantieri's comprehensive research failed to show any direct connection between an abnormally high blood-pressure and the cholesterin content of the blood. With nephritis there is generally an excess of cholesterin in the blood, even in cases with normal or subnormal blood-pressure.

SYMPTOMS AND DIAGNOSIS OF DISEASES OF THE NASAL ACCESSORY SINUSES.*

By S. G. DABNEY, Louisville.

Development. The maxillary antrum in the newborn child is miniature in size and is situated to the inner side of, instead of beneath the orbit; it acquires its permanent shape about the 12th and its full size about the 18th year. The frontal sinus appears as a separate cavity about the 9th year and attains its full development by the 20th. The ethmoid development begins about the 4th year and advances simultaneously with the frontal. There appears to be a great variation in the appearance and growth of the sphenoid; it probably begins about the 3rd year and attains its full size at maturity.

Bacteriology. Bacterial examination does not offer great aid in sinus diagnosis; in purulent cases any of the pus producing organisms may be found and in chronic cases several varieties are usually present.

Preceding History. The history of the case is sometimes of value in diagnosis; in a certain number dental disease may arouse suspicion of inflammation of the maxillary antrum; in others a preceding infectious illness, especially influenza, is important. Naturally acute rhinitis or habitual nasal obstruction is common and occasionally a preceding traumatism of perhaps violent vomiting may play a part.

General Symptoms. In addition to the symptoms dependent on long continued or frequently recurring pain such as insomnia, anaemia and irritability, we often find vertigo especially in frontal suppuration.

Before considering purulent inflammation of the sinuses, to which, I take it, this symposium is chiefly devoted, a few words may be said in regard to some non-purulent affections.

Acute Catarrhal Inflammation, with its headache, hebetude and fullness is too familiar an attendant of acute rhinitis to require extended description. Probably neglect of this condition and errors in the mode of life during its existence sometimes results in purulent disease.

Mucocoele generally involves the frontal and ethmoidal sinuses. The swelling in the orbital region, sometimes displacing the eye and causing diplopia, is the first and often the only symptom; hence the oculist is usually consulted. The growth is slow and painless; the situation is to the inner side or upper portion of the orbit. Palpation reveals a soft

mass, often elastic or semifluctuating. It is liable to be confounded with an orbital tumor.

Hyperplastic Ethmoiditis, attended by multiple polypi, is the result of recurring catarrhal attacks. The subjective symptoms are a sense of tightness and obstruction about the bridge of the nose, diminution or loss of sense of smell, sometimes frequent attacks of sneezing with profuse watery discharge and lachrymation, and of chief importance, *asthma.* Asthma is most common in those cases in which the ethmoidal cells are more or less packed with fine grapes-seed like polyps. Many cases are certainly much benefited and some are cured by the removal of this nasal condition. In addition to the symptoms mentioned, we often find conjunctival irritation as well as ocular pain and asthenopia and, occasionally, there is well defined neurasthenia. Objectively, the most prominent symptom is thickening and inflammation of the middle turbinate and the presence of polyps; not very rarely, however, the polyps are not revealed until the anterior portion of the middle turbinate is removed. It is not claimed that this condition alone is responsible for nasal polypi—their association with purulent sinus disease will be discussed later.

Purulent Inflammation of Accessory Nasal Sinuses. It is well to consider first those symptoms which are common to disease of any of these sinuses, though varying greatly both in constancy and in severity, and to consider next these symptoms by which we determine which sinus or sinuses are involved.

Pain is generally severe in acute cases but often entirely absent in those of long standing. On the other hand some headaches which have long resisted both general and other local treatment have been cured by the relief of chronic sinus suppuration. Even in acute cases the pain is not always over the sinus involved; thus in maxillary inflammation the pain may be felt mainly over the brow; in disease of the frontal sinus it is usually in the forehead; in the ethmoid at the root of the nose and in the sphenoid, either at the vertex or occiput. It is characteristic of sinus pain in general and especially that from the frontal sinus that it comes on an hour or two after arising and is most severe in the forenoon. Various explanations have been given for this, but none seem to me quite satisfactory. Both the intensity and the location of the pain, however, are subject to marked variations.

Tenderness is often present in inflammation of the maxillary antrum and frontal sinus. It is usually found in acute and sometimes in chronic cases. In the examination we should be careful to avoid the supra and

*Read before the Kentucky State Medical Association, at Bowling Green, Wednesday, September 3, 1913.

infra-orbital nerves. The two sides should always be compared. In examining the frontal sinus the tip of the little finger should be carried well into the upper inner angle of the orbit and pressure made upward and inward against the floor of the sinus, which is thinnest at this point. In the maxillary pressure should be made in the hollow of the cheek, remembering, however, that disease of a tooth or its root may cause tenderness there even when the antrum is healthy. Tenderness is a more important symptom and more frequent in disease of the frontal than of the maxillary sinus.

Discharge. As the frontal, maxillary and anterior ethmoidal cavities all empty beneath the middle turbinate anteriorly, we look to this locality for pus from them; for the same reason in inflammation of the posterior ethmoid or sphenoid sinus we expect pus in the posterior nares, trickling over the middle turbinate. The reappearance quickly of the pus after carefully wiping it away is especially significant. On the other hand the absence of pus on one or even on several examinations is no proof that purulent sinusitis does not exist, especially if the examination is made in the ordinary sitting posture. It is said that the pus from cases of nasal origin is due to anaerobic organisms and is not fetid, while that in the maxillary from dental disease is due to anaerobic organisms and is fetid. Certainly in my experience, the pus from the maxillary antrum is more likely to be fetid than that from the frontal sinus. Perhaps the fetid character is really due to defective drainage.

Subjective Offensive Odor. The perception by the patient of a disagreeable smell present in the nose is an important indication of pus in a sinus—generally in the maxillary.

Changes in nasal mucosa are chiefly found in and beneath the middle turbinate, though a deflected septum pressing against this bone and a general hypertrophic rhinitis are important causes of defective drainage. The middle turbinate is usually swollen and in acute cases, red and angry looking, while in the more chronic it is often pallid and puffy. It is not rare to find hypertrophy of the middle associated with atrophy of the inferior turbinal, and a condition of ozaena—indeed this disease is by some attributed to sinus suppuration. It is common to find polyps growing from and beneath the middle turbinate. Whether they cause or are caused by the sinus suppuration is a disputed point in rhinology.

Transillumination is of much value in diagnosing disease of the maxillary and frontal cavities. It is important that the room be dark and that the intensity of the light be under

complete control. Not only are the cheek and the infra-orbital region illuminated by the light in the mouth, but in many cases the pupil appears luminous and the patient has the perception of light. In disease the most characteristic appearance is a semicircular dark spot beneath the eye. It is claimed that this darkness is due to a thickening of the interior lining membrane, rather than to the presence of pus—a claim which is corroborated by the fact that we often find the darkness remaining even where the suppuration has long ceased. In the frontal sinus the best results are obtained, at least in my own experience, by carrying a small Tungstein light well up behind the orbital ridge as far back as possible in the upper inner portion of the orbit. This has been much more satisfactory than pressing the light, enveloped in a hood, just beneath the orbital rim, as is generally pictured in the text books. In the latter procedure the light appears to come over the bone and to make the cavity appear luminous when it is not.

The Roentgen Ray is of decided value both in outlining the sinus and in determining the question of disease in them. I have had no experience in its use in suppuration of the sphenoidal sinus but the plate and picture which I exhibit illustrate well the suppuration in the maxillary, ethmoidal and frontal sinuses, and at the same time outline the contour of these cavities, especially the frontal. Much advance has recently been made in the use of the X-ray in these diseases and I hope that this subject will be elaborate in the discussion.

External symptoms are most frequently seen in acute suppuration or in acute exacerbation of chronic suppuration. They occur, when present, in disease of the maxillary, anterior ethmoidal and frontal sinus. In the first there may be redness and swelling over the cheek; in the second, swelling at the bridge of the nose or near the inner canthus of the eye and in the third bogginess and swelling in the brow and in the upper lid. When complications arise these symptoms may be greatly accentuated.

Complications especially in the orbit and in the eye are so frequent, so important and so often the first recognized manifestation of sinus suppuration that they must be mentioned in diagnosis. Of these the most striking and probably the most common is orbital cellulitis. It occurs both in frontal and ethmoidal disease—as a matter of fact, however, these two are rarely absolutely separate, the upper ethmoidal cells being usually involved with the frontal. In orbital cellulitis the eye-

ball is pushed forward and otherwise displaced according to the direction of the pressure, there is more or less immobility; the upper lid is generally swollen and when raised diplopia is observed; there is often oedema and tenderness all around the frontal and orbital region; pain is frequently severe and sight may be interfered with by pressure on or inflammation of the optic nerve. In a youth of 18 seen not long ago, with this group of symptoms following an attack of grippe, an incision carved far back along the inner orbital wall evacuated pus from the ethmoidal cells and gave speedy relief. A second case very recently dismissed cured, is of interest from the medico-legal standpoint. A man 38 years old, without previous nasal or ocular symptoms and in excellent health, took a dinner of clam broth and several other things on the Pullman car. A few hours later he was taken with violent vomiting and a little later with purging. Next day he had severe pain and some swelling in the region of the right eye. I saw him 4 days later and found great oedema of the upper lid, brow and bridge of the nose with slight elevation of temperature and intense pain, and tenderness most marked at the upper, inner angle of the orbit. Transillumination showed the frontal on this side dark. On elevating the lid the eyeball was seen to be pushed forward and outward and diplopia was present. Operation revealed extensive disease of the frontal and ethmoidal cavities. Recovery was uneventful, but so tedious that I had two of my colleagues, see him in consultation, but without any suggestion of importance. The final result has been perfect except for a scar, without much depression. He holds the Pullman Company responsible for ptomaine poisoning and attributes his sinus disease to the violent vomiting. It is to be remembered that vomiting may be a symptom of acute frontal sinusitis, but on the other hand recent investigations have shown that vomited matter may be forced into the frontal sinus and set up inflammation there. In rare cases fronto-ethmoidal disease may cause disturbance in the ocular muscles without cellulitis. The skiagraph which I am exhibiting is taken from a lady of about 60 where the most evident symptom was ptosis of the right upper eye lid. She complained of headache, like a band running around the head from the brow. Her maxillary antrum had been opened through a tooth socket by a dental surgeon. Transillumination with the little Tungsten lamp carried far back into the upper inner part of the orbit showed the frontal of this side dark. Abundant pus was found beneath the middle turbinate, quickly returning after cleansing. Her ptosis has

been decidedly improved and her headache relieved by intranasal operation, though more radical external procedures may yet be demanded. A great variety of other ocular diseases have been attributed to the sinuses, especially the post-ethmoidal and sphenoidal; of these the most important are optic neuritis and interference in the field of vision without ophthalmoscopic abnormality.

Suppuration of the superior sinuses may lead to meningitis and brain abscess and this cause should not be overlooked on considering such affections.

Differential Diagnosis. Finally a few words as to the determination of which sinus or sinuses are involved. My already too lengthy paper demands that I be brief. In the maxillary sinus I usually first use transillumination; then look for pus beneath the middle turbinate; if found it is wiped away and the patient requested to lie on a sofa with the head hanging over, the face towards the floor and the affected side uppermost. After a few minutes, without blowing or hawking, the nose is again inspected and if pus is found beneath the middle turbinate its source is probably from the antrum of Highmore. A subjective sense of bad odor is an important aid in diagnosing this disease. Of course disease of a tooth whose roots go up toward the antrum is significant. In a certain, but I believe a small, proportion of cases, diagnosis can only be made from finding pus by intranasal puncture. We must remember that pus in the antrum may have simply gravitated there from the upper sinuses and may not indicate antral suppuration. The presence of pus in the frontal sinus is determined by the tenderness above described, by transillumination, by a radiogram, and by pus beneath the middle turbinate which returns after wiping away, with the head in the upright or slightly inclined position. Suppuration in the anterior ethmoidal cells is rarely found without disease of the adjacent cavities. It is usually visible after resection of the middle turbinate and opening the ethmoid. Pus in the posterior ethmoidal and sphenoidal sinuses is diagnosed by the presence of pus at the root of the posterior nares or trickling down the naso-pharyngeal wall, by radiogram, by deep-seated headache usually at the vertex or occiput and finally by opening these cavities after removing the posterior portion of the middle turbinate.

Vomiting.—Treatment.—In a number of instances vomiting can be immediately arrested by means of the pyloric reflex of dilatation, which consists of pressure or concussion of the fifth dorsal spine.—Abrams.

TREATMENT OF DISEASES OF THE
NASAL ACCESSORY SINUSES—
SURGICALLY AND OTHER-
WISE.*

By J. A. AND W. S. STUCKY, Lexington.

Because of the seriousness and danger to life and health from absorption of septic material, the obscurity and misleading nature of symptoms as given by the patient, the care and difficulty in arriving at a correct diagnosis, the close proximity to vital structures and the extreme care and accuracy required to successfully remove and treat, surgically or otherwise, the cause of the disease and establish and maintain unobstructed drainage;—all this gives the surgery of these sinuses a prominent place in the thoughts of the rhinologist.

This subject is also becoming of increased interest to the general surgeon and practitioner because of the number of systemic and local troubles emanating from these sources.

In this brief paper no attempt will be made to describe in detail the various intra and extra-nasal operations for relief of accessory sinus diseases, as large text books have been written on this subject alone and the operative technique fully described: but a few methods, especially in regard to post-operative treatment, that we have found to be of value will be given, and we hope more fully discussed. The diagnosis having been fully established, the treatment to be instituted is dependent upon several factors—the stage of the disease, whether acute, subacute or chronic, and the severity of the symptoms, both local and general, but in all cases the one important point is to create and maintain unobstructed drainage of all sinuses, and to look carefully after the general systemic condition.

In cases of acute sinusitis, we usually find the entire nasal mucosa swollen and inflamed and the sinuses, especially frontal and ethmoid, completely blocked, causing a negative pressure within the sinuses and a resulting pain and depression of a severe degree. In this type of cases systemic treatment is just as important as local treatment. Free purgation with large doses of calomel, followed in 6 to 8 hours by castor oil or salts is the first step in the treatment and a restricted diet urged. The local treatment consists in shrinking with cocaine and adrenalin, the area around the middle turbinate and infundibulum, then flushing the nares with a warm saline solution, preferably by means of a post-nasal spray. This treatment is given once or twice daily. Usually within a week the

nasal mucosa has returned to its normal state and all acute symptoms have disappeared.

In the majority of cases, however, we find the middle turbinate to be hypertrophied or diseased, and as this condition causes obstruction of the natural openings and thus interferes with drainage, its early removal will decrease the necessity of a more radical intra or extra-nasal operation later. In removal of the middle turbinate, the method used should be selected with reference to the anatomical conformation of the nares and to the individual preference of the surgeon. Personally, we prefer to remove the entire turbinate and as many of the anterior ethmoidal cells as can be reached by means of the curette and small biting forceps. Most text books advise removal of only the anterior 1-3 or 1-2, but it has been proven that there is no real physiological reason why the entire turbinate should not be removed, and our results have justified the method of complete removal. In cases where there is marked septal deviation which presses upon the turbinate a sub-mucous resection of the septum and an infraction of the turbinate are performed. Practically all intra-nasal operations on the turbinates, ethnoids, septum and frontals, can be performed under local anesthesia. In most cases we administer one half hour previous to the operation, morphine or heroin with atropin.

Immediately after intra-nasal operations a dropper full of argyrol, 25 per cent., is applied, with the head thrown far back, to the operated side and no packing is used, but instead a flexible perforated splint (Kyle's), is inserted within the naris. Since using this splint we are rarely troubled with hemorrhage and obstructed breathing, and the patient is prevented from "snuffing and snorting" and getting a loose clot. Then, too, nasal breathing and ventilation are not interfered with. These minor cases are usually kept in the hospital 24 to 36 hours.

In the Caldwell-Luk operation through the canine fossa for empyema of the antrum a thorough opening is made into the nose beneath the anterior one-third of the inferior turbinate and the cavity is lightly packed with gauze soaked in argyrol. This is left in for 24 to 36 hours, when it is removed and a small wick inserted to keep the wound open for a day or two. In these cases the antrum is irrigated daily for two or three days, then the wound in the mouth is allowed to close and ventilation and drainage take place through the nose.

Few cases of accessory sinus disease if treated properly will require an extra-nasal operation, but when the intra-nasal methods fail after a reasonable length of time, to effect the

*Read before the Kentucky State Medical Association, at Bowling Green, Wednesday, September 3, 1913

desired cure, an extra nasal operation should be performed and every portion of diseased bone, granulations and pus thoroughly removed. In the modified Killian operation, whether or not the ethmoids have been removed, we use no packing. A large perforated tube is inserted through the floor of the frontal sinus and out through the nose. The tube is removed in from 24 to 26 hours, or as soon as it will come out without use of force. When you desire to remove the tube, take hold of it at the lower end with a hemostat and exert slight tension and it usually comes away without trouble or bleeding. We have quit irrigating and mopping these wounds, as these measures cause irritation and frequently a mixed infection. The wound needs drainage and ventilation and will heal more rapidly and more completely when not kept moist with irrigations.

In all cases showing sepsis, urotropin in large doses, grains 10 to 20, every four hours, is given and a restricted diet, consisting principally of fruit juices, buttermilk, broths, etc., is kept up until all symptoms of septic absorption have disappeared. The patient is given complete rest—both mental and physical—and every effort is made toward forcing the resistive powers to go to the repair of the wound and not to be utilized in faulty digestion, assimilation and elimination.

In nearly every case of posterior ethmoiditis the sphenoid sinuses are also involved, but after complete removal of the middle turbinate and curettment of the ethmoid labyrinth, resolution usually takes place rapidly and completely within the sphenoids. In chronic cases, however, it is sometimes necessary to probe the sphenoid and widen the ostium, and thus allow freer drainage and ventilation. Much care and patience are required before the probe can be passed into the ostium but after thorough cocaineization, and with the aid of the long bladed Killian speculum which is passed between the middle turbinate and septum, the anterior sphenoidal wall can usually be seen. The anterior wall is extremely thin and all undue pressure is to be avoided. If successful in probing the ostium we can then widen the opening with the sphenoidal forceps and aspirate if desirable. In this as in other sinus conditions we rarely irrigate, but instead apply an antiseptic, such as argyrol, and allow plenty of air.

In conclusion, we need not emphasize that all treatment, both operative and post-operative should be given in a strict aseptic and antiseptic manner, in order to avoid localized secondary infection. Do a clean, complete operation, but do not "overdo it." Especial care should be given toward restoring to nor-

mal the lowered resistance caused by the condition which rendered the operation necessary; to this end attention is given to the internal secretions and excretions. Slow and unfavorable progress after many complete operations done with faultless technique is often due to injudicious food and insufficient rest. After major rhinological operations we give small doses of iodine three times daily until its effect is indicated by increased discharge of mucous from the nose.

THE PREVENTION OF TUBERCULOSIS*

By DUNNING S. WILSON, Louisville.

As that weak and emaciated physician lay surrounded by the snow and ice of the Adirondacks, he could scarcely have dreamed, though the hours of rest and solitude were most conducive to such dreams; I say that while he was slowly being nursed back to something like the semblance of his former self, he could scarcely have imagined that his precept and example would from such an humble beginning grow into the mighty movement which has for its highest and greatest object, the prevention of tuberculosis.

Slowly and gradually the voice of "one crying in the wilderness" impressed itself upon a more or less indifferent people and as the message came to persons here and there in that great metropolis of our country, citizens of New York City slowly aroused themselves from their lethargy and as a blind man groping in the dark sought the light of truth.

This movement following the line of least resistance and first being appreciated by the more educated and highly civilized of our country, resulted in efforts being put forth by them towards the eradication of this disease. The anti-tuberculosis crusade swinging down along our Eastern shores thence South, has come at last to "Our Old Kentucky Home" and we stand no longer ignorant but in the full possession of knowledge that comes from precedent and the experience of others so we can no longer evade the issue.

Six thousand funerals each year attest our laggardness. Six thousand of Kentucky's sons and daughters each year fill new made graves.

We commemorate in story or glorious pageant, the Battle of the Thames; Kentucky's part in the victory of Lake Erie and gather each year with tender memories about the graves of those who died fighting under the Stars and Stripes or under the Stars and Bars, but we must hang our heads in shame, must put on sack cloth and ashes when it

*Read before the Kentucky State Medical Association, at Bowling Green, Tuesday, September 2, 1913.

sweeps across our minds that nearly five regiments of our people each year move in solemn eadence toward that "bourne from which no traveler returns."

In this Year of our Lord nineteen hundred and thirteen, what are we going to do about it? It is not for us to worry over the sins of omission or commission of past generations, nor can we shirk the responsibility leaving the solution of the problem to future generations. It is now our duty to carefully analyze and inventory the weapons of offense and defense which we now possess. Let us not provide new weapons until we have carefully inspected the old ones, discarding, after due consideration the useless, the cumbersome and the ineffective.

The laws on our statute books are multitudinous with long and involved phrases which are supposed to elucidate but which more often confuse and befog. Let us strip them of their nonessentials making them sane and simple, comprehensive and understandable, determining to enforce them with kindness and fairness toward all, but with partiality toward none.

I do not propose to make this a medical essay or to dwell upon medical technique and will dismiss the scientifically medical in so far as it relates to diagnosis and treatment by saying; the physicians of our State must if needs be more thoroughly learn and vigilantly watch for the physical signs which will make them able to distinguish tuberculosis in the early stages.

If there is one great duty which the physician owes to his patients it is the duty of early diagnosing tuberculosis and when so diagnosed, whether early or late, to see that every person in the household is examined for evidence of the disease. When the diagnosis is made he must have courage enough to announce the same to the patient and family, so that while arranging for the care and treatment of the infected, arrangements may also be made to safeguard and protect the noninfected. Koch's demonstration of the tuberele bacilli despite all of its epoch making value, set back the early diagnosis of tuberculosis twenty years and brought about an almost abject dependence upon microscopical examinations for the diagnosis. This must no longer be, the diagnosis of tuberculosis must be made before the sputum is positive for tuberele bacilli.

The early diagnosis, however, is only a single factor in the prevention of tuberculosis and we must look to other and more potent agencies in order that definite plans be laid for the final abolishment.

Introspection should be our first move and if this is carried out to the last degree, we will

find that envy or jealousy, malice, egotism, unkindness born of selfishness, hatred and desire for self aggrandizement striking at the very roots and vitals of our existence handicaps us in this work as well as in every other phase of our existence. Politics, which like poker, seems to have a peculiar fascination for Kentuckians, is by no means the least of our handicaps.

The hundreds of different charitable and sociological organizations whether private or public sooner or later find that the presence of tuberculosis makes toward an economic moral and mental loss to the community out of all proportion to that of other diseases. The people of our State must rise up with one voice and insist that public health work must not be hampered by politics, cumbersome legal machinery, corporate or individual selfishness.

At the same time, public health authorities must change their view point considerably and realize that great as their services are to a community, they are only great in proportion as the knowledge derived is utilized for the purpose and because of its direct bearing upon our whole social life.

It is not enough to know that one or many individuals are suffering from a given disease, nor is it sufficient to know the methods of prevention. We may teach the cause and instruct regarding the prevention, but no definite, large results can possibly be obtained until we make every individual understand that the adoption of methods of prevention important as they may be to the individual, are much more important because of the individual's relationship to other individuals, either associating with them or as yet unborn.

It is Utopian to dream or work towards the establishment of a sufficient number of beds in Kentucky to accommodate from six to ten thousand tuberculosis sufferers, but it is important that institutions be established with not over three hundred beds for the care of the advanced cases making the county or a small group of counties responsible for their establishment and maintenance. This means the segregation, compulsory if need be, of a group of similarly afflicted persons who can be cared for, improved in health if possible and at the same time prove object lessons to the entire district which will soon come to a realization of the dire necessity of living under sanitary conditions, the fundamental principles of which are within the power of all to follow.

The prime object in the treatment of tuberculosis is to increase the physical resistance of the individual and thus in a natural way bring about a possible cure. The healthier our bodies, the less probability is there that

we will contract any disease and the prevention of all diseases is founded upon the premise that the greater our body resistance, the greater our longevity. Therefore, the methods which build up body resistance are the methods which prevent disease. If the methods used in attempting to cure tuberculosis are directed towards building up the body resistance, then it must follow that these same methods modified only in minor details are the ones which must be used to prevent other diseases.

It is a peculiar characteristic of our times that a community or a group of individuals, attracted by any particular subject, immediately form an organization and work toward the achievement of the object for which they are organized to the entire exclusion oftentimes of any other object.

It is unusual for such a community or group to analytically study existing agencies already operating along similar lines, with a view to utilizing, if feasible, such organizations to bring about the object in which they are interested and thus prevent the formation of a new organization. It is even more rare for them to determine before organizing just where, in the scheme of things, their organization is to find place and just what relation they will bear toward every individual or groups of such in their locality. Thus it has come about that we have organizations and committee meetings of these organizations until our days are crowded with meetings, oftentimes proving a most inefficient way of securing results.

We are forced for the present to accept conditions as we find them, but our aim must ever be toward a better and more harmonious coordination between these communities or groups of individuals, with a view to their eventual reduction in number when opportunity offers. It is not unreasonable to believe that an association organized for the study of the prevention of disease and for the improvement of Kentucky's citizenry, would have within its length and breadth, a comprehensive, coordinated and efficient program which would mean the upbuilding of the State in all of its integral parts along health, social and economic lines. Such an association through its many branches of endeavor would provide opportunity for work on the part of every man, woman and child and each could elect to render service in that branch which most appealed to them, knowing that whatever they did would be planned with due regard to its relationship with the *whole* work of the association.

The old adage that "competition is the life of trade" is certainly untrue when it comes to

modern business methods or is applied to any movement which has for its object the physical, mental, moral and spiritual betterment of our race. Those of us who have been or who are now awakened to a full sense of our social obligations outside of the bonds of blood relationship, must no longer seize haphazard what we can lay our hands upon and use it for the attainment of our object, no matter how worthy that object may be. We are sufficiently in possession of facts, large enough in numbers, are forceful enough in personality and should be sufficiently unselfish to insist that we bend every effort toward the elimination of waste energy, money, time and thought; that we set our house in order and calmly, dispassionately, lay the corner stone to a new structure upon the site of the old, pledging ourselves to a life of self-denial and sacrifice in the full knowledge that in so far as each does his or her part with relation to the other will results follow.

We talk of open air schools and establish them for the care of the weak, the anemic and the tuberculous, but the average normal child must spend his or her school hours in a school room deprived of the stimulation and joy of the open air; while caring for the weakly, the anemic and the tuberculous, we are at the same time providing facilities for the production of another supply of the weakly, anemic and tuberculous when we close our school room windows and shut out the fresh air from the supposedly well and strong. Why not give the healthy boys and girls every opportunity to keep so by having every school room an open air one?

We supply modified milk scientifically and carefully prepared to the infants only to have them later on pass from the careful watchfulness of the Baby's Milk Fund nurse succumbing in after years to the insanitary environments of our homes.

We erect sanatoria for the treatment of tuberculosis and point with pride to our cures, leaving the incurable in the home to spread infection and thus provide new objects for our egotistical solicitude.

Our hospitals for the insane, feeble-minded, the ruptured and crippled and the blind are full to overflowing but are our young men and young women sufficiently instructed in the fundamental laws known to every cattle breeder in order that their mating may be less veneered with the artificiality and nonessentials of our civilization, but more natural with the foresightedness, clean and clear mindedness of human beings who have eaten of the "tree of knowledge."

Natural selection and the law of the survival of the fittest may hold good in the brute

world and because of the operation of these laws finally eliminate the inefficient. Human beings, however, are not susceptible to these laws except in a very limited degree and owing to the sympathy which goes out to the weak and poorly, mankind still further impedes the operation of these laws and consequently, because of the very attributes which distinguish him from the brute, suffers the progress of the race to be handicapped.

The prevention of tuberculosis is not to be accomplished by antituberculosis organizations alone, no matter how excellently they may be managed. We must call into play and request the intelligent cooperation of the physicians, the sociologists, the lawyers, the employers, the employees, the charitable organizations, the federations of men's and women's clubs, the King's Daughters, the Baby's Milk Fund Associations, the play ground leagues, the tenement house commissions, the law makers, the boards of education, the public health officials, the churches and in fact every citizen of our State.

As a chain is only as strong as its weakest link, therefore, the prevention of the white plague must go hand in hand with the prevention of the black plague, the prevention of hookworm, cancer, typhoid, infantile diseases, poverty, drunkenness, abortion, blindness, feeble-mindedness, insanity, accidents, dishonesty, crime, crop failures and the wanton and improvident destruction of our forests or the wasteful dissipation of our natural resources whether by individual or corporation.

Finally, the warp and woof of such a scheme must be the leaven of human kindness and a sympathy which is a *motive* and *not* an emotion.

DISCUSSION.

Everett Morris, Sulphur: We have listened with a good deal of interest to Dr. Wilson's paper on one of the most important subjects that will be presented before this meeting. I say one of the most important because the disease is the most widely distributed one in Kentucky today.

The tribute paid Dr. Trudeau, that bold pioneer in the treatment of tuberculosis is just and timely.

I have the pleasure and honor in representing the Kentucky Board of Tuberculosis Commissioners before this body. This bureau was created and provided for during the last Legislature and is now carrying on an intensive educational campaign throughout the State. The chief avenues of publicity work consist of a free health exhibit car, lectures, visiting nurses, health leagues, exhibits for fairs, and the distribution of plate matter to the papers of the State along with carefully prepared pamphlets on tuberculosis. This is

the answer to the question. "In the year 1913, what are we doing about it?" There has been more work done in this good year looking toward keeping people free from tuberculosis than during the last decade.

The passion of the 20th century is civic betterment through cooperation. The tuberculosis commission asks for the heartiest cooperation of physicians in the State in this big fight against this relentless disease. But the responsibility should not rest upon any one profession, but on "The rich man, poor man, beggar man, thief, Doctor, lawyer, teacher, chief," and the amount of their fighting should be commensurate with their conception of civic duty.

I agree with Dr. Wilson when he says, "The discovery of the tubercle bacillus by Robert Koch, set back the diagnosis of early tuberculosis 20 years." Too many of us let Dr. South make our diagnoses when she should have been used only to confirm them. The time is coming when physicians will make diagnoses of incipient tuberculosis before the microorganisms can be discovered.

There are just two ways to stop the spread of tuberculosis. One is to make every consumptive harmless to his family, and to the community; the other is to keep our physical selves in such a condition that the defense against the germs is perfect. The first is largely a community problem; the second an individual responsibility. The new tuberculosis law has made it possible for every community to solve its problem by building tuberculosis hospitals. These can be built and maintained by a county levy and will serve a double purpose, namely, increase the chances of the sick to get well and decrease the chances of the well to get sick. In this way the sick will have the advantages of the best treatment, while the public, at the same time, will be free from any possibility of further infection from them. It is of greater importance to provide for this disease than for smallpox and some of the mental disturbances. Hospital care for the chronic, as well as the incipient cases is practical and in the long run a paying investment for any community. Our forefathers overlooked the importance of the solidarity of the human race "that every thing that's done in humans, injuries all of them the same and that the man who holds another in the ditch must stay in the ditch with him."

The medical profession must take the initiative in all civic movements looking to better public health conditions. Our responsibility is not confined to telling our clientele how to personally avoid tuberculosis but in interesting them in taking care of the unfortunates who can not take care of themselves. The county or district tuberculosis sanatorium is intended to meet this need. Each county in the State can establish one of these institutions under the new tuberculosis

law. A few progressive counties are now taking the necessary preliminary steps with the view of building a sanatorium. If you are interested in this humanitarian work write to the Tuberculosis Commission at Frankfort.

T. A. Frazer, Marion: In this fight against tuberculosis we physicians have not been as frank and honest with ourselves and our patients as we should have been.

I agree with Dr. Morris in regard to the diagnosis. We should not depend upon Dr. South to make the diagnosis for us. Usually, if we depend upon the bacteriologist to make the diagnosis, the disease has done such harm and has produced such destruction of tissues that the chance for recovery is small, but we should be perfectly frank. We should study the question of tuberculosis. How many physicians in this State have one volume in their library upon the vital subject of tuberculosis, a disease which causes one death in every seven in Kentucky, a disease that is wiping out our young and useful citizens at a time of life when they are worth most to their families and worth most as citizens of the State. We should not wait until there are cavities in the lung to tell patients they are tubercular, but by applying the modern methods of examination we should be able to diagnose tuberculosis long before a cavity appears in the lung. We should regard every case with suspicion that lingers for an indefinite time unless we know positively the disease from which the patient is suffering. I have found in the last few years that it is easy to make this diagnosis, and I have had practically every early diagnosis I have made of tuberculosis confirmed. We can use the vaccine long before we can find tubercle bacilli, and I believe it is reliable. I have used it in a number of cases and in every instance where I got the reaction time has proved it to be tubercular. We should not be looking to get away from tuberculosis, but to find it because it is all about us, and if this condition continues, one member of each family of seven is due to die of tuberculosis. If that family escapes the white plague some other family has got to lose two or three members to make the tally sheet balance. Let us wake up and go to work. Let us take upon ourselves the responsibility that is resting upon our shoulders to direct the people of the State of Kentucky how to fight this great monster.

Leon L. Solomon, Louisville: I should like to say a word or two with reference to Dr. Wilson's paper, bearing upon the question of "early diagnosis" of the tuberculosis; I believe that the diagnosis of tuberculosis will be far easier and safer, particularly the early diagnosis, if we bear in mind, that the one common factor, which gives rise to unilateral bronchitis is tuberculosis. So frequently we are willing to say, that the patient

has bronchitis, when it is impossible to demonstrate this condition, as a bilateral state, there being only a unilateral condition. Such bronchitis is, in the vast majority of instances, tuberculosis and sooner or later is easily so diagnosed. Bear this in mind and you have at your command an almost unfailing index to early diagnosis.

I want to say, furthermore, that I believe many, many cases of pleurisy, which we have heretofore treated as "simple pleurisy" were really tubercular pleurisy. They get well only to relapse, later on, and finally give rise to serious trouble. I will go a step further and say, many cases of pneumonia are tubercular, and not simple pneumonia, and, if we bear in mind the three conditions, (1) unilateral bronchitis, (2) pleurisy, and (3) pneumonia, we will be able to help vastly in the diagnosis of early tuberculosis, without being required to have "Dr. South vindicate us," in our diagnosis, by the finding of the actual tubercle bacillus.

UTERINE HEMORRHAGE AND ITS SIGNIFICANCE.*

By R. C. McCHORD, Lebanon.

A discharge of blood from the womb is pathological when it is excessive, and is to be classified as a hemorrhage.

Hemorrhage from the womb is significant of some abnormal condition, and its cause means much to the individual, depending in great measure on its prompt recognition and appropriate treatment.

During the period of functional activity of the female generative organs, from puberty to the menopause, menstruation, approximately every twenty-eight days, must be regarded as a perfectly natural process, and is an index of the condition of the health of the individual, so far as these organs are concerned. Hence, any frequent and positive deviation from the normal, constitutes valuable evidence of the presence of disease.

To better understand the abnormal, I would say that there are certain rules that apply to menstruation with great uniformity that should be clearly understood; but we must be prepared to know that in practice, irregularities occur in certain individuals, more particularly in the duration of the period and the amount of the flow.

Generally the custom established at puberty will follow the individual through the whole of menstrual activity, except when the accidents of pregnancy produce a change.

In studying individual cases for the abnormal, one should be careful to learn these

*Read before the Kentucky State Medical Association, at Bowling Green, Wednesday, September 3, 1913.

characteristics, and bear them in mind. In the time allotted, it will be impossible to discuss the many pathological conditions causing uterine hemorrhage; but it will be my purpose to consider the most important conditions in which hemorrhage from the uterus is significant of serious pathological changes, merely mentioning those of minor importance.

Uterine hemorrhage, at or near puberty, is usually due to two causes, viz: functional derangement and mucous polypi.

Functional menorrhagia at this time is due to some vaso-motor nervous disturbance, or to a relaxation of the tissues in general, caused by rapid growth and sudden full development.

Mucous polypi are found in the cervical canal and body of the womb. This structure being made up of circumscribed hypertrophies of the mucous membrane, varying according to the tissue from which they spring. They bleed freely, as the tissue is general menorrhagic. Granular hypertrophy of the uterine mucosa, like the polypi, occurs shortly after puberty, in a uterus often of normal size and position, without any known cause. Free and profuse menstrual flow being its chief characteristic. In older women, these two conditions are usually associated with myomata and hypertrophy of the endometrium.

Various benign diseased conditions of the endometrium, characterized by the older writers as fungosities, are more or less causes of hemorrhage, and often of a severe type, which saps the vitality and destroys the health of many women, who have gone, unsuspectingly, for years, laboring under the impression that the menorrhagia was a disease and not a cause or symptom. An exact diagnosis of these cases should be made in every case, when possible; as prompt recognition of the cause, and treatment, which is generally surgical, is followed usually by brilliant results.

In the young child-bearing woman, hemorrhage is most frequently caused by the accidents in connection with pregnancy and labor viz: retained products of conception, laceration of the cervix, misplacement, subinvolution, inflammation of appendages and pelvic congestion. Retained products of conception gives a history of miscarriage or abortion. The os is found dilated, enlarged and patulous, the body tender, enlarged and soft, followed by irregular hemorrhages. The diagnosis of the other causes, is plain.

The differential diagnosis of the cause of hemorrhage in a woman approaching the menopause is truly one of much importance, in connection with the subject under consideration.

Hemorrhage in a woman approaching this

period is significant of a serious disease and the policy of ascribing the cause at this time to the "change of life" or "primary idiopathic congestion," must be apparent; for it is at this time of life that we mostly encounter fibroid tumors, adenoma and malignant growths; the first manifest symptoms of these being hemorrhage.

Again, it must be remembered that we are dealing with a disease and not a symptom, and any error of diagnosis which would delay giving prompt attention to a malignant growth, might, for obvious reasons, prove disastrous to life.

In the great majority of cases of cancer of the uterus, we do not see these cases, until a slight irregular hemorrhage is called to our attention, and on investigation it is found that this condition has existed for weeks and even months. Its approach is insidious and the innate modesty and ignorance of women as to these dangers so great, that the so-called "inoperable cancer" is most often found to exist. Women must be taught that any unusual flow of blood, which is persistent, means something at this time, and on the first manifestation of such a condition, they should apply to their physician for examination and advice.

If we, as physicians, would realize what this cancer problem means; if we would realize that one out of every eleven women of all ages die of cancer and that past the age of thirty-five, one woman out of nine will likewise perish, and at the same time consider that its early recognition is our only hope of cure; probably we would be more earnest in our endeavors to educate our clientele as to its dangers and make them realize the significance of uterine hemorrhage.

DISCUSSION.

E. Clark, Falmouth: I feel that the subject which has been presented by Dr. McChord is too important to allow to go by without discussion. Probably during the session of the Association there will be no more important subject for consideration. The subject of hemorrhage, especially in women at or near the menopause, is very apt to deceive the patient and likewise the doctor. Women should be taught that a hemorrhage of an unusual character at that time should be investigated early and thoroughly, and if this was done, the death rate would be very much reduced from cancer of the uterus.

It will probably be of some benefit and interest to report three cases of hemorrhage that came under my observation. One of the women refused to be examined and died of cancer six months afterwards. In her case the growth was very rapid. The other women were examined, both were oper-

ated upon, and are well. If every physician throughout the land would insist upon a thorough examination of a woman with any unusual hemorrhage at the climacteric period, the death rate would be very much reduced.

W. W. Anderson, Newport: I would like to add this word in the way of discussion of this subject. Uterine hemorrhage during the child bearing period is most often due to non-malignant causes, but the fact that it is due to these ordinarily gives us no right to presume in any individual case that the conditions are non-malignant, and demands on our part the most searching care because, as Dr. Baldy, of Philadelphia, said a few years ago—I think the figures may be better now than then—but still are approximately correct, that only 2 per cent. of cases of cancer of the uterus, taking them all in all as they come to the physician, are ever permanently cured, that is, only two per cent., for the cases come too late. But they do not always come to the physician too late; he is too slow in finding out what is the matter, and he ought to subject the patient to the most searching examination to determine the diagnosis, the reasons for the hemorrhage and not presume it is a non-malignant condition until he is sure.

Edward Speidel, Louisville: The essayist mentioned in his paper one condition especially of uterine hemorrhage, a benign condition, that is very often overlooked or diagnosed incorrectly, and that is hemorrhage from mucous polypi. It is astonishing how often a hemorrhage of that kind is either not diagnosed at all or has been mistaken for a hemorrhage from cancer. The differentiation, as you can readily understand, is very simple. Vaginal examination and the fact that the tumor present has a pedicle leading into the cervix, makes the diagnosis. Even in instances of that kind the tumor mass may be sloughing and be covered with incrustations and hard places like the ordinary cancer, but by simply pushing the examining finger higher up the pedicle can be discovered.

The most important feature, of course, in making this diagnosis is that if you make a correct diagnosis of cervical polypus, radical cure of the patient can be brought about easily and completely. A woman, especially an old woman, may have been bleeding from month to month, and by simply twisting off the tumor mass even without anesthesia in some instances, she is cured apparently of the cancerous condition at once.

In many instances, patients again come to us who have not been examined. The fact of a continuous hemorrhage in a woman 50 years of age or more, who has passed the menopause, is in the minds of some physicians sufficient to make a diagnosis of a malignant condition, and in that way this benign and simple condition that gives

rise to so many hemorrhages in later life is overlooked.

W. A. Guthrie, Franklin: There is one condition which produces hemorrhage of the uterus which has not been mentioned. This condition is where we do not have any growth or pathologic condition so far as I can discern. These conditions have been treated by various methods without result, namely, by the use of the cautery, ennetting, and so forth.

A number of years ago I was in Philadelphia and saw Dr. Clark in a clinic operate on one of these cases. He had used all these remedies without results, and decided to do hysterectomy. After removing the uterus he opened it and divided it and there was no pathologic condition of the mucous membrane or in the muscular tissue so far as we could discern, but all the blood vessels stood wide open. There was no contractile power whatever, and he claimed there was such an arterial condition that the arteries never contracted under any circumstances, so that there is no local method of treatment whatever that will do any good, and the only hope for these cases is a complete hysterectomy, not being a malignant condition, as shown under the microscope.

I had a case not long ago of hemorrhage, the history of which I will relate briefly and ask your opinion about it. This woman was 46 years of age, and had the change of life 10 years previously. She came to me in a nervous condition, and previous to the visit she had had considerable hemorrhage from the uterus a couple of weeks before. I made a vaginal examination and found she had complete stenosis and continual oozing of blood from the cervix. There was some erosion, but no tumor of any kind. I advised the husband of this woman to let me remove a section for microscopic examination to determine whether or not the disease was malignant. He declined, and called in a specialist to assist in making a diagnosis of the case. He was a noted man. He made a thorough examination and decided that there was no symptom of malignancy; that it would not be necessary to make a section for microscopic examination. I disagreed with him. She is continuously passing this blood, and I am still of the opinion it is cancer, and that that woman will pass beyond the stage of relief. The husband is a wealthy man and could have had any examination that might be necessary.

Louis Frank, Louisville: This discussion opens up a tremendous field for discussion and remarks, as it deals with one symptom only which itself may be present in any one of a number of other diseases any one of which might have this manifestation as one among a number of symptoms. However, there are some points which have been brought out or touched upon by some of the gentlemen who have discussed the paper that I be-

lieve require reiteration, and I think there are one or two things to which attention should be called in connection with the points they have mentioned. I refer particularly now to hemorrhage in carcinoma of the uterus. We frequently make the error of looking upon all cancer of the uterus as cancer of the cervix. We should not forget the fact that we may have cancer of the body of the uterus in which there is no ulceration, in which there is no external manifestation which can be noted by visual examination or which may be felt by digital examination. So in these cases removal, as has been suggested by the essayist, of a portion of tissue from the cervix gives no clue to the cause of bleeding. I wish to commend the last speaker for saying the microscope should be used in all cases; this is good practice, because in many cases of carcinoma of the cervix and of the body of the uterus, if the diagnosis is made sufficiently early, a radical operation can be undertaken with the greatest benefit to the patient. But an early radical operation will and always must depend upon the pathologist and the laboratory diagnosis of removed tissues. The last speaker deserves commendation for the stand he has taken and should be upheld in it.

In cancer of the uterine body removal of a section of the cervix gives no index of what is going on. The disease is inside the cavity of the uterus usually at the fundus. If you should remove a piece of the tissue by means of the curette the microscopist should know where it comes from and how it lay in the uterus. Curettings should be removed in long sections, so they can be examined in the laboratory with reference to the anatomic relation to the uterine wall, other wise the pathologist may make an error. In cureting sections through the glands obliquely you will get at the bottom of some of the glands, the cells may seem to penetrate into the muscularis, and it is impossible for the most expert microscopist to make an absolute diagnosis at all times under such circumstances. Sections must be made transverse or parallel to the glands and not obliquely.

There is one other point in connection with carcinoma of the cervix to which I desire to call attention and we must still insist upon it, and that is, women should have examinations made if the slightest hemorrhage recur after the menopause or if they have a flow which exceeds the normal amount of the regular period at any time during the climacteric. The point I would make is with reference to profuse hemorrhage, namely that in cancer of the cervix it occurs not early in the disease, but after the disease has existed for some time. If we make a diagnosis early, it is of the greatest value to our patients and early operation will enable us to save the largest percentage of cases. I cannot agree with the statement quoted as having been made by Dr. Baldy that

only two per cent. of the cases of carcinoma of the uterus operated upon recover. We have better statistics than those in doing the radical Worthheim operation, taking out a large portion of the upper section of the vagina. If we would save a greater number of these women it is very essential that we should make an early diagnosis and operate promptly. The disease usually occurs at a time when they are in need of our greatest help, at a time when these women are of the greatest help to their families, and are most important and necessary members of the community. Every effort should be made to save them. If we would do them the greatest good, we should wage a propaganda for the examination of women during the period of the change of life. If the greatest good is to be done by surgical methods, whether radical or not, our diagnosis must be made before the time of profuse uterine hemorrhage which means ulceration. At this time the cases are on the borderline with reference to giving them the best chance. When they are beyond the borderline, they have gone too far for radical operation to give relief. If help is to be given to these women, it must be earlier than the time when the hemorrhages are profuse and irregular, namely, during the period of discharge and before hemorrhage manifests itself.

I would emphasize the one point that profuse recurrent hemorrhages in cancer of the uterus means ulceration, and usually at the time the disease has progressed to a considerable extent. One should be able to make the diagnosis at an earlier period. Early diagnosis, before profuse bleeding is essential if our results are to be improved and the mothers of our country saved the horrible agony of death from cancer of the uterus.

A. D. Willmoth, Louisville: I think this is one of the most important subjects that will come before this Association this year; in fact, it is one of the greatest importance that can possibly come before us.

In the consideration of uterine hemorrhage, we have some things to bear in mind that possibly have not been so thoroughly impressed upon us heretofore. First and foremost in uterine hemorrhage, the hemorrhage comes on at three different periods of life. First, the beginning of puberty; second, during the child-bearing period, and third, at the time of the menopause.

We are all thoroughly acquainted with the fact or should be that where hemorrhage occurs at the beginning of puberty, where there is a hemorrhage from the uterus itself, it is most generally the result of constitutional conditions. These hemorrhages have behind them or underlying them a condition of the lungs, the kidneys, or liver, or they have according to Deaver, a decrease in the calcium salts in the blood, and the administration of the lactate of calcium in three-

or four doses, per day of 10 to 20 grains each, will relieve them.

There is another class of patients that belong to the class referred to by Dr. Speidel, where you have in the young girl a small polypoid growth, situated near the internal os, which has to be dealt with in a mechanical way.

I want to discourage the early and indiscriminate use of the curette. I think of all instruments, unless it be the sharp pointed bistoury and grooved director, the curette has done more harm than any instrument ever invented. It is introduced into the uterus indiscriminately at all times and under all conditions. Certainly, young women at this age do not require its use until they have had the most searching examination made, and not meddling gynecology done on them. If you keep instrumentation out of the uterus, you are not so likely to see cases of infection. If you keep it from going beyond the internal os, you will not in after years see a young woman coming to you with a leucorrhœal discharge that is the result of infection of a healthy endometrium.

When we come to the childbearing period of life, we have retained products of conception that are left behind and that cause hemorrhage in which the diagnosis is easy. If a woman has reached the menopause and you have a hemorrhage to contend with, no man is justified to treat any woman at that age for a hemorrhage with medicinal means. It does not take long to exclude any constitutional cause; then for heaven's sake and for the woman's sake take a curette, remove a piece of the tissue and subject it to microscopic examination. You can do no harm at that age. Have the scrapings examined by a competent pathologist and learn early in the case the nature of the disease when you can do something for the woman. Even though she really has cancer, a radical operation will give her some show for her life.

In the young woman do not use the curette, but in the older women at the menopause use the curette early, removing specimens in long strips, and submitting them to a pathologist, and find out what is the matter with the woman, and in nearly every instance you will find you will have beginning carcinoma, and if you resort to early and complete operation, you give the woman the best chance for her life.

R. C. McChord, (Closing the discussion: The all important point in this matter, as I can see it is the diagnosis, the cause of hemorrhage. We should be very careful about that. Upon the diagnosis will depend the treatment or cure of the disease in these cases. If we are more careful, we would be better able to give these patients hope so far as the prognosis is concerned.

A hemorrhage at the beginning of puberty means one of two things generally, a functional

congestion or a mucous polypus, and it is astonishing how often we are consulted by young women who have persistent hemorrhage that have mucous polypi. If we make a diagnosis of mucous polypi, and use the curette, we relieve them. So far as the functional congestions are concerned, they take care of themselves in many instances, without treatment other than symptomatic attention.

As I have said before, the important point in this matter is early diagnosis. A great many medical societies in the different states of the United States and other countries have adopted the rule to subject every woman during the childbearing period up to the menopause to an examination. In other words, it has been suggested that they go to the family physician and be examined once a year. Cancer is on the increase, and it is claimed the only way we can control it is by having women examined at regular intervals, and get at the disease in time so that we can do something with it. Most cases of cancer of the womb are not seen by the physician until they have advanced to a point when a radical or curative operation is impossible.

When we realize that eleven out of every one hundred women over thirty-five years of age die of cancer, we must take notice.

SECONDARY PUERPERAL PATHOLOGICAL CONDITIONS.*

By J. K. W. PIPER, Russellville.

The above conditions are those being due to, depending upon and having their origin in the primary conditions existing at or immediately following the puerperium.

There are so many secondary puerperal conditions that are largely due to the same series of primary causes, that depend upon one another largely for their degree of seriousness that the writer will take up only those that seem to him to be most important.

The most remote or primary, as well as the most frequent and preventable, causes of pelvic diseases in the puerperal patients are sepsis, due to lack of antiseptic precautions; and failure to recognize, by failing to examine for and repair lacerations, on the part of the accoucher; and, lying too continually on the back; wearing too tight abdominal bandages, and getting up too soon after confinement on the part of the patient.

The poorer class of patients is more subject to these causes for obvious reasons—the patient's environment, and lack of skillful attention on the part of the physician or midwife.

The two most important general causes of

*Read before the Kentucky State Medical Association, at Bowling Green, Wednesday, September 3, 1913.

secondary pathological conditions are lacerations and infections. To these two causes, the latter depending largely upon the former, can be attributed the great majority of abnormal conditions in the pelvic organs. In the normal properly conducted puerperal period there should be practically no secondary pathological conditions.

Tears of the perineum often destroy the integrity of the pelvic floor, resulting in the displacement or prolapse of the pelvic organs, by reason of the weakening or complete destruction of their normal support.

Rectocele, with its chain of intestinal troubles, incontinence, autointoxication, etc.; cystocele followed by infection of the bladder, which may extend through the ureters to the kidneys, and retroversion and prolapse of the uterus and other pelvic organs, as well as conditions due to and following lacerations of the cervix, such as endometritis, sub-involution, tubo-ovarian inflammations and malignant conditions are some of the sequelae.

All lacerations increase liability to septic infections, and by the consequent congestion inflammation and following adhesions, with the weakened support promote sub-involution of the uterus, which in turn increases the liability to prolapse. Many of the sequelae result in a variety of conditions which may not appear for years later.

These pathologic conditions all have many symptoms in common and several conditions may exist at the same time, which dovetail into one another in such a way that it is hardly possible to diagnose their separate conditions unless we consider them singly, or to treat them successfully unless we treat them jointly.

Perineum: While it is impossible to prevent all perineal from being lacerated, by a systematic effort to protect them it is possible to reduce the number and frequently lessen the extent of the tear when it cannot be prevented. Preventive treatment is always in order, and, I believe, can best be done in these cases with the patient lying upon her side while the child is being born. In this position the perineum can best be supported and massaged, (which will frequently cause it to stretch farther) and the presenting part can be better seen and prevented from being expelled too rapidly, which in the great majority of cases is the cause of the tear.

When a tear does occur, unless it is submucous, which is rare, it can usually be easily diagnosed by dilatation of the vulva and inspection. This should invariably be done. Care should be used to ascertain the extent accurately before an attempt at repair is made. Here again preventive treatment of

many secondary pathologic sequelae should be the immediate repair of all lacerations of the perineum, if the patient be in condition to stand it. In some of our eastern hospitals repair is made before delivery of the placenta.

As the median tears do not usually involve the integrity of the levator-ani muscle, the pelvic floor remains undisturbed, but if the sphincter-ani be torn and not repaired at once it can never be so easily done afterward.

If the tear extends laterally, involving the vaginal sulci or towards the ischio-rectal fossa the fibres of the levator-ani muscle are liable to be divided, and the fascia opposite the vaginal outlet lacerated. In this condition the function of these muscles is destroyed and the pelvic floor can no longer support the pelvic organs as well as the terminal ends of the urethra, vagina and rectum, and if allowed to go unrepaired the muscles will soon retract and atrophy, and even though an operation for their repair is done later it is never so satisfactory, for they never regain their full power. If this condition continues involution of the uterus and vagina is arrested, the uterine ligaments become stretched by the increased weight, and prolapse of all the organs of the pelvis takes place. Immediate repair is always indicated, for it lessens the danger of infection as well as saves the patient from the possibility of the sequelae that so frequently occur.

The diagnosis of old tears is made by inspection and palpation. A relaxed, patulous vulvar orifice, frequently standing open, anal ring prominent, and more or less relaxed; and flat perineum which the patient is unable to contract or pull forward. If examined in the squatting or sitting position and she be required to bear down the anterior and posterior walls of the vagina roll outward.

The treatment is surgical.

The technic of primary and secondary operations for lacerated perineum is found in all text books and will not be described.

Cervix lacerations occur to a greater or lesser extent in the majority of first labors, but the large proportion heal without trouble. In lacerations that have existed for some time the symptoms are due to the lesions for which the lacerations are responsible. The most prominent of these secondary conditions are subinvolution of the uterus, displacements partly due to subinvolutions, chronic endometritis, chronic tubo-ovarian disease following the endometritis, and cancer.

The main symptoms are a feeling of weight in the pelvis, pain in the back and head, usually referred to the vertex, increased and painful menstruations, lacerations, a tendency to abortion, many reflex nervous symptoms

due to these conditions, and to the scar caused by the effort of nature to repair the wound.

Diagnosis is made by touch and sight, and if the condition has been of long standing the secondary pathological conditions are in evidence in a majority of cases. Any position that will expose the cervix will answer for the examination, but the Sims position is probably the best and a short bladed bivalve or a Sims speculum can be used. The cervix is blunt, indurated and harder than normal, the torn lips with rolled over edges, partly covered by intra-cervical mucous membrane can be seen, and the plug of scar tissue, tender to pressure can be felt at the bottom of the wound. To further prove the nature of the lesion a tenaculum or bullet forceps can be hooked in the edge of each lip and the latter drawn together. As this is the favorite site for the development of cancer, and as eversion of the intra-cervical mucous membrane without laceration occasionally occurs, and eversion of the cervix without laceration not uncommonly, a differential diagnosis must be made between these conditions.

In cancer the disease is rapid in its course; true ulceration is present and bleeds freely; the discharge has the characteristic odor of malignant growth and a microscopic examination of the tissue can be made if doubt still remains. In eversion or erosion without lacerations the diagnosis is made by the absence of the signs of lacerations and by the history of the case.

Treatment: Fresh lacerations should be stitched immediately if possible as preventive treatment. If none of the above named secondary conditions exists, which is a fact in more than half the cases of old laceration, no treatment is necessary; if they do exist, in advanced stages operative treatment is necessary and should be done, unless there are grave pelvic lesions which prevent it. Hard, sensitive scars in the angle of the wound, hypertrophy of the tissue, induration, cystic degeneration, endometritis, erosions, eversions of the cervical mucous membrane, uterine displacement or any conditions responsible for subinvolution are indications for surgical treatment.

Palliative Treatment: When the case is of recent origin, and the secondary conditions are not grave, local routine treatment may be of some benefit, not to cause the laceration to unite, for this is practically impossible, but to prevent mild uncomplicated secondary conditions from becoming grave. Hot douches of two or three gallons of normal salt solution taken in the recumbent position night and morning, will frequently lessen congestion, and if followed by a glycerine tampon placed

against the cervix every three or four days and allowed to remain from twenty-four to thirty-six hours, will frequently assist to deplete a slightly subinvolved cervix. Scarification or puncture of an eroded cervix so as to draw a few drachms of blood once a week in addition to the above treatment is often of marked benefit. Small cysts should be evacuated and wiped out with carbolic acid. I have seen much benefit to erosions derived from painting with Churchill's tincture of iodine, about every four or five days, in addition to the regular douche treatment. The antiseptic vaginal suppositories composed of glycerine, gelatine, hydrastis, ichthyol, etc., put up by the different drug firms, and the wool capsule tampon is an easy and convenient treatment.

Surgical Treatment: If the case has continued for some time a preparatory treatment such as described above may be advisable before an operation is done. The choice of the operation to repair the cervix depends upon the extent of the loss of tissue, hypertrophy, etc. Where there is but a simple lesion and small loss of tissue, trachelorrhaphy is the operation of choice, but if the laceration is stellate with great loss of tissue, or when extensive erosions with cystic degeneration or cervical erosion is present amputation is indicated. Great care should always be used in dissecting out all scar tissue, as it is in this tissue that cancer so often has its beginning. The technic of the operation is too well described in text books to mention here.

SEPTIC INFECTIONS.

The most common expression of septic infections is endometritis, local peritonitis, general peritonitis, tubo-ovarian inflammation.

Endometritis: Infection of the endometrium by septic micro-organism is the beginning of the majority of the inflammatory lesions affecting the pelvic organs. Post puerperal infection is the most common cause of this disease. Frequent vaginal examinations without proper septic precautions, unclean operations, introducing unclean fingers or hands into the uterus, criminal abortions and retained particles of placenta are among the most common causes. In the acute variety the symptoms are more apt to appear in three to six days after labor and are frequently ushered in by a chill, sometimes several, followed by a rise of temperature. In several cases that I have seen the chill has been preceded by a period of several hours of a feeling of well being. The fever course is of the usual acute septic, irregular character, and if the source of infection is not destroyed, continues to mount higher, the pulse becoming more rapid, compressible and weak; gastro-

intestinal symptoms occurring in the meantime, and the patient dies of exhaustion.

Diagnosis: The uterus is usually soft and flabby; the os uteri patulous and open, the vagina filled with the characteristic purulent secretions and lochia. The body of uterus is tender on bi-manual pressure. The differential diagnosis must be made between this condition and malignant diseases of the body of the uterus, fungoid or polypoid growths, sloughing off from the inner surface of the uterus, and from an incomplete abortion, by a careful examination of the discharges, if necessary with a microscope, and by a careful study of the history. A differentiation can be made between this condition and a fallopian tube or pelvic abscess by the intermittent character of the discharge of the latter accompanied by pain, and by a careful examination per rectum and vagina.

In uncomplicated chronic endometritis the slight enlargement of the uterus and the discharge are the only signs.

TREATMENT.

The treatment of postpuerperal variety of this affection is irrigation with hot antiseptic solution followed by normal salt solution in large quantities. This should be used through a return flow uterine douche that allows the return to come away freely, and as much as several gallons of this solution may be used. I have followed this irrigation in several cases with a few ounces of twenty-five to fifty per cent. solution of alcohol and water with apparent great benefit. The irrigation may be done every six or eight hours unless there is improvement. Curettage may be necessary if particles of the membrane are still retained. This should all be done with a dull curette and followed by hot antiseptic douche. If it can be ascertained that the parenchyma of the organ is the seat of infection hysterectomy may be necessary.

General septic peritonitis is practically the same as in non-puerperal conditions, is practically always fatal and will not be discussed here.

Local pelvic peritonitis manifests itself by a gradual rise of pulse (100 to 120) and temperature 101 to 103, accompanied by light rigors, muscular aching, localized abdominal or pelvic pain with slight tympanities; stomach unsettled; appetite poor; bowels irregular and skin clammy. It usually runs a slow course and is amenable to treatment unless the infection is very virulent. It must be diagnosed from general septic peritonitis and from non-peritoneal local abscess. The pelvic cavity should be examined per vagina, rectum, and by vaginal abdominal palpation, and if an abscess can be found it should be open-

ed and irrigated or wiped out and treated in the usual manner and drained. If none can be found, and the patient is gradually growing worse, the abdomen should be opened and a search made for the point of infection, and it should be treated accordingly. The most frequent situation in which an accumulation of pus is found is in Douglas cul-de-sac where it can usually be opened and drained through the vagina.

The patient should be nourished by highly concentrated foods in small amounts, heart and nerve stimulants such as whiskey and strychnine should be freely given. Saline laxatives and enemata to keep the bowels open. This condition is always followed by adhesions, which contract and have largely to do with mal-positions of the uterus, ovaries and tubes, sometimes matting them together in one common mass that is frequently impossible to treat except by abdominal operations. Adhesions frequently form between these organs.

Tubo-ovarian disease will only be referred to with respect to their complicating the diagnosis and retroflexion and introversion and the treatment of prolapse.

Displacement of the Uterus. Practically the only uterine displacements that can be considered strictly as secondary puerperal conditions are retroflexion and retroversions and prolapse. The latter are simply an advanced stage of the former. About one-third of all cases of retro-displacement are uncomplicated (frequently found in multiparae) and if associated with pelvic pains or menstrual disorders they require no treatment. About one-fourth of the cases are accompanied by and due largely to laceration of the perineum, involving the levator-ani muscle and are associated with a relaxed condition of the broad and round ligaments. The uterus is in a condition of sub-involution, hence the condition is due to an increased weight or pressure downward, and a lessened ability on the part of the normal support to hold the weight. Upon examination the cervix is found low down in the vagina and pointing forward. The fundus can be felt through the posterior vaginal wall or per rectum, in the hollow of sacrum. If the patient bears down, as in the act of defecation, especially if she be examined in a sitting position between two chairs, one buttock on either chair or in a standing position with the legs apart, the uterus will be felt to descend and the anterior and posterior walls of the vagina bulge outward.

In complete prolapse this condition is simply exaggerated. The vagina turns inside out, is reflected back over the uterus as it de-

scends through the pelvic outlet and vulva, dragging with it the ovaries and tubes, and a diverticulum of the bladder in front and the anterior wall of the rectum behind. This condition, as well as the symptoms, come on gradually. To the latter there is practically no end.

The best descriptive symptoms as spoken of by the patient is that she feels as though everything was going to fall out of her.

Back ache more or less relieved by a recumbent position: pain in the top and back of the head: pelvic pain increased by exercise or erect position: constipation caused by the pressure of the rectum on the sacrum: bladder symptoms, caused by residual urine, and endometritis and leucorrhœa. During process of formation while tissues are being stretched and dragged upon, the pain is much aggravated, but when the sacro-pubic hernia is complete the pain subsides to a great extent, and though the patient may suffer much inconvenience by the mass hanging between the thighs, if no further complications takes place she may go on for a number of years moderately comfortable. Probably one of the greatest dangers to life is from bladder infection which may extend to the kidneys.

In diagnosis of earlier stages the round mass felt through the posterior vaginal walls must be distinguished from uterine fibroid and ovarian tumors. This can usually be done by vaginal examination or by the careful use of the probe under thorough antiseptic precautions.

In later stages it must be distinguished from inversion of the uterus, in which condition the cervix forms a ring about the mass and no opening can be found through which a sound can be passed into the uterus. Also from cervical polypus, which by careful examination will be found to be hanging out of the uterus, and a sound can be made to enter the uterus from all sides and will pass completely around the mass.

TREATMENT—PALIATIVE AND RADICAL.

Paliative treatment can be used with benefit in early not too badly complicated cases. It consists of means to reduce congestion and to replace and to retain the uterus in its proper position.

The knee chest or the exaggerated Sims position, is best. In either of these positions, if the end of the finger is pressed against the front of the cervix and it is pressed back and at the same time the posterior vaginal wall is forced back by the body of the finger a column of air will inflate the vagina and the fundus will fall forward into its normal position, if there are not too many adhesions holding it back. Through a speculum that

the operator can best use, a tampon of cotton wool or gauze with a depleting mixture of glycerine and boric acid, such as mentioned above for local treatment, is placed so as to hold the uterus in position, or at least prevent its falling as low as before. The patient should lie in this position for a few minutes to allow the parts to adjust themselves, and should not be allowed to turn over on her back before getting off the table, but to assume the upright position from that in which she was when the tampon was introduced, so that the intestines will fall down on top of the antverted uterus to assist in holding it in its place. This tampon can be used every four or five days and be allowed to remain in place for from twenty-four to thirty-six hours, and the usual hot saline solution douche used after its removal and continued twice daily always in the recumbent position. The uterus can be placed in its normal position much more easily by the above described method than by the bi-manual method with the patient on her back, especially in fat people.

The patient may be taught to replace her own uterus by assuming the knee-chest position and forcing the posterior walls of the vagina back with her finger or thumb. She should do this upon retiring every night after using the douche.

If there is an absence of lateral inflammatory conditions, not too many posterior adhesions, and the vaginal outlet sufficiently closed to retain a pessary, many a selected case may be benefited by its use. The diameter of the vagina being greater near its cervical than at its vulvar end will ordinarily retain a ring pessary, which by spreading the vaginal walls and at the same time encircling the cervix, will have a tendency to support a retrodisplaced or descending uterus. While some form of the hard rubber ring pessary (the ordinary ring, Thomas or Hodge) will usually suffice, as there are no two cases alike, it is essential to success to use the one that fits. If it does not fit at first its shape should be changed until it will fit or it should not be used. It should not be too large as undue pressure will do harm. It can be introduced with the patient on her back after the fundus has been brought forward but she should be placed in the knee-chest position so that the uterus will be held forward by gravity and the pessary further adjusted if necessary, and the patient be required to assume the upright position without again turning upon her back. Whether or not it does what it is intended to do can be learned only by an examination made with the patient in an upright position. Especially in cases of prolapse in old women in whom for some reason operations are con-

tra-indicated pesary is advisable. These pesaries do not prevent the use of the douche or the vaginal suppository referred to above.

RADICAL TREATMENT—SURGICAL.

There are so many conditions due largely to the same cause dovetailing into and depending upon one another for their continuance that when we contemplate the cure of extreme retroversion and prolapse by radical surgical means we must consider the complications or be unsuccessful in our operations. In nearly all of these cases a series of operations is necessary. No two cases are alike.

Prolapse is nearly always accompanied by lacerations, ulcerations and other diseased conditions of the cervix, by endometritis and sub-involution of the uterus and frequently by cystocele and rectocele.

The patient should undergo a preliminary treatment for at least a few days before the operation, attention being given to hygienic measures in general and to diet. Constitution and local treatment should be given to meet the indications of each case.

If endometritis exists dilatation and curettage and other appropriate treatment is indicated before a cervix or perineal operation. If the cervix is lacerated it should be treated by trachelorrhaphy or amputation before the pelvic floor is repaired.

Where prolapse is complete the vagina and uterus should be replaced in the pelvic cavity, and where ulcers or erosions exist on the everted vaginal mucosa they should be treated by hot douches and other necessary medication, and the patient should be kept in bed until they are healed. A rectocele or vesicocele operation may be necessary, and finally repair of the pelvic floor by the appropriate operation, shortening of the round ligaments or if the patient is beyond the menopause ventral suspension of the uterus. The treatment of the causes usually relieves the sub-involution, but hysterectomy may be necessary.

There are many other secondary puerperal complications of more or less importance that could be mentioned such as phlegmasia-alba-dolens, parametritis, pyaemia, mastitis, puerperal insanity, and acute infections diseases, but time and space do not permit.

The principal points to which attention is called are the following:

The use of alcohol as an intra-uterine antiseptic, immediate examination for and repair of laceration; the upright or sitting position in which to make examination to learn extent of prolapse, and the knee-chest or Sims position to replace a retroverted uterus and adjust a pessary.

DISCUSSION.

H. H. Grant, Louisville: I have been asked to say a few words on this subject. There are two points that should be considered by an audience of this kind. We are obliged to realize that there is a time and place for everything, and we cannot expect here to be instructed in obstetrics and gynecology, and there are only a few points that as general practitioners we may regard as of practical interest in connection with this subject. One of these would be the question of immediate treatment of the patient directly after the puerperal state, with respect to traumatism that has obtained during that state, and secondly the treatment of septic conditions. I think it is well for us to remember with respect to the immediate surgical treatment of these traumatisms that as much harm can be done by improperly directed surgical treatment as by the carelessness that allows these women to have sepsis, and the temptation of those who are not prepared to do extensive surgical operations gives an opportunity which should be resisted, where the practitioner does not feel he can do as much good as he might do harm. For this reason, I would say of recent cervical lacerations they can be managed by a competent hand and should receive prompt surgical treatment, but those in which the attending physician feels he is not prepared properly to cope with had better be treated on the expectant plan until proper surgical aid can be obtained. Just what this should be will depend upon the surrounding condition, upon the knowledge of the attending physician, and upon the facilities he has and practically upon his own conscience in a very large proportion of cases.

I feel it is just as well to call attention of the general practitioner to the fact that the very best surgical skill is often misdirected and the very best results that are hoped for are not obtained in experienced hands and as much is undone by improperly executed operations as may be corrected where an operation has never been undertaken at all. For this reason, the attending physician is not a censor of himself. If he is confronted by conditions of this kind and believes that a secondary operation is essential, and realizes that he is not properly equipped, it is better for him to not undertake it.

With respect to the septic condition, there is one word I would like to say here. The essayist in his opening remarks stated such conditions could be prevented by proper attention and care. My own observation has been that in many instances septic infection occurred without its being possible to trace its cause and where the greatest care and precaution has been taken. For this reason, I do not think the attending physician should censure himself unless he realizes that some error of his own has been made.

Otherwise he is not to be censured for a septic condition that may creep in, especially where he has taken such precautions as the surroundings would enable him to take.

Care should be taken where chills and fever have occurred after abortion or at full term to see that nothing is retained within the uterus, and the exploration should be made with the finger or with a blunt instrument or with a blunt pair of placental forceps. Under no circumstances should acute conditions be everted, and the fingers, where a patient has gone the full term, make the simplest and safest method of exploration. The physician should satisfy himself that he has removed all loose pieces of placenta or other debris, and afterwards resort to irrigation which was suggested by the essayist. This irrigation may consist of warm water or one may employ a weak solution of iodine. You may use 10 per cent. of iodine in the uterus for the first irrigation as early as possible after the development of the septic condition. This has seemed to me a satisfactory means of removing the septic material and preventing its absorption.

A. D. Willmoth, Louisville: I want to emphasize the first remark made by Dr. Grant. As to infection following labor, if we are to consider that the attending physician at each accouchement is responsible for the infection that occurs in that woman, the medico-legal committee will be much busier in the next few months than it was reported as being last night. If the reports are correct, that nearly 80 per cent. of the women who come to the operating table for abdominal conditions are the results of social diseases, I fail to see why the obstetrician is responsible for such a large per cent. of the infection that follows labor. Certainly, it is true, many of the tubes lying in a dormant condition, are lit up by the contractions of the uterus during the expulsion of the contents of the uterus, and if the infection is set free in the abdominal cavity, it is something over which the attending physician has absolutely no knowledge or possible method of control. His only hope is to sit the patient up in bed at an angle of near 40 degrees and keep infection within the lower pelvis and prevent rapid absorption. This is worthy of mention and emphasis, and let enough stress be laid on the point to the public that we are not responsible for everything that happens.

The second point I want to speak of is with reference to the employment of the curette. It was also touched upon by Dr. Grant. I do not believe the use of the curette is ever justifiable within an infected uterus. You should go in with the finger. You can clean out with the finger any retained secundines that are there, and you do not open up any of the lymphatic mouths which will hasten the absorption of the septic material within the uterus. After it is once in-

vaded by you, the employment of hot saline solution, or a weak iodine solution, as the previous speaker referred to; together with application if you desire of packing of the uterus with iodoform gauze, which will give you a constant supply to the uterine wall, of a small amount of iodine, for the next few hours by lubrication of the iodine set free from the gauze. This will give you all you can hope for from medical treatment, or local treatment. If the infection is localized within the pelvis, operative work might be of benefit, but the number of cases is rare where the uterus should be invaded where infection has taken place. In those cases where we think the condition is local, it is the hope of the surgeon to control the thrombo-plebitic condition in the pelvic cavity. This however can seldom be done.

The next point of interest is the use of vaccine. I believe in these cases the use of vaccines is of untold value. You can certainly get results in many instances by the proper application of stock vaccines, and if you are prepared you may use autogenous vaccines, and if time should permit they are of course preferable.

Edward Speidel, Louisville: I would not like to leave the complete discussion of the treatment of puerperal infection in the hands of the two surgeons who have preceded me. I am more conservative than both of them. The conservative treatment of puerperal infection consists in strict antisepsis and under anesthesia of the full gloved hand being introduced into the uterus and by the aid of the other hand upon the abdomen palpating the entire surface of the uterus and removing anything within its cavity. No instrument of any kind should be used in a puerperal uterus. This is followed by hot intrauterine douches, whether hot normal saline solution or 10 per cent. iodine solution matters not, and the uterus is left severely alone. It is dangerous to pack a full term puerperal uterus with a tampon of iodoform gauze that would be necessary under such circumstances for fear of iodine poisoning or iodoform poisoning. The uterus should be left entirely alone and the further treatment of such cases should be conducted as we would conduct a case of typhoid fever. That in some instances vaccines have proven beneficial in cases of this kind is true, and they may be used in addition; but the main point is this: the uterus if entered at all, should be entered once only, and only one intrauterine douche should be used. The latest text book issued by De Lee, of Chicago, goes further than that. He does not advocate any manipulation of the uterus whatever, even if it is known portions of the placenta have been retained. He claims the portions of placenta soon become necrotic and after fatty degeneration escape from the uterus, and more danger and more harm are done the patient by the intra-

uterine manipulation than can be caused by the small amount of retained tissue.

Leon L. Solomon, Louisville: It is but natural that the argument touching the complications, that arise in the sick room following the puerperium, should take the direction of least resistance namely that of possible infection of the endometrium and the other pelvic contents, thereafter.

There came under my observation, some 5 or 6 months ago, a lady 43 years of age who had ceased to menstruate for some several months preceding my visit to her. Her presumption was, she had been pregnant, and ours was also that she had been pregnant.* The leucorrhœal discharge besides blood, contained elements found only after pregnancy. On account of the size of the uterus and the profuse hæmorrhage that followed it was determined to use the curette, and it was explained to the members of her family that it might be necessary to remove the organ as we felt there was a possible malignancy. The curette finding evidences to justify such a conclusion in the endometrium, hysterectomy was undertaken. The hæmorrhage had been so profuse for weeks before the operation and was so great during the operation that haste was necessary. The uterus was removed, and the pathologist handed in his report several days later of "apoplexy uteri," a condition which according to my reading, is quite unusual, and modern from the pathologic viewpoint.

I report this in conjunction with the discussion of Dr. Piper's paper, pertaining to the "puerperium and the complications accompanying it," and incidentally want to say that on account of the profuse hæmorrhage and the hurry, necessary to get the lady off the table alive, unfortunately both ureters were tied, a most unfortunate condition, as you can well imagine. No urine was voided, and after 36 hours, a ureteral catheter was passed proving both ureters entire occluded. The occlusion was removed, under difficulty, hæmorrhage again complicating our efforts, and being most profuse. The patient, not being able to withstand the shock of second operation and coincident loss of blood, perished as a result of it.

I report this case, not on account of this unusual complication in surgery, followed by fatal termination, but because of the interest, which attaches to the diagnosis of "apoplexy uteri," made by a very competent pathologist.

J. K. W. Piper, (Closing the discussion): I appreciate very much the discussion my paper brought out, and I have very little more to add except to say that my remarks in regard to curettment of the uterus must have been misunderstood on the part of some. I do not advocate curettment of the uterus after the delivery of a full term child, nor if it has advanced a material time,

but abortions frequently occur at one or two months and unless a man has a longer finger than I have, and a smaller one, he cannot always get into the uterus. Sometimes particles are left which are better taken out than allowed to remain. I mentioned the use of the dull curette but certainly no well informed man would use one and scrape sufficiently hard to do damage. He should use a small, dull curette or placenta or sponge forceps for removing particles which remain in the uterus after early abortions, but not after full term labor. If there has been a possibility of septic infection the use of the above instruments should be followed by an intrauterine douche of some mild antiseptic followed by normal salt solution.

MODERN METHODS OF INFANT FEEDING.*

By GAVIN FULTON, Louisville.

The manifold advantages of maternal nursing and its superiority over any other known method of feeding is self-evident and the scope of this paper will not include a discussion of this phase of the subject.

Suffice it to say that in spite of the alarming increase in the number of bottle fed babies only about 8 per cent. of the entire number legitimately belong to that class which will require other nourishment than is furnished by the maternal secretion. Clinical experience bears out two facts, namely: that the breast-fed baby is far better equipped to withstand the dangers and exigencies of the first nutritive period than the one which is artificially fed, and that the mortality from gastroenteric disease is about three times as high in the latter as in the former, perhaps even higher. It therefore seems that a free discussion of the present methods of artificial feeding would be prolific of interest to us all.

In approaching the subject I shall group all the proprietary foods, whether of malted grain, dried milk or what not, into one class and dismiss them with the statement that in the writer's opinion no one of them is capable of meeting the requirements of the growing infant and that their use is only justified in certain emergencies, and for a short period of time. To me artificial feeding just means one thing; the modification or adaptation of cow's milk to meet the requirements of the individual infant.

As breast milk is the only food which perfectly fulfills the necessities of tissue growth and development so, in preparing a modification of cow's milk successfully, we must approach as near as possible the percentage of

*Read before the Kentucky State Medical Association, at Bowling Green, Wednesday, September 3, 1913.

the food elements as they are found in normal breast milk. There are several methods for modification in vogue at the present time, all having their enthusiastic supporters among prominent pediatricists of the country. But no matter how they differ in the manner of their preparation they all depend upon two fundamental factors: First, a knowledge of the percentage relationship of the various food elements; Second, the calories to be obtained from their combination in definite quantities.

Top-milk mixtures, separated cream and skim milk mixtures whether prepared at home or in especially equipped laboratories are open to the same criticism, namely, the amount of handling necessary in their preparation increases the bacterial count to a great extent and encourages secondary changes in the milk which are not always noticeable at the time. Separated and gravity cream do not present the same chemical and physical arrangement of the fat globule as is found in the breast milk or even in whole cow's milk. Thus the infant is liable to a fat indigestion even when the fat percentage is suited to its apparent needs. Lastly, because of the general teaching of a few years back, that high fat mixtures would prove a panacea for dietary constipation and wasting of marasmus and allied conditions.

These methods make it too easy for the tyro or unthoughtful who raise the fat percentage to a harmful degree even to a healthy child. I remember a case of an emaciated, anemic infant four months of age which was supposed to have tuberculosis. It was being fed an incredible mixture containing 6 per cent. of fat, 8 per cent. of sugar and 5 per cent. of proteid. It had an elevation of temperature, vomiting, eructations, green acid stools and was losing weight rapidly. As soon as the digestive tract was thoroughly cleansed and the infant put on a suitable combination, the symptoms subsided and it began to gain in weight and the tuberculosis (?) disappeared.

The method to which I particularly desire to call your attention to-day is the one known as the simple dilution of whole milk. This method is based upon the premise that average whole milk contains the following percentages: 4 per cent. fat, 4.50 per cent. sugar, 3.50 per cent. proteid and the dilutions are made so many parts in 20. Thus if 20 oz. of whole milk contains the above percentages, then 1 oz. in a 20 oz. mixture will contain one twentieth of this amount which would be .02 per cent. fat, .225 per cent. of sugar, .175 per cent. of proteid. The above figures being established it becomes an easy matter to bring the percentage to any desired point by increasing or decreasing the number of ounces

of whole milk in twenty. This applies to the fat and proteid contained but the sugar percentage would always remain disproportionately low. In order to overcome this difficulty simply add enough sugar solution to the diluent of the mixture to bring up its sugar percentage to the desired point. This can be done in the following manner: If a 1 oz. in 20 mixture contains .225 per cent of sugar then a 10 oz. in 20 mixture would contain 10 times as much, which would be 2.25 per cent. Now if the desired sugar in this mixture was 6 per cent. you would readily see that it would be necessary to add of sugar solution the difference between the percentage desired and that obtained from the milk, which in this case is 3.75 per cent. In order to determine how much sugar this would be in actual weight simply multiply the amount needed which is 3.75 per cent. by the total number of ounces which is 20, and the result will give you the sugar in ounces necessary to complete the desired percentage of the total mixture.

If for purposes of convenience, such as lack of scales to measure ounces or parts of ounces, it should be desired to reduce this again to level teaspoonfuls, then multiply the above sum by 8 and this will give you the total number of level teaspoonfuls needed.

The percentage of fat and proteid in any given mixture can be recognized at a glance by following these very simple rules: Multiply the number of ounces of whole milk in a given mixture by 2 and this will give you the fat percentage in the mixture. Then remember that in simple dilutions, the relationship between fat and protein is always the same no matter how strong or how weak the dilution; namely as 8 is to 7, so that the protein percentage will be approximately one-eighth less than the fat. Example: A mixture containing 10 oz. of whole milk in 20 according to this rule would contain 2 per cent. of fat, 1.75 per cent. of proteid. On the other hand the reverse rule is equally true. In order to determine how many ounces of milk it would be necessary to use in a 20 oz. mixture to make a certain percentage, simply divide the desired fat percentage of the mixture by 2 and the result will give you the number of ounces of whole milk needed.

Example: A mixture containing 2 per cent. fat, 1.75 per cent. of proteid, 6 per cent. of sugar divide the fat percentage by 2 which would give you ten, the number of ounces of whole milk needed, then bring up the sugar percentage to the desired point as described above.

To make a 30 oz. mixture, increase all the proportions of the 20 oz. mixture one half,—to make 40 oz. double the amounts of 20 oz. mixture and so on as desired. This method

when once acquired has many advantages over other methods. In the first place its simplicity of preparation, ease of reckoning percentages without the use of complicated mathematics or laborious tables, the facility of changing the percentage up or down as desired by adding or subtracting an ounce of milk and the ability to furnish the fat globules of whole milk in their original form. Lastly the impossibility of making an extremely high fat mixture. The one objection to the method is the fact that the relation between the fat and the protein will always be the same and in the instance when high fat in proportion to the protein is desired, it would not be applicable.

The kind of sugar to use in milk mixtures for infants is still a vexed and mooted question. I believe the majority of infant feeders still prefer milk sugar in their practice. Up to two years ago the writer held this view also. Since that time, however, I have modified my opinion and have changed over to the routine use of cane sugar as has been advocated for so many years by Jacobi, replaced as occasion indicated by maltose. Personal experience has satisfactorily demonstrated to my mind that milk sugar does not practically bear out its theory. We know for instance that it is a much less staple sugar, that it favors lactic fermentation and encourages bacterial growth, and its constant use certainly increases the tendency to intestinal fermentation and sugar indigestion.

Cane sugar on the other hand is a preservative and retards these changes in the milk. It furthermore is just as readily split up into the end product of glucose and thus assimilated by absorption with no great strain upon the sugar splitting functions of economy. Since the first of January I have used the simple dilutions with cane sugar addition exclusively both in my private practice and in the clinics of the Babies' Milk Fund Association of Louisville. It has been my rule to start with a 5 oz. in 20 mixture containing 6 per cent. of sugar according to the age, weight and condition of the infant. Thus a healthy baby up to

- 1 month, would get 5 oz. in 20
- 2 months, would get 7 1-2 oz. in 20
- 3 months, would get 10 oz. in 20
- 4-5 months, would get 15 oz. in 20
- 6-7 months, would get 18 oz. in 20

Of course these figures would be changed up or down in accordance with the need of the individual baby, and no change would be abruptly made from one formula to another but the mixture would be increased 1-2 or 1 oz. at a time until the next formula and

strength is reached. It will be seen that as far as percentages are concerned this method leans about midway between the two extremes, the high fats on the one hand as advocated by Rotch and the high proteid as advocated by Finkelstein on the other hand. I have found that a larger number of infants will tolerate and thrive on a higher proteid than I formerly thought and as proven by Finkelstein, the protein content of infant food is far less frequently a factor in the nutritive disturbances than was formerly believed.

After having decided upon the percentage to be used in a given case it is then necessary to remember the caloric requirements in the case. According to Huebner's energy quotient, the growing infant during the first three months needs approximately 45 calories per pound of its weight. During the second three months 40 5-10 calories per pound of its weight, during the last six months about 36 1-2 calories. Generally speaking we may say that the average infant during the first year of its life requires in its food balance about 40 calories per pound.

It is a very simple matter to determine the calories to be derived from any given mixture. One oz. of whole milk in a mixture furnishes 21 calories. One oz. of dry sugar, whether it be lactose, cane sugar, or maltose, furnishes 120 calories. By adding together the number of ounces of whole milk contained in mixture and multiplying by 21, the calories furnished from the milk are obtained. Then add 120 calories for one ounce of sugar and proportionately each part thereof. Example: A whole, 10 in 20 mixture, 6 per cent. sugar, 10 oz of whole milk would give 210 calories and 3-4 of an oz. of sugar necessary to bring the mixture to 6 per cent. would furnish another 90 calories making a total of 300 calories supplied by 20 oz of the 10 in 20-6 per cent. sugar mixture. Divide this by 40 and you would have a 20 oz. mixture furnishing sufficient energy to supply a 7 1-2 pound baby 24 hours food.

The objection to this method of estimating the caloric value of a given mixture is that the energy power is figured from the mixture as a whole and it is impossible by this means to determine how many calories are furnished by the fat and carbohydrates and how many are furnished by the proteid. When this is desired, Moorehouse's rule is very satisfactory, and as it can be found in any text book, I shall omit it here. While it is true that all mixtures should have a caloric value approximating 40 calories per pound of weight it should be remembered that the caloric value is secondary to the percentage needed. The baby during its first year develops and gains nearly three times its birth weight

so that it is not only necessary to figure on the food supply containing enough nitrogen to make a complete balance of weight but also enough increase to allow for cell proliferation which is growth and development; therefore the proteid should be called upon to furnish little if any of the heat and energy required.

You may have a mixture containing correct caloric value, enough protein to care for the daily balance and the increase in growth and yet the infant remain at a stand still or even lose weight and still have no digestive symptoms. The explanation here would be that a sufficient supply of the protein given would be used up rapidly to repair waste and the excess would then be utilized in furnishing heat and energy which is not the legitimate province of protein. In other words the heat and energy production which should be performed by the fat and sugar has been thrust upon the proteid because of an insufficient amount of the two former elements, in the mixture, and so you can readily see the importance of the proper balance of the relationship between the fat, sugar and proteid. In many cases this can only be determined by the careful study of the stools verified by the clinical symptoms of the indigestion.

When the infant shows signs of fat indigestion the fat percentage should be lowered and the sugar required to furnish the greater part of the heat and energy. When the indications are of sugar indigestion or sugar and fat indigestion combined, the fat percentage should still be lowered and the sugar changed to maltose or even excluded entirely for a short period and the brunt of the work put on the proteid for the time being. In cases of fermental diarrhoea and sugar intoxication where it is necessary to change to malt sugar I have adopted the following plan with most satisfactory results. I substitute any good malt extract for the cane sugar in the mixture, in the following manner: It has been demonstrated, first I think in the Babies' Hospital, New York, that one dram of malt extract in a 20 oz. mixture increases the sugar percentage .06 per cent. With these figures in mind it is very easy to bring the mixture to any percentage desired simply by adding so many drams of the malt extract to every 20 oz. Below I will quote a series of cases ranging in age from birth to 1 year including healthy babies, babies suffering from various forms of indigestion, syphilitic marasmus and inanition which were fed exclusively in the manner I have attempted to describe above:

Summary of 24 cases treated at the Children's Free Hospital, Louisville, Ky., June 1 to August 1, 1913: 14 lived, 13 doing well, 1 unimproved.

Age: 10 under six months, 4 six to twelve months.

Diagnosis: 6 difficult feeding, 2 Rickett's, 3 malnutrition—gastroenteritis, 1 bronchitis, 2 syphilis.

Ten died—Age: All under six months.

Diagnosis: 1 broncho-pneumonia, 4 gastroenteritis—malnutrition, 1 pertussis, 4 syphilis.

Summary of 49 cases treated at Babies' Milk Fund Association, Station No. 2, January 1 to August 1, 1913: 25 under six months, 24 six to twelve months.

No deaths.

Average increase in milk: Two oz. per week up to normal age and condition requirement.

Average gain in weight of the 25 under six months of age, 4.4 oz.

In the first series of cases reported I wish to emphasize the fact that all the cases were **forlorn hopes**, three dying in thirty-six hours after admittance and two before the end of the first week, and any case saved should be considered a distinct gain.

DISCUSSION.

B. S. Rutherford, Bowling Green: I would like to ask the author of the paper if he has had any experience with lactic acid bacillus in the treatment of these cases.

Gavin Fulton: I have had quite considerable experience in the last two years with the use of lactic acid in the treatment of gastro-enteric diseases, but I did not bring that point out in the paper because I wish to mention the method of feeding. I have seen wonderful results from the use of lactic acid in the beginning, in that the stools change in from 24 to 36 hours. It is a routine practice with me to give lactic acid in gastro-enteric disturbances, although I did not mention it in connection with this paper.

J. R. Morrison, Louisville: I am sorry we did not have a larger audience to hear Dr. Fulton's paper, because this is a very important subject during this time of the year, and many of you can hardly appreciate, unless you study the charts, how easy it is by this method to feed normal infants. If you get the right patients from the start, those that are not over fat or over sugar fed, you will find this is an easy method.

At the Babies Milk Fund Association, I have had 60 patients coming there that are doing well this summer, and we have only five modifications they put out in the laboratory. The rest of the cases were in the families of the most ignorant people who could hardly speak the English language, and they make their modifications at home under the direction of the nurse. We had extremely few cases of diarrhea this summer, much less than in private practice.

Another thing the essayist brought out was the

caloric method of feeding. You should not go by the personal method of feeding alone, or by the caloric method of feeding, whether the food is agreeing with the child and it is gaining weight and doing well, whether it has the right food, but we must know something about the caloric value of the food, and it is certainly easy to estimate the caloric value because if you remember, a quart of milk represents 700 calories and an ounce of cane sugar represents 120 calories. You can easily find out what portions you are taking and add them up and find out the calories without any complicated method, remembering the figures which are considered to be accurate. You can then tell whether the child is getting too little food or too much food in a few minutes. This is a simple method of feeding.

In the last two years in the Babies Milk Fund Association we have had better results than when we used complicated fat mixtures. The babies have not died. They have grown fat, have cut their teeth earlier, and everything looks more favorable.

I want to emphasize that this is a simple and accurate method of feeding.

As regards the use of lactic acid, I have tried it in the treatment of diarrhea. In some cases it is efficacious but in talking about the treatment of diarrhea, you cannot get away from castor oil and diet.

PUERPERAL ECLAMPSIA; CAUSE AND TREATMENT.*

By EDWARD SPEIDEL, Louisville.

It is well to state at the beginning of this paper that the cause of eclampsia still remains a mystery. Our present knowledge of the condition simply consists of numerous theories that have been demonstrated and propounded by one set of investigators, only to be more or less completely refuted by others of equal merit and standing. All authorities, however, seem to be agreed upon the fact, that eclampsia is not a disease of the kidney *per se* and that as far as we now know the condition is due to faulty excretion on the part of the mother, allowing some poisonous product or toxin to be absorbed and accumulated in the circulation and being carried to the various parts of the body to produce that pathology and to give evidence of such symptoms as we recognize as eclampsia.

The dispute as to the origin of these toxins has practically dwindled down to the question as to whether they are of fetal or maternal origin.

It was claimed at one time the poison was produced in the placenta and emulsions

of such placenta injected into rabbits produced thrombosis, convulsions and death but later it was found that the same thing occurred with normal placenta.

According to another theory certain toxins are thrown into the circulation by the fetus in all pregnancies and that the ductless glands create antibodies to counteract their deleterious influence. When the ductless glands do not functionate properly then their toxins accumulate and result in eclampsia.

Those considering the condition of maternal origin, ascribe it to a hepatotoxemia, claiming that the toxins in the maternal blood due to the pregnancy are first conveyed to the liver, where they are converted into substances fit for elimination by the kidneys. If the liver does not functionate properly then these poisonous substances remain in the circulation and are even enforced by those in the liver, and as a result the kidneys, central nervous system and the capillaries are irritated and we have the symptom complex known as eclampsia. The main proof of the fetal origin of these toxins is based upon the fact that the symptoms in most instances disappear upon the death of the fetus, and that the convulsions generally cease after delivery.

The great similarity between eclampsia and parturient paresis in cattle, has given rise to the latest theory as to the etiology of this disease. It is claimed that the pathological findings in both of these diseases are so similar that it may be assumed that the same cause is responsible for both. In parturient paresis of cattle the mammary glands have been found responsible for the condition and treatment applied directly to them such as distention with air or oxygen has been followed by a rapid cure in most instances. The relation between the mammary gland in woman and eclampsia has, however, not been established and there surely is no room as yet for the extremely radical procedure of amputation of one or both breasts, for eclampsia as advocated by some of the most rabid exponents of that theory. In fact there are again so many points of dissimilarity between the two conditions that their relationship is rendered extremely doubtful. Recent investigations have shown the following points of difference. Eclampsia occurs most frequently in primipara. Parturient paresis occurred in primiparous cattle only six times in a thousand cases. Eclampsia occurred in all kinds of surroundings, parturient paresis only in badly housed cattle. Eclampsia occurs independent of diet, parturient paresis especially in overfed cattle. Eclampsia is not contagious whereas parturient paresis will often spread through a stable. Eclampsia is char-

*Read before the Kentucky State Medical Association, at Bowling Green, Thursday, September 4, 1913.

acterized by convulsions, parturient paresis never shows convulsions. Under the circumstances it is fair to assume that the mammary origin of eclampsia is still a matter of doubt at least.

The prophylactic treatment of this condition is based of course upon the assumption that the pregnant woman is in charge of her physician for at least three months before confinement and as this is true in only a small minority of labor cases at present, it is futile to go into great detail in regard to this part of the subject.

Careful attention to all that is included the hygiene of pregnancy should bring a woman to full term in safety in the majority of cases. Careful and frequent examination of the urine should be resorted to especially in the last two months, noting the total excretion in twenty-four hours and the percentage of urea. This is now considered of more importance than the detection of small quantities of albumen. A record of the blood-pressure is a valuable aid in prophylaxis, especially in those obscure cases that do not show the ordinary kidney symptoms. A blood pressure above 135 m.m. should be recognized as a sign of danger, if above 150 m.m. as indicating danger of eclampsia and if in addition attended by beginning blindness as a positive indication for interrupting the pregnancy in order to protect the mother from eclampsia.

In the curative treatment, the profession is unfortunately again divided into two camps, one class advocating immediate delivery, and the other noninterference. As the condition is undoubtedly due to the presence of a fetus in the uterus of the mother and as the eclamptic attacks in most instances cease after the delivery of the child, therefore the advocates of the active treatment claim that delivery should be effected at once under all circumstances. Those believing in the more conservative policy claim that forcible delivery is an added shock to a patient already in profound shock, secondly that the eclamptic condition generally brings on labor and relaxation of the cervix and in due time delivery takes place without resort to unusual measures. Those in favor of a conservative policy can follow the methods of Stroganoff, Hirst or Edward P. Davis.

Stroganoff, the distinguished Russian obstetrician, presents a mortality of only 7 per cent. in 700 cases of eclampsia, treated upon the following plan.

This method aims to prevent the convulsions by reducing the irritability of the nervous system and producing sleep by narcotics, watching over the regular action of the heart

lungs and kidneys, administering oxygen in abundance, keeping the patient under the influence of morphine and chloral, and only resorting to delivery, if absolutely necessary. One-fourth grain of morphine is first given, followed in one hour by thirty grains of chloral, chloroform being used in the mean time to control the convulsions if necessary. Another 1-4 grain of morphine is given the third hour, then chloral at intervals of three to six hours, the idea being to give sufficient of these narcotics to absolutely control the convulsions, to gain time for elimination, to await spontaneous delivery or finally to resort to any of the recognized means to that end.

Hirst's treatment which is described in detail in his text-book, is based upon the control of the convulsions with chloroform, the reduction of blood pressure and beginning elimination by veratrum viride, the use of gastric lavage and the introduction into the stomach of two ounces of castor oil and two to four drops of croton oil for brisk purgation. Hot vapor baths or the hot pack, for 30 minutes every four hours, for diaphoresis. One pint of normal saline under the breast every 8 hours for diuresis, if the veratrum viride does not effect the blood pressure sufficiently, then a resort to venesection and under ordinary circumstances allow labor to occur spontaneously.

Edward P. Davis has the patient kept under chloroform during the convulsions. If the patient is in labor with the cervix 2-3 dilated then he completes the delivery as soon as possible, otherwise he allows nature to take its course. If the patient is not to be delivered, then he resorts to venesection followed by intra-venous transfusion of normal saline, stomach lavage and hot packs. If the blood pressure still remains high then ten minims of veratrum viride are given and are repeated as often as necessary to keep down the blood pressure.

It is well to state here, that recent investigations have shown that chloroform causes the same pathological changes in the liver that are seen in eclampsia and that accordingly in this condition ether is the safer anesthetic.

It was also taught formerly, that morphine is especially contraindicated in eclampsia because it still further diminishes the secretions. One of the advocates of the morphine treatment gives sufficient of the narcotic, until the respirations are reduced to twelve a minute and he claims that the lack of secretion in the eclamptic is due to vaso-motor contraction induced by irritation of the central nervous system and under such circumstances morphine

produces vaso-motor relaxation, increased excretions and lowered blood pressure.

Zinke is another advocate of the conservative treatment and practically claims that the convulsions should be treated and the pregnancy let alone. He believes in medical measures entirely and presents statistics of thirty cases with a maternal mortality of 13.3 per cent. in which the treatment was limited to veratrum viride, hot baths, gentle catharsis and a strict milk diet.

As eclampsia is essentially a disease associated with pregnancy in the later months of gestation and as all that we practically know is that the condition is due to faulty elimination of some poison circulating in the blood, it has always seemed to me, that the presence of such a large tumor, the pregnant uterus with its fetus and liquor amnii, weighing easily from 12 to 15 pounds must interfere seriously with proper elimination, even under ordinary circumstances, therefore it has always been my custom to try to deliver the patient, as the first step in the treatment of eclampsia. Accordingly when the eclamptic attack occurred at or near term I proceeded more or less in the following manner.

Under ether anesthesia, venesection is practiced, a pint or more of blood being withdrawn from one arm. Simultaneously if the operation is being performed in an hospital then normal saline is introduced intravenously into the other arm. If the case is conducted in a private house then normal saline solution is introduced into the rectum. In this way elimination is practically begun as the first step in the treatment, as a pint or more of blood saturated with eclamptic poison is absolutely removed from the system and the rest of the poison remaining in the circulation, still further diluted by the normal saline solution introduced. Under surgical anesthesia then, with no resistance on the part of the patient, full manual dilatation of the cervix is then practiced, podalic version performed, the child and placenta delivered and the uterus irrigated with hot normal saline solution.

The opponents to delivery of the child in this condition claim that the necessary manipulations will incite additional convulsions and result in shock. It has been my experience that under deep surgical anesthesia with ether, the convulsions are controlled, the patient is completely relaxed and all the manipulations for delivery can be promptly carried out without resistance on the part of the patient. After delivery with the burden of the heavy uterus removed, it is fair to assume that the eliminating organs can functionate more effectively than before. The patient is

now in a safer condition, and further measures can now be used with more deliberation. For instance the writer prefers then to give a five grain dose of calomel followed in due time by tablespoon doses of Rochelle salts until free watery purgation has resulted, rather than resort to that drastic purgative, croton oil, which in some cases that the writer has seen irritated the lower bowel, that in later days the patient suffered more from the inflamed rectum, than from the eclamptic attack. I have met with no cases in my experience in which the patient after delivery could not take such medication by the mouth. In addition, after purgation is established, the bowel should be irrigated with normal saline solution or with plain water if the kidneys are much affected, and in this way the toxins that are set free in the intestinal canal are flushed out of the system. In addition if necessary hot wet or dry packs are used several times a day and if the urine is scanty, infusion of digitalis with sweet spirits of nitre is administered. The patient in the mean time is kept upon an absolute milk diet. If the attack occurs in the earlier months of pregnancy, then it is more advisable to follow a waiting policy and under those circumstances the writer controls the convulsions with a preliminary dose of 1-4 grain of morphine, supplemented from time to time with chloral and bromide of potassium per rectum. Elimination is then started and practiced with deliberation as outlined for full term cases and in some cases delivery is not effected until a week or two after the onset of the trouble. In all instances, however, in the writer's experience, evacuation of the uterus finally became necessary.

The value of veratrum viride in the medical treatment of eclampsia has always been a mooted point in a discussion of this subject.

Veratrum viride acts as a depressor on the vaso-motor centres, the result being a dilatation of the blood vessels and in consequence its action in eclampsia is practically due to a wide diffusion of the poison existing in the blood, in the capillaries of the system and a corresponding cardiac depression. In order to be effective and to prevent convulsions the pulse must be kept at sixty or below, so that the patient is practically too weak to have convulsions. The writer has used it effectively, in several cases, but always with dread and very much prefers the, to him, more rational method of venesection, where a definite amount of poisonous blood is at once removed from the body instead of having it scattered over wider areas as with veratrum viride. Williams tried it in a series of cases and found no advantage in its use and at times it

resulted in an alarming fall of blood pressure. Even Edgar, who is an ardent advocate of its use, states that unless the drug is used with great care, it may produce fatal results. He cites, especially, one case in which there was a fall of 146 m.m. in blood pressure in three hours, from 30 minims of the tincture and the patient was in profound collapse. The greatest difficulty in the use of veratrum arises from the fact that the various authors indiscriminately use the U. S. P. tincture, fluid extract and Norwood's tincture, all under the name veratrum and consequently the inexperienced must be greatly confused when first attempting to use it. Furthermore veratrum viride is used so infrequently that, unless the physician carries his supply in small original bottles, he is very apt to use large doses of a weak or inert preparation without result.

The writer in his treatment of eclampsia, as in all other obstetrical complications, is an advocate of surgical measures and it is his belief that no true progress will be made in that still most neglected branch of medicine, obstetrics, unless such surgical measures are thoroughly established. In spite of such a belief in surgical obstetrics, the writer can see no justification for Cesarean section in eclampsia. If the attack occurs in the seventh or eighth month of pregnancy, then the convulsions can be readily controlled by narcotics according to the method of Stroganoff, there is no indication and nothing is to be gained by a hurried operative delivery. At full term a competent obstetrician will always be able to deliver the eclamptic woman through the vaginal route under normal conditions. If the condition is complicated by contracted pelvis or obstructing tumor then it must be remembered that the operative delivery is performed on account of these complications and not on account of the eclampsia. In cases of this kind the surgeon without obstetrical experience should at least consult with an experienced obstetrician before subjecting a woman to such an formidable operation.

DISCUSSION.

Virgil E. Simpson, Louisville: While I have been much interested in the advent of Abderhalden's methods of biologic tests as applied to the diagnosis of pregnancy, I feel greater concern in the therapeutic possibilities, through its application, in the toxemias and particularly that of eclampsia. In fact, as Schwartz has well said, "the diagnosis of pregnancy is only a trifling part of this work."

In order to better understand its application to eclampsia as well as other toxemias, let us briefly recall the essentials upon which Abderhalden's

epoch-making work rests. The protoplasm of cells in one organ differs from that of others both chemically and physically, hence the difference in function.

Each cell in the body conducts its own metabolism.

Communication of products of cell activity between different organs is possible through the medium of the blood.

Under normal conditions the composition of the protein products of cell-groups entering the blood current are foreign to the blood and must be reduced to their original components, viz: Amino-acids, before they can enter the blood without disturbance.

Substances not so reduced are spoken of as blood foreign material, and the system responds to their entrance by the mobilization of ferments, commissioned to split up such foreign protein material.

Each enzyme is active only against the substance which causes its formation.

A proteolytic ferment has been found to be present in the blood serum of pregnant women and upon its presence rests his sero-diagnosis of pregnancy.

Abderhalden's theory is that free chorionic villi of an implanted ovum induce in the maternal organism a reaction which produces digesting ferments for placental tissue.

Now for the application. It is not irrational to conclude that in eclampsia the formation of protective ferments is deficient and hence intravascular digestion of placental protein is sufficiently imperfect to permit the accumulation of this blood-foreign material resulting in the symptoms-complex termed eclampsia.

Dienst has made some interesting observations on the blood changes in eclampsia. He found the plasma to be markedly deficient in albumin; even during pregnancy of otherwise normal women the amount of albumin was below normal. Coupled with this deficiency of serum-globulin was an excess of fibrinogen which results in a deficiency of antithrombin thus allowing the blood to become overladen with thrombin. Experiments showed that vessel cramp results from excessive fibrin ferment, the emunctories show inefficiency in consequence and the system becomes flooded with fibrin ferment and fibrinogen. Since the placenta produces fibrin ferment the relief from eclampsia on delivery is understood on this hypothesis.

Another interesting postulate is presented by our recognition of the pathogenic importance of secretions from pathologically altered gland substances. We must now recognize not only hypo and hypersecretion but also morbid secretion as well, which may consist of altered or unfinished substances from a gland. These not being "ripe" for the blood, as it were, act as blood-for-

eign material and in the case of pregnancy may produce the eclampsia.

These interesting findings suggest the possibility in the near future of a therapeutics with a serum from patients having large quantities of "protective ferments" or from animals so treated as to immobilize these ferments.

The chapter on eclampsia will be entirely rewritten in the near future and the subject taken out of the realm of the speculative.

Edward Speidel, Closing): I have nothing to say except the theory propounded by Dr. Simpson (Abderhalden's theory) is an extremely recent one and has not been subjected to tests as yet, consequently I did not include it in my paper as one of the supposed causes of eclampsia.

BUTTERMILK AS A THERAPEUTIC AGENT.*

By E. L. Gowdy, Campbellsville.

From the time sandal-footed solons traced the records of their culture and progress on the obelisks of ancient Egypt to the present time, investigators, whether they be poets, priests or scientists, have been searchers after the mysteries of the prolongation of life. Indeed, in ancient times the mission of the doctor was not to prevent disease but to prolong life. The really great doctors in the early history of medicine were not those who set bones, sewed wounds, shaved the nobility and cut hair, but rather those alchemists who, in their crudely equipped laboratories, divided their time between searching for the Philosopher's Stone and the Elixir of Perpetual Life. Other scientists in this early period thought this eternal life substance was something that could not be made with hands, and every schoolboy is acquainted with the name of Ponce de Leon, that aged adventurer whose last days were consumed in a search for the fountain of perpetual youth.

In spite of the high-powered microscope of science in general, the mystery of life remains about as much of a mystery to-day as it was in the days of Hippocrates. Is the little mass of protoplasm that quivers and vibrates under the microscope and that can be formed in the laboratory, Life? Is this little speck of protoplasm and the thousands upon thousands of little particles piled on top of each other the only thing that separates the ameba from the man?

The protozoa, if protected from chemie, thermic and bacteric changes, lives forever. It is true the same cell does not remain forever stationary, as after a few hours the one cell divides into two, the two into four, and so on in geometric proportion, but the origin,

al cell for this reason, while it undergoes changes, never loses its identity.

The great destroyers of the cells of the human body are the poisons that are generated in the intestinal canal by bacteria, of which the bacillus coli communis is probably the chief offender. This fact led Professor Metchnikoff, that modern Ponce de Leon of science, to believe that if something could be discovered that would counteract these poisons or destroy the bacteria we would be on the road to a long deferred old age. We are all acquainted with his lactic acid treatment, the result of his investigations and experiments.

Thus it would seem that the bacillus coli communis, that less than a dozen years ago was considered a necessary and harmless organism, associating itself with us immediately after birth and remaining with us till our dying day, was man's greatest enemy; and excluding it, except for accidental death (considering death from other bacteria accidental); we might live forever as the elixir of life is to be found in something that would overcome the toxemia of the colon bacillus. There is no doubt but that autotoxemia is the great cause of cell destruction, and for this reason, from another point of view, we must look upon the colon bacillus as our greatest friend. If it were not for something to prohibit cell multiplication the human body would soon become a monster too large for earth.

But even granting we could conquer the colon bacillus, what is the unknown, unseen and unfathomable something that causes the protozoa after it has undergone numberless sub-divisions to begin to change in size and shape till some cells go to form bone, others muscle and skin? We dissect from the body a bundle of nerves. They look alike; they are of the same cellular and chemical composition, yet some of these nerves will carry a message from the brain, others to the brain. What is it that causes the grain of corn to sprout, mature and die in one short season, the oak to live its 500 or 1000 years and man to exist his three score years and ten or a little longer before he goes to his grave with his death certificate signed "arterio-sclerosis" or some other indefinite term?

If there is any bacterium or chemical compound that can overcome the natural decay of the body (if there be such a thing as natural decay) it is still in the dreamland of science. The nearest thing thus far discovered toward accomplishing this is the lactic acid bacillus, but aside from this ultra-scientific feature, there is no doubt but that we have a powerful therapeutic agent in buttermilk. The laity have long known its value; they "feel good and grow fat on it, and indeed, it

*Read before the Taylor County Medical Society.

does contain a good deal of nourishment, but like the proprietary food advertiser, they give too much credit to the buttermilk, and not enough to the food they eat for which the buttermilk prepares the way. Painters use it for lead colic, and drunkards have long been acquainted with its value. Many doctors find it an excellent preparation, both locally and internally, in the treatment of erysipelas. Whether its action is due to the antiseptic action of the lactic acid or its property of supplying food to the infection is not known, but there is no doubt but that it is a helpful and soothing application. Occasionally we hear of a fond mother who has been brought out of the slough of despair when her marasmic baby begins to thrive on buttermilk. It is not the purpose of this paper to discuss buttermilk as an infant food except to say in passing that as such it is a disappointment. In the adult it supplies in increased amounts what nature is always supplying and in this way makes the intestinal tract better able to take care of the food ingested. The average individual has a very hazy idea of the process food goes through before the waste material is ready for expulsion. The elementary physiological facts of the phenomenon of digestion are but the beginning of that more complex physiology that is still more or less of a scientific mystery.

The intestinal tract is the home of a host of so-called normal bacteria of which the bacillus coli communis probably predominates. Just what part, if any, these bacteria might play in the progress of digestion is not thoroughly understood, but there is no question but that their activity under a number of conditions plays an important part in the utilization of food-products. The chief foods for cell nutrition are the carbohydrates and proteids; the carbohydrates which undergo changes into sugar of the six-carbon chain formation, will undergo fermentation; the proteids, in the presence of bacteria, or rather in the absence of sugar will undergo putrefaction, and in this putrefactive process the indols and skatols are formed that are so deadly to the cell. In other words, so long as there is plenty of sugar the bacteria will draw on this source of food supply and the result of this action will be an acid that might be of benefit to the human economy, but in the absence of sugar the bacteria will work on the proteid with resulting products of putrefaction. This is Metchinkoff's long life theory in which he recommends the reduction of proteid and the ingestion of lactic acid bacilli to supply an acid medium, which would inhibit, to a certain extent at least, the putrefactive action of normal intestinal bacteria. In order to inhibit as much as possible the poison forming action of the colon and other

intestinal bacteria, nature has placed a certain amount of normal lactic acid bacilli in the bowel; she goes even further: the sugars, as they split up, also form lactic acid.

Thus it would seem that the two ways to prevent putrefaction in the intestine is either to supply a large amount of sugar or an acid medium, of which the lactic acid bacillus is the most available. What is true of the colon bacillus is also true of the action of most of the pathogenic intestinal bacteria, the most important ones being the bacillus dysenteriae both of Shiga and Flexner and the bacilli typhosus.

As buttermilk is a cheap, agreeable and convenient form to administer lactic acid, we can readily understand the hope it holds out not only as an elixir of long life, but as a panacea for the acute diseases of the intestinal canal.

Wounds.—Treatment.—Treat all wounds on which great force has been exerted, and especially those contaminated by soil and dirt-covered objects, as if infected with gas bacilli. Leave open where possible and irrigate thoroughly with peroxide. Bandage lightly if at all. Inspect frequently and irrigate often. On first sign of symptom of infection, take smear and examine for *B. aerogenes capsulatus*. Open wound freely, if sutured, and if on limb place latter in bath or irrigate continuously. If condition extensive, expose field widely to air by free incisions. (Do not employ peroxide in full strength or inject in confined spaces or directly under tissues.)—Cramp.

Wounds of face and hands should be closed with subcuticular stitches, especially in women. To prevent subsequent stretching of scar, close superficial fascia with interrupted fine silk sutures before applying subcuticular stitches. After injuries to soft parts of hand, cleanse quickly by immersing in gasolene; after latter has evaporated, sterilize parts with tincture of iodine and alcohol.—Harper.

Reinfection with Diphtheria.—Reiche states that the records of the Hamburg hospital show 394 cases of diphtheria in the last seven years, in which there has been a preceding attack of the same disease in previous years. In the last two years, of the 4,761 diphtheria patients, 5.8 per cent. were known to have had a previous attack; the largest proportion, 10.9 and 15.8 per cent., were in young adults up to 25, and in adults between 25 and 50. In an additional 1.6 per cent., the second attack of diphtheria was evidently merely a relapse. The data presented confirm the absence of any immunization by a single attack of diphtheria. There were more cases of diphtheria in Hamburg in 1911 than at any time since 1895; 573 of the 4,761 cases in the last two years terminated fatally.

METHOD OF ADMINISTRATION.

SOME EXPERIENCES WITH PHYLACOGENS.

By OSCAR W. DOYLE, Louisville.

In presenting this paper on the subject of some of my experiences with phylacogens, I wish it to be distinctly understood that I am not waiving, in any way whatever, my faith in autogenous vaccines. Neither, as a remedial agent, have I entirely lost faith in stock vaccines, although my experience has proven to me that the results obtained from stock vaccines do not warrant as great faith as we may have in autogenous vaccines and phylacogens. In my work, phylacogens have produced such uniform, complete and satisfactory results, that I think they may properly be supposed to be thoroughly standardized. Owing to the limit of time which one may consume with a paper of this kind (it would not be proper, especially since phylacogens are so well known and have given such widespread satisfaction) for me to take up your time in telling anything of the many reasons which may be given for assuming the standardization of this product, nor to say anything concerning the method of production.

I wish to impress upon you that it is not my desire to in any way advertise any firm, nor any line of products, but the fact that phylacogens have proven such a powerful aid in my own work justifies me in assuming that a description of my experience may prove of some assistance to any who may wish to fall in line and obtain the same results.

My experience has been confined entirely to the subcutaneous use of phylacogens. I might say I have long been of the opinion that anything which produces such a radical change within the blood current had best not be administered intravenously, unless absolute control of the patient, under hospital regime, or under conditions very similar thereto, can be obtained.

After trying numerous sites of loose tissue, I have found the most satisfactory area for the injection of phylacogens, to be the loose tissue between the scapulae, or just beneath them. In some selected cases the loose tissue about the buttocks may be chosen with advantage, although great care must be exercised to avoid too deep an injection, because of the likelihood of puncturing a small vein, thereby obtaining too rapid absorption, in which event it would be virtually an intravenous injection, an accident that will not occur if proper precautions are observed.

The size of the dose is best determined, I believe, by individual experience. Personally, I rarely begin with a dose larger than 2 c.c., although in some cases I make the initial dose much smaller. The dosage must be regulated, in a large measure, not only by the general reaction, but by the local reaction as well. The elevation of temperature, the increase in the pulse rate and respiratory rate, are invaluable aids in gauging the degree of reaction. The degree of general malaise and aching is a good guide to the correctness of the dose. I have always found it advisable, where the malaise and aching continues, to

wait from 48 to 72 hours before repeating the dose.

The precautions I have enumerated are of great importance. As I will point out to you later, the correctness of the diagnosis is most essential, and the selection of the proper phylacogen is of the utmost importance. Great care must be exercised in keeping the patient under control, not only during the time that we are waiting for the reaction from the phylacogen, but also in carrying out any instructions that we may have given them. In the presence of heart and kidney lesions, if phylacogens are used, a smaller dosage is in order; I have found it wise to keep the reaction down to a minimum.

During the menstrual period the use of phylacogens should be avoided, as it is well known that the reaction during this period is very distressing, and will oftentimes cause the patient to refuse further treatment.

I wish to cite a few results that I have obtained in a number of selected cases. In some of these cases, as a matter of experimentation, I have deviated widely from the usual methods of using phylacogens. I will also give you my experience in some cases in which the use of phylacogens has not been successful. While, on the whole, they have proven beneficial in my hands, I have had some cases that have not been benefitted by their use; consequently, I believe a recital of these will be of some value, and in citing them I will give you the reasons, as I saw them, for the failure of the phylacogens, although in some cases I could find no apparent reason. Will be frank enough, which I believe is somewhat unusual, to tell you that in two cases where they failed, I was absolutely mistaken in the diagnoses. This I think should be told in fairness to you and the remedy as well.

Group I. In a series of fifteen cases of acute gonorrhoea, the five cases composing this group were treated with phylacogen from the start, with no medicinal aids, but with instructions to the patient to drink plenty of water and abstain from alcohol in any form, together with the other usual rules governing the conduct of these patients. In each instance there was slight diminution of the urethral discharge within the first forty-eight hours, but at the end of eight days there had been no further improvement. I then resorted to the treatment described in the third group of this series.

Group II. In the second five cases, phylacogen was used from the start, together with a simple cleansing urethral irrigant, consisting of glycothymoline, boric acid and water. In this group within four days the discharge had diminished until only a drop could be seen now and then, and this condition persist

ed until, at the end of two weeks, the treatment given in the last group of this series was instituted.

Group III. In the last group of five cases phylacogen was used from the start, together with an urethral irrigant composed of glycothymoline and boric acid, and in addition the injection of a ten per cent. solution of argyrol three times a day. In this group the discharge was noted by the end of the second week. However, the treatment was continued for ten days after it stopped, and no further discharge was noted. These cases were continued under observation for four weeks, and a precautionary round of phylacogen was administered. In the other three cases, one showed a disappearance of the discharge in three weeks, and the other two in four weeks. The end results were the same as in the first two cases. Except in one case, there was no involvement of the seminal vesicles, nor, so far, has there been any evidence of stricture.

In five cases in which I used mixed infection phylacogen splendid results were obtained.

FIVE CASES TREATED WITH MIXED INFECTION PHYLACOGEN, (M. I. P.)

All of these cases, in addition to the use of phylacogen, were treated with the usual surgical care which should be given to all cases.

Case I. Mr. C. D., age twenty-five; four fingers left hand mashed in machine. Hand dressed with antiseptic dressing. At end of thirty-six hours there was slight amount of pus; temperature 99 1-2 degrees F. Examination of discharge showed mixed infection. A dose of 2 c.c. of mixed infection phylacogen was given; no reaction observed. At end of twenty-four hours, temperature was 100 1-2 degrees F., 3 c.c. was given, reaction occurred in four hours. By this I mean, the first symptoms of the reaction were noted in this time; temperature elevated to 101 degrees F. At the end of twenty-four hours the temperature was normal but another dose of 3 c.c. was given which produced the symptoms of reaction in four hours, during which the temperature arose to 100 4-5 degrees F. In five days there was no further temperature noticed but an additional 3 c.c. was given. This case made an uninterrupted recovery.

Cas II. Mr. H. S., age thirty-seven, hand mashed in machine. Not seen by physician until three days after accident. Temperature 192 degrees F. and there was a very slight discharge of pus. Three c.c. mixed infection phylacogen was given. Symptoms of reaction was very severe; in twenty-four hours the temperature was 100 4-5 degrees F., 3 c.c. was given, with same reaction and conditions noted. In twenty-four hours temperature was

normal but an additional 2 c.c. was given and in three days an additional 2 c.c. was given. Improvement made and an uninterrupted recovery.

Case III. Mr. R. O., white, age thirty; fingers right hand badly lacerated and mashed in press. Wounds irrigated with a five per cent iodine solution and dressed with antiseptic dressing. Failed to report for three days, giving as his reasons that he felt too bad to come to the physician. At this time the temperature was 104 degrees F. He was ordered to bed and given 3 c.c. mixed infection phylacogen; no reaction symptoms were noticed. At the end of twenty-four hours, temperature 105, 5 c.c. given; reaction symptoms noticed in six hours, (aching, etc.) Temperature ascended to 106 degrees F.; general symptoms were very severe. At the end of twenty-four hours temperature 103 degrees F., 5 c.c. was given reaction symptoms occurring in five hours; general symptoms severe, (aching, slight diarrhoea—temperature 106. In twenty-four hours temperature 100 degrees F., 5 c.c. again given; reaction symptoms noted in eight hours temperature 101, joint aching severe. At the end of twenty-four hours temperature was normal, 3 c.c. was given at this time; patient states that if he had any reaction it failed to wake him up. In three days 3 c.c. again given, reaction very mild. Uninterrupted and uneventful recovery.

Case IV. Miss E. K., age forty-one; furuncles of neck, right shoulder, and arm. Temperature 103 degrees F., 2 c.c. mixed infection phylacogen was given, reaction symptoms noticed in three hours; temperature 103; general aching very severe. At the end of twenty-four hours temperature 100 degrees F., 4 c.c. administered; reaction symptoms noticed in four hours; temperature 104 degrees F.; slight diarrhoea and general muscular aching. At the end of twenty-four hours, temperature 98.4-5 degrees F.; general improvement marked. Considerable improvement of the furuncles, noticed in forty-eight hours, and an additional 4 c.c. was administered with reaction occurring in four hours, temperature 101 degrees F.; some diarrhoea and aching fairly severe. This case made an uninterrupted recovery.

Case V. Mr. M. D., age sixty-five, leg badly bruised by heavy weight falling on same. A marked varicosity of both legs had been noticed for several years. First seen thirty hours after accident. Great accumulation of dirt and necrotic tissues in wound. Two c.c. mixed infection phylacogen administered; no reaction. In twenty-four hours, temperature 101.1-2 degrees, 4 c.c. administered; reaction in six hours; temperature 103 degrees F.; no other symptoms of reaction noticed. In twenty-four hours temperature 100 degrees F.; 3

c.c. administered, mild reaction noticed in four hours; temperature arose to 101 degrees F. At end of twenty-four hours temperature normal. Two c.c. was given in two days and repeated in three days. Was given 2 c.c. in two days and an additional 3 c.c. in four days. The recovery of this case was slow, chiefly, as I believe, because of the age of the patient and the bad circulation due to the varicosity.

Phylacogen was of undoubted benefit in all of these cases and while the reactions would have been greater with larger doses; I am convinced that a little larger dose, or the small dose more frequently administered would have produced a more desirable result.

In reporting two cases of erysipelas I am not going to take the time to go into the minutae. One case gave a marked result of recession and beginning convalescence at the end of forty-eight hours. The second case I mention chiefly to emphasize the necessity of a correct diagnosis. This case I took to be one of simple mixed infection and so used a mixed phylacogen without obtaining any apparent results; when I discovered that I had been entirely mistaken and had a case of erysipelas to deal with. The administration of the erysipelas phylacogen gave most happy results and in three days a most profound and marked improvement was noticed in the patient with ultimate recovery.

In three cases of rheumatism treated with rheumatic phylacogen only one had any "arthritis deformans." In this case the use of the rheumatic phylacogen was not attended by any beneficial results at the beginning, because of the failure of the patient to answer in the affirmative any questions relative to the existence of a prior gonorrhoea. After obtaining this history a straight autogenous vaccine, obtained from the urine failed to give results. However, as soon as the phylacogen and gonorrhoea vaccines were given in alternating doses, each twenty-four hours, marked benefit was noticed. One other of the cases was a straight case of inflammatory rheumatism, with marked swelling of all of the joints, and there was marked anemia. The rheumatic phylacogen gave slight benefit and upon a blood report we used the hypodermic interjection of the I. P. & S. ampules. The use of the same seemed to supply that element of the treatment which was lacking and an uninterrupted recovery was obtained. This case has been under observation for nearly a year during which time no rheumatic symptoms nor any rheumatic sequela have been noted.

In closing, I wish to mention, briefly, five cases, in which I have been using tuberculosis phylacogen, experimentally. This phylacogen is purely experimental as yet, not having

been placed upon the market, but since the results in each case have been so very similar, I thought it might not be amiss for me to mention a few facts.

In each case a dose of eight minims of the tuberculosis phylacogen was administered, and because of the prolonged aching that followed, I have never repeated the dose in less than forty-eight hours. In none of these cases has the local reaction been very marked until after a dosage of 1 c.c. or more had been reached. In each case, following the reaction, there has been an increase in the cough and in the amount of expectoration during the twenty-four hours following the injection. After this time the cough would gradually subside and the amount of expectoration decrease. After the fifth injection the cough and quantity of expectoration have not been changed to any marked degree, although every case has exhibited a constantly diminishing cough and a lessening quantity of sputum. In every case the patient has commented upon the improvement they have noted in their general condition, as well as the marked improvement in appetite. Two of these cases have been reporting regularly at my office and have shown a gradual increase in weight. Each case showed an absence of temperature during the second twentyfour hours following the injection, and where the injection was repeated within fortyeight hours, there has been no elevation of temperature except during the reaction period.

From present indications, I am of the opinion that at some future date I shall have the pleasure of reporting some very interesting statistics concerning these tuberculous cases, and to show, at least, a very remarkable improvement in each case.

DISCUSSION.

Jno. B. Richardson, Jr. The only question that occurs to me is, how the essayist arrived at the conclusion that the phylacogen was what cured his patients. I treat a good many infected cases and have never used phylacogens, but nevertheless most of them get well. In such injuries as mashed fingers, toes, etc., I depend upon the use of iodine when the patient is first seen. I do not mean to be understood as saying that the phylacogens are of no value, but the reaction following their administration is so severe that I have not used them. I depend entirely upon the use of iodine, and have obtained uniformly good results in the treatment of conditions mentioned by the essayist.

Harry J. Phillips: Dr. Doyle appears to have had considerable more experience in the use of phylacogens than have most of us. I have had some experience with the rheumatism, mixed infection and erysipelas phylacogens, and it has

been my observation that, when properly administered in selected cases, they will practically always have a beneficial effect.

The most important thing in connection with the use of phylacogens is a correct diagnosis, and especially is this true in rheumatism. We know that heretofore we have been prone to class under the head of rheumatism nearly all of the aches and pains that human flesh is heir to; we have called "rheumatism" many things that were not due to the streptococcus rheumaticus, but in conditions that are caused by this bacteria, rheumatism phylacogen will do a great deal of good. It will not, however, correct the deformity in arthritis deformans; I have never seen any benefit follow its use in cases of this kind that were advanced?

The essayist is correct in advocating small doses of phylacogens to begin with. It should be administered in small doses, subcutaneously, in order to test out any possible idiosyncrasy on the part of the patient. If none develop, then the dose can be rapidly increased.

It is true, as Dr. Richardson says, that in the majority of cases the administration of phylacogen is followed by a very severe reaction. It acts upon the central nervous system, increases the pulse rate and raises the temperature. The pulse rate is frequently increased from 30 to 40 beats, and the temperature elevated from 1 to 5 degrees. I have had cases in which the reaction was so severe as to shake the bed, and the family and friends became greatly alarmed, but I have never seen any permanently ill effects follow the use of phylacogen.

I have also given phylacogens intravenously, beginning with a small dose and increasing it to as much as 1 c.c. I believe this can be done by almost any one after a little experience. It does not require the technic that we have to practice in giving an intravenous saline infusion; the needle is introduced directly through the skin into the vein, care being taken, however, to avoid wounding the distal wall of the vein. I have done this on several occasions, and I believe almost any one can do it after a little practice.

This paper is especially interesting in view of the fact that the essayist has used five different forms of phylacogen with uniform good results. I wish to again emphasize the fact that the most essential part of the treatment is to make an accurate diagnosis; then you can select the proper phylacogen and expect good results.

Jno. D. Allen: I believe that any agent, which can so devitalize bacteria that the white blood cells can digest at least twice as many of the bacteria causing a given infection as formerly, is a good remedy. There are several agents by means of which we can increase the resistance of the patient and thus raise the opsonic index, but the most direct way to raise the index of the patient is by the administration of vaccines or

phylacogens. Phylacogen is a vaccine. The only way in which phylacogen differs from vaccine is this: a vaccine contains dead bacteria and some of their toxins; phylacogen does not contain dead bacteria, but more of the toxin than is contained in vaccine.

There are at least two different kinds of bacteria which cause the two main classes of infection; namely, those bacteria which liberate an exotoxin and those which do not. In those infections caused by bacteria which liberate an exotoxin, I think it is clearly evident that the disease condition is due more to the toxemia than to the bacteria themselves. This is plainly demonstrated in diphtheria where, although only a small area is involved, the patient manifests a marked toxemia. The same is true of infections caused by the streptococcus, gonococcus and pneumococcus. In this class of cases I think we should treat the toxemia of the infection by the use of antigen or antibodies made from the bacteria that is causing it. It is a well known fact that bacteria grown upon a bouillon culture liberate greater quantities of toxin than do those grown upon an artificial culture media. Therefore, a phylacogen containing the bacterial toxin, and made from a bouillon culture is the ideal remedy in those conditions in which there is a marked toxemia. However, in the other type of infection, caused by bacteria which do not liberate exotoxins, the ideal remedy would be an autogenous phylacogen, or, rather, a mixture of phylacogen and vaccine. An autogenous vaccine has an advantage over a phylacogen in that we are employing a specific remedy to overcome a specific infection. It is a well-known fact that there are several different strains or types of the same class of bacteria; for instance, there are half a dozen different types of gonococci, twenty different types of colon bacilli, and the same is true in greater or less degree of various other classes of bacteria. Therefore, when we make an autogenous vaccine we get the specific type of bacteria that is causing the infection; in other words, we are using a specific remedy to treat a specific infection. Again, I do not believe that mixed infection vaccines or phylacogens should be used in cases where we can make a specific diagnosis. It has been demonstrated that the administration of a mixed infection vaccine will lower the index of the patient for a particular type of infection. Therefore, where we can make a specific diagnosis, a specific vaccine should be used.

A. C. L. Percefull: I have enjoyed Dr. Doyle's paper very much indeed. I would like for him to say in closing whether or not he has had any experience with the phylacogens in a gouty diathesis, where the joints become enlarged and painful.

J. Rowan Morrison: It seems to me there must be quite a good deal of difference between the results of laboratory experimentation and the clin-

ical experience of the many gentlemen who have used this type of remedy. In a recent article by Dr. Theobald Smith, of Harvard, he makes the statement that he does not believe a life has ever been saved by the use of vaccines, although he admits the effect of the presence of these organisms in raising the resistance of the host.

I agree with Dr. Allen when he says that we should make a specific diagnosis rather than to run the risk of destroying the power of the body to immunize itself by administering a mixture of all forms of bacteria. I have seen a number of cases in which phylacogens had been used. One man who was supposed to have been cured of "rheumatism" was later relieved of his trouble by anti-syphilitic treatment.

I hope Dr. Doyle will have better results in the continued use of the tuberculin phylacogen than did Dr. Barnes of the Rhode Island Sanitarium, who reported something over a hundred cases in which he had used tuberculin, and stated that he had obtained just as good results in cases where he did not use it.

In one of his medical essays, Dr. Wendell Holmes tells us of the "Weapon Ointment," an ointment that had great favor in the olden times. It appears that this idea originated first somewhat in the following manner: If one was wounded with a weapon of any sort, it was believed that the application of the weapon to the wound would be very helpful. Later the idea became prevalent that it was not necessary to apply the weapon that caused the wound, but an image of a similar weapon would do as well, and later it became prevalent to make ointments and apply to the wound. Finally some medical man decided that it would be better to put the ointment on the image of the weapon after washing the wound in clean water, tying it up in clean cloths. However for a long time it was very prevalent to apply the ointment to the image. The ointments were made of various and sundry substances, some apparently very wonderful. For instance one is described as containing the moss from the skull of a man hanged in chains, and various and sundry substances equally as absurd.

Lord Bacon, whom we all know was a very wise man for his time, speaking of this "Weapon Ointment" said that he was not able to convince himself that it was of any service at all, but on the other hand he was not able to say it was useless, because so many persons of knowledge seemed to think that it was of benefit.

It seems to me that in these days and times we are in somewhat similar quandary concerning the administration of some of these new biological products.

Dunning S. Wilson: I was particularly interested in the essayist's reference to the use of phylacogen in tuberculosis, because we welcome with open arms anything that promises to aid us

in the fight against this dread disease. There are one or two suggestions I would like to make to those who are trying out phylacogens, or any other remedy, in connection with tuberculosis. First, a period of at least two years must elapse before we can draw any definite conclusions as to the benefits to be derived from any remedy. Secondly, there must also be a control group of cases that are not taking the remedy, as nearly similar to the other group as possible. Furthermore, in each case a thorough examination must be made, as well as careful analyses of all the secretions of the body in order to preclude the possibility of any other disease being present. I think we can depend upon Dr. Doyle bringing in an opinion only after the foregoing essentials have been faithfully observed. The observation of three or four cases over a period of five or six months is absolutely worthless; especially if examinations of the chest are not made at regular intervals. Furthermore, the improvement must be real; not apparent. We care nothing about a gain in weight or a diminution in expectoration; they are but symptoms. What we do care about is the amount of healing of the lungs that has taken place. If that can be brought about by the use of phylacogens or anything else, we should be very glad indeed to have it presented to us.

Oscar W. Doyle, (Closing): I wish to say in explanation that I simply mentioned the use of tuberculosis phylacogen because it is entirely an advance in the treatment of this condition. I agree with Dr. Wilson that we cannot be too careful in reporting the results obtained from any remedy in the treatment of tuberculosis. I very frankly tell every tuberculous patient that comes under my care that I will be unable to give a prognosis of any kind under one year, and I believe two years should elapse before we can say that we have been able to obtain any permanent results. Of course, it is only natural, when we see apparent improvement result from any given remedy, to allow our enthusiasm to rise to a point from which we may get a very sudden and hard fall.

I have not attempted to in any way compare the results obtained from phylacogens with those of autogenous vaccines. I have had some very happy results from the use of the latter, and I tried to make it plain in the paper that I have not wavered in my faith in them.

Like Dr. Richardson, I have had some very good results from the use of iodine in the treatment of infected conditions, but in many cases in which it was not efficacious I have been able to get the desired results from the use of phylacogens. "The proof of the pudding is in the eating thereof," and the prompt response to phylacogen in cases in which the use of iodine had not been effective, certainly tends to prove that the phylacogen produced the results claimed for

it. As to the reaction, in the majority of cases I administer small doses, and I have not observed that it has been followed by such severe reactions as are reported by some men. I believe that large doses are nearly always responsible for these severe reactions, and they are apt to destroy the patients' desire to take the treatment.

No one will contend that phylacogen is a cure-all, although the man who originated them might naturally be expected to be more enthusiastic than others who have not had the same results that he claims to have had.

I have had no experience with the use of phylacogens in a straight gouty diathesis.

I agree with Dr. John D. Allen in every point he raised in his discussion. He mentioned the most important feature in connection with the use of phylacogens; namely, a correct diagnosis. We are not justified in administering any form of phylacogen in a case where we have not been able to establish an accurate diagnosis.

I have had some unusually brilliant results from the use of phylacogens, and I have had some equally brilliant results from the use of autogenous vaccines, and I hope to some day be able to compile these cases and compare them, each with the other.

THE CAUSE OF INGUINAL HERNIA,
WITH SPECIAL REFERENCE TO
THE RELATION OF THE LONG
OR MAIN AXIS OF THE AB-
DOMEN TO ITS MORE
FREQUENT OCCUR-
RENCE ON THE
RIGHT SIDE.

By F. T. FORT, Louisville.

Hernia is a subject to which I have given a great deal of thought for a number of years. Most of the literature, however, so far as I have been able to ascertain, has dealt with the cure rather than the cause of hernia. From time to time I have wondered what could be at the beginning of this common surgical condition. We all know, from observation, that inguinal hernia occurs more frequently upon the right side than on the left, and statistics show the ratio is about 2 to 1. There has been a great deal of discussion as to the reason for this, and the question whether or not all hernia are due to a congenital defect has long been a mooted point, each school having its advocates.

Macready¹ reports a series of 17,538 cases of inguinal hernia in the male, seen at the Truss Society during the years 1888-90, of which number 10,082 were right, 6,630 left, and 826 double. He states that the proportion of right to left hernia varies, not only according to the kind of hernia and to the sex, but in the

same sex at different periods of life. The great preponderance of right hernia in early childhood, and their high proportion until after puberty, has long been supposed to be connected with the descent of the testis; that is with the later closure of the inguinal canal on the right side. This influence appears to lose its ascendancy, after puberty, to some extent. The preponderance of right hernia over left has been variously explained by the use of the right hand in preference to the left, by the weight of the liver (Skenki), and by the inclination of the mesentery towards the right iliac fossa (Velpeau). The latter suggestions appear to have been accepted by the late Mr. Callender with respect to femoral ruptures, and has been applied by Mr. Loekwood to explain, as Velpeau did, the predominance of right hernia in general.

Sir Astley Cooper¹ conjectured the difference in frequency of right and left femoral hernia, was owing to greater exertion being made upon the right side. A more probable explanation was made by Knox, who thought that the cause depended upon the larger capacity of the right side of the pelvis as compared with the left. He says:

"In regard to the frequency of inguinal hernia with relation of the different anomalies of the testes, taken together, it is found that it amounts to 2.6 per cent, and the more complete the arrest of development, the larger is the proportion of ruptures in early life. In like manner, the ratio of right hernia to left is greater in each group than in ordinary cases, and the ratio is higher the more complete the arrest of development. It has also been observed that hernia, at whatever age occurring, generally, though not invariably, appears first on the same side as the anomaly."

"Though complete or partial patency of the processus vaginalis is regarded as an important predisposing cause of ruptures, at all events of those in early life, it is a fact, if evidence from examination of the dead be received, that hernia enters this passage in a minority of instances in which it remains open."

According to Joseph Warren², hernia is, as a rule, more frequent on the right side than the left, in the proportion of 7 to 4 or 5. Schinkiss thought it due to the larger lobe of the liver being on the right side; Martin to the inclination of the mesentery; Cloquet to the predominance of those who are right-handed. Malgaigne doubts that right-handedness has anything to do with the preponderance of right hernia over left and by figures seeks to show that hernia in right-handed persons are more frequently on the left. Thus of 313 inguinal hernias, forty were double, and of the 273 remaining 171 were right and

102 left; while of the 273, one in eleven was left handed.

Of 831,584 cases of hernia mentioned in the report of the City of London Truss Society³ for 1823, 24,316 males and 586 females had right, and 14,006 males and 511 females had left, inguinal hernia; the remainder were femoral.

Of 379 cases of inguinal hernia, reported by John Wood⁴, in 1886, 219 were right, 128 left and 23 double.

In a report of 4,505 cases of inguinal hernia by the New London Rupture Society⁵, in 1846, 4,382 were males, 2,509 were right and 1,873 left; females, 123, of which 70 were right and 53 left.

J. Cloquet⁵, reported 247 cases of inguinal hernia in males, of which 133 were right and 114 left; females 42, 19 right and 23 left.

Of 433 cases of inguinal hernia treated at the Leeds Infirmary⁵ from 1839 to 1841, 394 were males, of which 244 were right and 150 left females 39, 23 right and 10 left.

Of 4,852 cases of inguinal and femoral hernias treated at the New York Rupture Society⁵, 2,780 were right and 2,073 left, or 11.3 right to left.

Of 433 inguinal and femoral hernia reported by Cloquet⁵, 246 were right and 187 left.

Of 500 inguinal and femoral hernia observed at the Leeds Infirmary⁵, 300 were right and 200 left, or 1.2 to 1.

Karl Wilharm⁶, in 1902, reported his observations which covered 500 laborers who were sent to the institution with which he was connected for purpose of diagnosis or operation for hernia, and of this number 7.2 per cent. were right and 5.4 per cent. were left.

In 70 new-born males Camper⁷ found the processus vaginalis patulous upon both sides 34 times, upon the right side 14 and upon the left side 8 times.

In 100 new-born children, Engel⁷ found this process patulous upon both sides 60 times, upon the right side 30 times; and closed in all cases upon the left.

Zukerkandl⁷ examined the bodies of 100 children and found a patulous process upon both sides 20 times, upon the right side 12 times, and upon the left side 5 times.

In 108 inguinal herniae, Felizet⁷ found 63 cases upon the right and 39 upon the left.

Brenner⁸ operated upon 144 cases of hernia observed by him of which number 117 were children, among whom were 107 males, with bilateral hernia in 28; right-sided 65.

Of 115 cases of inguinal hernia reported by Goebell⁹, 111 were in males, and they were twice as common on the right as on the left.

Now, what is the cause of this more frequent occurrence of hernia upon the right side than on the left? I believe there are

four probable factors concerned in this: (1) in the production of either right or left inguinal hernia, I think there must be a congenital weakness of the inguinal canal, and I shall endeavor to show that this is greater and, therefore, more apt to result in hernia, on the right side than on the left; (2) the attachment of the mesentery in an oblique direction from the left side of the second lumbar vertebra to the right sacro-iliac joint; (3) the peristaltic wave ranging from the left to the right side and terminating in the small intestine at the ileo-cecal junction; (4) the relative positions of the leaflets of the diaphragm, the right being more or less transverse, while the left is placed more obliquely; (5) right side of pelvis being larger.

Bailey and Miller¹⁰ state that:

"During the early stages of development the testes are situated far forward in the abdominal cavity. During the eight weeks they lie opposite the lumbar vertebrae. During succeeding months, up to the time of birth, they gradually move caudally to the positions they occupy in the adult. This migration is brought about, to some extent, at least, by the influence of certain bands of tissue which are primarily like mesenteries. As the mesonephros develops and projects into the body cavity, it comes to be attached, on the dorsal body wall lateral to the dorsal mesentery, by a sheet of tissue which is called the mesonephric mesentery. Cranial to the mesonephros, this mesentery is continued as the diaphragmatic ligament of the mesonephros, which is attached to the diaphragm. Caudally it is continued to the inguinal region as the inguinal ligament of the mesonephros. As the mesonephros atrophies, its mesentery and the mesentery of the testicle are combined to form a single band of tissue, which, of course, is continued with the inguinal ligament. The latter now becomes the gubernaculum testis, a strong band or cord composed of connective tissue and smooth muscle. Its cephalic end is attached to the epididymis; its caudal end pierces the body wall in the inguinal region and is attached to the corium of the skin. The descent is brought about through the principle of unequal growth. As the body grows in length the gubernaculum grows much less rapidly, and since the caudal end of the latter is fixed, the natural result is a drawing downward of the testicle. This takes place gradually, and at the end of the third month, the testicle lies in the false pelvis; at the end of the sixth month close to the body wall of the inguinal ring."

As the gubernaculum draws the testis from the abdominal cavity, it pushes before it a pouch of the peritoneum, which afterwards becomes the processus vaginalis. In this pas-

sage of the testis from the cavity, the left reaches the scrotum first, which I believe is caused by a full or distended sigmoid pressing upon the testis from behind, and, after it has been lodged in the scrotum, continuing its pressure upon the inguinal ring, thereby causing a more complete pinching off, as it were, of the canal on the left side. At this early period of fetal life, the liver occupies the greater part of the abdominal cavity; its larger portion being on the right side possibly assists the gubernaculum in depositing both testes in the scrotum. The right side of the cavity being larger, and the right ring not having any pressure from the distended sigmoid, as on the left, it does not close with the same degree of firmness as the left.

The gut in early fetal life being almost a straight tube of uniform diameter, begins to develop more rapidly in proportion than does the rest of the body, and develops six primary coils which are pushed up into the umbilical column. A little later these coils are brought back into the abdominal cavity, the cerebral end first, which becomes fixed to the dorsal peritoneum and develops into the duodenum. The rest of the coils, with more subdivisions, are deposited within the abdominal cavity, the caudal end, which becomes the cecum, being the last to re-enter. The pancreas develops in the head of the duodenum, which remains fixed. The mesentery of the small intestine, which in adult life is 6 to 8 inches long begins on the left side at the second lumbar vertebra and runs diagonally across the abdomen to the right sacro-iliac joint. This mesentery grows in length until it averages 8 or 9 inches, and develops into a fan-shape, enclosing the whole of the small intestines, the greater number of coils being on the right side.

The diaphragm, which separates the thoracic cavity from the abdominal cavity, is, I believe, one of the greatest factors in the production of hernia. Its greater diameter is transversely. The liver is attached to the under surface of the right leaflet; to the middle leaflet from above, the pericardium is attached; the left leaflet is attached a little lower down than the right. The right leaflet, on account of the attachment of the liver, is more transverse, and any strain from above, as in coughing, or other violent inspiratory exertion, does not descend with the same force as the left. The middle leaflet, on account of its shorter attachment to ensiform cartilage and also to the pericardium, is held back, but the left leaflet, being free to act, transmits the greater amount of force from all expulsive movements, and, because of the oblique position of the left leaflet, this force is transmitted towards the right pubic spine.

The abdominal cavity is oval in shape, the larger portion being above. The diaphragm stretching across this larger portion, if it acted with the same degree of force in all directions, the main axis of the abdomen would be directed towards the symphysis pubis; but for the reasons enumerated above, I am led to believe that the long axis of the abdomen ranges diagonally from left to right, and that this deviation of the long axis, together with the more general weakness of the right abdominal ring, the fact that the mesenteric attachment passes from left to right, and that the peristaltic wave ranges from left to right, is responsible for the more frequent occurrence of inguinal hernia on the right side.

I do not believe that occupation influences the predominance of right over left inguinal herniae. In my opinion, if occupation did influence it, we would have a greater number of herniae on the left side, for the reason that, in lifting and doing heavy work, the majority of people are right-handed, and as a consequence the right leg is abducted and the left leg is adducted more frequently than the reverse, thereby more frequently relaxing the left ring and contracting the right. I further believe that, if the patency of the two rings were equal, we would, on account of the greater number of people who are right-handed, have more left than right inguinal herniae, even though the long axis of the abdomen be from left to right.

The frequency of hernia is greater than usually supposed. It has been variously estimated by surgeons of great experience, that from 1-16 to 1-8 of the human race is afflicted with this complaint. From similar sources, it has been found that about 80 per cent. of all herniae are of the inguinal variety. Now, taking these approximate figures and add to them the results of Camper, Engel and Zueckerkandl's examinations of nearly 300 newborn, mentioned previously, I think we are led to admit that nearly, if not all, inguinal herniae are of congenital origin.

From my experience in the anatomic room, I am led to believe that not in every instance where we have congenital weakness, do we have hernia; it is mostly in those cases where we have a relaxed condition of the viscera, for in the examination of intestines where there was no relaxation, it was impossible to draw the intestines through the external abdominal ring; and, again, I have seen splanchnoptosis with no weakness in the hernial region, where, after opening the body, I could draw the small intestine down below the scrotum, which I think, shows, on the one hand, that there must be a congenital weakness, plus great force, or relaxed viscera, before we can have a protrusion through the hernial rings.

CONCLUSIONS.

(1). That all inguinal herniae are due to a congenital weakness.

(2). That right inguinal hernia is more frequent than left on account of the more frequent incomplete closure of right inguinal canal caused by lack of pressure from behind and the right side of pelvis being larger than the left.

(3). That when you have a congenital inguinal weakness plus a splanchnoptosis a very slight jar or misstep will cause a knuckle of bowel to descend into patent opening producing very little if any shock.

(4). That if force enough could be applied to produce a traumatic hernia there would be great surgical shock, immediately following.

(5). That the peristaltic wave being from left to right, the larger side of the pelvis being the right, the attachment of the mesentery being from left to right and the left leaflet of the diaphragm being freer to act than either of the other leaflets the long axis of the abdomen changes when force is applied from above from the central line of the body to a line which might be drawn from above downward from left to right.

DISCUSSION.

Jno. B. Richardson, Jr.: I do not believe a paper of this character should go without discussion. I am not prepared to discuss the various points brought by the doctor, except in regard to the statement he makes that practically all inguinal herniae are congenital in origin. In this connection I would call attention to the fact that the number of damage suits arising from herniae which are supposed to have been caused by trauma, is constantly increasing. If the medical profession in general was aware of the fact that in the vast majority of these cases the hernia is directly due to a congenital defect, this might be checked. There is not a day in which one or more damage suits are not instituted based on a hernia which is supposed to have been produced by trauma, while, as a matter of fact, true traumatic hernia is of comparatively rare occurrence.

F. T. Fort, (Closing): I have very little to say in closing. I am firmly convinced, in my own mind, that practically all inguinal herniae are congenital in origin. I had a man come into my office the other day, who had been lifting some lumber and a hernia developed. At first he said he had never noticed anything prior to this time, but upon close questioning he admitted that there might have been a little protrusion there. If this man had fallen into the hands of a lawyer, a suit for damages based on a traumatic hernia would probably have resulted. I do not believe a man can suffer a traumatic hernia without giving evidence of great shock, if it is possible at all.

PUTREFACTIVE PHLEGMON.

By CHALLON GUY FORSEE, Louisville.

Putrefactive inflammation with the formation of an exudate, which in the beginning is sero-hemorrhagic in character, and later becomes foul smelling, contains gas and is associated with putrefaction or gangrene of the tissues is indicative of infection with putrefactive bacteria.

There are a number of processes which are clinically allied sometimes the formation of gas being the most prominent and at other times gangrene.

In all these cases pyogenic infection is common—usually the role played by pyogenic bacteria is of but little consequence compared to the damage by the putrefactive bacteria.

Putrefaction is closely related to fermentation, the former is a reduction and the latter an oxidation process. The first step in the process is peptonizing which faculty most putrefactive organisms possess.

There are formed in putrefaction numbers of complicated toxic and nontoxic substances, the so-called ptomaines, alkaloids, and toxalbumins. (This feature of bacteriology was known long before the most important bacteria was ever discovered.)

The name toxin is now applied to poisons secreted by living bacteria of which peptotoxin, muscarin and neurin are examples.

The principal cause of putrefactive phlegmons belong to a large group of bacteria of which the colon bacillus, proteus vulgaris bacillus aerogenes, capsulatus and bacillus of malignant oedema are the most important.

These bacilli belong to a widely distributed group being found in dirt and dust of the street. Cases of this infection have been reported when there was heavy snow on the ground.

The colon bacilli group stands between the putrefactive and the pyogenic groups, sometimes they are found causing emphysema and usually pyogenic conditions.

The conditions essential to the development of the putrefaction are the presence of degenerative tissue, and points to which the air does not have ready access.

If the putrefactive inflammation extends a phlegmon forms which develops more rapidly and is accompanied by severe local and general symptoms than pyogenic infection are.

Often within 24 hours an entire extremity becomes so oedematous and painful that the swollen lymph nodes can not be palpated and lymphangitis which is almost always present an indicated by red streaks, can not be seen.

The skin soon becomes pale and anaesthetic and large blebs with sero-hemorrhagic contents form; black discolored areas develop and soon form into black crusts which are cast off as the gangrene spreads.

Fluctuation can not be elicited but when the tissues are palpated an emphysematous crackling which is characteristic, may be elicited. When the tissues are incised the amount of destruction can be determined.

The incision passes through an oedematous or gangrenous cutis into a grayish green subcutaneous tissue from which gas bubbles, fat and shreds of fascia exude. Muscle are found to be in the same condition.

Everywhere a gelatinous, discolored mass of tissue is found from which an ichorous discharge and gas bubbles are found.

The fact that this class of bacteria is negative as to chemotaxis causing no emigration of leucocytes accounts for the character of the discharge.

Illustrative of this process, I wish to report two cases of putrefactive phlegmon:

The first, Mr. B., white, age about 30, a bartender, was seen at his residence: On examination, I found a large periproctile phlegmon. On entering his room the characteristic odor was observed, on examination a large gangrenous area around the anus was observed. This was carefully incised. The knife was reversed and the handle inserted into the phlegmon the entire depth of the history without causing pain. This was lightly packed and he was sent to the City Hospital where he came under the service of Dr. Asman. I will ask him to finish the report on this man.

Case II. W. V., colored, age about 50 years. Coachman, was referred to me by the late Dr. Marvin.

When I first saw him July 29, 1913, his entire back and neck was emphysematous.

He was removed to the Red Cross Sanitarium where the phlegmon was incised and trimmed away as much as possible and lightly packed with hydrogen dioxide and this ordered changed often. This was soon substituted by permanganate of potash 1-500. This was done because the perondi was painful.

Some of the discharge was stained and examined and it was found to be a single micro-organism which I took to be bacillus aerogenes capsulatus. Symbiosis was not present in this case for on the next examination within a week there were none of the bacilli formerly seen but a mixed infection of staphylococci and streptococci.

The area of destruction was as large as one half an ordinary grape fruit, extending from the spinous processes onto the left shoulder.

There was no history of injury in this case and the only focus of infection I could find that could be considered a possibility was a sinus of the jaw on the left side which had been caused by a decayed tooth and which had not healed though it had been 20 years since the tooth was drawn.

I do not know how this could have been the site of infection but this was the only one I could find. I judge this must have been endogenous putrefactive infection.

This man died of apoplexy nine weeks after I first saw him.

MEDICAL PROGRESS

DEPARTMENT OF GENERAL SURGERY.

GEO. S. COON, Louisville.

LEE KAHN, Louisville.

Border Line Pathological Lesions: Blood-good in Surgery, Gynecology and Obstetrics, discusses very interestingly and instructively Border Line Pathological Lesions, meaning thereby any lesion in which it is difficult to determine by the clinical history, gross appearance or microscopic section whether it is benign or malignant.

While in some instances a differentiation is unimportant for proper treatment, in many cases it is highly essential to determine whether the lesion is benign or malignant, because if malignant an extensive and radical operation offers the only chance of cure, and if benign an operation with less mutilation is sufficient.

In every series of malignant cases there is a large per cent. far advanced, inoperable, with no difficulty in diagnosis. In another group, usually the largest, the diagnosis can be made clinically and confirmed by gross appearance and microscopic findings.

In the third group, small in number but fortunately rapidly increasing are those cases, which are seen at such an early stage that none of the symptoms usually associated with malignancy are present. Clinically the tumor appears benign but on exploration is found to be malignant.

Until recent years, the number of patients with cancer of the breast applying for treatment in the early stage was about ten per cent. In the past two years the number has increased to twenty per cent. And as the profession and public become more alert and recognize the tremendous advantage of attacking these growths while clinically benign the percentage of patients applying for early treatment will rapidly increase.

That far better ultimate results are obtained in operations upon malignant lesions, clinically benign over those clinically malignant is clearly shown, provided the clinically benign lesion is operated radically and in one stage, the diagnosis being made by exploratory incision from the gross appearance with or without the aid of a frozen section.

The advantage of the early operation is strikingly set forth by statistics on cancer of the breast. "The probability of a cure when the breast cancer is clinically malignant and operable is about twenty-five per cent, while if the breast cancer is clinically benign and the radical operation follows immediately the exploratory incision, the probability of a cure is eighty per cent. However, if the malignant lump only is removed and then, later days or weeks after the microscopic examination is made, the complete operation is performed, the probability of a cure is less than ten per cent."

Thus it is seen that the two stage operation on the clinically benign cancer is far more fatal, than the one stage operation on the clinically malignant cancer. The author does not believe that the majority of surgeons fully realize the fatal error of the two stage operation, such as removal of the tumor or breast and later after microscopic diagnosis, the radical operation for cancer.

It might be argued that it would be safer to perform the radical operation for cancer in every case with lump in the breast. This would cause an unnecessary mutilation in many cases. The experienced surgeon by exploratory incision should be able to determine from the gross appearance, with or without a frozen section whether he is dealing with a benign or malignant growth.

However, the invariable rule should be that whenever in doubt the lesion should be treated as malignant and a complete operation performed. By following this rule, very rarely will the fatal error be made of treating a malignant case as benign. Probably about ten per cent. of the benign cases will by this rule be incorrectly treated for cancer, the only harm resulting therefrom being the unnecessary mutilation.

G. S. C.

Artificial Pneumothorax in the Treatment

of Tuberculosis: Murphy, in *Surgical Clinics*, presents cases and gives an extensive review of the use of artificial pneumothorax in the treatment of tuberculosis. The method according to the author is being extensively used in the tuberculosis sanatoria of Europe. The best time for giving the treatment is the same as for surgical tuberculosis in other parts of the body or during the early stage of the disease. By this means, the diseased part is put at rest, the contents of abscess cavities are forced into the bronchi, fever subsides, the cough lessens and the patient improves in weight and strength. The earlier the treatment is begun the better the prognosis, but good results are reported in moderately advanced cases.

The technique of the operation is described and is very simple and practically without danger in careful hands. Nitrogen gas is used because it is more slowly absorbed than other gases. The operation or injection should be repeated every two or three weeks, keeping the lungs constantly compressed until cicatrization takes place. The amount varies from 50 to 200 cubic inches, and is regulated by the dyspnoea and displacement of the viscera.

In discussing pulmonary hemorrhage, the author gives a very simple means for its management. A hypodermic needle is rubbed dull on a brick, introduced into the pleural cavity, the but end covered with cotton, as a filter. The skin is previously sterilized and punctured with tenotome. An artificial pneumothorax can now be produced by using the finger over the but end of the needle, as a valve.

On inspiration the finger is lifted and the air allowed to enter, and on expiration the opening is closed.

The cavity can be filled to any desired amount and should dyspnoea or cyanosis intervene by reversing the process, the cavity can be emptied. G. S. C.

Post-Operative Results of Trachelorrhaphy in Comparison with those of Amputation of the Cervix: Leonard in *Surgery, Gynecology and Obstetrics*, analyzes cases operated upon at Johns Hopkins Hospital during the past twenty years. Trachelorrhaphy and amputation of the cervix give almost equally good results, so far as improvement of the general health of the patient is concerned. In this respect the operations were very gratifying about ninety per cent of the patients receiving marked benefit.

Leucorrhoea which was present in a large percentage of cases was cured by amputation of cervix in sixty-two per cent. of the cases and improved in thirty per cent. Trachelor-

rhapsy gave forty-two per cent. of cures and forty-two per cent. improved.

Post operative hemorrhage occurs much more frequently following amputation than trachelorrhaphy. Five per cent. of cases of amputation bleed so profusely as to require resuture, vaginal packing having failed. In a number of other cases bleeding was controlled by the vaginal pack. In only two cases of trachelorrhaphy was the vaginal pack required and no case required resuturing.

Dysmenorrhoea was present in a large per cent. of the cases before operation. This was improved or entirely relieved in sixty-two per cent. of the cases, the results being about the same from either operation.

Trachelorrhaphy is followed by sterility much less frequently than is amputation of the cervix. The explanation being that due to cicatricial contraction that is greater stenosis of the cervix following amputation.

One of the most striking tables presented is the showing the marked tendency to abortion and premature delivery following amputation of the cervix. Only forty-five per cent. of the pregnancies reached full term and nineteen per cent. had premature deliveries. No such tendency followed trachelorrhaphy.

After amputation of the cervix the first labor is difficult in over one-half of the cases and rarely present after trachelorrhaphy.

The author concludes that amputation of the cervix interferes with fertility, is followed by a tendency to abortion, premature delivery and difficult labor. Hence, the operation should not be performed during the child bearing period, until all other means have failed.

Trachelorrhaphy in properly selected cases improves the general health, relieves dysmenorrhoea, does not interfere with fertility, has no tendency to produce abortion, premature delivery or difficult labor and should be the operation of choice in the child bearing period. G. S. C.

Cholecystectomy: John B. Deaver, (*Surg. Gynec. and Obstet.*, 1913, xvii, p. 667) granting the applicability of simple cholecystectomy in cases properly selected believes, nevertheless, that from a practical standpoint the surgeon will seldom be able to select such cases, and that as a rule some operation involving either drainage or removal of the gall-bladder must be employed to do the greatest good to the greatest number. There is practical unanimity concerning the advisability of cholecystectomy in such well defined conditions as hydrops with obliteration of the cystic duct, chronic empyema, calcareous degeneration, the cholesterol gall-bladder of Moynihan, gangrene, carcinoma limited to the gall-bladder and extensive laceration of

perforation of the gall-bladder. In all other than these enumerated the conservatively inclined hold to cholecystotomy on the ground that the gall-bladder is beneficial and should be preserved. On the other hand, those who advocate cholecystectomy argue that the gall-bladder is a vestigial and unnecessary organ and that permanent cure is not assured by drainage.

The precise function of the gall-bladder is, like that of the appendix, not definitely settled. The old idea of the physiologists that the gall-bladder served as a reservoir for bile during the period when it was not needed for digestion is inadequate considering its small size and moderate distensibility together with the fact that the average daily output of bile in the adult is 30 to 50 ounces. That the bile does back up in the gall-bladder during the intervals between digestion is certain, as is shown by the increased drainage from a cholecystostomy opening during the night. Nocturnal pain in cholecystitis may also be explained in this way, the gall-bladder being distended by the back-flow. The suggestion that it acts as a tension bulb has much to commend it. The evidence favors the belief that the gall-bladder has a desirable function even though its presence is not necessary to health. Although cholecystostomy in gall-bladder infections does not restore the organ to a normal condition it is surprising how many cases are permanently cured and the reformation of the gall-bladder is a very rare occurrence. Deaver has found the prepancreatic lymph nodes almost invariably enlarged in gall-bladder infections. Babcock has pointed out the role of cholecystitis in the causation of myocardial degeneration, but other organs suffer as well. When such a condition is present and the gall-bladder presents such serious alteration as to make the question of cure by cholecystostomy problematical cholecystectomy is advocated. The higher mortality of cholecystectomy is one of the strongest objections to it but the writer warns against being misled by the published figures of the relative mortality of these two operations with the reminder that cholecystectomy has been reserved by most surgeons for the more severe and complicated cases in which the mortality is necessarily high from the severity of the disease itself. Kehrer, who performs cholecystectomy more freely than other prominent surgeons in this field reports a mortality of 1.5 per cent in cholecystostomy and 3.7 per cent in cholecystectomy. Even here the cholecystostomies were in a group less seriously diseased. It is thus seen that this discrepancy is not so forbidding and warrants the operation when convinced that removal of the gall-bladder is the operation of choice.

Gall-bladders which are known from symptoms and appearance to have become the seat of chronic infection with periodical exacerbations will in the majority of cases be best treated by cholecystectomy. Bacteriological findings are given great weight in deciding upon the type of gall-bladders which shall be removed. A gall-bladder thoroughly and chronically infected which has evidence of chronic systemic intoxication and regional involvement of adjacent organs, notably the pancreas and peripancreatic retroperitoneal tissue is too dangerous a source of future trouble to rely upon cholecystostomy for permanent cure. While cholecystectomy is the operation of choice in this class of cases one will often content himself with cholecystostomy. In this case a large tube should be employed and not removed before two weeks have elapsed in order to create a firm sinus that will not close in less than six to eight weeks.

The ease or difficulty of cholecystectomy depends on the situation and degree of involvement by adhesions and inflammation; the stronger its indication the greater the operative difficulty. Deaver concludes with a description of his operative technic.

L. K.

Radium in Malignant Disease: Robert Abbe (*Lancet* clxxxv, 1913, p. 524) has studied the efficiency of radium on more than 750 cases in private, including epitheliomas of all parts; carcinomas of the tongue, throat, esophagus, rectum, uterus, breast; sarcomas of the skin, parotid glands, etc., besides goitres, tumors of the liver and mediastinum and a variety of naevi, moles, papillomas, etc. The numerous failures are attributed to inadequate amount, or insufficient time of application, or errors in using the proper rays. Three types of results are to be recognized in radium work, to-wit: destruction of tissue too closely in contact; stimulation and harmful results; and efficient retrograde degeneration of malignant growths with lasting benefits amounting at times to a surgical cure. The cases cited illustrate brilliant and even startling results and are not confined to the skin cancers only. Malignant tumors, however, must first be excised as thoroughly as possible and the bed of the disease be well radiumized to effect degeneration of malignant cells. Ulcerating types of cancer are rather the better ones for the use of radium, but when the mass of disease is too great it is not possible to penetrate effectually deep enough to produce the desired result, and it becomes the duty of the surgeon to reduce the diseased tissue to a shell as it were before applying radium. Many types of mammary cancer near the surface and involving the

skin may be radiumized without operation, while others must be incised and tubes of radium buried in the tumor. In destructive types of sarcoma the specific action of radium as a curative agent is illustrated in a remarkable way—demonstrating in the myeloid type its superiority to all other surgical measures.

In conclusion, there has been established: (1) an undoubted retrograde degeneration of malignant cells under correct dosage of gamma radiation; (2) effective use of radium lies in the application of a large enough quantity to avoid the stimulating action of little doses at short range; (3) the utilization of gamma radiation with its deep penetration can be made by removal of alpha and short beta rays by filtration through lead; (4) such filtration requires many times as long for sufficient amount of gamma rays to act as when other rays are eliminated by what may be called "distance filtration." One and a half inches seems in practice to exclude most of these and gives free and instant play of the entire gamma range without delay of passage through lead; (5) cross firing of several specimens simultaneously or of one large specimen moved successively to several nearby places is necessary for the best work; (6) normal tissue resists many times as large doses of gamma rays as are required to check and dissipate morbid growths.

L. K.

Technic of Intra-Abdominal Administration of Oxygen: William S. Bainbridge (*Am. Jour. of Surg.* xxvii, 1913, p. 364) describes the two methods of administering oxygen intra-abdominally. The continuous current method originally described by Thiriar in 1899 was employed by him in tuberculous peritonitis; the ascitic fluid having been first evacuated through a button-hole incision the gas was introduced continuously for ten minutes, a free outlet being maintained. It has been so used to flush the cavity after laparotomies to stimulate tissues, prevent inflammatory extension, increase phagocytosis, destroy germs and neutralize toxins.

The second method as first employed by Bainbridge in 1903 the oxygen is left to distend the cavity and be gradually absorbed without repetition or continuance of the current. The abdominal wound is closed except at the upper or lower end where the rubber tubing conducts the warmed gas into the cavity. An interrupted stitch is tied above and below the tube, another peritoneal stitch is taken at this point but not tied and a purse string suture encircles the tube also untied until the latter is withdrawn.

Uniformly good results by this method in over 125 laparotomies has convinced the au-

thor of the benefits of oxygen so administered in shock, nausea and vomiting; in overcoming negative intra-abdominal pressure after the removal of large tumors; in preventing adhesions; in septic peritonitis and certain types of tuberculous peritonitis.

L. K.

Puncture of the Corpus Callosum: Edward Archibald, (*Canad. M. Asso. Jour.* iii, 1913, p. 451). The problem of how best to give relief in cerebral compression from unlocalized tumor is in many cases difficult. Decompressive trephining may fail to give even partial relief; too much must not be promised. As a palliative measure it is often a grateful operation. The Cushing subtemporal procedure is universally acknowledged as the operation of choice for pure decompression. Sometimes, however, it proves inefficient; in spite of a large subdural hernia, the symptoms occasionally persist. The reason may lie in the co-incidence of a large hydrocephalus internus, such as is known to complicate tumor not infrequently. Experience of this kind led Anton, the neurologist at Halle, to puncture the roof of the corpus callosum as a method to relieve intercranial pressure. This created a communication between the ventricles and the entire cerebral and spinal subdural space. The communication, he argued, would remain permanently open on account of the current set up between the ventricle and the subdural space. Postmortem examinations verified the correctness of his views. The technic of the operation is as follows: On the right side about a finger's breadth behind the coronary suture and 2 cm. from the mid-line an opening is made with the Doyen burr about 1.5 to 2 cm. in diameter. A slit opening is made in the dura, taking care to avoid any large cerebral vein. Then a curved canula is pushed in over the convexity of the cortex till it strikes against the falx, which membrane guides the further progress of the canula downwards till the corpus callosum is reached. The instrument breaks bluntly through this structure with very slight force, whereupon the ventricular fluid is emptied, usually under some pressure. The author reports four cases in which puncture of the corpus callosum was performed by him. In the two cases of unlocalized tumors it was evident that neither subtemporal decompression or collosal puncture was in itself sufficient to get the best results. Each in turn had to be supplemented by the other. In the two cases of obstructive hydrocephalus of high grade in infants the puncture method proved temporarily of slight benefit.

MEETING OF COUNTY SECRETARIES.

The meeting of the County Secretaries was held at 8 P. M., September 1, 1913, and was called to order by L. C. Redmon, Lexington, who, in the absence of the President, Dr. Stine, acted as Chairman pro tem.

Cyrus Graham, Henderson, read a paper entitled "Councilors in County Organization."

COUNCILORS IN COUNTY ORGANIZATION.*

By CYRUS GRAHAM, Henderson.

I have often been asked "What are the duties of the Secretary of the State Association?"

I have never been able to answer that question satisfactorily until this year. I now know that his duties are to lie awake at night and try to think of some work to be done; or of some poor practitioner out in the bush, whom he wants to do something, and get right up, and without taking time to even clothe his graceful form in proper raiment, dictate an epistle to the aforesaid poor overworked practitioner, telling him that "it is absolutely necessary for him to get busy, that the entire society is waiting with expectant minds and anxious hearts to hear from him words of wisdom, such as only he can write."

So when, on August the 17th, I received a letter from the Secretary asking me to write a paper on the subject of "Councilors in County Organization," I looked up at my thermometer, hanging over my desk (saw that the mercury was threatening to spill over the top, I said, "Blankety! blank, I believe he lies awake at night trying to think of something for us poor devils to do.")

But gentlemen, I very readily recognized the fact of the importance of the subject mentioned. In looking over the Constitution and By-laws governing our Association, I find under the single word, Council, quite a number of important duties laid down, and many ideas suggested, which if carried out successfully would weld our Association into one of the most compact scientific bodies in existence, and one, the impact of whose combined will, working together, would brush away all obstructions.

This being my first year to serve in the important office of Councilor and not being familiar with my duties, I fear that I have been somewhat neglectful.

What little experience I have had during the past year has shown me the importance of the Board of Councilors, in contributing to the success of the entire organization.

It is of more importance to the profession, as a body, that the Board of Councilors have their regular meetings, during the session of the general body, than the reading and discussion of some of our scientific papers.

In our meetings at this time, we get more in accord in the workings of this unit, but also, more in touch with the ideas of members in the field. These meetings mean something "for the good of the order." They mean the perfecting of our organization for field work for the coming year, and the working up of a personal acquaintance with the Secretary of each County Society in our respective districts so that there will be harmonious effect for cohesive work.

The auditing of accounts, keeping watch over the character and cost of publications of our association, and the care of papers and all property belonging to the Association, is but a few of the duties devolving upon the Council. The success of a meeting, and the maintaining of the stability of the entire State Association depend upon the management of the Board of Councilors and the support they render to the officials in charge. Individually, each councilor is an organizer, whose duty it is to visit each county in his district at least once a year, cheering up the old members and boosting the new members up to an enthusiastic understanding of just what it means to each one, individually, to keep up the numerical strength of the organization. The co-operation of each local secretary by letter and personally with his district Councilor is absolutely necessary for success.

By visiting each county society, taking a personal interest in local affairs that pertain to the interest of the profession as a whole, we add to the strength of the organization and render more effectual the support given us by the different secretaries.

One of the most important duties of the Councilor is to act as peace maker. To know "When to take occasion by the hand" and lead some of our erring brethren into the ways of peace. *Canida par homines*, and while we labor here with commutual zeal, we all do strive in acts of altruistic benevolence and love, we should remember always, that we are "Brothers in peace, not rivals in command."

Doctors are very human creatures. The high tension of our lives in often yielding our health upon the altar of our profession, sometimes causes us to be impatient and sensitive. Then with us "trifles make the sum of human things, and half of our bickerings from our own foibles spring."

As a peacemaker between these little local factions, the Councilors can accomplish much. Not by "butting in," but by wise counsel

*Read before the Meeting of County Secretaries, at Bowling Green, September, 1913.

bring about a feeling of *conciliation*. By showing that we "are actors all," and although sometimes we may get mixed in our lines, a forgiving spirit, a more gentle tongue, a more genial hand-clasp and more knightly bearing toward one another, will redound to the benefit of us all.

Often the Secretary, by giving his Councilor an unbiased version of some local trouble, will aid materially in bringing the contending factions together in the bonds of unity. There is no pleasure in being a member of a society where there is a continual scrap in evidence.

As a rule, these disputes arise from some trivial matter. The idea in all parliamentary bodies is to let the majority rule. The doctor who will not belong to his association, as a rule, has only himself to thank, as his is the unfortunate one. Under kind and generous treatment, the fellow who is mad and swears "he won't come in" will realize that he has been acting a dessicated ass and return to the fold.

We should consider in all of our controversies, that among professional men, that motto of "Give and take the gospel, and we'll call the bargain fair," should be the sign by which we conquer.

I have become just enough interested in this subject to know that what a Councilor should do would make a book, but what he does do may be recorded in a page. We do not fully realize the importance of this branch of our association.

Collectively, we are the Board of Censors for the Association. The question of rights and privileges of the members, not only in the State Association but also in the different county societies, when they cannot be settled in the local society come up for final adjudication before the Board of Councilors. To the Council, the different societies have the privilege of reporting sanitary conditions in their counties, and they have the right to investigate and communicate as a body to the public.

If the Secretary of each county society would keep in touch with his Councilor and continually encourage and push forward any suggestion that he thinks will redound to the efficiency of the organization, he would help the cause very materially. A united and continuous pull on the part of every Councilor and each Secretary from his home county, can but result in a distinct gain in numerical strength, and it will also increase the moral and effective scientific working force of the entire body.

Then let us go to our homes, from this meeting, with the determination to visit, to inquire and to do all we can to promote and to organize for a better and more complete work-

ing body of scientific men laboring for the good of humanity.

"For labor is life, 'Tis the still water faileth, Idleness ever despaireth, bewaileth; Keep the watch wound, fo rthe dark rust as- saileth!"

And by doing this, we will place our Commonwealth in the forefront of other states in sanitary matters.

DISCUSSION.

Arthur T. McCormack: I would suggest that the councilors speak of the methods which they employ in the various districts, so that what they say will be of benefit to the other councilors and districts and speak of how the delegates and councilors can be of more benefit to the county societies and the district.

In the last two years the expenses of the councilors have largely decreased. The committee on Reports of Officers have noted this fact and they would like to have the councilors state how they can do the large amount of work they are doing without having any expense account, or very small ones, so far as practicable in the discussion.

C. Z. Aud, Cecilian: In answer to the last question of Dr. McCormack. I happen to have an annual pass over a railroad, and I can travel free. Most of my counties can be covered with my annual pass; therefore, I can travel without expense to the society.

In the last few years I have done a good deal of work by correspondence.

There is but little criticism that can be passed on the paper of Dr. Graham. He has well outlined the work of the councilors, but it must be kept up, and I believe that it is a work for the younger men of the profession. I think it is time, in my district, for you to have a younger councilor. I wish to say, however, the work has been pleasant to me, and it will be pleasant to some of you. I hope some of you will be placed in my position. I think it is a good thing to resign once in a while. (Laughter.) I want to ask you delegates to do a little more this year. The councilor feels better if he is invited. There are some county secretaries in my district who did not invite me during the past year. I would ask and urge that you delegates get to work and get us a spirit of interest in your counties. I have never yet visited a county in which we did not have a splendid day. We always have a good time. I was one of the first councilors elected, and have served every year, except the year I was your president of the Kentucky State Medical Society. Dr. D. C. Bowen, of Hardin county, was councilor during that year. I wish to take this opportunity of recalling this name, "Bowen," one of the sweetest and most worthy in the annals of Kentucky medicine.

J. W. Kincaid, Catlettsburg: Dr. Graham is beginning to get a comprehensive grasp in the short time during which he has been a councilor, of the multifarious duties which attend that office. The councilor who does the best work is the one who gives perhaps the most time to it. But when one comes to consider he has been over his district a number of times he cannot always see the necessity of going right back again next year and visiting the same counties if they are doing well, and if he has visited a county two or three times and they continue to do badly he gets discouraged. But we will suppose that if one is persistent he can get a sympathetic organization in every county in the State. I have organized one county in my district three different times rather loosely. Every time it has become unorganized, but there has been some new blood infused into the county, and I have the positive assurance from two or three of the new men and two or three of the old ones that they will be enabled to organize on a firm basis this fall.

I believe the councilor is not appealed to as often as he should be by the members of the profession in the various counties in the State for his disinterested advice in matters between doctors themselves, to say nothing of malpractice suits. Oftentimes misunderstandings and bickerings and things of that sort, a disinterested party, that lives outside of the county, can smooth over. It has been my pleasure to assist in that way in two or three instances in a profitable way; but unfortunately the doctors try to settle these things among themselves by keeping it fomented all the time and approaching each other in the proper spirit. Each thinks the other is a rascal, and there is no forgiving on one side or the other. If they should bring in the councilor as an adviser it would do lots of good.

I have only visited one county in my district this year. There have been a number of circumstances that have conspired to prevent me making the usual trips, chiefly owing to sickness in my own family this summer, and in the early spring there were conditions that demanded my attention at home.

The secretary of the county society will find the councilor of his district ready and willing and anxious to visit the society at any time that he is invited to do so, but I confess it is a good deal of a disappointment for the councilor to go into a county with the expectation of having a good meeting and only have three or four of the leading spirits in the county present when there ought to be 10 or 15 or 20. It may be, there is something lacking in the personality of the councilor that makes that possible. The best excuse these gentlemen offer in my section is that the distance is so great that they cannot come to the meetings under one or two days, and I have on some occasions taken some of the greater lights

along with me in order to stimulate interest. Dr. Shirley has been very kind as one of the neighboring councilors to come with me on one or two occasions and his genial presence has been sufficient to draw out a good crowd.

There is one thing I believe the councilors have not done as much as they should have done, and that is the organization of district medical societies; that is, a medical society composed of all doctors in the district to meet at some central town once a year. If a doctor can get out of his own county and mix with doctors in other counties, he feels he has a larger field, and some how or other I think a few of them will do things away from home they will not do at home. They have made their reputations at home and there is nothing more for them to gain, but in a district meeting, where there are men from surrounding counties, they will have a larger audience. I believe if we organize these district societies we will find it would really stimulate the county organization. I had the opposite view of that a few years ago when I and some other gentlemen in our county and adjoining counties were instrumental in putting into quiet rest a tri-state medical society we had namely, of Ohio, Kentucky and West Virginia, because we wanted to build up the county organizations. I believe it is really a mistake not to have district organizations. If the councilors with the county secretaries would go to work and get cooperation in the organization of district societies it would be a good thing for them.

R. C. McChord, Lebanon: As councilor in my district, I wish to say the principal trouble is with the secretaries of the county societies. The secretaries do not cooperate with the councilor as well as they should. In two counties in my district I have never in my experience as a councilor been invited by the secretaries of these counties to visit them, and that is one of the principal drawbacks to the work of the councilor, namely, the way in which the secretary if I may say so, acts towards the councilor. I believe if there was more intimacy between the secretaries and the councilors it would be better for the society. We all know that to make a society you must have an efficient secretary and unless you have a good secretary you cannot have a county society. What I want to say is this: I want to impress upon the delegates and secretaries of county societies that they should take the councilor of their district more into their confidence and invite him officially to visit them. We are all anxious and willing to help them, but where we feel that the secretary has not shown us the courtesy of inviting us to the county, we do not feel like going there.

The Chairman: Before we ask for a general discussion on this paper, we should be glad to hear from Dr. I. A. Shirley, of Winchester.

I. A. Shirley: I will try to answer Dr. McCormack's question in regard to why the expenses of the councilors have gradually decreased. I think it is the experience of every man that he will not charge for services that he does not render, and his expenses will be in proportion to the number of visits he makes throughout the county.

I am sure, the suggestion of Dr. McChord regarding the secretaries of county societies failing to invite councilors is a good one, and it would lessen the work of the councilor very materially if he were invited to visit certain districts. In other words, he would go there feeling he would be able to do something. However, so far as I can recall, I do not think I have been requested by half a dozen counties to come. I have simply made my appointments and gone. It is true, I have received the cold shoulder frequently. I went to the Courthouse to see a county judge, who was a doctor. I had never been in his county before. I said to him, "I want to see you across the way." He went over, and I said to him, "I saw Dr. B. this morning, and I want you and Dr. B. to join the society." He replied "Dr. B. and I cannot enter such a society together. It is not safe for us to be in the same room for a long period of time." I cite this illustration to show that this condition of affairs comes up every now and then. I said to my friend, do you recognize the fact that you are elevating that man very far above what he deserves; In other words, you are staying out of the society and debaring yourself from associating with the other members simply on account of one man, and he is keeping you away from it. My advice is for you to join the society, to go and speak to this man, and if you do not want to discuss matters with him, do not do so, but show your presence there and show the confidence you have in your profession. These are the things we come up against constantly in our work as councilors. Of course, we have our pleasant moments and a good time.

My work for the last three or four years has been largely by correspondence, and in the last year going about and looking up the have-beens and working the councilorship as a side line. It is not right for me to charge for that, but I charge enough according to what I do for the Kentucky State Medical Association. You organize a society, have the members pay their dues, and then next year they drop out and reorganize, it is usually very unsatisfactory. There is no trouble to organize but to keep them alive is the hard part.

I have seventeen counties in my district, and if I should visit every county society I do not know what my expenses would be. Some of these counties are inaccessible. It seems to me we can do good work by correspondence, after we know the situation. Much, however, can be accomplish-

ed by personal contact with these men. The work of the councilor is to keep the district organization intact, to keep it progressing. They do not seem to think it depends upon the individual member and membership, but they expect the councilor to do the whole business. It is a thankless job, without a cent of pay, and if we could impress upon the whole membership the necessity of their doing something and should do something we would have a much easier road as councilors to travel. I want to impress upon the membership of this Association with all the energy of which I am capable, that this is an individual work, and unless you realize that much depends upon all of us individually and collectively we will never accomplish anything. (Applause).

The Chairman: We have heard from the councilors on Dr. Graham's paper. They lay the burden upon the secretaries. We will hear from the secretary's side, and I declare the subject open for general discussion. The councilors have alluded to the fact that the secretaries fail to invite them to come to their societies. I should think they would have a standing invitation, but these standing invitations they do not feel like accepting. We would be glad to hear from any secretary present. Personally, I would like to discuss Dr. Graham's paper myself. There are several gentlemen on the program who are present, and unless someone else desires to discuss the paper at this time, I will say a few words on it myself.

I myself have been laboring under a false impression. It has never entered my head that it is the duty of the county secretary to invite the councilor to visit the county societies. We have expected him to come without an invitation. I must say, from now on, I will extend Dr. Shirley a hearty invitation each year to come and see us. The councilor can help us a great deal in medical society work. His presence will stimulate interest. With a cut and dried scientific program from month to month, it gets monotonous to the society members, and they say I will not go to the society; it is the same old story. Some fellow will tell about this or that thing, but if the councilor would drop in occasionally, let us know a day or two before, so that we can advertise the fact I am sure the attendance would be increased and the interest stimulated, and we might also furnish something to eat. Our councilor did not receive an invitation last year; I do not know whether he intended to make a visit or not, but I think he accidentally dropped in. We were mighty glad to see him and we had an interesting meeting. I think we should have at least one visit from the councilor a year, and if we can get more it will stimulate interest in the society very much. Our councilor will have an invitation from me as soon as I get home.

At this juncture, Dr. A. C. L. Percifull, took the Chair.

C. Z. Aud, Cecilian: Let me say a word or two in regard to the kind of invitation. The invitation mentioned is not a very acceptable one. How does the councilor know when or where to go? He does not know whom he will meet, if anyone. The county secretary should make preparations for him. He should ask the members as to the best time to invite the councilor. Not in mid-winter, when the roads are bad, when the country doctor cannot very well attend, but in a seasonable time. Have it well understood by the profession throughout the county. Get in communication with the secretary of the State Society, so that he can send out notices and give the councilor time to write letters to the various members of the profession throughout the county. All this work should be done in unison.

J. E. Wells, Cynthiana: I am not a councilor nor a secretary, but I have had some experience as councilor, and I want to take issue with Dr. Aud and some of the others in regard to the invitation to visit county societies and in knowing when one shall go. It is the duty of the councilor to know the exact date of every meeting held in his district; at least I consider it such. He should keep in touch with the county secretaries by correspondence and know when the county society meets, and the kind of meetings they are having, and when the meetings are not regular, or the work of the society is not up to the standard it is the duty of the councilor to visit that county and make an effort to correct the trouble and bring about a better state of affairs by injecting a little enthusiasm into them. I find that I had better success in going into a county a day before the meeting; going around and making personal visits to the physicians talking to them privately and finding out what the petty bickerings were and try to smooth them over and patch them up. This will give you a better idea as to how to proceed to bring about harmony to secure a long pull, a strong pull, and a pull altogether. When the physicians of a county get to know each other well, eat and work together they will make a good county society. We must mix a little of the social along with the scientific to make our meetings a success.

The councilor should be a judge of men; some doctors will not work on the off-side, and some do not make good leaders. I have seen some county societies kicked clear out of existence because of a poor secretary. You must have a good secretary. When I started out as councilor—when the State Society was reorganized—I wrote to every physician in the county before I was to visit the county; and tried to see him when I got into his town. At that time I had nothing but Polk's Medical Directory, and I found that I wrote to horse doctors, retired doctors, drug-

gists in the counties; and in making some enquiries in regard to some doctors in certain towns the men who lived there did not know there were such men in the town.

Now things are different because we have a directory that we can rely upon. My success was going into a town and finding out what the trouble was among the members of the profession, and smoothing it over and getting them together.

When a county society is meeting regular, having good meetings and working together harmoniously there is no special need for the councilor to visit them, but in the event of some friction or failure to have good meetings, it is the secretary's duty to notify the councilor and invite him to visit the society for the purpose of stimulating the members to take more interest. The councilor should at all times be in close touch with the secretaries of the county societies in his district in order to know where and when he is needed.

I agree with what has been said—that it is an easy matter to organize a society but not such an easy matter to keep the members together which is the main thing to do, and the hardest task the councilor has to perform. Some counties in my district had to be organized every year. They were great on organization—but not much to stick. We would have a splendid and enthusiastic meeting when we organized but that would be the only meeting that year.

If you can get the members to feel kindly towards one another—and make them understand the benefits to be derived from this organization, they will go to their meetings regularly, receive and impart information and do good work.

O. P. Nuckols, Pineville: This year we adopted an annual program and took the liberty of putting our councilor on the program for a paper to be read in August. Our society has been so harmonious for the last two or three years and we have worked so smoothly, we have had no difficulties for the councilor to settle, consequently, we have had no occasion to call on him for assistance in that particular capacity. However, we are always glad to have the councilor visit us, and, as I have said, this year we put him on the program for a paper at the August meeting, but his duties were such that he did not get to attend. In this case, I feel that we have extended all the courtesy that was due to the councilor of our district, and that we are exonerated from any criticism along that line.

M. M. Mcss, Bowling Green: I went to Simpson county some ten years ago and attempted to organize a society there and was elected secretary. It was my fortune to be secretary of the county society until I left there a year ago. I found it arduous work to be secretary of a county society and do the work properly and right. But I tried to keep in touch with my councilor

all the while and whenever a meeting was held I sent the councilor a very cordial invitation to be with us, as Dr. Rau will bear me out. He got an invitation to our county society.

As to papers at the county society, usually our committee on program consisted of secretary and secretary and secretary. As a rule, he was the committee and secretary all the way through, and I usually tried to put on men who would give us some sort of paper. I usually tried to put men on that would be there. Sometimes I went to vary the program and we would miss a paper, but usually we had some sort of paper. I have made it a rule to put men on that I thought would be present, and usually wrote a paper myself on some subject, not letting the members of the society know that I was going to write one or to read it in case of emergency. I always have something ready. It is the duty of the secretary, if he is going to be the whole show in a county society, to be ready at all times. I do not say that my papers were regarded as first-class, but they usually stirred up some interest. In a county medical society, if you have some sort of paper read, it will be the means of starting a discussion which is generally a good thing. The secretary should call upon some member who will be sure to give some sort of paper. I have the greatest sympathy for the county secretary. They all have my hearty cooperation in anything they may do, and likewise the councilors for that matter. I think the secretary of the county society should send the councilor a cordial invitation to every meeting. That is the point I want to make.

P. H. Stewart, Paducah: I have no doubt but what, so far as successful government and the interest in the county medical society are concerned, the burden falls entirely upon the shoulders of the secretary. In other words, he is the man who keeps in touch with the members and the man who keeps interest aroused, but in our part of the State, in our little neck of the woods, our councilor is a live wire. He is Dr. Richmond of the first district. (Applause). He does not attempt to make the doctors in the first district the goat, but he says we are his sheep and he is the shepherd and he looks after us.

So far as McCracken county is concerned, he does not wait for an invitation. I do not know whether this applies to the district, but he does not wait for an invitation, but follows the law laid down in the Constitution and By-Laws in which it is said that it is the duty of the councilor to visit each county in his district at least once every year, and when he gets ready to come to McCracken county, he calls up the secretary and asks him when is the next meeting night.

We meet twice a month. The secretary informs him. He asks the secretary to invite the membership, stating that the councilor of the first district will be present at that meeting. I am

sorry, and regret to say we have a fuller attendance when the councilor is present than we do when he is not, which I think speaks very well for the councilor, but not so well for our society.

I have had the pleasure of visiting some of the county societies with the councilor, and I know that so far as the counties I have visited with him are concerned, he does the same way, and while I am not a councilor, my observation leads me to the conclusion that the invitation from a county society is always outstanding to the councilor, and if he will make the effort to get in touch by correspondence with the secretary he will have no trouble in having an open date with any county over which he is councilor, and Dr. Richmond in the first district keeps up a regular correspondence school, not only with the secretaries of the different county societies but with the individual members. He makes every member of every county society feel like Richmond is personally interested in that man, and so far as we know he is and he will write a personal letter to the different members of the county society, asking them how the society is getting along, and he has that member and this member write him and in this way keeps up a closer contact with the personnel of the membership and the councilor. (Applause).

The Chairman: I am glad Dr. Stewart brought out the point that the constitution says the councilor must visit each county society once a year, but it does not say whether he should have an invitation to do that or not.

A. O. Sisk, Earlington: I am a little surprised at the timidity of the councilors. Why should they wait for an invitation to attend county societies in their districts? It is their duty to visit the county societies, to encourage its members, to advise them and if possible arouse enthusiasm among the members.

If they will only let us know the date that would be convenient for them to come, we will gladly make arrangements for them, and will give them a cordial welcome when they come. We do not know when it is convenient for them to come. I know I have invited the councilor to come to our meeting, and he wrote that it was not convenient for him to visit us at that time. Our State Journal has wisely provided a calendar for each month, and gives the date of all the county society meetings. Let the councilors consult this calendar, arrange the date to suit them notify the county secretary and I am sure they will all receive a royal welcome.

It might be well if the membership would get the habit of consulting this calendar too, then perhaps they would not forget the "meeting day."

Oscar Keen, Burkesville: I think Dr. Bullitt visited our county several years ago and got about half a dozen to come and organize a county

society. Since that time we have not had a councilor with us. It never occurred to me it was our duty to invite the councilor. I thought the councilor was one of the higher officers, a sort of supervisor of men, who intended to look after the interests of the county, and if they were not at work, keep them at work. If the idea had ever occurred to me that it was necessary to invite a councilor I would certainly have given him an invitation. I do not know, but it seems to me that if the councilors would do their full duty—and I am not criticising them—and go to some of the counties like mine and stir us up, talk to us, keep us together, and tell us what is going on and what they are doing for the societies in the various counties, we would do much better. As it is, we go along in that easy, go-as-you-please kind of way, and we do not care whether we go to the society or not, and if the councilor would drop in and tell the secretary that he would be there on a certain day, we would get the members together and get them started again. If something of that kind is not done, I do not know whether I will ever get them into our society.

We have not a regular place for meeting except in my office. There has never been a meeting except in my office. I furnish the light, the room and everything and they are welcome to meet in my office at any time. I have called up every doctor or member in the county, I have written each member of the county society, stating the date and time and place of meeting and assigning subjects to different members. Then I would telephone on the morning of the day I expected them at the meeting. If the councilor would send a word on a certain day and make a statement to each of the doctors, you will get them all interested, and I extend to the councilor of our district an invitation to come down at any time and we will give him a hearty welcome. (Applause).

W. W. Anderson, Newport: Being neither a councilor, secretary, delegate nor alternate, perhaps I have no right to be called upon to inflict anything upon you, but to make the bluff good, I will just tell you a little about our work and some of our views on the subject that has been discussed here. It has never occurred to us that it should be necessary to invite the councilor, and yet we have always invited him once a year when we have our banquet, and he always comes. (Laughter). We did have a councilor at one time who came without invitation, and without notice. He walked around in the community, then came to the meeting, and he had been much discouraged before when he saw us individually, but when he got us together he found we were not so bad as we looked taken singly. That was Dr. Wells. He has been friendly to us and has never told bad things about us since.

One thing we do not believe in is that everything depends upon the secretary. We see no

reason why we should depend upon the secretary. The secretary, to be sure, is the central shaft of the machinery through which motive power works, but we do not feel the program depends upon the secretary, and we do not believe the best secretary in the State can make a good program and keep doing it right straight along. A one man program is morally certain to fall into a rut. It should be a cooperative affair. I think programs ought to be announced much longer in advance than is the custom in most societies. We read the reports of the various societies and we find that Dr. So and So read an interesting paper, and Dr. So and So has been assigned to discuss such and such a subject next month. It is not time enough. It takes much more than a month to prepare a paper on any subject to acquit one's self creditably and deal with the subject properly before a scientific body. If we give the speakers time enough and give them to understand we expect them to do well, inasmuch as they have had time to do so, they will do better than otherwise. Let us get away from the idea of a short notice program. I would not attempt to prepare a paper on one month's time. I refused to prepare a paper for our hospital staff unless they gave me four month's time. This reminds me of the preacher who was a very ready public speaker and was asked to deliver an address on some set occasion, and he wanted to know how long an address he should deliver, and the committee replied, "We will leave that to you." "Well, he said, "if you want an address an hour long, I can deliver it tomorrow night. If you want one half an hour long, you will have to give me two weeks time, and if you want one that is really worth while I want a month's time to prepare it, and twenty minutes to deliver it." And so a doctor must have time to study his subject. Do not let us throw this responsibility upon the secretary or councilor, but let us get down to work.

There is one other point to which I desire to call your attention, and that is, we believe that in many of our counties we have nearly reached the limit of organization, and that what we want to put the emphasis on now is good scientific work. We believe we ought to have more clinical work in our society because it teaches, and we believe discussions ought to be prepared before hand and well thought out. Instead of throwing bouquets at one another there ought to be scientific, well thought out discussion. A man will get from his county society meeting, whether a councilor or ordinary member, just in proportion to what he brings to it. If he has given the program no thought before hand, he will get but little out of it. If he has given the subject thought, he will receive thought from someone else and he will discuss subjects more intelligently.

In our own society we prepare the program a year in advance, and our secretary and president

call up the men a week or two before their time and remind them that they are to read papers or to report cases, and if they find the essayists are going to fail them they get someone else. We have case reports, so that the doctors will never be disappointed for want of a program.

In regard to the social phase of our meetings, we hold them once a month in the evening at a place where we can have what is commonly called a Dutch treat, where there are facilities for buying suitable things, and every one stands his own expense and gets what he wants. We have weekly meetings nine months in the year and good meetings without these social features.

One other point, and I am through. Much has been said in regard to the councilor's work in settling differences between doctors. I would suggest that where there is some misunderstanding between doctors, that the offended doctor go to the other fellow and talk it over with him in a friendly spirit; get the two doctors together, and by exercising a little common sense, in 99 cases out of 100 they can settle any difference they may have and feel better towards each other and prevent stirring up the community.

F. G. Beard, Shelbyville: I believe I am in Dr. Aud's councilor district, and I want to make a few remarks in regard to what he said a moment ago about malpractice suits. I do not think he could come to our county and try those tactics on us as I do not think it would work. While he may be able to do it in his own county, he could not do it in our county. I rather think it is a bad idea. There are very few lawyers who will permit themselves to be bulldozed. In regard to that, there is always a "nigger in the wood pile" and that nigger is another M. D., and the way to get at the matter in order to settle a misunderstanding is to see the man personally, talk it over with him, and that will block the game. I have had some experience along that line in my county, and I think I have prevented three or four malpractice suits by means of tact and persuasion. I have not had one myself, and I hope I never shall.

Our county secretary three or four years ago had a case which was seen by two other doctors. The patient was a young woman. He made a diagnosis, and the other two doctors said she had another trouble. His diagnosis was she had gonorrhoea and had contracted it from her husband while the other two doctors said she did not. Then one of our distinguished lawyers, a congressman, filed a suit for the young lady, a petition was drawn up, I got into it, called the lawyer up, and he came in right away. I knew the congressman did not like me, but I went to work and got the petition withdrawn. If we could not have bluffed the fellow, we would never have done it in the world. The county secretary is the best friend I have. I saved his scalp. There were

two other doctors in this case, who made their diagnosis, but we all got together and there was no further trouble.

P. D. Gillim, Owensboro: I am not the secretary of the Daviess County Medical Society. We have a gentleman whom we have elected for life. I never expect to hold that office, consequently I am not conversant with the duties of the secretary.

I certainly have appreciated the discussion here on this paper. I consider the remarks made by the Campbell-Kenton man very pertinent. I feel like advising that if you have a good secretary, keep him. He is the most valuable asset the county society has.

A. T. McCormack, Bowling Green: This has been a very interesting discussion. It has been given from almost as many different viewpoints and as many different sorts of county societies as there have been speakers on the floor this evening.

Having been present in most of the societies in the State and knowing their innermost workings, as I have had the opportunity of doing through your kindness, it has been interesting to see the progress upward from the societies where they are still struggling with the primary difficulties of getting a few men together or of getting some man to read a paper. May we not look forward to the time, represented by such societies as Dr. Anderson's or Dr. Wells', when the thing that is to be considered will be how to get the best man to present the best paper to the society, thus giving the society increased knowledge and power, because that is the ultimate aim of the organization. If every society in the state were doing the work the societies that have been mentioned are doing, then we would be ready to begin to march forward to the goal we are after. Until then, in many of the counties we cannot do that. It seems to me that almost every speaker has told a part of the truth, and that the whole truth as to the value of the councilor, is contained in the epitome of all that has been said. Dr. Stewart has almost described the ideal councilor when he told us simply the plain truth about W. W. Richmond. He has been a model in all the capacities in which he has served his county, district, and State organization. He has been a model for us all to look up to and to follow, and Dr. Stewart's tribute to him has been but a plain statement of fact. To hear his discussion of the things that are going on in the first district is a revelation to any medical organization. There is no doctor in the first district who is wrestling with a problem, financial, professional, social, or otherwise, that Dr. Richmond is not acquainted with—with whom he is not fully acquainted in the spirit that he is trying to help that man to solve his problem, helping him to do the best things he can do. I do not think he ever got an

invitation to go anywhere, because he was always already on the way. (Laughter). If they needed him, he was there. He has devoted a large amount of time and money and great effort to the work of organization that we can only speak of because he is not here to-night. He is our model.

When we stop to consider what has been done by the councilors in the initial organization of the association we, gentlemen, can look back to the very beginning when as councilors they went about their counties to organize them and to get the first start. Dr. Wells had no conception, and no man in this State had any conception of what would be the result when he made his first visit to and report about Newport and Covington. It was not simply because Dr. Wells went there, these men have accomplished results which have made them one of the model county medical societies. It was because Dr. Wells was able to find and inspire the kind of young men ready to take hold of this work and do it.

At the beginning, the first thing the councilor has to do is to tactfully and forcefully use his judgment in selecting the men of that county who are competent to act as county secretaries or who have the germ of secretaryship in them. In Dr. Anderson's county society, the secretary is only a cog in the wheel of the perfect machinery of that body. To the society just starting, the secretary is absolutely essential, he is the foundation, because it is on the proper building up of the block that the success of the organization depends.

Someone wrote to Dr. Redmen that they could not come to his county society whenever they wanted to on a general invitation because the roads might be bad. Dr. Redmen never thought of such an objection as that. There are no bad roads in Fayette county. They can go anytime. The road from Winchester is always open.

The problem presented to the different counties by the different professions is an individual one. I always think of a little cousin of mine who studied German. He came home one night and father asked him a question in German. He looked at him in perfect astonishment. He had learned to read German very well; he could parse in German, according to the German grammar, but it never occurred to the teacher to teach him to speak German. Like the family Bible, he thought it was only used as a matter of worship and was something to be taken out on Sunday and looked at. The same thing applies to the conduct of a medical society, to its secretary or councilor or anybody else. Each one has an individual problem. When you go from society to society over the State of Kentucky and see the wonderful work that has been done and is being done, you are astonished. If you were to go to the Bell County Medical Society, or to the Knox County Medical Society, you would see

those men coming together from their mountain homes, bringing a whole bunch of clinical cases to the meeting, many of them cases of pellagra, that would make a professor of skin diseases or nervous diseases in our best colleges envious. He would give his right arm to get such a clinic before the American Medical Association and exhibit the cases. To see them bring together a lot of clinical cases showing the results of infection with intestinal parasites, as I have frequently seen them do, would be worth while to every member of the medical profession of the State. To give you an example of the possibility of what sanitation has done, all you have to do is to visit the mines at Cary. What has been done there has not been accomplished in the United States except in the Panama Canal Zone, or in Havana. To see preventive medicine applied in a country so rough and so rugged is a revelation. In hygienic matters you see remarkable improvements. You see the A B C of sanitation through the activities of that county association. They have determined to devote a month each year for five successive years to teaching the people in their mountain homes, hitherto considered a hopeless section, you may say, sanitation, hygiene, and preventive medicine. The same sort of thing is being done in Christian county. It is being done in Ballard county in the same way. Scattered all over the State these things are being grasped by the doctors and by the people who are anxious and willing to do the work. The attorneys are looking out for better methods of putting better ordinances on the statute books looking to better health regulations and better everything which leads to better health and longer life in the State of Kentucky. This is all due to the work you are doing in building up your county organizations. When you stop to think of it and look over the list of councilors, you will find they are men who have left their offices to visit their counties with a view to bringing about organization, and there is not one of them who does not stand out in bold relief as a splendid representative of this great profession. They stand amongst us and before our people in a way that will compare most favorably with the judges of our Court of Appeals. They are men willing to make the sacrifices necessary to do our work. (Applause).

As to the County Secretary, when you organize a county society at the beginning or organize a church, it dies if you do not have a live preacher, and if that preacher is called away to fill a better place, the church dies. We have dead churches all over the State. The county organization, like the church, must have a leader. When it develops, like it has in many counties where they are all leaders, so much the better. When the county

societies are developed by such men as take part in the proceedings of our House of Delegates and of our State Association, the problems of the county societies are solved, and all they have got to do is to measure the harvest, and that harvest is health and life. (Loud applause.)

Cyrus Graham, Henderson, (Closing the discussion): It was not my idea at all in answering Dr. McCormack's invitation to contribute a paper on this subject to stir up things. I do not like to get into a discussion, but gentlemen I have been secretary of my county society, president of the county society, and censor of the county society, and have held half a dozen other offices, and have been the whole cheese several times. In fact, I was secretary of my county society and had to get out of the State to get rid of it. (Laughter). If you would learn the problems of a medical society be its secretary. He is the man behind the throne. He is the powder in the gun, and every encouragement you can give him is just that much powder and that much force to act upon. It requires vital energy to be a good secretary. You must have a willing smile and a glad hand. You must keep in a good humor. If there is any disagreement between two members you must try and bring them together and settle it. You have got to learn the different idiosyncrasies of men, and the secretary of a medical society is in a position to learn these idiosyncrasies.

Dr. Wells made a very important point. I tried that when I was elected councilor. I sat down and took Polk's Medical Directory and got the names and addresses of every doctor, osteopath, etc., and I wrote them each a letter and asked them to answer. I tried to get an answer from every physician in the second district who is in active practice, and even those who never expected to practice. (Laughter). I went after those who were in active practice. I secured the names of every doctor in the district, and of every physician who was a member of the Association and gradually through the aid of the different county secretaries culled out the names of those who did not need any pushing, from those who were delinquent, and then with the assistance of the secretaries I have been trying to bring those delinquents into the fold. Dr. Sisk has informed me what a time he has had as secretary of his county. He has stated facts. It is hard to keep up an organization in Hopkins county. Notwithstanding this, some of the best association men we have are in Hopkins county. In counties like Henderson and Warren it is easy to keep up an organization, but in those counties that have never been well organized it takes a man of parts to make good as a secretary. What we want is association men. What we must do is to impress the laity with the fact that the men who do not attend the medical meetings—who are not members of their county medical society, are

not the men for them to employ. That the physicians who are members of their county societies are the men who will give them the best service, for they are the men who are studying new methods, new ideas and are trying to apply those ideas in a scientific manner. These are the men who when pestilence stalketh in the night are ready for the emergency. If we can impress this fact upon our people, we will have accomplished something.

Dr. Stewart, of Paducah, spoke of Dr. Richmond. Gentlemen: Dr. Richmond is a model councilor. He is the white chief, the kingly Arthur, and the like of him will not come again. Councilors are not made, they are born. He is not only a councilor, but a counselor. He is always ready to give the glad hand, and he makes you feel that the cheer from his warm heart goes with every hand-clasp. I wish there were more like him. He sets the pace, not only for all of the councilors; but for every doctor in the State of Kentucky. (Applause).

The Chairman: The discussions on this excellent paper have been very beneficial, but we have something more in store for us, and I will call upon Dr. Rutherford to come forward and read his paper.

B. S. Rutherford, Bowling Green, read a paper entitled "The County Society a Necessity."

THE NECESSITY OF COUNTY MEDICAL SOCIETIES.*

By B. S. RUTHERFORD, Bowling Green.

In this age of progress there is not a profession, business or trade that can achieve its greatest attainment without organization and co-operation.

The political government of our country is but an organization of cooperative forces, divided into different departments, each and all of which are absolutely essential to the success of the whole.

We have our county governments, our state governments, and our national government, all of which are indispensable links in the great chain of government affairs. The different trade unions that are scattered all over our country are but cooperative organizations, the purpose of which is to protect individuals against corporate greed and advance them in the skillful performance of their duties.

We have in the medical profession as cooperative organizations the County Medical Societies, the Tri-County Medical Societies, the State Societies, Tri-State Societies and societies in which several states are leagued and the great American Medical Association, all of which are important links in the great chain of organized and cooperative medicine.

*Read before the Meeting of County Secretaries at Bowling Green, September, 1913.

And in my opinion the most important of which are the county societies.

There are but a small proportion of the physicians in the United States who are not within reach of a county society. There is not a physician who attends these meetings regularly who is not a better practitioner and occupies a higher plane in estimate of the profession and laymen than he would if he had not attended them.

The beneficent influence of County Medical Societies reaches more physicians, perhaps, than all other medical societies combined. The county societies bring in close touch neighboring physicians and give them an opportunity to become better acquainted with each other and as we become better acquainted with each other we realize that we are not rivals or competitors but co-workers in a great cause and need each other's help and influence.

To illustrate the good that is being accomplished by county medical societies I will say a few words in regard to our own Warren County Medical Society. We never fail to have a meeting once each month. The physicians from the county will come from fifteen to twenty miles to attend. We listen to well prepared papers which are discussed by the members who have read up on the different subjects and prepared themselves to do so to the best advantage. As a consequence our society has become a source of education and instruction which we regard as of inestimable value.

Besides this our county society has fostered a spirit of congeniality and fellowship which universally prevails among our physicians.

I do not suppose there are two physicians in the county who could not meet on the best of terms and extend to each other the right hand of fellowship. I do not suppose there is a physician in the county who would not rally to the support of any other physician who might be imposed upon by an unjust malpractice suit, or any other unjust imposition. To illustrate, I will relate a conversation that I had several months ago with an attorney of our city. He asked me the question, why it is that physicians were so loyal to each other, stating, that such was not the case in the legal profession. He said he recently had a client to solicit his services in a malpractice suit against a physician of Warren county. That he did not know how the physicians found it out, but before night as many as a half dozen doctors had seen him in regard to the matter. That they gave him to understand that every doctor in the county would be arrayed against him in the case, besides by prosecuting so unjust a claim he would incur their undying enmity. To my own knowledge this same man went to several attorneys of our city for

the purpose of bringing suit, but the physicians were on his trail and as a consequence the suit was never brought.

Time and again we have thwarted the plans of the "shlyster" who exists everywhere and who would unjustly take all the life time earnings of a brother practitioner.

It is seldom, indeed, that one of these cases go to trial, and in the two or three instances in the history of the medical profession in Warren County in which they have, there has never been a verdict for damages rendered against a physician.

In my opinion the county societies are sentries from which originates either directly or indirectly practically all organization and cooperation pertaining to medicine.

Without the stimulating influence of the county societies we would not have any Tri-County societies or State societies or societies in which several counties or states are leagued as we have them to-day.

To be eligible to membership to the American Medical Association one must be a member of the county society and also a member of the state society. So without the county societies it is highly probable we would not have a national organization. So you can readily see they are truly a necessity as is expressed in the title of this paper.

I reiterate the fact that county societies are the centers from which originate the influence that is responsible either directly or indirectly for practically all organization and cooperation pertaining to medicine. To realize its importance, lets take a retrospective view and see what has been accomplished by these influences.

By organization infantile mortality has been greatly reduced within the past few years. Longevity to the human race has been extended about seven years. It has banished from our shores for more than forty years Asiatic cholera that once raged with such fearful mortality on the American continent that three millions of lives were lost in the republic of Mexico during the period of one year. It has entered the death region of the Panama Canal country where an individual could not sojourn but a few weeks without almost certain death, and made of it a health resort equal to almost any part of our country.

It has put under our control yellow fever that at times almost depopulated our southern cities and sent people panic stricken from their homes seeking places of safety.

It has robbed smallpox of its terror and in many other respects has accomplished that which has redounded to the good of suffering humanity.

In considering all this I think we should be very proud of our profession and proud of

any influence or organization that has been instrumental in the uplift, especially the county society, which has done so much with their educating and organizing influences.

In conclusion allow me to urge the members of this profession not to fail to attend their County Medical Societies. Do not fail to avail yourselves of the opportunities they afford to make you a better practitioner and a better man. You can well afford to lose the time for the benefit you derive. You need the recreation, one day off each month from business is not too much, especially when spent in this way. Remember you do not even have Sunday as a day of rest, in the discharge of your duties, which sometimes become irksome because of continued demands upon your service which entails a loss of much needed rest, remember that you are perpetuating a work engaged in by the Divine Master while on earth, and be consoled by the thought expressed in His own language that "he who administers unto the least of these little ones administers also unto me."

The Chairman: This excellent paper is now open for discussion. All of us see the necessity of county societies, and I hope some of you will see fit to discuss this very excellent paper.

As there was no discussion on Dr. Rutherford's paper, the nomination and election of officers were proceeded with, with the following result: Chairman, A. C. L. Percefull, Louisville; Vice-Chairman, J. F. Young, Monticello; Second Vice-Chairman, A. O. Sisk, Earlington; Secretary-Treasurer, Lillian H. South, Bowling Green.

OSTEOMYELITIS.*

By A. W. DAVIS, Morton's Gap.

The subject of osteomyelitis is one of great interest to me and has been one of considerable study and worry, especially one case in my early practice, when I was trying to make a mark for myself.

According to Nichols infectious osteomyelitis is an acute suppurative inflammation of the bone and is always due to infection of the bone marrow by pyogenic microorganisms.

Quite a few physicians think of osteomyelitis as a definite disease with always the same clinical symptoms, of local pain, high fever, systemic infection, etc., is not true by any means. Osteomyelitis is a common disease both in its acute and chronic form, the clinical picture is often obscure, and a mistaken diagnosis is not often infrequent. It is subject to which not only the general practitioner, but the surgeon should give more attention. On its proper recognition and prompt treat-

ment depends in many cases not only the life of the patient but in every instance the future function of the limb. Osteomyelitis is essentially a disease of the shafts of the bones, very seldom affecting the joint surfaces, but, as I will illustrate to you in one case in my series, it may be mistaken for a joint lesion on account of the close proximity.

Case I.—A. B., boy of 9, who gives a history of having previously been exceptionally well, not having had any of the diseases of childhood, was brought to my office on August 8th, 1908, suffering with pain on the inner side of left knee, no swelling or fever, I questioned his father closely in regard to an injury he might have had previously, but he could not remember that he had any, notwithstanding this I could not help but believe he had had one or rather had strained the joint, as he was a son of a sawyer and was constantly running and playing over the logs at the mill. I prescribed hot fomentations and gave the salicylates, but in about a week they called again, the father stating the pain had become more severe, boy was unable to rest at all, at this time there was a slight swelling in the middle third of thigh but no pain on pressure, pain was still referred to the knee. I told them to still keep up the same treatment. On August 24th, I was called to see him, the father stating that the boy's leg was swollen so badly, and as there was so much pain, he could not bring him to me. On reaching the home the parents said that about two days previous to my visit the boy got out of the house and started to the mill, about 100 yards away, after having gone about 50 yards he stepped into an ox-track and fell, his brother having noticed him at this time, the boy tried to get up but failed, they carried him to the house, the boy stated he heard something pop. On examination I found the whole thigh very badly swollen, considerable pain on pressure, very little redness, and peculiar to state no fever. The symptoms were so vague I was really up a tree, so to speak, but I could really see nothing but osteomyelitis. I stated to the parents that I would have to operate to remove, possibly, dead bone and drain, so two days afterward I went prepared, thanks to something or somebody, to amputate if necessary. I made a broad incision on the outer side of the thigh, there exuded a dark jelly-like substance. I introduced my index finger into incision, and I could sweep it around completely coming in contact only with needle like particles of bone floating loose. On removal of my finger there was a sudden gush of blood showing conclusively that the femoral had ruptured. I immediately had my assistant, Dr. W. B. Bailey, place an Esmarch around thigh very close to hip, which stopped the flow. I then informed the parents that

*Read before the Hopkins County Medical Society

the only chance for the child was amputation. With their consent I amputated three inches below the hip joint, removed all seemingly dead bone, cleaned out medullary canal completely, stitched up without tension and drained. Healing was perfect. He went along nicely until October 3rd, when he returned to me with stump enlarged to the size of a football, bluish red in color, there was no softening or fluctuation but I went into it with a knife anyway and only got a lot of blood. The boy died on October 12th of broncho-pneumonia. What has been peculiar to me in this case was: no chill, fever, pain only on inner side of knee, bone as rotten as wood for 4 inches in extent and overgrowth of stump afterwards. Looked very much like carcinoma.

ETIOLOGY

As stated by Mallory in discussing the etiology of osteomyelitis we can describe no single cause. Trauma, a neighboring or even distant infection of the soft parts, or some general debilitating or infectious disease produces a local resistance, perhaps a true area of necrosis, and offers the opportunities for the invasion of micro-organisms by means of the blood current. Bones undergoing development seem most prone to infection, and therefore the disease most common in early life, until the adolescent period is passed.

PATHOLOGY.

As there is so much that can be written about the pathology, I will not attempt to try to go into all of it but will give you the words of Goldthwait-Painter & Osgood, in their work on the disease of the bones and joints. The bone marrow is the primary seat of infection, the process usually starting near the epiphysis, but in the diaphysis of the long bones. The multiplication of the organisms produces a soluble toxin, which cause a necrosis of the adjacent marrow cells. The loose structure of the marrow may allow marked extension of the process before frank suppuration occurs, the dense cortex resisting invasion. Solution of the soft tissue of the marrow takes place, the trabeculae may break down, and cavities form in the spongy bone. In the early stages no macroscopic changes may be seen, but usually section is made so late that yellowish, greenish, or hemorrhagic pus, exudes. The irregular arrangement of the alveolar spaces and bony trabeculae with this irregular formation of necrotic areas gives a mottled appearance to the bone on section. Fairly early extension to the cortical bone takes place through the Haversian canals and an inflammatory exudate forms between the bone and periosteum, which is often stripped up for a considerable extent.

A subperiosteal abscess is thus formed. This abscess may break through all the barriers and discharge through the skin, though not rarely fatal toxemia and septicemia ensue before this takes place. Spontaneous fracture or joint suppuration sometimes occurs when the epiphyseal line breaks down. Beneath the stripped up periosteum there is necrosis of at least the superficial layer of the cortex, while if the inflammation destroys the endosteum the viability of the internal layer and the trabeculae may be lost. Sequestra are found where these necrotic areas lie one above the other. An involucrum is formed by the proliferation of the separated periosteum about the necrotic area. A shell of bone is thus built up about the necrotic sequestrum. The destructive process, as has been stated, is irregular in its extension and the repair process is therefore irregular, the granulation tissue and endosteal bone being distributed irregularly. Thus the diseased areas may be encapsulated by fibrous or bony formation and be shut off from the sound portion of the shaft. The regeneration of the cortical bone depends entirely upon the endosteum and periosteum, the bone having apparently little power of repair in itself. If, therefore, both endosteum and periosteum have been destroyed the dense, necrotic, sequestrum must be either spontaneously discharged or removed by operation, leaving a cavity which cannot be expected to close of itself. At times the entire necrotic shaft may be thus encapsulated in an ivory like case of newly formed bone, perforated in many places for the discharge of pus. I will not consider the various types only to classify: We have the acute circumscribed, chronic circumscribed, acute diffuse, the one we most often see, typhoidal, tuberculous, syphilitic, and spinal.

DIAGNOSIS.

Considering the diversity of types, it is obvious that the diagnosis of the condition must be based on the symptom complex, which varies greatly. I will give the acute suppurative or infective only, quoting Eisendrath, the ordinary infective osteomyelitis may arise (1) as complication of a compound fracture, of amputations (from the stump of which I removed a piece of necrotic bone yesterday), or operations on bones; (2) it may follow a slight trauma or exposure to cold and wet; (3) develop in the course of an infectious disease like pneumonia, typhoid, scarlatina, variola, etc. The clinical history is as follows: Disease begins suddenly with severe pain and tenderness over the affected bone, usually of the shaft. A chill often ushers in the disease followed by high fever. The temperature curve resembles greatly that of a typhoid,

being of a continuous type. The limb soon becomes swollen, tender and indurated. The skin glistens, is red, and feels hot. There is rigidity of the adjacent joints. If no surgical relief is given one of two conditions results; (1) a septicemia develops with high fever of a continuous type, rapid pulse, dry coated tongue, delirium, sweats, and diarrhoea. (2) In less severe cases the pus perforates the cortical portion of the shaft and periosteum, and appears beneath the skin as an abscess with distinct fluctuation. The patient may present himself with a sinus leading to necrotic bone, as I have seen in three cases, and give a history of such an acute onset as just described. If the medulla has not been sufficiently drained, the septic symptoms may persist. The fever shows a distinct rise in the evening with morning remissions. The part remains brawny and swollen and considerable pus continues to be discharged from the wound of operation or sinus. Chronic cases may result from the acute. If possible the X-ray should be used as it is the most accurate method of diagnosis except in early cases.

TREATMENT.

According to Ochnerin all cases of osteomyelitis the primary operation should consist in an incision extending some distance beyond each end of the infection in the bone and must penetrate all the tissues down to the bone, including the periosteum. The drainage can still be further improved by the application of a large moist antiseptic dressing, and of course complete rest. A saturated solution of boric acid, or acetate of aluminum, or thirty per cent. solution alcohol in hot water are most useful fluids for the purpose. The entire parts should be enveloped in the dressing and covered with an impervious substance like oiled silk or gutta serena tissue. Fresh solutions should be added from 3 to 6 times daily. The dressing itself need not be removed more than once every two to four days. The pain subsides almost instantly and within a few weeks the incision usually heals, with the exception of a circumscribed point in case the bone does not entirely recuperate. In the chronic cases, we should establish drainage with removal of sequestra, otherwise treatment should be as for the acute form, with a longer period for drainage. In the more severe cases, which do not progress favorably under drainage alone, total extirpation of the infected marrow is advised. The reparative power in the marrow is great, and if the entire shaft is opened and the medullary canal cleaned, no bad results need be expected if care is taken not to injure the endosteum, by curretting. Great care must be taken to preserve the periosteum intact since

only from this or the endosteum can new bone be produced.

I will call your attention to the following cases; C. H., age 26, night watchman. Was mistaken for a prowler by a fellow watchman and was shot with a Winchester pump shot gun loaded with buck shot in the middle third of the left thigh in front, the shot having penetrated a 3-4 inch oak piling before striking him, which only made a superficial bruise of the skin and muscle, he did not quit work from it. In about three weeks he developed typhoid fever and run the regular course of 23 days, never being very sick, his temperature was normal for 8 days when he had a chill, severe pain in the leg at the point where he was shot, swelling, redness. This kept up for ten days, when consultation was had, we went into the leg and found pus, blood and necrotic bone, in removing the sequestrum, the femoral was ruptured, there was absolutely no force used either, things were in a very rotten condition. I tied the vein, artery, nerve and all the sound muscular tissue I thought would hold en masse, and to my surprise, the man went along beautifully, not a spot of gangrene showed up anywhere, and the man is to-day a healthy house painter. Can climb a ladder as well as anyone.

M. P., age 44, had a right lower molar tooth filled some five weeks previous to my seeing him, he stated that the tooth had never ceased paining him since it was filled, swelling in the jaw commenced on the second day. When I saw him he was in a horrible condition, mouth about half open pus and blood running out in stream, awful foul odor. On examination I could feel that seemingly the entire jaw was rotten. I made an incision over the sequestrum and removed the entire body subperiostially, I did this without an anesthetic as he had a time to get a breath. There is no deformity and he can masticate his food to-day as well as he ever could, four years after operation.

I will not take your time to cite other cases, which were along similar lines as the ones already mentioned. I have had four of the lower jaw, four of the femur and two of the tibia.

Vincent's Angina.—Treatment.—In mild cases, best results from use of trichloroacetic acid. Membrane first removed by hydrogen peroxide and wiping with cotton swab; ulcer then anesthetized with 10 per cent. cocaine solution, and trichloroacetic acid applied a few minutes after. Usually 3 or 4 applications at 2 or three day intervals necessary. Tincture of iodine preferably where ulceration extensive. For pain, orthoform. Carious teeth to be cared for. General condition also to be improved.—Halstead.

EARLY DIAGNOSIS OF TUBERCULOSIS.*

By T. C. NICHOLS, Morgan.

The early diagnosis of phthisis rests largely on the history, the symptoms, especially the gastric disturbance, evening fever, and accelerated pulse, and the physical signs. The presence of the tubercle bacillus in the sputum is conclusive evidence of the disease. In all suspected cases the chest and the expectoration should be carefully examined. The onset of the disease is very insidious and is attended by dyspnoea, anorexia, dyspepsia, epigastric distress after meals, pallor, anemia and weakness. Later there develops a slight dry, hacking cough, referred to the throat or stomach and occurring usually in the morning with scanty glassy expectoration. Physical signs, inspection during the early stage shows slight depressions in the supraclavicular, and at times in the infraclavicular regions. Palpation serves to detect increased vocal fremitus over either or both apices, and imperfect expansion. Percussion yields a slightly impaired note in the early stage at either or both apices. Auscultation reveals, in the early stage, jerky inspiration with crackling rales at the apex and prolonged, high-pitched expiration. The microscopic examination of the sputum blood corpuscles and alveolar cells are present in the sputum and may be detected by the aid of the microscope with or without staining. Elastic fibers in the sputum are of great importance, as their presence signifies destruction of tissue somewhere in the respiratory tract. To examine the sputum for tubercle bacilli a small caseous particle should be selected and spread out in a very thin layer on a cover-glass or slide. It is allowed to dry in the air or by passing it through the flame of a Bunsen burner, smeared side up, three times. Ziehl's carbolfuchsin fuchsin 1; alcohol 10; 5 per cent. aqueous solution of phenol 90; is then poured generously over the entire specimen, which should then be held a short distance above the flame for a few seconds until steam is formed. The slide or cover-glass should then be thoroughly washing in running water to remove the excess of the stain. Gabbel's solution of methylene blue 2; sulphuric acid 25, and water 75, is then employed to counterstain the preparation for which a period of about 30 seconds is required. The excess of this stain is also removed by running water after which the specimen is dried and mounted in Canada balsam, the tubercle bacilli show as red rod on a blue background. Other recent diagnostic tests consist in the administration of tuberculin, the Chahette ophthalmic reaction, and the agglutination and serum tests.

*Read before the Pendleton County Medical Society.

PRESIDENT'S ADDRESS.*

By R. M. RANKIN, Covington.

I suppose it is incumbent upon the incoming presiding officer of this society, on this occasion, to present to you a forecast of the work we are to undertake.

The work done by this organization, during its past existence, has been commendable and recognized by friends, and the profession throughout our own State certainly, and perhaps in greater measure in other states than is possible for us to fully estimate at this time.

Next fall our society is to be the host of the State Society at its regular annual meeting, and in order to sustain our reputation for work accomplished, we should begin at once to plan, and engage to perform a greater, a better and a broader work.

To labor unselfishly for another is the best work in the broadest sense. The best work that this society can hope to engage in is work done for afflicted humanity, and by afflicted we mean not disease per se only, but sociological conditions, customs, and practices which in larger part produce disease. Work then is the means to the accomplishment of the task before us, and team work is the kind of work that produces results. Team work in this society amounts to just what it does in big business, or big undertakings of whatever character. It means, conception and performance; conception of the things to be done, and performance, doing of it. It means that we must do the thing for the sake of the society with the same energy, zeal and concern as if it were our own personal affair.

Our programme indicates what is expected along scientific lines. We have omitted the post-graduate course and for the present will have bi-monthly regular meetings. There will be two papers and two persons to open the discussion of each paper at each meeting. It was the idea of the programme committee to have the essayist furnish the discussers with a synopsis of his paper, that the latter may better study and discuss it.

The names of the discussers will appear in the printed programme, and their obligation to bring up their work will be considered equal to that of the essayist. Efficiency on their part will be considered just as important as that of the author of the paper. We feel quite sure that discussion conducted in this manner will be an improvement over what it has been, and that this will still further stimulate and improve the character of the general discussion. Any failure on the part of those taking part in the program will

* Delivered before the Campbell-Kenton County Medical Society.

be lamented when it is unavoidable, and the attention of the society called to it when it becomes a matter of negligence or indifference. It is to be hoped, however, that not a single member will fail to give the necessary time and use his best talents toward the fulfillment of his part.

I would suggest that the election of officers be held on the last meeting night in October in order to give more time to the program committee in which to arrange for the better convenience of the January and February essayists.

In connection with the scientific work, it might be well to state that the society has been proffered a meeting place at St. Elizabeth Hospital, which offer, if accepted, will no doubt be of very great advantage, both to the hospital and the society, the latter especially, inasmuch as clinical material, not otherwise at hand and available, may be procured. This feature, if consummated, should lend much interest and enthusiasm.

The reporters for the daily papers have promised to publish for us any item or items that we may request. Our State JOURNAL continually clamors for the news. These two avenues offer efficient means for the effulgence of the heretofore flickering and hidden light of our society. We owe it to the State JOURNAL to have some sort of report made to it of our meetings, we also owe it to the 125,000 inhabitants represented in this society by their family physicians, to have it published persistently that they may know we are not only working for their interest, but how we are doing it. I say persistently, because the public is slow to absorb knowledge of this character, and just as slow in acting upon it after absorption has taken place.

The parasitic patent medicine propagator is aware of this fact, and also is aware of the fact that the public is quick to forget, and so he practices the art of persistence in flaunting his wares before his misguided and self-advised customers.

It seems to me the time is coming, if it has not already arrived, when medical societies ought to become leaders in certain questions pertaining to the welfare of the citizens, and to this end I would suggest that the society appoint standing committees for civic purposes. Let us extend the interest of medical science from the consideration of individual cases to the solution of broader communal problems. Modern medicine is developing along these lines, and the attitude of the laity's mind and purse is favorable to it; indeed the work of the latter challenges that of the former for the honor of affording the greatest stimuli toward preventative medicine.

Working together, I believe it possible among other things, to have all food stuffs offered for sale in the cities of the two counties, either from stall, store or wagon, to be effectually protected from flies and dirt. If the Campbell-Kenton Medical Society would announce through the press that it meant to have this done, and if necessary it would enlist the aid of all house-keepers and have them refuse absolutely to patronize any vender who failed to effectually protect his wares, I believe it would be done, at least they would keep out dogs and cats. Since the crusade against dairies and their milk product in Kenton County five or six years ago, the decrease in the diarrhoeal diseases has been at least one-third. Physicians who have been in harness sufficiently long will verify this statement.

As a result of the vital statistics law passed by a recent legislature, the people are very much better informed as to preventable diseases and many other things pertaining to their physical welfare than ever before. Within the last fortnight I glanced at the records of death in the health department. There has been much improvement in the keeping of records, and any one who may learn for himself that there is plenty of room for still further improvement. Statisticians are indispensable to education and are doing more toward enlightenment of the world than any one calling.

We ought to render it possible for statistics to be obtained with more facility and accuracy.

I do not believe we will have done our full duty as an organization within the next year until the streets, alleys, back yards, stables, vacant lots, etc., have been inspected and all sources for the breeding places of flies have been reported to us and measures adopted looking toward the best possible riddance of same.

The medical inspector of schools has about 1200 pupils in charge, a number too great to be handled thoroughly. The health department too, for financial and other reasons is inefficient, over-burdened. Too much germ-laden dust is blown from dirty streets into our homes and breathed into our lungs.

I am unable now to outline in detail anything along these lines of preventive medicine, but express briefly the hope that if it meet the approval of the members, committees will be appointed to take up the work and prosecute it successfully.

"We must have our people learn that it is defiance to the laws of hygiene, that brings on sickness and disease. We ourselves, must learn that it is not sufficient for us to teach them the laws of obedience, right living and

well being, but we must force practice of these upon them."

I believe it possible for us to force the practice upon them by tact and persuasion as the health authorities of Fayette County, Ky., did to their dairymen. Once a month the latter see published in the daily papers the average number of bacteria in the milk from each one's dairy. Publicity forces them to obedience and proper practice in order to compete with his fellow for the sale of his products. Publicity of facts is what we need. Let us say that Mr. Dutiful Man at number 1914 Vital Street conducts a grocery and daily market, his goods are protected from flies, are clean, and his prices are right.

A more important fact for us to publish, however, is that the flies are born and reared in a manure pile in the rear of a stable at 1914 Mors Street. Let the committee on sanitation ascertain the location of every breeding place, whether in alley, back yard, stable or open lot, furnish us with the facts that we may through the press, acquaint the public and authorities with the same, and our victory will be half won.

In the name of our society, in the name of our State Society, and for the glory and benefit of humanity, let us up and at it. Having accomplished our purpose, we will doubtless have put our sister cities upon the map, and me thinks I can see, marking our meeting place, inscribed upon an unfurled banner, the plaudit, "Well done, thou good and faithful servant."

PYAEMIA.*

By J. E. L. HARBOLD, La Grange.

The subject allotted to me has been named sepsis. But I prefer the old name pyaemia. This tells you what to expect. While sepsis is divided into three heads, and defined thus: Poisoning by the products of putrefaction, and divided thus: *sepsis intestinalis*, *puerperal sepsis*, and *pyogenic sepsis*.

The first is caused by eating decayed canned meat, sausage, etc. The second the absorption into the circulation of putrefactive matter after childbirth, and the third pyogenic sepsis from the absorption of pus into the circulation causing abscesses in different parts of the body or in the bones.

When I began the study of medicine, when a person had a number of abscesses at the same time he was said to have pyaemia, and as such septic poison was described, and pyaemia meant blood poisoning. The word is derived from pyogenic which means producing pus. Now I do not mean to say the word sepsis was not known at that time for it was

known but not used as it is now. I doubt if the present way of speaking of sepsis is an improvement on the old.

Eriksen who was an authority in those days says: "pyemia" and not sepsis when writing his chapter on blood poisoning and speaks thus:

"The third condition which is present in many cases of pyaemia, and which is probably the active cause of many of the symptoms, is that of blood poisoning.

"Ichoraemia or septicaemia due to the absorption of ichorous or putrid matter and its entrance into the circulation."

In this paper I shall speak of sepsis as formerly called, pyaemia.

During the process of inflammation lymph or plasma is apt to be effused from the blood in the part which has partial death, and this lymph provided the vital forces below, or the treatment inefficient very liable to become pus: living matter of the very lowest organization, which, if by accident, finds its way into the blood through an abrasion, scratch or wound, is liable to give pyaemia, a contagious and infectious disease, due to the presence of the micrococci of pus. Rigors are indicative of pus growth; its progress, its volume, its rapidity, its destructive action can be appreciated, nay calculated by the intensity, frequency and violence of the chills.

The cocci of pyaemia, streptococcus pyogenes are seen occurring singly or in chain. These microbes bear culture well, and when injected into animals give rise to the disease in all of its malignancy. They also cause thrombosis and embolism.

I will relate the history of a case from my own practice that I treated soon after I began the practice of medicine. Give the treatment of this case and then give my treatment of such cases then and to-day.

Theodore H., colored, about 18 years old. Saw him first March 16th, 1877. The thumb at second joint was very much swollen, the skin was tense and glistening and had the appearance of pus in it. I lanced it but only a thin glossy fluid resembling synovial fluid escaped. His left shoulder over scapula was much swollen. I ordered poultices. Internally gave quinine and iron. He did not improve every much; the place I lanced continued to spread his thumb joint was completely disorganized. His shoulder was lanced about May 1st and continued to discharge pus in large quantities. On May 4th at my request, I took him to Dr. Holloway, who amputated him thumb, and suggested that I use a drainage tube in his shoulder. I had lanced the shoulder near the inferior angle of the scapula, and beside this opening, there was one higher up near the spine of scapula which had sloughed through. I used the drainage

*Read before the Oldham County Medical Society.

tube as requested and on the 7th the incised wound had healed so much I did not use it. On the 7th of May I removed the sutures from his hand, and found pus had formed. Locally I used carbolized oil. Internally tr. chloride of iron xxm to the dose. On May 9th I found necrosed bone in wound over the shoulder. His thumb was doing well. Began again to use drainage tube in shoulder. his temperature was 100 pulse 90. This case ran about as above until July 7th, 1877 he had paraplegia. There was an abscess at the junction of lumbar and sacrum measuring 8 1-2 inches long and 4 1-2 inches wide.

He complained of burning in this abscess and also the one at his ankle. A few days later the lumbar abscess broke and three-fourths of a cove oyster can of pus was caught. While he was unable to put his feet forward, if you moved them forward and then tickled his feet he would jerk them back. One peculiar feature about this ease is, his temperature remained so near normal. Generally he rested well at night; if he was restless then there was a rise in the temperature. About August 18th, 1877, he began to have night sweats and they were so profuse that where he lay it soaked through the mattress and wet the slats of the bed. Another thing strange about this case was the number of abscesses that were on his body and had been. First one on right thumb at same time one on left shoulder, one on occiput which remained about nine months and bursted, one in lumbar region, one large one across back from ninth rib on left side across to right scapula; one over humerus, one on left elbow, one on nates, one on right internal maleolus, one on right quadiceps extensor about middle of femur.

March 27th, 1878. There are at this time seven abscesses containing pus, and four wounds where there had been abscess which are discharging pus.

His mother said, "Whenever Theodore would hurt himself the sore was a long time healing. That on one occasion a bee stung him and it was nearly two years healing."

His knees are permanently flexed and cause pain when you attempt to straighten them. During January, 1878, his temperature began to rise and at times was 102 1-2, at other times his temperature was 96 3-4, pulse ranged from 86 to 114. He died June 23rd, 1878, having lingered one year, three months and seven days from the first time I saw him. He had paraplegia ten months. On June 23rd at 9:30, his temperature was 94 1-2. He died that day about 3:30 p. m.

One reason I did not open the abscess: Whenever a wound was made it never healed. I gave cod liver oil, and other such remedies.

To-day I would wash out these abscesses with peroxide of hydrogen. We did not have peroxide of hydrogen in those days 1877-1878. Internally in addition to the iron I would give echinacea also sp. tr of copper; also di-odiven.

DIAGNOSIS, QUARANTINE AND TREATMENT OF SCARLET FEVER.*

By R. B. CASSADY, La Grange.

When fever exists and inflamed sore throat and an eruption over the body, then the diagnosis of scarlet fever can be made. Later on we have desquamation. The most characteristic early symptom of a typical scarlet fever are intense redness of the faucial mucous membrane, sore throat, early and persistent vomiting, fever, thirst and increased pulse rate, the tongue at first may not show the characteristic strawberry appearance, but a coat with the papillae elevated. Sometimes an attack of scarlet fever is ushered in with a convulsion. Older children complain of severe headache and aching of the bones.

Von Lenks says that vomiting ushers in this disease more often than any other disease except pneumonia. "The temperature has no peculiarity about it. It may continue for some time especially if there be any serious complications, otherwise it gradually subsides by lysis towards the end of the first week.

Scarlet fever is an acute infection, specific and contagious disease. This disease presents several types, the mildest is scarlatina simplex and maligna or as Carlett classifies, I like best, simple, septic and toxic. The symptoms as has already been stated are ushered in abruptly, the rash making its appearance within twenty-four hours after the initial symptoms. It may be seen first upon the neck and chest, less often on the small of the back, it is a bright scarlet pin-point flash and occupies the sites of the hair follicles. the rash extends from above downward spreading in a few hours to the arms, usually in twenty-four hours it reaches to the trunk, legs and abdomen.

A point to note is that in contrast to measles and smallpox it is much less marked upon the face and cheeks. The dorsal surfaces of the hands and feet show the eruption, while the palmer and planter surfaces do not usually show the punctate scarlatina rash. The rash shows great variations, sometimes only a small portion of the body shows it and unless close observation is made it may not be observed at all and a faint eruption with slight sore throat with little or no fever may throw us off guard and not until some one in the family

*Read before the Oldham County Medical Society.

takes down with it never would have been diagnosed, as a case which recently came under my observation with Dr. Freeman. When it is diffuse it may be of an intense scarlet or almost purple color. Climate does not seem to affect the poison. It seems to affect America in the fall and winter, but malignant cases have been seen in mid-summer.

Eichart says it is least contagious during the period of incubation, most pronounced at the time of eruption and with the establishment of convalescence the desquamation power of contagion steadily diminishes and the average duration of the period of contagion lasts about six weeks. The greater number of cases occur between the ages of one and three years and next in frequency between 5 and 15 years, then the frequency gradually diminishes.

As to the stage of incubation, authorities differ as to the length of time between the exposure to the disease and the disappearance of symptoms. The usual rule is from a few days to a week, although exceptions will extend the time to several days longer.

The distinct specific case of scarlet fever is unknown, in spite of the immense scientific work. However, owing to the immense amount of work being done it will not be long before the factor of all infectious diseases will be discovered.

TREATMENT.

The first thing to do is to isolate and remove all healthy children and adults. The patient should be given a competent nurse. The best method is to select an upper room or two if possible, with a southern exposure. The nurse should have a cap completely covering her hair, her uniform should be boiled thoroughly after washing and soaked in 1 to 2000 solution bichloride. All secretion from the mouth should be burned and excreta disinfected and buried. The physician should protect his clothes by wearing a gown, which he removes on leaving the patient's room and he should be in the open air at least an hour before calling elsewhere. The temperature of the room should be from 68 to 72 degrees F. Fresh air must be admitted but no draught. Sunlight freely admitted unless this is painful to the eyes, which should be protected. A tepid sponge bath when temperature gets to 103, every night and morning. When the eruption causes intense itching the body should be rubbed with cold cream or carbolated vaseline. Stimulate the enunctories, keep the bowels and kidneys in good working order. A little lemonade or orangeade will be grateful and if fever is very high, aconite tincture, with spirits of nitre with syrup lemon. If pulse gets very weak 1-100 strychnia every three hours. It must be borne in

mind that children with toxaemia bear it well. Digitalis is also indicated if pulse is of low tension. Camphor and ether act well, hypodermatically.

The complications and sequelae of this disease are legion. Each will have to be treated on its own merits, the two most often met with are ear and kidney for which appropriate treatment will be instituted. There are also mixed infections sometimes of a very grave character. The gravity and sequelae of this disease make it one of our most formidable troubles to deal with.

Now as to hygiene and sanitation. These are measures or matters of education which is a slow process but I know of no other way, and there is being done some work along these lines. As to quarantine much can be done to eradicate and control this trouble. It ought to be done thoroughly if it is to be of any great value. Put up red cards with scarlet fever in large black letters, to remain for six weeks, with no one to leave the premises nor any one to enter the house, but the physician and nurse. This card ought to be front and back. In order for strict quarantine to be fully established it is almost absolutely necessary to have police protection in order to do this effectually, but out in the country this is impossible and it is very hard to do in little towns. I find the health officer handicapped, sometimes by lack of cooperation on the part of some careless doctors as well as some vicious and indisciplined, ignorant persons of the laity. I had a little experience along these lines not long since. A mother became very indignant because I prohibited her from writing letters. She said she would go to her neighbor and go into her kitchen and do anything for her without the least trepidation. So you see it is a matter largely of education.

There is much more that might be said but this will suffice this time.

DIAGNOSIS OF APPENDICITIS*

By R. B. CASSADY, La Grange.

The diagnosis of appendicitis is sometimes a very difficult matter and only opening the abdomen will reveal the true trouble within, but by careful palpation over McBurney's point, the diagnosis can generally be made out. Now, in order to make a differential diagnosis between this trouble and other troubles found in this region, is the rub. The varieties of this disease cut quite a figure. We have catarrhal, ulcerative, perforative, and gangrenous stages. The clinical are the acute and chronic recurrent cases. Infection, tumefaction and various degrees of strangulation of the appendicular blind sac appear to be

*Read before the Oldham County Medical Society.

the pathological explanation of appendicitis.

In some families there seems to be a hereditary predisposition to appendicitis. Edehols maintains that chronic appendicitis is the chief symptom and most important complication of movable right kidney. Acute pain in right lower abdomen which may radiate in various directions, pronounced tenderness in the right iliac fossa, McBurney's point; pronounced tenderness, as elicited of the appendix by palpation, nausea, vomiting, fever, accelerated pulse, diarrhoea or constipation may be present. Leucocytosis is a fairly constant symptom. Suppuration is provable by an exacerbation of previous symptoms and increase in size of the tumor or swelling located at McBurney's point, or in the lumbar region or elsewhere.

Perforation of the appendix may be indicated by severe pain, great tenderness and marked rigidity. Pronounced sepsis may be inferred from vomiting, rapid pulse and high fever.

Another diagnostic point I have found by observation that I do not find in any of the text books is made by flexing the leg upon the thigh and the thigh upon the abdomen with some force. If the appendix is involved it will cause great pain, if not a sense of relief is experienced, if it be colic or other troubles.

In renal colic and twists of the ureter the pain radiates into the groin and testicle and there is hematuria or hemoglobinuria. The urine should be examined for small calculi. In indigestion and enterocolitis we have no localized tenderness, no rigidity, no tumor, no tenderness of the appendix on palpation. So in intestinal obstruction palpation of the appendix gives negative results. So in cholecystitis or hepatic abscess we have tenderness on pressure from below the margin of the ribs upward. No tenderness of the appendix on palpation.

Gallstone colic pain radiates to the back on the right side and the appendix is free on palpation. Salpingitis, oophoritis and ectopic gestation are recognized by bimanual palpation of the pelvic organs and the latter is denoted by menstrual irregularities.

Perinephritic abscess on the right side may arise from appendicitis but is usually a complication following an operation for appendicitis if it is independent of appendicitis. The appendix is not tender to the touch.

Tubercular peritonitis is a slow process, palpation of the appendix may be impossible. Mueus colic gives its own characteristic symptoms and the appendix is found to be free on palpation. Coxitis. In young children appendicitis has been mistaken for hip joint disease as the appendix can readily be palpated in children, the differential diagnosis is not difficult. Acute rheumatic myositis of the

rectus abdominis muscles simulates appendicitis.

Appendicitis is usually associated with right iliac tenderness. The Widal serum test will settle the diagnosis in most cases. In typhoid fever the onset is slow and roseola is generally observed. Sibert, of New York, has reported two cases of typhoid fever combined with appendicitis.

Influenza, pleurisy, pneumonia, malarial disease, herpes zoster of the twelfth intercostal nerve and other infections which frequently begin with severe gastric intestinal symptoms, cannot be mistaken for appendicitis by any one who has learned to palpate the appendix.

ACUTE POISONING.*

By J. T. DIXON, Owensboro.

When a physician receives a hurried call to attend a case of acute poisoning his responsibilities begin at once. The importance of his duties in the case can scarcely be overstated. From the very beginning he must have absolute control of every faculty and not share in the general confusion and excitement so likely to be rampant on such occasions. He must be calm and collected for the full exercise of his best judgment that he may put into quick execution his thoughts. The very life of his patient will depend upon these two essentials: good judgment and quick action. So the thing most important in a case of poisoning is for the doctor to be cool and self controlled; for his task involves an intimate knowledge of practical medicine and chemistry and in some instances where a crime may have been committed he must have the analytical mind of a Sherlock Holmes, for of all crimes where skillfully executed, that of a poisoning requires the most learning, acuteness, skill and promptitude for its detection. If death has taken place and no finished history of the case can be had it is the duty of the physician to collect what evidence there may be in sight for future reference. It may be the means of saving the honor of the dead where suicide is questioned or it may be the means of saving the reputation of the living where a crime has been suspected.

Every physician should have at his command a good working knowledge of how to treat the most commonplace cases of poisoning. This does not necessarily require an exhaustive study of the chemistry and antidotes of each and every poison singly and separately, but they may be taken in groups, classified under three separate heads, and all those under each heading with few exceptions treated with the same chemical antidote. First the

*Read before the Daviess County Medical Society.

corrosives, which would include the strong acids and alkalis; second, the specific irritants, which would include arsenic, mercury, iodine, and phosphorus; third, the neurotics, or those affecting the nervous system, which would include strychnine, belladonna, aconite, opium, and other alkaloids, this is by far the larger group.

When studying the first group, the corrosive poisons, nitric, sulphuric or muriatic acid, or the caustic potash or sodii, for an antidote we would instinctively turn to an alkali for an acid poisoning, and an acid for all alkali poisoning. Each counteracting the other ideally. So with two agents, bicarbonate of soda and vinegar, both to be found in every kitchen, we will have at hand a very good chemical antidote for this group of poisons.

The universal antidote for the second group, the specific irritants, such as mercury, arsenic, iodine, phosphorus, etc., would be dilute egg albumin, fortunately another item to be found in every kitchen. However, the best chemical antidote for iodine is starch solution, and the best chemical antidote for arsenic is hydrated oxide of iron or dialyzed iron, a remedy that cannot always be quickly had, yet in the absence of this specific remedy, iron in any form is first made alkaline by mixing with common soda solution or lime water or ammonia water, is indicated.

In the third group, the poisons affecting the nervous system, such as strychnine, belladonna, aconite, opium and other vegetable alkaloidal poisons are all fortunately subject to the influence of one chemical antidote, tannic acid. You cannot make a mistake in giving a solution of tannic acid in any form of alkaloidal or ptomain poisoning since ptomaines are alkaloidal poisons. The potency of the tannic acid solution may be augmented by the addition of iodine in some cases.

It is a fortunate fact that the antidote for many of the common poisons is most always at hand in every household. We can find vinegar for the caustic alkalis, soda for the strong acids, eggs for the specific irritants, salt for the nitrate of silver. Some form of alcohol or epsom salts for carbolic acid, and for the great group of alkaloids, strychnine, morphine, etc., if tannic acid can not be had we can use an infusion of oak bark or even a pot of strong tea. Therefore we do not have to rush to the drug store for dilute acetic acid, when vinegar will do just as well, or calcium hydrate or carbonate of magnesia when common cooking soda will act ideally, or any other preparation of pharmacy when we have most excellent antidotes in commonplace things

Of course, if everything was favorable, certain pharmaceuticals in some cases of poisoning would be preferable and very desir-

able. But we don't want to sacrifice time, we want to realize that the element of time is of paramount importance and that we must use the simple, but active remedies at hand if we would save our case.

It is the duty of the physician to be familiar with the toxic element of such substances as paris green, rat biscuit, matches, fly paper, embalming fluid, etc., that may be innocently taken by children. This knowledge will enable him to administer the proper antidote.

In most all cases of poisoning the stomach tube should be used, while the antidote is being prepared or immediately after it is given. The contents of the stomach should be syphoned away and repeated washings with a more dilute solution of the antidote should be resorted to. There is one class of poisons, however, where the introduction of the stomach tube is contraindicated, and they are the corrosive poisons, the strong acids and caustic alkalis, because of the very great destruction to the tissues by their corrosive action, and because if the antidote is promptly given the poison is completely neutralized and made inert and does no further harm.

It is the duty of physicians to study most carefully the objective symptoms that he may properly class his case and apply the correct antidote. His case may be unconscious with no possible way to get a history or any information as to the character of poison taken. In this event he must know that arsenic in poisonous doses produces violent gastro-intestinal symptoms, vomiting and purging. That carbolic acid leaves a white eschar and has a characteristic odor. That nitric acid stains tissues yellow. That belladonna produces a fixed dilated pupil, dry throat and flushed face. That opium produces a contracted pinpoint pupil, deep slow breathing, and if the poison be in the form of laudanum, a characteristic odor. In fact, he should know the lethal symptoms as well as the physiological

In all cases of poisoning where the chemical symptoms of all the most common poisons. antidote has been given and all danger of further absorption passed, the subsequent treatment of the case must be symptomatic, requiring the judicious administration of physiological antidotes and the application of the principles of general medicine. We must be careful in our anxiety not to over treat the case and give repeated hypodermics at short intervals, thereby adding a new danger to an already exhausted patient.

Erysipelas—Treatment.—Local applications of buttermilk on soft rags, latter to be kept constantly wet with it, gave uniformly favorable results.—Arnold.

THE FORUM

To the Editor:

Those inclined to censure the Illinois Board of Health for refusing reciprocity with other states should read the Chicago Daily Tribune under date of October 27th and 28th, 1913. This paper sent a perfectly healthy reported to a large number of advertising quacks, and without exception the illustrious (?) M. D.'s found the reporter with serious disease and promised a cure for a cash payment of from \$10.00 to \$50.00. The Tribune in addition to the mere petty grafting makes the following charges, "That the pocket of a patient was picked by a "doctor" while the patient was on the operation table".

"That some of the quacks are at least morally and probably legally guilty of killing patients."

"That a number of quacks have maimed patients for life by malpractice."

"That at least one of the quacks habitually attempts to seduce his women patients."

"That two of the quacks operate their business under assumed names, and, living double lives, practice swindling down town while posing as respectable doctors in outlying districts."

It seems from the disclosures made by the Tribune, that the reasonable explanation of the refusal of the Illinois Board of Health to reciprocate with other states is not that they object to the standard of efficiency or character of doctors of other states, but to protect the citizens of other states from the innumerable dishonest, disreputable and quacks infesting Chicago. Surely their purpose is a laudable one.

Another warning might be profitably sounded. It is a well-known fact that Chicago is the "wickedest city in the world;" that murder, hold-ups and other heinous crimes are committed daily with impunity. That saloons, dance halls, gambling places and other luring places of vice are run wide open, quite frequently with disastrous results to the unwary. It is true that Chicago has innumerable honest, honorable and reputable physicians, and a number of medical schools which rank as high as any in the land; still would it not be advisable for the preceptors of medical students in other states, in view of the dangers encountered in Chicago; and to the fact that Illinois refused to reciprocate with other states except to graduates of 1907 and later, which is a direct injustice to these preceptors, to advise their students to go to other medical centers when the schools are as good and dangers a great deal less than in Chicago. To mention a few, New York, Boston, Louisville, Baltimore, Nashville, Philadelphia, Cincinnati, Atlanta, have all first class medical schools in which any student can perfect himself for the practice of medicine,

and without the danger to life and his moral character to be met with in Chicago.

R. H. C. RHEA.

1332 Lunt Ave., Chicago, Ill.

IN MEMORIAM.

The subject of this sketch, Dr. V. E. Smith, was born in Pendleton County, forty-three years ago. He was an active, industrious boy, attending district school and working on the farm, then finishing in the public school. After Butler High School he finished his school days at Georgetown College, teaching school in the country for a time, and reading medicine at home at nights, on Saturdays and between the school terms. He completed his education in Medical College at Louisville, graduating in 1893. He practiced medicine steadily until the spring of 1913, when he was stricken with the disease which terminated his life.

Doctor Smith had many lovely traits of character. He was a close student, a hard worker, a fine listener and possessed a retentive memory. He had a delightful manner, easy to approach friendly, and was an excellent Christian gentleman. A man who never spoke harmfully of others. One of the most beautiful things in his life was his unusual love for his father, who is still living, I think in his eightieth year. The last time I saw him was in the presence of the infirm old gentleman and I remember how hard he tried to assist his father to a seat in the car, when he could scarcely support his own body.

No member of our society could be missed more. It will be a difficult task to fill his place. You remember how clear he made all of his points? It was delightful to hear him. His influence was of such a helpful kind when you were in his presence you felt that you were in superior company. He was an honor to our profession. He loved humanity and had the most wonderful way of showing it. He had faith in us and we have been caught up in this faith of his. He has left behind him his mantle, but who among us is worthy to wear it?

Our society feels keenly its loss. It is not true that "the good that men do is interred with their bones." There is that in the human heart that cannot forget those who deserve our love and esteem whether they be living or dead.

H. C. CLARK,
W. A. McKENNEY,
Committee.

Vomiting of Pregnancy, Pernicious.—Treatment.—Sodium bicarbonate, 5 to 50 grains (0.3 to 3 Gm.) a day, recommended. Part of it often vomited, but some retained. Continue for a week after vomiting stopped. Bowels to be well cleared by colonic flushing. Veronal also found useful.—Lyon.

TYPHOID FEVER.

Owing to the mild winter, epidemics of typhoid fever have been reported in many small towns and country districts all over Kentucky. It is important to remember that typhoid germs are found only in the bowel movement and urine of those sick with the disease and that the only way a well person can get it is to swallow some of the bowel movement or urine of some one who has the fever. If a doctor will make this plain to each person he attends so that the bowel movement and urine may be properly cared for, typhoid fever will soon be a thing of the past and it is now the most serious disease in Kentucky. As soon as the people have been taught these simple facts and a popular conscience has been aroused on the subject, it will be considered just as criminal to scatter typhoid fever germs as to now scatter strychnine or any other poison.

The bowel movement and urine of those sick with typhoid fever should be discharged into a vessel containing a thick milk made from fresh, unslaked lime or should be thrown into a fire and burned. If received into the thick white wash, they should be kept there, at least, an hour and stirred with a stick once or twice so that the lime gets an opportunity to kill every germ, and should then be thrown out on the bare ground where the sunshine gets a chance to continue the destruction of what life is left in the mass.

It is important for the profession to remember that inoculation against typhoid fever is entirely safe and relatively certain. The Laboratory at Bowling Green is now able to furnish the typhoid serum in syringes ready for administration for ninety cents for the necessary three doses for a single individual or it will furnish enough serum in individual bottles to inoculate ten persons against ty-

phoid fever for \$2.10 or twenty-one cents for each person. In this instance the physician uses his own syringe, carefully sterilizing the needle. In administering the serum, it is important to remember, and it is equally important in giving all other hypodermics, that if one will make a little spot the size of a quarter with good strong tincture of iodine, letting it dry thoroughly, and then make the injection right in the center of this, that practically all danger of local infection is avoided; provided, the needle and syringe are sterile. Within the last two years a few more than six thousand inoculations against typhoid fever have been administered in Kentucky. Nurses and physicians and their families have been pretty generally inoculated. It is important that this movement be carried further and, especially, in our unsewered towns and villages and in country districts where there are no sanitary privies, and this includes practically all of them. Everybody who has not already had typhoid fever, should be inoculated so that they will not have it.

Circulars telling how to build this sanitary privy at small cost may be obtained by dropping a postal to the State Board of Health, at Bowling Green.

HELP.

Many of our members have noticed in the newspapers that Dr. Winters, of Newcastle, Indiana, has had a little daughter stolen from him. Everybody's heart was touched by his loss but Dr. A. S. Brady, of Greenup, writes a practical suggestion that every medical society of Kentucky be invited to ask for contributions to assist in getting up a fund to find the girl. Fortunately, she was found before this call could be issued, but we want to congratulate Dr. Brady on the suggestion and say that we believe that the medical profession of Kentucky would have responded to a man

in an effort to help Dr. Winters. The reason for the success of the Kentucky medical profession in its undertakings is that it is composed of men like Dr. Brady, who have hearts as well as brains, who are actuated by great motives and who know how to do real things that are worth while.

TO OUR READERS.

Half the members of the Association have paid their dues to the county secretary. They are all right and will be in good standing for 1914. These are the last numbers of the JOURNAL that will be received by the ones who have not paid unless payment is made immediately upon receipt of this issue of the JOURNAL. As long as practically every member will pay the dues some time during the year, why not pay now and not be dropped from the roll at all. Take your own case for example: Suppose you should be sued for malpractice some time in the next week or two, of course, if you are guilty of malpractice it would make no difference to you, but just suppose it is one of these ordinary, unjust blackmailing suits brought for a contingent fee by a shyster lawyer. If you are in good standing you would be defended against this sort of suit and unless your dues were paid, you would not be. It is important to remember that of the suits so far brought in Kentucky, less than one per cent. have been brought against specialists, and a little over 99 per cent. have been brought against general practitioners. Then, too, if you are now dropped from the roll, you will miss the JOURNAL for a month or so. Each number is worth more to you than the price of a year's subscription and you are worth more to the Association. Kentucky has the best lot of doctors in the world and we want to show to other states that we are a model for promptness in the payment of our obligations as well as in the services rendered for the common good. Remember that your county secretary is paid nothing for making these collections. He is doing your work for you simply because you have elected him to and it is not fair to him to make him devote the extra time necessary to dun and re-dunning every member or even any member. Please pay your dues today.

ABOUT OUR ADVERTISERS.

A great many readers of the JOURNAL run through the advertisements carefully each issue. We wish every one of them did so. As proud as the Council is of the readers and owners of the JOURNAL—3000 of the best doctors in Kentucky and their families—it is always as proud of its list of advertisers. These

advertisers really publish the JOURNAL. It is big or little, has more or less pages; consequently, more or less good reading in proportion as the advertisers pay us for space. In the past seven years, the JOURNAL has not cost the physicians of Kentucky a dollar but has been printed and published by our advertisers. It is important to remember that these advertisers are carefully selected from an immense number of people and firms who sell things to doctors. In fact, they are so carefully selected that the Council stands ready to guarantee any subscriber to the JOURNAL against loss from any transaction in regard to anything advertised in the JOURNAL. If there is another publication, medical or lay, in this country who does this we do not know it. Under these circumstances, we trust our members will read our advertising pages even more carefully before making a purchase and write our advertisers. If they cannot furnish you with the best products at the best prices, try somebody else but give the advertisers that are helping you and your JOURNAL a chance and remember all the time that the JOURNAL is between you and any financial loss if you deal with them. The whole thing just bears out Kentucky's motto, and in every single thing we do, it is important for the physician to remember "United we stand, divided we fall."

Psychic Heart Murmurs.—Rensch is convinced that heart murmurs are sometimes the effect exclusively of emotional or psychic influences. He reports twenty-four cases of the kind observed during a recent three months; the murmurs varied from time to time, alternating with normal findings. Vaquez calls them "office-examination murmurs," souffles de consultation. Bensch emphasizes as the special features of this group of murmurs their frequency; the exclusive location of the maximal sound in the second left interspace, close to the sternum, and only during systole—he never encountered them at any other point or during diastole; the changeability of the character of the murmur, during change of position of exercise, increasing in some and declining in others; loudest during deep breathing, and encountered in the delicate and pale and also in robust individuals. These murmurs in certain cases have led to far-reaching mistakes in diagnosis and in the making out of medical certificates, and he warns all to be on their guard with such phenomena in the left interspace. He reviews in conclusion the literature on the subject, although his latest citation from American sources dates from 1889.

ORIGINAL ARTICLES

DIAGNOSIS AND MEDICAL TREATMENT OF GASTRIC AND DUODENAL ULCER.*

By CHARLES G. LUCAS, Louisville.

A review of the current medical literature for the past two or three years will show much attention to the subject of gastric and duodenal ulcer. It reminds the writer very much of the discussion concerning acute appendicitis twenty years ago and like that condition at that time there remains much to be settled both as to diagnosis and treatment of the subject now under discussion. The wonderful work of the Mayos and Moynihan has brought forward many new ideas concerning both gastric and duodenal ulcer and step by step, the same wonderful advance in the use of the Roentgen rays in the diagnosis of gastric intestinal diseases has been of moment. We all know that many cases formerly classified under the heading of "gastric neuroses" must have an anatomical base and like in the old days when many cases of appendicitis were overlooked, we can look back and see numerous cases of gastric or duodenal ulcer that have either been overlooked or mistreated.

Surgery has proven to us that duodenal ulcer, formerly supposed to be a rare disease, is not so, and the male is more liable than the female. In 1000 cases operated upon at the Mayo clinic up to January, 1911, 74 1-2 per cent. were males; 25 1-2 per cent. females. From June, 1906 to January, 1911, of 621 authentic cases of gastric and duodenal ulcers that were operated, 201 or 32 1-2 per cent. were gastric and 401 or 64 1-2 per cent. were duodenal while nineteen or 3 per cent. had one or more ulcers of both the stomach and duodenum.

Concerning the diagnosis, W. J. Mayo¹ says, "The diagnosis of gastric and duodenal ulcers is not difficult and the differential diagnosis between a gastric and duodenal ulcer can usually be established but it cannot always be done nor is it essential that it should be. The duodenum above the common duct is a part of the stomach and not a part of the small intestine. It is derived from the primitive foregut the same as the stomach; its mucous membrane is thin and granular; it has no valvulae conniventes and is entirely unlike the small intestine. Apparently it is a vestibule to the small intestinal area and its embryology, its functions and its diseases are those of the

stomach. I believe that it would not be far out of the way if we classified it as part of the stomach, dividing the stomach into the fundus antrum, pyloric canal areas proximal duodenum."

In the diagnosis of this condition, we must group a number of facts, namely, the history, the laboratory findings and the Roentgen ray reports, and the physical examination.

A complete history is most important; the patient usually dates the beginning of the trouble a number of years back. The average, duration of symptoms in a number of statistics was twelve years. It is an important fact that these histories show that for weeks or months at a time the patient would be free from practically all symptoms only to have a recurrence. These recurrences nearly always come with the cold months, patient getting chilled, and the rerudescence apparently depending upon this; at times the whole trouble is started again in injudicious diet or over-feeding. During the warm months the trouble frequently subsides and the patient gets along comfortably.

The most striking symptom is pain, that in the duodenal ulcer is supposed to occur about two to four hours, or even as late as six hours, after eating and is relieved by food; to this peculiarity Moynihan has given the name "hunger pain"; where the pain develops three to four hours after food, he had always found the ulcer tucked back, that is, adherent posteriorly in such a manner as to prevent its delivery into the abdominal wound. So much strength does Moynihan place on a long continued history of indigestion; the relief of pain after food, the development of pain again in two to four hours, increasing in severity with possibly gas and water broth, that although this symptom complex may be present for years without producing any physical sign, it is therefore "not necessary to the attaining of any accurate diagnosis that any examination of the patient be made; the anmnesis is everything, the physical examination is relatively nothing."—(Moynihan²).

Pain is the most constant complaint: In Friedenwald's³ series of 1000 cases of ulcer of the stomach and duodenum, it was absent in only seventeen out of 529 cases. It was most prominent in those cases of hyperacidity. In 429 of the stomach ulcers, it was present in 94 per cent. In the 1000 cases, it appeared within the first hour after meals in 223; between one and two hours in 183; after two hours in 491, and in 38, it appeared irregularly. So far as the effect of food on pain was concerned in 212 instances it was aggravated; in 619 instances, relieved; in 109 instances, food had no effect. In Smithie's⁴ series of 140

*Read before the Kentucky State Medical Association, at Bowling Green, September 2, 1913.

proved cases of ulcer, without food retention pain had a definite relation to ingestion of food in 87.8 per cent.; irrespective of the location of the ulcer 83 per cent. had pain within four hours after taking food; in ulcers involving the pylorus, more than 64 per cent. had pain in from two to four hours after eating. In gastric ulcer we have pain earlier after meals, while in the duodenal ulcer it may appear so late that it is relieved by the ingestion of the next meal.

"Hunger pain" may be due to other causes than duodenal ulcer: Pfahler⁵ in his article on "Pain Explained by Roentgen Rays," says, "Duodenal adhesions draw a portion of the duodenum higher than normal. Then the descent of the duodenum is more abrupt, and at times it may pass downward to the left of the pylorus instead of to the right, as is normal. One can readily understand the nagging aching pain in these cases, which occurs especially where there is some associated inflammation of the gallbladder, duodenum, or stomach and which occurs especially several hours after a meal, for it is at this time that the angle formed by the adhesions is most acute, and the peristaltic waves are strongest in order to carry the food up over the highest point. Each time that these waves or the food contents pass, there is a pulling on the surrounding structure, which causes the pain. This explains, too, the intermitting character of these pains, for peristalsis in the stomach is not constant as one might suppose. It is excited by various factors, and at times is strong and at others weak. Then, too, the pain is more marked when inflammation is present.

Herschell⁶, while believing this view to be correct also adds: "That it may be due to the presence of continued secretion of gastric juice after the stomach has emptied itself or it may be a neurosis and not to be distinguished from the hunger pain so frequently met with in gastric neurasthenia." Allen A. Jones⁷, has contributed a paper on "hunger pain" in which while believing in the importance of hunger pains in duodenal ulcer calls attention to the fact that such ulcers not infrequently exist without pain, haemorrhage may be the first symptom to herald its presence. He also notes that hunger pain may be a symptom of achylia gastrica and of acid gastritis; in catarrhal gastritis the contents show an excessive amount of mucus and a low acidity; in gastrectasia, gastropotosis, enteroptosis or nephroptosis. He also calls attention to "that condition of painful emptiness of the stomach to which Boas gave the name gastral-gokenosis where while hunger is not present, prompt relief is given by eating. In pathological conditions of the gall bladder and ap-

pendix, it is found and the symptom may be an accompaniment of anaemia or a low state of general nutrition and strength. The author concludes his very able paper with this paragraph—"It seems an error to arrive too hastily at a diagnosis of gastric or duodenal ulcer in these cases and to hurry a patient to a gastro-enterostomy on this symptom alone."

From the standpoint of the Roentgenologist, pain in ulcer may be due to

- a. Hypertension (intragastic).
- b. Due to reflex.
- c. Due to irritation of parietal peritoneum. Mills and Carman⁸.

Vomiting: In Friedenwald's series this was a symptom in 67.6 per cent.; in Smithie's cases, in 70.7 per cent. this constituting 99 cases in which fifty vomited but had no haematemesis; 31 vomited and also had haematemesis while 18 had haematemesis alone. Vomiting may not be a constant symptom, but in a certain proportion of cases may occur immediately after taking food but more often about three hours after, about the time digestion is at its height. Owing to the relief offered, many patients induce vomiting. The use of soft food tends to prevent vomiting; of coarse food to augment it, hence many patients limit their diet because of this fact.

Haemorrhage: According to W. J. Mayo, not over 30 per cent. of his cases gave a clear history of haemorrhage although nearly 70 per cent. of haemorrhages were procured through a history of black stools. He thinks this symptom of least value, and as far as "occult blood" in the stool is concerned believes that it must be corroborated by other evidence of a substantial nature. On the other hand, Moynihan believes that "a certain degree of haemorrhage occurs in many cases without being recognized; the surface of the ulcer when fretted, probably bleeds a little and if the stools were carefully and regularly examined, traces of occult blood would surely be found." In Friedenwald's 529 cases of duodenal ulcer, a history of melena was obtained in 54 per cent. In these 529 the test for occult blood was made in 381 and was positive one or more times in 83 per cent.

Physical Examination: Usually some loss in weight is shown, although duodenal cases are thought to be little better nourished owing to the increased food consumption. The point of tenderness is upward and to the right from the umbilicus, although it may not be localized exactly in gastric ulcer. Occasionally, backache is complained of and Boas has called attention to tender points on the left side from the ninth to the twelfth dorsal vertebra. Wm. Gerry Morgan⁹ believes that even in a subjectively latent ulcer, slight localized tenderness or the least rigidity may

be made out. He mentions Hall's operated cases where tenderness was made out in 70%, while rigidity appeared in 66%, and states that he hesitates considerably to make a diagnosis if tenderness is absent.

Laboratory findings are of great interest taken in connection with the history of the case and are of real value. It has long been taught that in gastric and duodenal ulcer, hyperacidity was the rule, and Moynihan has repeatedly made the statement that "hyperacidity is duodenal ulcer." In Friedenwald's 128 cases of acute ulcer, hyperchlorhydria was present in 47.6 per cent of the 61 cases in the male and 37.3 per cent. of the 35 cases in the female, but 426 cases of chronic ulcer of long duration, hyperchlorhydria was present in only 8.3 per cent. in the male, 91 per cent in the female, the normal acidity being present in 22 per cent. and 19.9 per cent. respectively and hypochlorhydria in 18.6 and 21.8 per cent. On the other hand, in 529 cases of duodenal ulcer, the analyses were made in 402. Normal acidity was found in 48.5 per cent. hyperchlorhydria 35.2, hypochlorhydria 16.1 per cent.

I have always considered the test for occult blood, repeatedly made under suitable precautions, to be a very efficient help in the diagnosis of duodenal ulcer.

F. W. White¹⁰ of Boston, who has paid particular attention to the tests for occult blood, states that none of his cases of so-called hyperacidity, which gave a persistent negative test for occult blood in the stools and stomach contents had proved later to be chronic duodenal ulcers. On the other hand, he had repeatedly examined a large number of peptic ulcers and had not yet seen a single case where both stools and gastric contents gave only negative tests for blood.

Einhorn's¹¹ duodenal bucket: Some four years ago Prof. Einhorn, of New York, introduced his duodenal bucket for the purpose of obtaining the duodenal contents. Since that time the bucket has been used by himself and others in a great many tests for the purpose of determining the permeability of the pylorus and the presence or absence of blood in the stomach. The bucket is best introduced at night and is withdrawn the following morning. Before removing the bucket, a knot is made at the teeth to determine the length of the thread in the digestive tract, and naturally, the patient is enjoined from taking at the evening meal anything that might cause a stain on the white silk thread that could resemble blood, such as coffee, jelly, claret, etc., and according to Einhorn "the distance of the blood spot, from the knot at the teeth, gave the location of the ulcer; if the lower four inches are stained a golden yellow it will

show that the bucket had passed the pylorus, provided the length of the thread in the digestive tract on removing quite exceeded twenty-two inches. Therefore the pylorus is permeable if the bucket has been in the duodenum, and the contents are usually golden yellow, viscid and slightly alkaline. He also states that the thread test appears to be of importance not only in the recognition of the ulcer, but also as a criterion of the efficacy of our procedure; especially whether a cure has been accomplished or not. In those cases where perfect healing of the ulcer has taken place the test becomes negative.

Dr. M. Gross¹² of New York, suggests the use of his duodenal tube to aspirate the contents for the purpose of examination. He claims that he has not only found a chemical reaction but has also been able to determine the macroscopical presence of blood in the aspirated contents.

In an article in the *Journal A. M. A.*, upon duodenal ulcer¹³ it is suggested that patients with a history that points to the duodenum should have the contents examined by the simple regurgitant method, viz., the administration of a few ounces of olive oil after the stomach is washed out and is known to be empty. After a half hour, the oil is withdrawn. The oil seems to cause regurgitation, or at least an opening of the pylorus, which allows some regurgitation of duodenal contents into the stomach and the fluid and oil that is then removed will separate on standing. He suggests that an examination of this fluid will give a number of clues as to the condition of the duodenum. Complete examination of the urine and thorough analysis of the blood is always important in every case.

Röntgen Rays: Since subnitrate of bismuth was used by Rieder over nine years ago to demonstrate the gastro-intestinal tract, various media have come into use and with the improvement in apparatus, striking pictures may be obtained so that the use of the Röntgen rays is necessary to make a complete clinical record. In the larger cities it is now possible to send our cases to any one of several good laboratories and at the present time, the expense is the only objection. The findings in both gastric and duodenal ulcer are so tersely summed up by R. D. Carman²⁴ in a recent article that I reproduce here: The radiologic evidences of gastric ulcer comprise:

1. The diverticulum of perforating ulcer.
2. Visualization of the bismuth-filled crater of a callous ulcer.
3. The incisura, or transverse contracture, indenting the greater curvature.
4. Localized pressure tender point on the lesser curvature.

5. Residue after six hours.
6. Acute fish-hook form of the stomach, with displacement to the left and down.
7. Delayed opening of the pylorus.
8. Settling of the bismuth to the lower pole of the stomach, such as is seen in hypotonicity or atony.

In duodenal ulcer there may be:

1. Early free opening of the pylorus, with early clearance of the stomach.
2. Lagging of bismuth in the duodenum.
3. Residue in the stomach (sometimes in the duodenum) after six hours, if there is an obstruction from scar contraction.
4. Pressure-tender point over the duodenum.
5. Dilatation of the cap.
6. Irregular outline of the cap or duodenum.
7. Diverticulum of perforating ulcer.
8. Vigorous peristalsis, especially if there is obstruction.

Differential Diagnosis: The most important condition to be differentiated are cholelithiasis, and simple hyperacidity. In the former, the pain is more severe and may develop very suddenly at any time; I have seen numerous cases where the patient awakened from a sound sleep. It occasionally may develop a short time after meals and as described by the sufferer, is agonizing; such severity is not seen in duodenal ulcer. It is characteristic of gall-stone pain that the relief afforded the duodenal pain by food is lacking, in fact, food is far from the patient's thoughts. Many patients complain of the pain that radiates to the back or to the shoulder, disappearing with the attack. In gall-stone disease, there is not the periodicity of symptoms that we find in duodenal ulcer.

In simple hyperacidity, the history usually develops the cause—overwork, anxiety, and the various causes of nerve tension. Repeated examinations for occult blood in the stool are negative and the good results of treatment are soon apparent.

Medical Treatment: All cases demand treatment; the acute, because of the possibility of cure; the chronic for the same reason even if remote but also to relieve symptoms and though an operation is delayed a few weeks, the patient is usually in better condition to stand it.

The first and most important step is complete rest in bed. Two well tried methods have now been before the profession, one for many years and the other for a few years. I refer to the Von Leube and Lenhartz's. All cases of ulcer are not alike; however, the general symptoms may resemble each other, each case

has some special symptoms that enable the practitioner to vary either method of treatment according to the indications present. Von Leube bases his treatment on the fact that the relief of pain and promotion of healing would be best served, first, by rest; second, by feeding small quantities of soft, unirritating food at short intervals and gradually increasing the quantity and adding to the quality of the food as the case progresses.

In the following out of the Von Luebe method, if the patient has had great pain or has been vomiting, it is advisable for the first forty-eight or seventy-two hours to withhold all nourishment by the mouth, even the use of water and to feed per rectum. We find innumerable formulae of various distinguished physicians for use in rectal feeding. I think saline enemata are preferable to the nutrient as it has been shown that ordinary saline solution given by the bowel keeps up the caloric needs of the body, and are especially commendable because less gastric secretion is produced than where nutrient enemata are employed. Kaufman recommends enemata composed of water, sodium chloride and dextrose as being especially useful in preventing the untoward effects of complete starvation, when nothing is taken by the mouth, and by the use of the Murphy drop method, he states that one or two quarts of normal saline plus five per cent. dextrose solution may be absorbed in twenty-four hours. He believes that where the enemata are well tolerated and the condition of the patient demands it, that they may be used for eight or ten days or even longer. He refers to numbers of cases reported by various authors who enforced rectal alimentation, and total abstinence from nourishment by mouth for periods up to three weeks and the claim is made that this heroic treatment had yielded good results by allowing the ulcer to granulate and heal by the long rest given to the stomach.

After this enforced period of rectal alimentation, or if the patient is able to begin the cure without that necessity, the choice of method presents itself. Naturally, the first object in view would be to prevent the irritation and to allow the ulcer to heal. In the Von Leube method the effort is made to provide only soft non-irritating food that will leave the stomach in the shortest possible time; to continue this method day by day and as the patient's discomfort lessens, and his sense of well being increased, to add cautiously to the diet other articles of food proceeding from the liquid to the pap, custard or like foods and gradually after a space of three to six weeks return to normal, sensible diet, in which all coarse food is avoided. The ideal

food to begin the treatment is milk; it fulfills all the indications; taken in small quantities it gives no distress; it takes up any free acid that is present and remains but a short time in the stomach. In the beginning it may be given hot or cold as the patient prefers, about two ounces every two hours, and if well borne, after the second day this may be increased to three or four ounces at a feeding. Many patients have idiosyncrasies toward milk and in this case the milk must be modified; some patients will take the milk better cold than hot, others the reverse. Others take milk with equal parts of Vichy or take it flavored with vanilla, cocoa and cinnamon, while in other cases it may be necessary to modify the milk with lime water and sugar, just exactly as the modified feeding of milk to children. When the milk is well-borne, however, and the symptoms diminish, it is advisable to add to it after the third day increasing amounts of cream so as to avoid the one defect of this method of dieting, viz.: starvation. At the end of the first week eggs may be added to the diet either beat up in one or two of the milk feedings each day, or given soft boiled by themselves. The number of eggs may be increased from two to four a day and gradually adding sago and rice soups, boiled with milk and various gruels in addition. Butter can also be added to the diet at this stage, in addition to the cream, and besides furnishing high caloric value, can often be taken by the patient, particularly if frozen. Cream, soups and puree of potato will make a welcome change and relieve the monotony of the diet. It is advisable to withhold meat until at least the fourth week, and some clinicians put off meat even longer. It is a consensus of opinion, however, that relapsing cases should continue on the fluid or semi-solid diet for the full course of the cure if possible.

In addition to the soft diet, when the patient first goes to bed, Von Leube has the abdomen washed with alcohol, covered with boracic ointment and over this a flax seed poultice, which is changed every thirty minutes during the day. At night a binder wrung out of tepid water is placed over the abdomen covered by oil-silk or by a towel and kept on till morning. Naturally, if the patient has been the subject of haemorrhage within the previous three months, this procedure does not follow. A number of years ago the late Prof. Lenhartz, of Hamburg, advocated a different method of treatment, especially in haemorrhagic cases, with the idea that the loss of strength and nutrition due to the haemorrhage should be made up as quickly as possible. Lenhartz was of the opinion that the Von Leube method was difficult because of the

fact that the nutritive need of the patient was not satisfied by the diet, that owing to the anemia that was bound to develop, healing of the ulcer would be much delayed. Incidentally, Lenhartz's diet was intended to bind the excess of HCl which is so often present in gastric ulcer. Briefly, the diet consists of feeding with milk and rice, raw ham and butter. For the first day the patient receives two eggs and 200 c.c. of milk; the former is increased by one egg each day until eight are taken, but beginning on the third day patient receives twenty grams of sugar beaten up with the eggs; this is increased to thirty grams on the fifth day, forty grams on the seventh day, fifty grams on the ninth to fourteenth days. Milk is increased by 100 c.c. each until the ninth day when a litre is taken and continued to the fourteenth. On the sixth day thirty-five grams of raw beef are allowed; on the seventh day this is increased to seventy grams, which is continued to the end of the treatment. On the seventh day 100 grams of milk and rice are given and increased on the ninth day to 200 grams, on the eleventh day to 300 grams. Zwiebach, one piece or twenty grams was allowed on the eighth day, two pieces on the ninth and tenth, three on the eleventh and twelfth, and four on the thirteenth and five on the fourteenth. It is not until the tenth day that fifty grams of raw ham are added to the dietary and continued during the rest of the treatment. On the same day twenty grams of butter, which are increased to forty on the eleventh and continued during the course of treatment, are allowed. The feeding of the first day amounts to 280 calories; this is rapidly increased until on the sixth day it amounts to 1,135, on the tenth day 2,478, on the fourteenth 3,073. It is by means of this high caloric equivalent that Lenhartz endeavors to maintain the nutritional balance of the patient and at the same time to bind the HCl and relieve pain. It also relieves vomiting and the recurrent haemorrhage is much less than by other methods. He also claimed a quicker return to strength and working capacity, and lastly, permanent results.

Prof. Max Einhorn about three years ago advocated a new method for treating gastric ulcer that differs from all others in the fact that, by the aid of his duodenal pump, the feedings are thrown directly into the duodenum and the stomach is left at perfect rest. The duodenal tube is one mm. in circumference and 80 mm. long; at one end it has a small perforated metal capsule fourteen mm. long and twenty mm. in circumference. This tube is introduced into the stomach and allowed to remain. After several hours the

aspirator is applied and if it has reached the duodenum a yellow or watery fluid of alkaline reaction will be obtained. If, however, material obtained is acid, then the tube is partly withdrawn and a small amount of water and air forced through it and the procedure repeated. After two or three hours, as a usual thing, capsule is found in the duodenum at the first trial. Through this tube 240 c.c. of milk, one raw egg and fifteen grams of sugar and milk, well beaten, is passed slowly every two or three hours. After each feeding a small quantity of water is forced through the tube to clean it and followed by a syringe full of air, the end of the tube is then clamped until the next feeding. I had the pleasure of seeing Prof. Einhorn feed a case of ulcer by this method and it is astonishing what little inconvenience this patient had in retaining the tube in her stomach for over ten days, being entirely free from pain and practically maintaining her body weight. Dr. Wm. Gerry Morgan has modified the Einhorn method in feeding the patient by the Murphy drop method, attaching an irrigator to the duodenal tube so arranged that about 300 c.c. will pass through an hour, and claims to have had very good results. In fact, in some of his cases, feedings have taken place while the patients were asleep.

Dr. J. W. Weinstein²⁵, of New York, at the 1912 meeting of the American Medical Association at Atlantic City, advocated a new method. I quote from the abstract of his article that appeared in the Medical Record. He stated "that his method for the treatment of ulcer of the stomach was a combination of various remedies proposed at one time or another for the treatment of this condition. The diet was original; the other measures were not. This method did not require a stay in bed; the patient was allowed to go about his business as usual, but hard work was forbidden. His experience with the method had been confined to the chronic type of ulcer. The most of the cases treated belong to that type of ulcers known years ago as hyperacidity, but which had been shown conclusively to be ulcers. This class represented the syndrome of pain, heartburn, belching and sour eructations coming on one hour or more after meals, and with these this method had been a most pronounced success. As to the diet, the patient might take white bread, zwieback, toast, soda-biscuit, corn flakes, farina, cream of wheat, potatoes (mashed only), eggs (soft boiled, hard boiled if they agreed), sugar, fish (boiled only), raw or stewed oysters, baked apples, milk, buttermilk, zoolae, fermillae, viehey, weak tea (in moderation), cocoa. The articles forbidden were: any other food, ali-

fried foods, all seasonings, except the least bit of salt. Meats and broaths were excluded because they stimulated gastric secretion. This diet must be strictly adhered to for four weeks, when easily digested soups and meats might be added. Fried meats were forbidden and all the coarser portions of the meat—sinaews, tendons, burnt or charred portions—could be avoided. Soups and broths should not contain vegetables of any sort. To cure the ulcer he gave bismuth; the carbonate given once a day, in the morning on an empty stomach, had proved most satisfactory. The patient must not have anything for an hour afterward. He has found it expedient to cleanse the digestive tract once a week by the administration of a dose of castor oil to remove the bismuth which had a tendency to accumulate. To check the flow of hydrochloric acid, he gave atropine in doses of 1-100 grain three times a day, or extract of belladonna in doses of 1-5 of a grain. In addition he gave an alkali in the form of magnesium oxide in varying doses, according to the condition of the bowels. For patients who did not do well on this plan he gave, instead of belladonna and the alkali, olive oil in doses of one or two tablespoonfuls ten or fifteen minutes before meals. The stasis of food, if it existed, was met by lavage of the stomach seven hours after meal. If there was but little food present, it should be done twice a week. The motility of the stomach should be determined in every case before starting the treatment. The last step in the treatment was the application of wet compresses to the stomach every night. This course of treatment was carried out for eight weeks and the patient was questioned every week as to whether he carried out the instructions. The results had been very satisfactory and all of his cases had been of long standing, dating back as long as fifteen years, and had taken treatment at the hands of a number of practitioners. The great value of the method was in its simplicity and the lack of sacrifice on the part of the patient."

Dr. George Herschell, of London, makes a number of suggestions in the treatment of duodenal ulcer to which I wish to refer: He advised 1. To make absolutely sure that there is no possible infection from the mouth, even going so far as to suggest X-ray skiagraphs of the teeth.

2. He suggests obtaining some of the duodenal contents by either of the means heretofore spoken of and examine it bacteriologically and if any predominant organism is found, a pure culture is made from it and the opsonic index of the patient determined toward it. If this should be found lowered, a vaccine is made and injected into the patient.

3. He advocates absolute rest in bed with two weeks as a minimum and thinks three would be better.

4. An attempt is made to remedy any deficiency of antipyretic and antilytic substances in the blood and recommends normal horse serum for this purpose, given upon a full stomach.

5. The acidity of the gastric juice must be kept as low as possible, making use of eight or ten ounces of hot vichy water two hours after meals or of the various neutralizing powders.

6. Secure the stomach against distension by preventing pyloric spasm; by giving food in small amounts; by giving the drink, which should be hot water, not with meals but when the stomach is empty, so that it will pass out of the stomach and incidentally close the surface of the ulcer of duodenum.

7. Keep the bowels open freely.

8. Treat the anemia that may be present with hypodermic administration of iron in the form of cacodylate.

9. Follow the diet substantially as outlined above.

So far as drugs are concerned, that are of value in the treatment of gastric and duodenal ulcer, the number is limited. There are three indications to be fulfilled: first, neutralize any excess of acid; secondly, to prevent spasm; third, promote healing. The first indication is met by the use of antacids, particularly magnesium oxide and bicarbonate of soda. These may be given from ten to thirty grains each in powder form whenever the patient begins to feel uncomfortable and repeated three or four times each day, according to the indication. To prevent spasm, the extract of belladonna from 1-8 to 1-4 grain or the tincture from three to eight or ten drops, or atropin 1-200 to 2-100 of grain will suffice. Cohnheim has advocated the use of large amounts of olive oil, 200 to 300 e.e. introduced in fasting stomach each morning; when the stomach tube cannot be used, other observers report good results in the use of one ounce doses, three times a day. To promote healing of the ulcer, bismuth is the drug most favored, either the subnitrate or the subcarbonate. This can be given in a single large dose, one to two drams, in six ounces of water on fasting stomach, or may be given in smaller doses fifteen minutes before feeding throughout the day. After the fourth week many observers believe that beneficial effects are to be derived from the use, beginning with a quarter of a grain in a tablespoonful of peppermint water thirty minutes before feeding and gradually increasing the dose to half grain. It is customary with many clinicians to make use of

the Carlsbad salts in hot water in suitable doses toward the end of the first week. If the combination of oxide magnesia and bicarbonate of soda tend to diarrhoea it may be combined with chalk or bismuth. Bismuth, olive oil and nitrate of silver give the best results introduced through a stomach tube. Kauffman¹⁶ makes a special plea for the use of the tube in those cases of ulcer near the pylorus, accompanied by spasm and continuous hypersecretion and states that he has employed gastric lavage for over twenty-five years in numerous ulcer cases without any bad results, and believes that by removing stagnating and fermenting masses not only eliminates the constant source of irritation of the ulcer and gastric mucosa, but by cleaning the ulcer by lavage, it allows us to bring into full play all those methods of treatment which have been mentioned above. He makes the important suggestion that the cleansing as well as the medical treatment connected with lavage are the most efficient means of treating chronic gastritis, which is the underlying cause of the whole process.

In the treatment of haemorrhage, the first requisite is absolute rest, best secured by morphine hypodermically and repeated if necessary. The application of a light ice bag to the epigastrium aids in checking the flow of blood. The use of ice water by tube is recommended by Ewald; in this country Kaufman has been a warm advocate of lavage believing that thorough evacuation of the contents of the stomach will do more to quiet the organ and stop the bleeding than any other measure; this plan is also endorsed by Billings. Internally, good results have been obtained from adrenalin in repeated doses; from the use of bismuth, both by mouth in divided doses and in one large dose after lavage. In discussing Billings' paper on Internal Haemorrhage, A. S. Von Mansfield states that pure aluminum metal ground into powder and mixed with glycerine into an emulsion like paint 160 grains to the dose will almost magically stop haemorrhage from the stomach except from larger vessels. At the present time normal horse serum has been used extensively and many favorable reports are made concerning it.

How long should an ulcer be treated? This is a question hard to answer because different patients respond differently. I have long been of the opinion that a patient the subject of gastric or duodenal ulcer should submit to the rest cure for at least six weeks. If at the end of that time the symptoms have disappeared or have greatly improved, it is advisable to have him resume his ordinary vocation but under regular and careful medical

observation. His diet should be watched for at least a year, his stools should be examined regularly for occult blood and at first appearance of the return of symptoms, he should be placed in bed again and once more submitted to the rest cure. If, however, after the first six weeks, when the patient is up and about, he does not regain his strength as we should expect, the cure should be tried again for another six weeks, and after this we have little or no improvement and occult blood is still present in the stool, it is best to refer him to the surgeon. I believe that in the past many cases have been overlooked. This has largely been due to the fact that many practitioners take few or no notes of their cases; on the other hand, many cases have not done well because of the fact that they were not willing to submit to the absolute rest in bed and strict diet insisted upon by the careful clinician. I believe the time is coming when the diagnosis of ulcer will be made early because of the fact that every practitioner will take a more complete history of all cases and will make every test to help the diagnosis.

DIAGNOSIS AND INDICATIONS FOR OPERATION IN GASTRIC AND DUODENAL ULCERS.*

By A. DAVID WILLMOTH, Louisville.

With all that has been said and written about conditions in the abdomen it was not until recently that we had our attention directed to the great frequency of ulcers in this geographical area, and especially to ulcers in the duodenum. The knowledge now in our possession was gained largely by accident in operating for supposed gall-bladder troubles.

The information concerning these patho-

logical lesions must necessarily be had at the operating table and not from the post-mortem room, for it is a well known fact that many influences may become active shortly before or at the time of death that would mask the primary lesion and cloud the condition as it existed in life. In other words, changes and terminal infections may prevent a correct interpretation of the signs and symptoms manifested early in the disease, striking illustrations of which are seen in gall-bladder and appendiceal involvements also in extra-uterine pregnancy.

Ulcers in the duodenum are best divided for the sake of study into those that are acute (or punched out) and the chronic (or indurated varieties).

The acute form may be in extent anything from erosion of the mucous membrane to the sub-mucous or muscular coat, or may even extend through the entire wall and liver or pancreas or some other organ form the floor. The walls are undermined and irregular and often have a sloped appearance. When seen at the operating table, the acute ones of course, if perforated, look as though a large leather punch had been used to make the clean cut hole in the gut wall, while in the more chronic the wall will show a milky white or grayish white spot, soft and indurated riding the wall, or extending over it in flap shaped fashion which can be easily seen. In those cases which come for early diagnosis or those coming with symptoms complex for an opinion, we should have in mind the following facts, and in order to obtain these facts, let me insist upon the most careful taking of the patient's history. Commit no sins of omission.

Since males are more often affected than females in the proportion of from 58 to 42 (according to Friedenwald, *Journal Medical Sciences*, Vol. 144, page 164, 1912) to 79 to 21 (*Osler's System of Medicine*, Vol. 5, page 208) this must be taken into account in taking the case history.

The following table from Friedenwald is worthy of reproduction:

YEARS	MALES		FEMALES	
	NO.	P. CT.	NO.	P. CT.
10-20	31	5.8	24	4.5
20-30	85	16.1	74	13.9
30-40	87	16.4	62	11.7
40-50	66	12.4	25	4.7
50-60	11	2.0	32	6.9
60-70	27	5.1	5	
	307		222	

Age: So also age, while Oppenheimer found 15 cases in infants, we know this to be rare indeed, the most common time being around 30 years, from 30 to 40 furnishing 66

*Read before the Kentucky State Medical Association, at Bowling Green, Tuesday, September 2, 1913.

out of 330 cases. (Osler's System of Medicine Vol. 5, page 208).

The following table is in detail of 12,598 cases of various gastric disturbances studied by Friedenwald 100 of which had ulcers.

AGE	CASES	P. CT.
0-10	2	0.20
10-20	162	16.20
20-30	345	34.50
30-40	229	22.9
40-50	128	12.50
50-60	53	9.30
60-70	38	3.80
Over 70	3	0.30

After the sex and age, comes the personal history of the patient. Since a large percent of ulcers are found in those who fare sumptuously and stimulate their appetites with more or less alcohol, the mode and manner of living must be gone into, to the minutest detail, for when we turn from the definite and clear cut picture as often given by the patient to the physical examination we are at once struck with the absence of any findings of seeming importance.

In those coming for an opinion, the history will be about as follows: That for an indefinite time there has been a sense of fullness, with a persistent acid dyspepsia, with a distinct burning sensation some hours after eating (heartburn), belching of mouthfuls of sour water at the time digestion is at its height (waterbrash); loss of appetite may have occurred, but in many, a real craving for food will be found and the patient has gone from one diet to another with the hope of finding things to eat that would not be followed by pain. The character of food often determining the occurrence and severity of the pain.

Pain. As to the attack itself pain is the first symptom to attract the patient's attention, naturally they begin their story of illness at this point. Find out how long the patient has been having these attacks, how often they occur, what condition the patient is in between attacks, what effect if any has been made on nutrition.

As to the attack itself, find the exact site of pain, if it radiates, where to, the intensity of it, its character, when it comes on, how long it lasts, what gave relief, and what other symptoms accompany it. (Moynihan Duodenal Ulcers, page 9). Moynihan believed that the time of occurrence together with the length and intensity of the attack to be pathognomonic, but this assertion should be taken *cum grano salis*, for the classical hungry pain may, as Gunzberg has pointed out, be due to arterio sclerosis (*Deutsche Med Wochenschrift* No. 28, page 1318-1910). Pain, how-

ever, will be found in about 95.5 per cent. It is to be expected most often in those associated with hyper-acidity.

The severity, duration and distribution of pain will depend on the local condition of the ulcer. Those inflamed will have their sensitiveness increased, so also those whose surface has certain nerve fibres laid bare by necrotic processes will have their excitations greatly augmented.

The pain is due, as Pilcher has shown to the hydrochloric acid coming in contact with the ulcer and the reason for the relief after taking food being due to the activity produced in the duodenal secretions by the presence of food in the stomach. This secretion being alkaline in reaction counteracts the acidity of the stomach contents.

Pain will intermit in more than half of the cases for from one to twelve months. The following table shows an analysis of Friedenwald's one thousand cases of gastric ulcer:

CASES	MONTHS INTERMISSION
94	1 to 2
72	2 to 3
82	3 to 4
79	4 to 5
48	5 to 6
26	6 to 7
38	7 to 8
34	8 to 9
17	9 to 10
20	10 to 11
31	11 to 12
22	12 or more.
—	
563	

In duodenal ulcer the following table shows the intermission:

CASES	MONTHS INTERMISSION
53	1 to 2
36	2 to 3
44	3 to 4
37	4 to 5
34	5 to 6
17	6 to 7
23	7 to 8
29	8 to 9
9	9 to 10
15	10 to 11
14	11 to 12
5	12 or more.

It may be in severity anything from dull discomfort to the most intense, so that the patient will present a cold, clammy skin and anxious, pinched expression. The pain and discomfort coming at first only after the heavy meals of the day, finally being noticed about two or three hours after each meal. If the pain comes on as much as four hours after

eating, it generally means the ulcer is tucked posteriorly. If it comes earlier than two hours, you expect stenosis from retraction or a very active ulcer. Pain is usually located to the right of the middle line and above the umbilical level, in contradistinction to intestinal obstruction where the pain is continuous around the umbilicus.

If the patient is seized by a sharp, agonizing pain, referable to the epigastrium or radiating over the left side, or even to the dorsal region on the right, at the same time shows signs of shock due to gases in the free abdominal cavity, this pain being supplemented by the tenderness and heaviness in the region, together with the symptoms later enumerated, we are safe in suspecting a perforation. Tenderness may be found over the sight of the ulcer provided it is located anterior, and is almost always close to the right costal border, and often found to extend over the entire part of the duodenum.

Epigastric tenderness in cases that are perforated is most severe and comes on early. In most cases of duodenal perforations the tenderness will be moved to the right of the middle line, while in perforation of the stomach, it is to the right of the pyloric, or prepyloric area to be affected, and to the left if the lesion be in the body, or either of the curvatures of the viscus.

The greater tenderness in either duodenal or gastric perforation may be around the umbilicus and has been seen in either iliac fossa, particularly at times to the right caused by the spread along the paracolic grooves, and for the first few hours after perforation the area is quite tender as the epigastrium, making the entire picture look like one of perforating appendicitis. (Deaver, *Journal A. M. A.*, July 12 1913).

Rigidity. This very important symptom has been hinted at previously and now with all the emphasis possible, I beg of you to look for this important sign. Rigidity of the abdominal muscles sets in at once after perforation, is most marked in the upper abdomen, even to the extent of retracting the abdomen, making a transverse depression at the level of the umbilicus. In no condition do we have that board-like rigidity of the right rectus muscle as we see in the perforating ulcer of this area. It far exceeds anything but a most unusual appendicitis or gall-bladder involvement. Many times the scaffold abdomen will be found, and will continue until the peritoneal involvement causes enough distension to overcome it.

The involvement of structures so near the diaphragm causes a peculiar short, shallow thoracic type of breathing.

Could the symptoms be observed from the very moment perforation occurred, and watched the spread of tenderness from above downward, would render the differential diagnosis from perforation of the appendix very much easier, for here we have a spread from below in the iliac fossa to the upper abdomen.

Vomiting will occur in about 50 per cent. of the cases. It is to be especially looked for in those where perforation is suspected, or where stenosis has taken place, hence, a late symptom.

Jaundice, when present, indicates that the ulcer has invaded the ampullae of Vater. It being remembered that a chronic duodenitis may also produce it.

Temperature and pulse are of little value early as is shown in *Journal A. M. A.*, July 1913.—(J. B. Deaver).

TEMPERATURE	PULSE	RESPIRATION
98.3	104	24
99.4	92	24
99.	108	34
97.4	112	32
98.2	78	36
99.0	96	28

The next complication and symptom laid down by Moynihan of such great importance is hemorrhage. This symptom may be expected in approximately 23 per cent. of gastric ulcers, 26 per cent. in acute, and 40 per cent. in chronic duodenal ulcers (Moynihan *Duodenal Ulcers*, page 113). (Northagel *Encyclopedia*, page 245).

In many it amounts to the small loss caused by the food products teasing the ulcer surface, and is to be found only after close and painstaking examination lasting over many days. In the duodenal cases where a severe hemorrhage follows an acute exacerbation of digestive disturbances it holds up to the physician signs of eminent danger and lost opportunities. Being far more serious than gastric hemorrhage.

Bleeding from the duodenal ulcer may be in any one of four varieties. First, latent and insignificant; second, those that intermit; or infrequent and moderate in amount; third, those becoming worse after symptoms develop. In these the bleeding may be coming repeatedly and copiously, therefore perilous and perhaps fatal. In the fourth class, the hemorrhage is sudden, overwhelming and fatal.

It is in these cases that Einhorn duodenal bucket or catheter, or its modification by Morgan of the B. B. shot in a five grain capsule with a No. 8 braided silk cord attached and knotted 75 cm. from the capsule has been of such inestimable value. Its usefulness de-

pending upon its ability to come in contact with the bleeding surface save in the Einhorn bucket, where the duodenal contents, when drawn up, could be examined for a Camidge reaction and early gastric analysis. Such analysis showing little of importance save blood occasionally, and in the chronic ulcer hyperchlorhydria with retention of food.

(If gastric analysis would have shown more, we would not have had to wait for the surgeon at the operating table to learn most of what is now known about this class of cases).

So far, we have said nothing about the subjective symptoms, some of which may be said to be complications. The first of these, to make itself known to the patient is gastric dilatation, this being one of the two conditions associated with duodenal ulcer that Moynihan considers of such great importance.

Gastric stasis sufficient to prevent the stomach from pouring its contents into the duo-

Gastric stasis found in duodenal ulcer is due always to the contraction caused by the partial or complete healing of the ulcer, save in those cases where the stomach is able to empty itself in twelve hours. There it is due to pyloric spasm. Such spasm being reflex and protective as was shown by Cannon and Murphy.—(*Annals of Surgery* 1909, Vol. 43, page 512).

The slow emptying of the stomach affords a two fold protection. First, it protects the ulcer from the acid chyme (a protection it certainly needs). Secondly, it protects by producing certain symptoms a presence of which makes the patient more careful as to the quantity of food taken.

denum in from seven to twelve hours means a duodenal narrowing from pathological causes and is indicative of ulcer. (Einhorn and Gunzburg.) When such obstruction takes place even to a small degree, hypertrophy of the stomach wall muscles take place, (as it does in the heart or intestines from obstruction to overcome) and visible peristaltic waves are noticeable during examination if the stomach is filled.

Blood Test: Leucocytosis will show in perforated cases very early, due to peritonitis.

Shock: In perforation shock comes on only in proportion to the dissemination of the poison in the peritoneal cavity.

Lastly the X-ray has recently been perfected so that with a thorough preparation and a suitable machine the deposits of bismuth may be shown on the ulcer surface, also the shape and size of the stomach itself.

The following table of differentiation will serve to simplify the diagnosis:

DUODENAL ULCER.

- Age 30-50 years.
- Sex—Males.
- Numbers—Usually single, many times latent.
- Pain—Appears late after two hours, eased by diet. Not always referred to middle line. Radiated usually to right side, right costal margin or around to back.
- Season—Seen in cold and wet seasons.
- Tenderness—On right side.
- Cancer in Sear—Uncommon.
- Hematemesis not seen only in connection with malena.
- Malena often, and in excess of hematemesis.
- Symptoms—Orderly in appearance, such as natural history.

Definite attacks, due to recognizable causes, appearing at certain seasons, eased by diet, relieved by alkalies or lavage.

Pain, severe, but bearable; not abrupt in either beginning or relief, chill and sweats not seen; pain never so well localized.

GASTRIC ULCER.

Age—30 years.

Sex—Females.

Number—Often multiple, not so often latent.

Pain—Appears early within one hour, caused by diet, referred to middle line and radiates to left breast and costal margin, and may at times be felt down the arm.

Seasons—Not influenced.

Tenderness—Usually on left side.

Cancer in Scar—Not uncommon.

Hematemesis—Seen frequently.

Malena—Slight and infrequent.

CHOLELITHIASIS.

Such regularity never seen in gall stone disease.

Pain unbearable, abrupt in appearance and abating; food or alkalines do not relieve; chills and sweats as a rule.

Pain in right shoulder blade.

Malena and hematemesis never present.

Hepatic Cirrhosis: A careful inquiry into the anamnesis will clear up any doubts as a rule.

TREATMENT.

Any condition that threatens life in the proportion that ulcers in this area does, must be carefully and conscientiously considered before any line of treatment is even suggested, and especially the operative treatment necessary for relief. Both the internist and the surgeon claim certain of these cases. But all agree that medical treatment should be suggested in early or acute cases (of course not those that have perforated). All likewise agree that surgical means should be employed in the chronic and the stubborn cases. Moynihan advises operation in all cases where there has been repeated attacks, or where hemorrhage has occurred, or motor insufficiency is present.

The indications for any surgical treatment of gastric ulcer, according to Einhorn are as follows.

1. In large, recurrent gastric hemorrhages threatening life, the ulcer ought to be excised in the interval and a gastro-enterostomy established to prevent renewed hemorrhage.

2. Small losses of blood that cannot be checked and endanger life through their persistence require similar treatment.

3. Perforation of the ulcer demands always immediate operation (excision or in-

vagination of the defect and suture) as soon as the diagnosis has been made.

4. An ulcer situated at the pylorus and attended with peristaltic restlessness of the stomach and continued hypersecretion.

5. Advanced stenosis of the pylorus requires gastroenterostomy.

6. Duodenal ulcers accompanied by pylorospasm and beginning peristaltic restlessness of the stomach.

7. Gastric ulcers with formation of a tumor, no matter where the seat (pylorus, small curvature, etc) always demand gastroenterostomy, usually with excision of the tumor. If this tumor is situated in the lesser curvature and cannot be resected, it is still curable in case it is caused by simple connective tissue proliferation caused by ulcer formation.

Personally I do not believe that the acute ulcer should be treated surgically unless it is to relieve such complications as hemorrhage, obstruction, or perforation. Two things must be kept in mind in advising surgical intervention:

First, surgery is mechanical and must benefit in a mechanical way.

Second, not all cases are cured by surgery that submit to operative work. Many ulcers continue to give trouble after operation.

In those cases presenting the group of symptoms above outlined, giving us the so-called "acute abdomen" it seems to me that operation is imperative and should be done at the very earliest possible moment. We can make no mistake by opening, even though in doubt we will find the appendix involved most often, second, the duodenum, third, acute pancreatic perforation, fourth, perforation of the stomach or of the gall bladder (W. J. Mayo, *Journal A. M. A.*, July, 1913, page 38), all calling loudly for surgery, then why wait? All such cases should receive surgery within the first twelve to eighteen hours. Close the ulcer, or plicate the duodenum to obliterate its lumen and fortify the area with the gastrohepatic and the gastrocolic omentum. Make drainage for the stomach by gastrojejunostomy and drain your cavity and you will save the lives of those you have been losing. Surgery fails in its efforts directly in proportion to the length of time that intervenes between the initial seizure and the execution of the operation.

To summarize: The surgeon should operate in the following cases: First, when the symptoms are long continued and do not yield to medical treatment, and particularly when profound anaemia is resulting from the repeated hemorrhage. Second, to control bleeding that threatens life. Third, when perforation has occurred. Fourth, to treat subphrenic and

other abscesses that occur as complications. Fifth, to relieve constriction of the pylorus or an hour-glass contraction. Sixth, to relieve various indefinite symptoms, not necessarily due to the existence of the ulcer but following the healing of one. These symptoms are generally due to adhesions which either alter the direction of the pylorus, constrict the stomach, or tie the organ down to surrounding structures.

DISCUSSION.

William H. Wathen, Louisville: The subject of ulcer of the stomach and the duodenum and the pathology of gastric ulcer and carcinoma have been very carefully reviewed to-day, so that there is but little left for me to say. In methods of diagnosis and treatment of diseased organs in the abdominal cavity, much progress has been made during recent years. This has resulted from the direct inspection of the organs in the abdominal cavity, and the pathologic examination of specimens removed during the last few years. Cases of medical diagnosis of gastric ulcer are more often incorrect than they are correct, as has been shown by the work of Moynihan, where in over 50 per cent. of operated cases of medical diagnosis there was no ulcer in the stomach, and the pathology was usually found in the appendix. There is no way then of knowing positively the pathology of gastric ulcer or duodenal ulcer until the abdomen is open. It is difficult often to differentiate between gastric ulcer and appendicitis. There is often the association of appendicitis with gastric and duodenal ulcer and gall stones, so much so that there seems reason to believe that there is some etiologic connection. The acute ulcers per se are not the ulcers we are talking about, but the chronic callous ulcers. In acute ulcer, unless complications arise, the cases are seldom surgical, and they are very often or generally of septic origin; these cases usually

recover or die within a few weeks. These are not the ulcers that cause the chronic callous ulcers in the stomach or the duodenum. In callous ulcers we find one situated in the stomach, and three in the duodenum. We were told in the past by various internists, of whom Fenwick is a fair example, that there were ten ulcers in the stomach and one in the duodenum. Now we know there is about one in the stomach and three in the duodenum, just as we find 90 per cent. of duodenal ulcers in the first inch of the duodenum, and about 90 per cent. of gastric ulcers in the small curvature of the stomach in the pylorus. Ulcer in the last portion of the pylorus, known as the pyloric canal of Jönnesco, is seldom seen.

There is no curative treatment for chronic callous ulcer except surgery. Medical treatment may mitigate the symptoms, but it does not cure these cases. Medical treatment, if we go too far with it, sometimes injures these patients, because serious complications may develop. Rest of mind and body, proper diet, good hygiene and sanitation will do about as much as any medical treatment. In many of these patients, especially the duodenal cases, the symptoms will spontaneously disappear, to return in regular order. Patients should be carefully watched by a competent person, and should not be permitted to continue until there is obstruction with food retention, or there is danger of perforation with probably fatal result. The operation should be timely, should not be delayed until complications arise, and now that we have so many internists, who are good diagnosticians, since the surgeon has shown the pathology upon which the symptoms are based, these cases can be referred to a competent surgeon in time to do a proper operation and give the best opportunity for relief. In gastric ulcer it is usually best to excise the ulcer because of its etiologic relation to carcinoma, but this cannot be done in all cases, and if there is any interference with stomach drainage, a gastrojejunostomy is indicated. In duodenal ulcer an infolding by suture may be all that will be required, but if there is danger of obstruction a gastrojejunostomy should also be done. Carcinoma is seldom or never primarily in the duodenum, hence the resection of the ulcer would not be indicated as a precancerous operation. I was especially interested in Dr. MacCarty's paper on the relation of gastric ulcer to carcinoma. His examinations were in operated specimens where you get the pathology of the living at a time when much positive knowledge may be obtained. Pathologic examinations of postmortem specimens are practically worthless so far as giving any facts in the etiologic relation of ulcer and carcinoma, for these patients die of terminal infection and complications that have destroyed the earlier cancer lesions. While carcinoma of the stomach may usually be correctly diagnosed

by the operating surgeon and the pathologist, there are cases where neither know if the disease is benign or malignant, and no one can find the dividing line in ulcer and cancer. It has been shown that cancer on the body probably always develops in a pathologic lesion of some sort, congenital or acquired, then why not believe that this is also true in cancer of the stomach? As these cases are now being operated with less delay, I feel that we will finally show that cancer of the stomach is nearly always developed in a chronic ulcer.

W. W. Anderson, Newport: The interesting and profitable papers we have heard suggest a few thoughts to which I would like to call your attention. They suggest a plea for better service on the part of the general practitioner in making more careful observations, more diligent study of his cases. Let me illustrate what I mean in an extreme degree.

I was called about a year ago in consultation to see a case that gave a history of 20 years of chronic gastric hyperacidity, six years of which gave evidence, according to the history, of attacks of ulceration with hemorrhage, pain, and so on, and the last six months or more obstructive symptoms indicating the presence of cancer, and winding up with perforation and death. Such things ought not occur. A more careful study and examination on the part of the man to whom the case first comes may save many a life in cases of this kind.

Furthermore, I would make a plea for more exploratory incisions in doubtful cases. An exploratory incision in the hands of a competent surgeon is a matter of the least danger conceivable, and is much less dangerous than the continuance of the development of the condition. There should be more exploratory incisions to determine what the real trouble is in the doubtful cases where the disease is confined to these regions. Then a plea for more cooperation in the handling of these cases between the surgeon and the internist. We are now treating cooperatively cases which we did not do before. A case fell into my hands as an internist and was referred to a surgeon for exploratory incision. An ulcer that almost perforated was found, excised, closed, and the case is under our joint observation and care at the present time. And then a plea for more research on the part of the pathologist to determine what is the rock bottom cause of the whole process, for we have not got that yet I think. Is it not true that the majority of these cases give a history of chronic gastric hyperacidity? What is the cause of that? Is it not also true that these ulcers of the stomach and duodenum are usually found to be accompanied by at least local, if not general arteriosclerosis? What is the cause of that? And what is at the bottom of the whole process?

Dr. Wathen in his discussion has said that there is no medical cure for this condition. I would like to ask him, is there a surgical cure either for the condition that is at the bottom of this?

J. Garland Sherrill, Louisville: I wish to emphasize a few points that have been made by the gentlemen who have presented these papers, and one especially, that by Dr. MacCarty as to the difficulty of making a diagnosis or differentiation between benign ulcer of the stomach and malignant ulcer of the stomach. When the pathologist admits the difficulty he has in his laboratory of determining when an ulcer is malignant and when it is benign, we can readily understand how much more difficult it is for the observer with the patient's abdomen closed to be able to make this differential diagnosis, and then when the abdomen is open and under inspection, as surgeons, we are unable to clearly tell whether the case is simply an ulcer or a carcinomatous ulcer. I have had a number of these cases myself which have confused me considerably. Some of them have had infiltration, in one case the infiltration extending well into the liver, and I was positive in my conclusion that the patient was suffering from gastric carcinoma, with invasion of the liver tissue. The patient is well to-day, notwithstanding she did not have an excision of this diseased tissue, but simply a gastroenterostomy. Therefore, I must differ from Dr. Wathen's contention that the only treatment is surgical, or that the treatment for ulcer of the stomach of the chronic type is excision. I will admit that the ideal treatment is surgical for this condition, namely, removal in toto of the ulcerated area, but many of these cases will show a very marked improvement and even permanent recovery from a simple gastroenterostomy. This is especially the case where the ulcer is large, and where the difficulties of its removal are such that the patient will be unable to withstand the operation. These cases have in many instances gone on to cure; therefore, I do not believe it is correct to claim that these cases must be subjected to the removal of the ulcer. I will admit, that when the ulcer can be removed surgically, it is a very desirable thing. I believe also that some cases of even chronic ulcers of the stomach, where the infiltration has not been deep, will get well under properly applied medical treatment. The important thing to all of us, whether we be general practitioners or surgeons, or whether we be pathologists, is to be able to arrive at a conclusion that the patient is suffering from a serious lesion early. Certainly, it is not wise to wait for the development of a mass that can be palpably felt in the abdomen before operative intervention is undertaken. I must confess that in my work on the stomach I have the greatest aid from my confreres on the medical side. The value of

the laboratory research and the examinations cannot be overestimated. We are very fortunate in living in an age when the training of doctors is very much better than it was formerly, thanks very much to your fellow townsman, Dr. J. N. McCormack, who has aided us in this regard. Therefore, we are not so likely to find patients at the present time with a history of 20 or 30 years of chronic gastric disturbance. When I began the practice of medicine, the best of doctors frequently would have patients come into the office and say, "I am having trouble with my stomach," and the doctor would say, "You take medicine and report in the morning." That is all the examination or advice the patient received. At the present time no man has received proper education who has not thoroughly examined the patient physically and also gone into the question of stomach analysis, the analysis of all secretions, and has used the X-ray when it is indicated, and finally performed a surgical operation if it is necessary.

Louis Frank, Louisville: I would like to say a few words on this subject. I think to-day there is practically very little difference of opinion as to the line of treatment that should be carried out in chronic ulcer of the stomach. Thanks to the work that has been done very largely in this line, particularly at the Rochester Clinic, by Dr. MacCarty and his confreres, we know the ultimate termination of ulcers, benign though they be in the beginning and for a number of years, is from a clinical standpoint carcinoma. There can be very little doubt I think in the minds of any of us, either from the medical or surgical side as to the necessity in a certain class of cases of surgical treatment. I say a certain class of cases because medical men insist, some of them particularly, upon giving these cases without reference to chronicity, a six week's course of medical treatment. It is a very difficult thing to tell which are early cases, which are late, which have already undergone cancer changes and which have not. I am afraid of those men, and I think statistics, such as reported by Dr. Lucas, would tend to show that this sort of thing is all right. If they get only the early acute cases doubtless many recover under a course of medical treatment, but how are we to say how long the patient has had a gastric ulcer when he comes to us. Acute ulcer so recognized should be treated first medically, but should we subject all cases, because they have not been previously under medical advice to a six or eight week's course of treatment before advising more radical treatment? I hardly think so. There is no one who has more deference for laboratory work than I. All of our cases are subjected to a careful laboratory examination, but I believe in this particular field of diagnosis, in this particular field of surgery, we have been taught to depend too

much upon laboratory diagnosis. It has been at the expense of the clinical study of the case. Personally, if I had to depend upon the clinical history, or upon a laboratory report, I would prefer by all means the clinical history. The clinical study of the previous history of the patient, going back over years is of most value. This, in most instances, is sufficient with your physical examination, exclusive of laboratory findings, to enable one to make a diagnosis, and the treatment will depend upon one's judgment as to the duration of the disease. We want early treatment in these cases, surgical as well as medical. Early treatment as early diagnosis, depends upon getting a careful clinical history of the case, the anamnesis of the patient, and in this direction we have many of us been very derelict. We do not go into these cases carefully. We may spend a day or two in taking the clinical history which is frequently insufficient. Things will be brought out on the fourth or fifth day which you will not get in the first or second day's history. Careful history of the patient is a most important detail of diagnosis of these lesions, and then not too long with medical treatment. Do not wait for too many classical signs. We have the same things arise here which we speak of in connection with gallbladder disease. Someone wanted to know of Dr. Mayo how he found gallstones, and he replied, "We look for them; we know how to recognize them." So to-day I am satisfied that many cases of gastric ulcer are treated for chronic hyperchlorhydria. Every case of chronic dyspepsia or chronic indigestion means, as a rule, some organic disturbance, and not purely a functional disease. These are most often ulcers, duodenal or gastric, gallstones or appendicitis, all of which are best treated by prompt surgery. We believe then that all chronic gastric symptoms should be viewed from the standpoint of a surgical lesion. Ulcers, acute, medical treatment and rest for six to eight weeks, if recovery ensues watch for a relapse. Relapsing cases of ulcer, and chronic ulcer should all be subjected to early or immediate operation after the diagnosis is made as all non-acute ulcers of the stomach and duodenum are potentially carcinoma.

C. G. Lucas, Louisville, (Closing the discussion on his part): I think Dr. Anderson has touched on a very important point, that these cases need study. There is no question between the internist and surgeon as to what is to be done with a case of duodenal or gastric ulcer when the stage of obstruction of the pylorus has been reached. It is not our fault; we do not take all the blame. Patients take too many patent medicines. When a man comes to me, who has been losing flesh and lost a great deal, who has visible peristalsis, I never delay, I turn the case over to a surgeon within twenty-four hours. When a patient comes to me complaining of pain and hyperacidity, I

should like to examine his stools, examine his blood and urine, and put him to bed and see what results I can get.

I have a man who for fifteen years has had constant symptoms referable to his gastrointestinal tract. He was opened up under a diagnosis of gallstones, but no gallstones were found, but he did have a large duodenal ulcer the size of the tip of my finger. His condition was so bad that we thought nothing could be done for him from an operative standpoint. For fifteen months he has been in better shape than in the past fifteen years. I spoke to him with reference to having a gastroenterostomy done, and he says that he is in too good shape to consider it.

If we take these cases as they come to us, we do get some results from medical treatment, if we study them carefully. If a man has been suffering for ten or fifteen years, six week's medical treatment may put him in better shape. If he has occult blood in the stool, at the end of six weeks, then we should call in a surgeon and say we have such a case, and now is the time for him to take charge of it. I do not think we should let them suffer for ten years and then shove them over to the surgical clinic and have them operated on.

William Carpenter MacCarty, Rochester Minnesota, (closing the discussion on his part): There is really nothing for me to say after listening to these excellent papers and the very fine discussions upon the subjects.

I do not believe that there should be any discussion regarding the question of treatment of acute gastric ulcer, chronic ulcer and carcinoma. There is really no chance for discussion. If I had an acute gastric ulcer and thought it had perforated, I should send for a surgeon. If I had an ulcer which had been acute and had become chronic for several months, perhaps one or two years, or if I had an acute ulcer that had not perforated, I should not allow the surgeons to operate upon me but I would have a good internist put me to bed and give me some of his dietary and rest treatment. But if the ulcer remained for several months or for several years, then I would leave the internist and go to a surgeon, and have him explore to find out, with the aid of a cellular pathologist, whether I had chronic ulcer or carcinoma.

I wish to thank the members of the Kentucky State Medical Association for allowing me this great privilege of visiting my old state and meeting so many fellow Kentuckians in the profession.

A. D. Willmoth, (Closing the discussion): There are two or three points I would like to touch on, and one is the exploratory incision. I think the sooner we come to the point where the internist and surgeon both advise that an exploratory incision be made, the sooner we will be able to relieve many of the conditions that go on

to a fatal termination in people's abdomens that otherwise are obscure. An exploratory incision in a well regulated hospital made by a competent surgeon, who knows how to do abdominal work, can do absolutely no harm except to put the patient in bed for a few days, and he is satisfied of knowing what is there, and if anything can be done, he is satisfied that he has given himself every possible chance of recovery.

I want to call attention to one fact, and that is that all ulcers in the stomach or all of them in the duodenum are not all large ulcers that you have seen exhibited here this afternoon. That has been proven by Dr. William Mayo, who called attention to this in his last collection of papers, that many of the ulcers from which terrific hemorrhages occurred were linear ulcers, and we should look out for mere fissure whenever we operate. It being merely a fissure in the mucous membrane through which blood is coming and would have to be inspected closely, or one would open up the stomach or duodenum, as the case may be and overlook the ulcer completely. I would call attention to the fact that when you make an exploratory incision, do not overlook one of the small ulcers of the linear type that is giving trouble.

As to the incision of the ulcer, Dr. Sherrill spoke in very emphatic terms and very wise terms when he said that not all ulcers can be excised. Many of the ulcers we find so located that an excision would be fatal for the patient. These cases can be drained as suggested, and the patient will make a recovery, and the ulcer will heal, and the patient will die of some intercurrent trouble.

Fracture of Hip, Intracapsular.—Treatment.—Longitudinal traction alone often unsatisfactory in results. Longitudinal combined with lateral traction, however, or wide abduction in plaster of Paris, usually gives serviceable limb. Former far easier to apply and the more suitable the older the patient. Plaster-cast method requires much skill in application, and is better adapted to young patients.—Davis.

Gangrene.—Treatment.—Alternate hot (95 degrees F., gradually raised to 131 degrees F.) and cold (room temperature) baths up to knee used with success in a case of sclerotic gangrene of leg. Pain relieved and normal color regained. Alternate immersions practised 30 to 50 times, morning and evening for over a year.—Borchardt.

DIAGNOSIS IN GENITO-URINARY DISEASES: ITS NEGLECT; ITS URGENT NECESSITY; METHODS BY WHICH ITS REQUIREMENTS MAY BE MET.

By BRANSFORD LEWIS, St. Louis, Mo.

If I should recite the history of a patient who suffered for a year and a half the tortures of unappeased desire to urinate; who strained in repeated efforts to relieve an inflamed bladder and urinary tract; who during that time lost his general health; lost his means of livelihood; expended most of his money; received treatment during all of this period at the hands of practitioners of recognized standing, and at the same time if it were shown that all of his suffering came from the presence of two stones in his bladder that might have been detected in a few minutes' examination, but that such examination had never been made; if it were understood that so large an amount of suffering came from so simple a cause and one as readily relieved as that of stone in the bladder, I believe that you would agree with me, that this patient had not received his just deserts in the way of medical attention.

If I should relate the histories of four patients that suffered similarly, but from a different cause, namely, stones in the kidney; whose lost health and complaints had existed from fifteen to thirty years; who during these periods had been through the hands of twenty or thirty physicians in different parts of the country, all of whom had given prescriptions in lieu of treatment but had never subjected the patients to any form or method of examination, I believe you would agree with me, that these patients had not been dealt with as they should have been dealt with by those who received their confidence and their money.

If I should mention individually three or four hundred genito-urinary cases, human beings that suffered the pangs incident to urinary inflammations, infections and obstructions of various sorts, and who suffered this for indefinite periods of time, because the diagnoses were not made clear by any definite methods of examination, I believe you would agree that they, also, were not receiving a square deal in medical service.

Do not think that I am drawing on my imagination in these allusions. Please do not think I am sentimental for effect. These are

actual conditions that could be observed over and over again, time without number, every year in the practice of the genito-urinary surgeon.

If this be the case, let us arrive at an understanding of the situation, an acknowledgment of its appalling frequency and useless suffering on the part of humanity, and let us adopt methods that will obviate at least a large portion of such suffering. Introspection, now and then, should be relished by the wisest men.

In the first place let us agree that the history of genito-urinary cases and the symptomatology does not enable the practitioner, even the most expert, to make diagnoses of genito-urinary conditions. Symptomatology is unreliable and notoriously misleading for that purpose. The patient with right-sided kidney disease may have all his pain reflected into the left renal region; a kidney may become completely destroyed by a stone developing in the cortex and never a symptom of pain or distress in the years of its destruction; the stressful symptoms of urgency and frequency may be attributed by symptomatology to disturbance at the vesical neck, when, in fact, the origin of this distress may be located in the front or back part of the urethra, in the bladder, in either ureter, in either pelvis or either kidney. How farcical, then, and how futile to rely on symptoms to lead us to a correct interpretation of a case and its appropriate treatment. Let us agree that a reliance of this sort is out of the question.

What are the means and methods that will attain satisfactory conclusions regarding diagnosis, and lead us to success in treatment, instead of gently paving the way to the grave for confiding patients?

The means and methods of the present day are clear cut, are ample and well understood by those who practice examination and the use of various instruments of precision. Investigation along these lines will afford, in a few minutes, more useful and tangible information than one can get by studying the symptoms of a case for months.

To object that such instruments and methods are not within the possession of all practitioners, is to beg the question and does not make a material objection. The ophthalmoscope and X-ray machine are not in the possession of all practitioners, and moreover, they are not capable of being used by all practitioners; nevertheless they should be used on all patients who require them, whose eyesight is to be saved by the one, or whose life is to be saved by the other, and the physician who accepts a patient without giving him the bene-

*Read before the Kentucky State Medical Association, at Bowling Green, Tuesday, September 2, 1913.

fit of the use of such devices is not dealing justly with his patient.

If we agree in these premises, and the conclusion to which they irresistably lead, let us briefly review the means and methods that will give us satisfactory service for diagnosis, and take a glimpse at the widely varying pathological condition of the genito-urinary tract requiring differential diagnosis and appropriate treatment.

In the ensuing illustrations the steps of cystoscopy and ureteral catheterization are shown; the various positions of the instruments and the views obtained by the operator are given. They include, also, illustrations of the methods of applying high frequency electricity through the cystoscope to benign tumors of the bladder, and views of successive stages of recovery from such tumors under the influence of this method of treatment.

Illustrations of various pathological conditions connected with the bladder, the ureters, the pelves and the kidneys conclude the series of slides.

COUNTY SOCIETY REPORTS

Boone—The Boone County Medical Society held its regular monthly meeting at Burlington, on December 31st, 1913. The society met with the secretary, M. A. Yelton, who entertained with a banquet at the Boone House.

C. M. Friche, of Cincinnati, read a very instructive and entertaining paper on "Mucous Colitis," and exhibited X-ray plates showing how ptosis of intestines would cause the condition.

J. A. Richmond, of Bellview, read an excellent paper on "Pellagra," and reported a number of cases that had come under his observation while practicing in Southern Tennessee.

The following named physicians were elected as officers of the society for the ensuing year:

President, B. K. Meniffee; Vice President, J. A. Richmond; Secretary-Treasurer, O. E. Senour; Delegate to State Meeting, H. H. Hays; Board of Censors, M. A. Yelton, S. B. Nunnely and J. H. Blackburn.

The next meeting will be held at Walton, January 21, 1914.

B. K. MENIFFEE, Secretary, pro tem.

Boone—The Boone County Medical Society met at Walton, at the hospitable home of B. K. Meniffee. After a bountiful turkey dinner was served, the regular program was proceeded with.

J. E. Grieve, of Cincinnati, read a very interesting and instructive paper on "Heart Irregularities," which was enjoyed by all present.

M. L. Heidingsfeld, of Cincinnati read a paper on the "Diagnosis and Treatment of Skin Cancer," giving us lantern slide demonstrations.

This paper was equally as instructive and interesting as the other.

S. B. Nunnely and **M. A. Yelton** were appointed a committee to draft suitable resolutions regarding the death of the venerable mother of Dr. H. H. Hays, of Bullittsville.

We had the honor of having with us at this meeting, Drs. Grieve, Heidingsfeld, Langsdale, of Cincinnati; Crisler, McKim, Slater and McCord, of Ludlow; Dr. McCullum of Erlanger.

Only five of our own members were present: Drs. Yelton, Nunnely, Richmond, Senour and Menefee.

O. E. SENOUR, Secretary.

Carter—The Carter County Medical Society met in the office of Dr. O'Roark at Grayson, February 10th. Present: J. L. Lyon, Vice-President, Willard; G. B. O'Roark, Secretary, Grayson; J. W. Stovall, W. A. Horton, Grayson; H. B. Fraley, Willard; D. B. Wilcox, Grayson.

D. B. Wilcox read a paper on "What Would You Do?" which was highly appreciated. The doctor has a way of putting things all his own, that makes all his articles read like romance. I have often thought that if medical literature was worded as he words them, that they would be read with greater avidity and interest. He actually makes belly ache sound like belly ache. You can just see the contortions.

H. B. Fraley reported a case of septic cord, which was discussed at length.

G. B. O'Roark reported a case of probable brain tumor, and a case of congenital hernia.

On the whole we have a very interesting meeting. The boys are enthusiastic and are anxious for the weather to clear up that more of the members might attend.

Officers for 1914, were elected as follows: T. Bays, President; G. B. O'Rourke, Secretary-Treasurer; Board of Censors, W. A. Horton, J. W. Stovall and H. B. Fraley.

The next regular meeting will be held at the same place, March 10th.

G. B. O'ROARK, Secretary.

Calloway—The Calloway County Medical Society held its annual meeting on December 10th, 1913, and elected the following officers for the year 1914: President, E. B. Curd, Hazel; Vice-President, B. B. Keys, Murray; Secretary-Treasurer, W. H. Graves, Murray; Delegate, N. G. Evans.

We meet the second Wednesday in each month at 1:30 P. M.

W. H. GRAVES, Secretary.

Franklin—The Franklin County Medical Society met in regular session February 2nd, at 10 A. M., in the offices of Drs. Williams & Mastin.

Present: Drs. Budd, Mastin, Garrett, Wilson, Heilman, Minish and Williams.

After transacting usual business, and discussing clinical cases, etc., the regular essayist, Dr. A. Stewart, being absent and the other essayist, Dr. Budd asked that his paper be postponed till the next meeting, it not being yet completed, his request was granted.

Dr. Minish called the attention of the society to the death of Dr. W. Len Montgomery, which occurred at the King's Daughter's Hospital, January 12th, 1914, after a lingering and protracted illness, in the 61st year of his age. He is survived by his wife, who was married to him in 1879, she being Miss Lowdenback, a native of Owen county, Ky., having lost their only child, a son, twenty-one years of age, in 1904.

Dr. Montgomery was a native of Carroll county, Ky. After his graduation at Louisville University in 1888, he located at Lockport, where he continued in active practice until his death.

He was a conscientious and efficient physician, was much respected by his clientele and enjoyed the respect and confidence of his brethren in the profession, he was a good neighbor, a kind and affectionate husband and friend, a man of generous disposition, just and willing at all times to extend the same good fellowship to all with whom he came in contact, exacting no less from them.

We extend to his bereaved family our heartiest condolence and sincerest sympathy, it is ordered that this memorial be presented to his family and a copy forwarded to the Kentucky State Medical Journal for publication.

U. V. WILLIAMS,

L. T. MINISH,

Committee.

Drs. Minish and Williams having been appointed to prepare this memorial, when presented was unanimously adopted.

After which the society adjourned to meet again March 2, 1914.

U. V. WILLIAMS, Secretary.

Casey—The Casey County Medical Society met in the county court room in the courthouse in Liberty, on Thursday, January 29, 1914. The officers elected for the present year were: W. J. Sweeney, President; W. A. McBeath, Vice-President; Oscar Dunham, Secretary; H. F. Taylor, Member of Board of Censors; W. J. Sweeney, Delegate to the State Society.

A program was arranged for the next meeting which will be held at the same place on Thursday, Feb. 26, 1914. After interesting and encouraging talks in which all members present took part, and in which much enthusiasm was manifested the meeting adjourned.

OSCAR DUNHAM, Secretary.

Fleming—The Fleming County Medical Society met in the office of Garr, Brice & Garr, on December 17th, 1913, at 2 P. M., with J. C. S. Brice in the chair. Members present: C. R. Garr, J. C. S. Brice, T. B. Vice, J. P. Huff, Boone McClure, Clyde Garr, A. M. Wallingford, Jr., Chas. W. Aitkin and J. B. O'Bannon.

Minutes of previous meeting were read and approved.

J. P. Huff reported a case of "Tubercular Laryngitis Complicated with Typhoid Fever." Patient died second day after the fever was normal.

C. R. Garr reported a case of delivery of a woman of her sixth child. The labor was hard and was followed on the second day by a temperature of 102 and a local peritonitis. The patient finally recovered. The cases were discussed by all the members present. In the case of C. R. Garr it was general belief and expression that the source of infection was a pathological condition before and at delivery.

Boone McClure reported a case of "Puerperal Convulsions." Controlled the convulsions in this case with tr. veratrum in fifteen drop doses, hypodermically. The amount of albumen you find in the urine of these cases will not indicate the severeness of the convulsions you are going to encounter.

C. R. Garr: I think the blood pressure of these cases tell us much. It should be looked after.

Chas. Aitkins: I get happy results from Pilocarpin in these cases.

J. B. O'Bannon: I want to insist upon elimination in these cases. I think it is the secret of success. The society then proceeded to elect officers for 1914, as follows: President, Boone McClure; Vice-President, Clyde Garr; Secretary and Treasurer, J. B. O'Bannon; Censor, A. M. Wallingford, Jr.

J. B. O'BANNON, Secretary.

Shelby—The Shelby County Medical Society met the third Thursday in January, 1914, with the following members present: S. L. Beard, F. M. Beard, Eggen, Lawrence, McMurry, Sellers, Hughes, Buckner, Garvey, Nash, Allen and Locke of the State Board of Health.

E. D. Sellers of Fishersville, read a very timely paper on "Pneumonia," that brought out a very full discussion on this interesting subject, every doctor present taking part, showing that the subject of pneumonia has by no means been exhausted as yet and that every physician is keenly alive to the fact that the treatment of this disease is by no means ideal and that but comparatively little progress has been made along the lines of treatment in the last few years.

J. S. Locke reported on the progress of the hookworm campaign in Shelby county, and seemed highly gratified at the cooperation given him

both by the physicians and the laity. The doctor has decided to return in May for a short stay.

Harmon Nash entertained the society with a delightful three course luncheon that was enjoyed fully as much as the scientific part of the programme. For the February meeting Dr. V. R. Jones has promised us a paper on "Anesthesia," which, if it is like the doctor's former papers, will be a treat indeed.

W. E. ALLEN, Secretary.

Pendleton—The Pendleton County Medical Society met at Butler on this date with the following members present: Beckett, Brown, Clark, Cram, Daugherty, Hopkins, Kendall, McKenney, John E. Wilson, Yelton, J. F. Daugherty, Vice-President, elected in the chair.

We had a splendid report of clinical cases, which were discussed freely, and some splendid points brought out. We had only one paper.

C. H. Kendall on "Intestinal Obstruction," which was very good and was discussed by nearly all members present. After which we adjourned to meet the second Wednesday in February, 1914.

W. A. M'KENNEY, Secretary.

Whitley—The Whitley County Medical Society met at Corbin Ky., on February 5th, 1914, at the office of J. H. Parker with the following doctors present: J. H. Parker, C. G. Edwards, B. J. Edwards, C. A. Moss, Wm Cox and Dr. Parker, of Grays, Ky. There were several talks and discussions on medical subjects which were very much enjoyed by those present. There were also several very enthusiastic talks on how to make the Whitley County Medical Society one of the best in the State.

It was moved and carried to have a special meeting of the society at Corbin, Ky., on March 26th, 1914, and invite the county societies of Knox and Laurel counties to be present and make it a tri-county meeting.

C. A. MOSS, Secretary.

Tuberculosis, Articular. Treatment. Thyroid substance indicated in sluggish cases, especially if evidence of thyroid inactivity present. Does should be only 1-6 to 1-2 grain (0.01 to 0.03 Gm.) pro die, and patient watched for tachycardia.—Lereboullet.

Tuberculosis, Laryngeal. Treatment. Submucous cauterization found to heal 70 to 85 per cent. of cases performed with electric cautery. Easier than curettage, and there is no bleeding. Not suited, however, for superficial ulcers on posterior wall, particularly those on the cords, which do better on the old method of lactic acid applications.—Pettit.

NEWS ITEMS AND COMMENTS

Under the auspices of the Georgia Surgeons' Club, a sixty days' tour of the surgical clinics of Europe is being arranged for representative Southern surgeons, to wind up at the meeting of the Congress of Surgeons of North America in London the latter part of July, 1914. Those interested may secure details of the trip from Dr. R. M. Harbin, Secretary-Treasurer, Rome, Ga.

Not suited, however, for superficial ulcers on posing after being confined to the house, and bed part of the time. He having had an ulceration of the cornea.

Dr. W. L. Mosby returned January 4, 1914, from Rochester, Minn., where he had been for the removal of gallstones. He is improving rapidly.

Extra-Uterine Pregnancy.—Chiossone reviews the experiences with extra-uterine pregnancy during 1912, in the women's departments of the ten hospitals of Buenos Aires. There were only four deaths among the 105 cases, and in the fatal cases the women were already infected or exsanguinated. He comments on the variability of the symptoms observed and urges that before any abdominal affection in a woman in the child-bearing age is diagnosed, it is necessary to exclude extra-uterine pregnancy. A doughy resistance in the pouch of Douglas is suggestive of a tubal pregnancy, but about the only positive sign of an extra-uterine pregnancy is the expulsion from the uterus of decidual membrane. An important element in differentiation is a history of some gynecologic affection; the ovum scarcely ever locates outside of the uterus unless there is a predisposition from preceding pathologic changes for the abnormal embedding. Increasing hemorrhage always demands an operation, but if the hemorrhage seems to have stopped he leaves the case to Nature, ready to interfere at need. He gives the details of ten cases; in one the woman passed through two extra-uterine pregnancies. In conclusion he warns that it may be necessary in some cases to be wary in stating the diagnosis of extra-uterine pregnancy, as social and legal questions may be involved. There is always the possibility that the accumulation of blood may come from an ovarian or other tumor in the absence of pregnancy.

Sciatica. Treatment, Good results from X-ray treatment in 11 out of 13 cases. Rays directed usually over lumbar region, sometimes over nerve itself. Small doses only. In cases resisting ordinary medical treatment and galvanic current, radiotherapy should always be tried, especially when sciatica due to compression of nerve-roots.—Delherm.

ANNUAL DUES.

The Kentucky State Medical Association is a chartered body, each member receives his JOURNAL which actually costs more than twice the amount of the annual dues which are \$3.00, and in addition to this are defended from unjust malpractice suits.

Like every other organization which gives something for its dues, they must be paid promptly. Please do not overlook this matter, pay your secretary immediately, clear up this business transaction for the year.

EXAMINATION FOR TYPHOID CARRIERS.

We know that the typhoid fever germ dies after a few weeks residence in the soil, but a new supply is continually being deposited by perfectly well individuals who harbor these germs in their intestines and urinary tract, and are called typhoid carriers. Realizing the importance of discovering these carriers as soon as possible in order to protect the community against an outbreak of this most protean disease, specially prepared containers with minute directions for collecting material will be sent to any physician upon request by the State Bacteriologist, or can be secured at the local depot.

FRESH VACCINE POINTS.

In nearly every portion of the State smallpox is now raging and it is highly necessary that every means for its eradication should be resorted to. Ten thousand fresh vaccine points have been received by the State Board of Health and these will be sent out at any hour, day or night.

It is the duty of every physician in any locality which is now infected with this dread disease to provide himself with these points and should advise that all persons who may be exposed to the disease and those who have not been successfully vaccinated be vaccinated at once. This disease can be only stamped out by prompt action of physicians, and universal vaccination.

The points cost \$6.50 per one hundred. The Board does not receive any money, the account being sent direct to the manufacturer.

TETANUS.

At this season of the year when farmers are beginning their work, wounds from agricultural implements are common, and as is well known these implements are the source from which many of the cases of tetanus originate. Such wounds should be freely opened and thoroughly saturated with tincture of iodine and the patient given 1500 units of anti-tetanic serum, the immunizing dose. This prevents the development of the dreaded disease, lockjaw. If a patient has not received an immunizing treatment and lockjaw develops, it is useless to give small doses of the serum. At least 100,000 units should be injected in divided amounts, 20,000 units every four hours. A case of tetanus in a woman due to an injury of the leg has been reported cured at Hahnemann Hospital, Philadelphia after injection of 85,000 units of the anti-tetanic serum. Another case in our own community was cured. Tetanus developed eight days after a gun shot wound, 125,000 units of the serum was given during a period of three days. The patient made an uneventful recovery. This serum can be procured at the State Laboratory at a very reduced rate.

EARLY DIAGNOSIS OF TYPHOID FEVER.

The physician who has to treat a case of typhoid fever desires to know as soon as possible whether his patient has the disease. There are many cases of fever which in many of its symptoms simulates typhoid that the physician for several days is in doubt as to the nature of the case. Every physician in the State has the benefit of the best equipped bacteriological laboratory in American for an early diagnosis, or he can provide himself with the necessary material to make an immediate test at the bed side for this disease by means of Ehrlich's diazo reaction. This reaction has the following advantages: It can be easily and rapidly completed, requiring only about five minutes time. It requires little material, two or three test tubes and three different solutions.

The reaction is present in nearly every case of typhoid and is specific from a practitioner's standpoint. This reaction may differentiate between a relapse and a complication when other signs fail. This test has its disadvantages.

1. It is not absolutely pathognomonic.
2. It is not always present but the percentage of cases in which the diazo test does not respond is small.
3. It occurs in some other disease especially in acute miliary tuberculosis, but in acute cases of this kind the reaction is rarely, if ever, present during the first week. A specimen of urine should be sent to the State Laboratory within four or five days for the diazo test. The Widal reaction which is used in most hospitals and clinics has its advantages and disadvantages.

First as to its advantages:

It is pathognomonic of enteric fever, thus differentiating it from acute miliary tuberculosis.

It may respond when the diazo test fails.

Its appearance serves to complete the records of hospitals, Vital Statistics Department, etc.

Its disadvantages are:

It is of little or no prognostic value because it does vary or reappear with a relapse. It usually appears late. Some observers do not recommend its use until the second week. It is not always present in true typhoid and a negative reaction does not imply that the patient has not typhoid. A specimen of blood should be sent to the State Laboratory within eight or ten days for a Widal test. The observations of those who have used both the diazo and Widal tests are that where an early diagnosis from a therapeutic standpoint is most important the diazo reaction occurs in

much higher proportion of all cases than does the agglutination test, and is present on the fourth or fifth day. The following table of comparisons are given from "Williams and William's Laboratory Methods."

DIAZO

1. Appears early in typhoid, about the 5th day.
2. Reappears with relapses but not with complications.
3. Technic rapidly completed.
4. Does not differentiate acute miliary tuberculosis.
5. Not always present.
6. Occurs in other diseases not easily confused with typhoid.

WIDAL

1. Appears in typhoid, after the 8th day.
2. Relapses do not influence the test.
3. Technic in simple form takes several hours.
4. Not present in acute miliary tuberculosis.
5. Not always present.
6. Occurs in no other disease.

Therefore physicians should not be surprised that some reports from a laboratory should not give favorable indication of typhoid even though it be a true case and especially they should not expect a reliable report from the Widal when the specimen is sent in within a few days after the disease appears. Every physician should provide himself with the necessary outfit for sending a specimen of urine to the laboratory for the diazo test and after a sufficient length of time has elapsed to make a Widal reaction of value, a specimen of blood should be sent to the State laboratory for confirmation.

HOSPITALS.

The American Medical Association is making up a list of hospitals, furnishing acceptable internship for medical graduates. It will be very creditable to hospitals to be included in this list. None except of the best moral and medical reputation will be listed. If any reader of the JOURNAL is connected with a hospital of this class, which accepts internes, he is urged to correspond at once with Dr. N. P. Colwell, Secretary of the Council on Medical Education, of the American Medical Association, 535 North Dearborn Street, Chicago.

The investigation of hospitals by the American Medical Association is to be most highly commended. Too frequently, grave abuses have crept into the management of such institutions and it is highly desirable that they be investigated in a constructive way by experts as it is proposing to do.

SCIENTIFIC EDITORIALS.

WHAT WE KNOW ABOUT SCLERODERMA.

Pikeville is trying its best to be on the map. The newspapers have been working overtime to advertise Pikeville not for its wonderful location, fertile soil, mineral wealth or its beautiful women, but because it had a case of scleroderma, a disease hitherto unknown (?), wonderful (?) and puzzling (?). It is really ridiculous how a newspaper will take up a medical subject that is well known and speak of it as a disease that was never before known.

Is scleroderma so rare, so puzzling, so wonderful? Kaposi, in his text-book, says: "Although scleroderma on the whole is rare, still a sufficient number of cases are reported in literature, and there is no reason for publishing every case. I myself have seen a relatively large number of scleroderma cases, according to recent calculation, probably between 150 and 200 cases." p. 455.

Every dermatologist and practitioner runs across cases of scleroderma and the disease is not so mysterious.

The Pikeville case being of a child, may not be a real case of scleroderma. There is a disease among children that is almost analogous to scleroderma and it is called sclerema neonatorum. This disease may be present at birth or appear the next ten days after birth. The skin becomes of a pale, white or waxy color and has the feeling of hard leather. The disease, as a rule, commences at the lower extremities, spreads upward over the trunk, especially on the back, then, gradually over the rest of the body, the face, usually, being the least affected. True scleroderma, a disease mostly met among adults, usually starts on the face and upper part of the body. I don't see why the country physician should find this disease so puzzling. Its symptomatology is such that it is very easily recognized. At the last meeting of the American Medical Association, as in many former meetings, three cases of scleroderma were exhibited. Nearly every hospital, having a clinical out-patient department, will record cases of scleroderma. It is due to the lack of knowledge of dermatology among our students that such cases are not recognized. The student should be made to realize the importance of dermatology. Blunders are made quite often. We can recall cases of bromide eruption passed for small-pox; cases of mycosis fungoides and Raynaud's disease, for leprosy; on the other hand, cases of leprosy treated for syphilis; local tubercular affections treated for syphilis, etc.

For the sake of those unacquainted with the

chief characteristics of scleroderma, we will give a short resume of the latest findings in regard to this disease. According to the latest theories, this disease is not only of the skin, but of the whole organism, in which the fibroplastic process affects not only the skin, but salivary glands, axillary glands, bones, muscles and internal organs.

Scleroderma may be limited only to a certain area (*scleroderma circumscripta*), and the generalized or symmetrical type. The first form is not so serious and is amenable to treatment, while the latter form is, in the majority of cases, fatal. It usually starts on the hands or face, seldom on the feet, and it is usually of a vasomotor disturbance. It usually starts with Raynaud's symptoms of local asphyxia and local syncope, the process gradually going into hardening. The fingers usually get thin and shiny, immovable, covered with sclerosed skin and resemble a nail-mass (*sclerodactylia*—Bull's). Later on, shortening of the phalanges is noticed (*mutilatio*).

The histological examination throws very little light upon the etiology of this disease. The epidermis is scarcely changed; the subcutaneous tissue is firm and condensed, though no round-cell infiltration is present. The skin does not pit and cannot be pinched up. The contraction of the skin leads to disappearance of wrinkles; old persons looking younger than their years. We may fear that fashionable old women learning of these facts may be anxious to have scleroderma.

It is acknowledged that scleroderma cannot be connected with infectious or constitutional origin (*podagra*). We are rather inclined to think it is due to disturbance of the functions of some glands. At times we notice its similarity to Basadow's or Addison's disease; neither can you deny its relationship to myxedema.

Since the real etiology of this disease is unknown, some authors try to attribute it to nervous origin. Polotebney, who has made a special study of the etiology of scleroderma, claims it to be of angio-trophoneurosis.

The prognosis is rather unfavorable. Electricity, massage, roborant treatment, and thyroid extract have been found useful.

M. L. RAVITCH.

THE USE OF RADIUM IN LARYNGOLOGY.

In a review of the literature to the use of radium since its introduction in medicine in 1900, Prof. Rethi of Vienna credits A. Exner with its introduction into laryngology.

In 1903, Exner reported two cases of carcinoma, one at the angle of the mouth and the other on the faucial pillar, both of which

were cured by the use of radium. Since then it has been frequently applied in the Vienna throat clinic with varying results.

Its application in lupus and tuberculosis of the mucous membrane has met with favorable results by only a few—the most observers having reported failures.

In scleroma the results have been uniformly good. The results in papilloma of the larynx were also nearly all favorable, though a few failures have been reported. In one case of papilloma, in which radium was applied the growth subsequently became malignant. Polyck and others deem surgery unnecessary in cases of papilloma of the larynx since the advent of the radium treatment.

Radium was frequently applied in cases of inoperable carcinoma. Some of these were reported cured without recurrence—others were sufficiently improved to make the cases operable. On the other hand numerous cases have been reported in which the treatment failed.

Results also differ in the application for sarcoma—some brilliant results and some dismal failures having been reported. In inoperable malignant growths, with recurrent bleeding, marked secretion, foul discharge and pain, radium will in nearly every instance relieve the pain, but there were exceptions here as in the treatment of other conditions.

Excellent results followed the use of radium in teleangectasias and moles. It has also been employed with uniformly good results in scars about the mouth and the nostrils and in stenosis of the larynx and oesophagus, causing softening of the scar tissue without causing inflammation.

The variation in the results obtained by the use of radium depends not only on the extent of the diseased area treated, but also on the amount and radio activity of the rays employed, the method of applying it, whether or not the "cross fire" method is employed, and the thickness and composition of the screen, the size of the applicator, etc. In addition to these factors the susceptibility of the subject, climatic conditions, etc., play a part in the reaction to the radium treatment. Deep seated affections necessarily demand more intense radiation than superficial ones. In the deep seated affections the applicators are screened with heavier lead sheets than in the superficial affections, to absorb the soft rays and exposures, are more prolonged to allow the hard Beta and Gamma rays to penetrate deeper. To absorb irritating secondary rays and avoid painful burns, paper and gauze have been put over the applicator.

In superficial conditions as lupus and tuberculosis large doses applied with or without

this thin screen (platinum) and exposure for shorter periods is advisable. The same method is employed in parts where the applicator can not be applied long, as in the pharynx and larynx. Large malignant growths of the nose and naso-pharynx require intense radiation effect with more prolonged exposures.

In carcinoma radium seems especially to have a selective action affecting the diseased structures favorably without affecting the healthy tissues. It must be borne in mind that the applications applied mildly act as an irritant and rather increase the rapidity of growth and that only the more intense radiation is of service especially in carcinoma of the mucous membrane as throat specialists see it. As it is the deep cells which are not reached by radium treatment all operable carcinomata should be treated surgically rather than with the radium. Those which appear inoperable often improve sufficiently by radium application to become operable. Radium should also be applied at once when recurrence of the growth is noticed. It has also been used after surgical removal as a prophylactic measure. In other words it has been suggested to employ radium more as an aid to surgery than as an independent method of treatment. This is not only true of malignant growths but also of lupus. Radium has been used in malignant growths for purposes other than curative.

In summing up the disadvantages of the radium treatment in laryngology, Rethi speaks of the danger of causing perforation of the oesophagus if applied too long or too severely in strictures or growths. Cases of this kind have been reported by Exner. If the diseased structure involves a large blood vessel it may be eroded by the radium and fatal hemorrhage result. The application of radium in laryngology is especially difficult.

With special reference to the methods of application, Schindler in the October number of *Radium* says: In the mouth cavity the applicator was fastened to a rod of aluminum bronze wire, covered with cotton, the radium or mesothorium being held in place, after having been properly arranged, by having the patient bite on the cotton covered rod. In this way an applicator could be held in place for hours.

Two methods are available to bring the applicators into the larynx and both of these having been utilized. Either the applicator is passed in directly on a flexible rod *per vias naturales* after cocaineizing the mucous membrane, the application lasting as long as the effect of the cocaine makes it possible; or else the applicator is introduced directly into the larynx after a laryngo-fissure has been made.

In applying the radium within a tumor or in artificial openings the applicator must be covered with a sterilized rubber finger cot, which is finally disinfected with tincture of iodine. For the oesophagus a bougie was used into which the mesothorium applicator could be passed.

ADOLPH O. PFINGST.

LIFE AFTER DEATH.

“So when this corruptible, shall have put on incorruption,

And this mortal shall have put on immortality,

Then shall be brought to pass the saying, that is written

Death is swallowed up in Victory.

O! Death, where is thy sting,

O! Grave, where is thy Victory.”

Maurice Maeterlinck has written some interesting and beautiful books. His “Life of the Bee” and his “Blue Bird” are too well known to need comment and we were, therefore, much interested in a recent article of his appearing in the Century Magazine, with the above title. There is no question but that Life after Death is a debatable phenomena, usually spoken of in such terms as “spiritualistic,” “psychical,” etc., and perhaps a review, at the present time, of the attitude of this thinker, may not be amiss.

The physician, in his view of life, may see a great many cases where the spirituality or “soul-life” of the patient is promptly brought to view, but despite all of this and despite his high ethical and idealistic view, he is bound more or less to view life and spirit from a rather materialistic and deterministic standpoint. The physician is closely in touch with human life; it becomes his duty to watch it from the hour of conception; from the first faint wail that announces another spirit’s advent into this vale of tears, to the time when, with the last gasp, the weary lay down their burdens and sink peacefully to rest. No true physician, but what feels that his real endeavor in life is to mitigate suffering, relieve deformity, prolong life, increase the sum total of human happiness and to never do aught or otherwise to take or lessen it.

There are times when, even in spite of all his training, there comes to him a feeling, that he would like to see a suffering soul relieved from its mortal chamber and wafted down the stream, over those dark waters and to that unknown land, peopled with the radiant hope that makes life worth its living and death worth while the dying. But *cathanasia* is forbidden and he must bear, together with the sufferer, part of that burden, giving to him freely of his sympathy, fortifying his moral

character, that burdens seemingly too hard to bear may be lifted and lightened.

How wonderful! How marvelous! is that process of conception, wherein a human life is to spring into existence. What is Life? What is Death? What does Death mean? Where do we go? Where is hell and where is heaven? These are problems that occupy many minds, in many ways and indeed we really do not know what is life and what is death, but we speak of them only in known phenomena. Life is the activity of phenomena; death is their cessation. But a definition of this kind is so unsatisfactory that one hardly cares to waste the time to consider it.

“To every man upon this earth
Death cometh soon or late,
And how can man die better
Than facing fearful odds
For the ashes of his Fathers
And the temples of his Gods.”

—Macauley, Lays of Ancient Rome.

Have we from the finite, the materialistic standpoint ever really learned one single, solitary, definite thing or idea about heaven or hell? Religion does not tell definitely concerning these things nor has one traveler come back from that bourne to tell us of its horrors or its beauties, but we are bouyed up and sustained in life by the belief that such states or places exist. Man has tried to pass beyond the border line of life, to delve into the unknown regions where death has held sway and has passed judgment oftentimes on vague proofs, derived from super-normal (?) manifestations supposed to be found in telepathy, hypnotic sleep, phantasms and other phenomena produced by mediums.

Maeterlinck seems to think that it is a well established fact that a spiritual or nervous shape, an image, a belated reflection of life, is capable of subsisting for sometime, or releasing itself from the body or surviving it, of traversing enormous distances in the twinkling of an eye, of manifesting itself to the living and sometimes of communicating with them. The appearance of these apparitions is very brief and they are said to take place only at the precise moment of death, or very shortly thereafter. It might be here observed that instead of possessing a greater power, a greater spirituality, after the soul has become rid of the effete material of the body it seems inferior than when matter surrounded it, even tormented with trivial cares.

Do these spirits fret over their former corporeal existence, do they live around us without man perceiving them, despite their endeavors to make themselves known or to give us an idea of their presence? Or is the fault our own, in that we have no special organ of

vision by which we would be able to see them in their spiritual body?

Unfortunately, we are in the position of being materialistic and cannot but believe that these spirits and the spirit phenomena that have been observed are capable of another interpretation.

"Strange—is it not?—that of the myriads who

Before us passed the door of Darkness through,

Not one returns to tell us of the road,
Which to discover we must travel too."

—Omar Khayyan-Rubaiyat.

Many believe in these strange and unparalleled occurrences which they are pleased to call "facts" and which they believe to come indisputably from the other world. They base their "facts" upon a faith that they have in a medium, who they believe possesses extraordinary powers of looking into the future, a power of distant perception, a subliminal clairvoyance. But in the past these mediums have many times practiced deception. Insofar as we can view this matter, we cannot agree with the distinguished Belgian author, for the proof must be more decisive and we must have better witnesses than mediums, for we are greatly inclined to believe that

"The Gods conceal from men the happiness of death that they may endure Life."—*Lucan*.

and that while

"Death is the Golden Key that opens the palace of Eternity."—*Milton*.

still the only safe course that one can pursue, is to eliminate every living link.

We have no definite information of the future, nor do we know really what the soul is. To my mind, viewed from the medical and practical side, the *soul*, or better the "soul-life" of the individual, represents all those higher yearnings, those ideal and altruistic longings, that actuate and perpetuate the very best there is within us, whether this be brought about through general or special religious beliefs. We have all felt at times, like the melancholy Dane,

"I do not set my life at a pin's fee;

And, for my soul, what can it do to that,

Being a thing immortal as itself?"

—Hamlet, Act I, Scene IV.

Do the newly dead have to grapple with a fresh problem, with a new mode of existence, have to re-orient themselves as do we with a new life before they can adapt their souls and spiritual bodies to their new life, to their new reality? This would not at all harmonize with the Christian's idea of a re-birth, a springing from a terrestrial life, full armed,

cap-a-pie like Minerva, in the shape and into the presence of his Maker.

I believe that the thoughtful man would much rather know that he knows nothing than to feed himself upon the husks of an illusory and irreconcilable assertion. "I do not ask that they shall reveal to me the secret of the universe, for I do not believe, like a child, that this secret can be expressed in three words, or that it can enter my brain without bursting it * * *. For this secret must be as infinite, as unfathomable, as inexistent as the universe itself. * * *. I do not doubt that the facts reported are genuine and true; but what is even much more certain is that the dead, if they survive, have not a great deal to teach us, whether because at the moment, when they can speak to us, they have nothing to tell us, or because at the moment when they might have something to reveal to us they are no longer able to do so, but withdraw forever and lose sight of us in the immensity which they are exploiting."

But how will you explain these things? Is it unconscious reminiscence; if you will, suggestion at a distance, subliminal reading; an attempt to drag, by main force into the riddle, which seen from our side of the grave, is dark and impassioned enough as it is. What say the spiritualists? "If you refuse to admit the agency of spirits, the majority of these phenomena are absolutely inexplicable." Agreed, nor do we demand to explain them, for hardly anything is to be completely explained upon this earth. A large amount of interest is manifested in this phenomena because of curiosity and in many instances these manifestations are no more marvelous than some of those scientific *facts* which we have learned to use in our daily life without marveling at. Are these spiritualistic facts any more interesting, any more wonderful than our memory, our intellection, our imagination, our emotion, or some of the physical phenomena of chemistry or electricity. They interest us greatly by an appeal to our imagination.

What do the dead remember of the *old life*? Is memory's tablet blank or can they see and know the old world? With all the power of science and scientific investigation, this belief remains with many and has not radically confounded the idea which we are wont to form of death. To my mind Swift has truly said:

"It is impossible that anything so natural, so necessary and so universal as death, should ever have been designed by Providence as an evil to mankind."

They would at best prove, if we were bound to admit to them, that a reflection of ourselves,

an after vibration of the nerves, a bundle of emotion, a spiritual silhouette, a grotesque and forlorn image, or, more correctly, a sort of truncated and uprooted memory, can, after our death, linger and float in a space where nothing remains to feed it, where it gradually becomes wan and lifeless, but where a special fluid, emanating from an exceptional medium, succeeds at moments in galvanizing it. What brings into activity again the memories and the interests that the departed soul possessed in its terrestrial existence? The boldest bridge that men have ever attempted to build across the dark river of death has hardly been started, a single pier has hardly been built and it will take centuries of untiring and thankless efforts, of barren uncertainties behind them before we can hope for results and in the meantime, in joy and gladness, by the will of God and by their own hand many will depart.

“One more unfortunate
Weary of breath,
Rashly importunate,
Gone to her death.”

—Hood, Bridge of Sighs.

We wish to put ourselves unqualifiedly on record and we believe that thinking and scientific men will agree with us, that most, we would like to say *all*, mediums are, by the very nature of their occupation, by the very nature of their faculties, not only inclined to imposture, but their work is, as a rule, premeditated and rank trickery; “moreover it would be requisite for the mediums, who are generally people of merely average intelligence, suddenly to become great poets, in order thus to create, down to every detail, a series of characters differing entirely one from the other, in which everything, gestures, voice, temper, mind, thoughts feeling—is in keeping and ever ready to reply in harmony with their inmost nature to the most unexpected questions.” Ask yourself, gentle reader, how many *mediums* reach the high water level of the foregoing quotation?

On the contrary, we believe that this is largely brought about by unconscious suggestion, either when the subject was in a hypnoidal or hypnotic state, and in which the medium is extremely sensitive to impressions and suggestions, both auto and hetero. Maeterlinck says suggestively “Lastly to provide for every contingency before letting death come upon the boards, it would be necessary to make certain that atavistic memory does not play an unforeseen part. We carry hidden in our being all the past, all the experiences of our ancestors. If by some magic we could illumine the prodigious treasures of the subconscious memory, why should we not discover the events and facts that form the

source of that experience?” In conclusion let us ask ourselves; what have we of *finite, definite, materialistic, human, demonstrable proof? Nothing*. Spirits tell us nothing because they know nothing, and as we have said before, we would much prefer to accept nothing than to delude ourselves by a false belief that alas! too many are considering or actually expecting.

“So fades a summer eloud away;
So sinks the gale when storms are o’er;
So gently shuts the eye of day;
So dies a wave along the shore.”

—Mrs. Barbour, “The Death of the Virtuous.”

CURRAN POPE.

FUNCTIONAL AFFECTIONS OF THE HEART.*

By C. B. JOHNSON, Earlington.

In the short time allowed this very important subject, “Functional Diseases of the Heart,” it is impossible to do much more than merely touch on some of the diseases. It will, therefore, be my object to endeavor to say something that will be at least worth while and worthy of lively discussion.

There is one class of cases I desire to mention at this point and that is those patients who come to the physician complain and insist that they have heart disease when, as a matter of fact, you can not by the most careful examination find any organic or functional trouble. These will have to be placed under the head of hypochondriacs.

Then there is another class of functional disorders due probably to a reflex action, or from a general disturbance from some disease located elsewhere in the body. This class naturally disappears when the disturbing cause is cured.

The class that I will call your attention to is the one which apparently originates somewhere in the cardiac nervo-muscular machinery.

Anatomical disease of the heart may precede a functional disturbance but, on the other hand, a functional disease of the heart may terminate in an anatomical disease.

Doubtless all of you have had patients with organic heart disease when without any apparent cause you are called and find that they have a functional trouble complicating the disease, especially is this the case in overstrung, irritable or depressed people.

We find that those who are most liable to

*Read before the Kentucky State Medical Association, at Bowling Green, Thursday, September 4, 1913.

heart disease are those, who in early life have had neurasthenia or hysteria, or who by their mode of life have subjected the neuro-vascular system to many repeated insults.

In the class of functional diseases will place the following: Those due to certain changes in the blood as is the case in chlorosis, pernicious anaemia or Graves' disease, neurasthenia, tobacco or tea and coffee poisoning, certain gouty, rheumatic or dyspeptic conditions, simple intermittence, palpitation, arrhythmia, paroxysmal, tachycardia, pseudo-angina, angina-pectoris, bradycardia, Stokes'-Adams syndrome.

For us to get a proper understanding of these various diseases we should carefully consider the anatomy and physiology of the circulatory apparatus but will not at this time do so, because it could not be done in the short time allowed me, but would like to call your attention to that portion of the auriculo-ventricular bridge known as the bundle of His. This bundle of muscular fibres, etc., is traced from a point about 10 m.m. beneath the posterior cusp of the aortic valve and continues in a sharp curve over the upper border of the muscular septum between the ventricles and terminates in the muscle of the right auricle and muscular structures in the auriculo-ventricular valve. It is now firmly established that disease or division of the bundle of His is the cause of Stokes-Adams syndrome, or, heart block, as it is sometimes called.

I will only mention the functional diseases of the heart which are found in gout, dyspepsia, chlorosis, anemia, pernicious anemia and Graves' disease, except to say that the tachycardia is not only prominent but one of the most constant signs in the last disease mentioned. It is my purpose to consider more in detail two classes of these functional troubles viz: angina-pectoris and Stokes-Adams syndrome, but feel as if a paper on this important subject would hardly be complete without saying, at least, something about the other troubles so trust you will overlook the fact that none of them are gone into as fully as they should be.

First, let us consider those due to tobacco, tea and coffee poisoning, merely to say that they cause an irregularity and that their effect must be gotten rid of by at least six weeks' abstinence before a positive diagnosis of the cause of a functional disease can be arrived at. This of itself will frequently do away with all symptoms of functional trouble, and if so, the person will exercise excellent judgment in never returning to the habit.

Those troubles that are associated with gouty, rheumatic or dyspeptic diseases should be considered as merely complications of the

original malady and will be benefitted by the use of remedies designed to cure the underlying malady.

Those due to, or complicating chlorosis and pernicious anemia, as well as the other anemias, sometimes should be considered as merely secondary to them and will not be discussed now. We might almost claim that these are merely the causes of functional diseases and to these we will add Graves' disease and neurasthenia. Among the other causes of functional disease we should place these: female sex, diseases of the uterus, menstrual disorders, menstrual period, puberty, menopause, prolonged lactation, following acute or chronic diseases as typhoid fever, erysipelas and rheumatism. The crises of cerebral or spinal diseases, lesions at the base of the brain, neuritis of the pneumogastric nerve, organic nervous disease, melancholia, neurasthenia, mental emotion of some kind as fright, joy, sorrow, expectation and anxiety, petit mal, hysteria, chronic myocarditis, fibroid and fatty heart, valvular disease, hypertrophy, cardiac dilatation, heart strain, atheroma of coronary arteries and aorta, diseases of the stomach including indigestion, dyspepsia, and chronic gastritis, absorption of toxins from the intestinal canal, lead poisoning, tea, coffee, tobacco, alcohol and digitalis, over-exertion, excitement, sexual excesses, masturbation anemia, sleeplessness, uremia, gout and pyrexia.

The intermitten heart seems to be especially common in gouty families and when it appears in persons advanced in years it is an indication that the strength of the heart and of the heart muscle is beginning to fail. This trouble is frequently caused by the excessive use of tobacco and can be found in digitalis poisoning. It is probably produced by the cardiac diastole being prolonged at each beat to such an extent as to occupy the time usually allotted to two pulsations, the pulse will simply be very slow but quite regular. If the diastole of each alternate pulsation be prolonged we get the pulse consisting of two pulsations succeeded by a prolonged interval and so on; according to the diastole that is prolonged we get the intermittence at the 3rd, 4th, 5th, 6th beat, etc. When the intermittency comes on in the course of a severe illness, as typhoid fever, it is a much more serious character and makes the prognosis grave. It is also caused by the same things that produce palpitation, paroxysmal tachycardia and paroxysmal bradycardia.

In functional palpitation the patient becomes unpleasantly aware of his heart by feeling it throbbing. In some cases these sensations are not accompanied by any change in

apex or heart beat and the pulse appears to be normal. In more severe cases the impulse of the heart's action against the ribs is both forcible and hammering while the pulse may be slower or accelerated.

The causes of palpitation have already been mentioned but will call your attention especially to the fact that the tendency to palpitation becomes much greater when the patient has been weakened by debilitated conditions, either mental or physical. Also that irritation of the vagus and vaso-motor nerves, whether central or peripheral, may cause palpitation also reflex irritation of the cardiac nerves as by the distension of the stomach by too much food or gas, and by the presence of indigestible or irritating articles of food, by worms, scybalous masses, gall stones or grit, renal colic or calculi of floating kidney.

One cause which must not be forgotten is the diminished blood pressure which is sometimes caused by Turkish bath or warm foot or general bath or by the removal of fluid in ascites.

Palpitation of the heart is one of the most prominent symptoms in Graves' disease.

Then there is the toxic palpitation which sometimes occurs in gout, rheumatism, constipation, indigestion and more especially the absorption of toxins. From tea, coffee, tobacco and alcohol and even position will sometimes cause palpitation. The symptoms of palpitation come on suddenly with precordial pain or oppression with rapid tumultuous beating, the impulse being visible through the clothing, accompanied by dyspnea, anxiety and a sense of fullness in the throat or choking, the patient being unable to lie down; vertigo, flashes of light and faintness; the face may be pale or flushed and the pulse feeble or strong while the patient believes she is about to die.

Cardiac arrhythmia is a lack of rhythm or an irregularity in the cardiac pulsation. The physician sometimes has great difficulty in explaining the cause and significance of some cases of cardiac arrhythmia because it is a conspicuous sign when there is any irritation of thoracic, abdominal and hypogastric sympathetic chain or the direct nerve supply of the heart or even disease of that organ itself.

G. W. Norris makes five classes of arrhythmia as follows: Juvenile arrhythmia, extrasystole, perpetual arrhythmia, pulsus alternans and heart block. While L. Bard makes a clinical classification which has its advantages in that it indicates to some extent modification of the irregularities according to their dependence on or modification by the condition of other organs.

The progress is more serious when it is of muscular origin than it is when due to nerv-

ous causes. Also the time as when it occurs during convalescence from infections it is of very little importance. If it should occur during the course of the disease it is often of great importance.

Next we will consider tachycardia or paroxysmal tachycardia, or paroxysmal rapid heart, quick heart and rapid heart as it is called by different authors, while others make a difference between tachycardia and paroxysmal tachycardia.

This term is used to describe a train of symptoms which are unassociated with known anatomical lesions or reflex mechanism and is by common consent applied to all heart rates over 120. The heart rate in this trouble is very much faster than that in exophthalmic goitre and infectious diseases as it frequently attains a rapidity of 300 beats to the minute. The causes are not so very different from those already given so will consider the symptomatology. The first intimation of an attack is the flop or tripping of the heart, as it is called. There is a throb of the heart and a sense of fullness in the vessels of the neck. Other attacks begin instantly without any flop. The termination of an attack is as prompt as the beginning. The rapid rate may stop instantly followed by a long pause, then a full, strong impulse is felt over the heart accompanied by a sense of glow over the entire body. The patient as a rule prefers the horizontal position. There is a sense of constriction in the epigastrium, the face may be livid or pale, cyanotic, the jugular veins may be or may not be distended. The pupils have been known to be dilated, contracted and unequal in different cases and even to vary during a single attack, a rapid increase in the number of beats while the pulse is small, weak, easily compressed and often irregular with carotid pulsation. The respiration is slightly increased, rarely is there dyspnea. The expression is anxious and denotes suffering. There may be a systolic murmur but more usually the heart sounds are clearly defined. The signs of stasis do not appear unless the attack lasts considerable time and then there is danger of thrombi. The heart usually is exceptionally small during an attack and as a result the ventricle empties itself with each beat. In some cases the heart is abnormally movable, changing with the position of the patient. In almost every case the pulsation during an attack is double the number found immediately afterward.

The prognosis is good as far as life is concerned, but not so favorable in regard to the relief of the condition when the disease occurs as a pure neurosis or as the result of

some cause that permits of easy removal. When tachycardia develops in those suffering from chronic myocarditis or atheroma of the vessels it is liable to suddenly terminate in death.

The treatment of simple intermittency, palpitation, arrhythmia and tachycardia are very much the same and consist, first, in the removal of the exciting cause. When this is done you may reasonably hope for a cessation of the symptoms. For example, when indigestion, anemia, chlorosis, the use of tea, coffee, or some reflex trouble is responsible, then when these are sought out and cured then the heart disease will also disappear. During the attacks the best thing to do is to keep the patient absolutely quiet and in the recumbent position, while aromatic spirits of ammonia or Hoffman's anodyne should be given and a belladonna plaster or ice cap is applied over the precordium. If these do not afford relief then small, frequently repeated doses of digitalis combined with the bromides or the use of aconite and veratrum viride may prove of benefit. In the interval between the attacks it is sometimes of considerable benefit to give trional or drugs of this class and give various tonics. Probably as good results can be obtained from the employment of elixir iron, quinin and strychnine as any other remedy. Out-door life, exercise, walking, driving, cycling and mountain climbing all help to improve the general health and strengthen the heart. Cold bathing at the sea-shore or at home also helps to improve the general health. During the paroxysms in tachycardia the position frequently does good, the object being to elevate the vascular pressure. One patient will assume a squatting posture with the head between the knees, others will throw themselves down on the bed in such a position that they can bring all the muscles into urgent contraction. Each patient usually discovers the position for himself that will do the most good. Inhalation of two per cent. carbon dioxide will sometimes prove of benefit. Compression of the splanchnic area so as to force the blood into the heart causes it to beat slower. In most cases all that can be done is to rectify, nourish and invigorate the system as far as possible.

Pseudo-angina is an unsatisfactory term used to describe attacks of cardiac pain unassociated with pathological lesions of the myocardium, aorta or coronary arteries. There are several possible sources for the pains of angina and one of them is spasm of the coronary arteries. In this form of angina we frequently find all the characteristics of true angina while years later these same patients are able to perform severe physical labor

without any discomfort and are apparently well. It is quite possible that this form of angina is to be found associated with the cramps in swimmers.

The diagnosis is merely to differentiate between it and true angina and to do this it is necessary to elicit objective signs of disease of the aorta, myocardium, heart valves or the arteries. The pseudo-angina gives a sensation of fullness and pressure in the cardiac region. In this form of angina the patient may be capable of severe physical exercise in the intervals between attacks while in true angina there is a direct dependence between exercise and the attack.

True angina is most common in those past middle life and in men. Pseudo-angina at every age from six years up and most usually found in women. In true angina the attack is rarely nocturnal or periodical and is not associated with other symptoms, while pseudo-angina is often periodical and nocturnal and is associated with nervous symptoms. In true angina the pain is of short duration, agonizing in character, accompanied by a sense of constriction while the pain in pseudo-angina lasts one or two hours, is not so severe and there is a sense of distention more than constriction. True angina is usually a lesion of arterial sclerosis with a very good prognosis, while pseudo-angina is usually neuralgic in character and never terminates fatally.

True angina by some authorities is not considered as a functional trouble at all while by the majority it is so considered. By some it is called sterno-cardia, breast pang and neuralgia of the heart. Some of the causes are syphilis, gout, kidney disease, hysteria, over-exertion, mental emotions, habitual use of tobacco, pressure of an adjacent tumor, hypertrophy or dilatation of the heart, diseased condition of the aortic valve and myocardium and any condition where there is an increase in arterial tension. While the direct cause is an impairment of the blood irrigation of the myocardium which can arise in several ways. First, isolated disease of the coronary arteries unassociated with any affection of the aorta, aortic valve or systemic arteries.

Second, disease of the coronary arteries associated with systemic arterial disease.

Third, partial or complete occlusion of the lumen of the coronary arteries at their origin on account of the disease of the aortic valves or disease of the root of the aorta.

Fourth, vascular crises in the coronary arterial distribution due to vaso-motor influence which are not associated with anatomical lesions of the arteries.

The symptoms are: The pulse may be natural, but at times is unnaturally small, fre-

quent and sometimes irregular; there is usually extreme pallor or ashen gray color and an agony of expression which is not to be forgotten and often there are huge beads of perspiration. Frequently there is a numbness or tingling in the fingers or over the cardiac region. Shortness of breath and precordial oppression are present. The chest is fixed and the heart's action is weak and feeble. The chief symptom, however, is pain in the region of the heart. The lower end of sternum is the usual sight of the most intense pain but it may be to the left of the sternum in the precordial area. It usually extends up into the neck over the distribution of the third cervical segment and down into the arm following the distribution of the eighth cervical, first, second and third dorsal segments. There is always a sense of impending dissolution accompanying the precordial oppression. The attacks are always paroxysmal in character and last from a few seconds to half an hour. Inside of that time the attack has terminated either in relief of the symptoms or death.

The diagnosis has to be made between it and pseudo-angina and the main points of difference have already been mentioned.

In treating angina-pectoris, the first and most important thing to do is to attempt to relieve the attack. Chloroform may sometimes be used to an advantage. Morphine combined with atropine given hypodermatically is the very best remedy for the severe pain. At the same time using counter-irritation to the precordium in the form of mustard plaster or fly-blister. The patient frequently gets as much relief from the inhalation of nitrite of amyl as anything else. A patient who has had one attack should always carry a few pears of nitrite of amyl around with them to be used at the first sign of an attack. The inhalation of chloroform sometimes acts nicely. The use of nitroglycerine is good not only during an attack but in the interval when given every four hours proves of great benefit. When the trouble is associated with gout or syphilis appropriate remedies for these disease should be given. The increasing dose of potassium iodide is of great advantage even when there is no history of syphilis. The bromides are also useful and when they are to be given continuously for some time the bromide of strontium is the best. Arsenic and the nitrites, specially of sodium and silver, sometimes do good. Hot baths are not good and any exercise must be taken with great caution because any over-exertion is liable to bring on an attack. Even climbing of a very small hill may bring on an attack. When the attacks are frequent it is necessary to keep the patient in bed and the diet must

be carefully attended to, being careful to avoid any indigestible food. The mind must be kept at rest as much as possible as well as the body. Never allow the patient to get excited or into a passion if it can be avoided. It is hardly necessary to say that the excretory organs should be kept in good condition. The use of digitalis is contraindicated.

Bradycardia is always a symptom of Stokes-Adams syndrome, but should be treated as a separate disease. Any heart beat below 40 is to be classed as a bradycardia while sometimes it is reduced to seven or eight in a minute. It is found in a number of different conditions and classed by Riegel as follows:

First, when found in convalescence from acute fevers such as typhoid, pneumonia, diphtheria, acute rheumatism, etc.

Second, in diseases of the digestive apparatus, especially dyspepsia, but also in cancer and ulcer of the stomach.

Third, in some diseases of the circulatory system. More frequently those involving the muscular structure of the heart, and associated with deficient nutritive supply or obstruction of the coronary artery.

Fourth, in nephritis.

Fifth, from the action of toxic agents including uraemic poisoning, lead, tea, coffee, alcohol and digitalis.

Sixth, certain diseases of the nervous system, including apoplexy, epilepsy, brain tumors, especially those involving the medulla and cervical cord.

Seventh, in affections of the skin and sexual organs.

Eighth, finally, rarely in diseases of the respiratory system.

The symptoms are the slow, weak, small pulse. As a result of this slowness there are noises in the ear, vertigo, dizziness and rarely convulsions. While the first sound of the heart is soft and feeble the second sound is often inaudible. As this condition of bradycardia is always present in Stokes-Adams syndrome, we will now leave any further consideration of it except a few words about the treatment. In this, so far as the improvement of the systemic conditions are concerned there is very little material difference from those employed in the functional diseases already described.

As long as the pulsations do not become so slow as to fail to supply the necessary amount of blood to the system, the best thing to do is not to give any medication but endeavor by position and forced respiration by various means to whip up the lagging heart. If this does not have the desired effect, then we have to resort to the administration of the various heart stimulants either by mouth or hypodermatically always remembering that digi-

talismans and remedies acting as it does must be avoided. While atropine, aromatic spirits of ammonia, nitroglycerin, alcohol, caffeine citrate, mono-bromide of camphor, the various valerianates, amyl nitrite in the form of pearls and eactus may all be used to advantage. Sometimes morphine and drugs acting similar to trional and veronal produce good results.

Stokes-Adams syndrome, or heart block by some authors called, is put down as a disease while others claim it is merely a group of symptoms and not a definite pathological process.

However, it seems to be caused by disturbance in the bundle of His, which has already been described. The vagus may under some circumstances influence the conductivity of this bundle. In heart block the ventricular contraction may fail to follow one or more auricular contractions which leads to a slow, intermittent pulse. There may even be four auricular contractions to one ventricular and this fact can easily be determined by counting the pulsations in the external jugular vein. This can easily be done when the tricuspid valve is sound as the veins of the neck are then distended and the auricular pulsation can be distinguished. The real thing to determine between this trouble and bradycardia is whether the involvement in the rhythm involves both the auricle and ventricle or only the ventricle as is the case in heart block.

Some authorities claim that the entire symptoms may arise from irritation of the vagus trunk. The trouble usually occurs in patients who are past middle life and who have arterial-sclerosis. There is always bradycardia and arrhythmia present. The heart beats are commonly about forty but have been known to drop down to two and some cases are on record where there was no ventricular beats for over a minute. There are more auricular beats than ventricular bearing the relation of two to one, three to one and four to one in different cases. There is extreme weakness and the patient is unable to perform any manual labor. Sometimes there is decided dyspnea following exertion, persistent or more commonly paroxysmal. Fainting, convulsions and slumber apnea.

The cerebral symptoms are always present and vary very greatly in character, according to the part of the brain involved and may be merely syncope, epileptic or apoplectic in character with stertorous breathing or even Cheyne-Stokes respiration. The prognosis is always grave, though a prognosis for a short duration of life is not invariably justified.

The treatment consists in first trying to correct the underlying cause as rheumatism, syphilis, arterial-sclerosis and brain affections.

When the attack is on the object is to correct the brain anemia by lowering the head or even inverting the body. One patient prevented his attacks by getting down on his hands and knees and allowing his head to hang down. During the paroxysm the cardiac stimulants as ammonia and nitrates are useful and sometimes atropine does good when given hypodermatically. Rest, diet, tonics, regulation of exercise as well as the excretions, never forgetting the importance of syphilis and the employment of the iodides when it is even suspected.

FRACTURES AND RADIOGRAPHY.*

By R. C. FALCONER, Lexington.

CASE I.—FRACTURE OF STYLOID PROCESS.

The subject of this injury, a young man about 30 years of age, was thrown from a motorcycle, striking his hand outstretched

against the ground. He was first seen by Dr. R. L. Carrick, who referred him to me. The wrist presented the usual appearance of an ordinary sprain, moderate degree of swelling and no deformity. He complained, however, of acute pain at carpal end of ulna, intensified by pressure at this point, also on motion of joint. X-ray examination showed displaced fracture of styloid process. Joint splinted.

*Read before the Fayette County Medical Society.

Inspection, passive motion and redressing every three days, duration of treatment one month, no resulting deformity or disability.

CASE II.—DISLOCATION OF RADIUS AT ELBOW ASSOCIATED WITH FRACTURE OF THE OLECRANON PROCESS.

The subject of this injury, a boy nine years old, while romping fell on his elbow. Exam-

ance of a sprain. Moderate swelling, no deformity, function slightly impaired. However acute, localized pain at carpal end of radius prompted me to suspect something more than an ordinary sprain. X-ray examination showed a simple fracture of radius at suspected point, without any crepitus or displacement. Wrist joint was splintered for the usual time, followed by complete recovery. It might not be out of place to state that as a rule the radial epiphysis is united to the shaft about the twentieth year, but according to some modern observers aided by radiography, it unites several years earlier.

REMARKS.

The cases just reported serve to demonstrate the necessity and advantages of radiography. I am sure we all wonder how fractures, especially those of joints were ever treated without this aid to diagnosis. The character of injury, method of treatment, accuracy of adjustment are all materially influenced and determined thereby. The diagnosis

ination shortly afterward showed marked deformity of elbow joint due to backward dislocation of radius. Under anaesthesia the dislocation was at once reduced and the elbow placed in splints at right angle position. Next day the swelling was considerable, extension and flexion markedly impaired. Further more on palpating over the olecranon, there was a pronounced flatness where the point of the bone should be normally felt. X-ray examination disclosed fracture of olecranon tip, which is shown in the radiogram, chipped off and interposed between the articular surfaces of the humerus and ulna. (Compare injured with normal elbow of same subject). The right angle position was maintained throughout the period of treatment. On the seventh day, however, after receipt of injury the patient was anaesthetized the arm was extended and flexed, then redressed in right angle position. Inspection and movements of extension and flexion were practiced every three or four days. The case resulted in complete recovery, without any impairment of function or restriction of motion.

CASE III.—FRACTURE OF CARPAL END OF RADIUS.

The subject of this fracture was a male adult about forty-five years of age. Injury caused by cranking automobile. Wrist presented nothing more than the usual appear-

of any cases of apparent sprain or contusion associated with one or more definite bone lesions is cleared up by the Roentgen rays. In regard to the case of fractured styloid process

of ulna, this injury is associated with Colles' fracture in about fifty per cent. of the latter. In the treatment of fractured styloid process the bone usually takes care of itself when the wrist joint is splinted. and if the wrist is so treated it can be liberated in about three weeks with a good result. Referring to the case of dislocated radius associated with fracture of the olecranon, in a former case of this kind, that is fracture of olecranon, the fragment failed to unite, caused suppuration in the joint, and had to be removed, followed by a good functional result. As to the position of the arm in fracture of the olecranon if the degree of separation is slight I think the right angle position is desirable; if the separation is marked and inch or more, the arm should be dressed in position of extension, and so maintained by long splints, preferably made of plaster of Paris in such a way that they can be removed whenever necessary, for inspection and massage. In the event of wide separation with impossible reduction treatment by open method would be necessary.

Whether the arm is dressed extended or at right angle it should be gently, under anaesthesia, flexed or extended, as the ease may be, a week after receipt of injury, and then passive movements continued until it is safe to liberate the arm and substitute active movements. This treatment is calculated to prevent ligamentous or fibroid ankylosis.

REVIEW OF THE BULLETIN OF THE STATE BOARD OF HEALTH OF KENTUCKY, BIENNIAL RE- PORT, 1910-1911.*

By BEN CARLOS FRAZIER, Louisville.

The recognition of the practical use of vital statistics is general throughout. Kentucky is one of the first states to adopt a model law. The registration of deaths and births is as complete as most states. I take for granted the death registration is more complete than birth registration, as in the larger cities and especially in Louisville there are a good many babies born without either a doctor or midwife being present, hence no report. No doubt this is true in some of the rural districts also.

The report of the State Board of Health was a revelation to me and has been a constant source of pleasure and instruction since I began to observe it closely, which was, I am sorry to say, quite some time after I received the copy. It is of necessity incomplete even to where it ceases, but I am going to quote some figures from the State Registration of Vital Statistics that will bring some of the records almost up to the present time.

Before making any statistical returns, I

want to tell all of you that have not studied the volume, I am attempting to review, namely, Bulletin of the State Board of Health of Kentucky Biennial Report, 1910-1911, and do not attempt to cover all the points of interest but can only bring out a few points and hope to have a discussion that can be as general as you like. This volume will pretty generally inform you about members and officers and the various boards; and what is very important to many doctors, health laws and rules and regulations and court decisions. This day of frequent malpractice suits it may behoove us to keep in touch with the court findings and discussions for we can never tell but we may be next, and have such proceedings brought against us. I am glad to say, and I think I am stating facts, that there have been no decisions against the doctors in recent suits brought in our courts. You all probably are as well acquainted with them as I.

The amended law has made a School for Health Officers. I was not fortunate enough to be able to attend the recent meeting here for this purpose, but I am sure there will come good of one hundred fold from the instructions given. It was needed. You can but be struck by the great difference in the reports of the various Health Officers. Very few of them had received any training, in such work, consequently they were deficient both in observing and reporting what came before them, not only that but many were doing this at a great personal sacrifice, giving their time and labor without any compensation at all and those who received anything at all received little indeed. When there can be health officers qualified and paid for the work done, then we will have a death return small indeed compared to what it is now. The doctor is always interfering with his means of living by helping others to live better and longer, but what could be more commendable. Not one of you who is doing his duty, but sacrifices himself for someone each day. We are truly our brother's keeper. If we are let us do our duty well. If the health officer be equipped he can soon overcome many prejudices and objections that he will meet in people of his community that should help him, who will now put a stone in his way because they are not educated or else are so prejudiced as to be unable to see the good in reform when it interferes with their time-honored custom.

I have dwelt somewhat on the health officer but I want to commend the report in its entirety and this seems to be the most important. The health officer makes the report. The prevention of disease now is the cry. Teaching prophylaxis is now the feature of the day, not to get sick. How to keep well

*Read before the Jefferson County Medical Society.

should be bought, rather than paying for recovery. If you can only make the people understand, and that is a hard proposition, that the health officers are devoting time, energy and the best knowledge to keep the community in good general health, to prevent the spread of disease, when there is an occasional outbreak, to advise about sanitary situations, both in private and municipal conditions, you will have done a great deal in leading up to the millenium. A clean healthy body can more easily contain a clean healthy soul it seems to me.

When you look through the whole number of counties of the state and see tuberculosis as the leading cause of death in all but six we certainly should feel like renewing our zeal to keep up the anti-tuberculosis fight which has been well started in a great many counties. Carlisle had two more deaths from pneumonia and bronchopneumonia than tuberculosis; Leslie had 3 deaths from tuberculosis, 11 from diphtheria; Letcher had 10 deaths from tuberculosis and 10 from typhoid. Magoffin had 17 from tuberculosis and 17 from diphtheria. Mercer had 31 from tuberculosis and 11 from pneumonia. Perry had 6 from tuberculosis, 9 from diphtheria and 11 from pneumonia.

I take it that where diphtheria was the prevailing cause of death, antitoxin was not available, or else the cases were not recognized early. Typhoid fever only equalled in mortality tuberculosis onee, Letcher county, 17 each.

You all recognize the mortality rate in pneumonia has not changed much in a great many years. There are almost 20,000 affected with tuberculosis in the state and in 1912 there was very close to 16 per cent. of the deaths due to tuberculosis.

I want to openly criticize all doctors who do not tell their patients when they have tuberculosis, to allow a tubercular patient to labor under the idea that he only has bronchitis, when it is tuberculosis it is not only wrong for the patient's sake, but jeopardizes many people who would be protected if the tubercular patient were taught how to care for himself and protect others. The little children are the ones who suffer most from contagious disease and are the least protected. Where the carpets, curtains and other drapery, along with clothing and furniture are not kept free from contagion, children in the house for so long a time are continuously in danger. Especially does this apply to tuberculosis.

The State Board of Health has sent out circulars on prevention of contagious diseases to all the counties and towns in the State. This should do a wonderful lot of good in most communities. No doubt as the health officers now are instructed, they will invite a more

general discussion and encourage meetings of the teachers, ministers and the laity in the various counties where they have jurisdiction.

I was surprised to find that the sparsely settled counties or communities did not have the lowest death rate. Typhoid did not claim any death toll in Nicholas or Menifee counties. Menifee was second place low death rate, tuberculosis making such a claim as to put it second in spite of no typhoid deaths, 609 to 100,000.

Trigg was lower, 562 to 100,000.

Fayette with 2,062 to 100,000 was the highest death rate.

Monroe and Montgomery each with 357 from tuberculosis had rather large typhoid rate, 29 and 23 respectively.

Puerperal septicemia ranked tenth as a cause of death from preventable causes. We should consider this with great seriousness as it reflects on the doctor and nurse.

In looking over the counties, I find the following with more than 2 deaths reported for puerperal septicemia: Boyle 4, Barren 4, Bullitt 3, Fayette 4, Garrard 3, Hardin 7 with a small population. I do not venture an opinion as to such a large death rate with so small a population estimated, 22,667.

Jefferson 13, with estimated population of 266,636. Kenton, 5, Knott 4, Logan 4, Montgomery 3, Owen 3, Pike 3, Rowan 4, Shelby 3.

These babies should not be allowed to die for want of proper feeding any more than they should for housing.

We have not succeeded in getting the laity nor the doctors in the country and small town to take the serious and persistent interest in clean milk that should be taken. I hope the health officers all over the State will give this matter the time and personal attention that is due the babies in their respective counties. Based on the 100,000 population and taking 1911 and 1912 as the basis the births for 1913 should be almost 30. Diarrhea and enteritis in children between one and four years is causing a too heavy death toll.

Let us all help to make the registrar's statistics complete and true by reporting all diseases that are supposed to be, and to report all births and give exact causes of death.

DEATHS FROM PREVENTABLE DISEASES.

Tuberculosis	5,181
Pneumonia, bronchopneumonia	2,530
Diarrhea, enteritis; under 2 years	1,124
Typhoid fever	1,035
Meningitis	630
Diphtheria, croup	545
Influenza (lagrippe)	477
Measles	394
Whooping Cough	394
Puerperal septicemia (child-bed fever)...	161
Scarlet fever	73

We will expect a great deal from health officers, in pellagra, hookworm, in improving the milk supply, and in instructing the laity along with the small milk dealer in the smaller cities and towns of the State. Of the 29,955 deaths in the State in 1912, 5,162 were infants under 1 year; 2,342 were children between 2 and 4. If clean milk were being fed, and intelligently handled the rate should not be so large, as the death rate from scarlet fever, diphtheria and whooping cough is not large.

In a communication given out very recently from the State Registrar of Vital Statistics, it is stated, "There have been 114 from pellagra, mostly white, but a few negroes, Jefferson, Fayette and Christian counties furnishing the most of them, they being inmates of the State hospitals. There have been about a score of deaths reported from hookworm. Both conditions are comparatively new, so far as statistics particularly are concerned.

There are so many questions that could be reviewed with much good to all of us but I cannot cover the whole ground. I hope you will not confine your remarks to what I have presented, but will bring out any other feature of interest that I have not mentioned.

DISCUSSION.

C. G. Forsee: I wish to go on record as being of the same opinion as Dr. Frazier in regard to informing our patients that they have tuberculosis. Recently, in a discussion of this subject in a medical society of which I am a member, I was somewhat surprised to notice that most of those who discussed the subject stated that they hesitated to tell their patients that they have tuberculosis. To my way of thinking, it is a great mistake not to inform an individual that he or she has tuberculosis just as soon as we have established the diagnosis.

J. M. Morris: I would like for Dr. Frazier in closing to give us some idea of the death rate from tuberculosis two or three years ago as compared with that of the past year. It seems to me that, in spite of the educational work that has been done in the past few years, the death rate from tuberculosis is about the same as it has always been.

I would like to indorse what the essayist has said in regard to making it known to our patients that they have tuberculosis. I believe there is no greater mistake being made to-day than that of neglecting to inform these patients of their condition in time for them to benefit by the knowledge; in fact, I think it amounts to almost criminal neglect for a physician to fail to inform these patients of their true condition so that they may at once begin the proper treatment. No longer ago than yesterday, I saw a woman who had been treated for six months without being told the nature of her trouble, nor did her hus-

band know it. Immediately upon establishing the diagnosis, I did what the other physician should have done six months ago—told the family, and they immediately consented for her to go to the sanitarium and be treated. The failure to give her this information early enough for her to have received the full benefit of treatment amounts to criminal neglect, and I think this is true of any physician who wilfully withholds from the patient information as to the true condition until long after the time when proper treatment should have been begun.

J. Rowan Morrison: I wish to congratulate Dr. Frazier upon presenting a paper of this kind. We all need to look into this subject. While facts and figures may not be very interesting, they are oftentimes of great benefit to us.

In regard to the large number of deaths from pneumonia reported from Mercer county, I would like to ask Dr. Frazier whether or not there had been an epidemic of grippe, or something of that kind, in connection with these deaths?

Another condition I wish to speak of is whooping cough. I think the essayist stated that some 300 deaths from whooping cough had been reported. I daresay that, if the sequelae of this condition, such as broncho-pneumonia, and disorders of nutrition had been taken into account in compiling these statistics, the number of deaths would have been much larger. I think whooping cough is a disease to which the authorities should pay more attention than they do. In a most excellent paper read by Dr. John Lovett Morse, of Boston, before the Association of Pediatricians in Washington, last May, he stated that, after going into the subject very thoroughly, and writing to the health authorities of many cities, he had reached the conclusion that the mortality of pertussis was very high, probably greater than that of scarlet fever and measles together, and possibly above that of diphtheria. Whooping cough is a serious disease, to which we have not assigned the importance that we should; we have not been careful in segregating children who have it. I have repeatedly seen children with whooping cough playing around in Central Park with other perfectly healthy children, and some who were not so healthy—with nutritional disorders which would render them particularly susceptible to whooping cough. Therefore, I think we should make every effort to keep these children from associating with other children until some time after they have ceased to whoop, because we know that this disease may be carried by an individual for a considerable length of time after the paroxysms of whooping have ceased. It has been suggested that these children should be required to wear an insignia on the arm, indicating that they have had whooping cough. The health authorities should look into this question; whooping-cough deserves more attention from a public health standpoint than it receives.

F. C. Askenstedt: I should particularly like to hear the subject of tuberculosis discussed in connection with this paper, and to ask whether there has been any decline in the death rate from tuberculosis in this county that can be attributed to the tuberculosis movement?

Dunning S. Wilson: If my memory serves me correctly, the death rate from tuberculosis throughout the State has declined nearly one thousand during the past two years. Last year (1913) in the City of Louisville there were 410 deaths from tuberculosis; in 1912 there were 434; in 1911, nearly 504 and in 1910, 512.

Several things are to be considered in connection with statistics of the death rate from tuberculosis as well as other diseases. In the first place, whenever the question of any particular disease is agitated, there is always a swing of the pendulum upwards; in other words, more cases of that particular disease are noted. For instance, it has taken the medical profession a certain length of time to realize the necessity of being on the lookout for tuberculosis; it has also taken a certain length of time to become proficient in the diagnosis of tuberculosis in the early stages, and it will take a still longer time for them to learn the importance of notifying the health authorities whenever the diagnosis of tuberculosis is made. Therefore, whenever we agitate the question of any particular disease, whether it be tuberculosis, cancer, or what-not, we usually find that here are more cases of that particular disease in existence than we had theretofore imagined.

Another factor that must be considered in connection with mortality statistics is one of personal equation; whether or not the doctor signing the death certificate has the moral courage to state therein what was really the cause of death. We know that many physicians, when some other lesion, such as organic heart disease, kidney disease, or what-not, is co-existent with tuberculosis at the time of death, will assign the former as the cause of death, because they fear that, if they mention tuberculosis, it will prevent the family from collecting insurance on the patient. This is not true. We make the insurance companies pay the face value of policies on individuals who have died of tuberculosis every day. Like the suicide clause, it has been shown to be insufficient to invalidate the policy. Therefore, you are not doing the patient any good by not telling the truth. If death was caused by a chronic nephritis plus pulmonary tuberculosis, put it so. Nevertheless, statistics will vary, depending upon the personal equation of the individual.

Again, sometimes an accurate diagnosis is not made. I have no doubt that many cases of so-called pneumonia are really tuberculosis. Pneumonia does not mean anything. It may be a true pneumococcus infection, or it may be a

grippal, or an influenzal or a tuberculous infection. Pneumonia covers a multitude of false diagnoses. Therefore, I believe that the apparent increase in the mortality from tuberculosis sometimes noted in certain districts is often due to increased diagnostic skill on the part of the medical profession, plus courage on the part of the individual doctor to give the real cause of death.

Next, the increase or decrease in a certain district must be considered in the light of the ratio it bears to the population of that district. For instance, in New York City the death rate from tuberculosis has decreased 20 per cent. in the past twenty years. That does not mean that the actual number of deaths from tuberculosis is not as great, or possibly greater, than twenty years ago; but the population of New York has increased, while the number of deaths per 1000 of population has decreased. Therefore, in Louisville, or any other portion of the State, we must take into consideration not only the actual number of deaths occurring within a certain period, but also the ratio that number bears to the population.

Wherever an active anti-tuberculosis campaign has been waged, tuberculosis is on the wane. Frederick Hoffman, one of the best statisticians in the country, connected with the Prudential Life Insurance Company, in a paper read in Washington last year, showed conclusively that tuberculosis is on the wane throughout the entire country. In Jefferson County this is true more than in any other section of Kentucky, for the reason that it is the only county in Kentucky that has a sanatorium for the care of tuberculous patients. I think the medical profession ought to get behind a movement looking to two things; first, adequate funds for providing beds for advanced cases of tuberculosis; and, second, legislation compelling segregation. This is where the trouble lies. I can recall case after case of tuberculosis that came to the sanatorium, stayed there a few months and got a little better, and then went back to their homes or to cheap boarding houses, and back to work, leaving a trail of infection wherever they went.

Again, there should be some provision made for advanced cases. It is not the early case of tuberculosis that is a menace to the community; it is the advanced case. We must have segregation of these cases; we must be enabled to prevent them from going into a densely populated city and spreading the infection wherever they may go. The County Health Officer and the City Health Officer, in conjunction with the official in charge of tuberculosis work should have authority to say which cases should be segregated and to enforce segregation. This is a most important factor in the fight against tuberculosis.

R. E. Wilhoit: I would like to ask Dr. Frazier if he knows anything about the rules of quarantine in the public schools of Louisville. One of the parents of a child whom I recently treated for

chicken-pox told me the other day that the principal of the school which the child attended had told her that the child could not come back to school for one month. This child's little brother has been going to school right along, and did not stop while the other was ill with chicken-pox.

C. H. Harris: I believe that of all the dangers that surround us in this city, the worst is from those old chronic cases of tuberculosis that have not learned proper methods of living, care of the sputum, and so on. There should be legislation to compel the segregation of these cases, just as we compel vaccination. Small-pox has become almost obsolete as the result of compulsory vaccination, and proper legislation looking to the segregation of tuberculous patients who have reached the stage where they have become a menace to the community would be a great help in the fight against this disease.

I think Dr. Morrison also sounded a timely note of warning when he protested against the running at large of children with whooping-cough. It has been my observation that, of all the infections which occur in young children, whooping cough is most apt to be attended by fatal results. Congestion of the brain is often given as a cause of death when whooping cough is the real underlying cause. I think we should get behind the health authorities in an effort to segregate children with whooping-cough. Mothers have received the impression that it is best for a child to have whooping-cough when it is very young. That is the time it is most apt to be fatal. In a nursing child, a paroxysm lasting from five to fifteen minutes may cause death from exhaustion. However, as we have no specific, we can only let the disease run its course.

S. C. Frankel: I will take the liberty of answering the question asked by Dr. Wilhoyte in regard to the quarantine regulations in the public schools. I am sure that the parent of the child mentioned by the doctor did not correctly understand the principal of the school, and that he did not say that the child must remain home for a month. All of the principals have definite instructions as to the length of time a child must not attend school because of the various contagious disease. In chicken-pox the time is from two to three weeks. The rule is that a child who has had chicken-pox must remain at home until all the scabs have disappeared. The scalp, chest, back and arms are examined, and if any scabs are present the child is excluded from school until they have disappeared. The very earliest a child can return to school after an attack of chicken-pox is ten days, and it varies from that period of three weeks. However, any other member of the family may attend school during the period of illness.

Ben Carlos Frazier, (Closing): It seems that

I have presented a very small paper on a very large subject.

While the subject is in my mind, I would like to say that a great many principals in our public schools do not live up to the quarantine rules mentioned by Dr. Frankel. They are sometimes very arbitrary in their rulings. I am not sure whether or not the principals and teachers in the school have any instructions as to excluding from school a member of a family in which there is a case of tonsillitis, but I do not believe such is the case. Last week I saw a case of tonsillitis in a woman whose daughter was attending school, and as soon as the teacher learned that this girl's mother had tonsillitis, she sent her home and would not allow her to return to school for several days. I was quite busy and did not take up the matter with the authorities, but it was a bad thing for that girl. Here was a girl, thirteen years of age, running around to matinees, and roller-skating, when she would have been much better off at school, and I do not believe there was any justification for her being sent home.

The question of whooping-cough comes pretty close home to me, because both of my children were very sick from it. I think it is a dangerous disease in young children. I remember to have made the remark that I would rather my children had diphtheria than whooping-cough. They have had both, and they were much sicker with whooping-cough than they were with diphtheria. As Dr. Morrison brought out, children under two years old often die from whooping-cough.

Answering Dr. Askenstedt's question as to whether or not there has been a reduction in the death rate from tuberculosis, I will give a few figures that I have at hand: Exclusive of still-birth which are not included in the statistics given out by the Bureau, there were 29,555 deaths in this state in 1912. Of these, 9562 were infants under one year; 2,344, from 1 to 4 years old, and 7,346 were 65 or over. This gives a death rate of 12.9 per 1,000 of population. There was a decrease in the death rate from all preventable diseases except diphtheria and pneumonia; a decrease of 529 in the number of deaths from tuberculosis, and a decrease of 297 in the number of deaths from typhoid fever.

The point brought out by some of the speakers in regard to informing our patients that they have tuberculosis is one that should be emphasized even more strongly. It behooves us to stick together in the fight against tuberculosis, and teach our patients the necessity of proper living so as to protect others from the disease. I was glad to hear Dr. Wilson speak on this subject, as I do not believe there is anything that handicaps us so greatly in the fight against tuberculosis as those doctors who neglect to tell their patients the nature of their trouble, and insist upon their living in such a manner as to protect others.

The figures on infectious and contagious diseases reported during the past month or two are very interesting, because, in November only four cases of whooping-cough were reported, while in October only two were reported. It is evident that many of us have neglected our duty when only four cases of whooping-cough are reported in a month. There are few of us who have not seen that many case in the past four weeks.

ANESTHESIA.*

WITH PARTICULAR REFERENCE TO THE ANOCT-ASSOCIATION METHOD.—ILLUSTRATED BY CHARTS, DRAWINGS, LANTERN SLIDES AND THE CINEMATOGRAPH.

By LOUIS FRANK, Louisville.

The desire to dispel pain is older than the human race, and for thousands of years means were diligently sought by which it might be abolished. The inception of medicine was through surgery in the efforts to overcome the pain and heal the wounds inflicted in personal combat. Men thought of self before they looked for a Divinity, indicating that in the evolution of mankind, long before the thought of religion the ancient and honorable practice of medicine had its seed sown in the necessity of repairing the damage inflicted upon the individual in one way and another.

In the words of Hippocrates "*divinum est opus sedare dolorem.*" As the ancients, long before the days of the venerable Father of Medicine, were acquainted with Indian hemp, the poppy, etc., this reference was undoubtedly to the agony inflicted by the surgeon.

The search for agents which would permit of the painless treatment of wounds and such crude operative procedures as were necessary as a result of either disease or battle, was unsuccessful until the early part of the last century. We find that Velpeaus, two thousand years after Hippocrates, wrote with apparent resignation "*éviter la douleur dans les opérations, est une chimère, qui l'nest pas permise de poursuivre.*" The production of local as well as general anesthesia has been and was attempted by various and divers means, ranging from the "Stone of Memphis" to freezing, from Mandragora of the Iliad to Voltaic narcotism of Richardson."

Most of the efforts at anesthesia had to do with those agents which would act locally, and it was very early suggested that nitrous oxide, much used of late for general anesthesia, could be utilized in this way. However, very little progress was made in the actual application of local anesthesia until the discovery of cocaine in 1880. Since then, with the development of synthetic chemistry, and doubt-

less on account of the frequent alarming manifestations following the use of cocaine, other agents have been introduced, among which may be mentioned eucaïne, tropaeocaine, strovaine, alypin, the orthoform group, and, latterly, the least dangerous, but equally valuable, novocaine. The successful application of these agents had been made possible through the discovery of the hypodermic needle by Wood, though before that time Long had discovered the general anesthetic effect of ether. Morton had demonstrated it in 1846, and Warren and Bigelow had spread the knowledge to the medical world.

The relative merits of chloroform and ether, the two general anesthetics in greatest use, we do not propose to discuss in an extended manner. We do, however, wish to draw attention to a few points showing the greater danger of chloroform over ether. It was for a long time argued that ether was far more dangerous than chloroform, because of its post-operative effects and its action upon the kidneys. A very cursory review of statistics, however, would indicate that the average mortality from chloroform is, at the very least, one in three thousand; that of ether one in ten thousand; and these figures are taken from an average of six hundred and thirty-eight thousand four hundred and sixty-one administrations of chloroform, and three hundred thousand one hundred and fifty-seven administrations of ether. To give exact figures, the deaths from chloroform varied, taking the experience of thirty-six European surgeons, from one in thirty-seven hundred and forty-nine, to one in five thousand eight hundred and sixty; whereas ether shows a mortality varying from one in twelve thousand nine hundred and forty-one to the figure previously mentioned.

The action of both drugs is through absorption by the lipoids. Both produce marked depression, and their administration is accompanied by symptoms identical with those we have learned to recognize as due to shock. Chloroform has a particularly deleterious effect upon the parenchyma cells of various organs, notably the liver, in which organ fatty degeneration may be induced by its action, and a true cirrhosis ensue from its repeated administration. That its effect upon the kidney is not less harmful than ether we believe it also an established and proven fact. Its fatalities upon the operating table come so quickly through the heart, that the patient is dead before any attempt to save can be instituted. Each, however, has its place in surgery and there are cases in which one or the other should be employed to the exclusion of any other general anesthetic in the interest of the patient.

*Read before the Jefferson County Medical Society.

It has been noted for some time,—in fact for some years,—that the administration of an anesthetic in certain types of cases demanding operative intervention, meant practically the death of the patient, and we began to ask ourselves why this was. It was not an uncommon occurrence that profoundly septic patients in which a life-saving operation was demanded, did not recover consciousness after anesthesia, but would die in a comparatively few hours. It was observed that such patients came off the operating table profoundly shocked, clammy with perspiration, and in infinitely worse condition than when the operation was begun. This began to lead many of us away from ether and chloroform and to the use of that agent re-discovered by Wells in 1844 and long used in dental surgery, and often in the hands of charlatans, viz., nitrous oxide; it being noted that patients who were given nitrous oxide would recover, or at least that death did not ensue within a short time, that death was not determined by the operation, but when occurring followed as a result of the pathological lesion for which the operation had been performed. In other words, in these bad cases we learned that the anesthetic agent practically determined the outcome.

That nitrous oxide was apparently free from danger had seemed evident from observations in a great number of cases in which it had been given, and from the fact that those who had been and were giving it had not been especially trained in the use of anesthetics. Thus we find that Buchanan, in the *Medical News*, for 1893, comes to the conclusion, after careful study of many millions of inhalations of this gas, that the mortality was probably two in ten million five hundred thousand cases. It was very likely that the startling difference in Buchanan's table with reference to the mortality of various anesthetics led to a search for the cause, which had not only been productive of vast good, and of a more thorough understanding of the action of the various anesthetics, but of a better appreciation of anesthesia itself.

Much of the development and popularity not only of local but spinal anesthesia,—if one may be permitted to distinguish between these two, though the principles are the same,—may be attributed to the dangers and unpleasant sequelae of general anesthesia. That local anesthesia is ideal we do not believe. However, it has a distinct place in surgery, and should always be considered as one of the methods of choice in determining what is best for the individual patient before us.

Local anesthesia has been brought to a high stage of perfection by Braun, and to anyone who is interested in the subject we would ad-

vised a careful perusal of his book, the third edition of which has recently been issued. It is a classic and contains much interesting and valuable information.

No one longer doubts that operations of the greatest magnitude may be safely executed under local anesthesia, and with the use of novocaine, large quantities of which can be employed without fear of lethal dosage, Braun and others have accomplished resection of jaws, of ribs, have done nephrectomies, herniotomies, and in fact almost every type of operation. The principle of Braun's method is the same as that of the French "blocc a distance," and although the effect is similar to that of Schleich's infiltration method, it differs therefrom in that the injection is made beyond and around the operative field. This "leitungs" or conduction method we have used in a number of instances with the greatest satisfaction, although it has objections just as have all methods of local anesthesia. To obtain the best results a knowledge of the nerve supply to the part is necessary, also the direction from which the nerves enter the operative area.

The strength of novocaine solution recommended by Braun varies from one-half to one per cent., and to this is added a small amount of adrenalin. Of the one-half per cent. solution, which we have used repeatedly, as much as 200 to 250 c.c. can be injected without the slightest toxicity. The novocaine and adrenalin should of course be thoroughly sterilized, and for the injection we use a Record syringe of either 5 or 10 c.c. capacity. About twenty to twenty-five minutes should elapse between the injection and the beginning of the operation, otherwise the patient will by no means be satisfied with the method, nor will the surgeon be favorably impressed therewith.

The films illustrating operations performed under local anesthesia have been kindly loaned me by my friend Dr. Jacobson, of Toledo, Ohio; the lantern slide illustrations are from Braun, excepting those showing the syringe, which were made by Dr. Hays of this city.

What is the objection to the use of local anesthesia, and what also, may we ask, is the objection to the use of general anesthesia alone when there are no contraindications? As has been shown, ether and chloroform are tremendously depressing, in other words, they produce shock. To a far less extent, infinitely less in fact, this is true of other inhalation anesthetics, but least so with those which produce anesthesia not through toxicity but rather by their mechanical effect as it were, such as nitrous oxide.

The ideal method of anesthesia, as Crile has

shown, is a combination of local and general anesthesia, which he has termed the "anoci-association method." Morton robbed surgery of its excruciating agony, and through the introduction of asepsis Lister has been the means of "saving more lives each year than were lost in all the Napoleonic wars." So by the introduction of this last method we have robbed surgery of its psychic dangers, and have removed from the operating table one of the greatest and most constant dreads of surgeons, that element which, the operation itself successful, has resulted in so many fatalities, viz., shock.

The entrance of septic material into operative wounds is under our control, the selection of the operative case lies with us, the prevention of hemorrhage is possible to the careful surgeon; but with the necessity of more or less prolonged operations upon vital structures, it has not until the present time, i. e., until the introduction of the "anoci" method been possible for us to do any operative work, no matter how slight it might be, without greater or less psychic influence. While this does not always necessarily result disastrously, to show that it not infrequently does so, I need only again call attention to the septic cases previously mentioned where patients have died soon after coming off the operating table.

Upon what do the principles of the "anoci-association" method depend? As its originator says, upon the abolition of all noxious perceptions through the special and psychic senses. Of all the senses, pain (i. e., the perception of contact) is the oldest. In the primordial state it was through the contact sense that food was obtained. In the process of development the being also recognized and was made aware of its enemies through the sense of touch. In further evolution special organs were developed which enabled the being to detect and distinguish its enemies as well as its foodstuffs by sight, by hearing, by smelling, and by tasting. By development of the tactile sense and a more acute tactile perception and a lowered threshold, influences which were inimical to the safety of the individual were translated into pain. With the infliction of pain came the association of fear. Pain, fear, physical exhaustion, overpowering emotions, psychic insult, all being related, produce similar changes in the central nervous system corresponding absolutely with those which today we recognize as due to shock.

Fear was the dominant emotion of the being early in its career, it was greater than that of reproduction and likely overshadowed that of self-preservation, as it was through this emotion that the being was driven to seek

refuge from danger which it avoided even though hungry and desirous of offspring. It was the most necessary emotion for the existence and perpetuation of the organism. From it, by specialization, were evolved all other senses and emotions,—thus love, hate, envy, ambition, etc., all are offshoots of fear, biologically related to it, and may be translated into fear. It is to-day the most dominant emotion of the human brain, though frequently subconscious, neither the individual nor his intimate associates translating it as such.

Through the "anoci-association" method of anesthesia it is proposed to abolish all communication between the operative field, i. e., the painful area—the fear excitor,—and not only the conscious but the subconscious perceptions of the patient. It is further proposed to abolish entirely all psychic factors which may be of harmful influence to the patient. This latter is not necessary in all classes of surgical work, as in many instances it is very slight, though occasionally in the most robust patient, and not infrequently in operations performed upon children and women, tremendous harm may result from the presence of fear.

Moynihan has denominated the discovery of the "anoci-association" method of anesthesia as one of the greatest achievements in the entire history of surgery.

Our own experience with it has extended over a period of about eighteen months, during which time we have had ample opportunity to judge as to its usefulness, and have had quite a sufficient number and variety of cases to entitle us to express an opinion concerning its value. We have used it hundreds of times, and it has been in every instance entirely satisfactory; it has fulfilled its promise, and, in the words of a recent patient, "has robbed surgery of its horror."

When one considers that morphine is rarely necessary, and then only in the smallest dosage, following work performed under this method, when one notes the absence of circulatory disturbances following grave or prolonged operations, when one no longer hears complaints of gas pains after abdominal section, and notes the smiling and happy countenance of the patient after major operations under "anoci-anesthesia," one is convinced of the tremendous addendum to our surgical methods that we have in this procedure. In our hands numbers of patients have been successfully given the benefit of surgery, and this is notably in that class of cases with renal lesions, or who for other reasons were bad surgical risks, to whom we would otherwise have feared to advise the operations which were necessary for their relief and the

outcome of which by any other method of anesthesia, would likely have been fatal.

There is by this method a perfect and complete severance of all nervous connection, not only of the special senses with the brain but also an absence of all harmful psychic influences, and a subjugation of all excitation which might arouse the biologic associative memory of injury. The threshold of the brain, instead of being lowered to sensitive impressions, is raised. The brain cells are not exhausted in their effort through fear of damage to escape the trauma, as there is no communication between them and the blocked field of operation; nor is this communication reestablished until the injury has been practically repaired, i. e., until there is no longer any alarm sent out from the operated area, as reconstruction is going on, not destruction. In other words, the brain perceptions are absolutely shut off from danger through every avenue, hence no pain, therefore no biologic fear, consequently no nerve cell exhaustion, therefore no shock.

If one but bears in mind the response through pain and its closely correlated sensations to all unnatural or harmful stimulation, one readily appreciates why these patients have no post-operative fever or pulse increase, gas pains nor in fact any of the unpleasant sequelae which follow operation and may be a source of annoyance to both patient and surgeon.

It should be remembered that pain is really a conservator, a guard for the body, an "alarm bell" as it were. Braun very beautifully explains this, and from a biologic standpoint we must accept it as correct. Thus all infections manifest themselves by pain, or some symptom translated into pain. So perceptions of cold, of heat, of hunger, are dependent upon this association. Again, the absence of symptoms akin or related to pain in the very young and very old are due to the absence or growing weakness of this biologic associative memory.

The method in brief is as follows: From an half hour to fifteen minutes before the operation, the patient is given an hypodermic injection of morphine and atropine, morphine and scopolamine, or morphine plain, dependent upon the judgment of the anesthetist. The patient is taken directly into the operating room, where gas-oxygen is administered as the anesthetic. The field being prepared, the line of proposed incision is injected with a one-quarter per cent. solution of novocaine. After the incision is made through the skin and fat, the fascia and the muscles are likewise injected. The incision is then continued until the depth of the operative field has been reached. In abdominal work, after the peri-

toneum has been opened, it is reflected and well injected beyond the line of incision with novocaine followed by quinine-urea-hydrochloride in one-half of one per cent. solution. The mesenteries of organs to be operated upon in intra-abdominal work are also injected with novocaine solution before their division. This is true of the intestines, the gall bladder, the appendix, the uterus and the appendages. In kidney work the injection is made well around the kidney, though this organ similarly to other intra-abdominal organs, as a rule is not very susceptible to contact impressions. After the tissues have been divided all suture lines and areas in the track of ligatures and proximal thereto are injected with the quinine-urea solution. Before closing the incision, the muscles, fascia and skin are also injected well behind the proposed suture line with quinine-urea. Care must be observed in all cases to see that the novocaine solution is well distributed by pressure before cutting, and we should also be sure to inject the quinine-urea solution well behind the operative field.

We have within the past month performed three radical breast operations under this method of anesthesia, and neither of the patients had the slightest pain, discomfort, nor were they even aware of the operation. I mention these cases as they are outside the field of abdominal surgery.

Following this method we have been able to operate upon patients with enlarged thyroids which we would not have dared subject to the knife previous to the introduction of this procedure. We are satisfied that our mortality has been lowered, and the post-operative condition of our patients has been much more satisfactory and comfortable in every way.

The slides which we show you are taken from illustrations previously published, and are therefore not original. The film we had made to demonstrate the method and to show the absence of straining on the part of the patient during the operation, the absence of the necessity for the use of retractors in abdominal work, and to show with what complete satisfaction all abdominal operations can be performed under the "anoci-association" method with gas-oxygen anesthesia.

While we have not used gas-oxygen exclusively in our work, we give it preference as a routine measure in all instances. The expense is about one dollar for every ten minutes of its administration, but this has not prevented poor patients from receiving its advantages without any cost whenever it was deemed advantageous for the individual. In cases where ether has been given "blocking" has been done just the same, the latter being routine in all operations in a clean field.

The administration of nitrous oxide and oxygen for general anesthesia is not, however, without danger. This danger comes almost exclusively from inexpert administration. One may kill as easily or more easily by this gas than by strangulation or smothering with a pillow. It is absolutely essential to give a proper percentage of oxygen,—7 per cent. to 9 percent.—though 4 or 5 per cent. is enough to keep the pilot light going in the brain. Anesthesia is produced in structures in the order of their development, thus the brain being the highest, goes under last; hence the patient may talk and still feel no conscious pain. There is no increase in bleeding as with gas alone, no straining and for prolonged work it is much to be preferred, contrary to the generally accepted teachings and opinions. Jaecitation and rigidity are evidences of inexpert administration. So also is blueness as with the proper administration of oxygen the skin remains of normal color. The only cases in which it is not advisable or is contraindicated, are in the very young or in brain surgery.

In conclusion let me recommend that you give the "anoci-association" a fair trial, for as surely as you do you will subscribe to the expression of our English confrere that it is the greatest surgical discovery of the age.

DISCUSSION.

J. G. Sherrill: I wish to thank Dr. Frank for myself and on behalf of the Society for his elegant presentation of this subject.

The essayist stated that Crile gets a mortality of something like one per cent. in his goiter cases under this method of anesthesia. On the other hand, Dunhill, of Melbourne, Australia, has had a somewhat less mortality in 368 cases never refusing a case, and doing his work under local anesthesia entirely. There are many ways to reach a certain point and, in my opinion, the best and most direct way is the straight line. We know that we can do many operations under local anesthesia, but the surgical profession of American has not been fully awakened to the value of local anesthesia. I have myself done some very major operations under local anesthesia, having recently removed a large tumor, weighing eleven pounds, from a woman who was considered to be a poor subject for general anesthesia. She stood the operation well and went off the table with her physiologic equilibrium unchanged. I think the greatest value of the anoci method is in the mind of the man who devised it, but the majority of patients do as well, whether operated upon under local or general anesthesia. Everything we add to our technique lessens by that much our ability to do good work. Simplicity is the keynote of surgery. We can do major operations such as resection of ribs, removal of tumors, resection of the jaw, and so on, under local anesthesia. Why

tax your patients then, with a general anesthetic. I see no reason for prolonging the operation the length of time necessary to inject the abdominal wall for instance, when we are going to give a general anesthetic. On the other hand, I see little use for giving a general anesthetic if we are going to supply local anesthesia. However, each man works out his technique to his own satisfaction, and I contend that short operations, with little loss of blood little handling of tissues and little traumatism constitute ideal surgery. The wound does not pain the patient if there is no infection in it and no nerve fibres have been incorporated in the line of stitches. Infected wounds are the ones that give rise to gas pains, and if we handle the abdominal viscera unduly, pull it out and haul it around, that also will cause trouble. With proper technique we can get just as good results under one method of anesthesia as another. I have no desire to decry the anoci-association method of anesthesia, but I see no reason for encumbering ourselves with a great amount of technique when we can get just as satisfactory results from an uncomplicated technique.

Jno. R. Wathen: I think the society is to be congratulated upon having had one of the most entertaining exhibition that has ever been presented to it. It serves to impress upon us the value of illustrating our work and the work of others in such a way that we can all grasp it and benefit by it to a much greater extent than we can the ordinary stereotyped manner in which these subjects are usually presented.

The anoci-association method of anesthesia has attracted world-wide attention; largely, I believe, because of the reputation of the man who devised it. At the same time, I think we are all a little too prone to take up all sorts of fads and fancies. One should not be the first to take up a new thing nor the last to drop the old. After the value of a new thing has been fully demonstrated, then one should accept it. It will take many years to conclusively demonstrate the value of the anoci method of anesthesia. Recently, in a conversation with an operator in what is probably the largest clinic in this country, I asked him why they did not more frequently employ the anoci method, and he replied that, while it was undoubtedly of value in selected cases, they did not use it as a routine measure. I have used the anoci method in a limited way and in the future I believe I will give it even more attention.

Anesthesia is still in its infancy and I hope there will come a time when spinal anesthesia is perfected. If I am not mistaken, in Europe and, in fact all over the continent spinal anesthesia is taking the place of general anesthesia. I am inclined to the opinion that in the complete anoci-method—that is, local anesthesia in conjunction with nitrous oxide gas and ether we are giving just a little too much anesthesia. We do not need

it all to obtain satisfactory results.

As far as goiter work is concerned, I think the anoci method has been more or less of a failure in large goiters; in small ones and ligations, it is very nice indeed, but when it comes to heroic work I prefer to have my patient under a general anesthetic. One reason is that we are not dealing with a class of patients like those of Germany, for instance, who will permit the surgeon to commit almost any amount of traumatism without resisting.

I think this is one of the best papers we have ever had before this society.

E. O. Grant: I was associated with Crile for a period of a little more than a year, and during that time I helped him in something over 1400 operations under the anoci-association method of anesthesia. Since I have been here, Dr. H. H. Grant, with whom I have been working, has used it a number of times, and it has certainly been of great advantage. Dr. Crile's mortality during the year I was with him was 1.7 per cent. and the patients were remarkably free from after-pains, such as gas-pains. It is a real pleasure to work in a hospital where one is not called upon in the middle of the night to give a patient relief from gas pains.

Dr. Frank mentioned the cardinal principles of the technique which it is very important to observe; namely, careful injection about the line of suture, which prevents after pains, and extreme care in putting the proper amount of pressure on the tissues after novocaine is injected. Without proper pressure, the local anesthesia is of no benefit.

Another advantage is that there is very much less bleeding from the superficial wound under local anesthesia. If I am not mistaken, the mortality rate in the Lakeside Hospital has, in the past three years, declined from 4.7 per cent to 1.7 per cent. This is an acute hospital, where everything is treated; it is practically a city hospital, and fractures, goiters, and everything else are brought there.

Dr. Crile has done some wonderful work with this method in goiter cases. I have in mind two cases of extreme exophthalmic goiter, in which the goiters were entirely removed and the patients left the hospital without knowing that they had been operated upon.

As to the time consumed when this method is employed, that is largely a matter of experience, and is more than offset by the time saved in intra-abdominal operations, and the trauma saved, by not having to use tractors and by not having to use large sponges, etc. Therefore, in my opinion, as a time-saving proposition, and for promoting the comfort of the patient after operation, this method is incomparable to those heretofore taught.

F. T. Fort: I think this anoci method is merely a question of an individual getting results from

a certain technique of his own. I had the pleasure of seeing the work of what I believe to be one of the world's greatest surgeons recently, and he is perfectly satisfied with the results he gets from his technique. I think his mortality rate is as low as that of Crile, and yet he did not use the anoci method in a single one of more than a hundred operations that I saw him do. The anoci method may be of benefit in certain selected cases, but I believe it is simply one of those new things that come and stay awhile and then disappear forever. It adds to the danger in that it necessarily prolongs the operation a sufficient time to administer the local anesthetic in addition to the general anesthetic. Therefore, until it has been investigated fully and has been adopted by a great many men who are not now using, I do not know that I am very much in favor of this method.

Jno. W. Price, Jr.: I had the pleasure of working with Dr. Frank before he adopted the anoci-association method of anesthesia, and in looking back over a number of cases we had prior to its use, and comparing them with others since adopting this method, I can say that I am fully in accord with his views. It undoubtedly leaves the patient in more comfortable condition following the operation. The absence of gas pains has been especially noticeable; also, freedom from pain along the line of incision, and throughout the abdomen in general. Those who would decry this method had better give it a little further trial before they absolutely condemn it. The more I have seen of it, the better I like it, and I hope to see it used for some time to come.

Hugh N. Leavell: I would like for Dr. Frank to tell us, in closing, whether he has observed a trophic condition, locally, following the use of this method of anesthesia?

During my association with Dr. Dabney, covering a period of some ten years, we frequently used a combination of local and general anesthetics, and there was no doubt in our mind that shock was often averted by this means. Such operations as enucleation of eyes, cataract operations, and iridectomies often required general anesthesia, and during the last five years of my association with Dr. Dabney, we used a local anesthesia in conjunction with the general anesthesia, and found it to be of marked advantage in every way. That was some ten years ago, and probably preceded this block method of anesthesia to some extent. Be that as it may, the fact remains that there was less shock, better anesthesia, and the patient came out from under the anesthetic in much better condition than when only general anesthesia was employed.

It occurs to me that here is a possibility of trophic disturbance resulting from too much local anesthesia. It has been suggested by Dr. Grant that, in order to secure anesthesia from novocaine, it is necessary to use it under pressure.

We know that we can sometimes produce local anesthesia by the use of water under pressure as well as novocaine; the pressure itself has a tendency to produce anesthesia. Therefore, if the novocaine must be introduced under pressure, why may it not cause interference with the trophic condition of the nerve as well as its anesthetic condition?

J. B. Richardson, Jr.: I would like to ask Dr. Frank if it is a fact that it requires less ether to maintain anesthesia under this method than otherwise?

If I understood the essayist correctly, he made the statement that death from nitrous oxid gas and ether anesthesia will never occur except in the hands of those not experienced in its administration. I differ with him there. I believe that death will occasionally occur from anesthesia, no matter how expert the anesthetist may be in their administration. If I have misunderstood Dr. Frank, I will be glad to have him correct me.

E. L. Henderson: In reply to Dr. Richardson's question, it has been my experience, in giving this anesthesia for Dr. Frank, that it does require considerably less ether to maintain anesthesia than otherwise; in other words, it is not necessary to keep the patient as deeply under the influence of the general anesthetic as when the anoci method is not used. Under nitrous oxid and oxygen anesthesia, it is very hard to relax the patient sufficiently for abdominal surgery when this method is not used, but I have observed that when it is employed abdominal work can be done very satisfactorily under nitrous oxid and oxygen. We do not have the intestines coming out and the patient moving about as we so frequently do when the anoci method is not employed.

Louis Frank, (Closing): Answering Dr. Richardson I will say, my statement was that gas oxygen anesthesia was the **least** dangerous in competent hands of all methods of general anesthesia, but that in the hands of inexpert anesthetists, it might be the most dangerous.

Correcting Dr. Leavell's impression, Dr. Grant did not say that the novocaine was put in under pressure; he said that pressure was used when novocaine was introduced, which is entirely different. The pressure is employed simply to spread it.

We have not had a single case of suppuration in a clean wound following the use of novocaine and quinine urea. We have, however, seen a number of cases where drainage was employed, where there was a violent septic condition—a general diffused peritonitis, if you choose—that have healed directly up to the point of drainage by primary union. We use plain catgut for the skin throughout. I think this answers Dr. Leavell's question as to trophic changes.

I am not here to defend Dr. Crile; he is amply able to take care of himself, and of the anoci-association method, in this or any other audience.

But I do wish to say that the gentlemen who have not used this method except on two or three or a dozen occasions, and maybe then discarded it, are in no position to speak with authority. I would also call attention to the fact that before the introduction of any form of anesthesia, operations were much more rapidly and dexteriously done than now but how about mortality. We do not offer this method as a *sine qua non* for the eradication of mortality, nor can we, by this method alone, reduce our mortality. This is a physiologic age in surgery, it is our aim to maintain the patient's physiological condition as near the normal as possible. Neither is this method a fad that is put forward to attract patients and doctors. God forbid that any man who is respectable and who believes in his profession should resort to such means to attract business. "*Honi soit qui mal y pense.*" It requires, for the reduction of mortality, attention to every detail that will save the patient—save his nervous mechanism, prevent bleeding, obviate shock, and so on. Surgical judgment is a potent factor in the prevention of mortality, and the technique of the operation is only one of many factors. We do not put this method forward as a means of saving life, alone, without the exercise of good surgical judgment and without proper operative technique.

Whether or not the greatest surgeon in this country (and here one has the right to his own opinion as to who may be the greatest) has adopted this method, the fact remains that it has been adopted by such men as Moynihan, of England, and others who stand equally well, and they use it as a routine measure.

Dr. Henderson has answered Dr. Richardson's question as to the comparative amount of ether necessary to maintain anesthesia when this method is employed.

The General Hospital.—E. F. Stevens, Boston (Journal A. M. A., January 24) gives from the point of view of an architect the essentials of the ward and operating units of the general hospitals which he has recently visited and also of a number of American institutions recently planned and comments on them. The essentials can be classed under the heads of "comfort to patients and accessibility to service." In addition to the usually recognized essentials he mentions the therapeutic effect of color and the absence of noise from clicking latches, etc. Under accessibility he adds to the usual recommendations that of a special room for placing cut flowers in at night where they can be rearranged in the morning, and wash-basins for the doctors and attendants in the corridors adjoining the wards and attention to the width of doors and metal protection of corners that are liable to be bumped.

HARE-LIP.*

By D. O. HANCOCK, Henderson.

"How disappointment tracks upon the steps of hope."

This truth is perhaps never more true than when deformity is found in the new-born.

Death itself is often preferred as is suggested in the popular little poem of Ella Wheeler Wilcox:

"I married a girl with perfect health,
And virtue and spotless fame;

* * * * *

And I gave her the love of a heart,
Grown sated and sick with sin.

* * * * *

She was going to bring me a child,
And when in labor she cried,
With love and fear I was wild—
But now I wish she had died.
For the son she bore me was blind,
And crippled and weak and sore;
And his mother was left a wreck:
It was so that she settled my score.

* * * * *

Folks talk too much of a soul,
From Heavenly joys debarred,
And not enough of the babes unborn,
By the sins of their father scarred."

These lines apply more particularly to syphilis. But the underlying thought, heredity, transmission, should concern all parents and those who may become parents.

Our subject is one of faulty development,—of failure of Nature to do her perfect work. Whatever would tend to influence pre-natal life and cause these results are matters of deepest interest to child-bearing women.

Maternal impressions as an explanation is far-fetched and unscientific. Great sin and the wrath of God are likewise nonsensical.

Imperfect development in utero might result from disease; from impoverished physical condition of the parents, or from drugs, narcotics, etc. High authority states that, "As a rule it remains for the third and fourth generations to reap the full results of alcoholism." The parents of the cases before us now are not alcoholics. Their lives, however, have been described as "The short and simple annals of the poor," not destitute, but people who meet the responsibilities of life with honest toil; mothers who have had frequent pregnancies and who personally care for their children; fathers who go hard against the "bread and butter proposition."

The wonder is that there is not more of faulty development and deformity; that na-

ture is so true to type, in the face of so many things that hinder. In the more fortunate condition of life men and women also make true the lines:

"I said I would have my fling,
And do what a young man may;
And I did not believe a thing,
That the Parsons had to say."

Mechanical prevention of development by amniotic bands and adhesions is given as a cause of these deformities. And again they are said to occur from unknown causes.

Very early in foetal life a series of clefts appear on each side of the cephalic extremity, separated by rods of tissue called brachial arches. These clefts communicate with the alimentary canal. The first brachial cleft is between the mandibular arch and the hyoid arch. The mandibular arch develops into the superior and inferior maxillary bone between which is the buccal cleft, which closes early except the aperture for the mouth.

In development the superior maxillary bone does not unite with its fellow in the median line. The intermaxillary bone is interposed. This bone supports the incisor teeth. It sometimes projects far beyond the line of the gums, and is troublesome in doing operation for hare-lip.

These various clefts have usually coalesced by the ninth or tenth month of foetal life. Occasionally this coalescence fails or is incomplete. We are then confronted with the various deformities, one of which is hare-lip. It is produced by non-union of the intermaxillary with the superior maxillary bone, hence it may be on either side, single hare-lip; or on both sides, double-hare-lip. One of our cases is of this type. It is never central. Occasionally the inter-maxillary bone is absent.

Hare-lip occurs in about 1 in 2400 of all births; double hare-lip occurs in about one-tenth (1-10) of all cases of hare-lip.

The upper lip is formed in three parts, the central, or philtrum, which grows from the vomer and inter-maxillary bones. The two lateral parts are supplied by processes of the upper jaw.

Hare-lip may involve only the soft parts. And may be single or double. One of our cases is single hare-lip of the soft parts.

The conditions found in the two cases before us, before operation are well shown in plates No. 656 and 657, on page 733 of Wharton & Curtis. Text on Surgery, which I pass you. The parents of these children and those of you who were with me in operating them will recognize the correctness. Case 1 is a girl ten years of age, double hare-lip; failure of union on both sides, extending through lip and bone. The inter-maxillary bone protruded further than is shown in cut. Operated

*Read before the Henderson County Medical Society.

January, 1904. Removed inter-maxillary bone; dissected up the lip; approximated the tissues. We secured only partial union of the soft tissues. Operated again in August of 1904. No other operation. You observe that the vermilion border is about perfect. The lip is a little short; but the teeth are well covered and phonation is good. The nose is flattened. Otherwise little deformity. There remains some space where the inter-maxillary was, and there is absence of the upper incisors. She is a well-nourished school girl of ten, and helpful at home.

Case 2 is a ten-months-old girl. This patient had a single hare-lip of the lip only. We did a modified Nelaton operation. Dissected up the lip. Secured the parts with silkworm gut, and adhesive. Union by first intention. Removed sutures on seventh day. Continued adhesive for several days longer. This operation was done on November 5, 1913. After two months I exhibit the result to Henderson County Medical Society. The line of union is vertical and extends to the orifice of the nose, showing the extent of the hare-lip. You observe a slight deformity of the left alae. This is markedly better than before operation. The vermilion border is slightly exaggerated. But when the child laughs it is correct and symmetrical. The teat on the border is the apex of the V-shaped edge of the hare-lip pulled down after making the incision along the border. It will be removed by adjustment, absorption and cicatricial contraction.

Mean spirits under disappointment, like small beer in a thunderstorm turn sour. Or like the turtle, turn loose their hold on the desirable. And, so, many parents of hare-lipped children allow them to go on and through life uncorrected. A living evidence of their stupidity.

Not so with the cases now before us. I have had the faithful, intelligent and patient support of the parents of these children, and they have their reward.

Quinsy. Treatment. To relieve dysphagia, place on tongue 0.3 to 0.4 Gm. (5 to 6 1-2 grains) of dry orthoform or anesthesin powder. A few movements of deglutition, without previous admixture of saliva with the powder, will bring it in contact with affected parts. Measure also useful after operation on tonsils.—Hinsberg.

Renal Inflammation. Diagnosis. With patient sitting erect, but relaxed, lightly palpate lumbar muscles. If one kidney is seat of an inflammatory process, muscles on that side will feel firmer than normally.—Pottenger.

CLINICAL CASES

CASES OF OCULAR DISTURBANCE CAUSED BY NASAL DISEASE.*

By S. G. DABNEY, Louisville.

The dependence of disease of the eye upon the nose and accessory sinuses is well known. The following three cases are of interest, *especially because in none of them did the patient give a spontaneous history of nasal disturbance* and even on close questioning, no definite symptoms about the nose were mentioned. They came purely for an examination of the eyes.

Case I. Mrs. X., aged about 65 years, was referred to me by her family physician for ptosis of the right upper lid. She stated that this ptosis had existed for a year or more but had gradually increased. That in addition to this she had headaches, frequent and severe, and occasional double sight; she was also subject to "nervous spells" during which she more or less lost control of herself. Her daughter, however, a very intelligent woman, stated that she believed these nervous spells had always existed in her mother's case and were not of much significance. Notwithstanding this, the ptosis, the occasional double-sight and the headaches all strongly suggested some intra-cranial disease.

The ophthalmoscopic condition of each eye was normal and the sight with a correcting glass was perfect in each. On further questioning as to previous illness, this lady told me that she had had disease of antrum of Highmore on the right side and an opening had been made into the antrum through the tooth socket by a dental surgeon.

Examination showed that the antrum was now pretty clean (being washed out every day through this opening) but the middle turbinate was enlarged and inflamed and there was pus oozing from beneath it; pressure at the upper inner angle of the orbit under the floor of the frontal sinus showed great tenderness and trans-illumination of this sinus, made by carrying a very small Tungsten lamp as far back as possible in the upper inner angle of the orbit, showed this sinus to be much darker than the other.

In the further observation of the case, I became convinced that this was a case of involvement of all the sinuses on the right side, the posterior ethmoidal and probably the sphenoidal being diseased as well as the three anterior groups. As the lady was, however, not a good subject for a radical operation, I decided, first of all on doing what work I could

*Read before the Jefferson County Medical Society.

through the nose. A resection of the middle turbinate was made and later on a pretty thorough curetting of the ethmoid cells and the infundibulum up into the frontal sinus. Under these measures the ptosis has improved though it is far from cured; the headaches have become so slight as to give her but little annoyance and she has no more double sight.

I hope to do still further work upon the posterior ethmoidal cells and to go into the sphenoid if the symptoms demand. Meanwhile, she seems pretty comfortable, the nasal discharge has greatly diminished and the tenderness in the floor of the frontal sinus has disappeared so that external operation does not seem justified at present.

Case II. Mr. A., age 29, a professional man who uses his eyes a great deal was given glasses by me in November, 1909. For two or three years these glasses gave him entire relief. This fall he returned to see me complaining of headache in the left temple and in and around the left eye. He thought that his glasses needed a change. A careful examination, however, showed the same refractive error as before. On questioning him about his nose he said that he had not noticed much wrong, though perhaps the left side was somewhat less free than the right. A superficial examination showed nothing, but after shrinking the nose thoroughly with adrenalin and cocaine, there seemed to be some fullness under the middle turbinate. Further investigation showed a polyp pushing under this bone far back. A resection of the turbinate revealed numerous polyps in the ethmoidal cells; the removal of these by snare and curette quite relieved the symptoms.

Case III. A young lady of 19, consulted me in regard to discomfort in the use of her eyes, particularly the left. She had some pain in this eye almost constantly and was unable to use her eyes for more than a few minutes without great discomfort. The history seemed so plain of ocular disturbance that I tested this young lady thoroughly with the accommodation suspended. I also went carefully over the condition of her ocular muscles and of course made the usual ophthalmoscopic examination. I could find nothing whatever wrong with the eyes. Although there was no history of nasal disturbance I made an examination of the nose and found very extensive polypoid degeneration of the ethmoid.

The condition was far more marked on the left side.

In addition to the great number of small polyps, the ethmoid cells were filled with a semi-solid cyst-like material; the middle turbinate was partially resected and the ethmoid thoroughly curetted. It was somewhat

remarkable how soon the discomfort in the eyes disappeared indeed, the mother told me that within a day or two after the first operation the young lady experienced entire relief.

It is interesting to note that the father of this patient, a man somewhat past middle life, was operated on by me some years ago for very extensive ethmoidal disease with numerous polyps on both sides.

The literature in regard to the influence of nasal disease upon the eye is extensive. The ocular affections so produced are of the most various character and the theories to account for the relation between the nose and the eye are numerous and often conflicting. I have purposely refrained from entering upon any of these questions; to do so would be really to write an essay and as I understand it I have been invited merely to report a few cases.

DISCUSSION.

Adolph O. Pfingst: The cases reported by Dr. Dabney are very interesting, particularly because of the fact that they exemplify a condition that may exist in the nose without manifest symptoms. We may have diseases of the ethmoid cells without having a purulent discharge from the nose. These patients may go along for months and years without being cognizant of any nasal affection.

The fact that disease of the posterior ethmoidal cells may give rise to pressure symptoms has been suggested in the last few years, and is gaining favor among ophthalmologists.

It is not improbable that many of those cases of retrobulbar neuritis, in which the etiology was formerly in doubt are caused by pressure upon the optic nerve, due to ethmoid disease. Personally, I have never seen a case of optic atrophy following retro-bulbar trouble that could be attributed to ethmoid disease, but I believe that such a thing is possible.

Dr. Dabney is to be congratulated upon being able to relieve his patient as readily as he did. The treatment of ethmoid disease is a most difficult problem. We have to deal with a labyrinth of diseased cells and we never know how far the disease extends. Operations on this part of the body is extremely difficult, and we cannot tell how much improvement will follow.

Gaylord C. Hall: I have been very much interested in Dr. Dabney's report.

For the purpose of convenience, the symptoms of this condition are divided into three types: (1) the so-called reflex type, which is the most common, and into which I take it the last two cases reported by Dr. Dabney would fall; (2) those of a toxic character, from pus in the accessory sinuses, and (3) those of a pressure character, due to mechanical displacement caused by rupture of the accessory sinuses into the orbit. The latter type is, of course, the most rare. The

toxic symptoms are commonly those of disease of the optic nerve, enlargement of the blind spot and, to a certain extent, imbalance of the optic muscles. Reflex symptoms are the most common. While I may not be able to prove it to the satisfaction of others, I am firm in the belief that practically all of that large class of patients who have been carefully refracted and cannot wear glasses, come under the latter classification. It is a mistake to look into the nose with the expectation of finding a flow of pus from either side of the middle turbinal. These patients do not evidence pus in the nose on superficial examination, and that is the reason for their symptoms. Those cases where the accessory sinuses are drained satisfactorily do not, as a rule, manifest pressure symptoms.

I would like to ask Dr. Dabney, in closing, what was the nature of the double vision in the first case reported; whether it was due to actual involvement of the inner wall of the orbit, or whether it was due to some toxic disturbance? I believe a great many of these patients exhibit a slight degree of muscular paralysis which clears up after operation on the nose. It is not due to any trouble in the muscles themselves, but to innervation of these muscles from irritation on that side.

Jos. J. Shafer: From Dr. Dabney's paper we can learn how essential it is to make a routine examination of the nose and accessory sinuses in any disturbance involving the eye, particularly where we can not get a definite history as to the causative factor. When we recognize the fact that in acute and chronic catarrhal conditions of the nasal tract and accessory sinuses we have inhibited a great many bacteria, such as micrococcus catarrhalis, bacillus coryza, Friedlander's bacillus, Frankel's pneumococcus, all forms of staphylococci and streptococci, and micrococci we must admit that we have here an incubator of pathogenic bacteria. Consequently when the air chambers become blocked, interfering with ventilation and drainage, thereby lowering resistance, then these bacteria are taken up by the lymphatics and blood vessels to the ocular apparatus creating just such disturbance as cited by the essayist. How many cases of superficial punctate keratitis do we see that are concomitant or come on in three or four hours after an acute coryza. Here we must also admit that the lachrymo-nasal duct contributes to the pathology of a superficial punctate keratitis.

Some months ago I had the pleasure of reading Gerber's classical monograph, "Die Komplikation de Starnhohlenzungen" in the original German. He makes an accessory statement in one of his paragraphs and sounds a note of warning that under no condition should an operation be done in the nose in empyemic conditions unless the patient's resistance had been built up and proper elimination established. Such an opera-

tion as sawing off a polyp, cauterizing a middle turbinate, have produced grave ocular symptoms and caused purulent meningitis ending in death. The question arises, where do all these bacteria come from. They are certainly not all in the inspired air. From Frankel's exhaustive researches on the cadaver immediately after death, removing the accessory sinuses, he never found any pathological bacteria in normal cavities. Following Gerber's line of thought in many cases of empyema of the accessory sinuses there must have been, evidently, at one time a general sinusitis induced by a vicarious elimination of the naso-pharynx consequent upon a systemic condition.

S. G. Dabney, (Closing): As stated in the report, these cases were not selected because of their rarity, except the first one, which was a rather unusual case; the others were common and were used as illustrative cases.

It seems to be a fact that the central fibres of the optic nerve are more easily affected than are the surrounding fibres and that, therefore, pressure or toxic influence, either one, will sometimes cause a central loss of sight, or, as we call it central scotoma.

I agree with Dr. Pfingst in regard to the difficulty of curing ethmoid disease. I almost invariably direct my patients to come back within a few months. One man, whom I dismissed in the latter part of September after doing a good deal of work on both ethmoids, came back three months later with a slight return of the trouble. It is rather easy, in most cases, to give the patient relief, but absolute cure is difficult.

I am a little skeptical about this reflex business. I think the word "reflex" is sometimes used to cover a multitude of ignorance. In regard to those cases that all of us see, that fail to get relief from glasses, I do not believe the trouble is in the nose in the majority of these cases. Most of them have some underlying neuropathy—I do not mean an organic condition, but some error in the mode of life, some disturbance of the nervous system. Such conditions are, I believe, the most frequent causes of unsatisfactory results from glasses.

I agree with Dr. Hall as to the misleading results of a hasty glance into the nose. The second case I reported had no pus whatever in the nose, and until a very thorough examination had been made, no nasal trouble could be detected.

I have never used vaccine in these cases. I am very ignorant about them, but the impression I had received was that they are chiefly of value in chronic conditions. However, these cases are usually chronic. Dr. Shafer's suggestion may be a good one; perhaps we will find that the vaccines have a broader application than we suspect.

CHRONIC CONSTIPATION.*

(REPORT OF TWO CASES.)

By BERNARD ASMAN, Louisville.

My purpose in briefly reporting these two cases of constipation is to call attention to a type of this disorder which is as a rule easily relieved when properly recognized but which is frequently overlooked. Oftentimes, too, relief from the coprostasis is unexpected, is incidental to, or results directly from the treatment of co-existing rectal or colonic disease, and in this event the cure may almost be said to be accidental.

Perhaps all who have done rectal surgery have occasionally noted, sometimes probably with some surprise, that following some simple rectal operation *which required thorough stretching of the anal sphincter* that the patient afterward claimed to be entirely relieved of constipation of perhaps many years' standing.

This form of constipation first properly understood through the aid of radiography has been found to be more common than was supposed and from this the observation may be made that no case of constipation should in any wise be treated without first a careful digital and ocular examination of the rectum having been made.

The type of constipation referred to is that in which colonic motility is normal but in which there is fecal stasis in the distal colon and rectum, the accumulation taking place here because of impaired rectal reflex, the result of neglect or refusal to respond to the impulse to go to stool when the feces descend from the sigmoid and begin to fill the rectum. This so-called "call of nature" when repeatedly unheeded or postponed soon becomes much less insistent, the rectal pouch becoming exceedingly tolerant of the presence of feces and the desire to go to stool becomes feeble and irregular, thus favoring the progressive accumulation of large masses of feces in the rectum and pelvic colon—the condition now frequently referred to as the *dyschezia* of Hertz.

This accumulation in the rectum and sigmoid may persist for days, the stools, if any, consisting of only a part of the collected mass, are hard and dry and accompanied by pain. Fecal impaction may finally follow.

Presumably this form of constipation is often brought about through carelessness or false modesty but undoubtedly it is also often due to anal fissure, ulcerated hemorrhoids or other ano-rectal disease. Whether it may also be caused by an irritable and hypertrophied sphincter or whether such a condition of the sphincter is the product of the *dyschezia* is

debatable, as is also the relationship of Houston's valves. It might be mentioned in passing that auto-toxemia and neurasthenic symptoms not uncommonly accompany these conditions.

Case I.—Mrs. L., age 51, married, the mother of three children, (all living and healthy) fairly robust in appearance, but sallow in color, coated tongue, and exceedingly nervous, came under observation last week in August, 1913, because of pain in rectum which she stated had been giving her considerable trouble for the past four years, but particularly in the last month.

Personal and family history negative, as related to present complaint with the exception that during the past ten years she states she has been a periodical sufferer from muco-colitis the attacks becoming in the last year as frequent as every six weeks to two months and more and more severe in character. Constipation, present and pronounced for more than twenty years, necessitating the constant use of extremely large doses of the strongest purgatives.

Examination revealed the presence of large ulcerated internal hemorrhoids, a tight, unyielding sphincter ani.

Operation consisted in complete divulsion of the sphincter (of course without tearing its fibres) and the removal of the hemorrhoids; this being done without any reference or promise as to the constipation. On the third day after operation, without any purgative being given, there was a small fecal discharge through the anal dressing tube. On the fourth day the tube was removed and a purgative given resulting in a large bowel movement. On the sixth day the bowels moved normally without the use of a purgative. Uneventful recovery from the operation was made, and the patient states, December 15th, that she has since found it necessary to take only a small dose of cascara and that not oftener than once a week.

Case II.—Mr. C., a country merchant, aged 36, presented himself for treatment September 1, 1913, because of intense anal pain particularly during defecation, which had existed about one week and which seemed to be persistently growing worse. He said the trouble had its inception with the passage of an extremely large constipated movement one week before. Excruciating pain of a sharp, cutting character was felt at each defecation since, followed by painful throbbing and spasmodic contraction of sphincter ani for half an hour or longer. Upon examination a deep fissure at the mucocutaneous junction in the median line posteriorly was found.

It was ascertained that this man's bowels had not moved normally since childhood. He had at first resorted to the ordinary purga-

*Read before the Jefferson County Medical Society.

tives, gradually increasing the amount taken and changing from one to another, and in the past several years had been depending for the most part upon enemas—plain, glycerine, soap, etc. His anal sphincter was found to be greatly hypertrophied, tightly contracted and extremely irritable.

Under local anaesthesia his sphincter was gradually yet thoroughly divulsed, and the fissure carefully swabbed with saturated solution of nitrate of silver. This fissure healed promptly and unexpected yet pronounced relief from the long-standing constipation was at once reported by the patient. A report three and one-half months later is to the effect that the unexpected relief from constipation is still in evidence—that only an occasional mild laxative is required to keep the bowels in normal condition.

DISCUSSION.

G. S. Hanes: We not infrequently see constipation relieved by operations upon the outlet of the bowel. This is a mechanical affair. Many times if we could look at the alimentary tract of a patient suffering from constipation, we would find it normal, and functioning properly, but when the fecal material gets to the outlet it is obstructed. All the muscles are set in tetanic contraction and do not become released sufficiently to allow the fecal material to escape. In this connection, I would call your attention to the fact that every individual that has tight muscles is not necessarily constipated. That depends upon two things. We know that a great many individuals naturally have much softer fecal material when it enters the sigmoid, than others. A great many men who have investigated this question say that it is not uncommon to find hard fecal material in the proximal transverse colon; in other words, the watery material has been absorbed and the fecal matter becomes hard when half way through the transverse colon. But this is not always true. In many cases the fecal material enters the sigmoid and rectum in a semi-solid, or comparatively watery condition. In addition to this, there is often a catarrhal condition of the rectum, which acts as a stimulus, and thus the semi-solid fecal material can easily escape through a very tight anus. Therefore, we may often find the anal muscles very tightly contracted, and still the patient will not complain of constipation. On the other hand, however, if the fecal matter enters the rectum in a solid mass, and the individual has the condition described by Dr. Asman, he is always constipated, and these patients are not always relieved by operation. I noticed a report the other day by a surgeon who had done an ileo-sigmoidostomy without giving the patient relief. He had the same intensity of constipation as before. The liquid fecal material, when it came down into the sig-

moid, was, by reverse peristalsis, carried through the large gut around to the cecum, and he had the same degree of constipation as before the operation. This surgeon did not recognize the fact that, if he had relieved the surgical condition existing at the outlet of the bowel, the constipation would most likely have been relieved. Furthermore, I wish to add that the fecal material that came down into the sigmoid and passed around the large gut to the cecum, did not get there by reverse peristalsis.

Leon L. Solomon: We are all aware, I believe, that many constipated individuals, who undergo operations—no matter whether it is the bowel, that is operated upon, or whether the operation is for the relief of some pelvic disturbance, just so it keeps the patient under the observation of the physician or surgeon, for a more or less protracted period, are relieved of their constipation, at least, for a time, and it occurs to me, that this benefit is largely attributable to the fact, that, during the time the patient is under observation, whenever the bowels have failed to move, in the preceding twenty-four hours, the attention of the physician or nurse is called to the failure.

I believe that constipation is largely dependent upon a cerebral condition controlling the function of defecation. I know a gentleman, who, for years, has not had a movement of the bowels on Sunday, and, on numerous occasions, I have proved to his and my own entire satisfaction, that his habits, on this particular day of the week, are such as to overcome the "automatic condition," that, on other days, brings about an action of the bowels. This man is a wholesale merchant. Every day, except Sunday, upon his arrival at his place of business, at about half past eight or nine o'clock, he regularly empties his bowels. On Sundays, he seldom rises, until after his regular time for bowel movement has passed, and he therefore, misses the influence of the "automatic condition," that prevails on other days.

It is a most remarkable thing to me, in view of the abundant nerve supply of the lower bowel, that constipation should be as common as it is. Apparently, the Maker of us all, foreseeing that the human animal would be constipated, abundantly provided this portion of his anatomy with nerve filaments. As an example of its sensitiveness, we need only recall the fact, that, in endeavoring to revive an individual from the effects of chloroform, or in the resuscitating of an apparently still-born child, we almost invariably provoke respiratory efforts, upon introducing the finger into the rectum.

There is one thing I would like to call your attention to in connection with this subject of constipation and measures for its avoidance. Why should not the Jefferson County Medical Society go on record, as favoring the establishment of "public comfort stations" in our down-town

district? We American people have some mannerisms and customs that are peculiar to ourselves. We are more constipated than the Germans in Germany. Why? Because, in Germany, in every restaurant, in every cafe, you will see a rather conspicuous sign, reading, "For Ladies" and right next to it another one, bearing the inscription, "For Gentlemen." In Germany, where I resided some two years, as an unmarried man, I had no hesitancy in saying to a lady companion, "Pardon," and, leaving her, go to one of the stalls or apartments set aside for gentlemen. Likewise, the lady has no hesitancy in answering a "Nature's Call." It has repeatedly happened to me, that the lady, with the same "Pardon," would leave me, in order that she evacuate her bowels or bladder.

I would like to offer a resolution, that the Jefferson County Medical Society goes on record, as favoring the establishment, in the city of Louisville, particularly in our down-town district, of "public toilet rooms."

Bernard Asman, (Closing): As regards the prevalence of constipation it has been stated by some one that "every third man and every woman is constipated." While this is rather a sweeping charge observation forces one to the conclusion that the exaggeration, if any, is only very slight. Constipation is a subject of great importance to each and every one of us, whether engaged in general practice or in a particular specialty, for the reason that its relationship to many other diseases is quite intimate.

It was my pleasure also to read the report of the case mentioned by Dr. Hanes in which the operator did an ilio-sigmoidostomy and one of my reasons for reporting these two cases this evening was suggested to me because the author of the article referred to absolutely overlooked the fact that the obstruction to the fecal outflow might have been found right at the anus itself.

Furthermore, it seems that he also overlooked an easy way of stopping the flow of fecal material back into the cecum. It would have been quite easy to have done such an operation as we do when we desire to establish an artificial anus, with closure of the lower loop of the bowel. Then no fecal material could have gotten past the sigmoid flexure.

Dr. Solomon's suggestion in regard to the establishment of a public comfort station is, I think, a very important one, and I hope the Jefferson County Medical Society will go on record as heartily favoring a movement of this kind. If such a station were established in the down-town district, undoubtedly there would soon be fewer people suffering from constipation and, consequently, fewer people suffering from many other diseases.

POST DIPHTHERITIC PARALYSIS.*

By GAYLORD C. HALL, Louisville.

Mr. T. F. B., age 35 years. Referred to me the 25th of August, 1913, through the courtesy of Dr. B. J. O'Connor.

Patient had always enjoyed splendid health and had practically never been sick. Is traveling auditor for a railroad and has to use his eyes a great deal but has never experienced any difficulty in doing so. The illness under consideration began several weeks previous to the time of his visit and began while he was in the south. He returned to Louisville and was under the care of Dr. O'Connor who thought the attack suspicious of diphtheria, though no antitoxine was used and the local symptoms of the membrane formation, etc., improved with the advent of his more serious trouble. Was referred to me under the belief that probably there was an abscess deep down in the neck that was causing the distressing symptoms from which the patient suffered.

These were sharp, cutting pains, at times deep in the throat and inability to swallow either liquids or solids except after much effort. Sometimes following attempts at swallowing the material would be regurgitated; at others, having swallowed the food or liquid he would vomit very acid stomach contents. Liquid would often be projected through the nostrils due to an inability to shut off the posterior nares.

Examination showed very red and inflamed tonsils, the right side being larger and having a superficial ulceration. Cultures from this are were negative as to diphtheria bacilli.

The tissues above and behind the tonsils were searched very carefully with a small knife but no pus was located. The patient, however, expectorated large quantities of very thick,ropy, saliva and for that reason the esophagoscope was passed in order to eliminate the possibility of a stricture or a collection of pus low down. Careful examination with the esophagoscope failed to reveal either of the above conditions. General supportive treatment was instituted with local antiseptic remedies.

The patient complained of very severe pains in the throat and pit of stomach on attempts at eating and became very much depressed and apprehensive on account of his condition and his inability to swallow.

Five or six days following his first visit he suddenly complained of his eyes, chiefly for close work. He found, however, that things were blurred also for distance but that his chief disability was with close work, since he found it impossible to see the figures on the books he worked with.

*Read before the Jefferson County Medical Society.

Examination showed that he would accept in the right eye a plus .75 sphere; in the left eye plus 1 sphere, giving normal vision. Without this correction his vision was 6-9 in both eyes. For near it was necessary to add plus 1.50 sphere to the distant glasses.

September 3, 1913, examination under drops. Media clear; fundus normal; retinoscope, plus 2.50 neutralizes; accepts plus 1.50 sphere, both eyes. The glasses were ordered less .50 sphere, while for near plus 1.50 sphere was added at a post mydriatic refraction on September 7th.

The condition presented by this patient can best be explained by the assumption that he had a mild faucial diphtheria, his general robust health enabling him to check the advance of the disease though his system could not wholly assimilate the generated toxins without showing some disastrous results. This manifested itself in a partial temporary paralysis of muscles of deglutition together with the soft palate which was followed after about a week by nearly complete paralysis of the accommodation. Both of these improved under treatment, his difficulty with swallowing and with the soft palate being practically perfectly recovered when last seen. The disability with the eyes, however, has remained and considering the patient's age and his proximity to the stage of presbyopia it is the opinion of the writer that it will be permanent.

A hasty search of the literature brought out the following information. Osler regards paralysis as the most important of the sequelae, being a toxic neuritis due to absorption of the poison. It occurs in from ten to twenty per cent. of the cases. It may follow mild infections and is proportionately of more frequent occurrence in adults.

Quoting Woodhead, in 494 cases the palate was involved in 155; the ocular muscles in 197; other muscles of the body in 10; 91 of the patients died.

Dieulafoy says, in speaking of paralysis of the palate, "When the pharynx is also paralyzed, the dysphagia is so great that, in spite of every effort, the bolus cannot be properly swallowed, and food may lodge in the larynx, causing fits of suffocation, which may prove fatal."

Struempell agrees largely with Osler stating the paralysis is most important of sequella appearing two or three weeks after the throat trouble ceases and apt to follow mild cases. It attacks the soft palate by preference; the pharyngeal muscles may be hypoaesthetic at the same time, the vocal cords may be affected. There may be paralysis of the ocular muscles, those controlling the accommodation being most apt to be affected. A paralysis of the pharynx is sometimes left behind so that the

children have to be fed for weeks through an esophageal tube.

DISCUSSION.

Adolph O. Pfingst: This case should be interesting to all of us, because it represents two of the most common sequelae of diphtheria. The symptoms occurred in the order of their frequency; that is, paralysis of the throat first and the ocular muscles second.

In regard to paralysis of the muscles of the palate, I think we are often led to believe that we have a toxic paralysis when we really have a muscle inactivity, due to the inflammatory condition and edema of the palate itself. This occurs coincident with or soon after the active process while true paralysis of the throat comes on later—four to six weeks after the disease.

As to the ocular condition, I believe, as Dr. Hall, that the extrinsic muscles are most frequently affected, causing paralytic squint. I can recall several cases of convergent squint due to paralysis of the abducens muscles following diphtheria.

I differ with Dr. Hall in regard to prognosis in his case. I am inclined to believe that this man will regain the power of accommodation. I have seen several cases of post diphtheritic paralysis of the intrinsic ocular muscles and they all recovered.

One point in connection with these paralyzes has always been interesting to me; that is, the length of time the diphtheritic toxins remain in the body.

Although I have never been actively interested in deaths from anesthesia, I recall two cases where children were given anesthetics too soon after an attack of diphtheria which terminated fatally. In one of these cases, gas was the anesthetic employed, in the other chloroform. The particular point of interest in this connection is the question of how long the individual retains the poison in his system after an attack of diphtheria. In other words, how long a time should elapse after an attack of diphtheria before we can safely give the patient an anesthetic. I have looked up the subject repeatedly, but have been unable to find anything bearing upon it in the literature. I would like for Dr. Hall to refer to that point in closing. Personally, I believe that at least a year must elapse after an attack of diphtheria before an anesthetic can be administered with safety. In one of the cases of death from anesthesia mentioned above, the anesthetic was administered six months after the attack of diphtheria.

Jno. J. Moren: Dr. Hall did not report all of this man's trouble. He came to see me in October, having just returned from a trip in the South, and he had not had his clothes off for three or four days. He was unable to remove his clothing, or to feed himself, or to get on and off

a street car. He exhibited all the signs of a typical multiple neuritis. He was in my office to-day, and he has been getting along beautifully. All of his symptoms have disappeared, and he is going to work in about two weeks. His eyes are all right; at least, he made no complaint about them, and he tells me that he sits at home and reads and is able to pass away the time very nicely. He is not wearing his glasses, has no double vision, no difficulty in swallowing, or anything of that sort. All of his symptoms when he came to me were referred to the extremities. His paralysis was not complete—only partial. However, he was utterly unable to button or unbutton his clothes, orto feed himself.

Gaylord C. Hall: I have nothing in particular to add, except that, in the future, when I have any trouble with my eye patients I am going to turn them over to Dr. Moren.

FURTHER CLINICAL REPORT OF TREATMENT OF ALCOHOLISM.*

(PRESENTATION OF PATIENTS.)

By EDGAR W. STOKES, Louisville.

CASE I.

Mr. M., 51 at time he was referred to me by Dr. C. O. Neff of this city, was admitted to sanatorium September 17th, 1910, three years and four months ago; was presented before this society for the first time one year and six months ago by me.

Previous History. Habitual drinker for twenty years, had been treated for alcoholism several times, amount of alcoholic stimulants taken in twenty-four hours was one to two quarts of whiskey and many beers. Appetite very bad, would go for weeks at the time scarcely eating as much as one meal in two weeks, living almost entirely on alcoholics.

On examination patient was found to be suffering with intermittent hallucinations to a marked degree; greatly enlarged and painful liver; eyes bulging and complexion waxy. I was told by his intimate friends that he seldom noticed them on the street unless they stopped him; many of his friends thought he used some kind of drug.

Treatment first day, or 24 hours; Patient put to bed and given the following dose every three hours:

Fluid Extract Poke Rootmxv
Tincture Buck Beanmxv
Fluid Ext. Ergotmv
Fluid Ext. Gentianmxv
M. Ft. Dose No. 1. In wine glass
half full of water.

Also tinct. passiflora incarnata dram I. every every two hours, (one dose). At bed time he was given two improved c.e. pills.

Patient was given a hot bath of fifteen minutes before retiring.

Whiskey zii, given when called for on an average of once an hour. About midnight he was given sulphonal gr. xv. Rested but little first night.

Second day treatment: Same as first day with this difference: At night he was given three c.e. pills, whiskey zip about every two hours, and occasionally beer as patient called for it. Patient had a restless night sleeping only about three hours.

Third day treatment same as preceding days except tonic was given only every four hours, and while the patient did not now ask for whiskey he would drink it when proffered him, about every three hours, but complained that he could not take it well as it made him sick and nauseated him, stomach lavage in all cases when needed.

Fourth day treatment same as in preceding days, but patient now refused all forms of alcoholic stimulants, and was slightly delirious, or still suffering with delusions, but not so marked as when he came for treatment. He was given, at bed time, gr. xv of sulphonal; was asleep in about 45 minutes and slept all night. On the morning of the fifth day he awoke with mind clear and has been so every since. His general condition has constantly improved up to date. He has a complexion like a girl's, has not taken a drink in three years and four months, and tells me he has never had the slightest desire for alcoholics. He is here to-night.

CASE II.

Mr. S., engineer for the I. C. R. R., age 52 at time of treating; was admitted to the sanatorium June 23rd, 1912, referred to me by Dr. Moorman of this city. A periodical spreer, the quantity of whiskey he would drink in each 24 hours was more than a quart; drank very little beer. Would often have to remain from his work for weeks at the time, and would debauch all this time, he gave a history of being a periodical drinker for fifteen years or more; made a great deal of money and all but very little of it went for booze.

Treatment the same as in the preceding case and only varied, as in every case, to suit the demands of each individual patient. For instance, he had lost all desire for drink, by the end of the second day and had quit calling for drink. When I found it made him sick I did not give him any more. This patient was given six improved c.e. pills at bed time on first night.

Patient dismissed on the fifth day relieved, and he tells me he has been attending to business every day for the past eighteen months and has never had any desire for alcoholic stimulants of any kind, and will soon buy

*Read before the Jefferson County Medical Society.

himself a nice home with money he has saved since he returned home. He and his doctor are here to-night; ask them both.

CASE III.

Mr. J., of Cleveland, Ohio, age 32, was brought to Louisville by his father and referred to me by Dr. Henry Orendorf of this City. Was admitted to sanatorium September 18th, 1912.

Previous History: Had been suffering with delirium tremens several days before he reached Louisville; had been a hard drinker for ten years, getting on many debauches during that time; was taking more than a quart of whiskey in each 24 hours. The delirium had subsided before he reached here. He was extremely nervous, could not hold the glass to his mouth to take a drink, (the nurse had to do this for him). He lost all desire for food and was greatly nauseated when he attempted to eat or drink; he could not retain whiskey more than a few minutes; was using morphine to produce sleep.

He was dismissed, well, on the seventh day after entering the sanatorium and went home. He lost his wife from appendicitis the following week. He has passed through Louisville several times since his treatment and was to see me, and assures me each time that he has never wanted nor taken a drink. His treatment did not differ from the others, with the exception that he was given four improved e. c. pills at bed time the first three nights.

Mr. I., age 43, linotype operator on one of our large daily papers, came to the sanatorium for treatment eleven months ago.

Previous History: Always drinking while at work and off duty, for the past ten years; often too drunk to go to work; would borrow money from loan companies and take it home and tell his wife he worked for it, refused to leave home for treatment, said he didn't believe in it, but as he continued to be unable to work but only a few days each week, his wife finally persuaded him to take treatment. His treatment didn't differ from the others, he is here to-night, ask him.

CASE IV.

Mr. B., age 48, referred to me by Dr. C. E. Frey of this city, September 26th, 1913. Periodical drinker for fifteen years, drinking more than a quart of whiskey and many beers in 24 hours. His treatment did not differ from the others. He is here to-night. He was dismissed October 1st, 1913, five days after he was admitted and tells me he has never had any desire for a drink since taking treatment.

CASE V.

Mr. S., age 56, referred to me by Dr. Beverly Berry of Maceo, Ky., was admitted to sana-

torium August 20th, 1913, so drunk he did not know where he was. His physician brought him to the sanatorium.

Previous History: Had drunk whiskey practically all his life; for the past seven years he had not seen a sober day, except when he was away from home taking treatment, and had taken all, (so the doctor reported) that he ever heard of, and always returned home after taking these treatments drunk.

He had become partially insane at times, and was of great annoyance to his family, and friends, and it was with great difficulty he was persuaded to take this treatment. His general condition was very bad, he was drinking more than a quart of whiskey in 24 hours, had no appetite and seemed to subsist on alcoholics was delirious for first five days of treatment.

His case was one of the worst that ever come under the observation of the sanatorium. His mind cleared up on the fifth day, and he was dismissed on the eighth day after entering for treatment. His treatment did not differ from the others except a saline was given each morning at six o'clock.

I have a letter here from Dr. Berry which I will file with the secretary, which says: "When Mr. S. returned home he was not the same man as when he left, by any means. I see him daily. He has not taken a drink since his treatment and tells me he abhors the sight of whiskey. He is in good health every way.

CASE VI.

Mr. R., age 44; Central City, Ky., was referred to me by Dr. W. C. White of this city, March 9th, 1912. He had been drinking for thirty years. He had to be hauled home maudlin drunk every few days, but never had delirium. He did not think he could be relieved in five or six days. I agreed to let him stay as long as he wanted to, in order to satisfy himself that he was well.

This is the privilege of all patients who come to my sanatorium, and they will know when they are well without being told, but this man is about the only one who ever wanted to stay after he was well.

He stayed nine days, but had no treatment after the sixth day, and declared that he had no desire whatever for any form of alcoholic stimulants, though, before he took the treatment, he was spending \$40.00 per month for drink. I reported this case before this society eighteen months ago; he had been well only about five months at that time. His physician reported to me that he is still on the water wagon, and holding tight.

CASE VII.

Mr. A., age 43; referred to me by Dr. Bolling of this city, May 18, 1912, almost two

years ago. Periodical spree for many years. Was dismissed five days after entering sanatorium, entirely relieved of all nervousness and desire for alcoholics of which he had been taking something like a quart in twenty-four hours. His treatment was the same as others. Dr. Bolling is here to-night he will please tell us how this patient is doing. He was seen by me a few days ago and said he never has taken a drink since his treatment.

My article of eighteen months ago, published in the *JOURNAL*, describing a treatment for alcoholism, has caused a persistent demand on me for information concerning this subject. Since then I have had a much broader experience both with the treatment and patients, but this has not served to make any radical change in the treatment or the method of administering it. Many of these patients have drifted into this habit, unconscious of the fact that they were acquiring a condition which would likely terminate seriously, to their health and happiness. Often in the beginning it was only a morning toddy; then later other drinks were taken during the day, and gradually this vicious appetite and nervous desire for alcoholics appeared, which with the tenacity of a bull dog, holds its victim in its clutches, helpless. When the patient reaches this point in his drinking it ceases to be a pleasure and becomes a necessity.

It is a mistake to attempt to treat these patients at home; the alcoholic will do as he likes, not as the physician directs him to do, if he is in his own home.

As I have stated in my previous paper before this society, I believe with Hare of Philadelphia, we have no disease to deal with. Neither do I believe the tendency to consume alcoholics to be an inheritance, and with Dr. Hare I believe it to be a habit, and in many cases a habit that has produced degeneracy that permits the habit to exist.

In treating this class of patients, for convenience sake, I ignore the classifications such as: acute, sub-acute, and chronic alcoholism, as I believe this classification has little bearing on the treatment given or the results obtained, only in very exceptional cases where some organic disease has advanced to its last stage.

The classification I give is alcoholics with delirium, and alcoholics without delirium. In the delirium type I push the sedative as the case may demand; where we have no delirium no sedative is given, except the tonic mentioned from which I get some sedative effect—enough for such patients; but not a very marked sedative effect do I claim for it.

It is not my object to deal with the etiology, symptomatology and the various types of alcoholism, as time will not permit. Suffice

it to say, any sanatorium of consequence will be sure to get all kinds and all types, from the quiet unassuming to the delirious type.

One interesting point about these patients is the tremendous capacity some of them have for consuming alcohol. I saw one man drink a quart of whiskey in about 45 minutes, while he was making up his mind to take the treatment. A physician who does not see much drinking or is not constantly with the patient will scarcely believe you when you tell them of the enormous amount some put away and can continue to do so for years, and upon a physical examination show but few signs of the effects of it—usually an enlarged liver, not often cirrhotic, and some slight impairment of the digestive organs, and some patients suffer from insomnia.

In order to obtain the best results, I believe it is absolutely necessary for the patient to be kept under close observation and in an entirely different environment, made possible by placing the patient in a sanatorium with trained attendant night and day.

When a patient comes to my sanatorium he is usually in one of three conditions: He may appear to be fairly sober; he may be in a drunken stupor; or he may be delirious. He is assigned to an ordinary room without padded walls. He has an attendant—one capable of handling him without abuse. He remains in this room until he is well. If he wants a drink of whiskey (and usually does) he gets it. Remember, there is nothing so soothing to these fellows as a drink of whiskey. Of course, all the time he is calling for drinks, you can administer your medicine.

Now, coming to the vital question: What advantage has this treatment over the hypodermic method which is practiced by some of the profession? Just this—that it does away completely with the hypodermic needle and its possibility for harm. That it destroys all craving and desire for alcoholic stimulants. It corrects the nervous disorders; restores the appetite, and brings to the patient natural, restful sleep. It eliminates the crib, the padded and barred rooms. We have no such barbarous paraphernalia. It makes it no longer necessary for the patient to remain from three to six weeks in a sanatorium to get sobered up. It is no longer necessary to give hyoscine, morphine or bromides hypodermically or otherwise, thereby eliminating the possibility of their habit. Hyoscine given to alcoholics is a most dangerous procedure, even in the most skilled hands, and when continued for several days you will find the effect upon the nervous system is such that it will take your patient weeks to recuperate, and it has killed more alcoholics than it has benefited.

If you desire to make it necessary for

your patient to remain weeks at your sanatorium, hyoscine is the one agent that will do it.

Another dangerous procedure is the use of Turkish baths for hours at a time. These patients come to us over-stimulated. Now, to take these over-stimulated patients and place them in Turkish baths for hours, you make a grave mistake. The patient who comes out of this treatment alive is fortunate.

One potent factor in the treatment, is the trained attendant, and one who is reliable and competent. The patients comforts must be anticipated. I can not imagine anything more horrible for these unfortunates, than after a debauch they come to and find themselves in straight jackets, or in padded cells, and not a human being in sight for hours; perhaps famishing for water and cursed with that insatiable craving for a drink of whiskey. Dante's *Inferno* pictures no more horrible suffering. Don't ever make yourself believe that these inebriates are insane; they are human like you and know much of what goes on. I am sure you will agree with me that the humane way of treatment is the best.

I have relieved, permanently, ninety per cent. of the alcoholics that have come to me for treatment. These men you have seen to-night are living examples. The ten per cent. that is not cured, is that class of degenerates who have no incentive to do right by themselves or their friends and while relieved for the time being, will return to the old scenes of temptation and soon fall a victim again.

When a patient takes this treatment, he leaves the sanatorium with his nervous system in a normal condition, his appetite completely restored and he sleeps like a child, and with the old craving for booze entirely gone. You can trust him anywhere and not a drop of alcohol will he tamper with for he remembers the dangers of it.

When we stop to think how little medical science has contributed to the treatment of alcoholism, and how the old hypodermic treatment continues with hyoscine, morphine and other such alkaloidal products, with their harmful effects, its no wonder that a treatment of this kind creates comment and doubt in the minds of those who are loath to bid farewell to their old friend, the hypodermic syringe. Should you be in doubt, I ask of you to withhold your criticism until you have investigated this treatment and have seen more of its results like you have witnessed here to-night.

Medical science has contributed little new in the treatment of alcoholism in the last quarter of a century, until this treatment was given. Yet it has stepped forth in its mantle of glory and dealt a death blow to small-pox,

yellow-fever, malaria, diphtheria, typhoid fever and tuberculosis, and other dreaded diseases.

DISCUSSION.

Leon L. Solomon: Inasmuch as considerable prominence has recently been given by certain writers to the fact that inebriates are proverbially poor consumers of sugars and starches, I would like to ask Dr. Stokes' patient if, while he was drinking large amounts of alcohol, he consumed liberal amounts of sugars and starches—by this I mean bread, potatoes, cereals, breakfast foods and the like?

Patient: I ate breakfast foods a good deal until I lost my appetite and after that I ate very little of them. I did not eat very much sweets.

Leon L. Solomon: My reason for asking that question is that certain German authorities have for a number of years claimed that there is an insufficiency of sugars and starches in inebriates; that during the time they are drinking heavily they care very little for sugars and that, therefore, a prominent part of the treatment should be the substitution of large quantities of starches and sugars, particularly the latter. In the last issue of the *Journal of the A. M. A.*, I noticed a short report by a gentleman whose name I do not now recall, along this particular line. If this theory be true, it is natural to presume that in these individuals there would be a craving or demand on the part of the system for alcohol, since nothing supplies heat and energy in such abundance as alcohol, whereas we know that sugars and starches likewise supply heat and energy.

Jos. F. Dusch: Dr. Stokes has treated five patients of mine in the past two months and in each instance, in less than a week's time, these patients were back at work, and at the present time they are still on the water-wagon. I do not believe this treatment will put brains into a man's head, or give him an insurance policy against alcoholism, but it is certainly the most effective treatment I have ever seen.

Tetany. Prophylaxis. In pregnant and puerperal patients and after gynecologic operations, when Chvostek's sign positive and symptoms such as parasthesia of hands, itching, pains in fingers in sewing or writing, and muscular weakness or stiffness present, give calcium chloride in following form: *Calcii chloridi* (puriss) *zv* (20 Gm.); *syrupi menthae piperitae* (vel *syrupi rubi idaei*) *zij* (60 Gm.); *aqua destillatae*, *zx* (300 Gm). Dose of calcium chloride to be carried as high as 75 to 90 grains (5 to 6 Gm.) a day in adults and in newborn infants, to 15 grain (1Gm.).—Kehrer.

Toxemia of Pregnancy. Treatment. Free administration of oxygen seemed useful in a number of cases, some severe. May be given either by inhalation or subcutaneously.—Shears

CESAREAN SECTION, NAEGELE PELVIS.*

(REPORT OF CASE.)

By J. HUNTER PEAK, Louisville.

We have in DeLee's new book on obstetrics, a very fine description and illustration of a Naegele pelvis. One of the most typical of this class of pelvis—the obliquely contracted—is that due to disease of the sacro-iliac joint and the neighboring portions of the ilium and the sacrum. F. C. Naegele, in 1839, first described it, having collected 37 cases, but it was mentioned by various obstetric writers long before this, and Naegele found one in an Egyptian mummy.

All the findings of oblique contraction, and those due to exaggerated pressure of one thigh, are present in this pelvis, and since one wing of the sacrum is often atrophic, aplastic, or even missing, in addition to the distortion, actual reduction in the size of half of the pelvis is present, and, what is important from a clinical point of view, the narrowing of the pelvic lumen extends down to the very outlet. The innominate bone of the affected side is dislocated upward and backward, while the pubic joint is pushed to the healthy side. The linea terminalis of the healthy side is given an exaggerated curve, being straightened on the diseased side. In nearly all cases, a firm synostosis is found in the affected sacro-iliac pelvis and a sharp polemic was waged among the students of this pelvis as to whether this was primary or secondary. Naegele believed that, most likely, a primary congenital deformity of the joint existed and he did not deny that the entire change could be due to acquired disease. Hohl proved that the wing of the sacrum could be congenitally absent, but other specimens were exhibited which showed that characteristically deformed pelvis could be produced by acquired disease of the sacro-iliac joint. Breus and Kolisko find traces of ostitis in all so-called Naegele pelvis, and insist that the deformity is always due to arthritis, caries, or trauma of the sacro-iliac synchondrosis or other portions of the pelvis. Pelvis with congenital defects of the wings of the sacrum exist, but they do not produce such great deformity of the inlet nor do they show contraction of the whole length of the pelvic canal, as do these pelvis with disease of the sacro-iliac joints. Here the sacral and iliac portions are wasted, absorbed, and ankylosed. If the disease occurs in early life, the developmental portions—the ossification centers—are destroyed, and growth of the bone, of course, is rendered impossible. Now come the mechanical factors, the pressure of the trunk, the

lateral pressure of the femur, and the characteristic changes are brought about.

DIAGNOSIS.

It is usually easy to discover an obliquely distorted pelvis, but not so easy to decide on the actual pathology of it, nor on the degree of spacial contraction. Attention may be called to the deformity by an even, limping gait, a scoliosis or by the unequal length of the legs. Scars from old sinuses point to disease of the hip or sacro-iliac joints, and the history will usually show some infantile disease or injury. Spinal paralysis, rachitis, habit scoliosis, coxitis, gonitis, amputation of the leg, and spina bifida, have been the causes of the asymmetry in the cases which came under observation, and it was possible to decide in all of them how the deformity was produced. In addition to the scoliosis and the apparent shortening of the leg, one will notice the hip of one side higher and retroposed, the pubic region displaced to one side, and the hair-line oblique. The rhomboid of Michealis is asymmetric or tilted, and the gluteal fold lower on one side. Palpation of the bones confirms the above findings, and, in addition, discovers that the ischial tuberosity of one side is higher and the ramus of the pubis has a different direction on that side. Examining first with one hand and then with the other, and the fact that one-half of the pelvis is less roomy. External measurements from corresponding points may show a discrepancy between the two sides, but it is almost impossible to diagnose the kind of a pelvis from them. By excluding all the other varieties we may make a diagnosis of a Naegele pelvis, and this may be confirmed by finding the corresponding half of the rhomboid of Michealis reduced in size, the spine of the last lumbar vertebra lying close to the postero-superior spine of the ilium. On internal examination the corresponding half of the pelvis is very small and the encroachment of the ischium on the lumen persists even to the outlet. Ankylosis of the sacro-iliac joints may be palpated by the fingers per vaginam or rectum if exostosis and pericapsular thickening exist.

After the fact of pelvic distortion has been discovered, the degree of pelvic contraction must be determined.

A few cases of dislocation of the ilium upon the sacrum are on record. It is easily diagnosed if its existence is suspected. It causes persistent backache, difficulty in locomotion, and, if it occurs in labor, occasional dystocia.

September 15th, last, Dr. Melton called me to meet him in consultation to see Mrs. T. R., age 25 years, who was in her first labor.

Dr. Melton had made a diagnosis of Naegele's pelvis and at the time of telephoning

*Read before the Jefferson County Medical Society.

said, "I am sure that a Cesarean section will be necessary."

Examination revealed the history "that she had been in labor thirty-six hours." The attending physician said, he thought that he would wait until complete dilatation cervicæ had taken place just to see if a normal labor could be finished. Full dilatation was accomplished in fifteen hours; then strong pains continued for eighteen hours without any progress being made in the descent of the head. After I saw her normal pains continued up to the time of operation with no appreciable results. The waters had ruptured some hours before I saw her.

Further history was obtained that the patient had suffered from left hip-joint disease since she was five years old. The left leg was flexed at the body and the thigh was lying across the pubes with the hip-joint firmly ankylosed. The left leg was not nearly normal in length and very poorly developed. The left os-innominatum was not nearly so well developed as the right. The external genitals were normal but encroached upon by the left thigh. And the wonder, to those of us in attendance was, that she could have become pregnant at all for the position of the left thigh did seem to preclude the possibility of coitus.

Digital examination was made with astonishing results. The ischium on the left was displaced into the pelvic floor and could be felt immediately the finger was placed in the vagina. The whole bony pelvis on the left was displaced toward the median line decreasing the bony outlet to about two and one-half to three inches laterally the antero posterior diameter was quite deep.

The diagnosis made by Dr. Melton was concurred in at once and the patient was sent to the hospital, then prepared for Cesarean section. Viability of the child was apparent.

Able assisted by Drs. Onderdonk, Casper and Yeatts, we quickly did the ordinary operation. The placenta was anteriorly attached and was torn through. An eight pound baby perfectly developed was delivered and given to the nurse who soon had the little fellow crying lustily. After the removal of the after-birth, the uterus contracted nicely and all hemorrhage was controlled by closing the uterine wound. Operation finished and patient put to bed in about forty minutes in good condition. Mother and babe went home in fine shape on the eighteenth day. Both are still living and well.

Sections and ligations of both tubes were accomplished for obvious reasons at the request of the mother.

DISCUSSION:

Edward Speidel: Naegele's pelvis is supposed to be a very rare condition. Judging from the picture passed around, the patient did not show marked deformity at the superior strait. A typical Naegele's pelvis would show one side of the pelvis straight and the other side excessively curved. This picture shows considerable curve on one side and a very full curve on the other. It is probable, in this case, that the difficulty in delivery would have been encountered at the outlet of the pelvis. It must be remembered, in these cases of deformed pelvis, that the pelvis is tilted to one side, and, in consequence, the uterus lies more to the left or right than usual. Therefore, when labor sets in the uterus must be directed toward the median line in order to direct the head into the proper channel. Another thing to consider when the head will not enter the superior strait is that by the use of the Walcher position a certain amount of space can be secured, and by this means the head may be made to engage.

In many cases of deformed pelvis, we are greatly astonished to find that a child of ordinary size will pass through a pelvis which we could hardly believe would permit the passage of a child. Therefore, it seems to me that, before resorting to Cesarean section in cases of this kind, a careful examination should be made with the gloved hand, under surgical anesthesia to determine the capacity of the pelvis. Then, if possible, the head should be guided into the pelvic cavity, and possibly by a high forceps application the head may be brought down and delivery accomplished in a normal way. If the introduction of the hand does not disclose sufficient room then, of course, Cesarean section is indicated.

J. Garland Sherrill: I must take issue with what Dr. Speidel has just said in regard to the high forceps operation. In any case of contracted pelvis where the head does not readily engage, Cesarean section is much safer than the high forceps operation. Where the contraction of the pelvis is such that the attendant believes that delivery cannot be accomplished in the normal way, I think Cesarean section is indicated, and the operation should not be delayed until the woman is exhausted. Therefore, I would urge early Cesarean section before many examinations have been made and before the woman has become exhausted by attempts at delivery.

J. Hunter Peak, (Closing): Cases of contracted pelvis may be handled in any one of a number of different ways, when they are not exaggerated as this one was. In the first place, if the contraction is not too great, and the attendant has been engaged beforehand and understands the conditions, premature labor may be induced, and in that way save both the mother and child. So far as forceps delivery is concerned, it was impossible in this case. When the gloved hand was

introduced into the vagina it immediately came in contact with the deformity of the ischium, and there was absolutely no chance for that child, which was a well-developed eight pound baby, to be delivered at full term. The only reason I was not called into the case earlier was because the attending physician desired to see first whether delivery could be accomplished in the normal way.

If you will observe the pictures of Naegele's pelvis in the various books, you will find that this illustration comes as near to fitting every detail as any case I have ever seen.

TUBERCULOUS MENINGITIS.*

By J. A. O. BRENNAN, Louisville.

The sudden onset of this disease in a supposedly healthy individual with symptoms at the beginning not referable to the brain cause me to report this case.

Mr. C., white, age 42, occupation, clerk, mother still lives and enjoys excellent health, and his sister is also in good health. Father died of tuberculosis when quite a young man, never sick except when he contracted typhoid fever about one year ago and then he was confined to his apartment and hospital for nine weeks. He seemed to have recovered fully and about four months ago, developed a pleurisy of the right side which lasted some three weeks, but he finally entirely recovered from it. On about the last of November he called at my office although he had been suffering for some days previous, with great pain along the course of the right sciatic nerve, and everything that I could possibly do to relieve him was of no avail. Mobility of leg was good, and he had for some days after I first saw him no fever although he continued to suffer. He was, at the end of a week, unable to walk on account of great pain, but could move his leg in all directions while in bed with no discomfort. He vomited only a couple of times and that was the day before he entered the infirmary and the evening he was admitted. He was slightly delirious and had some fever before he went to the infirmary. Urine negative blood showed Widal positive. Wassermann, negative of both blood and spinal fluid. Spinal fluid found to be in normal condition. His mind cleared up for a while but it was not lasting. Aphasia ensued and pupils up to this time were equal and responded to light promptly, and all reflexes were normal. A few days later ptosis of the left eye ensued with unequal pupils and patella reflexes increased, ankle clonus slightly positive, Kernig's sign positive, also slight rigidity of neck, which later became more pronounced. Constant muttering and facial movements with arms and legs in con-

tinual motion towards the last. Dr. White very kindly examined the eyes and reported the following:

"Was called to see Mr. C., by Dr. Brennan on Friday. Found patient comatose, ptosis of left lid, semi-dilated pupil on that side; right eye pupil reacted to light slightly.

"Ophthalmoscope showed a neuritis, and the typical tubercles all over the retina. This in left eye.

"Right showed a beginning neuritis and numerous tubercles all over the retina; not so thoroughly developed but still they showed quite plainly. Saw the patient again on Saturday with Dr. Green, who was able to make out the tubercles. At that time there was not much change in the neuritis, but the tubercles were plainly visible; very little vascular condition; no tension at any time."

In closing I wish to thank Dr. Jno. Allen for his kind assistance in this case.

DISCUSSION.

Asa W. Nickell: This is too valuable a report to pass without discussion. It is one disease in the treatment of which the medical profession has, unfortunately, made practically no advance.

About 150 years ago Robert Whytt did the first work along this line in Edinburgh, and subsequently Dr. Gerhård, of Philadelphia, who made a special study of post-mortem work in children in the pediatric institutions of Paris, has done more to place this condition on a firm anatomical and clinical basis than any subsequent author.

There are some things rather peculiar about Dr. Brennan's case. Most of these cases that I have seen have been in children. It is rare under the first year, and most common between the second and fifth years. In the majority of cases, old tubercular foci will be found in the bronchial and mesenteric glands, or perhaps in the middle ear or urinary organs.

I would like to speak of the pathological picture observed in some postmortem work in which I have had some experience. After one thoroughly understands the pathology, the symptoms are of course better accounted for and more easily understood.

We noticed, in post-mortem work, that there was most frequently involvement of the meninges, particularly at the base of the brain, from which we get the term basilar meningitis. There may be slight turbidity and matting of the membranes, more commonly a turbid exudate, fibrino-purulent in character, which covers the structures at the base, surrounds the nerves, and extends into the Sylvian fissures. We noticed also considerable inflammation about the optic chiasm and along the Sylvian fissures and the interpeduncular space. Upon removing the arteries in the anterior and posterior perforated spaces, and look-

*Read before the Jefferson County Medical Society.

ing at them with a low objective, very often we found nodular tubercles present when not elsewhere. The lateral ventricles contained turbid material and the ependyma is softened, and the septum lucidum and fornix broken down. Also, the convolutions were flattened and the sulci obliterated. There is a tubercular endarteritis with the formation of intimal tubercles, due to implantation of the bacilli from the blood.

Practically all authors agree as to the heart condition in the first and second stages; it is usually low and very irregular. In the last stage of the disease the heart becomes weaker and the pulse rate becomes more frequent.

As to the ocular symptoms, in the early part of the disease the pupils are contracted, while in the latter stage they become dilated and are more irregular. In these cases that I have seen, of ocular palsies, the third nerve is most frequently affected. Associated with this we frequently see facial paralysis, paralysis of the limbs, and sometimes the hypoglossal nerve on the opposite side, which would indicate a lesion about the lateral and internal part of the crus.

Gaylord C. Hall: I would like to call attention to one point in connection with the ophthalmoscopic report. By "retinal tuberculosis" I presume is meant choroidal tuberculosis; retinal tuberculosis is practically unknown.

FOREIGN BODY IN THE EYE REMOVED BY MAGNET*

(REPORT OF CASE).

By J. M. RAY, Louisville.

This young man came to me on June 24th, 1913, with the following history:

On the 31st of May, 1912, a little over a year before I saw him, he had received an injury to his left eye while working on a punching machine in a machine shop, a piece of metal striking him in that eye. The sight of the eye was immediately affected. He was examined by a doctor, but the question whether or not there was anything in the eye was not definitely settled. The ordinary routine treatment was carried out, the inflammation subsided, the sight remained good and the man was satisfied. This state of affairs continued until October, 1912, when he saw Dr. Lederman, who examined him and found the sight in that eye to be 20-50. Although the eye was free from inflammation at the time, Dr. Lederman concluded, from his examination, that there was something in it. However, no further steps were taken.

I saw the patient on June 24th, 1913, thirteen months after the injury had been received. He had a convergent squint, in the right eye. The vision in the injured eye was 20-100; in the squinting eye, 5-200. He was suf-

fering from a low grade of iritis in the left eye. The metal had been in the eye so long that it had begun to rust, causing the peculiar stain known as siderosis. I examined the eye and discovered a mass on the nasal side, slightly below the horizontal meridian, in front of the equator of the eye. I could not distinctly make out a foreign body, but from the history of the case I was convinced that one was present. I told him the only thing to be done was to make an incision and endeavor to remove the foreign body with a magnet, but that the chances for a good result were not favorable. He declined the risk, as the left eye was at that time his best seeing eye. I saw him no more until September, 1913, when he returned to me with a fresh attack of iritis, the pupil being firmly bound down to the lens, a little exudate in the pupil, and the vision in that eye reduced to counting fingers. The right eye having become the better one, I explained to him the danger of sympathetic ophthalmia from the presence of the foreign body, causing frequently recurring attacks of iritis, and urged upon him either the removal of the left eye or an attempt to remove the foreign body.

As a preliminary to the operation I had an X-ray picture made, which was done by Dr. Keith, a metal cap, as suggested by Dr. Fox of Philadelphia, being inserted into the eye and held in place by the lid while the X-ray were applied. The picture showed the location of the foreign body with respect to the metal cap, and corresponded exactly with the location I had previously determined by means of the ophthalmoscope. I sent the man to the infirmary and, under local anesthesia, dissected back a flap of the conjunctiva, opened the sclera with a Bier's knife, applied a magnet to the lips of the wound and withdrew this piece of metal. It came out very easily and I was not forced to introduce the tip of the magnet into the wound. I then brought the conjunctiva over the scleral wound and sutured it.

I did this operation on the 7th day of October. Slight reaction followed but it soon subsided and the wound healed rapidly. He had no further attacks of iritis, although prior to the operation he had suffered recurring attacks every few weeks. I believe the eye will get better as time goes on. The vision in the injured eye is now about 2-200, nearly as good as in the other eye. The brown discoloration in the eye is disappearing and the chances are that his vision will increase as the hemorrhage disappears from the vitreous.

DISCUSSION.

Gaylord C. Hall: I wish to congratulate Dr. Ray upon the result he has obtained in this case.

*Read before the Jefferson County Medical Society.

Penetrating injuries of the eye come under three classifications: (1) those in which the eye is practically destroyed at the time of the injury and in which enucleation is, of course, the indicated procedure; (2) those cases which it is easily within the surgical experience of almost any one to relieve, and (3) those cases in which there is grave doubt as to the proper method of procedure. In my judgment, Dr. Ray's case would come under the latter classification. One must consider two things in dealing with such injuries. First, the disability incident to treating the patient along conservative lines. Of course, it is desirable to remove the foreign body at once, if possible; but where the patient is a married man, with a family dependent upon him, we should explain to him that, even though the foreign body is successfully removed, it means a long period of disability, possibly weeks or months before he can return to work; while, on the other hand, if we adopt the radical procedure and take the eye out, he will have irremediably lost the vision of an eye that might have been saved had he undergone the long period of disability required. With this explanation before him, the question must be decided by the patient himself. Theoretically, it is always desirable to save the eye, because it is practically impossible to tell just how much recovery one will have in a case of this kind. Sometimes the amount of vision preserved after proper treatment exceeds our expectations. Therefore, I think it is always preferable, where possible to treat these cases along conservative lines and save for the patient as much vision as possible. This is borne out by Dr. Ray's case because, in spite of the length of time the foreign body remained in the eye, the recurring attacks of iritis and the danger of sympathetic ophthalmia, he has been able to obtain a very good result. I believe this eye will remain quiescent now and that eventually the patient will have as good or better vision in it as in the other eye.

Dr. Ray's conduct of the case was admirable. I am sure that, had he not succeeded in drawing out the foreign body with the magnet, he would have employed the method advocated by Dr. Jackson at a former meeting of the American Medical Association in cases where the foreign body has become encysted by long residence back of the lens. Jackson attaches to the magnet a pair of scissors, with which he reaches through the sclera and cuts the membrane in two, thus freeing the foreign body which jumps to the scissors and is withdrawn. This is only necessary in cases where the foreign body, by long residence in the eye-ball has become encysted, and cannot respond to the magnet until freed of the encysting membrane.

CHORIONIC DEGENERATION.

By WILLIAM A. JENKINS, Louisville.

Mrs. G., white, age 28, married seven years.

Family History. Aside from a marked neurotic tendency the family history is good. They are all nervous. She has a sister who has had some pelvic trouble with an operation for the same. Mrs. G. has had the ordinary diseases of childhood. Her girlhood and young womanhood was otherwise uneventful. Menstruation was established at the age of 14. Regular in every respect. Last menstruation September 27th, 1914. Felt uncomfortable and went to the doctor many times since then. February 6th jumped off a car and ran a square. Had a bad night that night, on the 7th a slight bloody discharge appeared; better next day; remained in bed; symptoms about the same for several days. Saturday night, 1 A. M., I was called; found her in pain, some discharge present. (bright red blood) no temperature, normal pulse, no odor. Gave hypodermic of morphine and atropine, applied hot water bag, left a dose of chloral to be taken later, saw her again at 8 A. M. Sunday morning, no change, saw her again at 12 o'clock. Labor pains present. Cleaned out an hydatidiform mole, sent for Dr. Allen, Carretage.

THE INTRASPINOUS INJECTION OF SALVARSANIZED BLOOD SERUM IN SYPHILITIC AFFECTIONS OF THE CENTRAL NERVOUS SYSTEM.*

By CHAS. W. JEFFERSON, Louisville.

We know, quite well, that after years of treatment for syphilis, by our best physicians and in those cases where our patient has aided in every possible way, that syphilitic manifestations of the central nervous system develop. When these cases go on to a paresis or tabes dorsalis develops, and practically no result can be obtained from medication by mercury, they are referred to the nerve specialist, who because of his inability to attack the disease with drugs, puts them through a course of gymnastics and electrical currents and the spirochaeta has been allowed to thrive on with daily damage to the central nervous system, with a gradual increase of all clinical symptoms, and our authors on mental and nervous diseases give them from two to fifteen years to live a miserable existence.

Recently Doctors Swift and Ellis have devised a means by which the spirochaeta pallida may be killed in his stronghold, the subarachnoid lymph space, and thereby arrest

*Read before the Jefferson County Medical Society.

the prognosis of syphilitic affections in this locality.

The spirochaeta pallida, a positive Wasserman reaction, a pleocytosis and an increase in globulins having been found in the cerebro-spinal fluid of the so called parasyphilitic nervous diseases, thoroughly demonstrates the fact that an active syphilis exists, and strange to say that when the blood of these patients has been made negative by treatment, these conditions of the cerebro-spinal fluid still exists. Medication not reaching this locality in sufficient strength to kill the organism.

Doctors Swift and Ellis after finding these conditions to be present started a series of experiments on monkeys. Small doses of salvarsan and neosalvarsan were injected into the cerebro-spinal canal but were found to be entirely too irritating. Then dilutions of salvarsanized blood serum in normal saline were injected. The irritating properties were in this way judged by using the cell count of the cerebro-spinal fluid as an indicator. It was shown that a salvarsanized blood serum has a decided spirochaeticidal action.

To review briefly the meningeal spaces and the arrangement of the meningeal membranes is important in connection with intra-spinal injections. First the dura mater is adhered to the bone within the skull. Second is the arachnoid which lies between the dura and the pia mater. Third, the pia mater covers the surface of the brain and cord. Between the arachnoid and the pia lies the sub-arachnoid space which is in free communication throughout the brain and cord. This space contains the cerebrospinal fluid, enclosing the brain and cord on all sides, and the fluid in the cord is in free communication with that of the brain. Through the foramen of Magendi and Luschka, the fluid is in communication with the ventricles of the brain. In the sub-arachnoid space are the Pacchionian bodies, which are situated chiefly along the sinuses. They are the protrusion of the arachnoid membrane into the interior of a sinus. The cerebro spinal fluid is brought in close contact with the venous blood through these bodies, there being only a thin layer of dura and arachnoid between. The cerebro-spinal fluid is a clear thin liquid specific gravity 1.007 to 1.008. Normally it contains only traces of proteins. Figures as to the amount of this fluid vary from 60 to 80 c.c..

It has been shown that after withdrawal of any amount of this fluid it is rapidly replaced, and that if normal saline solution be injected without removal of any of the fluid, it is excreted with great rapidity. There seems to be a tendency for this fluid to contain nothing but its own constituents, and if drugs are given and reach this fluid they are very rap-

idly excreted. This is probably the reason for failures to reach and kill infections of the cord by internal medication, or medication in the blood stream.

Why the cerebro-spinal does not readily take up drugs when even given in the blood stream, and rapidly eliminates whatever is taken up, has not as yet been determined. Some of the articles which have recently been written on this subject claim the cord has a very poor blood supply, but this is certainly not true. There are of course areas which have not an abundant blood supply, but even these areas are surrounded by a capillary network.

The blood contains normally serum albumen, sugar, urea, etc., but these are rarely found in the cerebro-spinal fluid. Why then should salvarsan be taken up when administered in the blood stream. Flexner recognized this fact some years ago and introduced the direct injection of serum into the sub-arachnoid space for meningitis.

The intra-cranial pressure has been measured by boring a hole in the skull, dividing the dura and connecting the underlying space with a manometer. The pressure is always the same as that within the venous sinuses. The large veins are surrounded by the cerebro-spinal fluid, which would necessitate an equilibrium of pressure. So with the intra spinal injection of any substance where no fluid is withdrawn, would in itself tend to rapidly do away with the injected fluid. The normal intra-cranial pressure is between 50 and 60 mm. mercury.

Another point in cases of trauma where fractures of the skull exist and the fluid escapes it has been shown that large quantities, as much as 200 c.c. in a day is rapidly formed. This should do away with the fear of removing too much fluid within certain limits, before injection of any serum.

The case I am to report is one of tabes dorsalis, who came to me for treatment several months ago with the following symptoms and history.

Mr. F. S. C., age 37 years. Has had the usual diseases of childhood. Gonorrhoea ten years. The syphilis was a severe type. In January, 1913, he noticed he was getting extremely nervous, then the soles of his feet became numb also the ends of his fingers were slightly numb. This was followed by a stiffness of his legs and thighs. In March, 1913 he noticed a marked unsteadiness in his gait, was unable to walk in the dark without falling. He at that time consulted his physician who made a diagnosis of locomotor ataxia. He was put on mercury, chiefly inunctions, which he continued until I saw him, with a rapid increase in all clinical symptoms. On

examination, October 10th, 1913, findings were as follows:

Loss of knee jerk, ankle tendon reflex lost. Loss of sexual power, well-marked ataxia, unable to walk without aid of cane, great difficulty in arising after sitting down. Numbness in feet and hands. At times profound weariness, slight hypotonia. Tottered with eyes closed. Unable to touch nose with finger while the eyes were closed. Girdle symptom marked. The peculiar feature about the symptoms were that the patient had no lightning pains. Was referred to Dr. J. F. Simpson for examination of eyes. His report is as follows:

Vision in right eye 20-20 minus.

Vision in left eye 20-20 plus.

Pupils.—right eye slightly larger than normal. Left eye about normal.

Both react to light slightly, sluggish for distance. Disc whitened more in right eye than left.

TREATMENT.

1913.

Oct. 16.—0.6 gm. salvarsan intravenous.

Oct. 24.—One-half gr. salicylate of mercury, intramuscular.

Oct. 31.—Three-fourths gr. salicylate of mercury, intramuscular.

Nov. 7.—One grain salicylate of mercury, intramuscular.

Nov. 14.—One grain salicylate of mercury, intramuscular.

Nov. 21.—One and one-fourth gr. salicylate of mercury, intramuscular.

Nov. 28.—One and one-half gr. salicylate of mercury, intramuscular.

Dec. 3.—One and one-half gr. salicylate of mercury, intramuscular.

Dec. 6.—0.6 gm. salvarsan, intravenous.

Dec. 12.—One-half grain salicylate of mercury, intramuscular.

Dec. 19.—Three-fourths gr. salicylate of mercury, intramuscular.

Dec. 24.—One grain salicylate of mercury, intramuscular.

Dec. 30.—One and one-fourth gr. salicylate of mercury, intramuscular.

Potassium iodid was given at intervals in small doses.

(Blood Negative Wassermann).

1914.

Jan. 10.—0.3 gm. salvarsan, intravenous.

Jan. 11.—30 c.c. salvarsan blood serum, intraspinal.

Jan. 30.—0.5 gm. salvarsan, intravenous.

Jan. 31.—30 c.c. salvarsanized blood serum, intraspinal.

METHOD OF GIVING INTRA-SPINOUS SALVARSANIZED BLOOD SERUM.

First intravenous salvarsan was administered one hour later 40 c.c. blood withdrawn.

This was put on ice for 24 hours and the serum allowed to separate. Serum drawn off and centrifugalized. 12 c.c. serum mixed with 18 c.c. normal saline, solution. This making a 40 per cent salvarsanized blood serum. This serum is heated to 56 degrees centigrade for 30 minutes, which activates the salvarsan. About 22 c.c. cerebro-spinal fluid was withdrawn after lumbar puncture was done. Then the 30 c.c. blood serum slowly injected by gravity. This I believe the dangerous part of the administration. The fluid should be very slowly withdrawn. I wish to state that the needle used in doing the lumbar puncture was the one devised by Dr. Donald Clark while at the meningitis hospital, and I consider it very excellent for this purpose.

Symptoms following first intraspinal injection were none until five hours later, when patient had marked reaction. Pain in head, thighs and legs. Some twitching of limbs. Complained of vertigo. These symptoms were controlled by codein. The temperature ranged from 96 degrees to 100 degrees reaching highest point on following day. Pulse and respiration were practically normal. For several days following patient was extremely drowsy, had singing in ears but these symptoms gradually wore off. The laboratory work on this case was done by Dr. L. K. Bauldauf.

Cerebro spinal fluid before intraspinal.

One-half c.c. cerebrospinal fluid.

Wasserman Noguchi++

Globulins ++

Pleocytosis, 72 cells.

Cerebrospinal fluid at time of second intraspinal:

Wassermann Noguchi +

Globulins ++

Pleocytosis, 60 cells.

Symptoms following second intraspinal were much more severe than first. Morphine hyperdromatically was required to control pain in legs and head. Temperature ranged from 97 degrees to 101 degrees. Pain and temperature starting two hours after intraspinal. Nothing unusual about pulse and respiration. These symptoms gradually subsided.

At the end of the first week after first intraspinal all the symptoms of locomotor ataxia began to improve. At the end of second week patient's ataxia had improved to such an extent that he was able to walk without cane. He has gained in weight. The nervous symptoms are much improved.

In conclusion will say that I am much pleased with this treatment, and believe much can be done for this class of patients in the future. These injections are given every two

weeks until the cerebro-spinal fluid is negative to a Wassermann, until the globulins are normal, and until the cell count is not over five. Of course we cannot expect to repair damage to the central nervous system which has taken place before treatment, but the process is very probably arrested and no further progress of the disease has taken place in the cases where this treatment has been followed.

Would urge the physicians who have cases along this line, to give this treatment, as I believe it a great step forward in therapeutics.

I wish to thank Doctors David Morton and Leon Baldauf for their much appreciated assistance and interest in this case.

MEDICAL ETHICS.*

By J. W. ELLIS, Masonville.

Your committee on program requested me to furnish a short paper for this meeting on medical ethics, a theme that has been written upon and discussed in every medical society since the days when Esculapius, with the serpent coiled around his staff as the insignia of rejuvenescence, as well as the symbol of health and preventive medicine, went forth to fight the physicians' greatest antagonist—death. Everything has long ago been said that could be well said and that would be of benefit and profit to physicians on this subject. Our fathers in medicine have formulated and handed down to us certain fixed rules and regulations for our guidance, with the view of enabling physicians everywhere, at all times and under all circumstances to maintain the highest standards of conduct in their association with and relationship to each other. The Code of Ethics we have today is old and gray, and is the accumulated wisdom of the Centuries and a physician can scarcely go wrong when guided by its beautiful and beneficent teachings.

Webster says that Ethics is the science that treats of the principles of human morality and duty—moral philosophy—morals. Medical ethics then is the science that treats of the principles of medical morality. When one reflects upon the object, end and aim of the profession of medicine, its high and lofty ideals, its altruism and unselfish teaching, the pure motives and unsullied character one must necessarily have before one can become a true disciple of medicine, one wonders why a code of ethics should be necessary at all. Medicine is now and has always been regarded as one of the greatest of the three liberal professions. That medicine suffers no disparagement when compared with other professions, no one will deny. Cartesius, the

great philosopher, emphasized his convictions that if man could be ennobled at all that it would be accomplished by medicine alone. The great Hippocrates said, that whatever belonged to the domain of wisdom was contained in medicine. When the greatest pathologist the world has ever produced, Rudolph Virchow, said his aim is knowledge of man and his improvement, but reflected the sentiment that has actuated every true and loyal physician from the earliest dawn of medicine down through all the ages.

Pope in his incomparable essay on man evidently drew his inspiration from the medical profession when he said "Know then this truth, presume not God to sear. The proper study of mankind, is man."

All that has ever been said or written on medical morals that is worth while can be summed up, and is contained in that glorious old-fashioned rule, as laid down by Confucious and quoted by our Savior when he said, "Do unto another what you would that he should do unto you." The question at once arises: Can one always do as one would be done by? I unhesitatingly answer, yes. Any one with sufficient learning, knowledge and wisdom to minister to the ailments of afflicted and suffering humanity, surely knows enough to treat his fellow physician as he would be treated. No doctor is so stupid and dull as not to know that when he is called as consultant it is wrong and wronging to say in the presence of the laity, that he was called in too late, or that he has had many such cases and no deaths, or that if certain remedies had been given the patient would long ago have been well, or to shake his head and look wise as an owl, or to suggest questionable changes in attending physician's prescriptions, as not to know that he is laying the foundation for the dismissal of the regular attendant, upon which the laity will often times hastily build. "Alas! and alack," the day when doctors will descend to such nefarious practices. In a long and eventful career in medicine, extending over a period of more than forty years I have come in contact with but few of these despicable characters, and when I did their tongues were more deadly to my reputation as a physician than would have been the fangs of the adder or the fragrance of opus to my body. Shame on such conduct, it is wholly unworthy of any man, much less one claiming to belong to a noble profession. To the everlasting credit of the medical profession and its devoted devotees when these dark characters are once discovered they are soon eliminated from the ranks of all true doctors.

Strange to say the laity has never shown the medical profession that consideration justly its due. They have generally regarded medicine a trade, instead of the high and

*Read before the Daviess County Medical Society.

lofty profession it is—whose members are continuously trying to protect the people from the ravages of disease, and to strengthen against the assaults of death, and often rescuing them from the criminal folly of their own misdoings. Great business concerns that employ vast numbers of laborers often organize them into one body and promise them cheap medical service, and have the audacity to fix the fee, which is far below what it should in justice be, and then ask some physician to accept it. Life insurance companies, whose very existence depends upon the learning and skill of the physicians, have always and are still trying to place a low value on the physician's services by offering him eases at half price. The innumerable fraternal organizations with which our country abounds are continually driving these sharp bargains with physicians and are from day to day and from year to year the beneficiaries of the hard labor, skill and learning of the physician—the only man on earth suitably equipped to render the service absolutely required for his well being and the price for such service is fixed by the other fellow at about half its real value. These agencies that insist on placing a value on the physician's skill are wholly incompetent and when they do, it is always from mercenary motives. They have no more right to fix the price on a physician's services than the physician has to fix a price on their products, or the sweat of their faces, which he is never allowed to do. Physicians accepting these places do themselves an injustice as well as the medical profession at large.

IS THE DEMAND FOR THE SERVICES OF THE REGULAR PRACTITIONER GROWING LESS?*

By W. J. SHACKLETTE, Nolin.

All of us, no doubt, have listened to the stories of the good old doctors who lived and toiled in the days of our fathers, how that on horseback and with saddle bags astride they plod their weary way through pouring rains and blinding snows; over rocky hills and through marshy vales; through the stinging cold and stifling heat, day after day and night after night. That for weeks in and weeks out they would only get home for an occasional stop to replenish their stock of powders and extracts, and change horses then to hurry on to a long due call and on from one home of sickness to another.

In that day when people practiced more intense housing, when sanitation was little known and less practiced, it was not uncommon to find several or perhaps all of a family

ill from the same disease at the same time. In those days, one physician would often see more patients in their homes in a week than we will see now in a month.

We do not need to call to witness the experience of the doctor of the past generation to bear evidence to such conditions in practice. There are many doctors with us yet who can tell of some years of such experience and similar conditions.

I have talked with a number of physicians now living, who practiced in the eighties and early nineties and all relate a story of strenuous work. Even ten years ago the country doctor was called to visit, at least twenty-five per cent. more patients than at the present time. It was not uncommon for the older physician to see twenty-five or more patients in their homes in a day, and day after day. While the population has increased more than two fold throughout this section of the country, the same number of active doctors that attended to the practice thirty years ago, could to-day, easily make all the resident calls. The condition of which I speak has reference more especially to rural practice, perhaps being less applicable to city conditions. While the number of families in a given territory are much more numerous than formerly, the number of resident calls per family have greatly decreased. There are various causes that have contributed to this changed condition. Many new discoveries have been made as to the origin and spread of disease that has given great impetus to preventive medicine. Where, in former years, epidemics were frequent, widespread and of long duration, now they are rare, very local and of short duration.

Then, where the doctor was called upon to treat a large per cent. of cases of diarrhea, dysentery and allied affections, running courses of from two weeks to two months or more, now there is a very small per cent. of such cases and nearly all run very brief courses.

Typhoid epidemics once so prevalent throughout the summer and fall season, requiring a great deal of the doctor's time, are now rare indeed and the course of the disease is very much modified and shortened. Malarial affections once a very fruitful source of practice, now demands very little attention from the physician.

Other contagious and infectious diseases once so prevalent and demanding so much of the doctor's time, are now much less frequent, shorter in duration and necessitate very few calls from the doctor. Wounds and other injuries that formerly required a long period of attention from the physician, now, with modern treatment heal very quickly, often needing no more than first aid measures.

*Read before the Muldraugh Hill Medical Society.

Chronic cases that were treated by the family physician for months and sometimes for years, now soon drift into the hands of the specialist. (From whence they sometimes never return).

Quite a bit of custom has been lost through doctors prescribing proprietary medicines. The patient reading the printed directions and afterwards prescribing for himself or friend in supposed similar conditions.

Or, perhaps, their good friend, the druggist, suggests the remedy. Telephone consultations often answer the place of a call and the doctor loses the fee that was formerly paid for a visit. The great host of pathies, isms and irregulars that have sprung up in the past few years, though their pretensions may not stand the test and their popularity soon wanes, yet they detract a considerable toll of the fees that should go to the regular practitioner of medicine. The laity are becoming fairly well informed as to the nature and symptoms of disease and of the use of first aid remedies, and in many instances minor ailments are cared for without the aid of a physician.

The known and more uniform action of drugs, and the attendance of the nurse makes the doctor's prolonged stay with the patient more unnecessary and visits less frequent than in former years.

But notwithstanding the field of labor for the regular practitioner has greatly narrowed along some lines, yet there should be more remunerative practice for the doctor of to-day than there was for the good old doctor of thirty years ago. And especially is this true of the country doctor.

While the demand for medical services has diminished greatly along some lines it has developed along others and will continue to develop in proportion to the energy and study the doctor puts into it. The greater number of the rural physicians are not awake to the great opportunities that lie within their reach. Their neglect is the charlatan's and irregular's opportunities. The failure of the regular physician to avail himself of all therapeutic agents and methods of merit has left an open field that many so-called systems, that have sprung up, have rushed in to occupy. And not only have they occupied the neglected field but have invaded the regular's field of action. The physician should not allow himself to be taken away with "fads and fancies" but he should be all sufficient outside the realm of the regular specialist. And while the specialist has developed a field of his own and has become an absolute necessity, in many instances physicians might use more wisdom in referring cases, with profit to himself and often real favor to the specialist. The energetic and skillful physician

should be able to hold and to attend to nearly all the work in his scope of practice. He should know something of psychotherapy; he should know all that is practical of osteopathy and the secret specialties. Every physician remote from regular specialists, should be qualified and equipped to do refractory work and save to himself some good fees and protect his patients from the robbery and malpractice of the "speck peddler" and the itinerant specialist.

In fact the physician should be on the alert to avail himself of all useful and practical therapeutic means from any and every source. He should not be the first to accept the new and never be the last.

Right now, serotherapy deserves attention, and the physician who avails himself of it, wisely, is going to increase the demand for his services.

While there is a tendency with some doctors to make frequent and extra visits to patients, often in the same day and complimentary, there is a tendency with others, perhaps, to make their visits too few. The patient should be seen as often as seems necessary, and if the visit is necessary it is worth something and should be charged for accordingly. The physician who makes a practice of making extra and complimentary visits leaves the impression of a lack of confidence in his remedies, injures his professional brother and lowers the dignity of his profession.

Information given over the telephone, that takes the place of a visit or an office call should be charged for. And unnecessary consultations should be discouraged. A fruitful source of employment that the physician might more avail himself of, that has been greatly neglected, is office practice. This work should be energetically studied and encouraged. It is easier and more remunerative than the same time spent in making calls. To the wide awake and inventive doctor it is a profitable and ever developing line of work.

The office should be well equipped with necessaries, should be clean and inviting. A careful record should be kept of cases. Collections should be looked after in a business way. The doctor who dispenses can get much pleasure, information and profit in preparing many of his own medicines and formulas. There is much special work the general practitioner can and should do, and there are emergency cases and other cases that can not be induced to go to the specialist to whom the physician should be able to give the best attention possible at home. He should be eager for service but should not attempt anything only in cases of emergency, that he can not do skilfully and complete. There is a greater demand for the services of the energetic, con-

scientific physician to-day than ever before. And the demand for such will never grow less, and he will ever continue to be more and more necessary and among the world's greatest benefactors.

Contagious Disease Hospitals.—L. A. Lamoreaux, Minneapolis (Journal A. M. A., January 24), advocates an approach to the skyscraper architecture for contagious disease hospitals and describes the one beginning to be constructed in Minneapolis, which is to be eight stories high and which will have the advantages of economy of upkeep and of not requiring a large and expensive site. He points out also some conveniences of administration afforded by this type of construction of a city hospital.

Sciatica. Treatment. Marked improvement in 2 cases after a few daily subcutaneous injections of 1 c.c. (16 minims) of 1:1000 epinephrin solution.—Gaisbock.

COUNTY SOCIETY REPORTS

Daviess—The Daviess County Medical Society met at the City Hall, Owensboro, Tuesday, March 17th, 1914, at 10 A. M.

Morning Session.

Reading minutes.

Application and balloting for new members.

Report of cases.

W. L. Tyler read a paper on "Chronic Diarrhoea," Discussed by **R. E. Griffin** and **R. N. Philliatrean**.

Afternoon Session.

J. T. Dixon read a paper on "Some Problems in Infant Feeding." Discussed by **Ed. Barr** and **J. L. Carter**.

R. L. Schroeder read a paper entitled "The Laboratory Methods the General Practitioner Should Use." Discussed by **V. A. Harl** and **C. M. Rice**.

R. E. GRIFFIN,

P. D. GILLIM,

O. W. RASH,

Committee.

Greenup—The Greenup County Medical Society met in the Masonic Hall at Greenup, March 5th, 1914. Members present, H. T. Morris, A. S. Brady, E. R. Fitch, A. J. Bryson, C. E. Vidt, and A. P. Hunt.

Minutes of the previous meeting were read and approved.

C. E. Vidt read a most excellent paper on "Purulent Bronchitis." The doctor emphasized the importance of a more accurate examination of patients both physically and microscopically. The paper was very practical, scientific and interesting. Every member complimented Dr. Vidt for writing such an original paper.

A. J. Bryson opened the discussion and was followed by **A. S. Brady**, **A. P. Hunt**, **E. R. Fitch**, **H. T. Morris**, and closed by **C. E. Vidt**.

The following program was selected by E. R. Fitch for the next meeting to be held at Fullerton on April 2, 1914:

H. T. Morris, "Etiology, Symptomatology and Diagnosis of Pleurisy." Discussion to be opened by **J. I. Rathburn**.

A. P. Hunt, "Medical and Surgical Treatment of Pleurisy." Discussion to be opened by **M. W. Meadows**.

The Greenup County Society is now working and in good order. The next meeting will be the best ever held in this county.

A. P. HUNT, Secretary.

COMMUNITY PHYSICIANS.

We wish every medical man in Kentucky could have been present in the sessions of the Conference for Education in the South, which recently convened in Louisville. It was different from most National gatherings. While there were plenty of meetings of the regular orthodox sort in the different sections, most of the work was done in a big community demonstration in the Armory. Here were gathered together actual demonstrations from almost every community in the country which has distinguished itself by doing something as a community better than it has ever done before by individuals. When one had made the rounds and had had it explained to them how the community bought fertilizer, farm machinery or other manufactured products cheaper, as a community; how many communities had sold its live stock, fruit or berries at better prices because organized; how one community was building better homes, both for owners and tenants on farm land and how another was securing better roads or better schools by cooperation, it somehow begun to dawn on us that the possibilities of the development of community interests and community life in the rural districts of the United States has already begun. It was even demonstrated that a single community church in the country would show a broader road to Heaven, if well cared for by a resident minister who was worthy of the job, than the numerous by-paths that lead to Heaven from the scattered sects and neglected houses of the numerous denominations now parasitic in our country life.

No more interesting problem was presented than the community physician. In no

other state is the suggestion as worthy of serious consideration as in Kentucky because in many ways and in most counties in this State professional organization has reached its highest and best development, and our doctors realizing present conditions are looking forward to the future, unafraid of its development because they know from its history in the past that the profession of Kentucky is going to meet the demands upon it and serve the people of the State in a way which will command their confidence and respect.

Kentucky doctors realized among the first that the medical education of the last quarter of the last century was defective in that it taught us more about the diagnosis of disease and less about treatment. We realize that this has reached a point where it actually re-acted on our powers of diagnosis. Many of us have gotten so accustomed to prescribing nostrums, ready-made mixtures and pills, about the composition and physiological action of which we are equally ignorant, until we have lost respect for ourselves as doctors and command only that respect, or lack of it, which belongs to the peddler. In some communities it has already been demonstrated that a physician with the real spirit of leadership can teach the people how not to be sick, can eliminate a large part of his practice by getting rid of consumption and typhoid fever and other preventable diseases. In other words, a health conscience is created in the people of his community that makes them understand a personal responsibility for the existence of those diseases, whose methods of propagation we have already learned. Such a community physician must be supported in some way and a few of them have already agreed to do this by a voluntary assessment plan on all families.

All of this is in the formative stage, how-

ever, but it behooves the individual doctors of Kentucky to be thinking of such developments as this that they may not find us asleep.

HAZELWOOD SANITARIUM.*

(See Advertisement on Page xv.)

Through the courtesy of the Kentucky State Medical Association, the Association Sanatorium, (Hazelwood) for the treatment of tuberculosis is accorded full page advertisement.

The physicians of the State should know something of the history of this Institution and should in so far as possible, arrange to send their patients for treatment in order that they may be trained in the measures which will improve their own condition and protect others with whom they come in contact.

The Sanatorium which was opened September 1st, 1907, with ten beds, was made possible by the contributions from public spirited citizens who realized that some provision must be made for persons suffering from tuberculosis who could afford a moderate sum to secure proper treatment and instruction. The corporation which was organized, specifically states in one of its articles that it is not maintained for profit and each year citizens of Louisville have been forced to make up a deficit out of their own pockets.

A fire occurring February, 1912, destroyed the Administration Building but a new and modern building with adequate fire protection has taken its place, thanks to the contributions of Louisville's citizens. None of the funds obtained have come from outside of Louisville and yet patients from all over the State are admitted for treatment at \$12.50 per week which includes everything unless the patient is so ill that a special nurse is required which, of course, is furnished at actual cost.

When we consider that the results obtained at this Institution are equal to results obtained elsewhere and that the care and treatment at the price is equal to what costs from \$20.00 to \$30.00 a week in other Sanatoria, the physicians of the State can by sending their patients for treatment, do a great service to themselves and support a work which is worthy in every way.

Accommodations can now be made for sixty patients and certainly out of the six thousand or more persons suffering from tuberculosis in the State, there can be found (if the physicians will but support the work) enough persons who are able to pay \$12.50 per week to keep the Institution full.

It is hoped that even the price of \$12.50 may be reduced provided the beds are all occupied continuously as the only object of the corporation is to try to be self-supporting.

During all of the vicissitudes and trials through which the Institution has passed in the last six and a half years, there has never been one minute that the members of the Board did not believe that the physicians in the State would finally come to a realization of the excellent work which was being done and would support it by sending their patients in sufficient numbers to finally make the Sanatorium self-supporting.

The Sanatorium is located about three miles from the City at the top of a hill and is reached by the Fourth Avenue car. This puts it beyond the zone of smoke and dirt of the City and gives all of the advantages of pure air and sufficient elevation to afford the patients advantages of the country and yet none of the disadvantages of inadequate accommodations. The drainage is excellent and no effort or excuse is spared to give the patients the very best of care and treatment.

SCIENTIFIC EDITORIALS.

WHAT IS THE PRESENT STATUS OF RADIOTHERAPY?

It must have been the quiet but energetic and persistent work of the radium trust that caused such an active revival of radiotherapy in this country. For a time it seemed that this country, particularly the East, had gone radium crazy. Some unfortunate rich patients, afflicted with malignant disease, were fortunate enough to have applied to them radium in quantities, ranging in price from \$5,000 to \$100,000 but no benefit was derived from such expensive applications. A few fortunate physicians having access to and privilege of using this precious metal, must have reaped a rich harvest. My little mite of ten milligrams was not in it. I felt like "thirty cents" when I read of the quantities used.

Sensational and nonsensational newspapers have done a great deal of advertising of the wonderful and imaginary results obtained from the use of radium. As a result of such wonderful and glowing reports, fraudulent radium institutes sprung up in many sections of the country. It is true, that occasionally, one sees a case of cancer benefited by the use of radium. In my own practice a case of cancer of the inner canthus of the right eye was seemingly cured by the use of radium, but I used in connection with it a solution of methylene blue. In a few other cases benefit was derived but no cures ac-

*See advertisement on page xxv.

complished. Better and quicker results were obtained by me from the use of X-rays.

Gamma rays were used by radium workers in nearly every case. Now comes the announcement by Alexis Carrell and Abbe that gamma rays, which were considered the most penetrating and the most useful for therapeutical purposes, are not so active and penetrating and useful as the Beta rays, which were considered dangerous.

The history of radium reads like a fairy tale. In 1896, Becquerel observed certain radiations resembling the rays in uranium and all its compounds. Prof. and Madame Curie, in 1898, followed this discovery and obtained what was considered a metallic element from pitch-blend, an uranium metal. On the death of Prof. Curie, his wife continued investigations and, later, found radium.

Becquerel, in carrying a small piece of radium in his vest pocket, observed about a fortnight later a severe inflammation of adjacent skin. This was the first demonstration of radium's caustic and destructive action.

A little over ten years ago when I was attending clinics in Europe, the profession and the laity were radium mad. Even the staid old London was radium wild. X-ray, in many respects far superior to radium from a diagnostic and therapeutical standpoint, was forgotten for a while and radium was the chief topic. Even Sir William Ramsey, the great English scientist, became a very ardent follower of radium, and, later, discovered that radium had the power of being transmuted into helium.

Over-enthusiastic followers of radiology and radiotherapy made preposterous claims but their claims soon went into oblivion. The ardor of the enthusiast of radiotherapy, with few exceptions, cooled down and radiotherapy was abandoned for a while as are many other uncertain agents. Just about two years ago, Mesothorium was taken up by German scientists and was claimed by them to be superior to radium. As usual, preposterous claims were made for mesothorium. Mesothorium was soon abandoned, and was followed by a renewed revival of radium in this country. What is the real status of radium? Louis Wickham, Degrais and Abbe, the most enthusiastic workers, have rather become conservative of late in regard to the real merits of radiotherapy. The number of cures claimed by them now is not so great as it formerly was. There can be no real status of the value of radium therapy, since the properties of radium are not well understood. A variety of theories have been offered to explain its peculiar properties. Some scientists declare that radium is a source of earth heat and that it is probably of the same substance as that of the sun, since it is known to emit certain

gases of the same vapor as is given out by the sun. Much of the speculation among the therapeutic values of radium have been found unwarranted by actual demonstration, but that it will some day be found a very useful agent, cannot be disputed.

Surgery, if justifiable, offers at present the best and surest method in handling malignant cases.

M. L. RAVITCH.

ORIGINAL ARTICLES

MERCURIAL STOMATITIS.*

By EDWARD DUFF BURNETT, Anchorage.

The prevalent and indiscriminate use of calomel by the laity calls for a definite word of warning from the family physician. Our clientele should be taught the grave dangers that are likely to attend the unskilled employment of mercury in any form. They should be instructed never to use calomel or any of the mercurial family without the direction of a physician.

Every case of mercurial stomatitis should be a strong lesson to each of us, reminding us of the possible harm that may come from too frequent use of calomel. In many cases of constipation saline cathartic, repeated once or twice, will serve every need and oftentimes is better medication.

PHYSIOLOGICAL ACTION.

All of us recognize the alterative, tonic, antiseptic and purgative action of mercury, as well as its specific effect in syphilis. And too, we are familiar with its splendid result in certain inflammatory conditions.

When given over a period of time it is slowly eliminated and tends to have an accumulative effect that is quite harmful. The liver and the kidneys seem to store it up in larger quantities than do the other organs of the body. It should never be given in cirrhosis of the liver or where albuminuria is found.

We know that the mild chloride is a cholagogue only by reflex action, its purgative effect upon the upper bowel, especially the duodenum. It should always be preceded and followed by castor oil or a saline purgative.

During the administration of mercury in any form we should always be on the alert for the initial symptoms of mercurialism.

CHEMICAL ACTION.

Entering the stomach in any form, mercury is converted into a double chloride of sodium and mercury; then comes a union with the albuminous juices to form a complex

*Read before the Hopkins County Medical Society

molecule of mercury, sodium, chlorine and albumin. This is soluble in an excess of sodium chloride or albumin. This solution is easily absorbed.

Only a small portion is absorbed in the intestines, the rest being converted into a sulphide and excreted with the feces.

Mercury stimulates most of the glands of the body to the production of pathological secretions, especially the salivary glands and the pancreas. It is found in the saliva, sweat, milk, urine and bile but is excreted rather slowly. It is possible to find it stored up even six or more months after medication has ceased. Its excretion is facilitated by the presence of iodide of potassium.

The combination of calomel with hydrochloric acid or chlorides is apt to precipitate corrosive sublimate, a violent poison. It is thought at the present time that stomatitis is a septic condition arising from the mercurial awaking of some latent alveolar trouble or gingivitis.

CLINICAL REPORT.

The two following cases illustrate every day experiences and remind us that we can't be too cautious in the administration of mercury.

Case I.—Woman 30 years old; 48 hours after having had calomel, grains two in broken doses, developed the following: metallic taste; foetid breath; swollen and coated tongue; sore buccal cavity; headache; temperature 99 3-5 F.; slight tenderness over epigastrium; and increased flow of saliva.

She gave a history of having eaten a large amount of home made candy the day before taking the mercury.

Case II.—Man, 23 years of age, after taking 1-2 grain protoiodide of mercury three times a day for two days ate a raw apple and developed a sore mouth and belly in twenty-four hours. I found the following symptoms: Pulse 108; temperature 101 F.; diarrhoea; tenderness over the abdomen, especially the colon; headache; swollen tongue; several ugly ulcers in the mouth; sore gums; and loose teeth with the characteristic blue lines on gums.

TREATMENT.

Leave off the mercury at once. Eliminate by bowels and kidneys, e.g., sodium phosphate or castor oil and alkaline mineral water. Strychnine for support. Belladonna to control ptyalism. Liquid diet. Alkaline antiseptic mouth wash. Rest in bed in weakest cases.

Case 1 had a complete recovery in fifteen days and Case 2 in twenty-five days.

A very mild case of stomatitis calls for a simple mouth wash for several days and a mild saline laxative.

CONCLUSION.

Both of these patients had full instructions about diet while mercury was being taken and the dangers that sometimes arise. They were questioned closely and gone over thoroughly before mercury was prescribed. Some individuals are very susceptible to the action of mercury and care should always be exercised when prescribing it. All the more care is urgent because most of us prescribe it daily.

I report these cases that a note of warning might be sounded.

PSYCHOTHERAPY.*

By ANDREW SARGENT, Hopkinsville.

In the preparation of this essay I shall forestall criticism by saying that I will not attempt to present anything new or original.

Psychotherapy far from being new, is as old as the history of mankind, and was employed in ancient times.

The influence of the mind over the body was recognized by Plato, who said that the trouble in his time with physicians was that they treated the body too much and forgot about the influence of the mind over the body.

Galen insisted that without the confidence of the patient the physician will often fail. He also pointed out that though many physicians used different remedies to heal diseases; they all got good results, and he hinted that the influence of the physician on the patient's mind meant much in this matter.

Often the confidence of the patient in his physician does more for the cure of his disease than the physician with all his remedies.

Paracelsus said, "Imagination and faith can cure and remove diseases." Many such expressions of physicians of all periods might be quoted. The greater the physician, the surer one is to find the belief in such opinion.

Small minds have thought their remedies all powerful, but this was not true for the large minds, their remedies were helped always, they knew, by the patient's mind.

Mary Baker Eddy and Alexander Dowie are recent examples of the power of mind over body. What physician of ancient or modern times ever exhibited so many happy patients as they did, and though dead their works do follow them.

Cures at Lourdes is the subject of an editorial in the *Medical Record* of November 8th. Recently a circular letter was sent one thousand physicians in regard to Lourdes cures. The answers varied notably.

Despite a large degree of skepticism many conscientious practitioners have been found who admit frankly the cure of actual disease.

*Read before the Christian County Medical Society.

A list of prominent practitioners is on record as upholding the existence of a superterrestrial agency in some of the cures.

Several university professors have gone on record with attestations to this effect, including the late T. Gailliard Thomas of New York.

Among cases which yield to Lourdes treatment tuberculosis is well represented, including recoveries from lupus.

The average patient is a creature of habit, and is incapable of independent or original thought.

The most important factor for the beginning of psychotherapy is to secure freedom of mind from solicitude about self. Solicitude prolonged will make the normal heart miss beats, will hamper the action of the normal stomach in its work, will interfere with all its secretory functions.

Whenever there is anything organic the matter with important organs, then it is still more to be desired that the patient should not be solicitous. A crippled organ can be even more seriously interfered with than a healthy one. Hence all the distinguished heart specialists of recent times have insisted that the first and most important element in the treatment of heart disease must be to set the patient's mind at rest with regard to his heart, without this drugs have an extremely difficult task to perform, while with it they are readily efficient.

Broadbent and McKenzie have not hesitated to declare that this is absolutely the most important element of cardiac therapeutics.

In mild chronic diseases, particularly persuasions with regard to the seriousness of the affection present, and of its supposed incurability, do more to keep up the affection in a great many cases than almost anything else.

The pathology of a disease is always an important aid to its treatment, but we as psychotherapists must remember that pathology is only physiology under adverse conditions, and is nearly always a conservative process.

All sorts of remedies have been used by the medical profession, most of them quite innocuous, some of them slightly harmful, that have been supposed to produce definite therapeutic effects, and have actually cured many cases when first employed, though afterwards their therapeutic efficiency was recognized as nil, and they have been abandoned.

The mental influence aroused during the administration of them has given them all their remedial value, and has even enabled them often to counteract certain ill effects produced by them and do the patient good.

This is the element of mental influence in the history of therapeutics, and it makes it extremely difficult to decide as to absolute curative powers.

We have had literally thousands of drugs used in medicine because empirically, or on theory, they cured disease, and only some three score of them are left, and only half that many are used by physicians with any confidence of success.

Nothing illustrates better than the above the fallacy of new remedies. Cures by them may indicate either that the new remedy is efficient, or that it aroused hitherto latent powers through mental influence, and so gives relief. A new remedy is very prone to do this because of the enthusiasm with which it is taken up, and the confidence aroused by the doctor's hopeful attitude in giving it.

Not long since a distinguished French professor said to a young physician who asked him whether he, himself should take a much vaunted new remedy replied, "O, yes, and take it now while it is new and still cures, for after awhile it will be found not to cure."

It is not alone neurotic diseases, that is, affections consequent upon persuasion and mental states or so-called imaginary diseases that mental influence can do good.

In all organic diseases, however, there are always certain symptoms due to the mental states, to discouragement and depression, that are greatly exaggerated by concentration of mind on them. These conditions are only amenable to psychotherapy, sometimes these symptoms mean so much to patients that when they are cured they think the underlying disease is cured.

Specialists in the disease are agreed that "tuberculosis takes only the quitters." That is, those who give up the good fight and think they are the victims of an inevitably progressive and fatal disease. Hence the first element in the treatment of consumption is to remove unfavorable suggestion with hopeful and helpful ones.

If for instance the patient has any persuasion that because the disease is in the family it is hereditary and therefore almost necessarily fatal.

The present attitude of physicians to the inheritance of the disease is explained by saying it is contagious and not hereditary. If it runs in families it is because of contagion and environment. A member of a family in which tuberculosis exists on both sides is in less danger from the disease if he is well up to weight than a thin person without any such family history.

As a matter of fact a man with a family history of tuberculosis always has a little better resisting vitality against the disease than those in whose family there is no such history.

Even in cancer, psychotherapy has a place. Patients have been operated on, the cancer found inoperable, this decision has been mercifully withheld from them, but having

been operated upon, they are told, and naturally think they ought to get well. After such patients have lost some thirty or forty pounds they have been known to regain all that was lost and more too, the result of this encouragement, though eventually the cancer proved fatal.

In skin diseases psychotherapy has a definite place. All the chronic skin diseases are influenced by the mental state. Even warts have been charmed away by mental influence in so many cases that there seems to be no doubt about this influence.

The story has been printed that six typical cases of Pellagra were sent from the State Insane Hospital of South Carolina to New York to be treated, and they were all relieved of their symptoms before they could be treated.

In every form of disease external and internal, organic and functional, somatic and nervous, mental influence can do good. It prevents the inhibition of vital forces by removing dreads and contrary suggestions that so often tie up recuperative energy. It taps new sources of energy and enables the patient to use will power over tissues not active before.

Living on the will is no idle expression, for patients have been known quite contrary to all medical expectation to live to an allotted time after having willed to do so. On the other hand nothing is more fatal than giving up hope.

The will to live, the will to be well, the putting off of discouragements, all this represents an important factor for health both as regards the continuance of health and its recovery.

Have we as physicians done our whole duty by our patients until we have tried all known means to inspire hope and prolong life, and what is better than life itself the desire to live?

Urethral Cysts.—Two cases of cystic degeneration of the posterior urethra are reported by A. J. Underhill, Baltimore (*Journal A. M. A.*, January 24). They both followed previous gonorrhoeal inflammations and the conditions were discovered only by endoscopic examination. Solitary cysts of the prostatic urethra are not uncommon but differ from the multiple variety in the cases described where they were sessile and looked like pearls embedded in the mucous membrane. The local symptoms are not distinctive and the subjective symptoms are those characteristic of the neurasthenia accompanying many of the chronic diseases of the posterior urethra. Underhill believes the condition will be found much more frequently with the more general use of the endoscope. The treatment is dilatation followed by incision of the cysts under control of the eye.

HEAT PROSTRATION.*

By N. C. MAGRAW, Hopkinsville.

Having been requested to write a paper and select my own subject for this meeting, my thoughts turn to heatstroke as this is the hottest June I ever felt and the indications are that it is going to continue hot.

So I will define heatstroke as a depression of the vital powers the result of exposure to excessive heat. It manifests itself in three forms, as acute meningitis, heat exhaustion and as true sunstroke.

Heat exhaustion is the most common and is brought about by a lessening of the powers of the system to resist any great bodily fatigue also by overexertion and intemperance.

Structural changes rarely develop owing to the sudden action of the heat on the system and the rapidity of the symptoms. The left ventricle is contracted, the right heart and vessels are engorged with dark fluid blood, all the organs are in a state of venous congestion.

Sunstroke comes on suddenly with or without prodromes and is manifested by insensibility with or without delirium, convulsions or paralysis, flushed and hot body surface injected conjunctiva, rapid and shallow or labored and stertorous breathing.

Quick pulse either bounding or weak, and temperature ranging from 105 to 110 with suppression of all glandular action when death occurs, it results from asphyxia or from slow circulation.

Heat exhaustion develops with a rapid feeling from weakness and prostration, the face pale, surface cold, voice weak, the circulation rapid and weak, the respiration increased and vision grows dim. noises develop in the ears.

The patient becomes partially or completely unconscious, the patient falling unconscious with tremors and sunken, features and possibly convulsions.

Acute meningitis as a result of heat stroke is rare, but when it does occur, the symptoms are similar to cases due to other causes. It is of great importance to be able to distinguish at once between attacks of sunstroke and heat exhaustion. This can be done by the aid of the thermometer. Sunstroke is to be differentiated from alcoholic poisoning and cerebral hemorrhage by the history, season, occupation and the temperature.

The prognosis is usually favorable in heat exhaustion properly and promptly treated, less so in sunstroke, but of course that depends on the severity of the stroke, the previous health of patient and the promptness of the treatment, unfavorable indications are increased temperature, cardiac failure, con-

*Read before the Christian County Medical Society.

vulsions and absent reflexes followed by complete muscular relaxation; favorable symptoms are decline in temperature, stronger pulse, increased depth of respirations, restored reflexes and a return of consciousness. In any of the forms of heat stroke, the following conditions may result, vertigo, headache, insomnia, epilepsy, mental enfeeblement and monoplegia, paraplegia or hemiplegia. Prophylaxis is highly imperative especially in the aged and those that are run down from any cause.

We should live regular and temperate lives, avoiding all sorts of intemperance such as drinking, especially alcohol, eating and exercising, light weight clothing should be worn, and the rays of the sun avoided as much as possible. The condition of the secretions should be watched and kept active, especially the skin, and if sweating stops shelter and rest should be sought at once, mild cases of heat prostration require very little treatment in the way of drugs, a little judicious management such as the removal of the patient to the shade, loosening all constricting clothing, sponging with cool water, a cold cloth on the head. If any medicine is needed a dose of spirits of ammonia or nitroglycerine by the mouth. If temperature is subnormal a hot bath is indicated. Strychnia may be used a day or to if patient is nervous and weak. On the other hand sunstroke requires the most energetic and prompt treatment if we hope to save our patient.

The patient is in great danger from the high temperature, means must be resorted to to reduce it at once, nothing is better than the cold bath, if that is not convenient, rubbing with ice, is a good substitute, up and down the spine especially. A cold enema may be given with excellent results, some authors advise the hypodermic use of quinine sulphate or antipyrine. I have never used either.

To combat the subsequent rise of temperature the patient should be wrapped in a cold sheet, if restlessness and convulsions occur, morphine should be used and repeated if needed or the bromides and chloral may be given per rectum. Now if depression occurs strychnine 1-40, may be repeated several times if necessary. Hypodermoclysis and enteroclysis will be of value under such condition.

After the fever has been reduced the patient should be placed in a cool place, and ice cap on the head, small pieces of ice may be given to relieve thirst or gastric irritability with small doses of calomel to move bowels, a light diet such as skimmed milk or buttermilk, grape juice, or vegetable soup may be given a few days. During convalescence iron, quinine and strychnine may be given.

HEREDITY AND CHILD WELFARE.*

By JOHN D. TRAWICK, Louisville.

"And a little child shall lead them."

A responsibility is being placed upon the medical profession to keep pace with all the social interests working for the conservation of the child life of the nation, for it is being recognized as never before that in the welfare of the child lies the hope of the race.

You hear how environmental influences are being searched for agents deadly to infant survival, and see daily how the volume of evidence is growing to show that the whole mind of the nation is in accord with the Nazarene's judgment that should a man offend one of these little ones, it were better that a millstone be tied about his neck and he be cast into the sea. A study of the potentialities of the child already born soon leads a serious student beyond the fact of birth and the presence here of a physical organism with its endowment of worth or unfitness to the pre-conceptional era of the human individual. The truth is demonstrated that whatever exists in the new individual of resistance to disease, of stability of nervous system, in brief, whatever that individual may possess of ability to live and thrive must have been inherent that is born within him.

Close inquiry into the modern conception of laws of heredity gives proof that whatever of potentialities the individual may possess have been predetermined in the inheritance. That a man may acquire by his environment, and be the gainer by culture, and that every responsibility rests upon him to develop to the fullest all there may be inherent within his personality is perfectly true, but not more so than that an individual is capable of culture just in proportion to his potentialities.

A child resembles its mother because of the inherent determiner within the producing cells for likeness to the maternal parent. If a biological trait or character exists in a human individual it is present because of a determiner for that character previously existing within one or both of the producing cells from which that individual sprang. If within the producing cells, which by fusion are destined to make a new being, there should exist the determiner for any given trait, the new individual produced is as sure to have that trait within his potentialities as he is to resemble his parents. There need be no confusion here. Race, color, sex, character, all are predetermined within the producing cells, but every trait of biological character inherited does not always find expression in the indi-

*Read before the Muldraugh Hill Medical Society.

vidual, simply because perhaps the environment has not called into prominence the potentiality for the trait.

A child may inherit musical ability for instance from one or both parents, and by force of poverty or restraint of environment give no expression that it has musical bent until some chance gives opportunity for the potentiality to manifest itself.

But all the chance, opportunity, culture, training, or what not in its environment could not have put into that child inherent musical bent had it not possessed the potentiality any more than culture could have kept him from resembling his parents.

The force of this wonderful law of inheritance finds distinct application in what we term "constitution," or bodily resistance, in childhood.

Since we have shown, by implication, that whatever influence is to find its expression in the mature individual must first have found its biological beginning in the protoplasm of the producing cells, we must confine our attention as scientific investigators to those human influences that can truly be shown to effect cell protoplasm. In other words, for this consideration, we are interested only in those factors which can be proven to effect the producing cell, for thereby we reach the fundamental influences that affect child life, not only in part but in potential.

If any poison, for instance, is thought to have inherent effect upon a child's constitution it must be shown to have first an effect upon the producing cells which fused to form that child.

C. R. Stockard in the *Archives of Internal Medicine*, October, 1912, in an "Experimental Study of Social Degeneration in Mammals Treated with Alcohol," gives account of some experiments which call attention in a profoundly convincing manner to alcohol as a protoplasmic poison.

Alcohol was given to otherwise apparently normal guinea pigs by inhalation treatment.

A paternal test was applied by mating alcoholic males with normal females, which was a crucial test for effect of alcohol on the male producing element of the germ cell since the mother and ovum were unimpaired.

In the maternal test alcoholized females were paired with normal or untreated males. "Here the mother," says the investigator, "has two chances to injure the offspring, either by producing defective ovum, or by supplying unfavorable or diseased environment in which the embryo must develop."

The greatest chances for impairment of offspring lay of course in mating of two alcoholics.

The outcome of these matings was most con-

vincing, in demonstrating that alcohol may directly effect offspring through either parent, by producing changes within the protoplasm of the producing cells. The animals were never completely intoxicated, they were merely in a state corresponding to that of the moderate drinker or chronic alcoholic.

Nine control matings gave nine litters consisting of seventeen vigorous individuals. Out of forty-two matings of alcoholized animals only seven young survived and five of these were runts.

In the paternal tests there were abortions, still births, and early deaths. The maternal tests showed much the same general results.

When both parents were alcoholics, in most cases the matings resulted in no offspring, or very early abortions or in still born litters.

The single offspring born living from fourteen matings of alcoholic parents died in convulsions at an early age. In general the deaths of these unhealthy young followed symptoms of nervous disorders.

"Here are data to be reckoned with," says the *Journal of the American Medical Association* in which the experiments are commented upon editorially. "They invest the records of degeneracy in relation to alcohol with a new significance."

Guinea pig or human individual, it matters not. The assertion can be made without hesitancy that the producing cells are influenced by alcohol. The higher the organism the quicker is the poisoning effect noted of these drugs of the narcotic class.

Child welfare cannot be attained until the racial effect of alcohol as a poison has been understood and resisted.

In this relationship we must refer to the degeneracy, the epilepsy, the unstable nervous organism, immorality and criminal tendencies which act as train bearers to his spirituous eminence.

Alcoholism may be consequent upon mental defect, not antecedent to degeneracy, that is, chronic alcoholism is an evidence of previously existing mental defect, or degeneracy, is a mark of defective germ plasm in the parental stock. The child is defective not because the parent is alcoholic, but because it is the product like its parent was, of defective germ plasm. The child may be physically or mentally fit, and yet when maturity is reached exhibit alcoholic tendencies.

Alcoholism in the parent is apt to lead to earlier alcoholism or degeneracy in the offspring. Parental alcoholism accentuates the downward trend, with each successive generation the period of exemption from alcoholism and degeneracy is shortened so that the offspring becomes alcoholic or degenerate at a relatively earlier age.

It is upon families that are prone to degen-

eracy that alcohol appears to put the finishing touches and renders physique and ability of offspring more and more unsatisfactory with each successive generation acting to light up and determine the existence of a neurosis or psychosis which might otherwise be on the wane.

As interesting as this line of study would be pursued into the etiology of degeneracy in childhood we must give brief attention to another factor in the social order making for disease and degeneracy and death which springs from the misuse or violation of the very laws society has made for its own perpetuation and safeguarding.

Here again the evil is most deadly in that it works its worst within the producing cell. If syphilitic disease could be shorn of all relationship to posterity and be proven to infect alone the persons primarily involved, and with their passing end, so far as that personal history goes, yet would syphilis be counted as "slaying its thousands" and be worthy of national reckoning. But when there is added to this known personal history, the fact that in the offspring we find so much disease and hurt inherited we must class syphilis as a racial poison second only to alcohol in potency.

The modern treatment of this disease is particularly interesting to those of us who are studying the medico-sociologic questions of the day.

There has come no new generation, yet, since the newer treatment has come in vogue, therefore we cannot pronounce finally upon the hereditary influence of the disease as affected by the treatment.

Since then the deepest students are not yet prepared to say that the treatment will cure all cases, nor that cases apparently cured will remain so, we can only maintain our stand that syphilis is in every biologic sense opposed to child welfare, and the moral issue is unaffected.

These two health menaces are cited to bear upon our statement that resistance to disease can best be reckoned in terms of inheritance. All treatment, sometimes at best problematical, must remain more or less experimental so long as we are in doubt as to the inheritance of the child. Infant mortality, therefore, must first be studied in the incipiency of the child's forbears. Child psychology is a story but half told if viewed merely from the standpoint of the immature being.

Neuroses, tendencies, traits are but individual repetitions of previously existing tendencies, neurosis or traits.

Every factor to-day making for child welfare is significant in that we are to-day laying

foundations biologically for potential parents that their children may fare well.

THE QUESTION OF SEX EDUCATION.*

By H. J. FARBACH, Louisville.

I have often been asked, "what does all this sexual education and eugenic talk amount to, do you candidly think it is doing any good. is there such a great increase in venereal diseases and is there a venereal menace?"

The question itself answers the first inquiry. Any movement that brings about the recognition of an evil, social or political, is doing good.

Have venereal diseases become a public menace? Ask the mother, whose first born lies in her lap and rolls from side to side in their sockets two starring, sightless orbs. The sweet mysteries of a new life within her life that changed a care free, pleasure seeking girl into a loving devoted wife by its unborn, inaudible whisperings. Motherhood the fulfillment of her life, her part of the world's work. Long before it was born she had lived its life many times in dreams. She knew so well how to save it many heartaches she had had. And now in the very first week of its life it was blinded. Blinded beyond any hope. The boy that was to be the pride of her life, was and always would be a care and a burden.

Or again, ask the mother who holds another child. Not her first conception but her first child. Three times before she had tried to bring into the world a living amalgamation of her and her sweetheart's love. Each time the promise was greater as the time grew longer but inevitably the disappointment came. She miscarried. But this child her fourth conception, how carefully she had guarded it, how fearful she was each day of its intra-uterine life, that it too would not reach maturity. But it did and how expectantly she looked forward to its birth. The answer to her first half delirious question that it was a perfect child, filled her with a sense of contentment known only to a mother. But as she holds her two-weeks-old baby she knows in spite of all motherly tendency to overlook faults in her own, that it is not a perfect child. Its face is that of an old man rather than a cherub. A fan shaped eczema spreads from each nostril and it has "a cold in the head" in spite of all care. Ulcers and wheels appear here and there on the thin, wrinkled body.

Do these two children agree for or against the presence of a venereal menace? Have not these mothers sobs and heartaches gone unheeded long enough?

*Read before the Muldraugh Hill Medical Society.

A wedding in any family is a great event. The mother of the groom looks on the bride with a censoring eye. Is she thrifty and affectionate, will she take proper care of her boy and the home he is going to make? The father of the bride sees that the groom can support his daughter properly and that his family is one of good repute.

Much time is spent in the selection of clothes, the new home and its contents. The groom is a fine, big strapping, pleasant fellow. He was a little wild perhaps but since his courtship his conduct has been above reproach. Back they come from a glorious honeymoon to their home. The young husband has been alarmed once or twice by the appearance of a slight discharge but the all excited, rapidly learning little wife has made no complaint and he reconciles himself that there can be nothing serious until it is only a strain, that he has heard of so often.

A few weeks in the new home and a blushing happy bride is transformed into pale, stooped, lifeless, middle-aged woman. Vague pains and soreness have developed into a distress that makes her a bed-ridden invalid. An operation that unsexes her, makes her an old woman in a day, may be necessary to save her life. Instead of a loving, helpful partner the young husband has a neurotic invalid for a wife.

And so I could continue to relate actual happenings, each and every one different, for hours and hours. Granted, you say, this may be true, but it is the exception, not the rule. But is this true? Is it not rather the rule than the exception. The exception to-day is the young man who reaches the age of twenty-five without having been the host of a gonorrhoeal or syphilitic infection. A goodly majority of them, fortunately, have realized the gravity of these infections and have taken proper treatment.

But why is it possible that these diseases are so prevalent? The first thought and answer is prostitution. "Abolish prostitution and you will solve the question" we are told by enthusiastic, inflammatory, inadequately informed fanatics. Saner economists have said "segregate and regulate" prostitution. These have all been tried and have failed. Why? Because the sense of propagation is second only to the sense of self protection, we are conclusively informed by the fatalist. The inherent force of reproduction is so great that no civil or moral law or laws can control it and they hold up the history of the world to prove their statement.

This argument is strong I will acknowledge, I must admit that with all the efforts, and these have not been small, in the past, little has been accomplished. But my argument is

that these efforts have been made in the wrong direction. That the proper line of procedure is so simple and natural that it has been overlooked or perhaps slighted.

Man learned that the best way to check a rapidly advancing fire was to create in the path of that fire a space that contained nothing to burn. Life and energy was uselessly wasted in spectacular resistance on other lines but nothing was gained. An army that can not be defeated in the field can be starved into submission by siege. The process is slow, perhaps, but the results are sure and as it is with the big problem before us.

You can spend much time and money trying to regulate and segregate or abolish prostitution. You can paint horrible pictures and make dire threats from pulpit and press but in this manner you are fighting the results and not the cause of it all. How much would have been accomplished in the wars that have been waged so successfully against other devastating diseases as small pox, diphtheria, yellow fever, cholera, tuberculosis, if they had simply tried to regulate and segregate. The secret of success of these campaigns has been *prevention*, not the handling of the active infection.

The main factor in accomplishing prevention has been education. Mystery and misunderstanding are the two greatest foes we have to combat in any widespread campaign against disease. Venereal diseases are no exception. But the trouble with our present campaign is that it has been directed against the results and not the cause. What is the cause? Take the increasing prostitution, the increasing of venereal diseases, the increasing immorality and sift them all down to their basic element, down to the root that reaches far below any drouth line and it is there we find the cause. Hidden away by mystery, prudishness and misconception is the truth. And that truth is that we have been unknowingly but viciously teaching that sex is evil.

It would perhaps be interesting and entertaining to explain how this has come about but such an explanation does not lie within the limits of this discussion.

Here as in every malignant condition a vicious cycle has been established. Prostitution in the beginning made sexuality an evil. It converted sweet, sacred, natural instincts into lewdness, sensuality and licentiousness. These in turn made more prostitution and so the vicious cycle was started. And the public at large to-day is taking the view of the prostitute. They have allowed this debased element of society to define and defile the greatest force for good known to humanity.

The natural inherent feeling and instinct is not that sex is evil, but that it is sacred.

And the strange part of it is that this is not realized until the individual has reached maturity. No matter how lewd and licentious a life a man may have lived when he selects a woman for his wife and the mother of his children, when he sets about to accomplish the desire of his creator, he is inherently, unmistakably impressed with the sacredness of sexuality. And in every instance he is ashamed and remorseful of the things that in the past he has committed that in any way cast a blight or shadow on this sacredness.

Now, if this is true, and I feel sure that there are none that will gainsay it, should it not be given some weight? If this man, who has been taught from infancy that sex is evil, realizes in spite of all this training that it is sacred, doesn't it argue that if he had been taught from childhood that sex was sacred, that he would have lived differently. That he would have guarded rather than debauched it. Would not his view and opinion of a prostitute have been different, would he have risked venereal infection as he had. Threat and fear of consequences have had little or no controlling influence in sexual matters. Is it the threat of hell that makes biblical characters sacred to a child? I think NOT.

With the innovation of all the newer religious ideas, the respect for biblical characters is still evident. Even among the so-called atheists, free thinkers, Christian skeptics and even these in their bitterest criticisms do not lose the respect of the biblical character they learned in their early childhood.

Perhaps higher education, as they call it, has proven to them that Christianity is nothing but another mythology, but still these biblical characters remain as they were in early life even if they have ceased to surround them with their proper sanctity and sacredness.

Now if the manner of the birth of one child can be set down in writing and taught to the whole world in every language in a manner that does not shock, does not breathe of sensuality, why can it not be taught to every child, according to his understanding, the truths of sexuality. Begin the sex education of the child when you start his religious education, and in the same manner.

Until near the age of puberty sex distinction need not enter into this teaching. The generative organs of a child are primarily excretory organs and if instructed properly it will tend to lessen rather than increase to direct his attention to them.

But sex education must begin early to be effective. All too soon the young child gets an erroneous vicious idea of his sexual apparatus from vicious, older companions or from servants.

Ask any missionary who has been among primitive people teaching them for the first time a religion, who are the easiest converted and who backslide the least. It is the young children. Implant the proper idea before the wrong one gets a hold and the wrong one will never gain ascendancy.

It is a hopeless, useless task to try to segregate and regulate prostitution. It is impossible to abolish it. And by prostitution I do not refer only to that traffic which is carried on in public whore and assignation houses. I refer as well to the clandestine and illicit intercourse that is carried on in the very homes of the daughters.

The arm of the law cannot reach these. Venereal diseases are contracted as readily and as often in one instance as in the other. The time has arrived when we must recognize that every child in every home is subjected to these dangers. Innocently, perhaps, but the greatest of evils is the ones with the cloak of innocence.

You cannot abolish or even control these circumstances with threats or by fear. You have to stop fighting the results and get down to fighting the cause. How? First and before every thing else, the true definition of sex must be established. If the definition I have given it, that it is sacred not evil, is correct, then the task is an easy one. If this is not true, if this is simply a vamping of my own and sex is really and truly evil, then my ideas are wrong and useless.

But surely, that from around which emanates everything we have that stands for the best, love, morals, poetry, art, literature, music and even religion, surely the basis of all these can not be evil.

Teach then the proper attitude toward sexuality. This can be accomplished by calling a spade a spade and by preventing as much as possible a state of mysteriousness where sex is concerned. Explain birth and reproduction to the young child by biological and botanical examples he can understand. Show him that fertilization of an ova by serum is a beautiful, intricate process and not a lewd, shameful act. Explain that reproduction is a natural consequence of natural forces and not a mysterious, untalkable thing.

Then when the sex instinct becomes evident to him teach him and prove to him that by curbing and controlling it he is fitting himself for a man's work.

Is not this process a simple and natural one? Is there anything embarrassing or disgusting about such a procedure? And in the end, not this year nor perhaps in the next

ten years, but ultimately will it not do more to lessen prostitution, to increase morality and decrease venereal diseases than anything else.

SCARLET FEVER TREATMENT.*

By W. L. MOSBY, Bardwell.

The old saying that "an ounce of prevention is worth a pound of cure" holds good with scarlet fever as well as with all the acute infectious diseases. So prophylaxis is the physician's first duty, therapeutics afterwards. Immediate isolation of patient and watch carefully over suspects or those exposed, should be the rule, even where doubt or delay in the diagnosis is necessary, as the gravity of this disease is too great to disregard the right and health of others. An upstairs room, large and airy, provided with a fireplace for heat and ventilation with a temperature kept at from 60 to 65 degrees during febrile period is desirable, as it separates patient and nurse from the remainder of the family and affords quietude and contributes to restfulness and comfort of patient. Free ventilation without draft is essential, and may be secured by window-board or a frame covered with cheese cloth fitted in window. Screens are helpful to guard patient against drafts of air. Doors may be protected by hanging sheets, moist in 5 per cent. carbolic acid solution, or one to one thousand bichloride of mercury. All pictures, carpets and hangings, including unnecessary furniture and fixtures should be removed from the room, and the nurse or attendant should wear wash dresses and hair covering of oil silk or washable material. Before leaving sick room she should disinfect hands, face and neck with 2-1-2 per cent. carbolic solution or 50 per cent. solution of alcohol and gargle throat with Dobell or dilute liquor antisepticus solution. Physician should likewise use a long washable gown, closely fitting about the neck and reaching to the floor, head protected as directed for nurse, and exercise same care to disinfect all instruments brought in contact with patient. All dishes and utensils used in sick room should likewise be disinfected, as are clothing and bedding of patient, by soaking an hour or more in a 5 per cent solution of carbolic acid or one to one thousand sublimate or boiling. Room disinfection finally, is done by formaldehyde gas or sulphur dioxide being kept closed for a period of twelve hours.

PROPHYLAXIS BY DRUGS.

Belladonna was formerly recommended by the homeopaths and Spearisky claimed that arsenic was capable of preventing the dis-

ease but in view of further experience and observation their value is doubtful and should not be relied upon for this purpose.

J. Elgart, August *Medical Clinic*, Berlin, believes oil of eucalyptus is effectual in preventing scarlet fever and measles, and uses bags saturated with the oil around neck and the inhalation of 30 to 50 per cent. solutions of lime (aqua calcis) twice a day at first and then daily for four weeks. Milne, house physician for Barnade Home for boys used the oil by application to body from head to feet twice a day for four days and then daily for six more days and the application of a 10 per cent. phenol in oil to throat two hours first day and then at longer intervals using a swab the size of the child's thumb nail.

Was further claimed that no complications developed in those treated by inhalations of lime and that course of disease was much milder and shorter than with ordinary treatment.

This theory assumes that inhalation of infectious material is responsible for spread of these diseases and complete sterilization of respiratory tract with fumes of eucalyptus oil and other local methods mentioned will prevent its occurrence.

Preventive inoculation has not achieved much success as yet. Strickler injected children subcutaneously with mucus from nose and throat of patients sick with scarlet fever but disease was developed in a severe form.

Gabraitschewsky, a Russian physician, has used a serum of his own in about 50,000 cases with apparently good results, and so far its use is encouraging and deserves further investigation.

If the "ounce of prevention" has not prevented, we may judiciously select from the "pound of cure" on definite therapeutic indications, as we have no specific to offer in this disease. Patient should be placed in bed with a light cover during febrile period, and later guarded carefully against chilling of surface by drafts of air or exposure to prevent complications or sequellae, and carefully sustained on a milk or liquid diet, as largely milk as possible. An initial course of small doses of calomel frequently repeated followed with a saline is usually indicated and bowels should be kept responsive by hot intestinal irrigation 112 degrees F., which is of value as diuretic and stimulant assisting in elimination of infectious material. Salines may take the place of high enema if desirable. Baths should be employed daily, and more frequently if temperature is high, controlling it by this means if possible. Temperature of 104 degrees F., should be lowered by application of cold to head and chest and cold sponging as indicated. Cerebral symptoms

*Read before the Kentucky Midland Medical Society.

may be relieved by these applications and small doses of salipyrin, phenacetin or antipyrin. Insomnia and restlessness will be relieved by the same remedies. Should convulsions occur, the inhalation of chloroform and the administration of bromine salts will usually suffice. Hydrotherapy is beneficial in relieving nerve tension, lowering temperature, rendering patient more comfortable and relieving skin rash. We may assist in the prevention of nephritis by careful attention to the elimination by skin and bowels. Stimulants are unnecessary in mild infections but in severe septic or anginose forms, with weak or irregular heart action brandy or whiskey may be used to advantage and with quick pulse of low tension tincture of digitalis is indicated, one drop for a child four to six years old, four to six hours. Strychnine one two-hundredth to one one-hundredth of a grain may be administered where a nervous depression exists. In simple forms of pharyngitis a spray of Dobell solution or dilute liquor antisepticus every 4 hours is of value. Aural complications are better prevented by combatting nasal conditions which produce them, spraying and proper antiseptic application. An easy way of applying hot antiseptic solution to nose and throat of children is to place a soft rubber catheter on nozzle of fountain syringe with which we can easily douche nose and throat with boric acid solution or permanganate of potash one to eight thousand. Dermatitis and desquamation are to be treated by local application of carbolyzed salt solution or half saturated solution of boric acid followed with application of talcum powder, unless preference is given to ointments of a similar composition. Oil of eucalyptus should be considered in view of its reputed prophylactic properties. Colloidal silver ointment (ungt. crede) is thought to exercise an influence on the septic nature of the disease and influence condition of skin favorably. Patients should be kept in bed for from one week to ten days after all febrile symptoms have disappeared. In absence of complicating conditions this enforced rest will help to prevent their development. Also milk or liquid diet should be continued during this time. Prophylaxis also applies to complications and sequella as their development brings increased dangers to patient and responsibility to physician. High temperatures, quick pulse and unusual nervousness are frequent symptoms rather than complications in scarlatina and the ice cap with cold application, phenacetin and bromine salts with aconite will control these symptomatic manifestations.

Naso-pharyngeal involvement is almost uniformly present but not in a form suggesting dangerous involvement of nose and pharynx

and when either exists in such a condition it may be properly considered as a complication. Rhinitis calls for frequent syringing or spraying with warm solution, normal saline or permanganate of potash. Care should always be exercised not to carry the infective material into Eustachian tube thereby producing ear involvement adding another complication. Streptococic faucial involvement requires energetic treatment. Gargles are difficult to perform and better results are secured by topical application every 2 to 4 hours with swab of cotton on applicator, or direct spraying, the latter being our choice. Peroxide of hydrogen is cleansing and may be followed with permanganate of potash one to forty or sublimate solution one to five thousand.

We possess few better remedies than the old tincture chloride of iron, and it may be variously diluted with glycerine or water as per indications. Severe anginose symptoms aside from atomization with antiseptic solution and well directed local measures will require vigorous constitutional measures to support patient.

OTITIS.

Pain will be successfully relieved, for a time at least, with cocaine solution 4 per cent. or adrenalin which has a similar effect. Ear douche with hot normal salt solution will relieve congestion and often the pain will subside. Suppuration is frequent and when present paracentesis should be performed early, especially if bulging of membrane tympani is discovered and pain exists. After perforation the treatment for otitis media suppurata is carried out, the chief object being to sterilize canal and prevent mastoid complication.

CERVICAL ADENITIS.

This occurs more frequently after or with severe anginose involvement and may extend to pericellular structures. The application of ice bag over layers of cloth is useful. Flexible collodium painted freely over glands producing uniform pressure exercises a beneficial mechanical effect. Tincture of iodine in dilution or 10 per cent. ichthyol ointment is thought to influence morbid process favorably, and may be applied beneath ice bag. Pus formation calls for hot applications and later evacuation after it has formed. Tonics of iron and strychnine are generally indicated and well borne. Syrup ferri iodidi, I have found valuable.

ARTHRITIS.

Salicylates at present are our main reliance notwithstanding our ignorance as to etiology of this complicating condition. Acetylsalicylic acid may be required for pain combined with moist compresses applied locally. The local protective application to affected

joints may prove useful and give comfort to patient.

NEPHRITIS.

This is the "captain" of the many dangerous complications or sequella of scarlatina and sad pictures of its ruthless intrusion crowd our memory as we pen this paper. Unfortunately, we have found it easier to treat than to cure. Possibly our want of skill may explain the latter. An insidious foe ushered in by oedema of eyelids, hands and feet, accompanied by fever and a scanty highly colored urine with little or no nervousness may be our first intimation of its presence. Albuminuria is present. Warm baths two or three times daily, hot enemata of saline solution combined with mild diuretics, milk diet and absolute rest in bed should be our reliance. Severe cases with vomiting, convulsions and uremic complication will require hot vapor baths, 100 to 105 degrees for fifteen or twenty minutes and then envelope patient in hot blanket without drying, inviting free diaphoresis. Our chief efforts should be directed at restoration of functions of kidneys by diuretics, cupping dry or wet, hot baths, etc. Lumbar puncture and hypodermic administration of morphia and atropia have been used and recommended by Allaria and Sheffield, but personally I have had no experience in children with either. We may have nephritis occurring during third or fourth week of disease, with dropsical effusion into serous cavities with edema and uremic symptoms which will call for purgation, sweating and diuretics. All uremic symptoms occurring during a nephritis demand energetic treatment, the principle of which has been outlined.

Dropsy is counteracted by diuretin, digitalis, spartein, etc. Overtaxed heart may require digitalis, nitroglycerin or strychnine. Anemia calls for iron, preferably Basham's mixture, milk diet and absolute rest in bed a *sine qua non* in all forms and conditions of nephritis continued well on into convalescence.

Pediculosis Capitis. Treatment. Lay patient on back on bed with head over edge, hair lying in a basin beneath head on a chair. Pour 1:40 phenol solution over hair into basin and sluice backward and forward until hair thoroughly soaked, especially over ears and at nape of neck. Continue sluicing ten minutes, then lift hair from basin and allow to drain, without drying it. Then swathe head with thick towel or large piece of flannel and allow to remain for an hour. Finally wash hair or simply allow to dry. Method entirely safe with children of 5 years and over. Hair not damaged.—Whitfield.

FRACTURES OF THE LONG BONES.*

By P. N. BLACKERBY, Falmouth.

A fracture is a sudden solution of continuity in bone or cartilage. The term is commonly applied to bone. A fracture may be partial or complete; transverse, oblique or longitudinal; single, double, or multiple; simple, comminuted, compound and complicated. As you are all acquainted with the different forms of fracture, I will refrain from giving you a detailed description of each kind, as also the causes producing them which are many. The symptoms of fracture from which we make a diagnosis are loss of function, absence of normal contour, preternatural mobility, crepitus, and pain, shortening. As my subject is confined to fracture of the long bones which consist of humerus, radius and ulna of the arms and the femur, tibia and fibula of the lower limbs, and I suppose the ribs may also be included in the list, we will commence with the humerus. Fracture here occurs most frequently in its lower third, the proportion of fractures of the middle and upper being about equal. As it would make this paper too long to give a detailed description of the many fractures that may occur about the head and anatomical neck and lower end of this bone, we will content ourselves with the fractures that occur along the shaft of the bone and their treatment.

Fractures of the shaft of this bone, although chiefly caused by direct violence, are not infrequently the result of a fall on the hand or elbow, and may, in rare instances, be caused by muscular action alone. The displacement usually not very marked will be determined by the direction of the line of fracture. After bringing the ends of the bones in apposition by extension and counter extension and proper manipulation a cotton flannel roller or a common muslin bandage should be applied over a single layer of cotton batting which is placed next the skin. Now we have the choice of plaster of Paris or splints to hold the bone in place. I think the former preferable. Compression of the first bandage and of the plaster of Paris bandage should be snug but not too tight. The arm should be flexed with the forearm resting against the breast. The bandage should extend from the axilla to the metacarpal bones. As soon as setting of the plaster has taken place it should be slit throughout its extent, then if swelling enough occurs to threaten gangrene the former bandage is easily divided and compression relieved. The plaster of Paris dressing should be one-eighth of an inch or more thick. The arm should be held against the body by straps or bandage and retained in po-

*Read before the Pendleton County Medical Society.

sition for from four to six weeks. If splints are used we have the choice of a cup-shaped splint of either guttapercha, sole leather, wood or cardboard and using an extra short internal splint.

Fracture of the ulna in its shaft, occurs in its effort to ward off a blow, or as a result of a fall directly upon the bone. Diagnosis is not difficult, if compression be made by grasping both bones several inches from point of suspected fracture and pain and abnormal mobility be caused at that point, the diagnosis of fracture is fairly clear, if crepitus is obtained we can always be certain that a fracture is present.

As the treatment of fracture of the shaft of the radius is almost identical with that of the ulna they can both be given under one head, which consists after displacement if any has been effected and the broken ends in apposition, of two padded splints. The posterior, to extend from within one inch of the olecranon to the ends of the fingers, the anterior splint to extend from the elbow to the carpus, wrap each splint with a bandage to hold the wadding in place, apply splints so that the interosseous pads will push the muscles down between the radius and ulna. Then fasten them with a bandage made tight enough to prevent slipping. If in the course of a few days the dressing becomes loosened, it can be tightened by applying an additional bandage. The forearm should be carried in a sling. The treatment should be continued for about four weeks, when passive motion of the elbow and supination and pronation, should be made, and the dressing be readjusted for another week. This dressing will be found sufficient for all fractures of the shaft of one or both bones of the forearm.

In Colles' fracture the diagnosis is not usually difficult. The deformity which results from the backward and upward displacement of the lower fragment, the history of the accident and the pain at the seat of injury point to the character of the fracture. Crepitus may not always be elicited. The hand is directed toward the radial side, and the styloid process of the ulna is unusually prominent. After reduction has been accomplished a very satisfactory dressing is a snugly fitting gauntlet of plaster of Paris, extending from the metacarpo-phalangeal articulation to six inches above the wrist. The patient should be advised to move the fingers of the affected side a number of times a day, in order to prevent adhesion of the tendons to their sheaths. If plaster of Paris be not at hand, a posterior splint, padded, made of light board or heavy pasteboard, may be placed from the end of the metacarpal bones back near the elbow with a short anterior splint, extending half way in the palm of the hand, to several inches

above the fracture, nicely adjusted with a roller bandage or adhesive plaster. An extra wad of cotton placed between the splint and the dorsum of the metacarpus fixes the hand in semi-flexion, in which position the extensor tendons are kept tense and aid in preventing redisplacement of the lower fragment.

The shaft of the femur is usually broken by direct violence. Or indirectly by a force transmitted from below upward. In exceptional instances the fracture is caused by muscular contraction alone. The line of fracture is generally oblique, and the displacement is determined chiefly by the direction of this line. Diagnosis is not difficult. Preternatural mobility, crepitus, pain and shortening will usually determine the character of the injury. In the treatment of all fractures between the trochanters and the knee joint choice rests between the method by Buck's extension and the plaster of Paris dressing. When the fracture is below the middle of the thigh, the plaster of Paris dressing is to be preferred and may be applied without anesthesia, provided that by extension the muscles yield and the fragments come in apposition. The bandages need not extend higher than the level of the perineum, but should take in the foot. Whatever method is employed, immobilization at the seat of fracture should be maintained for five or six weeks.

Fracture of one or both bones of the leg are next in frequency to that of the radius, the clavicle, and the ulna. The upper end of the tibia is usually broken by direct violence, although a fall from a height upon the foot may produce a longitudinal or oblique fracture. The most common point of fracture is the junction of the middle and lower third. The fibula may be broken at the same level, or at a point above or below the line of fracture in the tibia, or this last bone alone may be broken. A fracture of the tibia near the ankle joint and a complete break of the fibula is of frequent occurrence. This is the well-known Potts' fracture and sometimes called railroad or street car fracture, since it is often caused by jumping from a car in motion. Potts' fracture is recognized by the peculiar eversion of the foot, the abnormal prominence of the internal malleolus, pain and loss of function. In most cases of fracture of one or both bones of the leg it is the best practice to reduce the displacement by extension and counter extension, and apply the plaster of Paris dressing at once. This should extend at least half way up the thigh, in all cases, in order to fix the knee joint. It is applicable to all fractures of one or both bones, from the knee down including the malleolus. Extension can usually be made from the heel and ankle by an assistant. A layer of cotton batting is placed next the skin, a dry muslin or

flannel roller, making firm compression, is applied, and the plaster bandages over this. The plaster cast should be split down the middle line, in front, to guard against swelling.

Compound fractures are treated by reduction of the deformity, free drainage where infection is evident, and strict antiseptic precautions. The plaster dressings should be made with a window for free inspection. Extension, if necessary, can be made in the usual way. Some years ago a mechanical apparatus was devised called an ambulatory dressing in which it was claimed the patient could move about as soon as applied, but as I have seen or heard nothing further in regard to it, suppose if used at all, it is confined in use to the hospitals. Laterally the open treatment of fractures has been done by some of the leading surgeons and was, I believe, first done by Lane, of London. This consists in cutting down to the bone at point of fracture adjusting the ends of the bone and fragments and holding them in place by means of plates of several different materials, screws, bone and ivory pegs, plates, etc. While this has been done in fresh fractures with sometimes, but not always, good results, I think this operation will ultimately be confined to those cases in which proper union has not taken place, and then only in hospital where the work can be done and watched by a competent surgeon with all the facilities of a perfectly aseptic technique.

Thanking you gentlemen for your forbearance with a not too interesting subject, I leave it with you, hoping to learn through your discussion of it a good many things I have overlooked or did not know.

Bladder Resection.—G. Kolischer, Chicago (Journal A. M. A., January 24), reports a case of malignant growth in the vertex of the bladder performed by denuding the whole anterior aspect of the viscus of its peritoneal covering and clamping the top of the bladder far enough down to insure the resection of the vertex and the tumor in healthy tissue, the clamp being applied under the control of the cystoscope introduced before the operation, which, however, in practice was found to be superfluous, as the incision could have been guided by palpation. The operation is described in detail and the healing was complete in three weeks. Three months later the interior of the bladder was apparently normal according to cystoscopic examination, except for a slight distortion upward at the seat of the excision, evidently due to an adhesion at the top of the bladder. While it is still too early to predict a permanent cure, the operation is a technical success.

THE IDEAL AND THE REAL IN THE PRACTICE OF MEDICINE.*

By G. G. THORNTON, Lebanon.

Just why it has never entered into the mind and purpose of someone abler than myself to discourse upon this theme I am sure I do not know, but possibly it has and that there is such an article in existence, that has escaped my attention. The ideal is doubtless the dream of the young man when he first resolves to take up the study of medicine. During his life up to this point, he has observed the active prosperous physician as he went about his daily work, and noted his close application to the duties of his profession and that people often spoke of his being so busy and so successful and that he received such good fees for his services. He has also noted the fact that he has seldom seen him about places of amusement, except when some one was unfortunately injured or was taken suddenly ill and he attributes his absence from these places to the fact that his calling has such a fascination for him that the pleasures of ordinary people have no attraction for him. He also remembers that when he has been out driving on good roads on pleasant afternoons to have frequently seen this busy doctor out, either driving a good stepper, or in his classy automobile, and notes further the fact that the community in which he sees him seems to be prosperous and that probably the pay is always sure. He sees doctors meet in consultation, he hears of their meetings at county, state, and national and international associations for the purpose of discussing how to raise fees and for having a good time generally.

He meditates on all this and as he sees it the doctor's calls come in just as he would have them, always on pretty days, good roads and where the pay is good, patrons are intelligent, the disease has nothing about it that is repulsive, the patient is pleasant and hopeful, and all he has to do is to spend a few pleasant moments and leave a few tablets or pills or possibly a prescription with intelligent friends or possibly a trained nurse and pass on to the next case which is just different enough from this to give variety and on and on, to the end of the day and at night he is just tired enough to sleep sweetly, and on the morrow to revisit these patients; finding that his medicines have been given and his instructions have been followed carefully and that some of the patients have so far improved that it will not be necessary for him to visit them again and when he returns to his office he finds enough new calls to take the place of any who have no further need of his services and these, too, are all of

*Read before the Muldraugh Hill Medical Society.

that same desirable type which makes the calling so fascinating. He finds that his medicines have always had the effects that he wanted and that he has told the patient and family what he expected and that his diagnosis and prognosis have always been correct.

To him, the doctor's life is one gala day of happy and successful experiences with few or no cares and nothing but pleasant associations. He never dreams of the anxieties of the young practitioner, about whom the people and especially the old doctors speak with an emphasis on the young doctor, about the days, months, and possibly years, that he sits in his office with patient solicitude and anxious expectation, for patients that seem slow to appreciate his ability, nor does he meditate on the self denial that he has practiced to reach this good day, nor does he think on the fact that during all of these years which he has spent in preparation for his life's work that it has been all out-lay and no income and that the investment may never prove an income producer, and can never do so, except while the doctor is working and that when he dies the investment is a total loss.

He and others never meditate on the fact that all of this time while an education was being acquired he might have been making money and putting it in some business where it would have been safe for himself, should health fail him or, for his family should he die. Not meditating on these things and with happy anticipations our young friend passes through medical college and with his high ideal we administer to him the Hippocratic oath and drill into him the rules of professional ethics. Let us now watch him as he meets and mingles with his professional brethren, and we will see him as his high ideals begin to give way to the real. We will see him locate in the town or community of his choice and there he will try to get in touch with his conferees and amongst them he will find one or more who boast of their fidelity to the high ideal in medical ethics, and he will note the fact that some of these speak in disparaging terms of all of the others whose name chances to be mentioned. He tries to find out something about a schedule of fees, and he finds that if such a thing exists it is observed as much in the breaking as it is in the keeping. He finds that one of the doctors who is generally regarded as being the most reasonable in his charges, has charged a man \$15.00 for simply tapping an hydrocele, and when he needed it done at a subsequent time and went to another man he did the same operation for \$5.00 and later another did it for \$2.50. He finds that when making visits to the country, one man will charge \$2.00 and another \$2.50 and at another place one will charge \$3.50 where one will charge \$5.00 and so on ad in-

finitum. And this is not always due to bad mathematics where the charge is made by the mile as estimated distances vary very much.

He further finds that a great many people—people who are about ordinary things reasonable and average people, have such faith in medical schools and boards of health, that they believe that inasmuch as all doctors have access to, and therefore read the same books and journals, and can procure the same medicines, that so far as ability is concerned they are about all alike and as they can judge a piece of goods and buy where it comes the cheapest by the yard or piece, so they will use the doctor who practices at the lowest price per visit or consultation. He tries to be accurate and scientific in his diagnosis, therapeutics and prognosis, but he finds that the man who treats most children's diseases as due to worms and teething, stands about as well and his opinion is about as much respected as the more scientific man. He finds that the man who always knows positively what the disease is with which his patients are suffering, be it biliousness, la grippe, catarrh, a little malaria, worms or teething, is often referred to as authority and his dictum goes at face value when, after exhausting all of his skill and ability, he still found himself in doubt as to the diagnosis. He explains various things in the symptomatology, and his theory of the management of difficult cases to his patients, and appeals to their reason for approval of his methods, and finds that people will tell him what good luck so and so has and that he always uses antiphylogistine in pneumonia, and that he said my stomach will not stand strong medicine. He finds that where he has made a diagnosis of probably appendicitis, and this man is called in he explains the condition to the family as being due to the fact that the bile is very acid?

When our young friend graduated he felt that the science of medicine was approaching perfection and that he could with the microscope, the ophthalmoscope, the cystoscope, the phonendoscope, the proctoscope, the thermometer, the sphymomanometer, the urinometer, the aspirator, by auscultation, by ocular demonstration, by percussion, by subjective symptoms and objective signs diagnose clearly and accurately all of the diseases with which he would ever come in contact. However, if he is honest with himself, it will not be long before he finds that in real experience, he meets up with cases that will be sick,—so sick that some of them will die and he will sign the death certificate, marasmus, uremia or, diagnosis doubtful. He will find that in spite of all his efforts, with scientific skill and instruments of precision, he will meet up with many cases where, if he is honest with himself he is bound to admit that the diagnosis is not clear,

or in other words that he don't know just what is the matter. Here he finds the careless and slipshod getting by with those ever handy terms, indigestion, neuralgia, biliousness, malaria, cold, lagrippe, womb trouble, and other terms that are common diagnostic dumping grounds, useful for covering up a great deal of inexcusable ignorance. He may, and doubtless will, call in a consultant in some of these difficult cases, and this man may be a specialist or a surgeon who greets him with the gentle information that if he had been called a little sooner, more could have been done, or, that the patient can only be properly treated in a hospital, to which our friend has no access, and here he sees his prestige and fee go aglimmering into the great ultimate. He hears much from the surgeon about cancer and other conditions being sent to him when it is too late with the implication that he and other general practitioners are to blame for such a state of affairs, and as he grows older and meditates on what he observes, and calls to his mind numerous cases of cancers that he has seen operated upon, where, the operation actually seemed to aggravate the condition and hasten the untimely end, he wonders just how much the surgeon has contributed himself to bring about the very state of affairs which we all deplore so much. The case that is operated on and not benefited, but that is actually hastened, becomes a living (so long as life lasts) walking, talking advertisement against the use of the knife in such cases that will have more effect to deter those whose attention is called to the bad results than all of the general practitioners and surgeons can ever overcome, and when they are dead, as long as the memory of friends is kept fresh the case is referred to by interested parties, with logic, that is so sound to them, at least, than no one be the general practitioner or surgeon can refute it. He sees the border-line cases where no one can tell positively whether the patient will be benefitted by an operation, but where there is a doubt that gives some grounds for hope, to which hope the patient is entitled. These cases he knows are entitled to be dealt with fairly, and given every reasonable chance, with a fair understanding as to what to expect as to the ultimate outcome. Even these cases that turn out unfavorable will inevitably create a bias against the use of the knife. He appreciates the fact that an early operation offers much and that a late one offers but little, but he feels and knows, that he is not wholly to blame for these cases reaching the surgeon too late, because often when the case is first seen by him it is even then too late for surgical interference.

Again in the very beginning of his career, when he has plenty of time to meditate and his income is hardly sufficient to meet his actual

needs and he meditates on how he may honestly increase same with the high cost of living staring him in the face, and with the general practitioner's fee practically the same for the last decade, he hears much of the division of fees and hears it loudly condemned by most all and knows it is practiced secretly by many, even those high up as general practitioners and surgeons, not always in St. Louis, Chicago and New York, but actually right at home. Not practiced openly, but by the general practitioner, notifying the surgeon that he has a case of appendicitis which he wishes operated on and that the surgeon may have \$100.00 if he will do the operation if he wishes at that fee and then, when the patient is ready to settle his bill the general practitioner collects the bill whatever he may choose to make it and pays the surgeon by his own check. The same course is pursued in hysterectomies and all major operations ad infinitum. If the surgeon don't come across, some other one will and as this man is doing a large practice he can make it worth while to the surgeon to sit up and take notice. With all of these things rapidly presenting themselves to the new man in the profession there is great temptation for him to accept the real as he finds it and to in a measure forget his high ideal. Nevertheless it is for the great body of the profession to maintain the real at as high a standard as it is possible, remembering that in every effort we have to contend with the human that is in all of us.

Recovery in Pneumonia.—From the study of the mechanism of recovery in pneumonia made with special reference to the crisis, in which he reviews the recent literature of the subject, L. Hektoen, Chicago (*Journal A. M. A.*, January 24), reaches the following conclusions: "The cure of pneumonia results from the destruction of the pneumococci in the lungs and in the blood. This is accomplished mainly by phagocytosis, probably to some extent also by antibodies in pneumonia, especially opsonins, and these appear to be specific for the group to which the infecting pneumococcus belongs. In rapidly fatal cases the defensive reactions are inadequate to destroy the pneumococci, which persist and multiply in the lungs and in the blood, and free antibodies have not been demonstrated in the blood. In favorable cases the pneumococci are destroyed more or less rapidly when the antipneumococcal reactions reach a certain height. We may assume this lysis results when the destruction takes place more gradually. Crisis is the effect of prompt destruction. In both cases, but demonstrated more clearly in crisis, there is an excess of free antibodies in the blood."

THE OPEN TREATMENT OF FRACTURES.*

By GEO. A. HENDON, Louisville.

It is not my purpose in this paper to discuss the relative merits of the two modes of management of fractures, open and closed. I am not proclaiming the superiority of either one over the other. They are not in any sense rivals for popular favor, since they are closely allied in the attainment of successful results. Neither one can replace the other. The open or newer treatment is not an usurper, but a tributary to the broad current of general good. No one is expected to adopt either method of treatment as a routine, but the wise course lies in the decision as to *when* the one or the other should be employed. I would approach the discussion of this subject by stating that anything I say in favor of the open method is not to be credited with a double meaning in that it might reflect upon the closed treatment. I also wish to classify some phases of the subject as settled and therefore not debatable. They are thus eliminated from the analysis: For example, every one knows that perfect functional results in fractures of the long bones is not incompatible with anatomic and cosmetic imperfections. We also acknowledge the fact as beyond dispute that the open treatment of fractures never will and never can become the universal procedure. The reasons are so obvious and numerous it would be unprofitable to name them. The real task before us is to aid in the selection of cases adapted to the open treatment and to stimulate interest in the development of knowledge pertaining thereto. I am not prepared to follow Mr. Lane quite so far when he says that public opinion and the law courts will compel the adoption of direct fixation in treating all fractures. But one has only to study the literature of the last three years to become deeply impressed with the rapid advancement of the open treatment. Darrach¹ reports 104 cases; Blake² reports 106; and Bartlett³ reports 80. There are twenty-five times as many articles in the literature as there was two years ago. Walker⁴, F. W. Huntington⁵, in discussion makes the statement that two years prior to the date of his speech only 18 per cent. of the leading American surgeons knew enough about the merits of the open treatment of fractures to discuss it, and now he finds on sending out a circular letter regarding this treatment that 95 per cent. of those to whom he applied agreed to the propriety and safety of the operative treatment of recent fractures in the hands of skilled surgeons. In 1911, at

Denver, President Harte, of the American Surgical Association, in his presidential address called special attention to this subject.

These advances have been made since Mr. Lane read his first paper before the Clinical Society in London, 1894, and in 1909 he read a paper before the American Medical Association that stimulated interest upon this side of the Atlantic. We know the question is agitating the surgical world at present as much if not more than any other subject. It cannot be arbitrarily dismissed or settled by any one man's experience or conclusions. It is a live issue and has been made so on account of the general average of results from the older methods of treatment falling below the mark of satisfaction. Whether it is the law courts, the X-ray, or surgical conscience that is the stimulus I do not know, but I do know there is enough of unrest to convince me that improvement in treatment of fractures is very much needed, and I believe the Lane plate offers up to now the most reliable device for direct fixation that is available.

In our consideration of the *open treatment* of fractures it must be clearly understood that the open method at present is a supplement to the closed, and in its present state of development is not a supplanting or rival measure. It is an amendment, not a substitute. Also, the open treatment of fractures and the treatment of open fractures are two separate propositions that are widely different from each other.

Despite having in Mr. Lane so powerful an advocate, I believe the open treatment would have long since languished, had it not been for fractures of the patella and olecranon. These injuries furnished examples of insurmountable obstacles to closed methods of treatment. Therefore, surgeons must persevere have persevered in their efforts to devise some direct means of fixation to meet the demands of such fractures. Again, some of the most formidable adversaries to the new treatment based their arguments upon their experience in the plating of compound fractures and cases of non-union,—the very conditions under which the plate is least apt to succeed.

The most favorable time for the operation is about a week after the injury. The most favorable cases are the *simple* fractures of the long bones. Probably the tibia or radius offers fewer anatomical difficulties than the other long bones. The most difficult object in the operation is to achieve the standard of asepsis required for this class of work. Even the gloved finger must not touch the wound, nor anything that has touched the hand must be allowed to come in contact with the wound. This is certainly a most difficult feat to perform, and can only be accomplished by much

*Read before the Southern Surgical and Gynecological Association, Atlanta, Georgia.

practice and a high grade of mental concentration.

In the earlier history of the open method much discredit fell upon it by reason of the abiding faith held by many surgeons in the infallibility of chemical antiseptics, and later on its popularity has suffered because of the failure of some of its patrons to realize the extreme refinement of asepsis essential to success. I have lately even seen the practice referred to as "a surgical aberration," probably by one who had failed to realize the importance of the details mentioned.

I have met with some difficulty in the operation in bringing the fractured ends of the fragment in perfect contact. It is the rule where the fracture involves a long bone to find a surprising amount of overlapping. It exists even in fractures of the tibia when the fibula is intact. Alignment can usually be achieved, however, by angulating the fracture outside the incision and buckling the ends of the fragments together. This maneuver is much simplified by smoothing the fractured ends with a saw. In so doing we gain a broad surface for contact without sacrificing enough bone to interfere with functional or cosmetic results. The advantages of broad smooth surface contact are important when concerned in the maintenance of alignment of fractures. One of the chief objects gained in this way is the certainty of bone against bone, or the elimination of that arch enemy of osseous union, the interposition of soft tissue. I have been much astonished at the revelation of the open operation, particularly the amount of injury done the soft parts by the jagged ends of the broken bone and the invariable presence of muscle or fascia or both impaired upon the sharp angles of the fracture. By sawing smooth the ends of the fracture, all this debris is removed en masse. In five cases of fracture of the tibia operated in this way I was fortunate enough to secure good results without using any external dressing except the usual gauze and bandage employed to protect the incision. And sandbags laid along either side. From the elevation reached through this experience I can fancy the dawn of an era in which broken bones will be joined together and left in their natural environment, like a severed intestine is now united and dropped back into the cavity with a feeling of security.

The leaders in this work have not, so far as I know, so expressed themselves, but I verily believe their ideal is enshrined in the achievement of a method by which fragments of bone may be held in alignment entirely by internal splint.

The phase of the subject which is of the most immediate concern is the selection of cases that demand open treatment. We shall

not discuss in this connection the class of men fitted to perform open operations on fractures, but will attempt to consider the proposition in relation to the ordinary every-day surgeon. Let us first notice the contraindication to the operation. It is not worth while to mention such obvious objections as improper surroundings or inability on the part of the patient to take anesthetics, etc. These conditions and similar ones are too well understood to necessitate discussion. Probably the strongest contraindication that might fail to be considered is the presence of infection or infectious material. In one of my cases that ended in disaster there was a compound fracture of the tibia that suppurated and failed to unite. After I thought all the infection had disappeared and there was only a small sinus remaining, I attempted the plating operation with the final result that amputation became necessary. In recent compound fractures the weight of opinion seems against plating, but experience and judgment are very conflicting upon that point. Huntington⁶ says in the next two years we are going to hear less said about placing foreign bodies in infected fractures. Darrach⁷ in a report of ten cases of compound fractures treated by direct fixation, cites four results as "good;" two were lost track of; one failure, and three were fair. Bartlett⁸ reports five cases—two healed by first intention; one granulated over plate; three got solid union, though the plate had to be removed. Plating a recent compound fracture is, therefore, a matter of delicate judgment and one's course is largely defined by the peculiarities of the case in hand. If direct fixation is especially desirable the methods of Lillianthal, Parkhill, or Freeman should receive special consideration in compound fractures.

The next phase of the discussion relates to the use of plates in cases of non-union. It is held upon good authority that the presence of the plate acting as a foreign body serves to delay union. Jonas⁹, in recent fractures. The deduction follows that the plate would by the same token act more as a hindrance than a help in cases of non-union. Our only case was one of five years' standing and involved the femur. The plate had to be removed eight weeks after operation and there seemed to be perfect union at that time, but the patient developed pulmonary tuberculosis and the union of bone dissolved before death, which occurred months after operation. Martin¹⁰ reports a case of radius and ulna fracture of middle third of shaft accurately plated more than a year, remaining clean and showing no union. "The long standing ununited fractures and vicious union are those which are most difficult, and in the case of the femur, dangerous. The internal splint is plac-

ed third by Martin in the list, for efficiency in treatment of non-union. I wish in this connection to quote from the report of a committee of the British Medical Association appointed to investigate the subject of treatment of fractures. In Article IX the report says, "Operative treatment should not be regarded as a method to be employed in consequence of the failure of non-operative measures, as the result of secondary operations compare very unfavorably with those of immediate operation. In order to secure the most satisfactory results from operative treatment it should be resorted to as soon after the accident as practicable." J. B. Roberts¹¹ reports a case in support of his contention that plating delays union, and points to reports of Darrach, Ashurst, Freeman and others as sustaining his position. The report of his own case, however, is not convincing. The question, therefore, will present itself in any given case of non-union whether it is better to expose the site of fracture, freshen the surface, remove soft tissue and immobilize the limb in external splint or resort to some means of direct fixation. I am of the opinion that in such a case the use of the bone plugs of Murphy should prevail. Percy¹² reported 14 cases of non-union in eleven of which steel plates were used. Three cases of fracture of the neck of the femur were treated by the use of the long screw. Union took place in all cases. This experience certainly speaks well for plating in this class of injury.

Let us now look at the positive side of the question and consider what are the indications for the use of the plate:

1. *In fractures that cannot be reduced by ordinary manipulation.* Such a situation develops frequently in impacted fractures and in fractures where one fragment is very much shorter than the other and overriding exists.

2. *Fractures that are difficult to maintain in reduction.* As in those where a process of bone is broken off; for example, a condyle of the humerus or the olecranon, and cases where the muscular attachment is so strong and the lines of force so directed as to pull the fragments apart, as in the femur.

3. Delayed union.

4. Where good cosmetic effects are especially desirable, as in the clavicle or forearm of young women.

5. In fractures communicating with a joint where imperfect alignment or over-production of callus is likely to seriously interfere with function.

The following indications are quoted from a report of American Surgical Association in *Surgery, Gynecology, and Obstetrics Abs.*, August, 1913, p. 170.

"The troublesome fractures that may with propriety be mentioned as probable candi-

dates for operative treatment are, (1) Fractures of surgical neck of the humerus. (2) The fracture of the lower end of the humerus. (3) Fracture of upper third of radius. (4) with dislocation of radial head. (5) Fracture of radius and ulna in shaft. (6) Fracture of upper third of femur. (7) Supra-condyloid fracture of femur. (8) Fracture of tibia and fibula near ankle."

Mortality. In my own work there has been one death which occurred twenty-four hours after the operation, but which could fairly have been attributed to associate injuries. J. B. Roberts¹³ collected reports of nine deaths following operations, but does not show a direct connection. Blake¹⁴ does not record a death in 106 operations. Bartlett¹⁵ records two deaths in 80 cases. Darrach¹⁶ in 104 cases reported has no record of death. I feel assured, therefore, that mortality of the operation per se is a negligible quantity, especially if resorted to in the recent period after the fracture and performed under the proper restrictions.

BONE PLATING—REPORT OF CASES.

The first was for a fracture of the femur at the junction of the middle and upper third and had occurred five years previous. The recovery took place with about three inches overlapping and non-union, in consequence of which a false joint existed. A month before admission the man was knocked down and trampled upon in a fight. The ligamentous formation of the pseudo-arthritis was broken. The subject of this report was a negro man thirty years old, with very low mental development even for a negro. An operation with the Lane plate was undertaken. The site of the fracture was exposed through a long incision upon the external lateral aspect of the thigh. The fragments of bone were found overlapped and separated laterally as much as four inches, a large cushion of muscle and fascia intervening. The strongest impression I had from this case was made by the extent of lateral separation as compared with the overlapping of the fragments. In fact the fragments could not be accurately described as being overlapped because they did not touch each other at any point. The ligament joining the two ends was composed chiefly of thickened periosteum, with some bone deposits in its substance, sparsely situated. The ends of the bones were sawed square and the plate fastened in position. The wound in the soft parts was closed with a single layer of deeply situated silkworm gut. The patient was given a Buck's extension with a five pound weight attached to make him lie quietly.

Affairs progressed favorably until three weeks had elapsed, when suppuration mani-

fested itself. The wound was opened and irrigated daily. At the end of eight weeks the plate was removed and bony union seemed at that time well formed. After four more weeks I am informed by Dr. Zimmerman, who succeeded me in the ward, that the union had since been dissolved.

The next case was one of compound fracture of both tibiae and fibulae, resulting from an automobile accident. The limbs were dressed in plaster of Paris, with openings over wound in the soft parts. At the end of three weeks this dressing on the left leg was removed and no union had taken place. A Lane's plate was applied at the operation. We were much surprised at the lateral separation of the fragments and the amount of muscle and fascia intervening. The ends were squared and fastened with a plate. One week later the opposite limb was treated in the same way. While both fibulae were involved only the tibiae were plated. The results in this case were ideal. No form of fixed dressing was used. The limbs were laid upon pillows. The wounds healed by first intention and the plates so far have not given any trouble.

The next case was patient No. 3 and operation No. 4. A boy of seventeen suffered a fracture of the lower third of the tibia caused in jumping over a ditch. The deformity was much greater than one usually sees in such cases and could not be reduced. The X-ray machine being out of commission at the hospital no radiograph could be taken. The fracture was exposed for plating, when the reason of the unreasonable deformity was plain. Both the leg bones were broken, the fibula was wrapped once around the tibia, the lower end of the upper fragment of the fibula presenting upon the inner side of the tibial shaft. There was considerable lateral displacement. The upper end of the lower fragment of the tibia was buried in the muscles of the calf. The ends were sawed smooth and plated. This boy got out of bed the night after the operation and stood on the broken leg with the result that it bowed backward. He refused to have it corrected and expressed himself as satisfied with his condition. Up to last accounts his plate has given no trouble.

The fourth patient and fifth operation was in a man who sustained a fracture at the juncture of the lower and middle third of the tibia. After eight weeks in plaster of Paris the fracture seemed to be united and there was no deformity, but after placing a little weight upon the leg it began to bend with the convexity outward and caused him great pain. Plating was proposed and accepted. Exposure of the fracture showed lateral displacement and ligamentous connection. The ends of the fragments were squared and plat-

ed. The result was all that could be desired. Up to now the plate has given no trouble.

The next case was a compound fracture of the tibia middle third, which became infected. The case was treated in a fenestrated plaster cast about eight weeks. The wound in the soft parts healed down to a small sinus that would scarcely admit a knitting needle and it was thought all the infection was overcome. No union of bone was apparent. Plating was advised and accepted. The limb was prepared and the sinus wiped out with iodine the day before. As the internal aspect of the limb had been the site of trauma and the skin was thin and delicate the incision was made upon the outer surface and the bone was exposed through the interosseous space. This proved a serious error, as considerable hemorrhage was encountered and controlled with great difficulty. The fragments were found overlapping and without osseous union. Plating was done. The case was infected either from a haematoma that formed in consequence of imperfect hemostasis or from the sinus remaining after the original injury. The plate had to be removed four weeks later and a splint applied.

The next case was one of comminuted fracture of the tibia with injuries of the thorax, the exact nature of which were not determined. The man died forty-eight hours after the operation, presumably from his internal injuries. He also had a broken clavicle, which was not plated.

I have had three additional cases since. One a Collis' which I found impossible to reduce under anaesthetic and did well after plating. One a simple fracture of middle third of Tibia, which also did well. One a compound comminuted fracture of the tibia and fibula which had to be amputated six weeks later on account of infection.

Scarlet Fever. Treatment. Salvarsan used in 109 cases. Striking effect on throat symptoms, especially in necrosing form, noted. Indicated in severe toxic forms especially. Good results even upon local application. Neosalvarsan not suitable.—Ochmann and Schrieber.

PUERPERAL FEVER.*

By ROBERT T. HOCKER, Arlington.

Puerperal fever is an infectious disease. In the large majority of cases it is caused by the septic inoculation of wounds, resulting from the separation of the decidua and placenta; and from their passing of the genital canal, in the act of parturition. As already indicated, there are abnormal conditions which occur during pregnancy and even in non-puerperal conditions that sustain a causative relation to the disease.

Zymotic fevers may cause in the pregnant woman, the same inflammatory lesions that are ordinarily associated with puerperal fever. Notably, we think, entero-colitis and dysentery.

A febrile paroxysm from any cause is exceedingly unfortunate for any wounded surface. This idea is proverbial in surgery. For the greatly diminished frequency of this heart-sickening trouble we are indebted to the immortal Joseph Lister, who in 1877, after ten years of patient scientific research demonstrated the great principles and practices of asepsis and anti-sepsis in the treatment of diseases. Now it would not only be considered but positively denounced as criminal, should we fail to meet our responsibilities in this way.

It is sad indeed, realizing as we do, that among the poor (many of them thank heaven, are God's poor) are yet dependent on the doctors, unworthy of the noble title and even worse illiterate mid-wives, who know nothing of anatomy, pathology, asepsis nor anti-sepsis. We will not attempt to draw a picture of their revolting management of their cases; it is too sad for contemplation.

Only twenty years ago, one-tenth of all deaths among women between fifteen and forty-five were due to child-bearing and one twentieth to puerperal sepsis. Surely nothing reaches the nobler emotions of the soul than that of a mother's life being the price of her bringing a child into the world. The mortality has been greatly reduced by the legal restrictions of the practice of medicine, giving us a better class of physicians and the increased number of extreme cases and many of the indigent being removed to hospitals, where nothing is lacking, which will contribute to their well-being.

Boehr's statistics show that one thirtieth of all married women in Berlin die in childbirth. We always expect death to exact a heavy toll from the extremes of life, but here it is our child-bearing women upon whom we are dependent for the perpetuation of the race, who

are carried away in the prime of life, in the beauty and strength of young womanhood.

The primary lesions are various and the classification includes, when we follow its ramifications, inflammations, superficial and ulcerative, of the genital canal. The uterine parenchyma, peritonitis, phlebitis, and pure septicemia.

Hippocrates, Galen and even Ambrose Pare and Sydenham, taught that the fever was caused by the suppression of the lochia and this theory was not found to be fallacious until 1801, when Bichat demonstrated that abdominal effusions in peritonitis were found in the male. The prevailing bacteria in puerperal fever are diplococci, spathylococci, but the most important factors are the streptococci. The bacilli are the offspring of putrefaction. They attack only dead tissue, which contains ptomaines and these enter the circulation producing systemic poisoning.

The period of incubation is brief. The indications of sepsis usually occur within three days of accouchement; after the fifth day attacks are rare; and after the seventh day we may feel pretty sure that our patients are safe.

Septic symptoms occurring within a few hours after confinement indicates infection prior to or during labor. In the great majority of cases the disease is ushered in by chilly sensations or a rigor, followed by a temperature from 103 to 106.

Phlebitis and pyaemia are indicated by repeated chills.

An elevation of temperature does not always indicate sepsis, as it occurs not infrequently where conditions are normal.

A pulse from 80 to 90, disturbed sleep and extremely violent after-pains are decidedly suspicious of pelvic peritonitis.

The initial chill is sometimes erroneously attributed to engorgement of the breast, with the above symptoms with tenderness of the sides of the uterus should be considered danger signals, and we should visit such a patient twice daily until there is decided improvement. The pain is lancinating as in all serous membranes. After pains occurring in the primipara or after the third day, are very suspicious. General peritonitis usually begins with the ordinary symptoms of pelvic inflammation, but the tenderness at first confined to one or both sides of the uterus gradually extends over the entire abdomen. The pain is violent and of a colicky character. It is intensified by slight bodily movements, jarring the bed and even the weight of the bed clothes.

From the accumulation of gases the abdominal wall becomes tympanitic and paralyzed. The fever usually, but not invariably, begins with a chill, with a temperature of from 103

*Read before the Carlisle County Medical Society.

to 106, pulse small and hard, ranging from 120 to 160 per minute.

As late as 1868 Meggs and Hodge, and there were no higher authorities on earth then than they, denied in toto the theory of inoculation. They insisted that physicians could never become, especially under the extremely interesting circumstances of gestation and parturition, the ministers of evil. Would to God that the views of these great teachers whose reputations were established in area exactly equal to that of civilization, could have been true. Many a heart-ache would have been spared the noble members of our profession.

Fortunately, investigation has brought to light truths that have been instrumental in saving the lives of mothers and preventing the wrecking of happy homes. Our own loved and gifted W. H. Wathen, took the position that puerperal sepsis never occurred, where proper care was observed by the accoucher. Only a small minority of the members of the Jefferson County Medical Society where these ringing words were uttered endorsed this extreme position.

That the ordinary carriers of infection are unclean hands, instruments, clothing, pads, washing material, cloths brought in contact during and after labor with the genitals of the patient is no longer called in question, by any intelligent practitioner.

About two-thirds of all cases occur during the winter months. It behooves every one of us to be continually on our guard against the disease. In addition to what has been already mentioned, make no more examinations than are absolutely necessary.

An interesting fact has come to light within about eight years, that is that only a small per cent of cases afflicted with gonorrhoea develop sepsis. Fortunately the lochia is antiseptic. The enceinte female ought always to be under the watch care of a physician. Anemia calls for iron and other tonics. Good blood is the best of germicides.

A doctor who is dressing suppurating wounds, who is attending cases of erysipelas, scarlet fever, diphtheria or other contagious or infectious diseases should not attend obstetric cases if he can avoid it. If he is obliged to treat such cases he should take a full bath, carefully disinfect his hands and arms, and use sterile rubber gloves. While streptococci serum is recommended as a prophylactic agent by high authorities Edgar says that streptococci have been more successfully combatted without the aid of serum than with it.

Supportive measures are indicated, whiskey, brandy, strychnine and digitalis as indicated, quinine in properly selected cases. Utero-vaginal drainage is very important.

The uterus in its engorged state is sometimes pressed against the pelvic floor and prevents the escape of the lochia. The detained lochia is a breeding place for bacteria; and favors the development of septicemia.

Gallant recommends a cervical drain inserted into the cervix.

Leopold reports five cases operated on within two or three days after the appearance of the signs and symptoms of acute general peritonitis with three recoveries. It is best to operate not later than the third day. Douglas' cul-de-sac should be opened to get drainage through the vagina. Drainage is the important factor in cases of streptococci origin. The antiseptic streptococci serum gives very satisfactory results. It should be given early.

Cold applications carefully used are preferable to phenacetin or other antipyretics on account of their depressing effects on the heart. Later hot applications are useful. Abscesses must be lanced and carefully drained. Endometritis is treated on general principles. Retained placenta should be removed by the fingers if possible. Mild cases will yield to the use of ergot, ice and vaginal douches. If lochia is offensive use hot carbolized water, one to seven thousand, or corrosive sublimate, 1 to 2000.

In severe cases uterus should be irrigated and treatment repeated if necessary, with a fifty per cent. solution of alcohol.

I used echinacae with good results in one case of septicemia, patient a very delicate woman, with apparently considerable poison in her system, recovered. I used other constitutional treatment.

I am painfully conscious that this is a very imperfect paper, but the subject is so comprehensive that I have only attempted a synopsis of it.

It is a fearful malady with which to contend, and our patients are entitled to our closest attention and deepest solicitude.

Sciatica.—Treatment. Good results from X-ray treatment in 11 out of 13 cases. Rays directed usually over lumbar region, sometimes over nerve itself. Small doses only. In cases resisting ordinary medical treatment and galvanic current, radiography should always be tried, especially when sciatica due to compression of nerve-roots.—Delherm.

Marked improvement in 2 cases after a few daily subcutaneous injections of 1 c.c. (16 minims) of 1:1000 epinephrin solution.—Gaisboek.

X-RAYS IN TREATMENT OF FRACTURES.*

By B. W. BAYLESS, Louisville.

Your secretary suggested to me as a subject, "X-rays in Relation to General Practice," as this is becoming a broader subject every day, now covering diseases of the head, chest, abdomen and bones. I thought I would confine myself to its relation to fractures. True this is more in the line of surgery but anyone in practice outside of the large cities comes in contact with fractures every few days.

In every case of injury where a fracture is suspected an X-ray examination should be made, one before and one after dressing. The examination before dressing will show if a fracture is present, the direction of the fracture and any loose fragments. The one after dressing will show the permanent relation of the fractured ends of the bone also if there is any angular deformity at the seat of fracture. If the patient is not seen soon after the injury it is sometimes with difficulty the fracture is made out, due to the amount of swelling and the pain caused from the injury and manipulation. In these cases with a great amount of swelling, even under an anesthetic it is hard to say if the bones are in perfect position. If a plate is made before dressing it will save a great deal of manipulation as it will show exactly in what direction reduction will be most easily accomplished.

A great many fractures are overlooked if an X-ray is not made as there may not be any deformity and the fragments may not be free enough to obtain crepitus, this is the ease in longitudinal and even in transverse fractures. Also there may be only an elevation of the periosteum but it is best to know the exact amount of damage done. It would not be best for the patient to use the affected parts even if there is no displacement as it would give the patient a great deal of pain on movement and the fragments may become separated; then they would not unite as rapidly as if in a position of rest and also the callus would be much greater if not held in the proper position.

A picture before and after dressing is protection in cases where any dispute arises later, for union will not always take place as in patients with syphilis. The jury only sees the present condition and position and not the position in which it was placed at the time of treatment unless you have preserved the pictures made at the time.

Fractures of the long bones when displacement is present are easily diagnosed but after

swelling has taken place and manipulation adds to it, it is not always an easy matter to say if the bones are in the best position even if the diagnosis has been easy. If a plate is made after dressing and the position is not the best another attempt can be made immediately and not wait until the swelling has subsided to see the position as then the callus has formed and it is a very difficult proposition to get a good reduction with callus around the broken ends and also the callus may involve a nerve when the position is not good.

In fractures of the small bones of the hand and foot the cardinal symptom of fractures, crepitus, is not always readily obtained so it remains for the X-rays to show the damage and position of the bones.

In comminuted fractures a piece is broken from the body of the bone and if separated from same will not unite and if not removed will give rise to a great deal of trouble, a fistula will form and the ends of the broken bones may become infected and amputation may then be necessary.

It is always better to take two plates, one 90 degrees to the other as the two will show displacements and fragments in all directions and if necessary more plates can be made at different angles.

Often in cases suspected of Colles' fracture, you will find only a lifting of the periosteum due to hemorrhage, this causes extreme pain, great swelling and discoloration.

In injuries to the spine it is very hard to be positive as to the exact damage as the manual examination is very different. There may be a dislocation of one vertebra and a fracture of another several vertebra from the dislocated one. In a case like this the dislocated vertebra would probably be operated on, as it would be more marked, to relieve the pressure symptoms and the fractured one overlooked, which may be causing just as many or more symptoms.

Fracture of the skull both of the base and vault, are now more easily recognized with the X-rays. An injury to the skull especially with a blunt instrument causes a great deal of swelling which makes it very hard to diagnose a fracture if present. A fracture may run some distance and the resulting hematoma caused by it produce grave pressure symptoms.

Depressing fractures are shown and exactly how much depression is present. The depression may involve only the inner table, the outer table remaining perfectly smooth with the surrounding bone and of course nothing to be observed on palpation.

When a fracture of the base extends into any of the cavities which normally contain air are easily diagnosed as blood fills the cav-

*Read before the Oldham County Medical Society.

ity displacing the air which is readily seen with the X-rays.

In injuries of the shoulder, fractures are not always present when suspected, but the X-rays show something that can cause as much pain as a fracture. These are the concretions in the subacromial bursa which are oval or round, and always occur on both sides, so if found on the injured side always look for them on the opposite side, and do not take them for fragments of bone. In abducting the arm they get caught between the greater tuberosity and the acromian process, similar to a mouse cartilage in the knee, except they are not in the joint. You also find concretions in the bursa on the inner side of the lower end of the femur but not so frequent as at the shoulder.

WHAT SHALL THE COUNTRY DOCTOR DO WITH HIS PATIENT?*

By E. J. BROWN, Stanford.

The object in writing this paper is to call the country doctor's attention to the fact that he "the country doctor" is sending or permitting by his own suggestion, his patients to go to the so called "city specialist," thereby losing both the confidence of the patient in him as a physician and surgeon and also the money that is so justly his. We have none but the kindest feeling for the city doctor, and what the city has given us as a profession, but we owe something to ourselves and our patients. The country doctor here alluded to, is the one who has spared neither time nor money to equip himself with the very best instructions, libraries, instruments, laboratories and all modern devices for the purpose of diagnosis and treatment. Have not clinical and didactic work been just as much to him as his city neighbor? His text books are just the same. The X-ray, microscope, the cystoscope or the phonendoscope reveal the same conditions to him as to the city man. Osler, Price and men of that class, who have made the profession something of which to be justly proud, have said the most accurate diagnosticians were country doctors. The country man keeps the pregnant woman under observation during her pregnancy, and is the "all and all" when she passes through the ordeal of childbirth. He circumcises the baby and guards it through its tender years, through the diseases of childhood with the vigilance of a mother. He attends any and all the family through pneumonia, typhoid, dysentery, meningitis, fractures, dislocations, sprains and bruises with perfect satisfaction to all concerned. Why can he not do the minor work which has much lower mortality than the dis-

eases mentioned, with satisfaction? The true and only answer is: He lacks confidence in himself. Appendicitis, cholecystotomy, prostatectomy and all abdominal operative lesions have much lower mortality than pneumonia, typhoid, or diphtheria, yet the so-called "specialist" is never considered in the latter, but most always in the former cases. For simple operations which can often be done in the office are frequently rushed off to the city to be separated from their minor ailments and their major filthy lucre. Varicocele, hemorrhoids, varicose veins, bone lesions, adenoids, pathological tonsils and many others too numerous to mention, which any man with good surgical skill and technique can perform as well and with as good results as any other man. These simple things take thousands of dollars out of the pockets of worthy country men, where it properly belongs.

The lack of confidence and getting in the habit of suggesting to the patient to see the city man, educates the people to expect it for any and all conditions before suggested; and no one to blame but the doctor for starting the habit. How much confidence from the people have we lost, and how many patients, just by suggesting to them, when in the city to drop in and let Dr. So-and-So look them over, only thinking of the city man strengthening their confidence in you; and giving him a five or ten to increase his love for you; but not so, he pockets the fee, fails to write you expressing his gratitude, but does not forget to prescribe for your patient and keep up correspondence with him, about his or her present, past and future ailments, while you are very deservedly left in the cold for your silly courtesy.

Let us be far from believing that any but a small per cent. of city men are disreputable enough to split fees or take your patient, but that is not the idea intended, they are yours, by virtue of confidence they have in you—"until you have sent them away and caused them to doubt you," they are yours because you know as no other one can their idiosyncrasies, they are yours because you are entitled to the money there is in it. We doubt whether it is fair for the city doctor to say if this advice is dangerous, pernicious and malicious, because it is to his penurious advantage to encourage us that we are incompetent to do work of this character. But we want a good, free expression from the country men, as to whether we are right or wrong.

Let's make no mistake, or do any injustice to any concerned, if possible to prevent it. We have described the class of men to do the work, now say—am I right or wrong? If wrong I am forever silent, if not, now to the remedy. What steps shall the country doctor take to correct the already existing trouble?

*Read before the Lincoln County Medical Society.

The man in the country who is absolutely alone, must show more self-confidence, keep up his reading and post-graduate work and get "busy" and do the work and get his lost confidence on the part of the people and himself restored. To the men in the country towns it is very easy. Where they have hospitals already there is no suggestion to make, only do the work when it comes up. The most to be said is to the men in a country town where there are, say, from three to seven doctors and no hospitals. The little imaginary jealousy that exists must be removed and realize you are friends. Get together, give each other consultations, sustain and support each other's opinions, thereby strengthening each other in the eyes of the public, and keep your patients at home. Where several men are in the same town, if you choose, let each one by mutual agreement, in his post-graduate work, look more especially after certain lines and better familiarize himself with that particular work. For example, one general surgery, another genito-urinary, gynecology, another vaccine and serum therapy, and so on. If it is impossible to have a thoroughly equipped hospital, improvise one by renting a suitable house, get a mature intelligent woman, who can be taught cleanliness, asepsis and anti-sepsis, fit up a few beds and run it at a very low cost, something on the order of a large family. Splendid work can be done and great results achieved if this method is adopted. You will know what wonderful results are gotten in country homes, with improvised operating rooms and paraphernalia. This is only an outline, to get an expression and if we are right we will give you a sure enough paper on the subject; if not right this is a plenty.

This is not any censure to the city doctor. I would not say one word except to commend him, because the best friends we have are city doctors, but let's be honest. Have I not spoken the truth?

Dysentery.—Treatment. Measures useful in form of dysentery sometimes epidemic in institutions discussed. 1. Isolate patient and put to bed. 2. Give calomel, 1 grain (0.06 Gm.), followed in two hours by mixture of dilute sulphuric acid, ziiij (12 c.c.); compound tincture of cardamom, zzzj (30 c.c.), in water, enough to make zzzviii (250 c.c.); zj oil, 1 tablespoonful every two hours; no other food. 4. Boiled water at frequent intervals. 5. In the aged, debilitated or arteriosclerotic, 1 teaspoonful of brandy every three hours.—Jones.

Eclampsia, Puerperal.—Treatment. Report of 11 cases in which squeezing out of colostrum from breasts, thoroughly carried out, appeared usually beneficial.—Walcher.

HYSTERIA.*

By J. W. HILL, Frankfort.

Modern neurology insists that the term hysteria must mean something definite. That the old composite picture of hysteria be discarded and a new picture painted which delineates a syndrome simplex in which can be seen a definite clinical entity.

Hysteria is one of the so-called functional, psycho-neuroses. The term functional, while vague and elastic, is in general use and serves a practical purpose, but the line of demarcation between the organic and functional is after all arbitrary and assumed.

And in the passing of old ideas and hypotheses it is becoming evident that all expressions of energy whether psychic or physical involve and are the result of organic but subtle changes in neurotic and cellular structure. Psychology assumes that the mind is divisible into three elements, viz:

Intellect, emotion and volition, these elements can be likened unto a musical instrument of three strings, each string having its individual limitations and essential to the whole, yet, in associative function infinite, when energized by the master artist which is neither one or all of the psychic elements but is the unseen and unknown force of all vital phenomena.

It is apparent that a morbid manifestation involving all three of the psychic elements constitutes a true psychosis or insanity, but a morbidity involving only one of the elements is the so-called functional psycho-neurosis.

To define the term hysteria has been the task of modern neurologists who assert that hysteria is primarily a disorder of volition or will. The occasion and limitations of this paper precludes an exhaustive analysis of the components of will. Suffice it to state, that will is the supreme principle of mind, it means power, action and energy. It is the universal initiative, it perceives and compares ideas, differentiates pain from pleasure; it originates desires and determines choice. The underlying cause of all morbid expressions of impaired or perverted will are due no doubt to cortical instability of unknown pathology which permits a sensorial registration in the great storehouse of consciousness, out of time, tune, and intensity to become the dominant note. This discordant note is suggestion, the word comprehending a state of receptivity in the conscious mind which sinking or repressed into the subliminal, there to become active and assertive in varied manifestations when volition or conscious will fails.

It is this intrusion from the subconscious, this forced suggestion which Babinski calls

*Read before the Kentucky Midland Medical Society.

"pithiatism" which, he asserts is the cause and cure of hysteria. The syndrome is completed by appearance of motor, sensory and psychic errors, these perversions or errors being the result of defective volition. From this it is assumed that the mind has a material basis not limited to cerebral tissue alone, as shown in the explosive motor storms, the riot of emotions and the various sensory perversions.

It is not within the scope of this brief paper to recite the text-book symptoms of hysteria, the disease must be differentiated from disorders of intellection and emotion. The sum and substance of the symptomatology of hysteria reduces itself to "retraction of the field of consciousness" plus an undue susceptibility to suggestion, the contention that this "suggestion complex" is in effect a psychic trauma of sexual origin is a plausible deduction. It logically follows that the sexual instinct being a predominant one, second only and closely allied to the great instinct of self preservation, should so crowd the afferent pathways to the seat of consciousness thus preventing the proper and orderly registration of these sensoria, this offending complex is an association of ideas, one of which is painful and dominant, which is repressed or submerged into the subliminal by the conscious mind. However, this sexual hypothesis can not be made absolute, it is irrational to assume that all painful or depressing ideas comprising this complex must necessarily and invariably be of sexual origin.

Relative to the various methods of psychotherapy, the numerous methods advocated indicate that there is no specific. One of the methods of treatment is founded on a curious anomaly or paradox "the hair of the dog is good for the bite," in other words the disease is caused by suggestion and cured by suggestion, the method is not new, simply newly exploited. The suggestion method comprehends a larger conception that mere asservation, it includes moral suasion, instruction, assurance, plus an element of faith, in short every element necessary to the make up of a forceful and convincing personality. However, it is only an aid or adjunct that all physicians employ, its results are overstated and exaggerated. It is the "Emmanuel specific" for all ills, in no wise different from all nostrums save the novelty of its exploitation. Likewise the method of hypnotic suggestion has been repudiated and discarded by reason of the fact that the success of the method depended on the subserviency of will in individuals whose primary trouble was defective will. The analytic method of Freud has its enthusiastic exponents. The method assumes that the causative psycho-generie error is stored somewhere in the field of consciousness and

by a process of uncovering, the occasion and nature of the complex is revealed, subjected to, and revised by rational thought.

Personally, I have not had the temerity to employ this method in but few instances. I am sure that some of my patients would resentfully have declined to accept me as their confessor. The method is complicated, demands a vast amount of patience, it is not free from outward results in that there is danger that a phobia or obsession be implanted.

The oldest and perhaps most generally used is the "white lie" method. This consists of deception, evasion and placebos, the method fails as other methods do at times, due in part, perhaps to the failure of personality of the doctor and the reluctance of physicians to make an outspoken and candid diagnosis of hysteria. There are other reasons to deter the doctor and negative his efforts:

1st. A considerable number of people yet regard the term "hysteria" as an opprobrium that it implies a silly affectation, which is resented as a gratuitous and unsympathetic reflection. This leads to the assumption and usually positive assertion that the doctor is ignorant of the true nature of the trouble. Especially true is this when dealing with hysterical crises. It is indeed difficult to successfully assure the patient and friends that a partial blindness, a loss of sensation in segmental areas, rapid breathing, and a sense of suffocation is not due to a serious life endangering cause.

2nd. On the doctor's part a lack of confidence, born of experience in efficacy of treatment and the patient, the basis of the patient's trouble being weak will. It is inevitable that they should lack the constancy of purpose to follow any plan of treatment, consequently they pass from doctor to doctor, each one inventing some novel course of treatment, which serves to submerge the morbid complex, until the novelty wears off.

The plan of treatment which I have employed with the best success has been "the plan" of isolation of the patient in charge of a competent nurse, who firmly enforces a rigid routine of conduct, withholding all sympathy, that element which they seem to morbidly crave, at the same time I invent some excuse to invade the rectum instrumentally, or lavage the stomach, this never fails to excite dread of each pretended treatment and calls forth protests, until in order to escape the ordeal they insist and assure that the rectal or stomach condition is much improved. Here the repeated assurance and reiteration becomes converted into a positive auto-suggestion. From these premises I mean to assert that active hysteria is incompatible with inflicted pain. There are individuals of the insane diathesis in whom any error of intellection, emotion or

volition will reduce to a true psychosis. The treatment of such cases is institutional and should not be attempted by the general practitioner.

In conclusion, in all cases of hysteria there are evidences of faulty metabolism. To restore all bodily function is essential.

A VERY PECULIAR CASE.*

By W. B. McCURE, Sherburne.

Some time ago I was called to see a woman 22 years old, five months pregnant, up to that time she had had no trouble, reported to me that she had so far felt fine, no trouble of any kind! I was called about 12 o'clock at night and when I reached her bedside she gave me a history of this kind. She had rested well after retiring about 9 o'clock, but woke up about 12 and found herself standing in the middle of the room, perfectly blind and suffering severe labor pains. She awoke her husband and he assisted her back to the bed and upon my arrival I suspected a premature labor but upon making an examination I found the cervix very rigid, no dilatation whatever, so I gave her an opiate which relieved the pains entirely and after keeping her in bed for three days she was up and about her household work as usual and told me she felt as well as she ever did, but just ten days from the first attack and at the same hour at night, she had the very same experience, by finding herself standing in the floor suffering violent labor pains as before, so being called again, found her in exactly the same condition as before and again suspecting a premature labor. But upon examination found no dilatation, so I gave her an opiate, had her remain in bed for three days, when she was up about her household duties as before. Just ten days later exactly at the same hour at night she found herself again in the floor under the very same conditions as above stated, but being busy when first called I was about two hours late in reaching her bedside and upon my arrival found her in hard labor and upon making a digital examination my finger came in contact with a foetus in the vagina which I had no trouble in delivering and after tying and severing the cord upon further examination found the cervix thoroughly dilated and the membranes very tense; so rupturing the membrane, the pains being very forceful, an excessive amount of amniotic fluid escaped and without any trouble delivered the second child and as soon as I could tie and sever the cord, the pains still being strong, I found to my surprise, the third foetus, and after delivering the third child the uterus being very

active, contracted down nicely and expelled two placentas, one placenta sufficing for one child and the other one sufficing for the other two children, the cords joining about four inches from the placenta. The uterus was firmly contracted, the patient not wasting any this being premature births, the children did not live but about an hour; two boys and one girl.

I stayed with the mother about two hours, some longer than I usually do after labor, and was getting ready to leave as the mother was doing nicely, the uterus firmly contracted and the mother said she was feeling fine; but in less than five minutes she said, "Doctor, I cannot see you, I am blind." Of course I at first suspected hemorrhage, but upon examination, I found the uterus firmly contracted, not wasting any at all and in less than five minutes she was dead.

Now the question is, what was the cause of this woman's death. As I should have stated earlier, this woman was the mother of two perfectly healthy children. I would like to hear from some of my brother doctors as to the cause of the symptoms and death of this woman.

MEDICAL ETHICS.*

By H. C. CLARK, Falmouth.

Recently there have appeared several articles in the medical press on the subject of medical ethics. All taking a happy view of the present conditions; throwing bouquets at the State and county organizations, and not a few at the good doctors, which is right and proper. Everybody knows of the individual and general improvement in our State, but not much was said about the short-comings within our ranks. I am one who believes good preaching is to tell us of our sins. There are just a few thoughts I wish to express along this line. It may not do you any good whatever to hear what I have to say, but it is giving me trouble and will do me good to have it out of my system.

I am forced to go straight at the question, not staying on one side the fence or the other. I must not attempt to excuse or cover up wrong doing, nor do I intend to try to carry water on both shoulders: nor yet to particularly magnify the trifling little acts thoughtlessly indulged in by my brothers. I shall endeavor to stay close to the text, hoping those of us who are hit will be benefitted and helped in future conduct, that we refrain from committing the acts that call forth condemnation by every honest and fair minded physician.

There is no fault to find with the Code of

*Read before the Fleming County Medical Society.

*Read before the Pendleton County Medical Society.

Ethics, or the Constitution of the United States. They were both framed by minds and hearts who were great in justice, truth and love for humanity. But has either the Constitution or the Code of Ethics brought us into reverential love and fear, which has made us true and loyal citizens, or good, clean, fair-minded physicians who love their country not for the protection obtained, or for the money to be made out of our profession, but grasping and holding the very spirit of the Constitution, or the Code of Ethics is the only thing which will qualify us, not for the dollars and cents we can make out of our calling, but what it could and should make of us as inspiring examples of upright men.

Benedict Arnold was a traitor; sold himself for money. You know how his life was ended. Esau sold his birthright for a mess of pottage, likewise any physician who puts a commercial value on his profession gets his reward, only in name is he entitled to mention in the roll call. He has never been where the "Shekina" of glory dwells; he is without the tent. When the test comes he is unable to say "Shibolet." He is holding his credentials and hanging on to the profession by unfair means; doing nothing for society work or the advancement of medical education and qualification; following in the wake of advancing hosts, coming only now and then in sight of the camp fires; satisfying himself on that which only a scavenger would have. Will reading a Code of Ethics reach such a person? Will you continue to let him drift along holding him in the society as long as he attends the meetings and pays his dues? Are you really doing him any good or doing your best for him and the society? By encouraging his indifference be careful, you may go to his level "first you pity, then endure, then embrace." You may be found defending him out of pity, then embracing the very things which are so destructive to him, and the good of the profession. Does he really at heart care a rap for the society, the Code or anything but a dollar? You know and so do I that the best evidence of friendship is not in the smooth, oily words but rather in the one who tells you plainly of your faults, gives good advice and helps you to do better. That is my aim and is meant for whoever needs this reproof, and I would think but little of you and less of myself if I only "spread salve" and endorsed wrong doing in order to make the hair lay smooth and be popular with somebody.

I am a friend to the profession and intend to help it to the extent of my ability, to hang on as long as I can speak, to the idea that money and practice is not to be the first and uppermost things to be considered. Be helpful in every way to each other, keeping in

mind the honor of the calling, and your own self respect. Put away your shams, masques, and hypocrisy. Quit your deceit, playing to the galleries, and prating about the "code of ethics," when you know but little of it, if one can judge from the way you act. Do not criticize a physician or his treatment of his patient unless in council with him, and then to him and him only. Be modest and gentlemanly when called in council. When council is called with you take no offense, be fair and honest, giving a true and full statement as to what the conditions and treatment have been. It is disgusting to see a physician when called in council swelling up with self-importance; looking the embodiment of wisdom, and giving sneering looks to the friends, making a display of his knowledge, being unduly officious; showing presumption and egotism on every hand, until he almost explodes with self-importance. His object is plain, his masque is seen through.

If called in council and find in your judgment there have been errors made, it is your duty to use your best tact in obtaining the consent of the physician in charge to change the treatment in such manner that the family may not see there has been a change made. That no possible impression may be left that would reflect on him or give yourself an opportunity to succeed him in that family. This is a very delicate phase of the consultation and will have to be handled with gloves. Many unhappy conditions have taken place among physicians at this time, but mostly unintentionally, by the consultant.

There are many little things I could call attention to which might be timely, if it were not for the fact that you are familiar with every point to be considered, you must be fair and a gentleman. Simply be governed by the Golden Rule and all will be well in consultation and in private practice, you will get a high or low ethical standing, the opinion of your confreres in great measure will be the opinion of the public.

Your chicanery and deception is not always hidden by your suavity and pretense. Playing upon the credulity of patience in many acts of stageing and four-flushing will bring practice and money, perhaps for a time, but ridicule in the end. You will find, if you play politics your dignity will suffer violence. To advertise is the game of the charlatan or quack doctor of the profession. See that you are worthy. You will receive the distinction; not you but the physicians and the public will place your name where it can be seen. In examinations be thorough: if you take any of the secretions for analysis do not pretend that you have examined it, when you have not. Do not have your patient expector-

ate in any kind of a bottle convenient, regardless of what it had formerly contained or its present condition; and report that you have had it analyzed when you did not do so. It is wrong to pretend, or work a fraud. Your sin will find you out.

In accepting contract practice you do so against the advice of the profession at large, and will surely injure your standing and bring you grief, sooner or later. The very ones who get you into it will impose on you, expect more attention each year, and finally employ another physician, and pay the regular fees for his services.

"THE COUNTY."

The fiscal court is composed of farmers, and two lawyers will contract with you to do the practice at a very low rate, but they do not reduce their fees. Is not your profession as honorable as theirs? Why should we work for the county for less than regular fees? Is it not true that we do more for charity than any other profession? Every physician does his share of practice for the worthy poor. Is it not also true that our expenses are as large as any other citizen. Did you ever hear of our getting our groceries or clothing at a discount because we are physicians?

CUT RATE PRACTICE.

Cutting prices to obtain business is disappointing and compromising; will lower the dignity of the man who indulges in this contemptible business. I have lived long enough to see these fellows get it in their own dish, when some new physician bids for the practice at a lower figure, and gets it. I have known a cut-rate doctor to go to an honorable physician to have a claim verified against a dead man's estate at double the price he got for his services while the man lived. Let me tell you, a cheap priced doctor is generally paid more than his services are worth. It encourages a disposition to neglect to do his whole duty, when only receiving half-pay.

I have been actuated in saying what I have, from the purest of motives; keeping in view the welfare of our profession, and hoping no one will be offended, and think nothing personal is meant.

"To thine own self be true, and it follows as the night follows the day, thou canst be false to no man," and only the Master can praise us, and only the Master can blame.

"You shall not work for money and you shall not work for fame, but for the joy of working. Each in his separate star drawing the thing as he sees it for God who sees all things as they are."

Finally my brothers, give a long and steady pull, and a pull altogether. Work constantly for the improvement of the State, and

county society. Individual success will be realized, and our ranks stand so close together that there will be no room for bickering or misunderstandings.

ATYPICAL PNEUMONIA.*

By O. W. BROWN, Lenoxburg.

There is no disease, perhaps, in the whole category of the practice of medicine that is of such vital importance to us as general practitioners as that of pneumonia. It is the most widespread and fatal of all diseases, and by far the most fatal of all acute diseases.

It attacks all ages, in all countries, and at certain seasons of the year it has been classed epidemic. It often strikes down the most robust at times when least expected, and strange as it may seem is most fatal in this class of patients.

The prevalence of this disease has not lessened any in the past few years, nor has its fatality been reduced, as has been the case with many other diseases. It has baffled the most scientific investigators from its earliest history to the present time, and the mortality is said to be even greater to-day than it was one hundred years ago.

We are all familiar with the ordinary form of lobar pneumonia and there is usually very little difficulty in making a diagnosis. But there is many different forms of pneumonia, and it attacks certain individuals in a manner that is most puzzling to even the painstaking diagnostician at times.

It is the atypical forms of this disease that demands our very careful attention, especially in old people and children.

While the pneumococcus is the germ which causes most cases of lobar pneumonia, as a rule, we must bear in mind that other infections are capable of producing in the lungs and in the individual, conditions which are not typical of a pneumonia. Such infections may be from the streptococcus, staphylococcus, and other infections microorganisms. These organisms no doubt in many instances render the soil more favorable to the production and multiplication of the pneumococcus. I believe practically all forms of atypical pneumonias are mixed infections, and also the frank lobar pneumonia that does not resolve has become a mixed infection.

There has always been a confusion among writers as to the real condition present, in young infants and children in these pneumonias. But I think it has been pretty definitely settled that capillary bronchitis and lobular pneumonia are one and the same thing. Most cases of pneumonia in children are of the atypical type, but it may be that all

*Read before the Pendleton County Medical Society.

the symptoms of an adult will be present. This condition may begin in a child with a convulsion instead of the chill so characteristic of the adult. Again the child fails to localize the pain and often refers to the abdomen as the seat of pain, or it may be complained of in any part of the body. Rusty sputum is very rare in children and there may not be cough for a few days.

Physical signs are slow in appearing in children and often we never detect rales at all. Often there is vomiting as there is in many acute conditions in children.

We usually have high fever, headache, delirium, great irritability, and a general appearance that denotes some serious condition. Some cases have muscular tremor, and perhaps contraction of the head and neck, resembling very closely that of meningitis. This contraction would naturally call our attention to the meninges, and it has been termed cerebral pneumonia. But we often have a meningitis complicating pneumonia in children, and this is perhaps the real condition present in these cases.

Any disease may be complicated by pneumonia, and no doubt is not recognized many times because of the obscurity of symptoms, or the atypical form.

Pneumonia of the aged is by far less typical than that of children as a rule. Here we often see but few symptoms (or none) to indicate pneumonia, and may make a bad blunder in the prognosis as well as the diagnosis if not very careful in our examinations and study of the case.

The onset of the attack is often obscure; the fever, pain, cough and expectoration are slight; the signs of consolidation not apparent. A distinct chill absent, but may have chilly sensations, low rise of temperature which may even reach 101. Pulse may not be quickened but little if any. But there will be great prostration if pneumonia be present.

It has been proven by post-mortem examinations that ninety-five per cent. of all deaths occurring in the aged from so-called senility have been pneumonia. We formerly heard doctors and laymen speak of patients dying of old age or senility, but we now know that our State Board of Health will not accept of this statement on a death certificate. There is no such disease as senility, and a large per cent. of these old persons die of this atypical form of pneumonia as has been proven in large hospitals by a post-mortem examination of the lungs.

I know the fatality of pneumonia to be very high in old persons and therefore we should give a guarded prognosis in all cases of illness in the aged, when there is any suspicion of pneumonia.

Another atypical form of this condition is the central pneumonias, and we may find this in all ages. The diseased portion of lung may be centrally located and mask most of the subjective signs, such as pain, cough, etc. It is only when the pleura is involved in pneumonia that there is very much pain, and this accounts for central pneumonia with absence of pain and also the difficulty of making a diagnosis from physical signs.

Another form there has been much contention about is the abortive pneumonia, or 48 to 72 hour pneumonia. This is to my mind a true pneumonia that is simply cut short from some cause and whether or not it is from medication or some other cause, I am unable to say. But in pneumonia as in all other infectious diseases, we have rudimentary and masked forms.

I am certain we have all seen these cases and perhaps attributed the knock-out to some of our new drugs we were using at the time. But how is it when called to another case manifesting every symptom of the ephemeral case, that the very same medication in the very same way will have no influence? I am forced to accept the theory that the individual anti-toxic process in the one case simply overwhelms the invading organisms, and in the other, that the organisms overwhelms the patient for a time at least, and perhaps for all time. These cases probably don't reach the stage of complete hepatization, or else hepatization having occurred, resolution immediately follows.

Pneumonia of the apex of the lung, not a very rare condition in adults, and quite common in children, for some unknown reason sometimes manifests a train of symptoms of very grave form from the very beginning. Surely we should find extreme nervousness, a more profound toxemia, marked cerebral symptoms, muscular twitchings and in fact all the symptoms resembling those of uremia in this condition more often than involvement of other portions of the lung? I am unable to say and would like to hear a word on this point from some one in the discussion.

Pneumonia of the alcoholic may be typical or atypical and in some cases a pneumonia may not be suspected owing to the preponderance of the symptoms of acute alcoholic intoxication. The patient may be suffering from pneumonia and delirium tremens at the same time. There may be but slight fever, no cough, no rusty sputum, little or no dyspnea and all the symptoms of a typical pneumonia absent. We know the alcoholic to be predisposed to this condition owing to his habits. Sometimes found in the ditch, fence corner, old out buildings, etc.

I wish here to report a case of migratory pneumonia that I attended last winter:

Young man, twenty-one years old, family history negative, except father has been a sufferer for the past thirty years from some sort of a nervous condition which seemingly has brought on all the symptoms of a confirmed neurasthenic. Personal history is that of a very anemic, overworked, slender, stoop-shouldered young man, but had never had any serious illness up to the present time. I found the boy, at my first visit, with a temperature of 105, pulse 160, terrific headache, considerable delirium, a cough with almost every breath, which caused agonizing pain about the region of the left nipple. Boy had been sick for five days and family giving him home remedies for grippe. I found complete consolidation of the lower left lobe which I think could explain to some extent, the embarrassed heart action. The heart seemed as though it were in a vise, and the apex beat almost unrecognizable. I gave the boy a hypodermic of morphine with atropine, gave a purgative (saline) applied an ice pack. Did not fix the side with adhesive plaster for fear of further hindering the heart's action, but should have used this had the other lung been the seat of the trouble.

Also gave strychnine regularly with enough codeine to prevent the cough and pain to some extent. The boy did very well for a time and there was improvement by lysis from the ninth to the fourteenth day, but his pulse never came below 120. Tongue had cleared, bowels acting well, pain and cough about ceased, was taking nourishment, sleeping very well and everything looked favorable for his recovery except the heart. I did not see him for three or four days when I was called and found all of the former symptoms with the lower right lobe involved. I resumed the previous treatment with added stimulation, watched the heart carefully, saw patient twice daily for five or six days when he seemed to improve so much that his father lifted him into a chair (without consulting me) to have his bed rearranged. He had not been in the chair more than a moment, so his father told me, till he died suddenly. This is a case where the profound toxemia had lasted so long and patient as well as his heart so exhausted, that his sitting in the erect posture simply brought on an acute dilatation of the heart. Had I a case similar to this one to treat to-day I would use the serum treatment freely, but yet would long for something more certain or specific.

While the treatment of many diseases has improved in the past few years by leaps and bounds and the terrors of a few years ago been conquered by modern scientific therapeutics, the treatment of this most fatal and

widespread disease is as yet in a labyrinth of the dark ages. The treatment from its earliest history down to the present day (to be sure) has changed immeasurable times, and all sorts of fads, specific in numberless therapeutic agencies has been offered to the medical profession as a means of combating and curing this disease, but all have come short and been found wanting. This may be, I believe, accounted for when we think of the many varieties of pneumonia and also that few cases manifest exactly the same symptoms. Ordinarily we make a diagnosis of lobar pneumonia or whatever form it may be, there is always a question as to whether it is caused by the pneumococcus, streptococcus or perhaps many other varieties of infecting microorganisms.

An infection of the lung or any portion of it seems to be rebellious to treatment in many cases and no doubt this accounts for the limited results by medication in tuberculosis. Owing to the histological construction of lung tissue it seems to be vulnerable, and unable to cast off infecting organisms as readily as some other organs of the body.

The treatment in all cases of this disease must necessarily be symptomatic, but a few points I have gathered from journals, text books, and my worthy colleagues of this medical society I feel free to proclaim. First and foremost, when called to see a case of pneumonia where patient is in great distress, get him quiet and comfortable if possible and keep him that way for a few days at least, then he will probably not need anything more as the severe headache and stabbing pain usually subside in a few days. Next most important step is plenty of fresh air constantly, night and day. Cleanliness of the body, mouth, nose and throat next. These three measures will apply to all types of pneumonia and many cases would require no more for the mild cases would get well without any care whatever.

For children and old persons I have employed a remedy that has undoubtedly been of much benefit in cases that did not do so well with other treatments. It is the carbonate of creasote suggested by Dr. Boggess in an article on pneumonia in the *State Journal*. It seems to meet the indications better than any remedy in my hands and may be given in all cases of pneumonia to advantage.

Strapping of the chest where there is much pain, is of advantage in keeping patient quiet. 1 z of guaiacol to the ounce of olive oil makes a good local application to rub into chest wall. Keep toxins eliminated as best we can by keeping the bowels, skin and kidneys acting well. Of course we understand that the whole treatment of this condition is to keep the patient's vitality up till the disease

has subsided, and we may do much by doing this. Strychnine and atrophine I consider the best heart and respiratory stimulants when indicated.

The cotton jacket, plaster of all kinds except mustard, and all kinds of wet poultices I consider a nuisance, and are uncomfortable to patient. But a mustard jacket to envelop the whole chest, left on till the skin is reddened thoroughly in the beginning of pneumonia seems to do some good especially in children. The ice pack relieves pain and quiets the patient, but in many families we are not permitted to use it.

Many of our cases of pneumonia we should visit two or three times daily. If a trained nurse is not in attendance for a case of moderate severity in the morning may be in a state of collapse in the afternoon.

Small doses of aconite or veratrum viride in the incipiency of pneumonia in sthenic cases, both in adults and children, undoubtedly relieves congestion to some extent, and seems to be particularly indicated in many cases in children. These remedies have the power of lessening acute inflammatory conditions of the bronchial mucous membrane and, if given in small doses often repeated there should not be occasion for alarm as a rule, especially in robust children, and these robust cases are the ones that these remedies are usually indicated in. Bleeding does good in these sthenic cases, but it is out of style and men are afraid of it, so I presume this fear prevents the doctor from insisting that it should be done.

Three "don't's" in the treatment of pneumonia, I remember, was instilled into me when in school. Don't over feed. Don't over-medicate. Don't over-examine. These three don't's I consider worthy of recognition for several reasons, but space will not permit of an explanation.

The vaccine or serum treatment we had hoped to be our sheet anchor for the relief of this condition, but from the experiences of other men, it has been a failure up to this time. Remember in the treatment of pneumonia, that we have an acute infectious disease to deal with, and to watch and control, if possible, every symptom that could possibly lessen the patient's chances for recovery.

Remember, that high pitched, tubular or bronchial breathing does not always indicate pneumonia, for it may be pleural effusion or tuberculosis.

Remember, that the extremes of life are especially prone to pneumonia and the symptoms in many cases atypical.

Remember the alimentary tract, and keep it clean.

Remember the patient's fight is only a few

days between life and death, and by your careful attention you may be able to tide him over a span that will enable him to enjoy many years of usefulness.

Remember, the patient is suffering from carbon-dioxide poisoning when dyspnea is marked, and give him plenty of fresh air if you have to fight the whole family.

Remember, that heart stimulants are not to be used until indicated, but in the aged stimulation is needed in most cases as a rule.

Remember, we will find the methods as advocated in text-books and literature very confusing if we attempt to carry them out in every case.

EPILEPTIC CONVULSIONS.*

By T. J. TOWNSEND, Owensboro.

The mysterious character of epileptic convulsions have confused the minds of the world's greatest philosophers, and through eventful ages the medical profession has failed to offer effective treatment for the more obstinate and severe forms of the disease.

Before the days of Hippocrates an epileptic convulsion was held in superstitious dread, it was regarded in the light of an evil spirit, and all honor is due the great father of medicine for divesting the disease of superstition, and properly classing it with nervous diseases. With the intelligent physician the evil spirits have vanished, and we are advised that numerous causes have been assigned, and are suspected to exist in the total make up of many cases.

Here I shall recall two patients that came under my own personal observation, both of which were promptly cured by removal of carious teeth.

The frequent and prolonged habit of cigarette smoking may lead to epileptiform convulsions which may be explained by the presence of wood alcohol that is produced from the rapid combustion of burning paper made from wood pulp.

I shall recall in my early practice an obstinate case of epileptic convulsions which gave a history of five years standing. The unfortunate man was a portly well-to-do farmer who weighed 240 pounds avoirdupois, he had acquired the habit of using opium, and requested me to give him a large dose of "hypodermic medicine," his bowels and abdomen appeared unduly distended, due to excessive eating and overloaded conditions.

This patient was treated to active purgatives for three consecutive days, with the best intention of producing copious movements of yellow bile. He was put on a low diet and

*Read before the Daviess County Medical Society.

only two meals a day, he made a smooth uneventful recovery, and survived many years in pursuit of his useful avocation.

Here, in this single case we have opened a wide domain for special inquiry, and serious contemplation, and we are reminded of a common evil that never fails to afflict the economy of man.

Here, recuperative energy is kindly displayed according to the Ordination of Providence, as manifested throughout the animal creation. The brute sickens—it refuses food from a friendly hand—it starves and makes quick recovery at the instance of an all-wise power—“*cura famis.*”

Here we are reminded of infinite wisdom—and that instinct possesses a power of practical sense—to starve, means elimination and recovery—to feed, means renewal of the intoxication; which, without intervention of some kind might lead to death. Catharsis liberate nature—restores inhibition, and united energy. Man purges, and the brute starves, either may secure good results in the line of cure.

The epileptic patient, after having been purged, should be taught negative means, that may prevent recurrent attacks of epilepsy, and that no agent can equal in value or efficiency a long conducted and rigorously low diet. With anaemic and half starved patients a liberal quantity of nonrishing diet is in order—while with the more robust class, “*cura famis* is the watchword; but in either case, the patient must be warned that a two meals a day system is the best for epileptics, and should be persisted in till victory is scored over disease.

The best and most learned men engaged in the healing art do sometimes disregard instinctive knowledge in the brute. With mental blindness we all may, at times, look with indifference at the law of protection. We are often tempted to traverse narrow paths that may lead only to the grave.

Instinctive and intuitive sense is greater than reason. We argue to suit selfish ideals, or to attain some special object or desire.

Here, we shall admit inadvertence and discredit the healing art. With his gift of greater intelligence, man is the only creature that wilfully and knowingly violates this exacting law of nature. Man eats and the brute starves.

Epilepsy is classed with the obstinate forms of disease. This is due to a failure to know in each particular case the assignable cause. Effort conducted with patience is needed to ferret out the cause of each individual case of epilepsy, and we are expected to succeed best when we know how to apply a surgical or a medical remedy.

In olden times, when Orbaeus had won distinction by enring fits—he has most assuredly accomplished a feat greater than that of any predecessor who had, hitherto professed a knowledge of epileptic and other forms of convulsions. When he had discovered that reflexes involved the great sympathetic nervous system in diseases of children, and that teething, and a high blood pressure from elevated temperature would cause a fit, he was reminded by analogy to adopt rational methods for treating convulsions. For teething children, it is proper to lance a gum at the focus of pain, and to actively purge the little patient; this will relieve the fits—we should not forget to apply a common sense rule to a more serious disease.

Liken unto a Phoenix that has been cremated to rise again, purified from its ashes—the spirit of Orbaeus shall linger through countless ages to bless afflicted humanity, and his generous spirit still hovers as an archangel to lead us from the vales of eluded mystery.

I believe in making diet a principle in the treatment of obscure chronic disease. We are facing a problem, and it is the greatest one of the twentieth century. Evil spirits and Pagan philosophers are vanished; *Petit mal* and *grand mal* with *white plague* and the *cancer*, are on trial with the American physician, and when a true verdict is rendered the dogma of theoretical science will surrender its tenets to the mildews that rust and corrode. Many ideas and ideals born in the eventful past do rise in triumph from the dust laden shelves of ancient lore, to intercept the steady march of the tripple foe.

How to cure diathesis, and to keep it cured is a question of difficult solution. It is a settled question in my own mind that intractable obstinate disease can only be conquered by changing the diathesis, and let me say, just here, there is only one way that it may be accomplished.

The farmer who gathers in, at early frost time, a lot of hungry, diseased pigs to make his meat for home consumption, can change the diathesis, and restore the health of his entire herd of animals by feeding them one kind of food. In the short time of three months, the corn fed animals are slaughtered to furnish the sweetest, most palatable meat known to the human race.

The hog is a scavenger brute, and the very meanest of its race; its voracious appetite is unexcelled—it will feed on putrid flesh, worms, bugs and reptiles—if killed before its flesh is purified by use of cereals, its flesh is nauseating and dangerous to human life.

The time is approaching when leprosy, cancer and tuberculosis will be cured by a

generous two handed diet of bread and milk. Plain food tends to strengthen the weakened chemistry of life. Pardon this digression—I shall return to epilepsy, and cite a few more causes. A compressed brain from an osteomegental irritation, that may involve the sexual organs in a state of disease; too frequent and excessive eating of unwholesome food—mal-assimilation, nerve pressure, disease of the eye, ear, mastoid cells, tight or ill fitted wearing apparel, intestinal worms, tea, coffee, alcoholics, tobacco, constipation, corns, excess, and imprudence of any kind that may tend to produce a feeling of discomfort or pain with a neurotic person.

PREVENTION OF TUBERCULOSIS.*

By S. M. HOPKINS, Demossville.

Next to religion, this is one of the greatest questions before the people to-day. The prevention of tuberculosis is a problem, in the solution of which, all professions, religions and people of all walks of life can work together.

The societies organized for this purpose are numerous. The only way to solve this question is a thorough education of the people in regard to the disease in all of its phases. The physicians should and are taking the lead in this educational idea. To produce tuberculosis two things are necessary, the seed and the soil. Koch, in 1885, discovered the seed, since that time the disease has been studied in a more scientific way. The germ usually, although by no means always, gets into the system through the lungs and upper air passages. If it finds lodgment in structures of feeble resisting powers it goes to work. This brings us to the question of heredity. We know that the disease *per se* is rarely inherited, but we also know that a low physical organization with poor resisting powers is hereditary. This is the so-called "tuberculous or non-resistant type," and offers a poor fight when invaded by any infectious disease. We must remember that the infection also invades the strong and robust, when from any cause their resisting power is below normal.

Some one has made a very apt comparison between the parable of the sower and the individual predisposition. The good ground in the parable is compared to the person whose powers of resistance are below the normal, who readily takes on the disease and succumbs to it.

The science of eugenics, which means the science of being "well born" advocates a reform in human breeding. They would have the fit bred with the fit, and thus eliminate the inherited tendency to disease. The science of

eugenics is not different from science of the up-to-date farmer, in the selection of the seed with which he sows his fields, and in the mating of his stock. He will exercise great care when he breeds for fine horses and cattle, when likely this same farmer would give his healthy daughter in marriage to a syphilitic or tuberculous husband without investigating his pedigree. Some of the eugenic laws that have been passed may be a little too drastic, but our laws should prohibit the marriage of persons having pulmonary tuberculosis.

The housing problem is very important. It is hard to teach people the value of well-ventilated rooms in the prevention of infection of one member of a family from another.

Since the successful use of vaccines as prevention in typhoid fever the efforts have been great to find a similar preventive vaccine for tuberculosis, but so far their efforts have failed.

Tuberculosis should be a reportable disease in the cities. Every county should have a salaried health officer, then this should be reported in the county districts. A health officer should visit every case of pulmonary tuberculosis, and give explicit instructions in a prophylactic way. Much of the advice of the family physician is not heeded, spitting upon the streets and in public places should be prohibited.

Whittaker said "a man walking the streets with tuberculosis, and spitting where he willed, was as dangerous as a man walking the streets with a many-barrelled pistol, and firing at random."

When called to a case of pulmonary tuberculosis our instructions should be plain and cover all points of the treatment well. We should tell the patient and family that the hope of recovery of the patient, and as prevention of infection of other members of the family depends upon plenty of fresh air. Have the patient spit upon paper or cloths and burn them. Every patient should have special drinking cup and dishes, and these should not be washed with the family dishes. A tuberculous mother should not be allowed to nurse her infant. Children should not be allowed to stay in the same room with patient with active tuberculosis. No one should sleep in same bed and not in same room, except when necessary to attend to needs of patient. Delicate children should be guarded against the contagion of whooping cough and measles, hypertrophied tonsils and adenoids should be removed as they form a nidus for growth of tubercle bacilli. All infected houses or rooms should be thoroughly disinfected.

*Read before the Pendleton County Medical Society.

MENSTRUATION AND MENOPAUSE; THEIR INFLUENCE ON THE VICIOUS CIRCLE.*

By WILLIAM J. THOMASSON, Newport.

Puberty and the climacteric are the times in a woman's life that either health and happiness or misery and distress become a part of her being, and remains such the rest of her life.

The reflex nervous system is always at its highest point of irritability during menstruation. Heat flashes, nervousness and general malaise are some of the most prominent indications that the menstrual flow will shortly appear.

Headache, a full feeling about the head, difficulty in breathing, nose bleed, dark circles under the eyes, and a general bodily discomfort, warn the parent that the girl is about to enter womanhood.

Menopause is the time in every woman's life that is not only dreaded by the woman, but by the members of her family as well. The individual with a pleasant disposition may become a demon, or the motherly woman we once knew, may seek forbidden pleasures or become addicted to strong drink or to the use of drugs.

The family ties are broken, vows are forgotten, old friends forsaken, and the once contented wife and mother becomes a seeker of pleasure in the places once shunned by she and her former associates.

Should she escape a change of disposition and character, she is almost sure to become morbid, a hypochondriac, or a chronic invalid. This condition may last for a few months or years, or it may continue till death puts an end to this wretched condition.

The menopause occurring at the proper time in life, or at about forty-five or seven years of age, is usually more kind to the gentler sex, than it is to those women who have been so unfortunate as to be ushered into the climacteric early in life by the removal of their ovaries during the years when they should be bearing children. The mental impression, the thought of being unsexed, the knowledge that they are unable to reproduce their kind, all influence the well-being of the individual.

It is especially this class of cases that prompt this paper, and our limited experience has taught us that many of the distressing symptoms that these patients have, might have been relieved by the proper treatment of the condition within the nose. May I venture to make the statement that some of these cases

that have been unsexed without any benefit or without the relief of the symptoms that prompted the operation, might have been benefited by the proper treatment of the nasal condition, and the woman spared the humility of being unsexed. Who knows, she might have been a happy mother instead of being a chronic, nervous wreck.

Do not understand us that the ovaries should never be removed, for we believe if they are diseased, the sooner they are removed the better. On the other hand, if there is a possibility that the organs are only in sympathy with some other part of the body, for instance, the cause might be located in the nose, the ovaries should not be sacrificed till all other treatment has been tried. For just as sure as the ovaries are removed, it matters not for what cause, you can depend upon the nasal mucus membrane, as well as other portions of the nasal economy undergoing pathological changes.

The nose is a long way from the generative organs. Yet one has only to visit his country cousins'; spend a few days on the farm, observe the herds, visit the studs. If you are unable to journey to the country, listen to the tom cats on the back fence. We wonder how they knew? Is it instinct, or is it stink that calls the merry chorus together? The buck traces the doe by the sense of smell. The female dog in rut, even if quarantined, will cause the gathering of an army of male dogs in a very short time.

Man does not use the sense of smell to trace the opposite sex, but nevertheless most of us have fond recollections of special perfumes that some of our friends in the past used, and the odor, even after many years, will bring back thoughts of early and vigorous manhood.

Dabney¹ says, "The use of perfumes from time immemorial, has been a conscious or an unconscious attempt to stimulate lecherous thoughts. Though in times of moral decay, women have unfortunately not been the only offenders. Cicero inveighs against the 'Spreading of unguents' and other odoriferous and erotic preparations upon the person, as the practice was much in vogue in the days of the Roman Empire and the Greek Republic, and not unknown to-day. Hence, we hear of 'intoxicating' perfumes well named, though few who use the phrase know the solid biological grounds upon which the expression rests."

The nose will tell when the young man has worshiped well but not wisely at the shrine of Venus. The nasal mucus membrane will tell the trained physician whether the woman is now, or going to menstruate in the next day or two.

The young man who enters your office with the stuffy nose, the nasal twang, and possibly

*Delivered before the Campbell-Kenton County Medical Society.

an acute impairment of vision does not have to tell you that he has partaken of the forbidden fruit. Relieve the acute congestion of the erectile tissue within the nose, caution him to abstain from all sexual excitement, give him a sedative, if he cannot control his animal passion, and the obstruction will promptly disappear.

Haverlock Ellis², in his six volumes on the "Psychology of Sex," treats especially of odors and their influence upon suggestion, emotion, religion and morals; action on the heart, vasomotor system and muscular activity. In one instance he speaks of the custom among certain Philippine tribes of lovers changing their garments to have the odor of the loved ones about them. Not infrequently the sexual inclination of one individual towards another is greatly influenced by olfaction.

Some odors excite and others repel. The method of salutation by rubbing the noses together, or touching the hand to some part of the face, common among many tribes of Africa, India and the South Sea Islands, is classed by Ellis as "Sexual attraction by personal odor."

Smelling by contact (as noted earlier in this paper) is possibly the earliest known salutation. This is exemplified also in the lower animals.

Seifert³ in his paper on the clinical study of the relation between the nose and the sexual organs, says—

"After a critical review of the literature and a number of experiments of his own, he arrives at the following conclusions:

First. Many symptoms point to a direct nerve connection between the nose and the sexual organs. The course of the respective nerve tract is yet unknown. There exists certain striking anatomic and physiological analogies between the several parts of the nose and the sexual organs.

Second. The objective noticeable nasal symptoms accompanying sexual conditions and functions seem to be influenced to a more or less pronounced degree by general circulatory and mechanical conditions.

Third. Numerous pathological conditions (including many of the menstrual anomalies and also quite often the *hyperemesis gravidarum*) may be explained by the assumption of a real nasal reflex neurosis or a previously existing nasal intumescence with the local and general sequela.

Fourth. The active nasal influence upon the sexual organs may be chiefly explained by the suggestive effect of the therapy.

As the euphoria of cocaine that varies in different individuals, and the relief of the nasal conditions causing nasal reflex neurosis,

this apparent nasal influence is furthermore due to the establishment of free nasal breathing and the alleviation of nasal engorgement."

Brettauert⁴ advocates nasal treatment for cases of dysmenorrhœa, not apparently due to any gynecological condition. He asserts that nausea, vomiting and pains in the iliac region often disappear after the application of a twenty per cent. solution of cocaine to definite areas of the nasal mucosa.

In a paper published by Dr. Wilhelm Fliess⁵ in 1897 attention has been called to the fact that certain areas in the nose, the tuberculum of the septum and the anterior half of the lower turbinate always become swollen, hyperemic and bleed easily upon the slightest touch during the menstrual period. All of these symptoms promptly disappear after the cessation of the period.

Drattauer details the histories of five cases in which the results in cauterization were very satisfactory. Other authors have also reported cases in which permanent relief was obtained by means of trichloroacetic acid, galvano-cautery, or bi-polar electrolysis, or by other rhinological treatment removing spurs, enlarged turbinates, etc.

Experimental research on influencing the sexual system by operation on the nose—Koblauch and H. Roeder.

"Though the animal operated on so as to destroy the so-called genital points in the nose, grew as well as the controls, they seemed sexually indifferent, and their genital organs were found practically rudimentary. Very likely there is some close connection between these points and the hypophysis."

If these researches are true, it emphasizes the importance of conservative surgery within the nose. Especially is this true in reference to the nasal mucous membrane during early adult life and during the child bearing period.

Let us examine the nasal cavities and learn why the sexual habits of the individual affect these structures.

The nasal cavities are two in number, these spaces are divided by the nasal septum, and each of these cavities contain three turbinate bones, and the lower border of the inferior turbinal and the lower and posterior portion of the middle turbinal is made up of erectile tissue, which is closely analogous to that of the glans penis. The tuberculum septi is also made up of the same tissue, and as this erectile tissue is located in the most vital portion of the upper air tract, it is readily understood why any abnormality within this region known as the vicious circle will affect the general health of the individual.

The petrosal nerve, and the sphenopalatine

ganglion is the connecting link between the nose and the sympathetic system.

When we remember the function of this system and the vasomotor control over the smaller blood vessels, and the arterioles, when we consider how little it takes to cause the act of blushing, we will readily understand how under similar conditions the blood can be sent to the erectile tissue within the nose, for in this region the resistance is much less than of the face and forehead.

In other words, the blood supply to the erectile tissue within the nose is influenced by vasomotor disturbances, and as the blood supply is abundant in the nose, this particular tissue suffers not only from vasomotor irritation, but also suffers in proportion to the excesses put on the other erectile tissue of the body.

The swell bodies (or erectile tissue) in the nose is supposed to take care of all the air that we breathe. This air must be filtrated, warmed and moistened by the erectile tissue. These swell bodies are called on every twenty-eight days to sympathize with the generative tract. Or, in other words, this erectile tissue becomes engorged twelve times a year during the child-bearing period.

This same tissue also undergoes engorgement not only at the menstrual time, but the changes of atmosphere affect the blood supply to this tissue, and all sexual excitement causes an increase blood supply to the swell bodies. Some investigators think that uterine or ovarian irritation will also cause the swell bodies to become engorged.

Is it any wonder that we find hyperplasia not only of mucous membrane in the nose, but of the bone and periosteum as well?

With the hyperplasia of the nasal contents, or in other words, the obstruction in the nose, due to the thickening of the bony turbinals and their coverings, preventing normal drainage of the sinuses, allowing the air to enter the lungs unprepared and in many of these cases the turbinal is in contact with the septum, causing pressure and a long train of nervous symptoms. This condition may go on for months or years, be called catarrh, nervous headache, or neuralgia. Many of these cases become nervous wrecks. Complain of painful menstruation, and go from bad to worse, till the ovaries are removed and then, instead of the looked for improvement, all of the previous symptoms are exaggerated, the woman is a misery to herself and to her family, and the sanitarium usually shields her till death kindly puts an end to her miserable existence.

What effect does the removal of the ovaries have on the turbinal bones? Does the removal of one ovary cause any nasal symptoms? Most emphatically yes! Our experience has

shown that all cases that have come under our observation, where the ovaries have been removed, have had nasal complications, such as severe headaches, stuffiness in the region of the vicious circle or sinns involvement, due to the obstruction interfering with the ventilation and drainage of the accessory cavities.

We have several cases under observation where one ovary has been removed, and the middle turbinal corresponding to the same of that, on which the ovary was removed, underwent hyperplastic changes

One patient in my series, a young married woman age 19, had no trouble at all till after marriage. Since that date has always had trouble with her nose, and complains of difficulty in breathing after coition. The symptoms are always worse following sexual intercourse. This condition has now lasted for two years.

What change, if any, takes place in the nose at the time or after the menopause? Owing to the long years that the erectile tissue in the nose of the woman of middle life has been engorged, the middle turbinal usually on both sides becomes very much enlarged and practically blocks the middle meatus. Later the mucus membrane loses its normal color, its luster is dimmed and the large thickened turbinal has a glazed white appearance.

If drainage is not interfered with, headaches may not be complained of, but it is in these cases that we usually have the severe headaches, the hot flashes and the chain of nervous symptoms due not to the menopause directly, but to the condition within the nose.

Many of the symptoms and much of the suffering that these women undergo at this time of life, and what was formerly looked upon as the normal conditions of the women at menopause, can be relieved by the proper treatment of the condition within the nose.

I want to report a case referred to me by Dr. Jenkins a few days ago.

Mrs. S., age 27, a woman poorly nourished, anaemic and very much emaciated. Menstruated first at the age of 19, regular till twenty, when she was married. Never menstruated after marriage till a few weeks ago. Nine months after marriage aborted at the fourth month. Two years after marriage gave birth to a living child, and four since, all living, the youngest six months of age. This woman had not menstruated since marriage till a few weeks ago. Then menstruation appeared the second day after a nasal operation. This woman complained of pain over the ethmoid, frontal and maxillary sinnses. On transillumination a positive shadow was cast in the region of the maxillary sinus. This cavity was at once washed out and twelve days later the middle turbinate and the anterior ethmoid removed. This operation was followed

twenty-four hours later by a brisk uterine hemorrhage, necessitating the patient to remain in bed. This hemorrhage occurring as it did, so soon after the nasal operation, was undoubtedly due to the influence that the genital zones in the nose have over the uterus and its appendages. Examination of this woman's uterus, since the hemorrhage, shows no pathological cause for the same.

Case No. 2. Mrs. L., age thirty-five, wife of a farmer referred to me by a neurologist for refraction and an ophthalmoscopic examination. Eye symptoms negative, vision 6-6.

Nasal examination showed both middle turbinates enlarged, and in contact with the septum. Their removal advised, operation refused. In this case we were able to shrink the nasal tissue temporarily, and relieve some of the nervous symptoms. This woman two years ago had both ovaries removed, and all of her symptoms have been worse since the operation.

Case No. 3. Mrs. —, age 44, had the left ovary removed April, 1911. The following fall began to complain of stuffiness on the left side of the nose. This condition was easily relieved by the use of adrenalin and the oily sprays for a short time. During the winter the obstruction did not yield so readily and some odor was noticed coming from the left nostril. This condition has continued till the thickened tissue is in contact with the septum and no longer yields to the adrenalin or cocaine.

The ozena is gradually increasing and the condition is nearing the point when the patient will have to yield to an operation for the relief of the odor within the nose.

These three cases are but a few that have come under my observation, but enough to emphasize the great importance the nose plays in its relation to the generative organs in the female.

Placenta Previa. Treatment. Pituitrin used with good results in 16 cases. If only a small portion of placenta presents, and especially if vertex presents and cervix is sufficiently dilated membranes should be ruptured and pituitrin given. In other cases employ combined version with pituitrin, and await spontaneous delivery, merely extracting arms and head. Where dilatation insufficient for combined version, insert small dilating bag or vaginal tampon, and later do version and give pituitrin.—Trapl.

EXAMINATIONS FOR LIFE INSURANCE.*

By F. M. STITES, Hopkinsville.

Examinations for life insurance require the exercise of delicacy, skill and sound judgment on the part of the medical examiner. Serious departure from the normal standard of health that is not even known to the applicant himself is so common that the medical examination is of vital importance to the insurance company and calls for all the skill and knowledge that present day diagnostic methods have developed.

Every applicant that is brought to the examiner must be questioned and investigated as thoroughly as possible and there is no place for a prejudice or a preconceived opinion in any case. Sometimes what was thought to be an impassable obstacle to securing insurance will prove a very trivial thing, and not infrequently an apparently sound individual will be found entirely unfit for life insurance.

There is no part of a modern examination blank that is not important, though a faithful examiner will never confine himself to the printed questions on the blank, but will follow any clue of importance that may develop during the examination. There are some parts of the examination, however, that require special care and attention.

Except in the large centers there is not much danger of an examiner being deceived in the identity of an applicant, though he should always bear in mind the possibility of deception unless he personally knows the applicant.

The family history is of importance in many ways, and it may require both skill and patience on the part of an examiner to approximate the truth of this history. The most trying revelations must be recorded at times, and nothing should be withheld from the medical department, however embarrassing it may be to the applicant. Suicide and death at the hands of a mob, tuberculosis and insanity, alcoholism and syphilis are exceedingly distasteful to record, but the family history would be of little use without the truth in such cases. Few applicants can give the ages of their relatives off hand and an examiner must patiently help by recalling the years of death, birth, etc. When a definite answer cannot be given the reason for the failure should be stated if possible. The brothers and sisters one-half related by either parent should be recorded even though not called for in the blank. The very prevalent habit of recording the health of all living relatives as good, is due often to carelessness, and may conceal a

*Read before the Christian County Medical Society.

case of tuberculosis or insanity that the company should be informed about. A more careful inquiry into the health of living relatives and the previous health of dead ones would be of great value to the insurance companies.

The applicant is apt to be very forgetful of his own personal history, especially as to illnesses. In those examinations where the long list of diseases is left off, the examiner should use care in securing a true record of all sicknesses, injuries or operations. A carefully read list of questions about diseases will undoubtedly serve as a reminder to the applicant and it is more difficult for one who is willing to deceive, to deny a direct question about a disease than to evade a general inquiry.

Careless diagnosis causes the examiner infinite trouble and annoyance. Biliousness, malaria, la grippe, bronchitis and tumor cover a multitude of sicknesses, and are practically meaningless until carefully investigated. Also the practice among certain doctors of exaggerating the seriousness of trivial indispositions may interfere with the decision in some cases. It is not rare for a rejection to be based on the diagnosis of appendicitis, gallstones or renal calculi when there was no real foundation for such a diagnosis. The statement that the applicant has had pleurisy usually means to the medical department as well as to the experienced examiner, that the applicant has had an infection of tuberculosis. This information is very important, but it is very unjust to the applicant to pronounce a slight pain in the side a pleurisy unless there is a real involvement of the pleura. Equally troublesome and unfair is the attitude of some men when referred to for information regarding the sickness reported by the applicant, in affirming as trivial and of no consequence serious conditions that should be known to the medical department.

The only remedy for these things is greater accuracy in diagnosis, and it is encouraging to note the increasing care in arriving at a positive diagnosis that is becoming prevalent. An incorrect diagnosis may not only cause a patient unnecessary anxiety as to his health but may cost him and his estate many thousands of dollars. The careful examination of the chest and abdomen cannot be too strongly emphasized. Inspection has become more important than formerly because of the frequency of operations, and the scars of operations should be looked for in all cases. If found they must be accounted for and examined to determine if they are well healed, and in abdominal operations to detect the existence or possibility of hernia. A scar on the chest will recall a forgotten empyema and the

shape of the chest will often show important facts to the examiner.

In every case the applicant should be weighed by the examiner on reliable scales, preferably physicians' scales in his own office, and the measurements of the chest and abdomen taken carefully with a steel tape. A fixed standard of height in the office of the examiner separate from the scales is to be preferred, and these things all show the importance of making the examination in the examiner's office whenever possible. Add to this the importance of quiet and freedom from interruption and the facility for securing authentic urine and it is perfectly apparent that the examiner's private office is the ideal place for the examination. The urine to be examined should be passed in the presence of the examiner in every case, except in the examination of women, and in these cases every care must be taken to avoid the possibility of substitution. There is no excuse for the careless examination of the urine. The tests are so simple, well known and easily made and so positive that the slightest abnormality can be detected.

Evasion as to the use of intoxicants or drugs is very common, and it is difficult to secure the exact truth as to the amount used and the admission of the use to the point of intoxication. Nothing short of a definite statement of the truth in this regard should satisfy the examiner and if he is in doubt he should satisfy himself by private inquiry.

The use of a copy or photograph of a former examination is improper except after the completion of the examination, when it may be referred to, to make sure that nothing of importance has been omitted. The truth is much more likely to be recorded if each examination is made independently.

In all cases where there is a doubt, the examiner must use every modern means to secure a true report of the applicant's condition. The pupils tell often of a beginning locomotor ataxia. The deep reflexes should be tested in case there is a suspicion of disease of the nervous system. In every case whether required by the medical department or not the temperature should be taken and the systolic blood pressure recorded.

The examiner should under all circumstances endeavor to maintain friendly relations with the agent. The agent will rarely try to interfere with or influence a competent examiner, and the examiner should try at all times to be in readiness to examine an applicant at the time appointed, and always as early as possible after the application has been secured by the agent. Often a few hours delay will cause the loss of the insur-

ance to the Company, and the commission by the agent.

The examiner is employed by the company and well paid for his services, and it is his duty not only to protect the company from unsafe risks, but equally to be careful that the company is not prevented from insuring the lives of healthy persons because of some carelessness or neglect on the part of the examiner.

The most difficult and delicate work of the examiner is in dealing with those applicants who have been previously rejected. They nearly always believe it was carelessness or prejudice on the part of the examiner that caused the rejection, and if the cause of rejection is known to the applicant he will usually try to conceal or minimize the condition that brought about the unfavorable report. After making the rounds of several companies these rejected risks may become quite expert in handling their cases, and if the agent is willing to assist, the examiner may have considerable trouble in securing the true facts. Of course the companies are largely protected by the former reports on such risks that are accessible to all regular insurance companies, but the examiner cannot take for granted that the company for which he examines has any other source of information than himself, and if he fails to make a full and accurate report on such cases, his own standing with the company must suffer. If only the applicant and agent knew it, a full and frank statement of the truth in every case will most often secure a favorable consideration by the medical department, and if by their other means of securing information the medical department finds that the applicant has made false statements or the examiner has failed to record an important or obvious condition, the whole case of the applicant is injured and his chance of receiving a policy much diminished, and the examiner's standing with the company lowered correspondingly.

Tinnitus Aurium. Treatment. To relieve stuffiness of Eustachian tube—the most frequent cause of tinnitus—inject in it with catheter a 2 to 5 per cent. solution of dionin, using sufficient force to cause it to enter tympanic cavity.—Randall.

Tapeworm. Treatment. Thymol in cachets of 0.25 Gm. (4 grains) to be given in the morning on an empty stomach for eight days. Worms usually expelled on third or fourth day. Twenty-three cases treated with success. All alcohol to be stopped during treatment.—Artault.

TREATMENT OF TUBERCULOSIS.*

By L. T. ECKLER, Falmouth.

After having fully determined that a patient has tuberculosis, the physician has confronting him a very interesting and instructive problem. A problem to be studied by him in its various phases. A problem to which science is at this time lending her most earnest endeavor; namely, that of a specific cure.

Truly and deservedly has tuberculosis been designated the "great white plague," maiming and devouring, as we all know, more human beings than any other disease. From time immemorial, statistics have shown that the death rate from tuberculosis is greater than that of any other disease. Oftentimes in crowded districts its percentage of deaths is equal to all others combined. It is, therefore evident that the treatment of such a malady is of great importance and interest.

Several times have we been delighted to notice reports from scientists purporting a specific cure, but, with each instance our delight has been turned to deep regret to learn that again a failure had been made.

Not only physicians, but the laity have become interested and have become educated that this is the greatest menace to the health and happiness of the human race. Therefore, the laity are demanding that we as physicians make a more earnest endeavor to prevent and cure the disease.

The first and probably the greatest problem confronting us is the prevention of tuberculosis or its spread. The medical fraternity has accomplished much needed legislation along this line in recent years. Laws regulating sanitation, and establishing sanatoria for the treatment of tubercular patients have been enacted. However, we are just now at the beginning of what can be accomplished by us as physicians. The time is now ripe, that we as an organized body, can accomplish much more needed legislation along this line.

The treatment of tuberculosis should be considered, first, as to prevention of the disease and its spread; second, the treatment of the disease in its active process; third, the treatment of special symptoms, and, fourth, the use of special remedies.

Chief among the prophylactic measures in preventing the spread of tuberculosis, is the collection and destruction of the sputum from the tubercular patient. Suitable cuspidors, or spit cups, should be used by every patient affected with the disease. The cup should contain an antiseptic solution, and it should be explained to the patient that he should invariably use the cup for his expectoration and

*Read before the Pendleton County Medical Society.

not dispose of it upon the floor or ground. The contents of the cups should be burned in order to make doubly sure the destruction of the bacilli. The stool and urine of such patients should be destroyed. The body should be bathed in an antiseptic solution at brief intervals, since through the sweat, which is abundant in most of these cases, some bacilli are deposited upon the surface of the body.

All food gathered from near the residence of a tubercular patient should be thoroughly disinfected. Many cases are traceable to milk from unclean or unsanitary milk stations. Dairies should be repeatedly inspected by competent veterinarians. All tubercular animals killed and their carcasses destroyed.

A patient suffering from tuberculosis is to be isolated. The room to be rid of any hangings or drapery that might furnish a lurking place for the bacilli. The floor should not be carpeted, and all upholstered furniture should be removed. The patient's bed and apartments become a source of infection. Therefore the clothing and dressings of the bed are to be repeatedly aired.

It is of paramount importance to instruct and educate, not only the patient, but those with whom he is situated, that tuberculosis is a disease about which there can not be too much precaution, and that the remainder of the family or friends must not use any thing that has been used about the patient or his bed, without the same being first thoroughly disinfected and sterilized.

There should be more written or published in our daily and weekly papers concerning the ravages of tuberculosis upon the human life and the manner of stopping its spread and preventing it.

Unfortunately, among the poor there is not sufficient means or sufficient room to be had to give them proper care and attention. Sanatoria, established and maintained for the treatment of such cases are very commendable.

There has been, from time immemorial, an idea that there existed a predisposition to tuberculosis in some individuals. If such be the case, then it is the duty of physicians to, if possible, remove such predisposition. Scrofulous tendencies should be overcome through hygienic measures, together with good nutritious food, and tonics.

Tuberculosis often follows other acute infectious diseases coming on during convalescence. It is the practice of many physicians to dismiss a patient suffering from an acute disease as soon as the acute symptoms have subsided, leaving convalescence to nature. It is true that nature is the greatest of all reconstructives, but many times the bacilli finds suitable culture media in the already weak-

ened system of the convalescent and soon an active tuberculosis develops.

A change of climate is often very beneficial to those predisposed to this disease as is also the regulation of the daily habits. Bathing the neck and chest in cold water followed with a brisk rub with a rough towel is of importance and has been practiced by the writer with good results.

Obstructions in the nose, enlarged tonsils and adenoids should be promptly removed, and surgical treatment given to glandular or osseous foci.

To discuss the treatment of all the forms of tuberculosis in a single paper would render it too long and wearisome. Therefore only pulmonary tuberculosis will here be considered, leaving the treatment of acute miliary and bone and joint tuberculosis to the discussion, which will, it is hoped, also consider tuberculosis of the special organs, kidney, liver, brain, etc.

By far the most satisfactory treatment of pulmonary tuberculosis is to be had out in the open air, which can be carried out in this climate by means of sleeping tent and other apparatus destined to add to the patient's comfort in open air. Patients afflicted with tuberculosis should be taught the extreme importance of fresh air. He should be instructed to keep out of doors as much as is possible.

It is the importance of this plan of treatment that causes the physician to advise his patient to seek an equitable climate. In choosing a suitable climate for the consumptive, it is necessary to consider the age and physical condition of the patient, and the stage of the disease. In any case, the climate most suitable is one in which the patient feels well and gains in flesh and in strength. Dryness, altitude, pureness of air and an abundance of sunshine are to be considered in selecting a climate suitable for such patients.

Medicinally the treatment of tuberculosis is to be considered with two main facts in view:

First, one with reference to destruction of the specific cause, the bacilli.

Second, with reference to increasing the body resisting powers of the patient, thereby rendering the culture grown less fertile.

Unfortunately the former plan falls far short of the desired results. From a study of the pathological conditions present in pulmonary tuberculosis it is evident that the destruction of the bacilli by means of medication is impossible. However much good has been accomplished through the administration of antiseptic and parasiticides. In laryngeal cases benefits are derived from the inhalation of such remedies, chief among which, in my opinion, is creasote. Patients soon tire of this plan of treatment; since, to be beneficial, it

should be inhaled during most of the wakeful hours.

The internal administration of antiseptics to arrest the growth and development of bacilli, is perhaps a better plan. This, too, falls far short of the desired effects. Among such remedies creasote has the confidence of most of the profession. Its use, to the extent of toleration by the stomach, has resulted in lessening cough, and lowering fever and in the patient gaining in flesh and strength. Night sweats have also been much benefited by its use.

Thymol, terebene, terpinhydrate, turpentine, carbolic acid and formaline, have been used as parasitocides in the treatment of this disease, but results obtained are far inferior to those derived from the use of creasote.

Guaiacol carbonate, is of late extensively used in pill or capsule. The active principal of guaiacol is creasote. It is, however, better borne by some patients than is its active principal.

The second main indication in the treatment of this disease, namely increasing the body resistance and mobilizing the culture media, or soil upon which the bacteria multiply and develop, is aided very materially by the use of the above antiseptics. Judicious efforts at proper exercise and proper feeding are of paramount importance in building up the body resisting powers, as are also cod liver oil and tonics, strychnia and arsenic and iron.

Nature's resistance is greatly increased by proper appreciation and application of pure air, climate and sunshine. High altitude, fresh atmosphere and an even temperature are of great importance.

The feeding of milk and eggs, fish, flesh and fats is a great assistance to nature in overcoming the ravages of the bacillus tuberculosis.

Raw eggs and fresh unskimmed milk should form or go to make up the routine diet. The hydrocarbons are badly needed in tuberculosis and should be given freely unless there is impaired digestion, when their use should be discontinued. Oftentimes there is a poor appetite, with feeble digestion, which can often be overcome by a brief change of climate, a trip to the sea shore, or resorting to a rigid system of feeding.

Bitter tonics, and mineral acids often aid wonderfully in producing an appetite and in increasing digestion. In rare cases the desire for food and the digestion and assimilation of it is increased by the use of the various wines or liquors, however, their use and abuse should be judiciously guarded.

Among the annoying symptoms of this disease, perhaps the greatest is cough; which, when dry and accompanied by pleuritic irrita-

tion and pain, should be controlled by the administration of heroin or codeine. Creasote is a valuable remedy to relieve cough. It should be given either by inhalation or internally. It lessens the secretion and relieves some of the irritation.

The usual cough mixtures usually disturb digestion and are to be discouraged.

Fever does not as a rule, become an alarming symptom. Should the temperature become excessively high, it is best controlled by hydrotherapeutic measures. Antipyretics should not be used, for the reason that, we have already a weakened circulatory condition and the use of antipyretics would produce a greater weakness of the circulatory system.

Diarrhoea is a most trying and troublesome condition in tubercular patients. A condition which often ends the scene, through excessive depletion. It is a symptom often overcome by strict regulation of the diet. The withholding of all solid foods and the allowance of easily digested and assimilated substances. Medicinally the astringent course is to be pursued. Bismuth, salol, acetate of lead and opium, thymol and beta-naphthol are useful and beneficial. Most cases develop profuse night sweats, which are best controlled by the administration of agaricin and atropin combined. The use of camphoric acid in 20 gr. doses has been recommended to be given two to three hours before time for sweat.

Special attention should in all cases, be directed toward the appetite and digestion. Many lives are prolonged if not permanently benefited by the maintenance of a good appetite and digestion.

Cod liver oil and hypophosphites assist in increasing the body resisting powers, while creasote lessens the fertility of the soil upon which the bacilli grow.

Much has been said about tuberculin, whose field of usefulness is, according to most authorities, in establishing diagnosis and as a means of prognosis. Many practitioners regard it as a remedy of much therapeutic ability; while others employ it simply as a test. Personally, I have had very little experience in its use. If there is good to be derived from its use, it should be used early in the disease, since in the later stages there is generally a considerable temperature which becomes higher upon the administration of tuberculin.

The use of tuberculin as a specific remedy for pulmonary tuberculosis has not been proven. In most cases where it has been used, it has been used in conjunction with other remedies, hence it is probable that some of the benefits supposed to have been derived from its use, could be attributed to such other

remedies. Too much confidence or importance should not be placed in drug medication in the cure of this disease. The chief importance is to keep up the patient's appetite and strength.

Tubercular conditions of serous and synovial membranes should be dealt with surgically. Tuberculosis of bone and joint is surgical in treatment. Medicinal treatment being not only useless but dangerous, in that valuable time is lost in such treatment. Procrastination in surgical cases often leads to irreparable destruction and often death.

It is impracticable in this paper to consider the various tubercular conditions found in the human anatomy. If it were not that the subject becomes tiresome and lengthy much more could be said in reference to various lesions found in the body.

It is hoped, however, that a free discussion will be entered into, and that the facts not here mentioned will be fully studied.

PREVENTIVE MEDICINE.*

By JNO. E. WILSON, Butler.

The term medicine is used in its generic sense. It means preventive measures.

The most common and efficient measures for preventing disease, are included under the subjects of hygiene and sanitation. General hygiene or sanitation has to do with the air, food, and water of a community; also the refuse, or waste. The kind of air we breathe affects mind, and body. Impure air prevents mental activity; it also vitiates the blood, altering functional activity, and thus laying the foundation for chronic and incurable conditions. Again, there is not a disease of the respiratory tract that is not directly benefited by abundance of pure air. The sick need it even more than the well. We need it at night as well as in the daytime. We need it in cold weather as well as in the warm. At every moment and everywhere it is a necessity. The best sermon, the finest lecture, or the nicest entertainment becomes a drag when ventilation is neglected. School children especially, have been neglected in the past.

The character of the water supply of a community is next in importance to the air we breathe. Water, free from specific disease germs, may vary much in its adaptation to human needs. All water is in danger of contamination from disease germs. For drinking, to boil the water and cool it is a temporary safeguard against disease. One of the safest methods of securing drinking water is to have a well cemented cistern, tightly closed at the top, catching the water from a clean

metal roof, in the winter rains, and filter through charcoal. All superficial springs and wells are dangerous. Drilled wells seem to be a very same way of securing water for domestic use. The various mineral waters are at least harmless.

Fresh, clean, wholesome food is of equal importance to health. The nations that do not recognize this are far inferior. Our Government has done much in recent years to advance the interest in pure food. It has directed laws at inspection, public education, and sanitation. By these measures, new conditions have been established in canning factories, bakeries, slaughter houses, and packing houses. It has also abolished the public drinking cup, regulated hotel linens, and has improved barber shops, maybe, a little.

Sanitation has to do with public health and embraces many important features. It has controlled yellow fever by discovering and treating the cause, namely the mosquito. Sanitation is working a crusade against the housefly as a carrier of disease, such as typhoid. It is really the science of health. It is the means of preserving healthy conditions in thickly settled communities, as towns, cities, and armies; and the special care of infants in cities, especially in the summer.

All these measures tend to make difficult the existence of disease germs.

Personal hygiene relates to the individual application of the above mentioned elements. The value of personal cleanliness is self-evident. Our grandmothers used to bind up an abrasion with salves, and thus nurse it for weeks. We now cleanse a wound, sterilize it, and it heals by "first intention," in a few days. Many germ diseases are avoided by cleanliness. Lack of attention to mouth, nose, eyes and ears lead to catarrhal conditions from long irritation. The hair and nails are hiding places for many of our worst enemies.

The care of the special senses is a conservative measure. Knowledge of the care of the eye is very important. Any small defect or injury may result in impaired function or total loss. The ears should be frequently examined and much deafness prevented.

The nostrils may be the seat of a variety of small growths which will produce catarrhal symptoms even to the extent of hay fever, and many reflex nervous symptoms. A removal of the obstruction is usually attended with prompt relief. In the way of avoiding many secondary diseases, this is preventive medicine.

If many of the so-called colds were treated earlier we would have much less of bronchitis, pneumonia, pleurisy and tuberculosis. There is a law in automobile instructions to the effect that an injury increases by the square of

*Read before the Pendleton County Medical Society.

the time over which it exists. This rule might well be applied to human ailments. Most of the work of the specialist and the surgeon are conservative and preventive in character.

The common drugs are potent preventive agents when intelligently used. I need not dwell on the use of quinine, mercury, iron, arsenic, iodine, etc.

The manner of disposal of waste in a home or in a community is an important health factor. Decaying vegetation, aided by heat and moisture becomes a fertile source of germ life. Slops and kitchen waste thrown upon the ground near the home is to be avoided. Wherever flies are, they are attracted there, and they are well-known disease carriers.

Wherever mold will form, it is an indication that is unhealthy. The cows that furnish our milk should be healthy for our sakes, and for their own. The dreaded disease of tuberculosis will eventually be controlled only by prevention, that is, by such general, and personal, cleanliness as will prevent its transmission from place to place, or from person to person.

OBSTRUCTION OF THE BOWELS, INTUSSUSCEPTION.*

By C. K. KENDALL, Morgan.

Intestinal obstruction is a term applied to a condition of the bowels in which, by reason of some mechanical impediment or intestinal paralysis, the normal movement of its walls and contents can not take place. In its acute form it occurs as the result of no less than six causes: First, congenital malformation; second, invagination, or telescoping of portion of the bowels within the other, or so-called intussusception; third, strangulation by bands, diverticula, membranes, or by attachment to other organs, and by the slipping of a coil of intestine through an aperture; fourth, as the results of the twisting of the bowels, called volvulus; fifth, from the lodgment of foreign bodies, as gallstones, etc.; and, sixth, intestinal paralysis and distention.

Chronic obstruction arises from stricture, from tumors in the bowels, from tumors external to the bowels, and from impaction of fecal masses.

Congenital malformations, usually consist in closure of the intestinal tube by reason of improper development, and exist in any part of the alimentary canal from the oesophagus to the anus. These cases are usually surgical, with a very unfavorable prognosis and are better treated by early surgical measures.

INTUSSUSCEPTION.

The invagination of this condition is composed of three layers of the bowels. The intussusception is composed of the entering and returning layers, while the receiving sheath constitutes the intussuscepiens. To the point where the entering is turned sharply upon itself to form the returning layers, the name, apex, is applied, the word neck, is applied to the ring which results from the flexure formed by the returning layers as it merges into the sheath.

Intussusception may be separated into divisions, according to the severity of the condition, or according to the part of the intestine which is involved. Rafinesque makes three divisions, namely, those which are ultra acute, death taking place within the first twenty-four hours; those which are acute death taking place within the first week; those that are sub-acute, death taking place within a month or upward. From an anatomical standpoint, intussusception may be divided into the enteric, in which the small intestine is alone involved; the ileocecal, in which the ilium and cecum, together with the iliocecal valve are turned into the colon, and the ilio-colic, in which the ilium is prolapsed through the ilio-cecal valve, the latter retaining its proper position, at least for a time. When the condition is called, colic, it involves the colon only. In still other cases, the rectum is only affected, forming the rectal type of the malady. In the great majority of cases the upper segments of the gut are received into the lower, but occasionally the reverse condition occurs, and when this happens the term, retrograde, intussusception is applied. Double and triple intussusception has occasionally been noted.

ETIOLOGY.

The causes of intussusception are not clearly understood, but probably depend upon irregular innervation of the intestine, whereby a sudden, spasmodic contraction of one portion of the bowels occurs, the adjacent being relaxed. Intussusception of this character is not infrequently met with at the post-mortem table, having occurred at the time of dissolution. Polyps of the intestine may be forced along the lumen of the canal, thereby dragging the wall at the point of attachment and causing intussusception.

The frequency according to Leichtenstein and Bryant, of intestinal obstruction, excluding hernia, was as follows: In 1652 cases, 657 cases, or approximately 40 per cent., were due to intussusception. It is evident, therefore, that this form is not rare. Intussusception occurs most frequently during the twelve months of life. After the fifth year it becomes comparatively rare until the fortieth

*Read before the Pendleton County Medical Society.

or fiftieth year, when it begins to increase in frequency. The ilio-cecal region is the favorite site of invagination at all ages, but ileum invagination is exceedingly rare. If colic form occur, it is usually at the sigmoid flexure.

PATHOLOGY.

The pathological changes resulting from intussusception consist in an extravasation of the blood into the mucous membrane and mesentery of the part affected, and in an acute inflammatory process in the walls of the intestine, which particularly affects the serous surfaces of the entering and returning layers, so that they become glued to one another. Not infrequently, however, this condition does not arise, and adhesions do not form. As a result of the strangulation of the invaginated bowel, it some times happens that this portion of the intestine sloughs away.

And if sufficiently strong adhesions have formed between the neck and the upper portion of the intussusception, the coming away of this slough may result in the recovery of the patient. Very large portions of the bowels have been known to be passed in this manner.

Pampier has recorded one instance in which 124 cm., Botteher another in which 112 cm., were passed. In other instances, however, if gangrene of the bowel develops, perforation and general peritonitis ensue.

SYMPTOMS.

These depend upon the degree of constriction at the neck of the intussusception. Usually the first symptom is sudden and violent pain. This sometimes ceases as sudden as it begins, the patient being in comparative comfort. After an interval the pain returns, and the paroxysms become violent and prolonged, with shorter intervals at ease. Pressure does not always elicit tenderness; indeed, it sometimes seems to relieve pain. Vomiting is even a more constant symptom than pain, and usually begins early in the attack, but in adults it may be absent. Of all forms of intussusception the ileum invagination is the one which is most frequently accompanied by early vomiting, chiefly it produces the most complete obstruction.

In children a very constant symptom is the passage of bloody mucus. Out of 108 cases, analyzed by Martin and Hare, occurring in the first year of life, this symptom was absent in only four.

Tenesmus and bearing down is also commonly met with. In about one half the cases the tumor can be felt through the abdominal wall, and under the pliable abdominal wall in children it should be most carefully sought for.

Occasionally in the colic type the invaginated bowel can be felt in the rectum. The

movement of the bowel may distinctly change the position of the tumor.

PROGNOSIS.

The prognosis in intussusception is not good. Treated by the expectant method, the mortality is about 70 per cent. according to Leichtenstern.

The statistics of Martin and Hare give a mortality of 90 per cent. The mortality is greater in children than in older persons. The sloughing and discharges of the intussusception is always to be considered distinctly favorable, Martin and Hare found that in 408 children in whom slough had not taken place 85 per cent died. While out of 149 who passed a portion of the intestine 41 per cent. recovered. Sloughing rarely occurs before the second week of the disease.

The treatment of intussusception consists in the use of a fountain syringe filled with normal salt solution at a temperature of 105 degrees, and this fluid is to be injected slowly at the rate of four ounces to the minute. The pressure in the hydrostatic syringe should not be over two pounds. This method is available only when the intussusception occurs in the lower portion of the bowel. If it is in the ileum it is valueless. If, after pressure has been continued for a period of half an hour, the tumor does not disappear under gentle manipulation, abdominal section must be resorted to at once.

The older statistics to this operation were not very favorable, most of them being gathered before the days aseptic surgery was as well understood as it is at the present time, when the operation gives a much lower rate of mortality.

INTERNAL STRANGULATION.

Internal strangulation by bands is the next most frequent form of intestinal obstruction, about 36 per cent. of the classified cases. The condition occurs most frequently in males between the twentieth and fortieth years, and seems to arise in the majority of cases from a former peritonitis, although the bowel is occasionally strangulated by slipping through the foramen of Winslow or through a slit in the diaphragm. Out of 151 cases reported by various surgeons, the small intestine involved in 133.

The symptoms consist in sudden agonizing pain which is constant, although it has paroxymal increments. The pulse becomes rapid and weak; the temperature is abnormal; the vomiting is persistent, and becomes fecal; this condition of the vomit rarely develops before the beginning of the third day. Constipation is present, but fecal matter may be passed from the lower part of the bowels once or twice. If a large coil of gut is involved, a distinct area of thinned intestine may perhaps

be found. While the presence of this train of symptoms in a young child would be indicative of intussusception, in an adult it is indicative of strangulation by a band, for intussusception is rare in adults.

The only method of treatment which is satisfactory is operative.

VOLVULUS.

According to this condition occurs in 8 per cent. of fatal cases of intestinal obstruction. According to Treves .025 of 1 per cent., and according to Martin and Hare statistics in 4 per cent. Sometimes the intestine is twisted for three or four complete turns. The condition occurs more frequently after middle life, and more frequently in men than women. In 18 cases collected by Haven, 16 were men. In Martin's and Hare's 100 cases 64 were men. The twist is about the mesentery as an axis and involves the small intestine; occasionally it may appear in the colon, rarely the stomach may be affected. The twisting of the intestine interferes with its circulation, and this, combined with the decomposition of the intestinal contents and the resulting distention, soon produces peritonitis and even perforation. The abdomen is prone to become immensely distended.

The symptoms are absolute constipation, vomiting and abdominal distention. Meteorism is constant. The points in favor of a diagnosis of volvulus are the advanced age of the patient, the fact that the disease usually occurs in a male, that the pain is not as agonizing as in other forms of obstruction and the obstructed bowel is greatly distended.

The prognosis is much more favorable than other forms of intestinal obstruction. When intestinal obstruction is due to paralysis, the ease is most frequently some injury or an operation upon the abdominal contents. There is simply a dilated or kinked intestine, and the failure in peristalsis is due to paralysis of its muscular fibres. This is the obstruction which all abdominal surgeons greatly fear as a sequence of operations upon the peritoneal contents.

TREATMENT.

When the volvulus is due to paralysis after operation it is to be treated by the administration of concentrated salines repeated until the bowels are moved. When distention has reached a very great degree and vomiting is present, salines are no longer useful. The rectal tube should be passed in the hope of exciting peristalsis and drawing off gas. The patient should be frequently stimulated and the rapidly interrupted faradic current should be applied to the abdominal wall, or one pole may be placed in the rectum and the other passed to and fro over the abdomen.

If this condition is not due to paralysis after operation purgatives are absolutely contraindicated, and enemata can be of no value. Such cases should be subjected to surgical operation.

Obstruction from foreign bodies, arise from such articles as coins, pebbles, knives and scissors, gallstones and enteroliths. While gallstones are generally small, they may at times be very large, and are often greatly added to by concretions. Thus, Leichenstern states that one such stone was five inches in circumference, and he describes an enterolith nine inches in circumference. Such a stone is usually formed by concretions about a foreign body, as a cherry stone. Cases of intestinal obstruction of this character are, however, very rare, about 0.2 of 1 per cent. of all cases. The obstruction is usually found in the small intestine, sometimes at the ilio-cecal valve, and usually more frequently in females than males.

SYMPTOMS AND TREATMENT OF ACUTE ARTICULAR OR INFLAMMATORY RHEUMATISM.*

By FINIS LONDON, Woodburn.

Owing to the frequency of rheumatism at this season of the year, I feel like the committee on arrangements acted wisely in selecting rheumatism as one of its subjects for discussion, though I am afraid before they hear this paper through they will come to the conclusion that they didn't act very wise in making a selection to talk about this part of the subject.

Hines, I believe, was correct when he said, "The symptoms vary much in their severity."

The disease often begins abruptly, though many cases are preceded by a prodromal period of one or two days at which time patient feels unpleasant, aches in joints, complains of chilliness and possibly sore throat.

From my own observation I believe the greatest number of cases are insidious in onset, rather than sudden.

The involvement in most cases is multiple, especially if the ease is one of very great severity, the disease shows its predilection for the larger joints such as the shoulder, knee, elbow, ankle and wrist joints, none are exempt, not even the smallest. I think all agree that involvement of a single joint is possible, but not so common. Another peculiarity is the tendency to travel from one joint to another, and many times from a more recently infected joint to a joint primarily involved.

The most noticeable thing about the joints

*Read before the Warren County Medical Society

is the swelling, which no doubt, as has been said, is caused by the effusion into the joints, and inflammatory edema of adjacent structures, as ligaments, tendons with sheaths and muscles owing to this involvement of adjacent structures, is the reason why Tyson prefers the name acute rheumatism rather than acute articular rheumatism.

I believe there are but few diseases which give so much pain and render an individual so helpless as a severe case of rheumatism, the pain many times is so acute as to make it very difficult to give patient necessary handling, as adjusting of bed clothes, linen, etc.

The fever which accompanies rheumatism is indefinite in its duration and irregular in its course, this I suppose is due to the extent of involvement.

I have seen temperature reach as high as 104 or 105 degrees, do not recall of ever seeing a case with temperature reaching 108 or 110, as is recorded in our text books, and may have been observed by some of you gentlemen here. This extremely high temperature is said to occur in the meningeal form, and is associated with cerebral symptoms, such as severe headache, delirium, unconsciousness, cyanosis and ending frequently in death.

The cardio-vascular symptoms are of very great importance in this disease, the pulse is rapid, 100 or more beats per minute, often pulse rate and temperature do not compare with each other. Andrew says, "Cardio-vascular complications are liable to occur in any case, even the mildest, or at any stage of the disease."

Endo-carditis is said to be the most frequent cardiac complication. No authority that I have noticed gives it at less than 25 per cent., and one, LeLancey, gives it at high as 60 per cent. The left side of heart is oftenest involved, and the mitral valves more frequent than the aortic.

Pericarditis is said to occur as a complication in at least 10 per cent of cases, is recognized by the characteristic loud friction sound in contrast to the soft blowing murmur of endocarditis.

Myocarditis is said to occur also, but not so frequent as either one of the others mentioned, fortunate for the patient that it is absent as often as it is, for it is considered a very serious complication.

Another symptom which no doubt many of you have noticed is the free perspiration with its peculiar odor. This free perspiration often gives rise to the sudaminae, other skin eruptions as erythema and urticaria also occasionally occur.

The function of the kidneys is interrupted, quantity of urine is diminished, highly colored with specific gravity increased, the deposit

of urates is marked and albuminuria is often present, especially to a slight degree, though possibly not any more so in this disease than in many other acute febrile diseases.

The subcutaneous nodules spoken of by Barlow and Warner, consisting of small firm bodies attached to tendons and fascia situated near joints and more frequent in children than adults, together with such pulmonary involvement as pleurisy, bronchitis, or pneumonia are to be regarded more as complications than symptoms of the disease.

I know quite well the symptoms recited in this paper are lacking very much, and have failed to mention many signs and things you observe in a case of rheumatism, however I hope what has been said will be sufficient to give a reasonably good idea of this so common and much dreaded malady.

Now to the second, or last, part of our subject, namely treatment. This interests the patient more than anything else.

The stride, or advancement, in the treatment of this disease no doubt compares favorably with that made in the treatment of most other diseases which the physician is called to treat, so the old idea, (blankets and six weeks) has lost many of its former advocates.

I suppose all agree with Stengel, that the most important elements in treatment of any case of rheumatism, are rest, diet, and medicaments; from the first patient should be put to bed and remain there until it is considered safe for him to be up, rest and quietude no doubt benefit patient in many ways, first, as we are dealing with a condition attended with fever, which causes loss of tissue as is occasioned by any other acute febrile disease. Second, quietude and rest lessen blood pressure and cardiac action, by so doing cardiac complications may be avoided or greatly reduced. Third, rest also adds to the patient's comfort and is essential for the subsidence of the local lesion.

The old rule requiring patient to lie between blankets, is not so universally practiced to-day, but all favor the patient being dressed in flannel and having a warm bed.

In addition, there must be something done for inflamed joints, its effect is two-fold: First, satisfies the patient's mind and causes him to believe you are doing something for him. Second, for the real worth and merit there is in it, as for the local applications recommended I am sure I could not begin to enumerate them, they all possibly possess some worth, and each one generally has his favorite. When pain is very severe benefit may be had from fomentations applied to joints wrung out of hot water, or from Fuller's lotion, or lead, water and laudanum. Some one has suggested as a local application

ether, alcohol, oil of gaultheria equal parts of each and soap liniment to make one pint.

Andrew suggests the local application of salicylic acid together with lanolin, oil turpentine and benzoated lard.

The highly recommended preparations for local use, made by the different pharmaceutical houses no doubt owe most of their virtue to the methyl salicylate which they contain. Stengel says he has seen marked improvement both in local manifestations and secondary fever follow application of splints and casts.

The disease, like all others, is one in which patient's vitality and strength must be sustained by administration of a reasonable amount of food, possibly no article of diet serves the purpose as well as milk and light broths, in addition to this limited amount of whites of eggs, in form of orange ade, or egg albumen, etc., may be given. After acute symptoms have subsided in addition to what have been mentioned patient may be given meat juices, cereals, etc., plenty of water, either plain or in the form of lemonade, should be given also.

The remedies given internally for the control of this disease as you all know are really two, namely, salicylic compounds and alkalies. These remedies may be given separately or in combination. Belonging to the former group the two used most are salicylic acid or salicylate soda, some prefer salicylic acid or one of its compounds of which aspirin, I am sure, is the best; others prefer salicylate soda, these agents lessen the pain, mitigate the fever and Williams thinks protect against cardiac complications, though others do not credit them with the latter.

My opinion is that in treating rheumatism with these agents, the physician must find out which one is best suited to patient, personally, I do not believe salicylate acid or aspirin is the drug for all cases. I have more than one time seen patients who would complain after taking aspirin, of the burning sensation in the stomach.

Stengel thinks salicylate soda may be given to most all cases if given in solution and followed with alkali.

The alkaline treatment is said to obviate the occurrence of heart complications, especially endo-carditis and shorten period of convalescence.

It may happen that what has been mentioned for relief of pain may not be sufficient, in such event, morphine or some kindred preparation may have to be used therefore caution should be exercised in the use of such drugs, less dependance be acquired.

Such complications as hyperpyrexia, cardiac involvement, etc., are to receive same treatment as if they should occur in the course of any other disease.

I feel like the subject would be incomplete if I did not make some mention of the serum treatment, which is being put forth to-day. It was thought this might prove to be the one thing long hoped for. As for myself I am not able to say what it really merits, for my experience with it has been very limited, from what I have noticed from reports. I am sure it has not yet proven to be what it was hoped it would be.

PREVENTIVE MEDICINE.*

By O. W. BROWN, Lenoxburg.

The subject of preventive medicine is so exhaustive that an attempt to even present the most practical side of the subject in a short paper as this will be, will only give us a text for the discussion. This I hope will be taken up by every member present.

The doctor (unlike all other business men) is free and willing to impart knowledge to his customers that will lessen his earnings and thereby cause a depreciation in a business that he has spent months and years to learn. How many business men of this or any other town or city would make this sacrifice so freely as the doctor? I dare say there is none who would advise their customers to live in such a manner that their purchases would be reduced each month and year.

But this is exactly what the conscientious, self-sacrificing and scientific medical man is doing every day. Even if this advice should be remunerated in dollars and cents, he would never be paid for the real good and happiness that he is responsible for.

Preventive medicine has revolutionized the whole world in the past few years. Time was when smallpox, yellow fever, cholera, plague and many other diseases caused desolation of whole cities, and even empires were almost depopulated by these terrors of a few hundred years ago. History tells us that the decline of the Roman empire was really due to the prevalence of malaria, that sapped and undermined the health of its people, rendering them inert in both body and mind. Today how little we think of malaria as a menace to our business world.

Only in very recent years we know of the horror-stricken inhabitants of our Southland when a case of yellow fever was reported in some of the southern cities. Hundreds and even thousands would wend their way to safer climes, while those that were compelled to remain died in great numbers.

Why is it that the citizens of that Southland can now lie down to peaceful slumber and know for a certainty that the yellow

*Read before the Pendleton County Medical Society.

death, (as it has been called), will not claim them if they only obey the doctor? It is preventive medicine.

Major Reed sleeps the sleep of a martyr after being stung to death in his improvised cage, in order to prove to the world that yellow fever was caused by the bite of a certain kind of mosquito.

We all remember the failure of the French to build the Panama Canal, but it was not for the lack of finance or genius on their part. It was simply the germs that cause yellow fever, dysentery and malaria. This hotbed of disease has been made just as habitable as some of our most modern and up-to-date cities, from the very fact that American science in the way of preventing disease has proven to the world that infinitesimal microorganisms were holding a country captive, and no doubt would be to-day were it not for the untiring efforts of American doctors.

It is said that in the Civil War between the states, more men died of preventable diseases than were killed by bullets. Even in the late Spanish war we can recall the ravages of dysentery, typhoid fever and malaria, all preventable.

One credit must be given to all the different phases of preventive medicine, but at present the serum, vaccine and bacterin treatments seemed to be foremost in the minds of most medical men. When a thing has been proven to us, and we no longer have room for argument we sometimes wonder why we were so dull not to understand sooner. When Robert Jenner discovered the vaccine for smallpox more than one hundred years ago, there were skeptical medical men then, just the same as to-day. His new treatment was branded as a farce from far and near, and he was proclaimed a fakir, but we don't have to plead for his sincerity and what proved to be a life-saver at this time.

This vaccine has been the forerunner of all other remedies discovered along this line, and has proven that there is an absolute certainty in the prevention of smallpox in most all cases or individuals.

For more than one hundred years after this vaccine was used, there was no successful treatment of disease along this line, but in the short space of seven or eight years the bacterial vaccine therapy has assumed proportions of great magnitude. In fact it has drifted to extreme bacteriotherapy. Although the profession does not recognize that a scalpel and a license to practice make of any physician a skilled and competent surgeon, it has come to pass that the possession of a syringe and a bulb of commercial stock vaccine implies an expert bacteriotherapist.

This, we can readily understand, may do

great harm, and it undoubtedly has from what we can glean from literature.

Bacteriologists tell us that diseases are caused by germs, and recently it has been stated that every departure from the normal state of the body or any part of it is directly or indirectly brought about by some sort of microorganism. This would imply that our only hope of combatting all forms of diseases is by the use of bacterial vaccine therapy. This may read alright to the over-enthusiastic bacteriologist, but in practice we have found it to be erroneous, for these remedies even in the hands of experts along this line fail utterly in many cases. Drug houses have exploited these remedies in the past two or three years to the medical profession and used case reports signed by M. D. till I am afraid many have become over-zealous and made to believe unauthentic statements.

I have not used vaccine therapy except in well defined cases that seemed to call for this special form of treatment, and have seen good results in all but one.

No doubt many failures are due to a faulty diagnosis, too large dosage, too long or too short intervals between doses, stock supplies that have deteriorated, contamination during manufacture, failure to have a report from a bacteriologist on the case.

But with all the failures tabulated and the cures recorded, we yet have a happy medium to choose from and do wonders toward preventing and curing diseases that a few years ago were beyond our control when drug medication failed.

If the bacterial factors were known and could be isolated in all cases we could hope to obtain much better results from bacterial therapy. But the etiology of many of our diseases are not yet known, and therefore this plan of treatment in such diseases is purely empirical, yet we are justified, I believe, in many cases to use a bacterial or vaccine product that we know to have been successful in other similar cases without waiting for a report from our bacteriologist, for with uncontaminated bacterial vaccines in proper doses, skilfully administered, direct harm is most uncommon.

Typhoid vaccination has become compulsory in many countries where many individuals are compelled to live in closed quarters, and it is astonishing to know how the death rate has been reduced. It is impossible to gather together several thousand men as in our armies and navies without finding some that are typhoid carriers. This explains why in former years our soldiers died of this disease in great numbers. To-day few deaths are reported among armies and navies be-

cause of preventive medicine and typhoid vaccine.

The Canal Zone of twenty years ago and of to-day should so impress upon the medical men and laity as well, that American bacterial therapy along with general preventive medicine has come to stay.

Fronde, after visiting the Isthmus in 1885-6, wrote as follows: "In all the world there is not, perhaps, now concentrated in any single spot so much swindling and villainy, so much foul disease, such a hideous dung-heap, of moral and physical abomination as in the scene of this far-famed undertaking of nineteenth-century engineering. The scene of operation is a damp, tropical jungle, intensely hot, swarming with mosquitoes, snakes, alligators, scorpions, and centipedes; the home even as nature made it, of yellow fever, typhus and dysentery, and now made immeasurably more deadly by the multitudes of people who crowd thither."

Colonel Gargas estimates the number of deaths that took place during former times at 22,000, all preventable diseases, and all among laborers attempting the task that this Government is about to complete.

I refer to this as an example of modern movements in the way of preventive medicine. It explains very forcibly what this subject means to this and all other countries and behooves us to be ready to grasp any and all remedies that tend to annihilate and prevent such death dealing diseases.

Bacterial and vaccine therapy constitutes only a single phase of this subject, and hence it is difficult to discuss this without referring to other things equally important. One phase of this treatment I wish to mention only to condemn that is, the "rheumatism phylacogen." We don't know the etiology of any form of rheumatism and when we use a conglomeration of bacterial products that we know nothing about nor what the effect will be on our patient, I believe we are practicing empiricism and should steer clear of such remedies. In the first place the dose is so bulky and must be repeated so frequently that most patients will not permit its use. Secondly, the reaction following its administration is so intense in some patients as to cause alarming symptoms. It seems to cause a severe shock to the whole system in some cases and even death in some, so if we had any assurance of a cure it would be a question whether or not to use it. I used it in one case with good results, but am now afraid of it and would insist on leaving it out of the rheumatic remedies.

Bacterial vaccine therapy might be compared to drug medication in a sense, for if we know the physiological action of a certain

drug and find a disease that we know it to be indicated in, we will usually get the desired results. But if we know nothing of the action of a remedy and are not familiar with the etiology of the disease in question we can't hope for brilliant results. Just so with bacterial medication. We must first understand if possible the prevailing organism present, and then choose the appropriate vaccine or baeterin.

It was formerly taught that most all the cases of infection of a severe type were of the streptococcus variety, but this is not the case, for some very severe infections are of the staphylococcus strain, or perhaps many different varieties of cocci may be present. So it is the skilful use, and not the abuse of these remedies that should interest us most.

NEWS ITEMS AND COMMENTS

It is a pleasure to note that the Pitman-Myers Company of Indianapolis has changed its name to the Pitman-Moore Company. This is in evident recognition of the effective work and high standing of the President of the Company, Mr. Harry C. Moore. The Pitman-Moore Company is one of the best of the pharmaceutical houses. The inspectors of the State Board of Health have especially found that their thymol and soda capsules are the most effective of any they have been able to secure. The JOURNAL predicts a useful and successful future for the Pitman-Moore Company.

Dr. John A. Jones, aged seventy-six, a physician of Calvert City, Marshall County, died on April 15th after a short illness of pneumonia. He had been a member of the Kentucky State Medical Association and of his county society for many years and his death will be lamented not only by the members of this Association and his large clientele but by his many friends throughout the State.

At the home of Hon. John W. Sisco, on Thursday evening, January 29th, there were united in marriage two of our most popular young people in the persons of Dr. Charles McClure, of Cox's Creek, this county, and Miss Mary Sisco, of Bardstown. Dr. McClure is one of our most active, energetic, popular and prosperous Nelson county doctors, and numbers his friends by legions. To say that his bride, Mary Sisco, is popular is only a mild expression: to know her is to love her. Her joyous greeting coupled with her sweet smile, which she gave to all who met her, made her a universal favorite we predict for such a union a happy life and from our heart we hope that our prediction will be true.

THE FORUM

JOHN G. CECIL.

TO THE EDITOR:

It was with deep regret that I heard of the death of my classmate and friend, John Giles Cecil.

In September, 1877, we entered the Hospital College of Medicine, Louisville. In a short time we were friends. For the spring term of lectures of 1878 a free scholarship was offered to the two first course students standing the best examination on all branches. Dr. Cecil and I got the appointments. By this time we were the best of friends, he calling me Jodie and I calling him Johnny.

At the beginning of the fall and winter term of 1878, each of us knew that the first prize of the faculty for the best standing on all branches would be won by one of us but our friendship remained the same. I do not believe either of us ever had an envious thought against the other. But Johnny got the medal.

On the night of the 26th of February, 1879, at the Public Library Hall Johnny was awarded the first medal. When the curtain dropped, I was the first to congratulate him on his success and there was no envy or soreness in the congratulation; for I knew I was beaten by one who had contended for the prize and that he was worthy of it in every respect.

Miller, LaBrey, Gilmore, Mothershead, McKinley, Cecil, and perhaps others that I have not heard of, of the class of 1879, have passed into the waiting room of the Great Physician.

The members of the faculty that signed their names to the diplomas of the class of 1879, Frank C. Wilson and Dudley S. Reynolds are all that are now living.

"My heart's desire and prayer to God," is that "When the mists have cleared away," and "the roll is called up yonder" that we will meet 'over there.'"

I offer this as a tribute to my departed friend and classmate.

J. F. JONES.

Hospital Architecture.—R. E. Schmidt, Chicago (Journal A. M. A., January 24), sketches the construction and architecture of the ideal large charity hospital in all its departments from the administration building down to the garbage incinerators. The article is not capable of a brief abstract as it is all details, but it is worth reading as a contribution, the result of a careful study of the subject.

MEMORIAL ON THE LIFE OF DR. THOMAS OVERTON MEREDITH, HARRODSBURG, KENTUCKY.

Dr. T. O. Meredith was the son of Dr. Joseph Shelton and Marsella Meredith, was born August 3rd, 1863, in Goodland County, Virginia; died January 30th, at Rochester, Minnesota. He received his literary education in the country schools of Louisa County, Virginia, and in private schools; his medical education was received in Baltimore, Maryland, at the Baltimore Medical College. His resources were meager and he took the four years' course in two years, receiving the highest marks and medals in most classes and second highest in others, and was graduated in 1887. He took post graduate courses with Mayo Brothers. As a private citizen he helped organ-

DR. T. O. MEREDITH

ize the Citizens Bank of Burgin, Mercer county, Kentucky, at first called the Farmers' Bank and was its President about fifteen years, when he resigned, having moved to Harrodsburg, Kentucky. He was Mayor of Burgin many times, was nominated and elected with no effort on his part.

Dr. Meredith was instrumental in building the public school building, and after enlarging it including a high school, and also helped to build the town water supply and improve the general health of the town and was interested in all the progressive improvements that benefited the community. He was a member of the Knight Templars, Knights of Pythias, Macabees and Woodmen. He was a railroad surgeon for both the C. N. O. & T. P. and Southern Railroads, while he lived in Burgin, and also in Harrodsburg, and read many papers before the conventions of Railroad Surgeons, and was President of the St. Louis and Louisville Division of Southern Rail-

road Surgeons, and was a member of the Kentucky Railroad Surgeons' Association, Mercer County Medical Society, Central Kentucky Medical Association, and its President; member of the Kentucky State Medical Association and was a devout member of and elder in the Presbyterian church; was married twice; his first wife was Miss Mary Ella Rinehart, of Covington, Va., his second wife, Miss Mary A. Rice, of Burgin, Ky., and was blessed with seven children, Mary Ella, Lucille, Virginia, Alide, Elizabeth by his first wife, and William Rinehart, Joseph Shelton and Ann Overton by his second wife.

Dr. Meredith was specially congenial and companionable, an affectionate, devoted and exemplary husband and father; his home life was well regulated and ideal, no favoritism was shown to any one member, but all treated alike, he was patient, forbearing, kind, and just and gentle to all within and without the home circle, with whom he daily came in contact. He tried to live an ideal Christian life, a loyal Kentuckian and American citizen; he honored and blessed every station of life he occupied; and it can be truly said of him that those who knew him best honored and loved him most. He was a living example to pattern after, his last letter to his children from Rochester, Minn., the day before he was operated, upon was replete with affection, devotion, solicitude and love for their happiness, success and welfare and is indeed truly pathetic and with an abiding trust in the Great Physician who doeth all things well.

The following eulogium is from the pen of Dr. Steele Bailey, Robinson, Utah:

Dr. Meredith had a wide and extensive practice during his professional career of over twenty-seven years, a large share of the most important cases coming under his care. His knowledge was well-grounded in principles, his perception quick, and his action prompt. His interest in the affairs of his profession was very keen.

He was one of the early members of the Central Kentucky Medical Society and was a constant attendant of its meetings.

He presented numerous reports of cases and pathological specimens occurring in his practice, and a number of papers on medical and surgical subjects came from his hands, expressing his ideas with great accuracy in plain English.

He was unusually liberal in his views of medicine and kindly charitable to all practitioners.

Professionally he stood high among his conferees, and socially he occupied an enviable position. His family relation brought him into influential connection with some of the best families in the county, and his domestic relations were peculiarly happy.

Comparatively early in his professional life

his practice became lucrative; he lived with wise economy and acquired an abundant competence.

As a member of this society his record was clear and convincing.

His ambition was to gratify those he served, and in the performance of his duties his sound sense and conservative views on all questions won for him the respect and esteem of his colleagues.

He has left behind him the memory of a noble character worthy of our emulation.

S. BAILEY,
J. TOM PRICE,
J. G. CARPENTER,
Committee.

COUNTY SOCIETY REPORTS

Breathitt—The Breathitt County Medical Society met March 13, 1914, in Jackson, and elected the following officers for the year 1914:

President, O. H. Swango; Vice President, Wilgus Bach; Secretary and Treasurer, Earl Mooreman.

EARL MOORMAN, Secretary.

Caldwell—The Caldwell County Medical Society met at the city hall in Princeton on Thursday, March 12, 1914, with the following in attendance: L. J. Spickard, Fredonia; L. O. Young, Cobb; Frank Walker and W. P. Morse, Farmersville; R. W. Ogilvie, C. J. Pollard, P. R. Shelby, J. M. Moore and W. L. Cash, Princeton.

The meeting was called to order by the president, C. J. Pollard, and the minutes were read by the secretary, R. W. Ogilvie, after which they were adopted.

This being the first meeting the Society had held within a year, the election of officers was called for. A few talks were made, advocating the election of new men for each of the offices of the society, and in keeping therewith the following officers were elected for 1914: President, L. J. Spickard; Vice President, J. Z. Barber; Secretary-Treasurer, W. L. Cash; Delegate to State Association, J. M. Moore; Alternate, Frank Walker; Board of Censors, L. O. Young for three years, and W. P. Morse for one year.

The society adjourned to meet again on the second Tuesday in April.

W. L. CASH, Secretary.

Christian—The Christian County Medical Society met in the Avalon, Hopkinsville, Tuesday, March 17th, at 12 o'clock with the President presiding.

There were present 34 members, 6 dentists, 1 druggist and the Rev. L. B. English.

At 12:30 we were invited out to dinner, that had been previously arranged by our popular launderer, Mr. T. L. Metcalf. After thanks we did justice to a three course dinner followed by

an after dinner talk by H. C. Beazley as spokesman for the society and address by Rev. English, his subject being "Brotherhood of Man."

After reading and adoption of the minutes of the last meeting and transaction of some new business the chair entertained a motion from Dr. Keith, seconded by Dr. Bell, for the chair to appoint a committee of not more than two to receive contributions from the members to be spent by the committee in presenting Mr Metcalfe a token of our appreciation of his kindness. Motion passed unanimously and each member freely contributed \$2.00.

J. A. Barker, Perkins, Williams and Barnes all presented clinical cases for diagnosis. All the cases received close examination and were freely discussed.

D. B. Roach read a very interesting paper on Sero-Diagnosis and illustrated his paper with black board drawings. The discussions of this paper proved that it was a live paper on a live subject.

Owing to the lateness of the hour we adjourned leaving the balance of our program for the next meeting, the third Tuesday in April.

W. S. SANDBACH, Secretary.

Daviess—The Daviess County Medical Society met at the City Hall on Tuesday, March 17th.

The President, Dr. J. M. Stuart, presided and forty-eight members were present.

C. M. Rice presented a transfer card from the Hancock County Medical Society, and was admitted to membership.

R. L. Foster, who lately came here from Oklahoma, was admitted to membership.

F. M. Sherman reported a case of facial paralysis. An interesting discussion followed. Some took the ground that treatment would do no good; others thought it would—all gave a favorable prognosis.

A. McKenney reported a case having periodic fever, but quinine did no good.

Ed Barr reported a case of double tubal pregnancy. Both tubes and ovaries were removed, but woman still menstruates regularly.

F. A. Miller reported case of man who fell suddenly in convulsion. Had never before had symptoms but urine was loaded with albumen.

J. T. Dixon read a paper on "Some Problems in Infant Feeding." Quite an interesting discussion followed in which Ed Barr, J. L. Carter, J. W. Ellis, C. H. Todd, W. E. Irvine, and J. W. Barnhill took part.

R. L. Schroeder read a paper on "The Laboratory Methods the General Practitioner Should Use." Discussed by C. M. Rice, J. T. Dixon, J. Glahn, O. W. Rash, W. T. Stirman and A. McKenney.

J. J. RODMAN, Secretary.

Harlan—The Harlan County Medical Society met in the office of the Secretary. No papers were read but several subjects were discussed.

The society meets the first Monday in each month.

WM. M. MARTIN, Secretary.

Henderson—The Henderson County Medical Society met in regular session at Henderson on January 12th, 1914:

The President, W. A. Poole, made a short talk in which he outlined the work of the club for the ensuing year.

D. O. Hancock handed in his report on the Annual Banquet in which he stated it was a great success in every particular.

P. Ligon made his report as retiring secretary and treasurer. The report showed the finances to be in good condition.

Thomas Sellars made application for membership in this society, and his application was referred in the regular way to the Board of Censors.

D. O. Hancock presented two cases of hare-lip that had previously been operated upon and then read a paper on "Hare-lip" which was very interesting. The following doctors took part in the discussion: Cyrus Graham, W. S. Galloway, W. A. Poole, B. J. Neary, and D. O. Hancock closed the discussion.

B. J. NEARY, Secretary.

McCracken—At the annual meeting of the McCracken County Medical Society held December 19, 1913, the following officers were elected:

O. R. Kidd, President; E. B. Willingham, Vice President; Delia Caldwell, Secretary; H. P. Lewis, Treasurer; Vernon Blythe, Censor; H. G. Reynolds, Delegate for 1914 and 1915.

As this was a called meeting for the election of officers, the regular meeting falling on Christmas eve, there was no other business.

DELIA CALDWELL, Secretary.

McCracken—McCracken County Medical Society met on January 14th at the Woman's Club. After interesting reports of clinical cases by Drs. Vernon Blythe and C. E. Purell, the society adjourned to the dining room where a delightful banquet was served. Covers were laid for twenty.

DELIA CALDWELL, Secretary.

Owen—The Owen County Medical Society met at the office of Drs. Foster and McBee, on March 5th. All members present except one.

The meeting was very interesting from beginning until adjourned.

G. Purdy gave an excellent talk on "General and Local Treatment of Chronic Catarrh of Nose and Throat."

The discussion was led by W. E. Foster.

A. E. Threlkeld read a very interesting paper on "Early Diagnosis of Pregnancy."

This was followed by a general discussion.

Meeting then adjourned to meet with J. W. Botts, the first Thursday in April.

J. H. CHRISMAN, Secretary.

Pendleton—The Pendleton County Medical Society met at the office of John E. Wilson, at Butler, Ky., with the following members present. Beckett, Blaydes, Brown, Daugherty, Eekler, Ellis, Hopkins, Kendall, John E. Wilson, J. Ed Wilson, Woolery, Yelton, J. A. and J. H. Caldwell, of Newport visiting. The meeting was called to order by Dr. W. H. Yelton in the absence of the President.

This was Tuberculosis Day and **John E. Wilson** read a paper on "Diagnosis of Tuberculosis."

S. M. Hopkins read a paper on "Prevention of Tuberculosis."

T. T. Eckler read a paper on the "Treatment of Tuberculosis."

These papers were very thoroughly discussed by nearly every member present, and all seemed to enjoy the papers and discussion thoroughly. We also had a splendid report of clinical cases. This meeting was enjoyed by all present.

W. A. MCKENNEY, Secretary.

Shelby—The Shelby County Medical Society held its regular monthly meeting in Shelbyville, Thursday, March 19th, with the following members present: Drs. Hughes, Morris, F. M. Beard, Holt, E. B. Smith, J. N. Smith, Buckner, Lawrence, Nash, Berryman, Sellers and Allen. In the absence of the President, Lowry Beard, J. N. Smith presided. The essayist, Dr. Jones, not being present an informal session was held in the forenoon.

At high noon the society sat down to an elegant dinner, the conception of our homeopathic brother, E. B. Smith, who for once laid aside his well known tendency to serve out portions in infinitesimal quantities and outdid his allopathic brethren in the number and variety of well prepared and elegantly served viands, all well ahead of their season. The amplexness of this feast was only surpassed by the enjoyment of those fortunate enough to be present.

V. R. Jones, coming in during dinner, read, at the afternoon session, his paper on "LaGrippe." This paper was an unusually good one and showed serious thought and extensive research on the doctor's part in its preparation. Its appreciation by the society was shown in the very full and animated discussion which it brought out, nearly every member taking part.

W. E. ALLEN, Secretary.

Warren—The Warren County Medical Society met in the Council Chamber on January 14, 1914,

with the following members present: Drs. T. W. Stone, Briggs, V. U. Moss, Lewis, Strother, Simmons, Hall, Blackburn, South, London and Rutherford.

The house was called to order by the president, T. W. Stone, who made an interesting talk in which he expressed desire that each member would contribute his part to making this a successful year of our meetings, and advised that in the production of our papers that we not copy from text, but to rely largely on our personal experience with the diseases upon which we write.

The secretary then read the minutes of the last meeting which were approved by the house. A motion was then made and carried that each essayist be limited to twenty minutes in reading his paper, the member who opened the discussion to ten, and other members to five minutes each.

There being no other business the house then took up the regular program of the meeting, which was as follows:

J. H. Strother on "Lobar Pneumonia in Children," and **J. F. Rogers** on "Broncho Pneumonia in Children." The discussion to be opened by **V. U. Moss**.

J. H. Blackburn on "The Indications for Operation for Gall Stones," the discussion to be opened by **A. T. McCormack**.

Dr. Strother was not present.

J. F. Rogers read an interesting paper on the subject, "Broncho Pneumonia." The discussion was opened with a very practical talk from V. U. Moss. He laid particular stress upon the gravity of the disease and from his years of experience was able to give us valuable advice in regard to its treatment, after which each member of the society interestingly discussed the subject.

J. H. Blackburn then gave an interesting talk on the "Indications for Operation for Gall Stones."

A. T. McCormack not being present the other members of the society proceeded to discuss the subject.

A motion was made and carried that a committee of three be appointed by the President to arrange a program for the next meeting. Drs. Reardon, Blackburn and Rutherford were appointed.

Although the entire program was not rendered on account of the absence of two of the essayists, we had a very interesting meeting.

There being no further business to come before the house, a motion was made and carried to adjourn.

B. S. RUTHERFORD, Secretary.

Tapeworm.—Treatment. Thymol in cachets of 0.25 Gm. (4 grains) to be given in the morning on an empty stomach for eight days. Worm usually expelled on third or fourth day. Twenty-three cases treated with success. All alcohol to be stopped during treatment.—Artault.

\$2.00 YEAR

TOBACCO, ITS EFFECT ON LONG-EVITY.

By E. S. FREY, Louisville.

It has been said that some very brilliant members of the Jefferson County Medical Society, men in the zenith of their career and usefulness, have met an untimely death, caused by direct or indirect over-indulgence in the use of tobacco.

The use of tobacco in its various forms is so general that the subject is of almost universal interest. The smoker may not be willing to give up his indulgence, but he is entitled to know its dangers, while educators and others who have anything to do with the young, whether by example or by precept, will appreciate scientific facts with which to back up proper deductions from experience.

Columbus was the first European to discover tobacco. When he and his companions saw the Indians smoking it, and blowing the smoke through their nostrils, they were as much surprised as they had been at the first sight of land. Sir Walter Raleigh, in the sixteenth century, found tobacco on the plantations of Virginia, and introduced it into England and Ireland.

Tobacco was formerly used as an infusion in the treatment of dropsy, in spasmodic asthma and the paroxysms of difficult breathing in emphysema. Five drops doses of wine of tobacco was a popular remedy for hiccough and an enema of tobacco was a very effective remedy in the treatment of tetanus. In the form of an ointment, tobacco was used in prurigo and scabies. But so many unfortunate accidents have resulted from the external

and internal applications of tobacco, that other remedies have taken its place.

Tobacco contains a powerful alkaloid, *nicotine*, in combination with malic acid. It is an oily, colorless liquid, strongly alkaline in reaction. Its taste is hot and acrid, and its odor peculiar and disagreeable.

Lee, in his analysis of tobacco, found in smoke from 100 gms. of tobacco 1.165 gm. of nicotine, 0.146 pyridin and collidin, the former derived from the destruction of a portion of the nicotine, the latter from combustion of the fibre in the tobacco. In addition there is H. C. N. 0.08 gms. ammonia 0.36 gm. Carbon monoxid; the vapor of tobacco contains numerous basic substances of the pycolinic series, and cedes to caustic potash, hydrocyanic acid, sulphureted hydrogen, fatty acids, phenol, creosote. Also aldehyds, particularly aldehyd furfurol. The smoke of a single Virginia cigarette, according to Langet experiments, may contain as much furfurol as is present in two ounces of whiskey.

Strychnia is according to Houghton, a true physiological antagonist. Ergot, digitalis, belladonna, ammonia and alcoholic stimulants, antagonize the effects of tobacco on the heart and arterial system.

Tobacco is a decided motor depressant, a severe and very depressing nauseant and emetic, it is locally an irritant to the mucous membrane, and produces burning pain at the epigastrium. The emetic effect is due to three factors—its cerebral action, its local irritation of the gastric mucous membrane, and third, its specific emetic property. Its active principle, nicotine, diffuses into the blood with great rapidity. It corresponds in the mode and intensity to hydrocyanic (or Prus-

sic) acid. In two cases narrated by Taylor, a fatal result ensued in three minutes and five minutes after a toxic dose. Death comes through its paralyzing action on the muscles of respiration.

The amount of nicotine inhaled during smoking depends not so much upon the tobacco smoked, as upon the form in which it is smoked. The greater the condensation area between the point of combustion and the entrance into the mouth, the more nicotine will be inhaled.

Tobacco differs widely in its action upon different individuals, and no sweeping statement can be made. Smoking raises the blood pressure by vaso constriction, accelerates the heart and respiration, and increases the intestinal movements. This explains the pleasure so large a number of people take from the use of tobacco. They claim it increases the mental energy and output, and in some measure augments the power of judgment by exciting the nerves of the brain. The moderate smoker, thus defends his stand, but he can not long content himself with a few puffs daily. The quantity of tobacco, is increased, more stimulant is needed, the habit is established and this veritable poison now holds you as a slave.

Gastro intestinal derangement now manifest themselves. Gastric hyperacidity is one of the early symptoms of nicotine poisoning. The various derangements of the stomach accompany the excessive use of tobacco seem to be productive of cardiac neuroses and we have the "tobacco heart."

Inhalation of tobacco smoke often excites a bronchial catarrh. It is pointed out by some, that the mere breathing of an atmosphere laden with tobacco smoke from the smoking of others is almost as bad as direct inhalation. One often sees nicotine poisoning in people who have been in such an atmosphere without not having been smoking at all themselves. Tobacco is responsible for chronic gastritis, chronic rhinitis, in acute and chronic pharyngitis and laryngitis.

Many prominent authorities tell us the continued use of tobacco has a causative effect upon arterio sclerosis and cancers of the lip, mouth, pharynx and larynx.

President Grant, and Emperor Fredrich, the present German Emperor's father, both died of laryngeal cancers, and eminent physicians tell us both were excessive users of tobacco. No doubt this was the direct or indirect cause of those malignant growths.

The rock on which the treatment of these conditions most frequently depends, comes to grief, namely the unwillingness of the tobacco user to pay the price of his recovery in self restraint and self denial.

Every physician of experience well knows how such patients will use every argument to induce the physicians to believe that the latter is mistaken in his judgment, that smoking never hurt him, that he is in reality a moderate smoker, that his digestion is greatly improved by smoking, his teeth preserved, that it disinfects, etc.

Man is always ready to impair his physical constitution provided he can strengthen his intellectual sentiment thereby. Undoubtedly many tobacco users have lived to a great old age; that they might have been healthier and longer lived without the use of tobacco is quite probable. It is also a well known fact that many of the most useful old men of the world have been abstainers from tobacco, and it is also a fact that men, whose physical power and endurance was tremendous, were non-users of tobacco.

Constant, relates of Napoleon, that he once took a fancy to smoke for the purpose of trying a very fine Oriental pipe, which had been presented to him by a Persian ambassador. The lighted pipe was handed him. But scarcely had he drawn in a mouthful, than the smoke penetrated into his throat and he said in disgust, "Take that away from me!—my stomach turns." He renounced forever the pleasure of a habit which he said was only fit to amuse shuggards.

When asked if smokers were desirable members of his Polar expedition, Commander Robt. E. Peary replied. "As for taking a man with me who is dependent on the use of tobacco, I should as soon think of taking a man who had to have pie."

Every athlete knows that tobacco hurts his wind. Sharpshooters and riflemen know that their shooting is more accurate when they do not smoke. A great billiard player, who does not smoke, once assured me that he felt sure of winning when his opponent was a smoker.

A tennis player began to smoke at the age of 21 and found that men whom he had before beaten with ease, could now beat him.

The habit of chewing tobacco and using it as a snuff and as a dip is probably much less common than smoking, but it has all the bad feature of the latter and is certainly much more offensive. Indeed the bad effect of tobacco on the physical and mental development of children is so well known that the law of many states make its sale to children a misdemeanor, punishable by fines and imprisonment. Doctor Seaver, Director of the Physical Laboratory at Yale, tabulated the record of the students entering that university during nine years; all the young men were examined and measured. The smokers averaged 15 months older than the non-smokers. They were also shorter in stature. Nicotine interferes with growth, and its effect in that re-

gard is very measurable. At Yale, during the four year course, the non-users of tobacco, although taller when they entered gained 25 per cent. more in height and 26 7-10 per cent. more in girth of chest than do the habitual users. Doctor Hitchcock, of Amherst College, found even greater differences. The difference in the lung capacity is very striking in the two classes, and has been noted by all observers. It shows the effect of tobacco on the respiration, nicotine being a potent motor-depressant. As regards the effect of tobacco on the mental processes (it is more difficult to interpret the meaning of statistics. Out of the highest scholarship men at Yale, only 5 per cent use tobacco; while of the men who do not get appointments, 90 per cent. use it.

The symptoms of tobacco intoxication are, vertigo, somnolence, disturbed capacity for intellectual effort, abnormal moods, amblyopic symptoms, neuralgia, uncertainty of movement, a form of ataxia, tremor, muscular contractions, irregularity of heart action, or palpitation, emaciation, bradycardia, insomnia, amnesia, transitory aphasia, disturbance of judgment, etc. A true and characteristic psychosis, having origin in tobacco intoxication is fairly well established, according to Kjellberg, Schwartz, Frankl, Hochwart. It is observed that the true psychosis is invariably found in excessive and prolonged users of tobacco. With reference to the nervous complexes, due to the abuse of tobacco, there is noted, among very excessive smokers, a premature mental weakness, a kind of senility at an age around 50 when such organs are infrequent. There is no extreme dementia, but rather a certain reduction of the mental horizon, a distinct decrease of energy. Frankl, Hochwart cites the case of a physician, "aged 40, a great smoker of cigarettes, whose memory had become so defective as to lead to the commission of serious errors in his practice."

A physician, a healthy man of 31, whose first attempt at smoking began at 5 years of age and who finally became a very excessive smoker, noted suddenly, in his 28th year, that his memory for names became very deficient and he developed a tremor.

The internal revenue report shows that the use of tobacco is on the increase. During three months of 1912 in the United States, 3,800,000,000 cigarettes and 1,950,000,000 cigars were consumed. It is therefore seen that in spite of the public school instruction as to the physiologic action of tobacco and its dangers and in spite of the anti-tobacco leagues, the consumption of tobacco is enormously on the increase.

Professor Huxley said, "For forty years of my life, tobacco has been a deadly poison to

me." God does not fix longevity. Who does them? We all do. We have not the right to blame a cruel deity for untimely deaths, which are actually due to carelessness and bad habits, pernicious in character, and a refusal to exercise the common sense which is also an inspiration from the Almighty.

Let us keep up with scientific progress, let us as medical advisers, practice what we teach. The public looks to us to lead them by example and precept in all matters of health and prevention of disease. Let us shun this habit of using tobacco, which pollutes the body and shortens longevity. Lovers of perfect health and longevity, should beware of a custom and habit that has injured many others and will impair their bodies and shorten their span of life. Let us say with Charles Lamb:

Farewell to tobacco, the
Stinking 'st of the stinking kind,
Filth of the mouth and Fogs of the mind,
Africa, that brags of her foison,
Breeds no such prodigious poison,
Henbane, Night-shade,
Hemlock, Aconite—nay
All four cannot excel tobacco in a pernicious way.

DISCUSSION.

Leon L. Solomon: The doctor's paper is so scholarly and concerns a subject that affects so many of us, that it appears to me a serious word in discussion of it will not be amiss.

If I may be permitted to refer to a question asked by a previous speaker, I would say that when the essayist referred to tobacco as a central emetic, he meant in contradistinction to its action as a local emetic. If I am not correct in this, I will be glad to be set straight. Rarely does an individual smoke tobacco for the first time without experiencing more or less nausea, which occurs, as a rule, immediately, or shortly after he begins to smoke—shortly after he takes the cigar or pipe into his mouth. This is probably the result of reflex action, from the mouth to the gastric nerve endings, but the central emetic action of tobacco is apparent almost immediately after the nicotine is introduced into the blood; the vomiting center is at once affected, and the emesis is more pronounced and more protracted than that which follows the administration of apomorphia.

I think this is a most important subject and one deserving the intelligent consideration of the Jefferson County Medical Society. It is my belief that there would be very much less smoking if men began to smoke after they became men, and then experienced for the first time the nausea and vomiting that almost invariably accompanies the first cigar. The habit is usually formed during boyhood, and the individual soon forgets the

emesis, general relaxation and weakness that follows the first smoke. I recall my first smoke, in which I indulged, clandestinely, of course, when I was a lad of about fourteen years. That was before cigarettes were as generally used and as easily procured as they are to-day. I smoked off and on, though not to any great extent, until I attained the age of twenty-three or four, when I went to Germany and, cigars being so cheap there, I began to smoke cigars, as a student, and smoked continuously and excessively. I want to say right here that any man can quit smoking if he so desires, just as readily as any man can quit alcohol if he so desires. I threw my cigar into the water as the boat was leaving on the return trip. The reason I quit smoking was because I had in mind taking up the study of pediatrics, and I do not know of anything more objectionable to invalids and children than a tobacco-laden breath; in fact, a breath smelling markedly of tobacco is offensive to a great many adults—it is to me.

Just how much tobacco a given individual may smoke with impunity is impossible to determine. I know a lawyer of repute, a man about forty years of age and a bachelor (and they say that bachelors smoke more than married men) in whom three cigars a day will have a marked influence upon his ability to argue a case or prepare a brief; it also has a pronounced effect upon the rate and volume of his pulse: I think the essayist has most beautifully illustrated the effect of the use of tobacco upon men who do brain work in his citation of the statistics of various universities. Unquestionably the first influence of tobacco is the stimulation of the circulation, directly and indirectly. I speak now of the man accustomed to its use, upon whom tobacco has an influence wholly different to that of the man who is not accustomed to it. Undoubtedly this is what keeps many a man wedded to his pipe or cigar, despite the fact that he knows it is doing him harm. I believe we could do lasting good if, as individuals, we would make it plain to our patients that over-indulgence in tobacco unquestionably leads to vessel changes, and to the conditions that are dependent upon vessel changes.

Walker B. Gossett: We all know, of course, that immoderate smoking is injurious, just as immoderate eating and drinking is injurious. I remember the first cigar I smoked, when I was eight or nine years of age, and it nearly killed me. I did not begin to smoke again until I had graduated in medicine. We have very few pleasures in this life, and if we indulge in them moderately, no harm is done. In the morning after breakfast, I light my pipe, read my paper and get a great deal of enjoyment out of it, and I do not believe it does me any harm.

While I was practicing medicine in Missouri, we saw an old man, about ninety-eight years old, who had pneumonia. He had smoked and drunk

to excess all his life, and we felt sure he would die. The old doctor I was practicing with advised not letting him have anything to drink. However, at my suggestion, we finally decided to give him all he wanted to drink, putting a bottle of whiskey by his bedside every morning. He drank about a quart a day and got well. Six months later he was still well.

Of course, we should not indulge in anything to excess, but I do not see any harm in a moderate amount of smoking.

M. Casper: I enjoyed Dr. Frey's paper very much indeed.

A great deal depends upon what one calls moderate smoking. We never see a poker player who ever lost anything, and it is much the same way with smokers,—it is always the other fellow that smokes to excess. Some individuals can stand more smoking than others. I do not believe there is any doubt that a laboring man can stand more tobacco without any apparent or real injury to his system than can a clerical or professional man, who uses his brains. The latter are usually of more nervous temperament, and are more prone to the excessive use of tobacco. The late Dr. Cecil told me on several occasions that he believed tobacco to have been his downfall. From a series of experiments recently carried out in France, it has been pretty conclusively shown that arteriosclerosis is very frequently directly traceable to the use of tobacco.

I believe I could call the names of at least a dozen physicians who stay away from the meetings of the Jefferson County Medical Society for the sole reason that the fumes of tobacco are obnoxious to them. Personally, I have a decided idiosyncrasy against tobacco. As a young doctor, I persistently tried to become accustomed to tobacco, with more or less success, but it always left a disagreeable effect, and I finally gave it up. Whenever I come here to a meeting I absorb enough smoke to give me a headache for the next two days. It also tends to produce nervous symptoms, and as I have a decidedly neurotic temperament, I frequently stay away from the meetings on that account.

Dr. Frey has covered this subject thoroughly and scientifically, and I for one enjoyed it immensely.

David C. Morton: Some of the speakers have said that arteriosclerosis is, in many cases, directly traceable to the excessive use of tobacco. I think that is rather a broad statement. We are too prone to jump at conclusions of that sort. It might be interesting to know that arteriosclerosis is as frequent in non-users as in users of tobacco. Arteriosclerosis is essentially a disease that attacks individuals of a very definite anatomical type, and individuals of that type are prone to develop arteriosclerosis whether they be users of tobacco and alcohol or not. I mention this simply to put the brake on, as it were, on any

such sweeping statement as that the use of tobacco is an essential factor in the development of arteriosclerosis.

In regard to the use of tobacco in this room, I am one of those who smoke, and I am amazed to hear that there are as many as a dozen physicians in Louisville who do not come to the meetings because of an idiosyncrasy against tobacco. We spend approximately two hours here every week and if there is one physician who does not come because he cannot stand the smoke, then I for one say that we should seriously consider the matter and determine whether we, as individuals, will or will not smoke in this room.

Ellis S. Allen: Dr. Frey has gone into this subject very thoroughly and has given us an excellent paper. I do not believe there is a physician who smokes who does not realize that he is doing himself an injury; that he is intoxicating himself, and it is simply a question of who can stand more than another. There is no doubt that a man who uses tobacco and lives to be ninety-eight, would live to be older if he did not use tobacco.

In regard to Dr. Morton's remarks about arteriosclerosis, we know that this condition is the result of thickening of the arterial walls: that the muscles in the arterial walls, upon which the heart's action so materially depends, lose their effectiveness in the presence of arteriosclerosis, and that this is directly caused by intoxication or irritation of the muscle cells in the arterial walls. Wherever we have irritation or poisoning of any cell protoplasm, there is some resistance to the poison unless it is sufficient to kill the cell directly. Repeated poisoning of the protoplasm of the cells will result in thickening, and make the cell respond less sensitively to nerve impressions and impulses. As a result of this constant thickening, the avenues for carrying the blood are constricted; there is a tendency to passive congestion, with deposits of lime salts, which give us a hardened artery. When an artery becomes hardened it throws more work on the heart, and compensation takes place only as long as the arteries can carry sufficient nutrition to the heart. Arterial constriction results in thickening of the heart muscle; therefore, we have deterioration of the cardiac muscle also. So, with a muscle that is not helping the heart, and with a heart that is not receiving its normal blood supply, it is only a question of time until the heart does less and less work, and the patient becomes an invalid, or it causes his death. Take these little streeturchins, who begin to smoke early, they never become fully grown. Why? Because brain and bone can grow only when they receive a definite amount of nourishment. These individuals have early arterial changes, with the result that these structures receive an insufficient blood supply and cannot grow; the arteries cannot expand and feed them. It is a well known

fact that an athlete who has by training developed wonderful muscular ability, if he stops training and then tries to train again, he cannot attain his previous condition, simply because the arteries have not contracted but have remained stationary. They have lost their elasticity and the heart, not getting the proper amount of nutrition, cannot hypertrophy.

Personally I am very fond of smoking. My brother, who conducts the laboratory was absent for a week or two recently, and I did his work. I felt the need of something stimulating, so I opened a box of cigars and I believe I smoked twelve in one afternoon, and I was about half crazy for the next two days.

Milton Beard: I do not know that I am personally qualified to talk on this subject in view of the fact that I have never yet smoked a cigar or taken a chew of tobacco, but I have had many opportunities to observe people who did. I agree with Dr. Solomon and Dr. Casper that the use of tobacco is particularly harmful to the nervous system. As an organization and as individuals, the members of this Society should endeavor to teach the public and teach them right. The use of tobacco, and particularly in the form of the cigarette, which has come into such general use, is very harmful in the young. It is harmful for several reasons. These individuals begin to smoke while very young; they begin when the propensity to do anything conservatively is not very strong. Furthermore, cigarettes, perhaps, contain more of the alkaloid than does tobacco in any other form. It is a matter of fact that neither the Government school at Annapolis nor at West Point will receive as a pupil anyone who is addicted to the use of cigarettes. It is also a matter of fact, as we who are accustomed to treating drug habitues know, that there never was an individual addicted to cigarette smoking and the use of morphin, who was cured of the morphin habit, who did not also quit smoking cigarettes. It is utterly impossible to successfully treat the drug habit unless the tobacco habit is given up also, and these individuals must avoid the use of tobacco if they expect to remain cured of the drug habit.

The use of tobacco is a baneful habit, if habit it is. From a neurotic standpoint, it sometimes acts both as a cause and as an effect. An individual with some nervous trouble will smoke perhaps twenty or thirty cigarettes a day. The cigarette smoking predisposes to nervousness, and the nervousness in turn predisposes to the more excessive use of cigarettes. Thus it acts both as a cause and as an effect, and oftentimes does a great deal of harm.

W. F. Boggess: There is no question but what nicotine is a poison; there is also no question but that different individuals are affected differently by that poison, according to the individual's susceptibility. One man may smoke twenty or twen-

ty-five cigars a day and apparently not feel it, while in another one cigar may produce a distinctly toxic effect, just as one person may drink eight or ten cups of coffee a day and never feel any bad effects from it, while another may drink one cup of coffee and be kept awake all night. However, while the susceptibility of the individual plays an important part, there is no question but that every man who smokes constantly is getting a bad effect on the heart, the nervous system and the blood vessels. I used to smoke twelve to fifteen strong cigars a day, until I found that my heart was beating 120 and skipping every fourth or fifth beat. I have not smoked for ten years, but I have a crippled heart—a heart that was only functionally disturbed at first but later became organically affected. I have no high blood pressure, but I am sure that my life has been materially abbreviated by the amount of smoking I formerly indulged in.

Nicotine is a poison, and one that frequently leads to the use of other drugs to bolster it up when the individual fails to get the desired effect. When any man becomes dependent upon any artificial stimulation or sedative for normal action, he has reached the danger point; they are apt to go from one thing to another, and they suffer mentally, nervously and physically.

Dr. Allen is right when he says that any toxic agent will produce arterial changes. There is no question but that the use of tobacco will lead to arteriosclerosis and changes in the cardiac muscle. I do not agree with Dr. Morton that a man to have arteriosclerosis must be anatomically predisposed to that condition; it is almost invariably the result of a toxic condition—either auto-intoxication caused by faulty metabolism, or due to the constant inhibition of nicotine, alcohol, or any other toxic agent. The constant use of tobacco by a laboring man is not as positive in its effect as in a man of sedentary habits. A working-man with a good strong constitution and nervous system can stand considerably more nicotine, without any apparent effect, than can a man who does office work, or who leads a sedentary life.

No drunkard, morphin habitue or tobacco-user ever acknowledges that he indulges in more than a moderate amount. "Moderate" is too indefinite a term to use. Therefore, if we, as medical men, desire to indulge in these things, we should be perfectly honest about it and say that, while we know they are doing us harm, we are willing to take the consequences for the pleasure they give us. Nevertheless, the fact remains that nicotine is a poison and, when constantly put into the system, it will produce structural changes and be a potent factor in the production of premature senility, if you choose, or in producing changes in the arteries and blood vessels that will tend to shorten the individual's life.

E. S. Frey, (Closing): I simply wish to thank the gentlemen for their generous discussion of my paper.

HISTORY OF TYPHOID VACCINATION.

By PETER S. GANZ, Louisville.

The employment of vaccination for the purpose of producing active immunity against typhoid fever took its origin in the researches of Chantemesse and Widal, in France (1888), Brieger, Wasserman and Kitasato, in Germany (1892) and Bruschettini, in Italy (1892) who proved it possible to vaccinate an animal against fatal doses of typhoid bacilli by previously injecting doses of cultures of the same microbe sterilized by heat, or the soluble products (endotoxins) secured by autolysis from the bodies of the bacteria. In 1896 Pfeiffer and Kolle, in Germany, and Wright, in England, took up the question of typhoid prophylaxis anew. Wright introduced antityphoid vaccination in the British Army, in 1898, and his experience soon became so extensive that he was considered the chief authority upon the subject—in fact, the general use of typhoid vaccination at the present day is in great part the result of his efforts.

The more recent work of Leishman, in England; Pfeiffer and Kolle, in Germany; Vincent, in France, and Russell, in America, has placed the procedure on a firm basis as an effective prophylactic measure.

DOSAGE FOR IMMUNIZATION.

The dosage of typho-bacterin almost uniformly employed for immunizing consists of 500 million killed bacteria for the first injection and 1000 million for each of the two subsequent injections, three injections usually constituting the prophylactic treatment. Russell states that this dose is designated for a healthy man weighing 150 pounds, and is to be diminished for women and children in proportion to their weight.

Reaction of Bacterin. The symptoms following vaccination are usually confined to a slight headache and malaise, and a local reaction consisting of a red and tender area, about the size of a hand and sometimes tenderness in the axillary muscles. In some few individuals there is a more severe general reaction consisting of headache, backache, nausea, vomiting, herpes labialis, and rarely albuminuria and some loss of body weight.

Hatchel and Stoner in analyzing records of 1306 cases found that redness and local tenderness were present in all cases. Malaise followed the inoculation in 775, headache in 635, muscular pain in 106, nausea and vomiting in 60, chills in 57, and rise in tempera-

ture in 884 cases. In 1160, or 56.7 per cent., constitutional symptoms were absent. The temperature following injections ranged from normal to 101 degrees F. in 785, or 38.4 per cent.; 101 degrees F. in 82, or 4 per cent, and in 17, or 0.8 per cent., it exceeded 103 degrees F. In those exhibiting systemic reactions analysis of 874 records showed that the reaction occurred after the first injection in 132 cases; after the second 255; after the third injection 382. After the first and second injections extreme reaction occurred in 59, the second and third in 14, the first and third in 10, and after all three in 33. In 246 of the 884 having a systemic reaction this lasted from 1 to 6 hours in 14 cases; it persisted from 6 to 12 hours in 96 cases it disappeared in from 12 to 24 hours in 89, from 1 to 2 days in 43 cases, from 2 to 3 days in 5 cases, from 3 to 4 days in 6 instances, in 5 days in one; and it lasted over 10 days in two persons.

Duration of Immunity. Russell states that we do not yet know definitely the duration of immunity following antityphoid vaccination. It apparently begins to diminish at about the same time as immunity to vaccination and it is possible that it may last nearly, if not quite as long. "We know also that the immunity is not absolute, for in the year 1911, among 80,000 persons vaccinated in the army there were 12 cases of typhoid with one death," due to intestinal hemorrhage, and in 1910 there occurred 6 cases among the vaccinated, with no fatalities. The fact that the immunity is not absolute is no objection to its use, but is rather an argument for its repetition at intervals to be determined in the future as the lessons of experience become clear, just as we now do in the case of smallpox. We should revaccinate against typhoid fever at the beginning after the third year.

Results of Vaccination. The Surgeon-General of the United States Navy reports that there have been more than 62,000 inoculations with typhoid prophylactic in the United States Navy since January, 1912. Of this number a small fraction of 1 per cent had reaction requiring excuse from duty, and only a small percentage had reactions causing any inconvenience. There were no serious results.

REMARKABLE RESULTS FOLLOWING USE OF VACCINE, IN BRIEF.

82,000 United States Soldiers immunized up to July 1, 1912. The typhoid rate dropped from 3.03 per thousand in 1909 to 0.3 per thousand in 1912. A reduction of 90 per cent.

61,622 British Soldiers immunized in India during 1911. With a death rate of 0.17 per cent.

24,795 Japanese Soldiers immunized in

1909. Death rate 1 case typhoid per thousand.

30,000 persons immunized in Memphis, Tennessee, during the recent typhoid epidemic. About 1 per cent. death rate.

2,044 persons immunized in Baltimore during 1911-12. Not a single case of typhoid fever occurred among these persons.

1,381 nurses and hospital attendants in Massachusetts hospitals were immunized. Only 2 cases of typhoid fever developed.

Typhoid Bacterin in Treatment. In the treatment of typhoid fever with typho-bacterin we are dealing with a problem entirely different from that connected with immunization. Here we have a person already infected. Typhoid bacillus colonies are localized in the intestinal tissues and from these colonies the bacilli find their way into the blood. Agglutinins, opsonins, and bacteriolysins are always present during the course of the disease. Yet that good results have been recurring in numerous cases by the injection of killed typhoid bacilli is now beyond question.

Simple discusses the subject as follows: "Reaction. When dead typhoid bacilli (or vaccines) are injected into the tissues, it is the product of the metabolism of the bacteria which act; and these products are the results of the action of the tissues at the seat of injection. Here we get a localized toxic effect on the tissues, and a consequent local production of bacteriotropic substances, which find their way into the blood. On the other hand, when—as during an attack of typhoid fever—the bacteria are broken up in the blood stream, the liberated toxin is diluted by the whole volume of blood, and served out of the tissues in such a diluted form as only tardily to give rise to an immunizing response. In such a condition we get the full toxic effect, but only a slow immunizing effect or cure, and although a cure does eventually come about.

Russell in his explanation of how typhoid vaccine is beneficial in typhoid fever, adheres to the views put forward by Wright. He holds that the subcutaneous tissue produces antibodies freely, and that, as it is not ordinarily involved in typhoid fever, subcutaneous injections of vaccine in this disease do good by throwing this unused centre into action. Wassermann and Citron as the result of their experiments on rabbits with dead typhoid bacilli injected subcutaneously have also arrived at this conclusion.

Dosage and Administration. The dosage of typho-bacterin used in the treatment of this fever is different from that employed in immunization. As a general rule, a smaller initial dose is employed (from 50 million upward) and the subsequent doses is given at

shorter intervals from 3 to 5 or 7 days, are governed by the effect of the first dose.

Meakin and Foster seem to have used the largest doses. In 41 cases treated their initial dose was 1 billion. Eight days later a second dose of 1,500 million was given and at the end of the second period of 8 days, if it was found necessary, a third dose of 2 billion was given. In many of the cases the fever terminated so rapidly as almost to be by crisis.

Callison reports a collection of 323 cases of typhoid fever treated with vaccine with 17 deaths and 20 relapses.

My personal experience in the treatment of typhoid fever was as follows:

I treated ten (10) cases in all, eight cases treated with bacterin with beautiful results. Every case reaction set in after the first injection of 125 million bacterin, temperature dropped gradually in 36 hours from one to two degrees. In from three to five days another 250 million germs were used, the temperature gradually became normal and all remained so, the typhoid facia disappeared, the delirium cleared up, tongue, which was heavily coated, cleansed, all patients became violently hungry and were on the road to recovery. In all these cases the bowels were emptied by enema every other day, when temperature remained normal for eight days, feeding of soft food was begun and as conditions allowed was increased. No relapses occurred in either case, one case was complicated with lobar pneumonia which died in the second week, no benefit from the bacterin. One case in which bacterin was used had intestinal hemorrhage, no effect from bacterin no reaction on account lesion.

I do not believe that bacterin should be used during third week in stage of intestinal ulceration. The bacterin should be used as early as possible for the best results from serum. In no case have I had unpleasant symptoms to follow the use of bacterin.

I wish to mention four cases complicated with bronchitis. Recovery.

The injections were made in the skin on deltoid muscles.

In all cases Mulford's bacterin were used, the package contains 4 bottles marked A, B, C, and D, each bottle contains 125, 250, 500 and 1000 million killed bacterin. It is my opinion that the vaccine treatment of enteric fever is sound and practical and will grow in favor as time will go on.

DISCUSSION.

W. B. Gossett: If I understood the essayist correctly, he said that he had seen ten cases of typhoid last year and ten this year. While I do not mean to question his diagnosis, I think it is very unusual to see so many cases in this city

since the completion of the filter plant. Personally, I have not seen a case of typhoid fever in three years, and I have heard doctor friends of mine say that they had seen very little typhoid fever in the past two or three years. I have, however, seen a number of cases which a good many years ago might have been diagnosed as typhoid, starting in with fever and a tongue very similar to that in typhoid, but after a good purge, followed by aspirin and phenacetin, the symptoms would clear up in from three to seven days.

Virgil E. Simpson: I have enjoyed the essayist's paper very much indeed. It is a very practical question that confronts us. In the December, 1911, number of "Progressive Medicine," editorial comment was made to the effect that, at that writing, the typhoid vaccine did not appear to offer very much as an adjunct to the therapeutics of typhoid fever. The same publication for December, 1913,—two years later—states editorially, that there is no vaccine, the status of which is more definitely fixed, more satisfactorily settled, than that of typhoid vaccine. This comparison, I think, embraces, in a terse form, the history of the use of typhoid vaccine and the results obtained, as a prophylactic as well as a therapeutic measure.

As has been clearly indicated by the essayist in the statistics quoted, the use of typhoid vaccine as a prophylactic measure has long since passed the stage of experimentation. In army and navy circles especially, the administration of typhoid vaccine for the purpose of preventing the development of typhoid fever has been attended by such unquestionably beneficial results, that we need to no longer quibble over minor details. It has only been comparatively recently, however, that much use of the vaccine has been made in the treatment of typhoid fever. It should be borne in mind that the typhoid vaccine does not act as an anti-toxin, which, immediately upon its injection into the system begins to at once neutralize the toxins produced by the bacillus that is responsible for the infection. During the first five days after the introduction of typhoid vaccine into a normal individual, as a prophylactic measure, there is no appreciable increase in the opsonins, agglutinins, or bacterial alexins of that individual; but after the first five days have elapsed, and during the succeeding twenty-five days, there is a steady increase in the blood of the contents I have enumerated. In an individual who has typhoid fever, the process of the establishment of immunity has already begun; therefore, the reaction following the administration of typhoid vaccine in such an individual will be manifested earlier than in a normal person consequently, the intervals between the administrations of vaccine may be shorter than would be indicated for the purpose of establishing immunity in a perfectly healthy individual. It has been

shown by Leishman and his associates that, quite unlike our experience with most forms of vaccines, the use of stock typhoid vaccine, either as a prophylactic or a therapeutic measure, is attended by almost, if not quite as good results as are obtained from an autogenous vaccine. As stated, this differs materially from our experience with other forms of vaccine therapy. For ordinary infections I prefer to use an autogenous vaccine, but it seems that an attenuated vaccine, singly, gives as good results as a mixed vaccine of a highly virulent type.

Some interesting work has been done by Besredka in conjunction with Metchnikoff, in working out a new process of obtaining typhoid vaccine; namely, to sensitize the bacteria before they are standardized or used as immunizing agents. Ordinarily, in using a vaccine, we inject a quantity into the system, containing a number of dead germs, and depend upon the well known vital reactive power of the body to produce bacteriolysis; in other words, we expect a reaction to ensue, in consequence of the presence of the germs, which will produce an amboceptor, which in turn unites the germs with the complement which always exists in the blood, resulting in the destruction of the organism. Besredka's theory is based on this hypothesis; that if we are able to sensitize the bacteria before their introduction, by mixing the germs with a serum obtained from some animal that has been immunized against that particular organism, we have gained a step in shortening the process of the disintegration of the bacteria. In other words, diagrammatically (illustrating on blackboard), we understand that the bacteria constituting what is commonly recognized as the antigen must be united by the amboceptor with the complement in the blood before the destruction of the micro-organism can take place. This complement in the blood exists normally. The bacteria is the insulting agent, and when introduced into the system in the form of vaccine, before the complement can combine with the bacteria and bacteriolysis occur, there must have been formed the amboceptor, which unites the bacteria with the complement and enables bacteriolysis to take place.

In the use of so-called sensitized vaccines, we have a micro-organism that has been added to a serum obtained from one of the lower animals that has been immunized against that organism. The process in brief is as follows:

First a quantity of blood serum is obtained from an immunized animal, a horse or a goat, into which dead typhoid germs have been introduced at intervals, in increasing doses, until what would originally have been a fatal dose can be introduced without causing a reaction. A culture of typhoid bacteria is grown on agar for twenty-four hours, washed in saline solution, filtered and added to the serum from the immunized animal, and allowed to stand at laboratory tempera-

ture for twenty-four hours. Then standardization, according to the method of Wright, is carried out. Thus, upon introducing the bacteria already combined with the amboceptor into the system, the process of bacteriolysis begins at once. There is no reaction following the introduction of the sensitized vaccine.

Another phase of the subject of vaccine therapy that has been quite interesting to me, and one upon which I was in hopes that the essayist would touch, is in reference to typhoid carriers. We have learned a great deal about the propagation of typhoid fever that we did not know when I was a student. It has been estimated by careful observers that four or five per cent. of all cases of typhoid fever end in being typhoid carriers. It has been also estimated that perhaps as large a proportion as twenty per cent. of all cases of typhoid fever that develop are the result of infection conveyed by these typhoid carriers. It has been stated by authorities whose right to make the statement cannot be questioned that probably one out of every five hundred individuals, taking them as they come, whether they have had typhoid fever or not, are typhoid carriers. Clinically we recognize two types of carriers, the contact carrier and the secondary carrier. The first is an individual who, while having never had an attack of typhoid fever so far as the clinical symptoms go, yet harbors in his system typhoid fever germs. This can be explained on either of two hypotheses; that the germs infecting an individual, such as, for instance, a nurse or a doctor who has been attending a typhoid patient, are not sufficiently virulent to produce symptoms which would lead to a diagnosis of typhoid fever; or, that the individual's resisting power, while sufficient to prevent the development of the disease, is not sufficient to entirely destroy the germs that infest his system, and these germs find their way into the gallbladder, kidneys, periosteum of the bones, etc., and may remain in situ for a long time. These are called contact carriers. Possibly some of them are cases in which typhoid fever really existed, but was not recognized. I am of the opinion that many cases of summer diarrhoeas, milk infections, and so on, in children, that last anywhere from ten days to two weeks, are really typhoid fever, and these children become typhoid carriers of the other type, comprising those who have had typhoid fever and recovered, but following recovery still harbors typhoid germs, and eliminates them in the urine or feces.

Medical treatment of typhoid carriers has been demonstrated to be almost worthless, except when given early—that is, while the patient is still in the convalescent stage; but after the patient has recovered, and the condition has become essentially a chronic one, but little can be accomplished by drug therapy, except possibly by the use of nrotropin in cases where the kidney is at fault.

These individuals, especially where they happen to be engaged in occupations where they must come in contact with food products, constitute a menace to the public, and it is here, I take it, that the typhoid vaccine will accomplish almost as much good as it has been demonstrated to have accomplished in the prevention of typhoid fever.

Another thing I would like to impress upon the members is the value of early diagnosis of typhoid fever in connection with vaccine therapy. It is an unquestionable fact that the earlier the vaccine is used, the better the results will be, and this is true with respect to any treatment, the object of which is to head off the condition and remove the cause. Since in the normal individual into whom we inject the vaccine, it requires at least five days to bring about any appreciable increase in the agglutinins, we can readily understand that to wait until a positive Widal reaction can be obtained, means a loss of valuable time. Therefore, I would insist that it is far wiser to make a blood culture in these cases rather than to wait until the time when a Widal reaction is positive.

Ellis Duncan: I have enjoyed this paper very much indeed. As a medical officer in connection with the organized militia, I had occasion to make requisition on Major Russell, to whom Dr. Ganz referred, for a quantity of typhoid vaccine to be used as a prophylactic among the men who are members of the regiment. I administered a prophylactic dose to between 125 and 150 men and while in every instance there was a distinct and appreciable reaction, in no case was it sufficiently severe to be more than barely noticed. Dr. Cutbert Thompson reported to me that one of the men had come to him suffering from intestinal hemorrhages, and he suggested the possibility that the prophylactic dose of typhoid vaccine had something to do with it. I think this is very doubtful. I do not see how intestinal hemorrhages could possibly result from the administration of dead bacteria; they are supposed to be caused usually by the activity of live bacteria in the intestinal mucous membrane.

I gave the vaccine in accordance with the advice of Major Russell; that is, five hundred million (1-2 C. C.) at the first injection, one thousand millions (1 C. C.) after an interval of ten days, and another thousand millions (1 C. C.) after a second interval of ten days, 2—1-2 C. C. being administered in that time.

Major Russell advises the use of the vaccine every three years. I do not know whether Dr. Ganz mentioned that or not. In the U. S. Army the men are required to be re-vaccinated every three years, and every man who re-enlists must take it again. The cases reported by Dr. Ganz certainly indicate the beneficial results to be derived from its use.

Leon L. Solomon: The subject of this paper might well be divided into discussions of the use

of typhoid vaccine as a prophylactic measure and the use of typhoid vaccine as a therapeutic measure. It appears to me that there is little room for argument as to the efficacy of typhoid vaccine as a prophylactic, which seems to have been conclusively demonstrated by its use in the armies and navies of the world—England, Germany, Russia, France, Italy, Japan, as well as our own standing army of some eighty-two thousand troops. To my mind there is no more brilliant chapter in the entire history of medicine than the recent chapter on the prevention of typhoid fever by the use of bacterins. Sustaining evidence of the success of this measure, that will last for years to come, was given recently on the Mexican frontier. The results achieved by our army officers everywhere, particularly as concerns typhoid fever, have been brilliant, as witness the results obtained in Panama from the hygienic measures adopted there in order that the canal might be built.

As has been so plainly brought out by Dr. Simpson in his discussion, the question of the employment of typhoid vaccine as a therapeutic measure is entirely different. I agree with Dr. Simpson that it is a mistake to wait until we have proved our diagnosis of typhoid fever by a Widal reaction before administering the vaccine. In some cases in which typhoid is later proven to exist, the urine will not show the presence of the bacteria. Therefore, it may be a loss of valuable time to defer the administration of a therapeutic dose of vaccine in such cases. Indeed, I am inclined to the belief that no serious harm would be done by administering a therapeutic dose of vaccine when we have done no more than establish a reasonable clinical diagnosis of typhoid fever. I am aware that this would not be, strictly speaking, scientific management, to proceed with the therapy before we have fully established our diagnosis, but the bacteriology of typhoid fever upon blood examination is not always uniform, and may lead us astray. Digressing for a moment, I wish to agree with the gentleman who said that it is unusual to see so many cases of typhoid fever in this city at the present time. I have seen very few cases of typhoid since the completion of the new filter plant—indeed, but few cases were reported to the health officer last year, and it may be that some of us are derelict in our duty in having failed to report cases that came under our observation. I saw three cases of typhoid fever last summer, in which the diagnosis was later confirmed. In one of these cases, in the early stages, bacteriological examination revealed nothing. All of these cases were treated by the ordinary dietetic and hygienic measures, clearing out the intestinal tract early, and the administration of intestinal antiseptics later. In two of the three, lysis occurred at about the thirteenth day, and in the other at about the fifteenth or sixteenth day. I say "about" because it is al-

ways difficult to determine just when the disease began.

I wish to say again, if you will pardon the unscientific statement, that I believe it is a good plan to administer a therapeutic dose of vaccine upon making a reasonable clinical diagnosis of typhoid fever, even before it can be confirmed by a Widal reaction or a blood test. I believe, furthermore, in repeating the dose at short intervals, relying upon the clinical manifestations in conjunction with laboratory examinations for guidance as to the interval between doses.

Wm. A. Jenkins: Vaccine therapy may be said to be the medical "Land of Promise." However, to be conservative, we must still hold the whole question of vaccine therapy sub-judice. We cannot say anything against it, and I admire the gentlemen who have the hardihood to come forward with their correlated, carefully recorded cases, and stand up for their belief. We all feel that, at some time or other in the distant future, there will come a glad time when many, if not all, of the acute infectious diseases may be met and conquered early in their career along these promising lines. There is only one possibility of making an error along this new therapeutic line, and that is to allow our enthusiasm to outrun our judgment. When it has been thoroughly tried out by reputable clinicians, and practitioners of accredited standing all over the country, and there has been accumulated a mass of evidence sufficient to convince the average practitioner that it has come to stay, then it will be taken hold of generally.

Just one word in regard to sensitized vaccine. This idea is not really new; it has been worked on in laboratories for a long time, and one or two of our enterprising pharmaceutical houses are now putting out sensitized vaccines.

I wish to mention one point in connection with the preparation of sensitized vaccines (which, however, may not be of much interest to the general practitioners, because we do not prepare our own vaccines). When an ordinary bacterial vaccine is placed in the sensitized serum, obtained from an animal that has been immunized to that specific disease, it should be allowed to remain for only a short time. If allowed to remain longer than that they are apt to take up something else that may prevent the bacteria from uniting with the natural complement, thus destroying the efficacy of the vaccine. After remaining in the immune serum the required length of time, the bacteria are filtered, washed and prepared for use.

R. Hays Davis: I cannot agree with the gentleman who believes in promiscuously injecting typhoid vaccine in cases in which the diagnosis of typhoid fever has not been established. So many conditions resemble typhoid fever that are later found not to be typhoid, and if we inject every patient that has a coated tongue, with high temperature, with typhoid vaccine, we will make

many mistakes and unquestionably do harm. I cannot conceive of a vaccine being used in diseases other than that for which it is intended, without producing harmful results. Certainly, it will not do the patient any good to inject typhoid vaccine for a condition which may be a septicaemia, or military tuberculosis, or some other condition that resembles typhoid fever. There are scientific methods by means of which most cases of typhoid fever can be diagnosed, even in the early stages. We know that the blood culture is positive in ninety per cent. of cases if made early, in the first few days of the disease; the longer the disease runs, the less likely is the blood culture to be positive. After the first few days, we have the leucocyte count, which we know is low in typhoid and high in septicaemia and other conditions. It is also low in miliary tuberculosis, but here we have other differential signs. After that we have the Widal reaction, which is positive in the large majority of cases of typhoid. In addition to these measures, we have in typhoid fever, the presence of rose spots, which practically never occur in other conditions. We also have a slow dirotic pulse which is highly characteristic of typhoid. Furthermore, we have bronchitis occurring at about the eighth day in typhoid, when it usually occurs early in other conditions. In addition to these, there are various other things to be taken into consideration before resorting to the injection of typhoid vaccine. The trend of evidence seems to be that the typhoid vaccine, as a curative measure, may be of some value, but its use in this way is still more or less in the experimental stage, and has not attained the status that its employment as a prophylactic has.

Charles Farmer: I would like to ask the essayist for what period of time immunity is established in an individual after the use of typhoid vaccine as a prophylactic measure. Last summer I treated an attack of typhoid fever in a young man who had formerly been in the U. S. Navy, and had been vaccinated against the disease fourteen months previously.

Leon L. Solomon: One of the speakers has seen fit to discourage and class as dangerous the administration of a single dose of typhoid vaccine as a therapeutic measure, even before the diagnosis of typhoid fever had been fully established, which I advocated in my discussion, at the same time admitting that it was somewhat unscientific. This gentleman seems to have overlooked the fact that we have before us reports which show that millions of individuals have been given a prophylactic dose of the vaccine without doing them any harm.

P. S. Ganz (Closing): I wish to thank the gentlemen for their generous discussion of the paper. The question often asked is, "Does the vaccine ever do any harm?" It is claimed by the manufacturers that never, in a single case, has the use

of vaccine resulted in harm. They state, however, that its use is contra-indicated in the presence of tuberculosis, chronic or acute arthritis, albuminuria, etc. I have read the records of all the different manufacturers and have written to them, and they claim that they have never known a case in which death resulted from the use of bacterins, although in some instances a dose of three millions of germs has been given at one injection. Therefore, in cases where there is a reasonable suspicion of typhoid fever, I do not believe the administration of a single therapeutic dose of the typhoid vaccine in the average individual, as advocated by Dr. Solomon, would do any material harm.

SURGICAL TREATMENT OF CERTAIN ACUTE AND CHRONIC DISEASES OF THE PALPEBRAL AND OCULAR CONJUNCTIVA.

By M. F. COOMES, Louisville.

First: In specific and nonspecific purulent inflammations of the conjunctiva where the chemosis is extreme, and especially where the sub-conjunctival tissues become so infiltrated that the lids can neither be closed nor opened, and that cleansing cannot be properly accomplished, and that applications cannot be applied as they should be applied, then the conjunctiva should be cocaineized and freely snipped with the scissors so as to permit free drainage from the infiltrated tissues; one-fourth of one per cent. solution of cocaine is quite strong enough for this purpose; in fact, the snipping of the conjunctiva can be done without any anaesthetic whatever because the distension of the tissues renders them anaesthetic to a considerable degree.

If the snipping does not give the proper relief, canthotomy should be performed. The cut in this instance should be made horizontally, and not upwards and outwards, at forty-five degrees, because in this instance the only thing needed is temporary relief of tension.

If the subject is a young infant, which is frequently the case, it will not be necessary to stitch the conjunctiva and skin together—a procedure which might be necessary in adults, because of the greater likelihood of the parts not adjusting themselves properly.

TRACHOMA.

This disease, as we all know, is peculiar to itself in as much as it has the peculiar deposit known as the trachomatous body or bodies, chiefly beneath the conjunctiva, that is in the sub tissues, and sometimes in the conjunctiva itself. Medicines will not cure this disease, although they may palliate. All cases of trachoma are curable by proper surgical inter-

ference. The milder the case, the more amenable to surgical treatment.

The surgical treatment consists of two procedures, the first of which is the expression by means of the use of the Knapp roller, or some other such device. The expression should be thorough. If the case is a mild one, and of short duration, the expression will be sufficient; but if there is spasm of the orbicularis palpebrarum muscle, there should be a free canthoplasty. Great care should be taken in making this cut, with the scissors extended along the line of continuation with the free border of the lower lid, which is upwards and outwards at the angle of about forty-five degrees.

The object of this cut is to evade the tendinous portion of the orbicularis muscle. By making the cut through the muscular fibres, you not only relieve spasm, but in the process of reparation, new tissue is built in between the ends of the muscular fibres, thereby increasing the length of the muscle, and rendering pathological spasm impossible; whereas, if the cut is made through the ligamentous portion of the muscle, as soon as union occurs between the divided ends of the ligaments, you are very likely to have a return of the spasm, and the result of your operation will only be evanescent in its effect, in as much as the spasm will return as soon as union is completed.

The canthoplasty cut is best made with a good strong pair of blunt pointed scissors—a small Mayo scissors with blunt point is admirably adapted to this work. Great care should be taken in stitching the conjunctiva and skin together. The angular stitch should always be placed first by introducing it into the conjunctiva opposite the angle in the skin wound, letting the needle pass out through the sub tissues, and up through the integument one-fourth of an inch external to the edge of the wound. The adjusting and tying of this stitch arrests hemorrhage and brings the other two sides of the wound in apposition, so that the introduction of the two remaining stitches is rendered easy.

The stitches should remain three days, and in their removal great care should be taken not to leave any portion of the thread, as it results in troublesome lid abscesses. Silk is the best ligature material—linen thread will suffice.

In many of these cases of trachoma we have panus in varying degrees, and unless the spasm of the orbicularis muscle is kept under control sufficiently to prevent friction, other than normal, the panus will be slow to clear up, and in many of the advanced cases, that is where there is great vascularity of the cornea, ulcerations and other complications will arise, and the results of these complica-

tions will often produce serious defects in vision by leaving scars and opacities in the cornea.

PAPILLIARY HYPERTROPHY, OR SO-CALLED GRANULAR LIDS.

The great pathological distinction between trachoma and papillary hypertrophy is the fact that in the latter form of disease there is no foreign structure or substance connected with it—the thickening of the lid is due to excessive cell proliferation or growth building up the individual papillae, thus making them broader and longer, until finally the lid presents the peculiar granulated surface, which is not a true granulation, such as we have in the reparation of tissue, but is simply an increase in the size and the length of the papillae. Each of these little papillary bodies must have its nerve and blood supply. The larger the papillae, the greater the blood supply, and of course, any unusual irritation applied to the eye, or to these individual papillae, produces an increased flow in the blood stream which finally amounts to a state of chronic congestion—hence, any unusual action of the orbicularis muscle will produce an excessive amount of irritation over and above that which exists in the lids where there is no spasm. With this understanding it is perfectly plain that there are two things to do, from a surgical standpoint; the first is to get rid of the spasm of the muscle by canthoplasty, as is done in cases of trachoma. The next thing to be done is to establish a new condition of affairs in the hypertrophied papillae, and there is nothing to equal the crushing process with the Knapp roller, or some other similar device.

The object of this operation is to break up adhesions between the individual papillae that may have occurred, and to establish a new set of blood vessels in the hypertrophic mass, and also to bring about an atrophic condition in the papillae—in other words to reduce them to their normal.

This line of treatment is the most satisfactory of all forms of treatment applied to such cases, because of the speediness and certainty as concerns results. With proper management, in from ten days to two weeks the trauma, resulting from such operations as canthoplasty and the use of the Knapp roller, has subsided.

There can be no comparison between the results obtained by proper surgical management of trachoma and granular lids and that of any line of medical treatment that may be instituted. As far as pain is concerned, the canthoplasty and expression with the Knapp roller is not worse than the application of stick copper, or the strong solutions of sulphate of copper—in fact, I know of nothing

more painful than the application of copper sulphate solution in the eyes; it is prolonged and harassing.

Another great objection to the use of copper, silver, alum, and other astringents and irritants is that it requires a great length of time to accomplish any results, and even then the eye lids are deformed, and frequently much of the cornea is left opaque. Copper should never be used.

The four local applications upon which I mostly rely are, first of all, boracic acid with normal saline as a general wash and cleanser; secondly a solution of eserine containing one grain to the ounce of water. This application acts as a myotic—closing the pupil and keeping out the light, which is so intolerable to many patients. Further, eserine is a great stimulant to the blood vessels, and has a most wonderful reparative effect upon the cornea in many of its ulcerated conditions, especially where there are a number of small ulcers scattered over its surface. There can be no harm from its use in these cases. It can be applied night and morning for an indefinite period of time without any evil results occurring.

The next local application of great value is pyoktonin (blue); watery solution of five or ten grains to the ounce may be applied to the conjunctiva sac with impunity, and practically without pain. It is particularly valuable in those cases where there is a sluggish, mucopurulent discharge. This application once each day for three or four days usually clears up this condition, which otherwise is difficult to get rid of. Furthermore, there is no danger of any staining of the cornea, whereas some of the silver salts are not to be reckoned in these cases, and particularly the nitrate of silver.

Lastly, but not least, one of the most valuable local applications is a saturated solution of the muriate of ammonia. This is preferably dropped upon the everted lid once each day. For the instant, it is very painful, but the pain is so evanescent that patients tolerate its application with impunity; no harm whatever can result from its use.

In conclusion, I wish to say that I am firmly of the opinion that if the surgical treatment of trachoma is followed up strictly in all cases of this disease, we would soon eradicate it from the State, for the reason that there would be very much less danger of contagion by the transmission of the disease from one person to another, because of the very short duration of the disease under surgical management; in other words, I believe that the surgical treatment should be compulsory in all cases as soon as the diagnosis has been made, because such persons are a menace to the community, as well as to themselves.

DISCUSSION.

S. G. Dabney: I have listened to Dr. Coomes' paper with a great deal of interest, especially since he is not in accord with the views generally held. We all like to see a man who has the courage of his convictions, and whose experience entitles him to consideration. Most of what Dr. Coomes has said, however, is not to be found in either the older books or the new ones, and is hardly in accord with the experience of most of us. Perhaps we are all prone to practice too little some of the things he referred to.

I think Dr. Coomes over-estimated the value of canthotomy. Perhaps most of us do it less than we should, but I hardly believe it will accomplish as much as the essayist seems to think. In the first place, I have never seen occasion for it in a baby. A baby's tissues are soft and flabby, and are not of the same firmness as an adult's. In purulent ophthalmia in adults it is an admirable procedure. Some years ago I saw in consultation a doctor who had contracted a purulent ophthalmia of one eye from treating a gonorrhoeal case, and suggested canthotomy which helped him very much indeed.

I wish Dr. Coomes had touched upon removal of the tarsal cartilage in cases of old chronic trachoma. This is an operation that has been very much discussed lately.

I cannot agree with the essayist in regard to copper. I have tried all sorts of medical agents, and I believe practically every oculist will agree with me that, if there is one remedial agent in trachoma, it is copper. However, I think it is important to impress upon the laity that surgery is more effective and more permanent in its results than any medical treatment of trachoma.

I have never used quinin-urea about the eye.

One condition which we never see mentioned in the books as indicating operation, and which has often given me a great deal of trouble, is that condition of the margins of the eye-lids which we used to call a strumous condition, the lids being thickened and red, with considerable inflammation about the hair follicles and adjacent tissues. I have often wondered if firm expression would not do good in such cases. I have never tried it, having always employed medical treatment, but I would be glad to hear Dr. Coomes relate his experience with such conditions.

I cannot agree with the essayist in regard to eserine. In many people it produces ciliary spasm, and I cannot help but think that in cases of trachoma with corneal ulcer, it would be very apt to produce iritis. Certainly we very often see congestion of the iris, with a narrowed pupil in corneal ulcer, and for my part I would hesitate to give such a patient a solution of eserine and tell him to go home and use it.

It is strange how our experiences with the same drug differ. Dr. Coomes finds that atropin fails to give the patient comfort, while so many

of us have noted the opposite effect, although it undoubtedly dilates the pupil and lets in more light. There are three things we hold to in the medical treatment of trachoma—*atropin*, hot applications and *bluestone*—both before and often after operative treatment.

Gaylord C. Hall: I can subscribe to a good many things that the doctor has mentioned in his paper, particularly the use of *eserin*. Before I used it, I was of the same opinion as Dr. Dabney, but upon trying it in certain cases of ulcer of the cornea, I found that the patient was very promptly relieved; whereas, previously the application of *atrophin* had not afforded relief.

In regard to canthotomy, I think a distinction should be made in its use in the inflammatory conditions in the eye. Where we have an acute inflammatory condition with chemosis and much swelling as in purulent ophthalmia we take a scissors insert at outer canthus and cut outward as far as possible. This temporarily relieves the pressure. We, however, do no plastic work. It has been also recommended that radiating incisions in the bulbar conjunctiva may be necessary in cases of excessive chemosis although I have never found this procedure necessary.

The operation I do in trachoma is not a canthotomy in the sense of being merely a slit. It is more properly a canthoplasty. The external canthus is extended outward to the external angular process. Then inserting the points of a scissors underneath both skin and conjunctiva the tarsal ligament is felt for, cut loose and a small portion excised above and below.

The rationale of the treatment is this: the main feature of the pathology of trachoma is atrophy which effects both the conjunctiva and tarsal plate. This is accompanied by an inflammatory action the whole resulting in increased pressure against the globe which results in ulceration and pannus.

Old cases of trachoma show an involvement of the free edges of the lid with a tendency of the hairs to turn in further increasing the liability to ulceration and pannus. The operation described is therefore always done in old cases to relieve the pressure already existing and in all of those except very recent cases to prevent pressure which will develop when atrophy takes place. The pressure being relieved the tendency to ulcer formation and pannus is practically obviated.

In advanced trichiasis following old cicatricial deformity, I do not believe that canthoplasty or canthotomy will meet the indications. We must do much more extensive surgery, and I believe the best operation for a condition of that kind is the Hotz Anagnostakis operation, consisting of an incision parallel with the ciliary margin of the upper lid, and about three or four millimeters above the ciliary margin. This (illustrating on blackboard) will represent the palpebral slit. If there is a surplus of tissue in

the upper lid, I always excise between these points and take off the redundant skin. Then I pick up with forceps the fascia and fibres of the orbicularis muscle, exposing the upper portion of the tarsal plate. If it is much thickened, I slice out a portion with a very thin knife. After this is done you will find that the lid is much more freely movable. Next comes our sutures. The operation I do differs from the Hotz Anagnostakis operation in that, instead of using a single suture, I use a mattress suture, in order to secure firmer union.

By pulling on the ends of the threads after the suture has been placed, one can judge the amount of correction required, and regulate it to any degree necessary to cause a turning out of the ciliary border of the lids.

There is one other method of dealing with these cases, which I have tried to my chagrin; namely, removing these lashes by means of electrolysis. I do not know what the experience of others has been, but when I tried to eradicate these lashes by electrolysis, they sprang out faster than I could dispose of them. Therefore, in extreme cases I have resorted to the other operation, which has been attended by complete success.

M. F. Cocmes, (Closing): First, in regard to the use of eserin. Eserin does two things; it shuts out the light and stimulates circulation. I would feel absolutely at a loss in a case of corneal ulcer if I could not use eserin.

Dr. Dabney stated that many of the points brought out in my paper could not be found in the books. I did not find them in books; they are the result of nearly forty years' experience, and I wish to thank Dr. Dabney for bringing out that point.

I have never seen iritis result from the use of eserin. We are all afraid of certain things, but I see no reason why any one should be afraid of eserin. I never use a solution of less than one grain to an ounce of water, and I have never had any bad results from it. I have not used atropin for ten years and never expect to use it again. Eserin and atropin are absolute opposites so far as the effect on the pupil is concerned, and it is rather peculiar that men of the experience of Dr. Dabney and myself should differ so widely in regard to such things.

So far as the distinction between trachoma and ordinary granulated lids is concerned, there is just as much difference as between daylight and darkness. In trachoma we have something embedded in the conjunctiva that does not belong there. It is a foreign body, and it is easily diagnosed, whether they be in abundance or in moderation. In trachoma if we will blanch out the conjunctiva, we will find these little bodies, or nodules, in it; in granulated lids we may blanch the conjunctiva as much as we please, and we

will find a smooth surface; these little nodules are not present.

As to the use of copper sulphate, of course we all go more or less by our own experience, but I believe we can get so much better results from muriate of ammonia. When we put a saturated solution of nitrite of ammonia in the eye the stimulation is so great that it turns the conjunctiva white, but the patient goes out of the office feeling good. On the other hand, we may leave copper there for twenty-four hours and it does no good.

Take a case of trachoma that it is desired to operate on. I simply slip a needle under the skin, evert the lid and inject the trachomatous conjunctiva full of quinine urea and operate twenty minutes later. The immediate result is always good, just as in the case of the woman I reported. We all know how sensitive the face is. In this case, I filled everything up with quinine urea, and then made a linear cut from the edge of the lid to the lip, nearly four inches in length, and she said the only pain she felt was when the needle was introduced.

There is an operation that may be done much more quickly than that outlined by Dr. Hall, in children, and the results are so much better. There are two things to do. First, as in the case of the woman I reported, take a large piece of skin out of the upper lid, going clear down to the cartilage, and stitch it up. If we stop there, with or without canthotomy, we do not get results. The thing to do then is to take a cataract knife and cut along the margin of the lid, inside the lash, and let it granulate from the bottom. By this means we get the lash turned up with practically no deformity at all. There is nothing new about it, but this is one of the most satisfactory operations I have ever done.

I wish to thank the gentlemen for their discussion.

Fracture of Forearm.—Treatment. To correct overriding of fragments, attach to hand, anteriorly and posteriorly, as separate straps, zinc reaching from above wrist to 6 inches beyond extended fingers, and fixed above wrist and about knuckles with encircling strips. Apply usual oxide adhesive plasters 2 1-2 inches in width, splint dressing and also a plaster-of-Paris encasing bandage, including hand and lower arm. When this firm, include beneath enveloped forearm, by more turns of plaster bandage, a light, flat wooden splint projecting 1 or 2 inches beyond extended fingers. To a cross-piece at end of this, projecting an inch, attach the double adhesive strap from hand with tacks, thus keeping bony fragments from overriding.—Miel.

CLINICAL CASES

ACUTE RHEUMATISM.

By ASA W. NICKELL, LOUISVILLE.

In submitting for your consideration this evening a brief resume of this important subject as held by our most modern investigators and my subsequent report of an unusual case, I desire to place especial emphasis on some phases of this disease which will doubtless elicit some interest, especially among those of experience, and who have the most graphic conception of this infection.

I will speak a word as to the prophylaxis, but have purposely omitted the direct treatment and that of such complications and sequelae as hyperpyrexia, cardiac complications, anemia, meningitis and chorea, trusting these will be taken up in the discussion.

Acute rheumatism is an infectious disease which manifests itself by its tendency to involve the joints and serous membranes elsewhere: recognized and characterized by an exudative non-suppurative inflammation of the joints with a pronounced tendency to secondary involvement of the endocardium, particularly that of the mitral leaflets and left chamber of the heart (especially in children, during which period aortic lesions are relatively rare,) the pericardium, heart muscle, the pleura. Occasionally, however, the peritoneum and meninges. The most serious sequel of this disease is that which results from its involvement of the cardiac valves. In mild cases of endocarditis of rheumatic origin, almost complete resolution may take place, leaving perhaps a slight thickening of the valves and endocardium. Most usually, however, considerable crippling of the leaflets from inflammatory thickening, adhesions and secondary contraction occurs and valvular deformity and defects result. The mitral valve is most frequently disturbed and the aortic next in frequency, lesions in the right heart are rare.

Etiology of this disease has been discussed since the early history of medicine. Formerly some special secretion or rheum, various chemical intoxications and numerous acids were supposed to be important etiological factors. Among these lactic and uric acid have held a high place. The acid hypothesis was suggested by the acid sweats and highly acid condition of the urine. Recent bacteriological investigations throw some light on the micro-organisms responsible for the disease. An anaerobic bacillus described by Achalme and other French observers, resembling the anthrax bacillus had been considered of importance but his findings have not been sustained. Now the majority of recent in-

vestigators indicate the organism generally present as a streptococcus or diplococcus, somewhat allied to the streptococcus pyogenes and pneumococcus. This has been found in the blood of patients and fluid obtained from rheumatic joints in patients suffering from rheumatism. Their absence sometimes on microscopic examination of joint fluids is explained as due to the fact that the micro-organisms have been destroyed, or retained in the tissues of the synovial membrane, while the fluid exudate is sterile. This organism was named by Poynton and Payne, as the "diplococcus rheumaticus" and they and other recent investigators regard it as the specific cause of the disease. Mantle, Klebs, Singer, Popoff, Leyden, Westphal, Wassermann, Ainley, Walker, Longscope and Malkoff with Poynton and Payne, have reported that this organism has been repeatedly recovered, grown in pure culture and shown to produce an acute arthritis in a large series of rabbits by inoculation. This was regarded by Poynton as a short chain streptococcus in "family" resemblance, and a diplococcus in relation to species. It is very small, retains Gram's stain feebly, shows greater resistance to drying. It produces acid readily and more profusely than the streptococcus pyogenes. Its tendency to abscess production is less than the latter. The numerous reports bearing on the intimate relationship between infection of the tonsils, accessory sinuses, pharynx, bronchiectases and other foci in relation to rheumatism and endocarditis, shows strongly that rheumatism is not only an infection but is associated largely with chronic and acute tonsillar infection from which the streptococci are most frequently isolated. For example, D. J. Davis in the analysis of 45 cases of rheumatism found a diverse flora on the surface of the tonsils, but in the crypts found nearly pure cultures of streptococci, representing different strains, nearly all of which when injected in the rabbits in small doses produced arthritis and the streptococci were recovered and regrown from the joint lesions. It would therefore seem from the reports of many skilled observers that not only may the tonsils be diseased and filled with pathogenic organisms, without perhaps the patient recognizing any serious trouble as an angina, but the organs may appear normal at a casual examination, while they may contain pus and act as an incubator for pyogenicococci. The effect then of such destructive processes in such susceptible tissue as the tonsils, the many grades of toxemia produced by their absorption must be considered. Even when there is no real bacteriemia, the body tissue is unquestionably affected by the materials generated by the constant germ activity with the resulting

destruction of tissue. Such may be of special frequency in childhood when such a process may produce no more evidence of rheumatism than the so-called "growing pains."

Dr. Cheadle's excellent summary for believing rheumatism infectious is: the occasional epidemic prevalence, the variability of type, the incidence upon the young, occurrence of tonsillitis, endocarditis, pneumonia, erythema, rapid anemia, tendency to acid albuminuria, the implication of the joints, the relapses, the nervous disturbances and the specific power of salicylic acid, are all suggestive of an infectious disease. Some claim we can go little beyond this assertion at the present, that neither finding the germs in the affected tissues, nor the production of arthritis in animals with recovered organisms is sufficient to prove the *causative factor*, as many diseases are associated with an arthritis and many germs will produce this condition in animals. *But* we must admit that the streptococcus or diplococcus is found with remarkable regularity by Poynton and Beattie and produces in susceptible tissue, the chief lesions and complications of acute rheumatism with alarming constancy. The fact that the organism is arranged sometimes like a diplococcus and then like that of the streptococcus, is interesting in its relations to the findings reported by those investigating the flora of diseased tonsils. Recent statistics show coincident tonsillitis in 80 per cent. of cases of acute rheumatism and sometimes an acute or slight tonsillar infection antedates rheumatism by three or four weeks. Then we are bound to admit the close connection between certain known infections whose etiology we can demonstrate and the phenomena of rheumatism.

In consideration of the morbid anatomy of rheumatism we note the lesions are in structures which are very active, as a joint, muscle tendon and heart. The association of heart involvement is so common in children that it is considered to represent typical ravages of the infection. Macroscopically, the joints present the typical features of involvement. Rheumatic nodes can be felt beneath the skin in the tendons of the digits, the patella, and region of the occiput, in small oval masses. In endocarditis, the endocardium is swollen and anemic with the presence of warty protuberances and are most frequent on the mitral aortic valves. In myocarditis, the walls appear stretched and flabby. The pericardium may show adhesions between its layers and sometimes a certain fibrinous exudate. Microscopic examination discloses three zones as being constant: the outer zone of swollen connective tissue, one of cellular exudate and one of necrosis with exudate. Where there is pericardial and joint involvement, the fibrino-

cellular exudate, furnishes constituents for the fluid in either pericardial or synovial sacs. Warty growths on the valves are fibrin. Malignant endocarditis is rare. When present there is an area of ulceration while in myocarditis, there is often found areas of fatty degeneration.

In view of the almost conclusive information, concerning the cause and portals of infection, I believe that proper care of the nose, throat, and teeth in children and adults constitutes the first procedure in prophylaxis. We must also consider prompt treatment anywhere about the upper air passages and especially the tonsils. The early removal of adenoids and diseased tonsillar tissue is imperative. Not entirely because of the relationship between focal infections and acute and chronic arthritis, but because of poor nutrition and retarded development, which may and perhaps does, influence the future of such unfortunates.

(REPORT OF CASE.)

I regret that I have lost my record of this case and will as best I can recall some of the salient points. It was a peculiar case of rheumatism, exhibiting one feature that I have rarely seen in such cases, that of such pronounced and prolonged delirium. The patient was a German gardener, about 50 years of age, subjective history unsatisfactory. Objective, an angina preceded this attack with all its symptoms, then the typical symptoms of inflammatory rheumatism, inflammation about the joints with considerable effusion into the sacs, præcordial oppression, et cetera. I had him removed to St. Anthony's Hospital the early part of March and kept him there perhaps six weeks or more. After he had been there a short time he became delirious and during the succeeding 24 hours, looked as if he might die at any time, soon he became stronger and more violent and when occasion presented would leave his bed and try to get away and kept the other patients in an uproar, but by the close vigilance of the orderlies we kept him in bed where soon his condition became so grave and he was so weak that he was not difficult to control and he just lay there for several days with a low muttering delirium, till after a prolonged and aggravating period he began to clear up and in about ten days was comparatively lucid. I had Dr. Cecil see him with me on two occasions and did not change the treatment in any way. I did not give him antistreptococci serum or the phylacogens because I was afraid of the reaction from the latter agent with his condition present. He had a genuine pancreatitis and for some time it seemed as though the heart sac was filled with fluid and

the sounds scarcely audible. Finally the condition cleared up and the patient left the hospital. This was one of the worst cases of the kind I have ever seen and for that reason I desired to report it.

DISCUSSION.

J. M. Ray: I read an article recently, on the subject of the relationship between the tonsils and tuberculosis, in one part of which, quoting from Wright, who is one of the best pathologists in this country, he said that, while tuberculosis may be contracted through the tonsils, he does not believe this is true in the vast majority of cases. I think we can say practically the same thing in regard to the relationship between the tonsils and rheumatism. A great many people have tonsillitis who do not have rheumatism, and vice versa. Simply because the two conditions sometimes occur simultaneously is no reason for believing that the tonsil is the avenue through which the rheumatic infection gains entrance into the system. Practically all of the investigators along this line have been able to trace the infectious organism into the tonsil, but none of them has been able to positively determine how it gets from the tonsil into the circulation. Tuberculous infection, for instance, may get beyond the tonsils, into the lymphatic glands of the neck, and stop there. I am inclined to agree in the opinion that, in early life, during that period when we think we know that the tonsil has a function, its removal really means the removal of a barrier to the entrance of various infectious organisms. Later on in life, after the period when the tonsil has a function, it becomes a disease-promoting organ, and may then be removed; but as long as the tonsil has a function, which is to protect the system against various infections, I think it is best to leave it in situ. If the tonsil promotes disease by the absorption of infectious material, then why not also the mucous membrane of the pharynx and naso-pharynx, which offer a much broader surface for absorption than does the tonsil. Some time ago I saw a child who was subject to recurring attacks of follicular tonsillitis, the recurrence having become sufficiently frequent to demand radical treatment. I removed the child's tonsils, and the mother believed, of course, that the child would never have any more systemic trouble from that source. However, in time the child developed follicular spots similar to those that had appeared on the tonsils, and exhibited the same evidences of sepsis that it had before the tonsils were removed.

C. H. Harris: I fail to see anything unusual in the case reported by Dr. Nickell. It is not uncommon to see delirium in a case of active rheumatoid arthritis. The only feature that might be considered unusual is the fact that the man had pericardial effusion, myocarditis, endocarditis and pericarditis, and got well in four

weeks. I do not know what the doctor's treatment was, but if he cured endocarditis, pericarditis, and myocarditis, with effusion, in four weeks, he certainly obtained a remarkable result.

Asa W. Nickell, (Closing): I think Dr. Harris is a man of some experience; but Dr. Cecil, with all of his experience, as internist and teacher, said that this was one of the most unusual cases he had ever seen. I did not state I cured this man in four weeks but at the expiration of six or eight weeks he left the hospital for the home of his sister where in three or four months he resumed his duties. I leave it to the Society as to which opinion of the two gentlemen they should attach the most significance.

This man had a myocarditis. I believe that, in the presence of any toxin in the system, whether it be from influenza, pneumonia, diphtheria, or rheumatism, if the heart has to deal with it very long the patient will have a myocarditis in greater or less degree. We may have an endocarditis sometimes and not leave much pathology behind. Also, according to some of the best clinicians in this country, we may sometimes have a myocarditis of severe type, with an entire absence of frank symptoms.

I have great respect for the opinion of my friend Dr. Ray, but he must confess he differs absolutely from that of D. J. Davis, of the Northwestern University of Chicago, and others who have been employed by Research Bureaus of this country to investigate the etiology of rheumatism on Rhesus monkeys, etc. They not only find this poison in the tonsils, but in the accessory sinuses in the antrum of Highmore, and in the pharynx, and they have demonstrated this in 80 per cent. of cases by taking this poison from the tonsil and injecting it into rabbits, producing the typical symptoms of this condition. It seems to me that is almost conclusive evidence of the relationship between the tonsils and rheumatism.

PERIOSTEAL SARCOMA.

(REPORT OF CASE.)

By GUY P. GRIGSBY, Louisville.

The history of the case that I wish to present to-night is as follows. Rose H., colored, age 19. Family history negative as regards malignancy, has had the diseases of childhood but has never had any serious illness up to the present time. Has in fact been unusually free from any sickness. The present trouble began, she thinks, about four or five months ago. The first thing that she noticed was the presence of a small tumor about the size of a walnut on the outer side of arm just a little below the shoulder joint. Careful questioning I could not elicit any history of injury or anything else that might be considered as a causative factor. This growth was painless

and in consequence she paid no attention to it. It rapidly increased in size and a little before X-mas she consulted her family doctor who is colored. He treated it upon the supposition that it was an inflammatory condition based upon the fact that she was running a little temperature, the pain, and the local condition. The tumor increased in size and he consulted two of the local doctors and they advised bringing her to the city. After examining her I made a tentative diagnosis of sarcoma and advised an X-ray. Dr. Keith has made two very beautiful plates that are more or less confirmatory of the original diagnosis, that of a periosteal sarcoma. The term "osteosarcoma" has very unfortunately crept into the literature of tumors, and is used to signify a sarcoma which originates from bone regardless of the structure of the tumor. I believe that it is better to classify these tumors as myelogenous and periosteal sarcomas of the bone. Myelogenous sarcoma may appear in connection with any bone of the body especially the lower jaw and the epiphyses of the long bones, rarely in the diaphysis. They are made up of several structures, small or large round celled, spindle celled, or mixed. They often show great numbers of giant cells. Contrary to general opinion sarcoma are not confined to any period of life, but may occur at any age. However periosteal sarcoma are perhaps oftener found in the young patients. The tumor is usually firm but may be extremely soft. The growth is often spindle shaped and gradually surrounds the bone, metastases are likely to occur relatively early, and the tumors, as a rule, are very rapid in growth. There is danger of confusing the diagnosis with syphilitic lesions and especially with tuberculosis, which cannot always be done by a Wasserman or the tuberculin tests, for it must be remembered that a syphilitic or a tuberculous individual may develop sarcoma. It is even more difficult as in this case when it is near an articulation. They may also be confused with inflammatory processes.

The continued growth, the outlines of the tumor, the continuation of the growth whether the part is functioning or at rest—inflammatory processes especially the chronic ones are improved by rest—favor the diagnosis of sarcoma. The skiagraph after all is the most important means in arriving at a correct diagnosis. The diagnosis of the case in question is based upon the local appearance of the tumor, the rapidity of the growth, the involvement so early of the surrounding structures, the age, and the X-ray findings. The treatment, of course, is palliative, as it has advanced so far that surgical intervention would only promise a very early recurrence.

DISCUSSION.

C. B. Spalding: I am very glad indeed to have seen this case. The treatment and the ultimate outcome of the case are to me the most interesting features. I would like to know what Dr. Grigsby proposes to do for this patient. My own opinion is that not much can be promised, as the glandular structures and muscular tissues underneath are apparently already involved.

Ben Carlos Frazier: Dr. Grigsby did not refer to the treatment in his report of this case. The most interesting question in connection with this patient is, how long will she live, and whether or not she will have changes in the mediastinal glands and lungs before very long. As the doctor said in his report, it does not appear that there is anything to be done for this patient that holds out any promise.

W. C. Dugan: This is certainly a very interesting case. In view of its rapid growth, and the feel of this tumor upon palpation, I do not believe there is any question that it is a periosteal sarcoma, or what is called a vesiculating osteosarcoma, where the blood vessels become calcified, and the growth is very rapid, soon involving all of the soft structures. I have seen two such cases, both of which ran very rapid courses, bearing out what Dr. Grigsby said in regard to treatment—that only palliative measures are indicated. Shoulder-joint amputation will do the patient absolutely no good.

H. H. Harris: Do not these conditions oftentimes follow trauma?

Guy P. Grigsby (Closing): Answering Dr. Harris' question in regard to trauma, it is true that trauma is very frequently a factor in the etiology of these tumors. However, a sarcoma may occur with no apparent cause, as it did in this instance. I was careful to bring out the point in the report that I tried to elicit a history of injury, but was unable to do so. The phase of this subject that is most interesting to me is that of diagnosis. I have been unfortunate enough to have seen two similar cases within the past year. One of these was seen later on by Dr. Vance, who did a shoulder-joint amputation, followed by recurrence and the death of patient within three months. Both of these cases went unrecognized for a period of six or eight months, until there was absolutely nothing to hope for from operative interference.

One of these cases was in a man about 32 years of age. As stated in the report, the development of sarcomata is not confined to any certain time of life—they occur in the old as well as the young. The periosteal type of sarcoma, however, is more prone to develop in the young.

Whenever I see a tumor, no matter where it may be located, the first thought that occurs to me is the possibility of malignancy. My first step, therefore, is to eliminate malignancy, and

not until I have done that do I proceed to some other explanation of the causation of the tumor. In this way there is less likelihood of overlooking such conditions as this until it is too late for successful surgical intervention. The first case I saw had been under the observation of her physician, a colored doctor, for more than three months, and had been examined by two other doctors, none of whom had recognized the condition. The diagnosis is a very pertinent question in connection with this subject, and should not be overlooked.

ABSCESS OF LIVER.

(REPORT OF CASE.)

By S. T. YEATTS, Louisville.

Patient M., colored, female, age 45, weight 144 lbs. She had been a resident of Louisville for a number of years, occupation, a seamstress and housemaid, had been married 22 years, one child born. The patient had been in good health, with the exception of occasionally an attack of indigestion, also two attacks of severe pains in region of liver, about one and two months previous to this trouble.

On March 16th, I was called by Dr. L. T. Cheatham, of this city to see this woman, the diagnosis already made, abscess of the liver, sent to the Red Cross Hospital and ready for operation. I found her with a pulse of 120, temperature 102, suffering with a great deal of pain in region of liver, also a distinct bulging over the painful area.

Under gas anaesthesia administered by Dr. W. O. Onderdonk, the field of operation was first cleansed by benzine, allowed to dry, then painted over with a 50 per cent. solution of iodine, the incision was made over the most bulging portion which was the outer border of rectus muscle. After dividing skin, fat and fascia of rectus muscle, the fibres of this muscle were necrotic and full of pus, the liver was adherent to abdominal wall covering over a large area, hence it was not necessary to enter the abdominal cavity to open the abscess.

Upon opening the abscess there escaped a large quantity of typical chocolate colored pus, drainage tube inserted, wound closed, patient put to bed with no marked depression or shock.

Within two days following the operation, her pulse and temperature returned to normal, appetite increased, bowels became regular. In 7 or 8 days permitted to use the head rest.

Drainage tubes removed on third day and at this time she was given the bacterins; giving a dose every 3 or 4 days, but the drainage remained profuse.

She had a dry hacking cough, all the time

as they do when the diaphragm is involved, though her respiration was not interfered with until about the 10th day. She developed trouble with left lung. Supposedly an infarction, respiration became embarrassed, temperature and pulse went up. Her condition grew worse until the 14th day, when she died.

Post mortem could not be obtained.

DISCUSSION.

J. Hunter Peak: I had the good fortune to see this case with Dr. Yeatts. I have seen a number of these cases, and in most of them the termination has been similar to that reported. Those cases of abscesses of the liver that I have seen have usually followed some condition below, such as typhoid fever or appendicitis. In this case, however, there was no history of any abdominal condition prior to this attack.

This case was interesting for more reasons than one. In the first place, the patient had always enjoyed good health; there was no history of any previous intra-abdominal condition that might have led to an abscess of the liver. Furthermore, it appeared to me that Nature was endeavoring to take care of the condition, and for a while it seemed that the abscess would open itself. The liver has no capsule to prevent it from swelling, and in the presence of an inflammatory process it sometimes swells to such an extent as to fill almost half of the abdomen, and in this particular case the liver seems to have become attached to the abdominal wall, which had been infiltrated by the pus, as pus was found between the psoas and rectus muscles, and some of the fibres of the muscles were necrotic, making it very urgent to open the abscess and, if possible, without contaminating the abdominal cavity. For a time it appeared that the patient would get well, but the infarct or embolus in the lung soon wound up the case.

Virgil E. Simpson: I would like to ask what character of vaccine was used in this case.

S. T. Yeatts, (Closing): We used vaccine containing streptococci, staphylococci and colon bacilli, after an examination had shown those organisms to be present.

AN UNUSUAL CASE OF PREGNANCY.

By C. E. FREY, Louisville.

On the evening of the 23rd of last month, Mrs. C., with her adopted daughter, 11 years of age, came to my office for consultation. The mother complained about the girl's breasts, saying "they kept wet, some fluid was coming from them." Upon inspection of the breasts I noticed a coloration around the nipples, the diameter of the pigmented circle being very large, possibly 1 1/2 or 2 inches. Slight pressure of the nipple brought forth

a little watery milk. The girl, having a long and tight corset on, I requested the mother to return with her the following night, dressed loosely without corset. Both appeared at the appointed time, the girl put upon the table and on auscultation the fetal heart sound was made out quickly and positively. Taken off the table and in the standing position ballottement revealed the foetal head upon digital examination, per vagina. Both were informed of my diagnosis, the girl strenuously denying having had intercourse. But the following morning admitted her seduction in July of last year. I report the case on account of the girl's youth, she being 11 years old last month, having been born in March, 1903. The girl is a typical blond, weighs 116 pounds, height 4 feet 10 inches, menstruated at the age of 9, suppression of menses since last August. The girl became pregnant at the age of 10 years and 5 months.

A CASE OF SCLERODERMA CIRCUMSCRIPTA.

By M. L. RAVITCH, Louisville.

Sister L. B., of Henderson Academy, was referred to me by Dr. W. W. Wilson of the same city. Patient, who is thirty years of age, began to complain of general weakness two years ago. She had a general pruritus and a tingling sensation all over the body for the last year. About seven or eight months ago, she noticed a parasthesia of the fingers of the right hand. Shortly afterwards, there appeared a marked tension of indurated skin above the elbow. It gave rise to an exceedingly unpleasant feeling so that the patient had a sensation of having part of the skin in a straight jacket. This form of scleroderma which we found in this patient, usually occurs in oval or rounded patches and is known as morphea or circumscribed scleroderma.

Histologically, we notice changes in the corium, there is an increase in the connective tissue with here and there hyaline degeneration; later on, we see atrophy of the stratum corneum and the papilla.

The latest investigators acknowledge that the etiology and pathogenesis of this affection are unknown. The consensus of opinion among the investigators is, that this affection is rather a disorder of the functions of the glands.

The prognosis is not as unfavorable as in general scleroderma. Some cases have been known to yield to treatment. Roborants, massage with emollient remedies, electro-therapy are very useful agents.

MEDICAL PROGRESS

DEPARTMENT OF GYNECOLOGY AND ABDOMINAL SURGERY.

By A. D. WILLMOTH and CHAS. FARMER,
Louisville.

Some of the Newer Methods of Reducing the Mortality of Operations on the Pelvic Organs.—Dr. Geo. W. Crile from *J. A. M. A.*, Oct. 25th, 1913.

Since the inauguration of aseptic surgery the mortality in all abdominal operations has been constantly falling, due to the improvement in technique and the more careful selection of cases for operation.

The saving of the handicapped patient is one of the important problems of surgery, particularly the patients with hypertension and hypotension, the result of infection or organic diseases. Operations on these patients can be safely done if the operation can be postponed to bring the patient to a condition safe for operation.

The dangers in hypertension cases are embolism, thrombosis, renal insufficiency, angina, pneumonia and cardiac failure. Psychic and physical strain produce identical results in patients with hypertension and the seat of danger is in the brain tissue. This has been proven by experiments on animals. The physical substance of the brain cells is exhausted. Emotional stimulation also produces an increase of the internal secretions, epinephrin, thyroid secretion and glycogen.

If an operation could be performed so that no traumatic impulses could reach the brain, or all emotional stimuli connected with the operation could be abolished or reduced to a minimum, then the dangers from an operation would be only those which result from the local injury inflicted. It is claimed that anoci-association accomplishes this.

The operative procedure under this principle consists of the administration of solacing drugs to lessen the pre-operative strain, the administration of inhalation anaesthesia to obliterate harmful impressions during the course of the operation and the progressive use of a local anaesthetic to prevent the passage to the brain of traumatic stimuli from the field of operation, and finally the use of a local anaesthetic of lasting effect that the tissues may be kept relaxed and painful after effects are eliminated.

Ether possesses certain dangers for patients with hypertension. There is a period of excitement in its earlier stage. Nausea and vomiting are dangerous in these cases. In nitrous oxide gas there is much danger of harmful after results.

The complete technique is as follows: An hour or so before the operation the patient receives a hypodermic of morphine 1-6 of a grain and 1-150 of a grain of scopolamin. The anaesthetic may be administered in the patient's room or he may be conveyed to the operating room and the anesthetic given there. When the patient is anaesthetized the division of tissue is preceded by nerve blocking by the use of a solution of novocaine, 1-400. Each division of tissue in the course of operation is preceded by the injection of novocaine. The skin and subcutaneous tissue are injected, then the fascia, the remaining muscle or posterior sheath and the peritoneum. Momentary pressure is exercised on these structures after the solution is injected so that the anaesthetic effect may spread. Next, the peritoneum is everted and a 5 per cent. solution of urea and quinine hydrochloride is infiltrated, and subjected to momentary pressure. The effect of this will last for several days and wound and gas pain are minimized.

If no cancer or acute infection in the field of operation the meso-appendix, the base of the gall-bladder, the uterus, the mesentery, or any portion of the peritoneum may be injected.

C. F.

Cancer of the Uterus.—Some Points to be Observed in the Early Diagnosis.—Dr. Rufus B. Hall, *J. A. M. A.*, October 14, 1913.

Dr. Hall states in this article that though cancer of the uterus has received more attention than all other diseases peculiar to women, most of the study has been directed toward the development of operative technique rather than the problem of early diagnosis.

It is important that the family physician who sees the patient early should make a diagnosis in time for operation. If a diagnosis is to be made early it must be through the education of the laity by the family physician.

The woman should be carefully supervised during the cancer period which is placed at from 37 to 47 years of age, not that cancer does not occur earlier or later than this period but it is most frequent at this age. The slightest complaint, whether pain in the back associated with a slight watery discharge, leucorrhoea or pruritis should be inquired into. During the past five years for every operable case that came under his care there were sixteen inoperable in cancer of the cervix. In cancer of the body it was one to five. It is the family physician's duty to examine into every symptom referable to the sexual organs of a woman just as carefully as if he believed that she had cancer. He would thus save many patients and avoid a great deal of criticism of himself when the patients reach the inoperable stage.

The trauma of labor plays an important etiological role in the production of cancer of the cervix, and this should be borne in mind. More than 98 per cent. occur in women who have borne children. The early symptoms of cancer of the cervix in the order of their appearance are first, watery discharge; second, irritable bladder; third, a little irregular bleeding; fourth, disagreeable odor. The watery discharge may be present four or five weeks or three or four months before the patient considers herself ill.

Soon after the appearance of the watery discharge, the patient urinates more frequently than usual. There is associated with the watery discharge a pruritis. The irregular bleeding is not an early sign of the disease. The disagreeable odor so much spoken of by some writers is a late symptom of the disease.

If cancer is suspected from the above history a careful vaginal examination should be made. If malignant disease is present a hard nodule will be found in the angle of a laceration. It bleeds very readily when touched with a probe.

The early diagnosis of malignant disease of the body of the uterus is neglected. It rarely occurs before the menopause. The first symptoms are a watery discharge with irregular bleeding coming on several years after the menopause. Associated with this discharge is an annoying pruritis. The bleeding becomes more profuse as the disease extends.

With this clinical history the physician should make an examination. The uterus will be found enlarged and more sensitive than normal. A probe passed into the uterus shows that it measures three or more inches in depth. Slight instrumentation causes a free discharge of blood. If not sure of a diagnosis after this examination the uterus should be everted and a microscopic examination made of the scrapings.

C. F.

Hemorrhage from the Non-Pregnant Uterus.—Dr. John B. Deaver, in Volume Transactions of Section of Abdominal Surgery and Gynecology, *A. M. A.*, 1913, gives a very exhaustive paper on this all important subject. He calls attention to the confusing classification that is made of uterine hemorrhage and charges such confusion to ignorance of the exact principles underlying menstruation.

Dr. Deaver in dividing the subject from a practical standpoint speaks of hemorrhage occurring during three periods of female life—puberty, child-bearing period, and the menopause and states that all are due to either local or constitutional causes. Under constitutional causes he places hemorrhage due to interference with or departures from the nor-

mal in the internal secretion or secretions from the ovary and other ductless glands. The changes thus produced in the uterine flow may be in quality, quantity, or regularity.

In all cases of hemorrhage the following well known constitutional causes should be looked for and ruled out. Hemophilia should be especially inquired-after. Anemias including chlorosis, leukemia, high-blood pressure, infections, fevers, arterio-sclerosis, syphilis, chronic diseases of the heart, lungs, liver, and kidneys.

The curette once so popular should be saved for the last and then only to be used as a temporary measure. One in every five cases generally speaking derives no benefit from curetting hence curetted unnecessarily.

If patient has had leucorrhoea, with its resulting thick endometrium, such cases may be benefited by the curette.

Local causes may be found in almost any of the pelvic diseases such as gonorrhoeal or puerperal infection of the uterus, myoma, polyp, or cancer, tears, retro-displacement, tubal, ovarian, or tubo-ovarian disease.

In hemorrhage due to local cause or causes, the indications for treatment are obvious and the extent of interference is controlled by the extent of the involvement. A very large number in this class is due directly to parturition. These cases are benefited in most instances by the scientific use of the curette, its use hastening the return to the normal.

Puberty and the menopause furnished the most difficult cases for diagnosis and for relief. Hemorrhage at puberty may be due to ovarian disease or to some form of infection or polyp but are rare, most cases being "essential" hemorrhage.

Contrary to the general belief, many are the result of mild hemophilia which, however, may be severe enough in some cases to produce death. A few the result of chlorosis and some the result of syphilis. Mitral stenosis deserves special attention. Such cases should never be confounded with the endometritis cases and should not be curetted and great care used in the examination, since nervous shocks are prone to produce a morbid mental attitude toward sexual and mental life.

Hyperthyroidism is believed by Deaver to be another cause of increased and irregular bleeding.

Dalehe's explanation of the rapid growth of the body and sudden development and maturation of the ovary unsettling the normal equilibrium and causing a so-called "ovarian ataxia" in which there are periods of hypersecretion followed by hyposecretion should not be confounded with macroscopic disease of the ovary. Again Deaver believes that there is a direct relation between calcium

metabolism and menstruation and would advise that in the treatment the calcium index be determined and if low, suggest the use of 10-20 grains of lactate calcium three times daily.

He believes that calcium is the only remedy of definite value although many others such as ovarian, adrenal, thyroid, pituitary extracts, animal serums, ergotine, styptician and hydrastin are used and believed by many to overcome the cause and control the hemorrhage.

Dr. Deaver's paper is of inestimable value to the profession if in no other way by the beginning his treatment in warning against the too frequent use of the curette.

Treatment: Nothing is so effective as rest in bed for those cases of essential hemorrhage. If hot douches are used they should be limited to married woman but should be avoided in young girls. If the application of heat is desired it should be obtained by hot rectal injections but its use is questioned in any case, since cold to the abdomen in the form of ice bags is far more efficacious.

Deaver's conviction (and also many others) is that the vaginal douches as a routine measure do more harm than good. They are one of the many local treatments that swell the number of women both married and unmarried who suffer from psychoneurosis. Weekly changing of pessaries, unnecessary vaginal examinations, digital massage of the uterus, as done by the osteopaths are also followed by disastrous results. X-rays should not be used for the control of hemorrhage because of its destructive influence on the ovaries.

In hyperthyroidism too much should not be expected from ligation of vessels and removal of portions of the gland, since the symptoms are possibly due to disordered secretions more than to excessive secretions. Thyroid operations should not be done in the young until all other means have failed.

Gelatin is uncertain by the month and danger of sepsis too great to be used subcutaneously. Electricity is a local treatment hence to be condemned.

To Summarize: The treatment of uterine hemorrhage at puberty consists in quietude, rest in bed, free action of the bowels, ice to the abdomen, together with the use of calcium and such other drugs as have been mentioned. Above all time must be allowed for these cases to improve.

Again he warns against the use of the curette. In hemorrhage at or near the menopause Dr. Deaver calls attention to the prevalence of cancer and strongly urges the use of the curette, as being the only means of diagnosing cancer of the uterine body, a condition for which there is no excuse for overlooking,

until the patient is far advanced and beyond recall.

Inspection and section of the cervix is necessary to exclude cancer there. If the cervix or body are at all suspicious a complete panhysterectomy should be done.

If no pathology can be found by eurette you are reasonably certain that the case is one of fibrosis of the internuscular structure along with sclerosis of the uterine vessels. Sclerosis of the uterine vessels is not to be confounded with a general arteriosclerosis.

Deaver calls attention to the fact that the change is the adventitia and media. The media is diminished in size because the muscles are relaxed by fibrous tissue. The intima is not involved and the lumen of the vessel is not encroached upon, a point in differentiating from syphilitic atheroma.

The uterus itself may be small, apparently normal, in others large and soft, in still another class large and firm. The sclerosis is common to all forms.

The treatment in these cases has for its object the preservation of the organs, for this reason X-rays has its advocates, but it must be remembered that atrophy of the ovaries and uterus takes place after its use for any length of time. The results obtained from electricity in any form is not as a rule permanent.

The application of steam has some advocates in the hemorrhage during child-bearing period, but the utter impossibility to regulate the destructive atmoæusis places it as Deaver had said into a class of remedies never tried.

Where the hemorrhage is severe packing has to be done but should only include vaginal packing unless one is certain of asepsis.

Deaver believes that all cases of hemorrhage due to sclerosis should be relieved by complete removal of the uterus.

Hysterectomy is to be especially recommended in these cases as in the polyp cases a diagnosis is sure and certain and conservative treatment can be carried out.

In cases over forty the supra-vaginal hysterectomy should be done with the removal of both ovaries.

A. D. W.

Pancreatitis, Subacute. Treatment. 1. Rest. 2. Limitation of diet. 3. After acute attack of pain has passed off, cholecystostomy.—Archibald and Mullally.

Pellagra. Treatment. Gelsemium followed by much improvement in 5 cases. Fluid-extract, 3 or 4 drops every four hours, given. Discontinue drug if ptosis or diplopia occurs.—Blosser.

MEDICAL PROGRESS

DEPARTMENT OF OBSTETRICS.

By FLORENCE BRANDIES AND BEN CARLOS

FRAZIER, Louisville.

I.

Wm. Kohlman in *New Orleans Medical and Surgical Journal* for March, in writing of Cesarean section in ante-partum hemorrhage claims that the quality of obstetric operations has improved in treatment of this complicating emergency as in other important obstetric-al crises.

In placenta previa the two old well recognized procedures have been version according to Braxton Hicks and metrensis. Without discussing the merits of these he states that reports from many institutions show a mortality of mothers from 7 to 10 per cent and more, and children from 60 to 70 per cent. Sepsis has been given as the cause of death of the mothers in only 10 per cent, while loss of blood has claimed the majority of the victims. Cesarean section has therefore in recent years been looked to as the solution of this great problem; he gives three main points in favor of this radical procedure: First, intra-partum hemorrhage prevented, as dilatation of lower uterine segment not necessary; second, in case labor set in and loss of blood makes termination imperative, a pro-Cesarean may yet save mother and child; third, Cesarean prevents post-partum hemorrhage.

Kohlmann cites Kroening and Seisheim as advocating this method of delivery in selected cases as in placenta previa centralis and lateralis, complete dilatation not having taken place. The great reduction in mortality of mother and child must without doubt accord to this operation, the place it so justly merits.

He reports a case of pregnancy at eight months, multipara with repeated hemorrhages of varying amounts, examination showed placental tissue presenting over os—labor pains felt during two hours; diagnosis, placenta previa centralis. Operation, Cesarean section. Mother and child both did well and left the hospital on ninth day.

He reviews history of hemorrhages in accidental, premature separation of placenta and calls attention to the greater danger to both mother and child in this condition than in placenta previa—this would suggest Cesarean section as operation of choice.

He quotes Goodell, Branus, Hertzfeld, Stefens and Zweifel and from all we gather the overpowering mortality record, and lays great stress upon the dangers of post-partum hemorrhage. After reviewing the various causes productive of accidental hemorrhage, Kohl-

mann reports a case of that character in which there was danger of post-partum hemorrhage in which he advised and did a conservative Cesarean, delivered the mother of a much-longed for living child weighing five pounds and six ounces and uterus contracted so promptly and well that there was not more loss of blood after delivery than is usual in a normal birth. This excellent result he ascribes to the use of pituitrin, which was given hypodermically in dose of 1 c. c. just before incision of uterus. In this case also mother left hospital together well early in puerperium.

II.

The Southern Medical Journal prints the paper of Stuart McGuire read at the Southern Medical Association meeting at Lexington, Ky., subject being "Evolution of Treatment of Ectopic Pregnancy."

After referring to history of knowledge of condition, of procedures in handling same he pays a fine tribute to our own McDowell, who opened the abdomen for other conditions; why not for this one—it was not, however, until after the publication of Parry of Philadelphia in 1876 in which he analyzed 500 cases of ectopic pregnancy, and reported a mortality of 67.20 per cent. that this appeal for help was answered by Lawson Tait, who undertook a death grapple with this dire emergency and reported a case of death from failure to operate; this shamed him so he opened the abdomen in a case of ruptured tubal pregnancy in January, 1883.

This first attempt met failure but within the next six years he reported 39 cases with but two deaths—a triumph indeed!

From Tait's triumphs to the even greater ones of Joseph Price the story goes and as McGuire says history rests.

The still unsettled questions facing the surgeon are those of:

1. *Drainage*: In a case of ruptured tubal pregnancy without infection, close abdomen without drainage.

2. *Saving Ovary of Affected Sides* Never remove sound ovary—thus avoiding possible sterility and premature menopause.

3. *Immediate Operation*: Operate on unruptured cases as soon as diagnosis is made and on ruptured cases also as soon as patient is seen.

4. *To Remove or Ligate Opposite Tube to Prevent Repetitions* After recital of opinions of other operators, McGuire reviews histories of his own primary and secondary operations and voices the conclusion that the chances for subsequent pregnancies are fair and should be accorded to every woman. He fears operations little and values babies highly.

III.

The Medical Herald, March, 1914, publishes the papers of a "Symposium on Pregnancy" which were presented before the Medical Society of the Missouri Valley, at Omaha, September, 1913, the titles being:

1. "Diagnosis, Course and Management of Normal Pregnancy."

2. "Abortion, Diagnosis and Treatment."

3. "Ectopic Pregnancy."

4. "Advice to Expectant mothers."

5. "The Medical and Hygienic Management of Moderately Abnormal Pregnancies."

The last contains a strong plea for early and frequent visits of the expectant mother to her chosen medical advisor.

Dr. Strong advising that the physician see the patient; have her bring specimen of twenty-four hour urine and not leave it at office but allow an inspection of aspect and examination of pulse in addition. She urges early recognition of even slight abnormalities of pelvis, and in such cases insists upon especial care given to diet of mother and exercise of same—thus regulating to some extent the size of child and somewhat the ossification of the head. The most important aid to the first being work for the mother—exercise calling into play the abdominal muscles which hasten the engagement of the head, forcing it into the pelvis. She describes the practice of a large maternity hospital of New York, which makes every expectant mother do her part in scrubbing the floor of the ward—this is good for obvious reasons.

She next reviews the diet; forbidding oatmeal, whole wheat cereals and fresh milk—sweets are also tabooed. Buttermilk, all fresh green vegetables, meat in moderation, also eggs and bacon sparingly, with fresh fruits, except bananas, are allowed. Water, pure and fresh must be used freely.

The doctor insists upon explicit directions and upon the use of such terms as each individual may understand—avoid technicalities. Attention to pulse, quality and rate, examination of urine; free and frequent, regular evacuation of the bowels, never taking patients word as to the amount of fecal matter passed—always insist upon more.

Care to prevent engorgement of liver by above method, and in cases of toxæmia she advocates the use of calomel in 10 grain doses even before serious developments arise.

Under hygienic management she advocates baths, neither hot nor cold; keeping the skin active to the point of perspiration. Care must be taken to ascertain the effect of baths upon pulse and pressure especially in even mild cardiac or renal involvement. She outlines a diet in renal and hepatic insufficiency and insists in both instances in withdrawal of

meat and judicious use of water and lemonade.

She summarizes thus: "Be sure of your pelvic diameters; a diagonal conjugate of 2 1-2 inches being the province of the surgeon.

If diameter be moderately decreased keep baby small and mother strong by proper diet and regulate work or exercise.

For toxemia, diet, and free elimination by skin, kidneys and bowels." F. B.

IV.

The Journal of October 25, 1913, in an editorial on the work of Murlin and Bailey on "Further Observations on the Protein Metabolism of Normal Pregnancy" rejoices in the fact that this important work should serve to dispel some of the illusions current in regard to the supposed perversions of nutrition frequently connected with the late period of gestation; that so much has been asserted regarding the supposed deviations from the normal in this period, so much emphasis has been placed on the dangers from a high ammonia percentage, that it is a satisfaction to learn the conclusions reached by the Cornell investigators.

In general they believe that peculiarities in the composition of the urine of normal pregnancy as regards its nitrogenous constituents may be accounted for on purely physiological grounds.

I.

USE OF PITUITRIN IN OBSTETRICS.

Pituitrin like many other valuable medicinal agents is used for many purposes, but we will only discuss its use as an oxytocic as that is where it has been most used and with best results. There are many reports now both from home and abroad setting forth its use and effects. Most reports are quite similar, usually quite complimentary to the action of pituitary extract, though some are much more inclined to limit the use of it than others. Personally I am inclined to think we have not learned just how much to expect from its use and it may be that some have condemned it before they had used it, or become acquainted with its use to give an unbiased consideration.

Malinowsky reports favorably and gives charts showing the rhythm of uterine contractions, normal, violent and tetanic excited by doses of this material. The effects according to Malinowsky of 1 c.c. of pituitrin lasts for one hour. The duration of each pain is diminished and so are the intervals. Tetanoid contractions spoken of by others, he seems to think a physiological curiosity as he has never found the into do harm either to mother or child. 1 c.c. of pituitrin is quite enough for a dose and should only be used from ampules. Smaller doses are less satisfactory.

There have been practically no bad results from the use of pituitrin to the mother in properly selected cases. The second stage of labor is where the best effects are to be looked for from its use. Some very gratifying results have been reported from the use of pituitrin in puerperal convulsions. Its use of course, is given with the desire to hasten delivery. With a high blood pressure already present and recognizing that pituitrin raises the blood pressure you have a contraindication for its use, but the effect is transient and if rapid enough to cause spontaneous delivery or to bring the head on the perineum where forceps can be easily applied and thus bring about a hasty delivery, the desired end has been accomplished.

If, however, you have a poorly dilated os with a high blood pressure and the administration of pituitrin should further raise your blood pressure it seems that eclamptic convulsions are very apt to be the result. I would not hesitate to use one dose (1 c.c.), but I would not venture further if not successful with the first dose.

Benson says, that the action of pituitrin in the average case is nothing short of wonderful. He has used it in seventy-seven cases with only one failure to have marked effect on the pains. He further states that in the multipara cases where he has used pituitrin there were few after pains and they were of short duration. Benson, as well as Edgar and others, lays great stress upon the necessity of a fresh preparation used only from ampules. He also warns against the possible dilution with alcohol which he seems to think interferes with the action of pituitrin.

Chloroform in the early administration of pituitrin retards its effects and should not be given until the head is quite low. The fleeting action of pituitrin calls for repeated doses to have a continued effect and there has been a warning sounded against the slowing of the fetal heart sound, however, there has been no fatal case to the baby reported, except in the first stage of labor where compression of the placenta or deep rupture of the cervix. Very few authors advise the use of pituitrin in the first stage.

Most others also claim that the most positive results are in multipara rather than in primipara cases. The preparation is supposed to be better in full term than in premature labor. In fact quite a number of reports think its action in abortion or premature labor is uncertain, though there are some other gentlemen reporting cases where they have gotten good results from its use in abortion. Cardiac and renal diseases are contraindication for its use as observed by men who have had most experience.

Pituitrin has no place in normal labor and its administration should be confined to cases in secondary inertia.

DeLee, in *Practical Medicine Series*, says it has become necessary to sound a grave warning against pituitrin. He states that, as we all recognize, it as a most valuable drug, yet it is being most fearfully and criminally abused. He further states that pituitrin is a very useful agent, adding so is the obstetrical forcep, but the man who will use the forcep without scientific indication is no more criminal than the man who uses pituitrin without scientific indication. The use of pituitrin in deformed or contracted pelvis is of course a contra-indication to its use. B. C. F.

II.

TREATMENT OF THE THIRD STAGE OF LABOR.

There are three methods ordinarily recognized in the treatment of the third stage, first, the Dublin, second, Crede, and third, Ahlfeld. It was not until 1861 that Crede taught by his familiar technic to express the placenta as soon as the child was born. This slowly gave way to the expectant method of Ahlfeld. It was not many years later that Crede himself recommended waiting for half an hour for the normal delivery of the placenta.

I have always thought that the kneading of the fundus in normal cases was unnecessary, and frequently harmful. According to Ahlfeld the uterus should be left entirely alone and the attendant only satisfying himself occasionally as to the consistency of the contraction. B. C. F.

III.

PRIMARY RESTORATION OF THE PERINEUM AFTER LABOR.

All perineal lacerations should be repaired at once if the patient is in sufficient hygienic surroundings to insure clean work. Some authors advise that repair in primipara is more or less useless because in subsequent bearing of children laceration will again occur and the premature repair has been useless. This seems to me to be rather poor reasoning as there is always a possibility that the mother will not bear further children and even if she should there should be sufficient perineal support to give her some comfort even up to the time of the next pregnancy, when a laceration might not occur. Of course, there is a possibility of the lavator and being sutured too high, to cause a certain amount of stenosis of the vagina. In very few cases is it necessary to freshen the tissue as careful suturing will bring the muscles well in apposition, and good results will be obtained unless there are shreds with blood supply not sufficient to heal. Very small lacerations, of course, should be let alone because there is a certain amount of

repair that take place anyway. These small tears I usually leave unrepaired. B. C. F.

IV.

NURSING BY PUERPERAL WOMEN.

It has been a general belief that a great many women could nurse their babies if they only had sufficient inclination and the doctor and nurse were persistent enough in their efforts to assist her. A few authors have gone so far as to say that any healthy woman who has the desire can nurse her child. It seems to me that anyone making a statement of this kind has had very little experience and observation in the breeding of lower animals because it has been definitely proven that a good many lower animals have not sufficient milk to maintain their offspring, and the same thing applies to the human. Many families are poor milkers, often a daughter cannot nurse her child and it will be found that the mother could not nurse her children. I have had very few mothers under my care who refused to nurse their babies and quite a number have made persistent efforts, even having all the attention and help possible, but could not possibly furnish enough milk to maintain their children.

There are some galactagogues that are of some service and these along with nutritious food, rest, lack of worry, sufficient exercise to keep up appetite usually will place a mother in a position to nurse her child if her mammary secretions are at all worth while.

However, occasionally with every advantage there are certain mothers who are unable to nurse their babies sufficiently to have them grow. Women who bear children late in life are much less likely to be able to nurse their babies than those who have borne children in the late teens or early twenties.

Of course, chronic diseases, puerperal sepsis, and such conditions are indications for the child not to even attempt to nurse its mother.

Women usually prefer to nurse their children both from the pleasure of nursing and to save a certain amount of trouble and care that a bottle baby causes irrespective of the fact whether the nurse or mother is to care for the baby. All mothers should be encouraged to nurse their babies if their health is such as to warrant the belief that they can do so without jeopardizing either their own health or that of the babies. B. C. F.

Femphigus. Treatment. Case of refractory pemphigus in which intravenous injection of blood from patient's husband, without previous defibrination, was followed by complete recovery. —Practorius.

VENEREAL PROPHYLAXIS.

By IRVIN LINDENBERGER, Louisville.

The bibliography on this subject is most extensive. A summary of same is not appended.

For those who through ignorance or other reasons do not need preventive measures, it can be said that there is not the shadow of proof to show that continence is damaging to health; to those that do, I think there can be no question that the time has arrived to endeavor to regulate and control the spread of venereal disease.

That prostitution is the principal source of sexual disease is not disputed. Prostitutes who are the especial objects of police care are demoralized, they spread demoralization, cause enormous waste, and inevitably and invariably spread disease. Losch has estimated the annual cost of prostitution in the German Empire at something like \$125,000,000. This outlay may be contrasted with that spent by the Prussian Government on its entire educational system, i. e. \$50,000,000.

Kelly estimates that venereal diseases cost America three billion dollars a year. These figures seem underestimated rather than exaggerated. The Chicago Vice Commission estimates that the profits accruing from prostitution in that city alone amounted to \$15,000,000 annually.

Fiscer thinks that 10 per cent. represents the leucic cases in the United States, and he further states that there are 250,000 deaths each year due to venereal infection. Morrow states that 75 per cent of adult males acquire gonorrhoea at some time, and that from 5 to 10 per cent acquire syphilis. He bases his figures not only on his own observation, but on the opinion of such men as Neisser and Fournier, and on the statistics found in the clinics and dispensaries of continental Europe. In this connection he calls attention to the unreliable reports furnished by our hospitals, because cases of the primary diseases are not admitted, and only in the practically incurable stages. are venereal cases given housing under such titles as arthritis, prostatitis or endometritis in gonorrhoeal patients, and general paresis, tabes dorsalis, aneurysm and so forth, in specific cases.

Osler puts syphilis next to tuberculosis, pneumonia and cancer as a death dealing agent. A conservative estimate puts 10 per cent of the insane in the Massachusetts asylums due to syphilis, and the yearly cost of their maintenance is \$300,000. Morrow also assures us that 80 per cent of infectious peculiar to women are due to gonorrhoea. Were it not for that disease the gynecologic depart-

ments of the hospitals might be almost done away with, for from 75 to 80 per cent of all operations on the female genital tract are necessitated by gonorrhoeal infections. Gonorrhoea is not considered so malignant by the general run of men, but as a matter of fact with its quite occasional complications it is quite a serious condition. Rosenstein ventures the opinion that 20 to 25 per cent. of the inmates of our institutions for the blind are the results of gonorrhoea alone. At the present time 35 states and territories have laws concerning ophthalmia neonatorum. Our own State passed such a law at its last Legislature.

Concerning the source of supply of prostitutes is the startling fact that practically the total derivation is from the lower working classes, and usually the unmarried women of these classes. Very rarely indeed a person of some education, social standing, and personal charm is met with. Most cases have had only rudimentary training, and evidence shows causative relationship between mental defect and prostitution, but however, far from being the only relationship. The relation of the home is one of many causative factors in the production of prostitution.

Cities and countries differ in race, ideals and traditions, and while bad housing, emphasized by some as a marked factor in the causation of the "social evil," is of less importance than the racial traits of the dwellers. In the Ghetto of New York City, perhaps the most congested district in the world, containing many houses unfit for human habitation, prostitution among the Jewish girls is rare. I judge they must follow the 22nd Chapter of Deuteronomy, for here we have the practical results of religious education. Up to April 1st there have been from outside this city over 200 women turned away from The Business Woman's Club, not that they do not want them, but they have no accommodations for them. The future of some of these girls can be surmised as a result of their leaving a good home in the country, or a good home in the city.

The arguments pro and con concerning any method of control of vice and venereal disease have never up to the present time had the unanimous verdict of any society or organization. There is a unity in three recent reports, i. e. the Police Commissioner of Boston, the committee of Fourteen in New York, and the Mayor's Vice Commission in Chicago. These committees all agreed on the need of stern repression of open vice, of a more wide-spread dissemination of medical knowledge among lay adults, of sound thorough education of the young in the fundamentals of sex hygiene, of strict enforcement

of individual responsibility, and of the paying of a "living wage" to girls employed in the industries. They also recommend the abolition of the rear door and hotel features in connection with the saloon. Of especial significance is the fact that the committees are unanimous in the belief that crusades, and the like, are harmful, particularly when conducted, as they often are, by misguided fanatics.

Part of this seems not impossible of accomplishment in a determined community, for Iowa with its Injunction and Abatement Law has one phase of the solution solved. A law similar to this was introduced in our last Legislature, but failed of passage.

The United States has no law against infecting others with venereal disease, as shown by the recent decision of the Supreme Court of Mississippi. Dr. Isadore Dyer, of New Orleans, reports a case of a patient with primary syphilis who refused even charitable treatment, and carried a book wherein she kept a record of the number of men she had inoculated. When she was first seen she declared that the number had reached 219, and she would not be treated until she had had revenge upon 500 men.

The question of personal prophylaxis as to whether we should recommend means by which infection may be more or less combated is not unassailable. Only a few days ago I suggested to a Father the advisability of his son using prophylactic treatment, as I knew he laid himself open to infection occasionally, and he advised against such a procedure, saying it would make it too easy for him.

There can be no two opinions as to the benefit to be derived from such treatment in our soldiers, both army and navy. The results on the U. S. S. Ranger as regards prophylaxis against venereal diseases are merely confirmatory of those obtained on the U. S. S. Concord, on which ship, of 281 known exposures followed by the adoption of prophylactic measures, there resulted only two cases of venereal disease, both of which had exceeded their time limit on shore, and, as a result, treatment had been delayed. The commanding officer of the Concord states that during the first five months in which these prophylactic measures were in force there was not a single case of gonorrhoea or syphilis contracted by the crew. The statistics regarding the measures above are overwhelmingly in favor of prophylaxis of this kind.

Moral arguments may be adduced against such a procedure, but are hardly to be considered as reprehensible as the present wide sale of condoms. These articles are purchased with malice aforethought, whereas medical prophylaxis can be based only on the supposi-

tion that venereal disease is the punishment for transgression, an obsolete and Puritanical view, that is detrimental to any cause, and that carried further, would intimate that no attempts should be made to cure venereal patients. If the prophylactic properties of these packages now on the market were generally known, their sale would go far toward reducing the prevalence of venereal disease among men, and, therefore, among women. I personally believe, from statistics adduced from Naval Medical Reports, that if every illicit or dangerous intercourse were followed by a reliable prophylactic, in a few years we would witness the passing of the scourge as complete as the eradication of yellow fever, typhoid and malaria. The Washington State Medical Society recommended that all houses of prostitution be compelled to provide prophylactics to their patrons, and in Newport, R. I., prophylactic tubes are in the regular houses of prostitution of that place.

A few of the arguments for and against the official regulation of prostitution are as follows:

A. Medical examination is inefficient. In many cases venereal diseases can be diagnosed only by the specialist, and with the greatest difficulty.

A. With the aid of the Wassermann reaction and modern methods of cultures and staining of the gonococcus, diagnosis is not difficult, certainly not so in cases likely to produce infection.

B. Regulation does not regulate, and segregation does not segregate.

B. Efficient regulation is a matter of money, and can be obtained by paying for it.

C. It is impossible to control all women practicing prostitution; even in cities where regulation is most favorably carried out only a small proportion of the prostitutes are under control.

C. Regulation is not a means of eradicating venereal disease, but for every infected prostitute that is controlled a certain number of cases of venereal diseases are prevented. The lower class of prostitutes are the ones that always come under control, and are those in whom regulation is most necessary.

D. At best regulation affects only the woman, while the men are quite as virulent spreaders of the disease.

D. Whereas a man has intercourse with one woman, a prostitute has intercourse with twenty or more men. But a very small proportion of infected men will practice fornication, as they all know they are infected. Some women are not aware of their condition, whereas others will continue their trade for financial reasons. The Chicago Vice Commission reports one girl who had intercourse

with 45 men in one night. It should be borne in mind that if the woman, though not herself infected, may be the carrier of disease from one of her patrons to others of the series.

E. It is impracticable to house all the prostitutes that are infected in public institutions.

E. The large number shows the urgency of reducing the amount of venereal disease. Only those in an infectious state need be incarcerated. It would seem that "606" may greatly diminish the time required to make syphilis non-infectious. Gonorrhoea is a curable disease.

Because a system is inefficiently administered, it does not follow that it is without value. No methods should be branded as inefficient unless they have been definitely proved to be so. Too much should not be expected in a short time, as, owing to the character of venereal disease, and of gonorrhoea in particular, little can be hoped for except by prolonged effort.

There were on March 30th of this year, as given me by the Chief of Police of this city, Col. H. Watson Lindsey, 121 houses of prostitution; 81 houses of assignation, making a total of 202. The number of inmates of regular houses were 500. Number answering calls, 72. Total number of prostitutes 572. There have been closed since January 1st of this year, 18 houses. Number of prostitutes leaving the city in the same time, 65. His department regarding the features as pertain to crime is thoroughly systematized, and cooperation with him, I know, would be most gladly welcomed regarding any health feature.

The debasing effect of alcohol on the moral sense as a causative factor, I will not enter into.

If I were to go before a meeting of criminal jurists and argue that it is useless to imprison thieves because the punishment does not diminish the number of thefts, but, on the contrary thefts are on the increase, I believe they would look on me with something more than surprise. It is nearly, but not quite the same thing for a physician to give his own personal opinion that the regulation of prostitution is the cause of increasing the spread of venereal disease.

There is much truism in the fact that physicians eager to equip themselves as specialists in venereal diseases go to the crowded clinics of Paris, Vienna and Berlin, all regulated places, because there disease is found in greatest abundance and richest variety. In Paris regulation has been in effect 50 years, but the scientific manner of handling it does not approach that of Germany. I judge regulation does do some good or they would not have kept it up for this long.

The law of Norway to me has many features that could with much advantage be used in the United States. In order to assist the health, not the police authorities in controlling the diseases in question all physicians are required to report daily, usually without names (names are given when the physician feels that the patient is likely to spread infection, or when the patient is sent to a hospital), their venereal patients, to furnish the patient with a copy of the laws relating to the communication of venereal disease, and to require the patient to sign a statement acknowledging the fact that he or she has thus been explicitly warned.

Attention is called to the following sections of the Penal Code, Section 155. Whoever, with knowledge or conjecture that he is suffering with a contagious sex disease, infects or exposes to infection another person, by means of sexual intercourse or immoral contact, shall be punished by imprisonment for not more than three years. The same punishment is provided for those who connive at enabling any person who is known or suspected to be afflicted with a contagious disease, to infect in the above manner or expose to infection, another person.

Section 358. Imprisonment for six months or less is the punishment for any one who, without calling attention to the danger of infection: (1) causes a child to be nursed, knowing or suspecting the child to be afflicted with contagious syphilitic disease, or engages any one to nurse such child or, (2) Knowing or suspecting that he (or she) is suffering from contagious syphilitic disease, enters the household of another as servant, or remains in such service, or receives a strange child to nurse it, or aids in bringing about such conditions. The same punishment is provided for those who engage or, having engaged, retain, any person known or suspected to suffer from contagious syphilitic disease, as nurse for a child, or who aids in bringing about such engagement or retention of service.

Regarding the warning, the following is given to the infected party.

I herewith acknowledge that Dr. _____ has called my attention to the following points:

1. That I am suffering from, say, syphilis.
2. That my disease is contagious for at least _____.
3. That, I am punishable, if I in any way expose others to infection. Copies of Penal Code, Sections 155 and 358 received.

Date Signature.....

The physician also endeavors to ascertain the source of infection, and the person inculpated is reported to the Health office. This latter individual on calling by invitation

(You are respectfully requested to report at office No. 55 Akers Street, third floor, as it is desired to talk to you) is informed of the nature of the charge, the name of accuser being withheld, and is invited to submit to examination at a hospital or by a municipal physician. No compulsion is applied, the advantages of knowing the truth, and that offer of free and skillful treatment in complete privacy, form the entire inducement.

If disease is thus proved to exist, treatment can be compelled, to the extent of forcibly confining the infected person in a hospital. Reliable persons receive ambulatory treatment at the hands of municipal physicians, women, at the Board of Health office where a woman physician is on duty. The police are invoked only if an individual having been "denounced" neglects or refuses to comply with the summons of the Health Department. Persons who, having knowledge of their infectious condition, communicate disease, are punished with imprisonment for not exceeding three years. The Danish is quite similar in many respects.

As to the solution, I will not dwell on the ideal, the abolition of prostitution. Education is being strongly advocated, and is of undoubted advantage, but let this education come from the home, where often religion is made part of it, or the family doctor, for it is doubtful to my mind if all the magazine, picture shows, and many "Social Evil" lectures really do the good intended they should, even if given by sincere, well-meaning persons. Wilson states that the medical students furnished a larger percentage of venereal infections than any other student group at the University of Pennsylvania. In many families a sense of false modesty prevents most parents from giving any instruction to their children upon sexual matters, and indeed, it is the testimony of most persons that the discussion of the anatomy and care of the genital organs, the source and dangers of venereal disease, and the subject of the social evil, are topics which were rigidly excluded from discussion in their homes.

I would advise the abolition of houses of prostitution, houses where a madame can hire out girls and make a profit therefrom. The abolition of intoxicating drink in houses that do exist. The advisability of advice by the physician of prophylactic tubes where he is of the opinion it would do good. The adoption in part or in whole of the Iowa Injunction and Abatement law, and part or in whole of the law of Norway.

As to a solution, or to a state of betterment for this city, as at present nothing is being done, I would suggest, that knowing, and having the record of 500 prostitutes in regular

houses, I would make it incumbent by ordinance, that the madames should be made to report the cases of venereal disease that may exist among their number. This method is followed in Detroit, Mich. It is not recommended that these houses be licensed, and regular medical examination be made of the inmates, because medical inspection without doubt tends to produce a false sense of security and is insufficient to prove the absence at all times of disease.

To have a better understanding with the keepers of these resorts, known to the police, they should be notified that inspectors from the Board of Health will make occasional visits at these houses for the purpose of examining inmates. These visits to be made at unannounced and irregular intervals. No certificates of good health are to be accepted whatsoever, or none given.

When an examiner finds one or more of the inmates ill with a venereal (contagious) disease, the house is to be placarded with a large placard with the one word, "Quarantined," printed in large type. If the keeper of the house or her physician reports the case before it is discovered by the examiner, the patient is to be given the alternative of going to the hospital or having the sign up.

After the quarantining of one of these houses in Detroit, reports of at least 20 cases of venereal disease were made in one week, with the request that the patients be removed to a hospital. Competent medical examiners and proper hospital accommodations are necessary for the above.

Is it a question of "what can not be cured, must be endured," or should we attempt to better the problem, for the nation that solves it will outstrip all others.

PIONEER MEDICAL JOURNALISM IN KENTUCKY.

By J. G. HENDRICK, Central City.

A few months past I contributed a number of excerpts from "The Western Lancet, Vol. 6, May, 1847. As they were published in the JOURNAL, therefore of some interest, I concluded to contribute excerpts from the July issue, 1847. *The Western Lancet* was a bi-monthly, published at Lexington, Kentucky, edited by Dr. L. M. Lawson.

"Article 1. Original Communications.—Procidencia Uteri, an inaugural dissertation submitted to the examination of the trustees, and medical faculty of Transylvania University for the Degree of Doctor of Medicine, on the 20th of January, 1847, by John Nash LeGrand, of Warren county, Mississippi.

Displacements of the uterus have been known to the medical profession since the days of Hippocrates. They result from mechanical violence, disease of the ligaments, sustaining the uterus, uterus itself, or from constitutional derangements. They are rarely, if ever primary affections, but the sequence of other diseased conditions. When from disease of the uterus or ligaments, the character of the suffering will be in accordance, when from violence the cause is apparent, when as sequence of disease of the general system the character of suffering will be as variable as the primary affections. Notwithstanding the amount of talent, industry, research, and investigation, have signally failed to cure them.

Procidentia uteri may be divided into three stages: First, the os uteri is lower in the pelvis; second, the uterus has descended still lower in some instances resting upon the perineum. In the third the uterus is precipitated from the pelvis.

The author enters upon a lengthy discussion of disease of uterus, and constitutional diseases bearing indirect symptoms in the uterus. I will give a few excerpts. It will be seen that he was materially influenced by theories at that time recently promulgated, that many ailments of the uterus are influenced by constitutional affections, and sometimes entirely reflex neurotic. Graily Hewitt of London in his exhaustive treatise on diseases of women issued in 1882 taught that constitutional ailments were prime factors. At the present day gynecologists realize the fact and direct treatment accordingly. The author says, "It is evident from consideration of the causes of procidentia, the general health preceeding, and accompanying procidentia, must be more or less impaired. It has striking, and intimate sympathetic relationship with the skin, stomach, brain, kidneys, bowels, and nervous system. They may appear to have consumption. A ease is given by Professor Dudley, patient had all the symptoms of phthisis pulmonalis. On postmortem examination no disease of lungs, abdominal viscera healthy. But the whole uterus, posterior walls of bladder, and front walls of rectum entirely destroyed. I am persuaded that physicians would succeed more promptly, and satisfactorily by directing treatment to the organ first diseased. Restore healthy condition of stomach, bowels, skin and nervous system. Investigation should be made with patient erect, to ascertain the degree of prolapsus, sensibility of cervix and os, heat, size and weight of uterus, relaxation of vagina and perineum.

TREATMENT.

The treatment relied on has been astringent injections, pessaries, recumbant posture, pads, cushions, and steel springs. I have derived no beneficial results from them in some instances injury. If the disease has a constitutional origin their general health has been restored, in spite of the treatment, the local affection has of necessity been relieved. Dr. Hamilton first attempted cure by producing adhesion of vaginal walls, this was abandoned. It is necessary to restore general health necessary to take the weight of the uterus from relaxed ligaments, rigid recumbant posture. She should be on carpeted floor of a large well-ventilated room, shoulders never raised till suspensory ligaments have strengthened to sustain the uterus, diet regulated, secretions and excretions attended to, amusement varied, her skin, body and limbs sponged daily with salt water, or with coarse towel saturated with salt brine well dried before use. Exercise is necessary, how? Direct her to roll herself from side to side of room as many times as her strength will allow, direct her to fasten her feet to stirrups of soft material tied to furniture, attempt to draw the article attached, then take stirrups in hands, exercise same way, twice daily or more, give as little medicine as possible. As to time taken from floor, six or eight weeks in mild cases; if long standing, several months or more than a year. Galvanism to loins, vulva, rectum, I augur well, will give it a trial, when ligaments are sufficiently strong, patient allowed on feet, or feet and hands. Exercise in open carriage, pelvis elevated above shoulders for several weeks safer, a hammock is an admirable mode of exercise.

Article 2. Remarks on a Peculiar Epidemic Fever in Miami County, Ohio.—By G. Volney Dorsey, M. D., of Piqua, Ohio.

The doctor describes a section of country which is level, low, and marshy, no drainage, but rich mouldy soil producing rank vegetation, much fallen timber, water bad for family use, of course intensely malarial. He says "The fevers of this region are not usually more severe or fatal than those of the surrounding country, have in some seasons presented peculiarities which are worthy of note. The month of June, 1842, I was called in consultation to visit a family where five persons were ill of this prevailing fever, one was dying, two scarcely expected to live. I copy from my note book the following symptoms. After the chill in the beginning of attack, there comes on severe vomiting, coldness of extremities, burning, and sense of weight in stomach, strong pulsation in epigastric region, rapid, feeble pulse, tongue with thick white fur, constipation, great difficulty in re-

lieving coldness of extremities, sinapisms, hot friction, blisters frequently in vain, matter vomited at first viscid mucous, but become bilious, assuming a peculiar greenish blue appearance, similar to a mixture of bile and indigo. After a few days continuance of symptoms accompanied with difficult and laborious respiration, frequent sighing, became dull and comatose, strong pulsation of carotids no increased heat of head, eyes dull and glassy, stupor and death closed the scene.

No delirium, epigastrum, right hypochondrium uniformly sore. Of the five in family mentioned four died in spite of treatment and advice of several physicians. I saw no more cases that season. The year 1843 the same time and neighborhood, the disease broke forth with severity. I was again called. Scarcely a family exempt. In several families from two to five cases, symptoms differed in no material respect from those of previous year. Instructed by unfortunate issue of cases previous year, convinced that inflammation of stomach existed, I resolved to use the lancet unspairingly. On first visit I bled every case, ordered to be repeated if obstinate vomiting recurred in my absence, it was repeated in several cases three or four times, blisters and cathartics employed, every patient recovered under these means. On Stillwater river the disease also prevailed. I recommended to the physician a similar course; it was almost uniformly successful, where neglected the issue was very generally fatal. Blisters to stomach, spine, over coeliac plexus, and endermic application of morphine were advantageous. Opium, by mouth, was not well borne, calomel and opium accustomed to reliance was not beneficial, in many cases hurtful. As soon as irritation of stomach had subsided patient free from thirst and burning. I used cold infusion of quassia and orange peel drank freely, and found beneficial. The disease prevailed in the infected district in 1843, several cases in 1844, no cases in 1845; during the warm weather of 1846 I met a few cases. The Western practitioner familiar with localities where the disease usually termed "sick stomach," or "milk sickness," is said to prevail will have recognized in the described symptoms supposed to indicate its presence, this was the common name given to the disease.

The existence of a disease communicable by drinking the milk, eating the butter and flesh of beef cattle is acknowledged in the West. This poison is restricted to particular districts various attempts have been made and are making to follow to its source this poison, it has been located in the water, earth and various plants. The rhus toxicodendron eaten by cattle will produce disease known familiarly in the

West as "trembles," how far this disease can be communicated to human has never been shown. In those districts where cattle are so affected epidemics frequently prevail, symptoms resemble effects attributed to "milk sick" to defy diagnosis. I have been unable to lay down any diagnostic or distinctive marks between the cases. The disease does arise in the human without introduction into stomach of poisoned food, a peculiar miasma has the power of giving the peculiar symptoms of this disease. May it not arise in the same way in cattle and from them transmitted by flesh or milk to man. Bilious fever becomes under circumstances so concentrated and virulent as to pass from infected to a healthy subject. Closest scrutinizing observation will probably determine the "milk poison," to be an epidemic fever. The lancet and epispastics are our most important therapeutic agents." The theory of Dr. Dorsey that "milk sick" was intense malarial infection or miasma as he termed, advocated by others became to be accepted. The compiler of these excerpts began the practice of medicine in 1868 at a village located on Green river at the confluence of smaller river and creeks, and lakes, the timber was being cut in the bottom lands for market, leaving the tops to decay on the wet ground, malaria was exceedingly rife, frequently the intensely epidemic type described by Dr. Dorsey with the symptoms, but the "milk sick" idea had been abandoned.

"Article 3. Open Scirrhus of the Cardiac Orifice.—Cure by B. Rush Mitchell, M. D., U. S. Navy.

"The annals of the profession, so far as I am acquainted, present but few authentic cases of cure of the disease. I thought the presented case might not be an uninteresting detail.

Mrs. W., married, age 48, of sallow, cadaverous hue, active habits, spare frame, came under my notice when attending physician of St. Louis City Hospital, she held office of matron. Her mind and body active, she, however informed me she had been subject to organic disease of stomach, an utter incapacity of passing into the stomach any solid food. The bolus would pass easily to a point corresponding to the cardiac orifice. After remaining from 1 to 10 minutes, pain was experienced, the bolus was ejected. Digestion of fluid was painless and perfect, its passing causing no uneasiness, upon which she had lived for years. She was attacked with severe dysentery at that time there were also thirty patients in hospital of typhoid grade. Her idiosyncrasy forbade opium, her disease was combated with calomel and krameria, a blister to abdomen, acto plumb,

port wine, wine whey, soon discovering periodicity directed quinine. She began to complain of pain of cardiac orifice, hyoseyamus was ordered but continued for only twenty-four hours at which time vomiting set in, ejections being glarry, tinged with blood, a few streaks of pus, shortly a copious dejection nearly capacity of the chamber, dejection wholly ill conditioned pust, yellowish white, or milky, slight consistence, odor powerfully intolerant. For three weeks dejections and ejections of same character and quantity continued, no food or medicine being retained, emaciation and loss of strength to render patient unable to help herself. Diagnosis by myself and Dr. Knox, ulcerating scirrhus of cardiac orifice, which was confirmed by consultation with Dr. Beaumont, late of the U. S. Army, and Professor Johnson, University of Missouri. Nitrate silver in pill, act. plumb. sulph. zinc, astringents, strong acids, counter irritation. Ox-gall, nutrient injections, sponging with whisky all unavailing, none of the remedies retained, instantly rejected. I devoted more time to Mrs. W., determined to employ the following mixture: Cupri sulphas. zi; spts. lavender comp. zi; tinet moschi, ziiii; aqua zzii. M. I directed a teaspoonful every two hours, first dose soon rejected, second remained fifteen minutes, given ten minutes after first; third dose wholly retained. I directed six doses be given. In the morning I learned all doses retained, dejections diminished in quantity and frequently, morphus-like, epigastric pain measurably subsided, allowed no food nor drink. Patient feeling much better, desired partridge meat to suck, allowed. The prescription continued every three hours. In 36 hours she took 120 grains sulphate of copper, the remedy was continued at longer intervals for two days, followed by a week's use of calomel and dandelion pills. Ten days from retention of copper prescription was able to sit up in sick chair, by accident she discovered the passage to stomach was free to largest bolus, seven months from illness in better health since young days. The ease, I think, is a remarkable one. To the combination of euprisulphus aided by the iron constitution the favorable termination is fairly ascribed.

In "Department of Reviews and Notices," Velpeau's Surgery, Von Behr's Anatomy, Wm. Lawrence on diseases of the eye, were noticed.

In Department American Summary, were a number of extracts from American journals. One from a paper by Lewis Shanks, M. D., ("*New Orleans Medical Journal*") several cases of dysentery, severe type, he used ice internally and externally, ice rubbed over en-

tire body, immediately dried, well rubbed with coarse towel, repeated for several days allowed patient same time to eat ice. Morphine, acetate of lead, blister and hot fomentations, injections, and occasionally the lancet were used." As many as nine extracts on the effects of ether as an anesthetic, giving record of deaths subsequent to use of ether.

The following is of some interest, "On the Cure of Phthisis by Exercise of the Lungs and by Fattening," by M. Bureaud-Rioffrey, *Comptes Rendus* T. xxiv, p. 11. Researchs and autopsies proved tubercules are inorganic, unassimilable foreign bodies, it is necessary to prepare the way by which they may be expelled. Exercise of the lungs may fulfil this indication, by strengthening and dilating bronchi. It is necessary to regulate and adapt respiration to the strength of patient and demand of pulmonary combustion. In repairing the waste we ought to endeavor to fatten to prolong life and change constitution and tuberculous diathesis." The fattening theory was revived by some not very many years past, but abandoned because the fact was evident that food of quality and quantity that could be digested and assimilated should be given. "The following is significant: 'Clinical Statistics of the Learned Profession,' (*Med. News*, London,) 'From a statistical document recently published in the *Moniteur*, it should appear that of all the liberal professions medical men furnish the smallest number of criminals, impossible to fix a fractional ratio as with other classes. Since the year 1829 not more than two physicians have been tried as criminals at the assizes. In the ten years from 1829 to 1839 there were tried in the various criminal courts, forty-one thousand six hundred and seventy male prisoners, above the age of twenty-five, among these thirtythree priests, thirty-three lawyers, seventy-five notaries, sixty-six tipstuffs, but not a single medical practitioner.'" It is with just pride and satisfaction that the medical profession can at the present date and for ages past refer to court records to sustain the assertion that no other profession, not excepting the ministry, furnishes fewer criminals.

Editorial Department.—"We learn from the *South. Jour. of Medicine and Pharm.* that Dr. J. Lawrence Smith, one of the former editors of that journal, has since his arrival in Constantinople, been appointed Geologist and Inspector of Mines to the Sultan of the Ottoman Empire."

"The National Medical Convention—The National Medical Convention convened in Philadelphia on the 5th May last (1847) and remained in session three days. A large number of delegates were present, although not

representing equally the different parts of the union. The following officers were elected: President, J. Knight, of Conn.; Vice Presidents, A. H. Stephenson, New York, Geo. B. Wood, Philadelphia, A. H. Buchanan, Tennessee, J. Harrison, Louisiana; Secretaries, R. D. Arnold, Georgia, A. Stille, Philadelphia, F. C. Stewart, New York. At the close of the session the convention resolved itself into the "American Medical Association." The following officers were elected for the Association: President, Dr. Chapman, Philadelphia; Vice Presidents, Dr. Knight, New Haven, Dr. Stevens, New York, Dr. Moultrie, South Carolina, Dr. Buchanan, Tennessee; Secretaries, Dr. Stille, Philadelphia, Dr. Dunbar, Baltimore; Treasurer, Dr. Hays, Philadelphia. Baltimore was designated as the place for the next meeting." The session of the American Medical Association this year will be the sixty-seventh if the physicians of the northern states convened each year during the Civil War from 1861 to 1865 or even some years after the war terminated physicians of the southern states did not attend.

Dr. Hamilton, of East Liberty, Ohio, makes the following remarks in relation to the use of quinine in malarious fevers of that locality. "This district is malarious. During the past season the fevers assumed a congestive character chiefly intermittent, unless checked promptly by free use of quinine, proved fatal. A good many cases assumed gastro-enteric form, with vomiting of blood, large evacuations from bowels, resembling beef brine, which prostrated patients in a few hours. The treatment was sulph. quinine doses 5, 10 or 15 grains combined with morphine or opium every two hours, brandy almost ad libitum. This practice was successful, not losing one patient where it was promptly adopted, where not used or used sparingly, the disease was very fatal. The prejudices against the use of this Sampson of the *Materia Medica*, are fast giving way, fear of its administration when there is headache or a little fever is beginning to vanish."

The compiler of these excerpts located on Green river in 1868 and at intervals the section of country was visited by epidemics of intermittent fever of the type described by Dr. Hamilton, termed "congestive", quinine was the sheet anchor. As he says, quinine in large doses given in time was successful. But the physicians were frequently too late reaching patients, therefore many died. Physicians in the same localities now do not encounter such epidemics, the country is cleared, and cultivated, and drained, and protection

from mosquitoes by screens common. During these epidemics practice was laborious and trying, pathetic to devotees of the profession.

COUNTY SOCIETY REPORTS

Caldwell—The Caldwell County Medical Society met in the city hall at Princeton on Tuesday afternoon, April 14, 1914, with the following members in attendance: L. J. Spickard, J. N. Bailey, P. R. Shelby, C. J. Pollard, J. M. Moore, I. Z. Barber, W. L. Cash.

The minutes of the last meeting were read and approved, and a report of the financial condition of the society was made. Upon motion President Spickard appointed a committee to examine and audit the treasurer's books.

The scientific program was then taken up, and C. J. Pollard read a very interesting and instructive paper on "Some Newer Preparations," and called especial attention to the use of anti-typhoid vaccine, phylacogens and pituitrin, and protested against the indiscriminate use of the last named preparation. There was a general discussion of this paper, and the essayist was complimented for the presentation of the subjects.

The society adjourned to meet again on the second Tuesday in May.

W. L. CASH, Secretary.

Henry—The Henry County Medical Society met at the office of the secretary, in New Castle on Monday, March 30th, 1914.

In the absence of the president and vice president, the meeting was called to order by the secretary.

W. B. Oldham was chosen as temporary chairman for the meeting.

A. M. Zaring, having moved to St. Mathews, which is out of the county, it was decided to elect a president to fill the vacancy made by his absence.

Everett Morris was unanimously chosen as president for the year, 1914. Upon being elected president of the society, Dr. Morris resigned as delegate and Jno. C. Hartman was elected delegate with O. P. Chapman as alternate.

Upon motion it was decided to formulate a program for the entire year as to papers to be read before the society and the following physicians are appointed:

Papers for April meeting, Jno. C. Hartman, E. E. Howard and Thos. J. Hower; for May, A. P. Dowden, Webb Suter and Louis Coblin; for June, W. B. Oldham, O. P. Chapman and O. M. Humston; for July, E. E. Biekles, C. J. Renfro and O. P. Goodwin; for August, W. L. Nuttall, F. D. Hancock and W. J. Morris; for September, W. W. Leslie; C. R. Johnson and W. F. Asbury; for October, Curtis Hancock; O. M. Humston, A. P. Dowden; for November, Jno. C. Hartman, John

Murdock and J. R. Guthrie; for December, Everett Morris, C. R. Martin and A. G. Elliston.

The above named physicians are requested to complete their papers two weeks prior to the date of reading and forward them, typewritten, to the secretary, who will read them if the writer is unable to attend the meeting.

Paper on "Constipation," was read at this meeting by **W. L. Nutall**. The paper was discussed by nearly all members present.

There being no further business the society adjourned to meet April 27th, at 1 o'clock P. M.

OWEN CARROLL, Secretary.

Henry—The Henry County Medical Society met at the Court House in New Castle on May 27th, at 2 o'clock P. M. Meeting called to order by **A. P. Dowden**, President pro tem.

Present, **W. B. Oldham**, **O. P. Chapman**, **E. E. Beckers**, **W. L. Nuttall**, **Jno. C. Hartman**, **E. E. Howard**, **Webb Suter**, **W. J. Morris** and **Owen Carroll**.

E. A. Guillion, Editor of the Henry County Local and County Judge **Luke Kavenough**, were also present, as was **Dr. John McDonald** of the state of Washington, who gave the society a nice talk and entered into the discussion of the papers.

E. E. Beckers read a paper on the subject "The True Physician."

J. C. Hartman read a paper on "Infantile Diarrhoea."

E. E. Howard read a paper on "Aneurisms." The papers were discussed by all present and a generally good meeting was held.

A. P. Dowden, **Webb Suter** and **Lewis Coblin** are assigned for papers at the May meeting.

On motion, meeting adjourned to meet May 25th.

OWEN CARROLL, Secretary.

Warren—The Warren County Medical Society met in the Council Chamber with the following members present: **Drs. Lillian South**, **Heiser**, **A. T. McCormack**, **Freeman**, **Strother**, **Arnold**, **Wright**, **Moss**, **Rogers**, **Huddle**, **Cartwright**, **Drake**, **Blackburn**, **Francis**, **Marks**, **Neal**, **London**, **Keen** and **Rutherford**.

The program of the meeting was the "Etiology of Rheumatism" by **Dr. London**.

"The Treatment of Rheumatism," by **Dr. Keen**.

"The Relation of Rheumatism to Tonsillitis," by **G. E. Townsend**.

The discussion to be opened by **Dr. Lillian South**.

As there were not present at the opening of the meeting, any of the essayists, a motion was made and carried that we have a report of cases.

H. P. Cartwright reported a case of rupture of the paranehyma of the lung with profuse hemorrhage and pneumo-thorax.

B. S. Rutherford reported a galloping rhythm of the heart and explained its mechanism.

Both these cases were interestingly discussed by the members of the society.

Finis London read a very excellent paper on "Etiology of Rheumatism," which was followed by an interesting talk by **Dr. Keen** on the treatment of this disease.

G. E. Townsend, who was to have read a paper on the relation of rheumatism to tonsillitis, was not present.

L. H. South opened the discussion which was followed by a general discussion by the members of the society. There being no further business, a motion was made and carried to adjourn.

B. S. RUTHERFORD, Secretary.

Warren—The Warren County Medical Society met at the Council Chamber on December 10, 1913, with the following members present: **Drs. Grubbs**, **Stone**, **Briggs**, **Arnold**, **Huddle**, **Helm**, **H. P. Cartwright**, **F. D. Cartwright**, **South**, **Townsend**, **Hall** and **Rutherford**.

There being no program for this meeting, a motion was made and carried that the house proceed to the election of officers for the ensuing year.

B. S. Rutherford was elected secretary pro tem.

Drs. Stone, **Grubbs** and **Briggs** were nominated for president, after which the house proceeded to vote by ballot. **Dr. Stone** receiving the majority of votes cast was declared elected.

J. H. Strother was nominated for vice president. There being no other nominations, the secretary was instructed to cast the vote for **Dr. Strother**.

Nominations were then declared in order for permanent secretary. **Drs. Arnold** and **Rutherford** and **Briggs** were nominated. The house voted by ballot. **Dr. Rutherford** receiving the majority of votes was declared elected.

Nominations were declared in order for a delegate to the State Meeting. **Drs. Hall**, **H. P. Cartwright** and **Arnold** were nominated, after which a ballot was taken and **H. P. Cartwright** receiving the majority of votes was declared elected.

G. E. Townsend was nominated and elected as Councilor.

H. P. Cartwright reported an interesting case which was discussed by the members of the society.

There being no other business before the house a motion was made and carried to adjourn.

B. S. RUTHERFORD, Secretary.

Paralysis, General. Treatment. Hexamethylenamine, gr. x (0.6 Gm) thrice daily, found effectual in preventing retention of urine and avoiding necessity for catheterization.—**Baird**.

THE COMMUNITY PHYSICIAN.

In further consideration of this important subject, it is important that we clearly understand what is meant by a community and then consider the functions and opportunities of a community physician.

A community, for our purposes, is a settlement within somewhat definite boundaries containing from three to six-hundred families, who can be made to understand that the practice of medicine has reached that point in its development where scientific supervision of health and living conditions will prevent about seven-tenths of the sickness and nearly one-half of the deaths which are now occurring, prematurely. Such a community must understand that the physician who will devote his time to systematic prevention of disease is entitled to a reasonable compensation for such services. It has been suggested that where three hundred families compose a community that they agree to each pay the community physician \$10 a year for his services. These services will include such supervision of their living methods, such education along health lines as will keep the individual composing it from being sick, as far as possible, and in case of sickness, the physician would attend the cases. In such an arrangement, it will be seen that it would be to the interest of the doctors to prevent sickness and that this would rapidly become the important part of his work.

On the other hand, looking at it from the standpoint of the physician: It would be his first purpose to create such a health conscience as would prevent any one having a preventable disease from spreading the seed of it to others. He would supervise the building of sanitary privies at every house in his community; he would teach the tubercular to ex-

pectorate only in the containers that could be burned; he would so actively supervise the emptying of vessels containing typhoid stools into sanitary privies or other fly proof, watertight, disinfecting vats as would effectually prevent this disease. He would see that every child was vaccinated by the time it was six months old and re-vaccinated at the necessary intervals; he would inspect the school or schools in his district frequently, thus discovering defects or disease at their beginnings rather than after thoroughly developed. He would carefully supervise the isolation of contagious diseases; he would talk to the mothers not only about the kind of lunches taken to school but about improving both the variety and quality of the food supplied to the workers of the household. He would help supervise the screening of kitchens and dining rooms; in other words, it is contemplated that the community physician is, in a large measure, taking the place that was once occupied by the family physician, becoming the leader in his community and knowing the living methods of his various families in such a way that he could help them to the best results in good health and long life.

Such development as this is surely coming and it would be well for you to begin to discuss it with the leaders in your community and to consider it from every standpoint that it will find you prepared when called upon.

DR. D. B. WILCOX.

It is with sincere regret that the JOURNAL announces the death of Dr. D. B. Wilcox, for many years secretary of the Carter County Medical Society. As a friend and a physician his neighbors in Carter County will miss him, but as a leader in the medical organization of the State, his loss is well nigh irreparable. The State Association has been very fortunate in finding in most of the counties a county

secretary who would undertake the arduous duties of this office with real knowledge as to its difficulties and with a real purpose to get everything possible out of the development of a real county society. The success of the county society can be measured by the effectiveness of the county secretary. The Carter County organization is a good one because of Dr. Wilcox's effectiveness and we trust it will be as fortunate in the selection of his successor.

AN EXHIBIT WORTH WHILE.

The H. K. Mulford Company will have a moving picture show at the Atlantic City session of the American Medical Association in the Hotel Chalfonte, which will show the different processes employed in the production of their biological products. This exhibit will be particularly interesting to the Kentucky doctors who attend the session of the American Medical Association because through an arrangement with the Mulford Company, our State Board of Health is supplied with Mulford's biological products excepting diphtheria antitoxin.

The H. K. Mulford Company deserve credit for taking advantage of this new manner of displaying their latest methods.

A. M. A.

The annual meeting of the American Medical Association will be held at Atlantic City, New Jersey, beginning June 22nd. This will be a most important and enjoyable meeting and it is hoped that as many of our members as possible will arrange to take advantage of it.

Atlantic City in June is delightful and it will be an especially valuable trip if you will take your wife along and let her get the ocean breezes and the stimulation to be gotten from the change in air and scene.

MEDICAL EXAMINATION.

The examination for a certificate to practice medicine will be held in the auditorium of the Henry Watterson Hotel in Louisville, beginning June 15th, next, and continue for three days. It is important that this be borne in mind by those of our doctors who contemplate moving to other states, whose certificates were issued without examination. Many states require an examination in Kentucky before they will grant reciprocity.

SCIENTIFIC EDITORIALS.

AS TO THE ABORTIVE TREATMENT OF SYPHILIS.

Attempts to abort syphilis by the way of excision of the chancre, has been tried long ago. Such attempts may be traced to the times when syphilis was not so well understood as it is now. Even at this time this momentous question had its advocates and antagonists. According to the statistics of Crivelli, out of 454 cases of excision of chancre, 104 of them were absolutely successful; according to Ehler's, out of 584 cases of hard chancre, 137 were successful after the chancre had been excised. This method was then strongly condemned by some syphilographers, and though the great Ricord stood for excision, his pupil, Fournier, was antagonistic to this theory. I remember about two years ago, at the meeting of the A. M. A. at Atlantic City, in the symposium on syphilis, in discussion, this question of excision was brought up again. From my own conviction and thinking I was on the side of those who advocated the excision of the chancre. The chancre, to my mind, is a local infection and local manifestation on the part of the body to rid itself of the invaded organism. Looking over the literature on syphilis, many cases were reported to have been aborted by either excision or thorough cauterization.

Jai, Lang and others have strongly advocated excision method in abortion of syphilis. In the last decade when the study of syphilis was more developed (since the discovery of spirochetæ, reaction of Wasserman, etc.) the question of aborting syphilis received a new light. Thanks to the very simple method of Burri, it was possible to find the pale spirochetæ the first few days of the appearance of the chancre. With the discovery of Wasserman test it was possible to tell whether syphilis was aborted in the system and whether one or the other method of the treatment was effective. Since we can make by the present methods the diagnosis of syphilis in the earliest stage, we should then be able to combat the disease with the first appearance of the hard chancre.

Klingmueller used the method of excision, complimented by salvarsan, in 56 cases of hard chancre with negative Wasserman reaction, and 60 cases with positive reaction. He received better results from mixed treatment than from salvarsan alone. Hecht also experienced great success in aborting syphilis with mixed treatment. Neisser advocated the early excision and thorough cauterization in conjunction with administration of mixed treatment. Stern, Scholtz and many others

had the same experiences. In Scholtz's 70 cases of indurated chancre, under early treatment of salvarsan and mercury, 60 cases remained with negative Wasserman.

Voss, of Halle, advocates early excision of the chancre or application of Paquelin cautery and administration of salvarsan and mercury. Earing followed this method successfully and in one of his cases had a reinfection a few months afterwards. Jadassohn insists upon early abortive treatment of syphilis and adds, that any physician that is going to wait for the manifestation of secondary symptoms after the hard chancre has appeared, is undertaking a great responsibility and is doing his patient a great injustice. Hallopeau, who is regarded as the most original authority on syphilis, in cases of hard chancre, injects in the neighborhood of the chancre, heetin (an arsenal preparation), with the addition of novocain, then, he gives mercury and iodine.

In the last two congresses in Rome and London, the best authorities on syphilis, advocated early abortive treatment. The only two noted syphilographers that were strongly opposed to abortive or early treatment of syphilis were Mulzar, of Strassburg, and Gaucher, of Paris. They claim that early abortive treatment, complimented by salvarsan, is liable to prolong the course of syphilis. But any new idea always has its antagonists.

In going over the literature in regard to abortive and early treatment of syphilis, particularly since the discovery of salvarsan, the preponderance of opinion is in favor of it.

We are also inclined to follow the abortive treatment. Since syphilis is a chronic systemic disease, requiring from three to five years, and longer, of active treatment, would it not be preposterous not to adopt a treatment that would cut its course to a few months? Would it not be a blessing if we could shorten the duration of typhoid fever to a few days, as we may expect it will soon be done?

Syphilis, it must be remembered, has other phases. Clinical and experimental data show that in the beginning it is purely a local disease. The process of it may be summed up as follows: After a suspicious coition, the spirochetæ are deposited on an abraded or irritated skin; nature, trying to protect itself against the invasion of said spirochetæ into the deeper tissues, sends out protective fluids which envelop the spirochetæ, trying, so to speak, to choke the invading enemy. The result of this process is the formation of the chancre. Why not eradicate this chancre, thereby aiding nature in its previous efforts? If we do not undertake this step, the spirochetæ in the majority of cases, overcomes the

effort of the protective fluids and succeed in entering the deeper tissues. Once we allow the primary stage to go on into secondary, and treat the secondary stage, we can not say that we initiate the abortive treatment; we may call it early treatment but not abortive since under abortive treatment we have to deal with the purely local condition. Once we get a general or systemic condition, giving positive Wasserman reaction, we can not call such treatment abortive. To us, when we speak of abortive treatment of syphilis, only those cases count which have only a local primary manifestation of a sore in which are found pale spirochetæ of Schaudin, which give a negative Wasserman.

M. L. RAVITCH.

WATER.

In pre-historic times the astronomers and geologists tell us that space consisted of a vast nebula of self-luminous, gaseous matter very highly heated and that as a result of condensation and cooling the earth took form. This geological view, differing as it does entirely from the theological one, maintained that at that time water was dissociated or separated into its two gases, hydrogen and oxygen and owing to the earth being at a temperature in excess of 3,632 degrees F. these gases could not combine to form water and as the molten state of the earth probably maintained a temperature 6,000 degrees C. a considerable time had to elapse before it was finally cooled sufficiently for the water to form first as steam and then to condense to the liquid state. Up to one hundred and thirty years ago the general view held was that of Thales, one of the Seven Wise Men of Greece, who said "Water is the element, the principle of things," but it was in 1718 that Priestly and Lavoiser showed that it was composed of two gases. Later it was found that it could be decomposed by electrolysis and the two gases measured. Hence, it will be seen that water at last in the form of its elements is older than even the earth itself and water at least can be said to have existed since "the beginning." Water may exist in three states; *gaseous*, *liquid* and *solid*, but this is not remarkable because it is possible to transform nearly every substance into these three states, but what is really interesting in this regard, in water, is that it can be accomplished within the range of ordinary temperatures, which is rather extraordinary.

To the *gaseous state* belongs steam and atmospheric water vapor. The absence of atmospheric water vapor, which is usually found in arid desert regions, no clouds are formed, there is no rain and as a rule such a

place is not only devoid of life but is practically uninhabited. At the opposite extreme is to be found the disagreeable climates that are hot and humid and in which the atmospheric vapor is tremendously increased.

Money may make the mare go, but certainly steam practically makes the world move. What would we do without the wonderful motive power of this agent? From the tiny infantile mechanical toy that it moves to the terrific explosion of such a volcanic mountain as Krakatoa seems a wide step and yet it is this tremendous range of power that makes steam such a remarkable agent. Steam is that condition of water which is stable at temperatures of 100 degrees C. at an ordinary atmospheric pressure. *Liquid water* which is the most interesting and important of any form is really "*wet water*." In this form it is the most fascinating of all chemical substances, besides being the most useful. It forms 75 per cent. of the human body and without it nothing could live; it covers two-thirds of the earth's surface to an average depth of 12,500 feet; it is the best solvent known; is essential to all chemical action and without it nearly all branches of science would be at a stand-still. It occurs as rain, fog, dew, river and ocean water, spring water, etc.

When the vapor of the atmosphere condenses around small particles of dust in the air, clouds are formed or if very near the surface a fog. If the small particles run together it will fall as rain. Dew is nothing more than water that has condensed out of the atmosphere onto cold objects. Pure water is odorless, tasteless and in small quantities colorless, transparent, liquid; in large quantities it becomes blue in color and very near opaque. It never occurs pure in nature, its nearest approach being rain water after it has rained for sometime and the next nearest melting snow. It can be purified by distillation, one distillation being enough for ordinary purposes, but in many chemical and particularly for intravenous work it should be re-distilled. When re-distilled it is practically a non-conductor. It is only slightly compressible.

Under a normal pressure water boils at 100 degrees C. It is a powerful refractor of life. Many substances when dissolved in water lower its freezing point that is one reason why salt is used in the freezing mixture when making ice cream. The stirring serves two purposes; bringing all parts in contact with the cold and causing more rapid crystallization of the contents. If water is perfectly still the temperature may be lowered several degrees below the freezing point, but a jar will cause it to freeze immediately. Be-

sides lowering the freezing point, dissolving a substance in a liquid also raises the boiling point.

When an acid, base or salt is dissolved in water, the molecules of the substance are split up in two parts, each part being charged with equivalent quantities of electricity. These charged particles are called *ions*. A compound which yields ions is called an electrolyte, all others such as sugar, for instance, are called non-electrolytes. Of all common liquids, which dissolve substances, water has the highest power. Water is never a side issue in chemical reaction, it is really the most important and the fundamental thing in them.

When a soluble solid, no matter how great its specific gravity, is placed in the bottom of a vessel and covered with water, it will in time diffuse through the entire liquid until it is homogenous, though the force of gravity is pulling continually against it endeavoring to keep it at the bottom. Solid water consists of snow, hail, frost and ordinary ice. *Snowflakes* are assemblages of minute crystals of ice from the aqueous vapor in the atmosphere. They always assume a hexagonal shape. Snow is only white to the eye because of its great refractive power compared to the crystals. Under the microscope it is transparent. It forms when a cold enough wave passes over a moist atmosphere condensing the water; it then crystallizes.

Hail, on the other hand, is formed when rain passes through a region of atmosphere sufficiently cold to freeze it. Just as dew condenses out of the atmosphere on a summer night or a winter night when the temperature is low enough, frost forms. *Frost* has played and continues to play an important role in changing of the earth's surface.

Water, when it cools, contracts until it reaches a temperature of 4 degrees C., and then it begins to expand slowly at first until it very nearly reaches 0 degrees C., and is about to freeze then it increases very sudden in volume. Water is used as unit for specific gravity measures. In freezing water gives off a very large amount of heat, so that we can understand why there is a warning up just before a snow storm.

Ice is often seen to contain dirt. If the water was stirred while freezing so that the crystals would separate small they would be very nearly pure. Certain compounds have the power to crystallize, with a greater or less amount of water. The "water of crystallization," as it is called. Some chemical substances, like calcium chloride if allowed to stand in the air will attract the moisture and become wet; they are said to be *deliquescent*, others like sodium sulphate tend to lose their

water of crystallization on standing open to the air; they are called *efflorescent*. Few people know what an enormous percentage water plays in the nourishment of the human body. A human body weighing 150 pounds contains about 113 pounds of water and requires daily for its sustenance, either as a liquid or combined with food, 5 1-2 pounds of water, this equals more than one-half gallon. Volumes have been written of the effects of water as a corrosive agent in geology, under the action of frost, rain, waves, rivers, glaciers, lakes, oceans, subterranean waters, etc., both upon the interior and exterior of the earth.

It has seemed to the reviewer that so few of us in the pressure of the modern practice of medicine realize the many inherent values of water, nor do many stop to reflect upon its powerful potency as a therapeutic agent, internally and externally. It has therefore seemed interesting and pertinent to review the values of water per se. To enumerate its therapeutic activities in merest outline would require more pages than can be devoted to a scientific editorial.

CURRAN POPE.

THE INFLUENCE OF DIET IN SKIN DISEASES.

While the importance of diet has long ago been considered an influential factor in general practice, it is only in the last few years that it has been found to be even more so in skin diseases.

It was the Vienna School that held most all dermatoses as purely local affections of the skin. Vienna School's opinion or rather dictum was followed for a long time. In the last decade a reaction has taken place, and the theories, so long held by the Vienna School, were doubted. New ideas sprung up and the causes of a good many skin diseases previously taught to be due to external influences, were found to be due to metabolic disturbances. Bouchard was the first man to teach us the importance of auto-intoxications, particularly those arising from the intestinal tract. The amount of the indican in the urine corresponded with the amount of intestinal putrefaction. Diet of course played a great role in production of putrefaction as was often ascertained. I think it was Lichenstein, then Sobolew, and in our country, White, that have found the prevalence of indicanuria in skin diseases induced by faulty diet. After extensive experimentations it was found that in many dermatoses the skin condition improved or got worse again with the state of the gastro-intestinal tract.

Every pediatricist and general practitioner knows well that an unsuitable diet may be the cause of skin affections among children in the

first years of life; in adults, on the other hand, the diet may not have such an apparent influence.

Eczema of seborrheic type in healthy children very often is the result of over-feeding, and over-abundance of milk fat is the most obnoxious agent. This over-abundance of fat enters the system as a foreign protein and causes anaphylactic reaction, terminating in eczema. In such cases it is advisable to limit the quantity of milk feeding, particularly rich milk, and instead give them different kinds of soups, buttermilk, fruit juices and cooked fruit which will be found both grateful and useful. Eggs are not well tolerated by children suffering from eczema as they may act as a foreign protein and cause the same anaphylactic reaction as milk fat does.

Finkelstein's opinion that eczema in children is caused by the accumulation in the organism of sodium chloride which acts hygroscopically, causing the skin to ooze or to form urticarial eruption, is rather speculative and erroneous. It may work well in a few individuals, but experience teaches us that the diet of salt-poor milk is surely injurious. Bruch, who has made extensive experiments in child-feeding, has insisted that Frankelstein's idea is wrong. In his timely and practical article in the *Monatsschrift für Kinderheilkunden*, for 1909, he showed that by enriching the organism with sodium chloride eczematous processes were greatly improved, while washing out the salt, would make the conditions worse.

A strict and limited diet is, anyhow, permissible and useful in well-fed children. In addition to this, local treatment is a very important factor. The bad results, reported from local treatment of the skin of nurslings, is rather rare. And the rare cases are the result of unscientific and careless local treatment.

A strict limitation of meat diet has been found useful in a great many cases, particularly in strophulus in infants; while in cases not based upon intestinal toxemias, the diet has little influence.

In skin diseases of adults, you can expect much from a certain diet regime. Certain cases of pruritus, of urticaria, dependent upon idiosyncrasy to certain foods, are, of course, amenable to treatment by changing the food. In acne vulgaris it may be found, that ingestion of fatty material is injurious, particularly, since such material is absorbed and deposited in the sebaceous glands. In Rosacea, agents that cause flow of blood in the face, such as coffee, tea and alcohol, are very injurious. The influence of diet in psoriasis has been found a very important factor in causing the latter disease. In my editorial on

the "Etiology of Psoriasis," the reader will find that diet plays an important role as a causative factor in this disease.

In looking over the long list of skin diseases and in seeking their causes, we cannot help admitting the fact, that diet in a great many cases is quite an important factor.

M. L. RAVITCH.

ORIGINAL ARTICLES

CURRENT MEDICAL EVENTS.*

By J. T. REDDICK, Paducah.

Our secretary asked me at the last meeting of the society to prepare a paper for this meeting on the newer things in medicine. The very newest thing is a news item sent out from Chicago under date of March 6th, and published in the daily papers. I quote the article:

"Dr. G. Frank Lydston announced last night at a meeting of the Chicago Medical Association that he had successfully transplanted the generative gland of a dead person to the body of a living man. Dr. Lydston declared that when he had been unable to find a subject willing to undergo the operation he had made the transplantation upon himself.

An operation performed January 10th, 1914, he said, seemed to have been successful. The gland was taken from a youth of 18 who had been dead seventeen hours.

Dr. Lydston said if the operation should prove a permanent success it may be a new remedy for Bright's disease, hardening of the arteries and ailments due to premature senility. The surgeon said he had been unable to find any record here or in Europe of such an operation ever having been performed.

Dr. Lydston also said he had implanted in a woman of 59 years the generative organs of a woman of 17 years, who had been dead from violence twelve hours. This operation, he said, had been performed too recently for him to predict results. The wound, however, he declared, was healing rapidly, and the operation gave evidence of being successful."

The next newest thing in the way of medicine is another newspaper article sent out from Cincinnati just a few days ago. As yet we have seen nothing in medical literature to corroborate these articles and as a rule physicians are slow to accept these newspaper statements until we have further confirmation or proof of their genuineness. However, the very high professional character of the surgeons quoted and the ethical standing of the gentlemen, inclines us to give these state-

ments much credence. I also quote the article sent out from Cincinnati:

"A discovery by which surgery is made painless, after, as well as during operations, was made public here by Dr. Chas. A. L. Reed, who, in his demonstration at the Cincinnati General Hospital, declared that the era of painless surgery had at last dawned. He has used the method successfully in abdominal cavities and in the removal of cancers and tumors. He related the case of a very fleshy woman on whom he had operated for conditions which under old and yet prevalent methods would have caused great agony. Instead, she did not know that she had been operated upon; awakened immediately without pain or sickness, asked for the newspaper and innocently arranged to go to hear Tettrizza singing that evening, when told what had been done. She went home at the end of three weeks without even having had a twinge of pain. Dr. Reed then demonstrated the method on a patient from whom he proceeded to remove several tumors and some of the bodily organs. She was awakened immediately after the operation entirely free from pain. Dr. Reed calls the method 'Anocithesia,' which means without fear or pain."

ABDERHALDEN'S TEST FOR PREGNANCY.

One of the newer things in medicine, and one that is much discussed at the present time is Abderhalden's test for pregnancy. It would require too much of your time to go into a full discussion of the preparation of the material for the test, and it would require a careful study on the part of any one to understand it. I would not be qualified to give you anything like a comprehensive description of the test without a more extensive study of the matter. Abderhalden has performed more than two hundred tests. "Schlimpert and Heney examined 316 cases. In 39 non-pregnant cases all gave negative tests. The sera of 28 pregnant women all reacted positively, even one who had gone over her period but four days. Ekler had constantly negative results in 25 non-pregnant individuals, while in 37 pregnant women he always obtained the reaction. Most of his pregnancies were in the first week; four were ectopic pregnancies and six were incomplete abortions¹."

A NEW LABORATORY TEST FOR CANCER AND SARCOMA.

Dr. T. G. Davis, in *California State Journal of Medicine*, Nov. 1913, says: "The urine should be carefully collected, fresh. No preservative should be used except that when it is impossible to make immediate examination. Hydrochloric acid in the proportion of one part to ten of urine may be added, this being

*Read before the McCracken County Medical Society

the proportion used in the test. Select a flat bottomed flask of about six fluid ounces capacity, with a narrow neck, that the ether may be brought up into it and easily seen and separated. To 100 ccm. of urine in the flask add 10 ccm. of hydrochloric acid. Heat over a slow fire until ebullition begins; turn out the fire and allow it to cool slowly for a time, after which cooling may be hastened by immersion in water. When cold add 30 ccm. of ether. Cork, tying the cork to prevent evaporation. Turn the fluid upside down several times during the six or eight hours required to complete the test. Avoid hard shaking which interferes with separation of the ether. While in cases of pronounced or extensive cancer the ether will acquire a markedly red color in as short a time as twenty minutes, he has found six or eight hours necessary for the complete extraction hemo uro-chrome by the ether. The author claims the test will give evidence of the presence of cancer before it can be seen or determined by palpation or any other method. He claims the test has proven positive in a large percentage of cases.²²

The medical world is now eagerly watching for every thing which will throw any light upon the early recognition and etiology of cancer, and this becomes necessary from the fact that the number of cases are rapidly increasing. Frederick L. Hoffman, statistician for the Prudential Insurance Company, in an address recently delivered, states that cancer is becoming more prevalent in the United States every year, and that now its death toll is greater than that of tuberculosis. In the United States the death rate per annum is 75,000; for the civilized world, nearly half a million. Among men between the ages of 45 and 64 the proportion of deaths from cancer is 7 per cent., among women 16 per cent. Dr. Willingham gave this society a good paper a few weeks ago along the same lines as this paper and spoke of the treatment of cancer by radium.

PITUITARY EXTRACT IN OBSTETRICS.

Pituitary extract is quite well established in medicine, but as it is one of the newer things and a very potent remedy, capable of doing much good, there is danger that we may become over-enthusiastic regarding it, from the very optimistic advertising circulars sent out by the manufacturing houses, and do harm by its discriminate use. From some of the advertisements we are led to believe that it is safe to use at any stage of labor.

Having had some experience with the drug and having kept well up with it in the hands of others who have had a much larger experience, I am forced to the conclusion that we

ought to be just as careful in its use as with any of the active drugs.

The pituitary gland is divided anatomically into three parts, the anterior and posterior lobe and the infundibulum, but physiologically it seems to be divided into only two parts; the anterior lobe having one action, the posterior lobe and infundibulum another. The anterior contains some unknown substance which is absolutely necessary for the life of an individual. The posterior lobe and infundibulum, on the contrary, are not indispensable to life, but contain some principle which has a marked physiological action as a vaso-constrictor and uterine stimulant. To the best of my knowledge, there are on the market to-day, only three extracts of the pituitary gland, two made by American and one by a foreign firm, and all of them from the posterior lobe and infundibulum³.

The remedy is put up in ampules, the dose being 1 to 2 cc. Edgar has given 4 cc. The remedy should be given by intramuscular injection. I have never observed any local reaction from its use or any more pain than from any ordinary hypodermic puncture. I began its use about one year ago, and will give you briefly my experience taken from my obstetrical record.

Case I. Lina H., age 40. Para II. Strong, muscular, colored woman. Labor began at 5 a. m., pains slow, short, and inefficient; cervix soft and dilatable, roomy pelvis. 1 cc. pituitrin at 8:45, pains strong and regular in 7 minutes, and child delivered in 15 minutes.

Case II. Bessie W., age 22. Primipara. Labor slow, pains inefficient, cervix soft. 1 cc. pituitrin, pains hard and regular in 8 minutes, but had to deliver with forceps.

Case III. Marie T., age 17. Primipara. Began having pains at 6 p. m. I was called at midnight. Pains slow, os slow dilating. Pains stopped at noon, began again at 1 p. m. Os about size of dollar but soft and dilatable. 1 cc. pituitrin, pains hard in ten minutes and labor soon complete.

Case IV. Dinkie B., age 30. Para VIII. Strong, healthy colored woman, short and fat, had been in labor 6 1-2 hours, pains slow and inefficient, os about four fingers dilated, cervix thick and hard. 1 cc. pituitrin. Pains hard in ten minutes and very large child delivered in 22 minutes, no lacerations.

Case V. Bessie G., age 34. Para III. Pains inefficient, cervix dilatable. 1 cc. pituitrin, in few minutes hard and rhythmic pains and labor terminated in short time.

Case VI. Drusilla P., age 30, para VI. Membranes ruptured before I arrived and all the liquor amnii had escaped, child high up and could hardly be felt by finger and held in that position by a short cord wound around

neck. Cervix dilatable and pains slow, short, and doing no good. 1 cc. pituitary liquid, pains hard in six minutes and child delivered in a short time.

This is the extent of my experience with pituitary extract, which has been altogether very favorable and indeed almost magical in some cases. I might have used it oftener but I do not believe it has any place in normal labor, and my cases were well selected cases, only one of which, case IV, was there any rigidity of cervix. In that case the rigid cervix, which was about four fingers dilated, softened rapidly under the regular, hard pains.

In my opinion pituitary extract is of unquestioned merit in obstetric practice, but should not be used in undilated cervices, for we can never tell when we have a friable, diseased cervix, and we can not tell how hard the pains are going to be, and there is danger of a rupture of the uterus. We should also always have an anaesthetic so that we may control the pains if necessary. I believe it a much safer drug than ergot, for it produces strong, intermittent, uterine contractions, whereas ergot is inclined to produce tonic or tetanic contractions.

J. Clifton Edgar, of New York, recently reported a series of 70 cases classed as follows:

In the first and second stage	39 cases
Immediately after the third stage	19 cases
In Cesarean section	6 cases
For the induction of abortion	6 cases

I take pleasure in giving you some of his conclusions:

"Full and even small doses of the drug in the first stage of labor have caused in our case fatal compression of the fetus, premature separation of the placenta, and deep rupture of the cervix."

"Pituitary extract acted promptly and efficiently in most of our thirty-nine cases of inertia in the first and second stages. Its action was more positive in multipara than in primipara; it acted better at full term than in premature cases; also better in second than the first stage of labor when administered shortly after the spontaneous rupture of membranes."

"In the nineteen cases in which the drug was used immediately after the third stage for post-partum hemorrhage due to inertia, our results were disappointing. So much so that we consider its action here most unreliable and not as positive as the ergot preparations."

"For primary inertia in abortion cases, our results with the drug were disappointing."

"We consider the use of the drug in the first stage a dangerous practice, liable to cause death or deep asphyxia of the fetus,

separation of the placenta, uncalled for laceration of the cervix, and possibly uterine rupture."

"We look upon the use of pituitary extract before full dilatation or dilatibility of the cervix as equivalent to the use of ergot at this time. In fact it is probably more harmful than ergot, by reason of the more powerful contractions produced and the uncertainty of its action."

"We have repeatedly observed prolonged tempestuous contractions, when the drug was given in the face of too much resistance, closely simulating tetanic contractions of the uterus (tetanic uteri)."

"We have repeatedly observed both in private and hospital practice that 0.2 gram. of pituitary extract, half the usual dose commonly employed, produces such prolonged and powerful contractions that uterine rupture was imminent and anaesthesia was required to control the action of the drug on the uterus⁴."

Herz, a German writer recently reported a case of uterine inertia after prolonged labor in a young primipara who also presented a flat, rachitic pelvis. The fetal head was in mid pelvis and the cervix two fingers dilated and rigid. One cc. pituitrin was injected. Within a few minutes the pains became stronger and after a period of twenty minutes became tetanic in character. About one hour later the patient collapsed, after a very severe pain, and presented evidence of uterine rupture. The pains continued and she gave birth to a very small, asphyxiated infant. The placenta was delivered spontaneously. Subsequent examination showed that the cervix was entirely separated from the lower segment of the uterus and the fetus and placenta had been born through the tear. The parametrium were involved on either side. The vagina was packed and the patient treated expectantly. Two weeks later an examination showed fairly good union of the lacerated area.⁵

Septicemia. Treatment. Fixation abscess advised, consisting in injection of 15 minims (1 c.c.) of spirit of turpentine in cellular tissue of thigh, loin, or deltoid region.—Charles.

LABORATORY METHODS THE GENERAL PRACTITIONER SHOULD USE.*

By RALPH L. SCHROEDER, Owensboro.

While humanity has been the recipient of inestimable blessings at the hands of physicians who knew little, if anything, of laboratory methods, the day has come when failure on the part of the general practitioner to avail himself of such means in the diagnosis of human ailments is inexcusable.

Generally speaking, the diagnosis of a case is of greater importance than the treatment and is made possible only by a careful study of the history, symptomatology and the laboratory findings.

Within recent years many advances have been made in laboratory methods and at present the chemical, pathological, bacteriological and X-ray laboratories each constitute a specialty. Consequently, much of the work in each of these departments, to be dependable, must be done by experts. This is especially true of pathological and major X-ray work. When we consider the technical skill required and the grave responsibility attached, for instance, to the examination of a specimen of suspected carcinomatous tissue upon the findings of which a diagnosis rests, it seems evident that work of this nature belongs to the expert pathologist. I do not mean by this that the general practitioner is not capable or qualified to do this work in exceptional instances. The average man, however, has done neither true nor major X-ray work and while the X-ray is one of our most valuable aids in diagnosis generally, aside from its use in case of accidents, it must of necessity play a minor role in the laboratory of the general practitioner.

The chemical laboratory, on the other hand, while of equally great importance and perhaps more often consulted, lends itself admirably to the average physician. It would hardly be possible to-day to find a doctor's office in which some pretense is not made at this nature of work. Even here, however, some facts must be faced and I believe it is safe to estimate that fully fifty per cent. of physicians in active general practice to-day are wholly incapable, even granting the necessary materials be furnished them, of making a reliable, complete, qualitative, quantitative, chemical and microscopical examination of the urine. Many men who make a routine of examining for albumen and sugar do not bear in mind the fundamental requirements for a dependable test of even this nature.

The examination of the urine from one voiding as frequently practiced is of no def-

inite value but often misleading. As in the case of indicanuria, large amounts may be found at certain times even in one day while at others only a trace can be detected. The same holds true of certain forms of albuminuria and in the estimation of the percentage of urea. In examination of the urine the specimen should be taken from the 24 hour voiding. The complete analysis of this, the entire amount voided in 24 hours being known, rarely fails to give us trustworthy and interesting information.

While the microscopic examination should often be made the result must frequently be modified by other means before it is of definite value. Thus, while the microscope may show blood or pus in the urine it does not reveal its source. Simple clinical procedures have been devised whereby this can be determined. By having patient void successively into three glasses we determine if there is blood or pus in the first and second only or in all three. If the third glass is free, we know the bladder and structures above are not involved and the lesion lies anteriorly or in the urethra. If the third glass reveals blood or pus we know the lesion lies either in the bladder or higher in the ureters or kidneys. To determine further a simple test may be used based upon the knowledge that the normal vesical mucosa absorbs practically nothing. Inject 10 or 15 grains of potassium iodide dissolved in several drachms of water and test the patient's saliva by having him expectorate into some ordinary starch paste acidulated with nitric acid. If the test is of a vesical lesion we get the positive reaction usually in the course of one-half hour. Should there be no vesical lesion, the potassium iodide is not absorbed and a negative reaction means the ureters or kidneys are involved. Blood from above the bladder leads us to suspect tuberculosis of the kidneys and while the examination of the urine for the tubercle bacilli is not a satisfactory procedure, the history of the case, the physical findings and the use of the Von Pirquet followed by a positive reaction will determine the diagnosis. If there remains doubt, as to the diagnosis, a cystoscopic examination and catheterization of the ureters is of great value, but the general practitioner is rarely qualified to carry out this work himself.

The ordinary tests for albumen such as Heller's and the heat and nitric acid are not sufficiently delicate to deter faint traces of albumen. The detection of such traces is frequently of greater importance than that of larger amounts. Uries modification of the saline acid heat test is reliable in showing such traces. A few cubic centimeters of a saturated filtered saline solution acidulated to two per cent. with acetic acid are boiled in a

*Read before the Daviess County Medical Society.

clean test tube. Overlay this with the urine and if albumin is present in the most minute quantity a white line is readily seen at the point of contact.

Some few tests of the urine are practically diagnostic. Thus the finding of casts of the granular or epithelial variety indicate nephritis, of indican, intestinal indigestion or fermentation, the Diazo reaction, typhoid fever. From our present knowledge, it would seem that the Diazo should be chosen by the general practitioner in preference to the Widal. It is simple of technic, appears early when the diagnosis is of greatest importance, reappears with relapses and is practically specific with the exception of acute miliary tuberculosis from which it can be distinguished by Russo's test.

The sputum is usually examined to determine the presence of the tubercle bacilli. In collecting a sample for examination care must be exercised to get the true bronchial contents and not merely saliva. The finding of the bacilli in any number is of course diagnostic, yet the absence of bacilli from the sputum does not prove the patient free from tuberculosis. All possible means should be utilized to establish the diagnosis in these cases before the bacilli appear in the sputum and upon this early diagnosis depends in great measure the success of our treatment. The sputum may also be examined for albumin and elastic fibres. The finding of albumin, in the absence of valvular lesions and nephritis is strongly presumptive of tuberculosis.

For the purpose of clearing up the diagnosis of chronic gastric diseases, the test breakfast and analysis of the stomach contents are frequently indicated. In interpreting the result of such examinations care must be exercised not to be governed too great by the findings. The presence of food remnants, lactic acid, Boas-Oppler bacillus, low acid index, blood and the absence of free hydrochloric acid is not pathognomonic of cancer. The same findings may obtain in other conditions such as latent calloused ulcer and reflex pylorospasm. Cases have been reported in which cancer of the stomach was accompanied by a normal or even high acidity. These tests, however, may be readily made by the general practitioner and in selected cases are of great value.

With the advent of bacteria therapy has come an increased demand that more attention be devoted to bacteriology. If we are to expect favorable results from the use of the various bacterines it is obvious that the exact causative organism must be known. A general failure on the part of practitioners to avail themselves of the laboratory in determining this point has resulted in the various polyvalent mixtures now flooding the market.

The use of such preparations is in no way scientific and while there are exceptional cases and extenuating circumstances, where the symptomatology is specific or a delay would be detrimental, the use of stock vaccines without a laboratory diagnosis is to be condemned.

In many suppurative or chronic conditions the proper examination of the blood, especially the differential count, is of great importance. The question of operation in cases of acute appendicitis depends largely upon the blood picture. So in the various anemias, typhoid, malaria, syphilis, etc.; valuable information can be obtained from blood examinations.

The amount of laboratory work the general practitioner should do and the method he should employ are questions that can only be decided by the individual. Such are the facilities at present for having much of the special work done by experts in the various fields of laboratory work in private or public laboratories that the average physician will limit his work to the more ordinary examinations which require but little equipment and not much special training.

The laboratory but rarely makes a positive diagnosis and at all times the findings must be qualified, modified, and acted upon only in accordance with the accompanying symptomatology and physical findings.

Syphillis.—E. B. Krumbhaar and C. M. Montgomery, Philadelphia, (*Journal A. M. A.*, January 24), found 3 per cent. of a thousand new consecutive cases in the outpatient department of the Pennsylvania Hospital syphilitic which they consider probably less than half of the actual proportion that had contracted the disease. They give an analysis of 108 cases tested by the Wassermann reaction and conclude that their experience will be equalled elsewhere. As regards the proportions encountered in the general medical dispensary, the manifestations of the disease in such cases are often obscure and misleading, and they form a group quite distinct from the type ordinarily found in the dispensaries for genito-urinary, surgical or nervous diseases where distinct symptom-complexes or localizing phenomena are commonly encountered. Students should be instructed as to these atypical forms of syphilis and be impressed with the need of being constantly on the lookout for them. Dispensaries should have, as nearly as possible, a definite routine treatment for these cases, salvarsan having a prominent place and every available means, including the cooperation of the social service department, utilized to insure the carrying out of proper treatment.

RECENT METHODS IN HOSPITAL ANESTHESIA.

By C. N. CHIPMAN, Washington, D. C.

More real progress has been made in the study of anesthetics and anesthesia during the last ten years than during the preceding sixty-five years which have elapsed since the first public demonstration of anesthesia was made. For many years little attention was paid to the administration of anesthetics, either in the selecting of the anesthesia agent, the method of giving the same, or the equipment used. Any old way was good enough, the chief object in view was to have the patient completely narcotized, it being an iron-clad rule that the patient must never move or cough after being placed on the operating table for fear they might disturb the surgeon in some way. It made little difference if it required days and sometimes weeks of the most intense nausea and vomiting to recover from the effects of the anesthetic. It is little wonder that a patient having had an anesthetic in those days and requiring the second went to the hospital in greater fear and dread of the anesthetic than of the operation itself, because of the smothering and choking before and the nausea and vomiting following. They also did not fail to inform their friends needing an operation what a very pleasant time they would have taking the anesthetic, so that many dragged along without the much needed operation rather than suffer like their friend. This state of affairs is probably accounted for by the fact that anesthesia has always been under the direct supervision of the surgeon, generally administered by a nurse, or an untrained assistant. And as the old saying "we can not do two things at the same time," the surgeon needing all of his time and attention for the operation, the anesthetic was neglected, the surgeon often getting a bad result, and the patient worse than a bad result, a pine box sometimes being required to end the story.

A young surgeon called in a nurse, unqualified with respect to anesthesia, to anesthetize for a short, and as far as life was concerned, an unnecessary operation, when doctors were easily available for the purpose. The patient died in less than ten minutes. The result was a court procedure, and the necessary removal of the doctor to another locality. Another physician desiring to examine a man for hemorrhoids called in a dentist to administer nitrous oxide and oxygen. The patient died in the doctor's office. The result was a court procedure, the question being that dentists should not use nitrous oxide and oxygen for surgical purposes, unless specially trained.

So you see there is the medicolegal aspect as

well as the risk the patient undergoes in using an untrained anesthetist. The courts hold a surgeon responsible if he uses an untrained anesthetist acting merely as an assistant. In these days of specialism anesthesia can no longer be considered merely a part of the surgical procedure. Mortimer suggests that in becoming a "specialist," the anesthetist opens himself to actions for damages on account of injuries sustained during anesthetization.

Up to about three years ago the hospitals of this city were using untrained anesthetists, internes, students and nurses. About that time I collected the number of anesthetics given during the previous five years in all of the hospitals of the city. The results during the days of untrained anesthetists were about eight deaths from chloroform, or one out of every 243 persons anesthetized with chloroform dying.

There were some four or five deaths from ether, or one out of every 11,000 persons anesthetized with ether dying. These statements show beyond a doubt that in untrained hands ether is much safer than chloroform.

Within the past three years all the hospitals, with two or three exceptions, have employed trained anesthetists. So far as I am able to state to-night, within the past three years there have been some three or four deaths from ether and one from chloroform. The deaths referred to above were ones that occurred during the operation; several occurred during primary anesthesia before the operation had been started, so that they are straight anesthetic deaths.

The recent chloroform death was of that character, the patient dying before the operation was started. The anesthetist had been using chloroform for years and thought it was safe, but he only had the same result that every one obtains who uses much chloroform.

It is now conceded that chloroform which has played such a stormy part in the drama of anesthesia, should never be used alone, or as the terminal anesthetic. Personally, I think it should not be used in any form. As late as 1908 in some of our hospitals, chloroform was used for fifty per cent. of the operations.

INTRAVENOUS ANESTHESIA.

General anesthesia by the intravenous route was demonstrated as a possibility by "Ore." in 1872, who used chloral hydrate as the hypnotic agent. Since that time it has been used by various members of the medical profession, like many discarded or forgotten surgical procedures, because of the apparent novelty rather than any good results obtained. It is

a method that will never be of general use. The only good feature is that it produces a quiet anesthesia. The objections are high death rate, special training required, extensive apparatus, keeping a fluid at even temperature, scrupulous asepsis required in opening of the vein and introduction of the cannula, danger of septic thrombosis, and last but not least, the introduction of 500 c.c. to 3000 c.c. of fluid into the veins is a serious objection because of the increased oozing and overloading of the heart. R. C. Coburn recently stated that although a very small amount of ether is administered in the intravenous method as compared to that used in the inhalation method, we have a greater ether toxication when the intravenous method is used.

RECTAL ANESTHESIA.

L

The oil-rectal method is a possible but not a practical way of administering ether and producing anesthesia. Unlike the method above, it requires little in the way of equipment, 6 ounces of ether, plus 2 ounces of olive oil, a douche can and small rectal tube are all that are required. The objections are very often light anesthesia, or again very deep narcosis, irritation of rectum, etc. R. C. Coburn also claims increased ether toxication by this method.

SPINAL ANESTHESIA.

Spinal anesthesia is not a universal anesthetic, although it produces the greatest degree of muscle relaxation with the least protoplasmic disturbance. Even if skillfully administered it is probably more dangerous than a transient and light narcosis under ether or nitrous oxid and oxygen. Spinal anesthesia causes an earlier and more marked fall in blood pressure than other anesthetics, with a slowing and weakening of the heart action, and should therefore be used with caution or avoided in conditions of marked hypotension of the circulatory system. Spinal anesthesia requires a more highly developed technique and a greater degree of watchful supervision than does the use of ether. Spinal anesthesia is relatively safer in the young and robust than in the enfeebled and toxic. Spinal anesthesia has a high death rate.

INTRATRACHEAL INSUFFLATION ANESTHESIA.

Meltzer and Auer have shown that continuous insufflation of air into the trachea under moderate pressure is capable of ventilating the pulmonary alveoli of effecting the necessary exchange of oxygen and carbon dioxide and sustaining life for many hours when all respiratory movements have been abolished

by curare. They have shown that it is the most effective and ideal method of artificial respiration known. They have developed the method of intratracheal insufflation anesthesia with the following conclusions:

1. Intratracheal insufflation, administered with accurate control of the strength and amount of ether vapor, is a new principle in anesthesia which in certain classes of cases has many advantages over other methods.

2. The difficulty of intubating and the necessity of inducing full surgical anesthesia, before this can be accomplished, makes this a method unsuitable for many short, simple operations. Its use should be restricted to the cases in which it has special advantages.

3. It is absolutely safe both as to administration and freedom from deleterious after effects if a proper apparatus is used.

4. It is an ideal method of differential pressure for operations involving the opening of one or both plural cavities, greatly reducing the danger of intra thoracic operations.

5. It prevents aspiration of mucus or saliva, vomitus, blood or other foreign matter into the trachea, simplifying and decreasing the danger of operations on the tongue, jaws, mouth, nose, pharynx, etc., preventing aspiration pneumonia.

6. It is especially useful in operations about the head and neck. The anesthetist is out of the way; the operative field is easily kept sterile and obstruction of the upper air passages is absolutely prevented.

7. The degree of anesthesia is under perfect control. Over-etherization is impossible at or below 21 per cent. by weight of ether vapor.

Ether may be used also in the same manner for intratracheal and intrapharyngeal anesthesia.

Nitrous oxide and oxygen may be substituted for ether in the above methods with even better results, because the gases are under great pressure in the cylinder, so that no pump is needed; nitrous oxide and oxygen is the safest anesthetic, also nitrous oxid does not irritate the lungs as does ether.

THE DROP METHOD.

The most universal anesthesia to-day is ether by the drop or open method. Some men advocate that all operative cases can be anesthetized by this method. The simplicity of the technique, the small cost of the material, and a simple open inhaler, makes it an anesthetic that may be given at any time or place. By this method it is possible to anesthetize the patient, quietly, without any excitement or coughing, carry them through a serious and prolonged operation and have the patient react within a few minutes with little or no

nausea and vomiting. Do not misunderstand me as advocating this method alone, for it is by the utilization of combinations and sequences that were practically unknown until within recent years, that renders the modern which has helped so materially in the reduction of the mortality statistics as applied to anesthesia.

NITROUS OXID-OXYGEN ANESTHESIA AND ANOCI ASSOCIATION.

Of the general anesthetic agents now employed, the combination of pure nitrous oxide with oxygen, when properly administered, is the safest, the most agreeable and the freest from postanesthetic complications.

Anoci association is the word coined by Crile, of Cleveland, and used by him to designate a condition of the patient in which harmful stimuli are prevented from reaching the brain by blocking or paralyzing the receptor mechanism by anesthetics or narcotics. With this dissipation of nervous energy there results a general functional weakness which causes a condition clinically of shock. In speaking of the part played by anesthetics in producing brain cell exhaustion, he states that although ether anesthesia produces unconsciousness, it apparently protects none of the brain cells against exhaustion from trauma of surgical procedure.

He further states that the negative evidence that inhalation anesthesia offers little or no protection to the brain cells from trauma is derived from the following experiment:

A dog, the spinal cord of which had been divided at the level of the first dorsal segment, and then kept in good condition for two months, showed a recovery of the spinal reflexes, such as the scratch reflex, etc. This animal is known as the spinal dog. Now in this animal the abdomen and hind extremities have no direct nerve connections with the brain. In such a dog a continuous severe trauma of the abdominal viscera and of the hind extremities lasting four hours caused not the slightest change in either the circulation or respiration and no microscopic alteration of the brain cells. Judging from a large number of experiments on normal dogs, under ether, such an amount of trauma should have caused not only a complete physiologic exhaustion of the brain, but also morphologic alteration of all the brain cells and physical destruction of many.

We must, therefore, conclude that although ether anesthesia produces unconsciousness, it apparently protects none of the brain cells against exhaustion from trauma of surgical operations. Ether is, so to speak, but a veneer. Under nitrous oxid-oxygen anesthesia there is

approximately only one-fourth the exhaustion after equal trauma as under ether. Either nitrous oxide protects or ether predisposes to exhaustion under trauma.

Such men as Teller, Gwathmey, Huvette, Gatch, Henderson and others have found that nitrous oxide and oxygen anesthesia causes little or no shock, and does not produce nephritis, pneumonia or any of the degenerative changes so common after ether or chloroform anesthesia. The only practical danger of gas oxygen anesthesia is that of asphyxia, caused by the fact that nitrous oxide must be given from eighty to ninety per cent. pure, so that the gas will act on the nerve cells and bring about the proper anesthetic state. The patient can pass from profound anesthesia to the conscious state within sixty seconds, and for that reason the extreme rapidity of induction and elimination makes the administration of nitrous oxid and oxygen the most difficult general anesthetic to administer properly.

ADVANTAGES OF NITROUS OXIDE AND OXYGEN ANESTHESIA.

1. Rapidity of action.
2. No unpleasant sensation to patient.
3. Absence of post-operative complications.
4. Very little post-operative vomiting.
5. Absence of pneumonia, nephritis or blood changes.
6. Little or no shock.
7. Lack of dread should future anesthesia be required.

DISADVANTAGES.

1. The necessity of a trained anesthetist, and an expensive apparatus.
2. Cost of the nitrous oxide and oxygen.
3. Rigidity in some cases; although this can be entirely avoided by using Crile method of local infiltration of 1-400 solution of novocaine, so that it is possible to have complete relaxation in all cases.

As a preliminary to ether, I believe nitrous oxide and oxygen has no equal. With preliminary of morphine, nitrous oxide-oxygen and local infiltration of solution of novocaine it is possible to operate upon a patient and they not know anything about the operation until the wound is redressed or entirely well. This is accomplished by taking the patient to the hospital and not telling them the day they are to be operated upon. They are daily given a hypodermic of sterile water, enough nitrous oxide-oxygen to put them to sleep and a bandage is applied over the place to be operated upon. The day of the operation morphine sulphate, gr. 1-3, atropine sulphate, gr. 1-150, is substituted for the hypodermic of sterile water and with nitrous-oxide-oxygen anesthesia and local infiltration of novocaine

anesthetic the operation performed. They are returned to their bed as on former days without pain, shock, nausea or vomiting, or any unpleasant conditions. This method, when properly carried out is the ideal anesthetic. This method can be used with few exceptions if the proper technique is carried out.

IN CONCLUSION.

1. Ether by the drop or open method is the anesthetic in most universal use and is the safest in unskilled hands.

2. Nitrous oxide-oxygen with a preliminary of morphine sulphate, gr. 1-4, atropine sulphate gr. 1-150, and infiltration of a local anesthetic is the ideal anesthetic.

3. Every large hospital, should have as a regular member of its staff an attending anesthesiologist, as is the case in some, whose authority in his special department should be as complete as is that of the attending physician or surgeon in their field.

THE TRUE PHYSICIAN.*

By E. E. BICKERS, Port Royal.

There is no greater calling for man than that of a true physician unless it be that of the ministry, there is no business that carries with it as great a responsibility as does the practice of medicine and of surgery, in his every day duties he is dealing with the lives of his fellow man, a mistake in the treatment of the case may snap the brittle thread of life and launch that human being into eternity.

If he is a true man and physician his highest ambition is to see the sick restored to health again. There is nothing that brings him more pleasure than to see one that has been almost at death's door with some bad disease, to see them rapidly returning to health again, and it is very gratifying to the physician to think that by his masterly skill and his good knowledge of therapeutics he has been enabled to overcome the disease and return his patient to health again. He is a man of all men that must keep his wits together because he never knows when he may be called to attend some one that is almost at the point of death from some accident, when all other attendants are scared out of their wits from the appearance of a bleeding artery, or a post-partum hemorrhage when you are called to attend the lying in woman and find her in esclamptic convulsions. It is these cases that require judgment and a steady nerve to tide them over these precipices and land them on the right road to recovery.

There is no class of professional or scientific men that have contributed more to the general

welfare of the world than have the men of the research laboratory. They have given the world the benefit of their researches and it has been through these true men of science that medicine and surgery has been made what it is to-day.

The writers of the world's history have written pages as an eulogy to some noted general who has slain his thousands and conquered his enemies and gained the victory for his cause. They have also paid honor to that statesman that has gone forth in the defense of his country's rights; they have erected marble slabs to the memories of the sleeping heroes of the world that have won honor and fame in times of war and peace. But in their wild rush to pay honor to these men that have won fame in the world's history they have forgotten some of the greatest heroes that are to-day sleeping beneath the sod of the valley; such men as Jenner, Kotech, Loeffler and many others that have given their life and time to science.

The time will come when these men that have given their lives to this great cause, in order that the world may be made better, healthier and happier by their having lived in it, will take their places among the heroes of the world, and before the close of the present century the people of the entire world will be speaking praise of these great men of science.

It has been the mission of the true physician in all ages and in all climes, to teach the people how to keep from getting sick, something that no other class of business men would do, try to put themselves out of business. It matters not in what part of the civilized world you may go you will find the physician's preaching preventive medicine. The physicians and health boards are the guardians of the future welfare of our nation. Had it not been for the health officers when would the Panama Canal have been dug Never! It had been undertaken on previous occasions but had been given up on account of the bad sanitary conditions; men could not live in that country, but to-day the Panama canal zone is as healthy a place as there is in the United States.

What have the physicians and health boards done for the South and other tropical countries. They have practically eliminated some of the most dreaded diseases that were so common in that climate from the list, namely yellow fever. The time was when this disease would come in the form of an epidemic and would almost paralyze all forms of business. people would leave that land of sunshine and flowers by train loads, going to a more healthy clime.

But through the skill of the health officers

*Read before the Henry County Medical Society.

of the national government, aided by the local men of the South, a few years ago found the cause of this dreaded disease and by means of prophylactics have practically driven that disease from the Southern ports.

In the great struggle to find the cause of that disease some three or four men of the national board of health lost their lives, being infected by the yellow fever mosquito. Yet, the people of the nation and, especially of the South, in their great rush to pay honor and tribute to men that have contributed to the world some valiant service, have forgotten these men that have made the South what it is to-day, a health resort for the whole world.

The man of leisure can now invade the ports of the South and escape the cold winter winds of the north with the assurance that he will not have to flee on short notice to escape yellow fever. The physicians and health boards have been of more real value to countries in the tropical regions than any other class of professional and business men. The law of disinfection, the law of quarantine and isolation have added more to the real value of the country than any other law that has ever been enacted by any law making body.

There is nothing that can add more to the wealth and happiness of a country than good health. By the means of vaccination and quarantine, some of the most fatal diseases we have had to deal with in the past have almost been eliminated from the list, especially small-pox. At one time it was one of the most dreaded of all diseases but to-day the severity is almost nil. You can hardly make the people believe that it is small-pox.

Diphtheria and scarlet fever a few years ago would break out in a community and render that community almost childless, but to-day by the law of quarantine and isolation aided by the therapeutic use of the serum therapy we can confine it almost to a few cases.

Typhoid fever has been the bane of humanity ever since the hour of his existence but is being placed on the list of preventable diseases by means of a vaccine. No doubt before the dawn of another decade typhoid fever will be one of the diseases that we will scarcely hear of.

So year by year we are adding to the list of preventable diseases until before the close of another quarter of a century the acute infectious diseases will be a thing of the past.

So, summing up the life work of the true physician we find that no class of business or professional men have contributed more to the world's good than have these men that have given their life work in order that man may know how to keep well. His life has been one of privation and sacrifice, and sacrifice with

no eight or ten hour system, but on duty twenty-four hours in the day three hundred and sixty-five days in the year, with small pay for what he has done for humanity.

But in the evening of his life when the sun is setting behind the western hill of time, he can sit down with a clear conscience feeling that he may not have accumulated wealth but he has given something to suffering humanity that is far more valuable than gold or silver, a life of true devotion.

Now that the business, commercial and social world no longer add new charms to his life; the political world with the harrangue of the political demagogue as he scales the heights of the political arena in his endeavor to proclaim that tariff reform or the election of United States Senators by popular vote, are the essential requisites to good government, no longer disturb the peaceful mind of this man that is in the declining years of life enjoying the thoughts of a well-spent life and hoping by the many good deeds and true service that he has given to suffering humanity, that the Great Physician, who has been the balm and giliad of man since the dawn of his existence will take notice of these many noble deeds and give him a life in that land of eternal bliss where there will be no night:

Liberation of Formaldehyd.—The liberation of formaldehyd hexamethylenamin in pathologic fluids has been studied by Paul J. Hanzlik, Cleveland (Journal A. M. A., January 24), who had previously shown that decomposition of hexamethylenamin takes place only in acid urine and gastric juice and that it does not occur in the body fluids that are neutral or that are truly alkaline and in normal conditions. It seemed possible, however, that the reaction of certain pathologic fluids might be truly acid and they therefore have tested the urines, cerebrospinal fluids, bile, edema as ascitic fluids in various diabetic patients to determine the distribution of hexamethylenamin and free formaldehyd and the reaction of these fluids in various pathologic conditions. In twelve urines in patients suffering from nephritis, the behavior of hexamethylenamin was found to be the same as that in normal persons. Examinations of cerebrospinal fluid, bile, and various pathologic serums and the blood of diabetics revealed no free formaldehyd, and it can be contended, therefore, that no bactericidal action could have been expected. The conclusions deduced from their studies is: "The decomposition of hexamethylenamin in pathologic fluids obeys the same laws as in normal circulating fluids, and fluids in vitro under different clinical conditions. That is, the liberation of free formaldehyd from hexamethylenamin depends on the hydrogen in concentration of the fluid (true acidity)."

THE DUTIES OF THE ANESTHETIST.*

By EMMETT F. HORINE, Louisville.

Until about fifteen years ago the anesthetic was usually administered by an untrained assistant or by a nurse. The potentialities for harm when this was the case were very great. An agent powerful enough to produce unconsciousness and complete insensibility to pain should be carefully used and only by an experienced person. The life of the patient is truly in the hands of the anesthetist and he must be prepared for any emergency that may arise. Can the surgeon afford to place the life of his patient in the hands of one unskilled in anesthesia, such as an untrained assistant or a nurse? I grant that a nurse may successfully anesthetize for some time but sooner or later an emergency will arise demanding more medical knowledge than she it is that the degree in medicine gives the legal possession and then trouble will ensue. True, that it is the degree in medicine gives the legal right to administer an anesthetic though it does not confer the moral right. For an anesthetist must not only possess medical knowledge but he must fully understand the physiological action of the agents employed and by clinical experience know which anesthetic to select for each case.

The anesthetic of to-day cannot be a slave to any one anesthetic. It is foolish for one to say that he gives ether and never any other anesthetic, or that he gives only chloroform, or as some say: "never anything but nitrous oxide and oxygen." As is well known there are certain indications and contraindications for each drug. This being true it follows that to give an anesthetic in the face of certain contraindications would not only work a grave hardship on the patient but it would also show the anesthetist to be incompetent. The competent man is the one who can skilfully administer any one of the three known agents, nitrous oxide, ether or chloroform either alone or in combination or sequence. In addition a fine sense of discrimination must be used in selecting the agent or sequence in each particular case. Nitrous oxide which is ordinarily the safest anesthetic becomes dangerous if used in unsuitable cases. Ether is safe and in some clinics is used in a majority of the cases but it also has its limitations. Chloroform is the most dangerous but in certain cases it is especially indicated. The expert considers every factor in the case at hand and then selects the agent which will be the safest and which will produce the least after-effect. One must always be prepared to change to a different agent should indications

for such change arise. Without doubt some of the deaths during anesthesia can be attributed to the use of an improper agent.

In administering an anesthetic one assumes a moral obligation which is indeed weighty. Where possible the patient should be examined on the day previous to the operation. The fear of the anesthetic is a real one and the patient should be reassured. Most patients are considerably more worried at the thought of having to be anesthetized than they are over the operation itself and some are positive in their assertion that they will never awaken. The anesthetist must always attempt to gain the confidence of the patient by approaching him or her in a calm, quiet and dignified manner so as to in no way cause excitement or alarm. If he can inspire the patient with confidence a far more satisfactory anesthesia may be obtained.

But whether the examination be made a day or two prior to or immediately before the operation, it should be conducted with the following points in view.

1. Determine the exact condition of the patient's heart and lungs.
2. Take pulse and respiration and make an estimate of the blood-pressure.
3. If the urine has not been previously examined it becomes the duty of the anesthetist to see that this is done.
4. Obtain the previous anesthetic history, if any.
5. Give orders with reference to the preliminary hypodermic.
6. Decide upon the anesthetic and sequence most suitable taking into consideration the nature of the operation.
7. Above all, try to win the full confidence of the patient and by voice and manner inspire him or her with your ability and with your earnest desire to do your best.

Before the anesthetic is begun all foreign bodies should be removed from the mouth. During the period of induction care should be exercised not to startle the patient. Absolute quiet on the part of the onlookers should be insisted upon during this period. It is best to exclude relatives and friends from the room though of course in certain instances it is well to have them remain. The anesthetist must keep his whole attention on his work and under no condition should he allow outside influence to interfere with it. The steps in the operation should be from time to time observed and the depth of anesthesia regulated accordingly. The respiration and pulse should be watched and in the more serious cases estimations of the blood-pressure should be made at either five or ten minute intervals.

A permanent record of each administration

*Read before the Muldraugh Hill Medical Society, April 10, 1914.

should be made which should include the following data: Name, age and address of patient; date; findings at examination, rate of pulse and respiration, blood pressure; anesthetic employed; diagnosis; operation; name of surgeon and physician; names of assistants and witnesses. In addition it is well to state time when anesthetic was begun and when the patient was fully anesthetized as well as length of operation. The amount of anesthetic used should be given as well as patient's weight. The careful man usually visits his cases on the day following the operation for the purpose of ascertaining if nausea occurred and if any unusual symptoms arose.

The anesthetist must know the exact condition of the patient during the entire operation. He must be ever watchful and he should notify the surgeon of any alarming symptoms. By constant watchfulness trouble may be anticipated and therefore quite often prevented. As a rule stimulants and hypodermoclysis or intra-venous saline are not needed but the anesthetist should see that they are in readiness should untoward symptoms arise.

At the end of the operation the condition of the patient is carefully noted. The anesthetist should now see that the patient is safely placed in bed and left in charge of a competent person, special instructions being given if necessary. If the operation has been performed in the home and no nurse is present, the anesthetist should remain until satisfactory symptoms of recovery have been observed.

In conclusion I agree perfectly with Neff who says that: "Whether the case is an apparently simple or a critical one, it should be remembered that the good anesthetist, like the good surgeon, is he who, besides being competent, has a conscience, and feels his responsibility, who appreciates that there are some who are anxiously awaiting the outcome, and have a deep interest in the life that is in his hands."

Plague in Porto Rico.—S. B. Grubbs, Providence, R. I., (*Journal A. M. A.*, January 24), gives a history of the bubonic plague in Porto Rico in 1912. It was first discovered in a squalid district of San Juan and the positive diagnosis was given to the governor by the director of health, three days after the case was discovered. The governor promptly proclaimed the existence of plague and measures were taken at once to clean up the city and eradicate the disease. Of course, a panic resulted and radical measures were proposed but these, however, were not deemed necessary and the panic quickly subsided. In all 56 cases occurred with 36 deaths and the infection was completely destroyed in three months' time.

FOREIGN BODY (STEEL) IN THE EYE BALL—METHOD OF REMOVAL.*

By J. H. HESTER, Louisville.

On May 19, 1913, Mr. W. D., of Peoria, Ill., age 22, occupation laborer, was sent to the Illinois Charitable Eye and Ear Infirmary by his family physician of that city, and as I was House Surgeon of this institution at that time, it became my duty to look after this patient as he was placed on my service.

He gave the following history: Ten days ago he was attempting to take a door off the hinges, with a chisel, when a piece of steel, from the head of one of the screws, struck him in the right eye. The pain and loss of vision resulting therefrom caused him to seek medical aid; so he consulted a specialist of that city. He was under this doctor's care for about ten days, and during this time several attempts were made to remove the steel with a giant magnet, but to no avail. The doctor then advised the removal of the eye, but he refused to have this done. He then consulted his family physician, who advised him to come to this institution.

Condition when patient arrived at hospital: Right eye vision, could only see a bright light when reflected in his eye from a mirror, but could not point out the direction of the light, or in other words poor perception and no projection; lids normal; marked conjunctival and ciliary injection; cornea had a perforating wound about 5 mm. in length, pointing at about 8 o'clock, anterior chamber filled with blood; iris lacerated and slightly prolapsed. Left eye vision, 20-20-1.

Treatment and subsequent history: It was my custom when a patient came into the hospital with a history of a piece of steel in the eye-ball, to try to remove it with the giant magnet, and failing in this, he was sent to our X-ray man for a diagnosis. In this case the giant magnet was used with no results; so this patient was sent, and an X-ray made, which showed foreign body in right eye as per diagram which I will now pass around. It took twenty-four hours to get this report, and in the meantime, I had Dr. Dodd, one of the head surgeons of the institution, see this patient and he suggested the removal of the eye if pain continued until morning. When morning came the patient had slept but little, and then only when under the influence of morphine. By this time I had my X-ray report which showed the foreign body and location of same. The patient was prepared in the usual manner for enucleation, however before doing this, I had decided to try another method of removing the steel; so I did

*Read before the Jefferson County Medical Society.

a posterior sclerotomy on the outer side of the eye ball, about ten m.m. back of the limbus. I again tried the giant magnet with no results. It then occurred to me that I could take a strabismus hook and place it in the eye near the steel and attach the magnet to the hook, hence removing the steel in this way; so I did this and as soon as the current was turned on I felt the resistance of the steel. I gently removed the hook by raising the magnet and when it came out I had a piece of steel size 1x2 1-2x5 1-2 m.m. I lost no vitreous, and the patient complained but little while removing the steel. That part of the iris which was prolapsed was removed. This was all done under cocaine and adrenalin anesthesia. Atropin and dionin were put in the eye, bandage applied, and patient put to bed with a hot water bottle to his eye. The patient slept well the following night, and did not complain of any more pain. The eye was treated in the usual way, and at the end of one week the eye had cleared up till patient could see shadows. One week later patient was discharged. Condition: Right eye, could distinguish objects. Left eye vision had remained same during all this time.

I had a letter from the patient about four weeks after he left the hospital, in which he stated he could count fingers at a distance of ten inches with the injured eye.

This book should have the title "Ten Sex Talks to Mothers of Girls." The writer has very little patience with the efforts of some would-be reformers to teach such information as is found in this book to young girls, congregated together in the school or elsewhere, unchaperoned by their mothers. The proper person to teach a young girl sex relations is her mother in the privacy of the home surrounded by home influence and freed from the curious comment of some in any crowd of girls, who would twist the lesson to an unholy use.

In the matter of teaching sex to school children by the teacher, the cart is put before the horse and a great deal of harm would result from this kind of crusade. If all minds were pure and all teachers were informed of what to teach and how to teach it, only good could result. Unfortunately, neither of these conditions obtain and the putting forth of such books as this into the hands of young girls, in the writer's opinion, is but serving as a stimulation to a morbid curiosity which is being gratified by an attendance upon social and problem plays which have to do with sex relations. Such material as this would be read with the same avidity by the type of mind that fairly consume the cheap and questionable literature of certain magazines which play for popularity and feed these victims with literature of unsavory and immoral flavor.

BRONCHITIS.*

By C. E. VIDT, Russell.

The unusual prevalence of bronchial disturbances in the last few months has, undoubtedly, instigated a request for a review of the more common bronchial conditions, and certainly such a review is not amiss at this time and meeting. I will not attempt to cover the subject in its entirety, but will limit my remarks principally to symptoms, diagnosis, and differential diagnosis.

At the present time the world at large is at war vociferously with tuberculosis, and this is especially true in Kentucky. Much has been said and as much more has been written with reference to the early diagnosis, management, and prevention of this intractable disease. Capable and masterly essays have been read and listened to by the members of the numerous medical societies, and, which in turn were followed by eloquent and scientific discussions. Not only is this interest limited to the medical fraternities, but the various magazines and daily papers have propagated and heralded the importance of early medical attention, to every reading individual to the most inaccessible portions of our States. I doubt very much whether the increased demand for medical attention by the general public for respiratory troubles is due to an increase over the average amount of cases we have previously seen at this time of the year, but am inclined to believe that the constant lecturing, splendid work done by the various organizations, and the daily press, have educated the public to a point where they see the importance of early medical attention. This to the practicing physician should be considered with a great deal of responsibility, for upon his interpretation of the chest-findings of an individual who presents himself for some disturbance within the thoracic cavity, and his verdict, depends the future welfare of that person. Unless the physician takes advantage of such an opportunity and uses all the knowledge and skill which he possesses in making an early diagnosis, he certainly is depriving that patient of his just rights. Again the movement on foot to eliminate tuberculosis will all be for naught unless we physicians take the matter up from this point and use all the methods that we possess in making a definite diagnosis when the case presents itself.

Acute bronchitis, without a doubt, is one of the most frequent conditions for which the physician is called upon to prescribe. Prescribe probably he does well enough, but how often does he examine the chest of his patient to determine whether or not there is an

*Read before the Greenup County Medical Society.

underlying condition, possibly tuberculosis, which very frequently is the case, and of which the patient is not aware? By considering these cases too lightly the patient innocently loses a great opportunity, and later may give rise to serious trouble.

SYMPTOMS.

The history of these cases carefully taken will prove of inestimable value. Cough which at the beginning is hard and dry, is the most conspicuous symptom. Shortness of breath is occasionally present in a mild form, and the temperature, if any, rarely exceeds 101 degrees F., if beyond this it would be well to look for a more deep-seated involvement. The expectoration at first scanty and mucoid, gradually becomes more abundant and mucopurulent. The physical signs with the exception of auscultation are practically negative. On auscultation we will find dry rales of a sonorous type, transient in nature, and, in a great majority of instances, invading both lungs. I wish to lay particular stress upon this one point, that is, the bilateral tendency of this condition. A subcrepitant rale is also heard, occurring during both inspiration and expiration. It is wiser and safer to guard one's diagnosis of a unilateral bronchitis and have the patient return at short intervals for further examinations. These symptoms together with the history makes bronchitis readily distinguishable from other cough producing affections.

DIAGNOSIS.

The history, presence of the dry sonorous rales; the subcrepitant rale occurring during both inspiration and expiration, coming and going; a clear percussion note and the bilateral tendency is sufficient to make a definite diagnosis

DIFFERENTIAL DIAGNOSIS—CHRONIC BRONCHITIS.

This is not usually difficult. The history and various moist rales, more pronounced at the bases of both lungs posterior, with otherwise negative physical signs, usually suffice to differentiate it from other bronchial disturbances.

TUBERCULOSIS.

Here is where the physician's utmost care and knowledge is called upon. I refer here to tuberculosis in its incipency, for here only does it resemble somewhat bronchitis, for after we have the stage of complete consolidation the diagnosis is not difficult and the period when treatment will be most beneficial to the patient will have passed.

INSPECTION.

From this we may learn nothing. There may be a slightly diminished expansion of the infraclavicular spaces of the infected side as compared to that of the opposite side. In some instances the general appearance may be suggestive, and the respiration a little more rapid.

PALPATION.

Palpation is usually negative, there may be an increased vocal fremitus.

AUSCULTATION.

A change in the breath sounds is undoubtedly the first evidence of the disease. The abnormality shows itself principally in a prolongation of the expiratory murmur and a harsh inspiratory sound. Subcrepitant rales at the end of inspiration are also heard.

PERCUSSION.

Percussion generally elicits a slight impairment of resonance in the region of the clavicle. By having the patient to hold his breath at expiration, dullness may be detected.

To differentiate this condition from a bronchitis of a mild and prolonged type is at times difficult in the early stages, but by careful questioning, observing, and painstaking examining of the chest, together with the tuberculin test, competent Roentgen ray examination, and blood picture, a definite diagnosis can in the great majority of instances be arrived at.

The Small Hospital.—How to make over a dwelling-house for hospital purposes is told by J. A. Hornsby, Chicago (Journal A. M. A., January 24), in a very fully illustrated paper. He gives illustrations of three such remodeled dwellings. He says: "In contemplating the equipment of one of these small dwelling houses for hospital purposes, about the only thing that need be thought absolutely necessary is a small sterilizing plant made up of water, dressing, utensil and instrument sterilizers. This plant adequate in size should be as follows: two 6-gallon water sterilizers; one dressing sterilizer 16 by 24. One utensil sterilizer 16 by 18 inches; one instrument sterilizer 6 by 9 by 12; cost of sterilizing-plant, \$300. The balance of the equipment for a hospital of this sort follows, with approximate prices which will have to be paid for the several articles, the whole equipment to cost approximately \$952.50 plus \$40 for each patient more than one, since the bed equipment for only one patient is omitted." The details of this further equipment costing the price mentioned are given in full.

THE MEDICAL TREATMENT OF APPENDICITIS.*

By A. P. DOWDEN, Eminence.

In attempting to give you a paper on the "Medical Treatment of Appendicitis," I am aware of the fact that I am liable to start something. However, I believe we should not be "the first by whom the new is tried nor yet the last to cast the old aside," and anything I shall say this afternoon will be based upon my reading and what I have learned by actual experience at the bedside. In the earlier years of my practice, and the years are not yet heavy on my shoulders, I was taught and believed that as soon as a diagnosis of appendicitis was confirmed I ought not to stop until the appendix was out of the abdominal cavity. I may be growing old, I hope not, but I am trying to grow more conservative.

Don't understand that I shall say anything in condemnation of, or in opposition to, surgery. Far from it; I believe in surgery but I also believe the internist has a part and a very important part; and that in the treatment of appendicitis, like every thing else we fast Americans undertake, the pendulum has swung too far and we are too hasty in our surgery. Before the paper is ended I hope to cite you a few cases in my own practice where a few years ago I wouldn't have rested until the patient was operated upon; to-day they are alive and well and under medical treatment and their bank account has not been depleted by some surgeon and hospital. I ask you in your discussion, and I invite your discussion and sharp criticism, to remember that this paper deals with the country doctors' cases where the only help he can get is from his brother practitioners and a trained nurse. I am not speaking as a city man who has within easy call a rubber-tired ambulance, trained assistants and a hospital at his convenience.

I would not have you think every case can be carried through without an operation, but I believe most of them can if seen early enough by the doctor and treated by *him* not by the patient's family. In support of this proposition I cite you to no less authority than Dr. Beverly Robinson of New York City, who states in *May Clinical Medicine*: "I feel convinced that in a very few years from the present time an operation for appendicitis will be extremely rare, and we shall have gained real wisdom and shall guide our patients with united advice to seek the best means of prevention and cure."

As my paper deals only with the treatment I will not go into the pathology or diagnosis.

Suffice it to say, sudden abdominal pain, at first diffuse, later localized over the appendix, nausea, vomiting and frequently constipation, slight fever, 100 to 102. The pain may be colicky and sharp or dull and aching, and may radiate in testicle or down the right leg, usually increased by movement or coughing.

Palpation, reveals localized tenderness, tumor may or may not be palpable after 24 or 48 hours. Chill may or may not occur at the outset. Our diagnosis of appendicitis confirmed, what do we expect? We expect, as a rule, that it will terminate in one of three ways: resolution, abscess or diffuse peritonitis.

Nine-tenths of our patients when we see them have been given a purgative; something to increase peristalsis, this is the very thing we wish to avoid. Once we are sure that we have appendicitis to deal with, we should get the intestines in a splint so to speak, as quickly as possible by absolute rest, nothing by mouth and opiate enough to quiet peristalsis. Of course we all have our preference in drugs. As a routine measure with me after I have made my diagnosis I give hypodermically the H. M. C. tablet of Abbott which consists of hyosine hydrate 1-100, morphine hydrobromate gr. 1-4, cactoid gr. 1-64; repeat in from six to twenty-four hours as patient suffers pain or tenderness for the bowels to move. I relieve the lower bowel with enema of glycerine and warm water allowing water to fill the bowel slowly with syringe not elevated over 18 inches, and of course have the patient use the bed-pan. Once I get the lower bowel empty (which I try to do the first 24 hours of the attack) I leave it alone except to pass a rectal tube if gas accumulates.

Locally: Ice-pack at least 45 minutes out of the hour the first 48 hours. I am aware of the fact that there is now some criticism regarding the use of ice but as stated at the beginning of this paper I am writing from personal experience and it seems to me heat would hasten the formation of an abscess, the complication we would be trying to avoid.

Treatment: Calcium sulphide to saturation for its action in limiting or preventing suppuration. If there is evidence of a severe infection usually give a combined vaccine consisting of streptococci, staphylococci, bacilli coli communis, and diplococci pneumoniae, eserine, grains 1-50 hypodermatically to control the accumulation of gas.

Diet: Absolutely nothing for 72 hours, except occasionally a sip of water. After the acute symptoms have subsided temperature becomes normal, patient's appetite returns, I then begin feeding as we would a typhoid patient, liquid food, semi-solid food and

*Read before the Henry County Medical Society.

gradually back to solid food, depending upon and being guided by the amount of distension, character of the pulse and disappearance of the tumor, etc.

This in the main has been my method of treating diseased appendices that have appealed to me for relief during the past four years. In that time I have had one operated on within 15 hours from the time of my first visit, it being his fifth attack and showing profound shock when I saw him and the operation revealed a pin-hole perforation. A fecal fistula followed the operation but in six weeks from the day of the operation he returned to his work as a blacksmith and has been well since. Two other cases were seen by me in consultation; both had been given a purgative before their doctor saw them; both were operated upon as quickly as possible and recovered after a stormy convalescence. One other case I have in mind was operated on immediately after an attack. I think that this operation was unnecessary as he made a complete recovery under the treatment mentioned above and seems entirely well. Opposed to these cases I can cite you one of a young lady whom I saw at the beginning of the attack, who ran a typical course, has since married and given birth to a child and has had no trouble since. I could mention several others who have had no trouble after being treated along the lines mentioned above. Now do not understand me to say that every case can or should be treated by the internist and not by the surgeon; but I do believe that the majority of cases is seen early, before over-anxious friends have given, or the patient himself has taken, a purgative, and if *he can be controlled* by the doctor, can be cured without surgical interference. I believe we have been in too much rush to carry our patients to some hospital. I believe they have a better chance to leave them where we find them, treating them along the lines mentioned, of course studying each case as the emergency arises and meeting it believing the middle way of wisdom between surgery and medicine is the safest for our patient.

This afternoon, at my request, we have before us a gentleman who is a very good illustration of the point I am trying to bring out in this paper. In February, 1913, Mr. S., a farmer, was operated upon by me for hemorrhoids, Dr. Zaring giving the anesthetic. He was just recovering from a moderate attack of grippe, was anemic, took the anesthetic very badly and showed considerable shock when the bowel was dilated. However, his recovery was uneventful and on April 5th he came into my office complaining of pain around the umbilicus. As he had taken a dose salts before he left home I sent him

home to bed. I saw him three hours later; his temperature was 98, pulse 50, respiration 22; abdomen very much distended and he was rolling in intense agony although his wife had given him two 1-4 grains of morphine by mouth. Tenderness most marked over the right quadrant, nausea and vomiting. I immediately put him on the treatment above. At midnight his temperature was 100 and ranged from that to 102 for four days.

This man had absolutely nothing by mouth for six days except an occasional sip of water and very little of that. After the first week's illness the tenderness began to subside; he rapidly improved and has been doing everything a farmer can find to do ever since besides building four miles of road. He has not had a sick day since and does not know he ever had an appendix. I can cite you other cases about whom some of you know that have been cured and have remained well, treated along these lines.

You may, in your discussion, doubt my diagnosis in some cases (none of us are infallible of course), and my answer to that criticism is that I have seen, and so have you I suspect, cases operated on for appendicitis when the appendix showed no evidence of ever having been irritated. I have seen other cases operated on after a severe attack where the appendix had sloughed away. It had been obliterated by the violence of the attack and would never have given any more trouble. Only last week I had a patient that required a complete hysterectomy for a multiple fibroid of the uterus. The appendix was found very much elongated and had to be dissected out of its sheath and its entire length bound down by adhesions. Evidently this patient had had a number of catarrhal attacks, but told me she had never had a doctor until she noticed this tumor due to the fibroid. Here was a case where ignorance was bliss.

In conclusion: If we can see our patients early before they undertake to treat themselves and handle them along the lines mentioned above, I believe the majority of cases will recover promptly without operation. Then teach them how to live in regard to diet, regular habits, etc. Our results will be just as good, if not better, than in the past and our patients will not delay sending for us as they do now.

Scarlet Fever.—Treatment. Salvarsan used in 109 cases. Striking effect on throat symptoms, especially in necrosing form, noted. Indicated in severe toxic forms especially. Good results even upon local application. Neosalvarsan not suitable.—Jochmann and Schreiber.

INCIPIENT PULMONARY TUBERCULOSIS.*

By A. J. BRYSON, Fullerton.

We have for our discussion to-day, one phase of the most important of all the varied ills to which the human family may ever become a prey.

Any subject involving the question or any manifestation of any part of tuberculosis, must necessarily, for obvious reasons command our especial attention and consideration, and then too, when we are considering the beginning, the incipency, the time when a correct interpretation of the condition may mean so much to the tubercular patient, a time that may mean a prolonged life of more or less usefulness, or it may mean the beginning of a premature and untimely result, especially so should the condition pass unrecognized at this time.

In many diseased body conditions, the beginning does not especially concern us, or in other words, I mean to say the future management and the ultimate result do not hold the same concern that tuberculosis does in its incipient period. If the early tubercular is left undirected, unguided and unmanaged, we can readily imagine, in fact we are made to realize the actual outcome from our almost daily observation.

The magnitude of the involved subject might be made more impressive by mentioning the fact to you, that there are something like 20,000 cases of tuberculosis in our own state at the present time. A large per cent. of these cases have passed from the incipient type, thereby adding greater risk to the uninfected and less hope for recovery to themselves.

My circumscribed observations, and my limited time in the preparation of this paper, must of necessity, forbid my entering into a detailed consideration of every particular involved, hence I shall content myself by attempting to direct our attention to some few of the most important connections. It seems useless to me to attempt to go into a review of the historical facts as regards our subject to-day, suffice it to say, however, that the profoundest consideration has been given by medical men to the study of tuberculosis throughout the various medical ages, and that one man in particular has proven the infectiousness of phthisis by animal experimentation, previous to the time of Koch's wonderful discovery. It was left, however, to the great Koch to place our understanding of tuberculosis on a much more solid foundation by his wonderful bacteriological efforts.

In considering incipient phthisis, the most important thought that occurs to my mind is that we recognize the disease before it has passed from its incipency, and also, that the study of the prophylactic side of this question is of the greatest concern. If we can impress at all the importance of these two parts of this great question our time will not have been wasted.

Etiological Factors and Causes. The fact has long since been made evident, especially by Koch and many others, that the specific cause of tuberculosis is the tubercle bacilli. There are, however, many things that help pave the way, that help to offer an invitation for the tubercle bacilli to take up their abode in susceptible lung tissue. There seems to be a peculiar susceptibility on the part of many individuals to tubercular infection, why this is so is rather difficult to explain at times, for direct heredity is not admitted only by some few, but we do know that a lowered general vitality may be handed down, the probabilities are that a general lowered resistance on the part of the patient would offer the best explanation.

The anatomical makeup can be mentioned as another predisposing reason, by this we mean chest contour, etc., thoughtlessness as regards full and free breathing, especially in those that may be predisposed otherwise, manner and mode of life, environment may be quite an important factor, habits, occupation and lack of education may all act as favorable factors under certain conditions. Diseases, especially bronchitis, pneumonia, measles, pleurisy and influenza are all important as causes at times, preparing the way for bacterial invasion by the almost ever present tubercle bacilli, foods and especially meats, can be the cause often, more so in the past than at present, milk very likely has been the means of infection in a large per cent. of instances, but at present the dairying is controlled rather carefully by municipal and state authorities, thereby making the likelihood of getting tubercular infected milk much less than formerly.

Emphasis, however, should be made of the fact that all who live with, or have the care of, open cases of tuberculosis, must be in great danger of contracting the disease; this really is nothing other than environment.

Symptomatology: The symptoms found in the incipient type are more or less indefinite, however, these indefinite symptoms should and must be considered very carefully for our patients' welfare. In a large number of instances there will be found a tired or weak feeling, especially following slight exertion, a

*Read before the Greenup County Medical Society.

peculiar pallor of face, languor, anorexia and some fever. The fever is one of the most important findings, to get a correct meaning the temperature should be taken every two hours over a considerable period of time, not losing sight of the fact that we have at times even an apyrexia, which usually occurs in the early morning hours. A continued pyrexia found to exist at more or less regular times with other suspicious symptoms should be considered and almost positive finding. The mode of onset and manner of beginning is so different in different cases, that the physician should always be keenly alert and on the lookout in all suspicious cases.

Hemoptysis is an initial symptom in quite a large number of the early cases, any case in which bleeding occurs that cannot be accounted for to the complete satisfaction of the physician should be looked upon as a beginning tuberculosis. In quite a few patients most all symptoms are referred to the stomach, possibly from having no appetite as is so often found, much care should be exercised in this class to avoid a mistaken diagnosis. Cough, usually slight in early cases, is present in practically all instances of phthisis pulmonalis; it may be so slight as to even escape notice on the part of the patient or physician, and these cases may go on to considerable lung involvement with no appreciable cough. The amount of sputum expectorated is usually very little, but the patient can often be made to recall having had to cough and expectorate at least slightly on arising. In still other instances the beginning may be with a laryngitis. A great many times the condition can be traced back to the history of a neglected "cold" or an attack of bronchitis that was not properly appreciated, this unfortunately is found to be all too true, necessitating that we ever be on our guard in all suspicious cases.

Physical Findings: "The physical signs in the initial period are very indefinite, nothing is perfectly plain at this time, our search should then be more diligent for this very reason. Inspection will often disclose a long flat shaped chest, a lack of expansion might be noted, an unusual depression above or below the clavicle will be quite frequently observed, a variation from the normal resonance or rather an impaired resonance is expected to be found. tactile fremitus might possibly be increased over that part of lung tissue involved. this is quite true if the disease has lasted for some time. Auscultation will usually reveal some very fine moist rales, found at or near the close of inspiration, the breath sounds are most often very much enfeebled or weakened. The whispered voice sounds are increased in intensity, and,

of course, all these signs and symptoms are soon to be found much increased, but that takes us away from our subject of the incipient type into the advanced stage of phthisis.

Diagnosis: That an early diagnosis in this disease is desirable cannot be contradicted, that it is not easy by any means to make a correct diagnosis in early incipient cases is also very true, but for the sufferer to secure most benefit an early diagnosis must be made, hence we should make every effort to arrive at the earliest possible diagnosis. We should ever keep in mind the word "early" when considering the question of diagnosis in initial tuberculosis. Given two or more suspicious symptoms; say the presence of a little pyrexia and even a slight loss of weight that cannot be accounted for readily. Why not call it incipient tuberculosis until otherwise disproved? It would be far better to make an error in this way that to have the case pass on unrecognized into an advanced stage. In all suspected cases, a thorough, painstaking and repeated examination of the chest should be made, going over every part of lung tissue carefully, the same process to be repeated at a number of different times. Repeated examinations of the sputum should be made for the presence of tubercle bacilli, however our diagnosis should be made if at all possible, before the bacilli have made their presence known in the sputum. Mention might be made here of the use of tuberculin as a diagnostic agent, most likely some form of the skin test would best serve the purpose for general uses, with a little experience one can readily interpret the findings, the forearm offers a convenient place for testing, cleanse thoroughly, do not use strong antiseptics, scarify at two places some little distance apart sufficient to cause serum formation, inoculate at one point by applying about one drop of tuberculin. old. The reaction may be expected within from twelve to thirty-six hours. I have merely mentioned this plan, a number of others could be used equally as well.

Prophylaxis: The prevention of tuberculosis is one of the greatest problems confronting the medical profession to-day, and also that every layman is or should be vitally concerned in this great question. The incipient case is not so dangerous during the real initial period, but when we recall that so few of the incipient cases remain so very long, and how dangerous open tuberculosis is to individual and public health in general, enough emphasis can scarcely be placed on the importance of prophylaxis as applied to this disease. It is only within recent years that an effective and organized effort has been made in the prevention of phthisis pul-

monalis. The question has been agitated to the extent that we now find thoroughly organized associations, clubs and anti-tubercular societies in most all parts of the civilized world that are making a determined fight against "the great white plague, it goes without saying that it is the duty of every physician to be in this fight, in fact it is the duty of the physicians to be at the very head of these moves in order that they may help direct this important crusade. In the rearing of children parents should use every sensible means in preventing or safeguarding the child against tubercular infection, this necessarily, presupposes the parent to be familiar with the prophylaxis of infection, which, however, is by no means true at the present time, this recalls us to state that it would be best by far to have every case of tuberculosis isolated. An especial care should be exercised over children during school life, furthermore, I believe every public school teacher should be made familiar with the fundamentals of bacteriology, at least to the extent that he could fully understand the infectiousness of this or other diseases, he could then so instruct his pupils and the resulting good could scarcely be estimated. If such tubercular patient was properly advised as to the protection of others, and would faithfully comply, one of the very strongest prophylactic measures will have been accomplished. Often the question of marriage comes to our notice in which one or both of the contracting parties are tubercular, now in so far as the theory of the matter is concerned, we have a pretty clear idea, but making it a practical proposition is another thing altogether. All cases of open tuberculosis should of course be advised strongly against marriage for many reasons, among others there would be the question of progeny, but I am not going further here, else we get into the matter of "eugenics" a question I do not care to take up in detail to-day. The employees in shops, factories, etc., should be made familiar with the many ways in which infection might come about, an excellent plan it seems, would be for them to have proper instruction along this line at stated meetings. All places used by the public should be cleaned often, made and kept sanitary if at all possible. Let us continue to live in hope that there will yet be produced a perfected product against tubercular invasion, and let us hope too, that Kentucky will soon make provision for an "all-time" health officer for each county, something that failed to receive the proper attention at the last meeting of the General Assembly.

Treatment: There is no fixed plan to follow that can be applied to all tubercular

eases alike, there is probably no disease requiring so much fact on the part of the physician as this one does, true, no doubt as a result of the long continued indisposition. It is very essential for the physician and patient to have a complete mutual understanding. So many factors come up for consideration in planning any line of management or treatment in these cases; among others would be: The family connections, the financial standing of the patient, the social conditions, the place of treatment, etc., as we understand at the present there is no known specific in the treatment of tuberculosis, there are however, a few things on which the consensus of opinion is pretty well united, viz: a life in the open air, a suitable plan of rest and exercise and a generous, well-balanced diet. I fully believe that every initial case of phthisis should have treatment in a sanatorium. More than that, every case that is physically able should have a period of sanatorium experience, not so much for the benefit of the advanced consumptive, but for the gain to prophylaxis by way of the instruction given the patient while a resident at the sanatoria. The selection of a suitable climate will not be taken up by me here, I prefer to leave that open for discussion. If our patients cannot take advantage of sanatoria treatment they should at least have the sanatorium plan of treatment. Practically all of incipient patients show the presence of fever, every patient manifesting pyrexia should have more or less absolute rest until the temperature returns to the normal point, but very little exercise should be taken for several days after the return to normal, then the plan of "rest and exercise" should be instituted. Space and time forbid of a more detailed account.

Drugs have a very minor place in the treatment of early cases of tuberculosis. Not that we want to dispense entirely with their use in these patients, for many times they can be used to advantage, but we no longer depend on medicines alone to cure patients suffering from tubercular infection. Considerable attention has been given the use of tuberculin, especially in treatment of early involved cases likely when a perfected product along this same line is produced and the indications for administration more fully appreciated, the results may be far better than those gotten from tuberculin at present. Many things have purposely been omitted in composing this article, morbid anatomy, prognosis, etc., have been left out in order to give more time to those that seemed to be of more practical value.

However, I hope you will discuss every phase of incipient tuberculosis most vigorously.

THE FORUM

To the Editor:—

If every county society had officers who would take a personal interest in the welfare of their societies, it would soon be found that they would become so vitalized that if a member who had been an absentee for some time, should happen to attend a meeting, he would scarcely know where he was. The office of secretary is of course the most important, and if he is enthusiastic and not discouraged by frequent failures, but keeps everlastingly at it, injecting a little spice and variety into his notices, his labor will be rewarded in the end by a full measure of success. I wish that more of our county societies had such an one.

The Carter County Society is fortunate in that respect as is shown by one of his recent notices which follows:

J. W. KINCAID,

Councilor Ninth District.

Grayson, Ky., April 9, 1914.—Dear Doctor: I wish to inform you that the next regular session of the Carter County Medical Society will be on the 14th inst. Please be here and especially those who have topics assigned them. We are planning an "Out of Door" session to be held at the Caves some time this summer. We can invite Dr. Kinnaid and others from Ashland and Catlettsburg out, have a day off and a jolly good time.

If Dr. H. T. Sparks will furnish us with a paper on the subject, "Physician and Surgeon a Misnomer," and Dr. Harvey Fultz on "The Feasibility of a County Hospital," and Dr. D. B. Wilcox on "Mr. Tapeworm Captured," humorous. We will have a meeting next time worth attending.

Dr. Wilcox is the only known doctor, to me, in the county that has been able to capture a real live tape worm, and if he will only tell it in his own language, it will be sufficiently humorous. Dr. Burton can give us a few pointers on catching the imitation worm, as he successfully routed a covey of Quaker fakirs, and thereby became the hero of the hour, rendering the county an inestimable service. He deserves a Carnegie medal.

The members of the society will be pleased to know that all the doctors of the county, belong to the county and State societies except five and one of them. Dr. Logan, of Kilgore, says he and his dues will be here next Tuesday.

We would be glad if those to whom topics are assigned will send in their paper, if they find they cannot be here.

Fraternally yours,

G. B. O'ROARK, Secretary.

TWO REPLIES TO DR. RAVITCH'S ARTICLE ON "SCLERODERMA," FROM PIKE COUNTY.

PIKEVILLE IS TRYING TO GET ON THE MAP.

Some time ago there was a letter printed in the JOURNAL, under the above caption, written by one of our medical friends from the city of Louisville, to-wit: Dr. Ravitch. He says, "Pikeville is trying to get on the map" because there happens to be a case of "scleroderma" in the town, and the patient, a child, who was in no wise responsible for having the "disease" and not even responsible for its being here. The doctor refers to this as being a "common disease", which is not true as this disease is not common in Kentucky, neither is it common in any of the adjoining states. He makes a few rash assertions then copies the balance of his article from the authorities which have given a good description of the disease in question, most doctors prefer the text-book "reading" to that of a "medical journal" article if it is to be copied as the one referred to has been done. The only article worth reading is one containing the facts and what the doctor has learned by actual experience at the bed-side, it is not worth while to write an article and copy all except a few unfounded assertions. There are something like (4000) physicians in Kentucky, very few of which ever saw a case of "scleroderma." I venture the assertion that 90 per cent. of the physicians of Kentucky including the City of Louisville, never saw a case of the asserted "common disease," scleroderma.

The purpose of this letter is that I want the medical profession to think, and think, and think, and know, that all the "fools" in the medical profession don't live at Pikeville, and in the mountains of Kentucky, either, what do you say, members of the profession? We of the mountains have always heard the expression used "quack doctors," and we believe this applies to the "fellow" who was trying to practice medicine without being prepared, or qualified to practice medicine, in any of its various branches. The above applies to the Louisville "man" only, if his practice corresponds to his writings. If he is not a "quack" the best proof to the profession would be for him in his next article to eliminate the "text-book" part of his article and tell us what he really knows, and what he has done himself while he has been in the medical profession. I want to say further if a little "sense" is good for the country doctor a little more would be good for a "specialist" living in the metropolis of a great State,

like we have in Kentucky, as the specialist should be one in whom other people living in rural districts could depend on for advice in his line.

In conclusion I wish to say for the benefit of the "Louisville Specialist" that Pikeville now has a permanent place on the map, and that it is located on the banks of the "Big Sandy River," and that people even live beyond Pikeville, many of which places the "specialist" would do well to visit, that he may become a "wiser and better man."

With all due respects for the specialist, I am,

Yours truly,

H. H. Stallard, M. D.

Pikeville, Ky.

May 6th, 1914.

In reply to an article of April 1st, written by Dr. Ravitch will say that it is a great pleasure to have a little article published in so great a journal as the official organ of the Kentucky State Medical Association, but I certainly had a different feeling when I read the article "What We Know About Scleroderma." Dr. Ravitch makes the assertion when beginning that every practitioner runs across cases of scleroderma, I will not answer that statement as every member of the Kentucky Medical Association knows that is false.

I spent four years in the Medical Department of the University of Louisville, and I observed a few things but never saw a case of scleroderma during the whole time.

The Pikeville case of scleroderma was on exhibition at the meeting of the Southern Medical Association at Lexington and some of the greatest dermatologists of the South failed to recognize it. The faculty of the University of Louisville, and I'm proud to be numbered among her alumni for she is the greatest medical institution in America, recommended to us that there was no better text-book, for the general practitioner than Stelwagon.

On page 553 under Etiology, Stelwagon says, both types of scleroderma are infrequent, the diffuse type is rare, the circumscribed variety much less so.

Dr. Ravitch would have us think that the Pikeville case, being a child, is possibly a case of sclerema neonatorum but this child is 8 years old and only developed this disease one year ago, that I think he will find that the word neonatorum wouldn't apply, and also (page 559) Stelwagon says sclerema neonatorum is extremely rare.

Whether Pikeville is trying hard to get on the map I am not able to answer, but she has the location, she has the fertile soil, and Pike county has any other county "skinned a

bloek" when it comes to mineral wealth, and if you don't think her women are pretty ask our worthy State Registrar, W. L. Heizer. He knows.

Now, just a word in closing, I can't believe that Dr. Ravitch ever saw or could even recognize a case of scleroderma and for his benefit, we will have the little child at Pikeville, when the Pike County Medical Association meets on the first Monday night in June.

P. C. SANDERS.

NEWS ITEMS AND COMMENTS

The Boyd County Health League was organized about three months ago, and on April 14th opened in Ashland a free dispensary for the treatment of tuberculosis patients. They have employed an efficient visiting nurse, in the person of Miss Bogard, and the medical service is being attended to by assignment of its members by the Boyd County Medical Society.

Dr. A. P. Banfield of Catlettsburg, was in New York, doing some post-graduate work in his specialty, eye, ear, nose and throat. He returned about May 10th.

Dr. G. W. Moore, of Ashland, has recently accompanied one of his patients to Rochester, Minnesota, to consult with Dr. Mayo with reference to an operation for goitre.

THE WALKER HOSPITAL.

Our readers will note that the Evansville Sanitarium has changed its name to the Walker Hospital. We are glad to call attention to this change as it shows a recognition of the worth of one of the best men and most skillful surgeons in the country. Kentucky is to be congratulated that it is near enough to have access to Dr. Walker's work.

Alimentary Galactosuria.—Maliwa tabulates the findings in twelve cases of liver disease, in ten of orthostatic albuminuria, and twenty-one other patients, after ingestion of 40 gm. galactose, fasting. The data demonstrates that intolerance for galactose is by no means an unequivocal symptom of insufficiency of the liver. The kidneys often have something to do with it. When the latter is the case, the galactose elimination begins abruptly and in large amounts, dropping off equally abruptly. With insufficiency of the liver, the curve of elimination is generally more protracted.

COUNTY SOCIETY REPORTS

Adair—The Adair County Medical Society came out from its winter quarters on May 14th, 1914, invigorated by its long winter nap, and met in Dr. Cartwright's office with the following members present: S. P. Miller, President; U. L. Taylor, Secretary; W. R. Grissom, E. T. Sallee, W. F. Cartwright, C. M. Russell, Garland Grissom, N. M. Hancock and B. J. Bolin. We were encouraged by two distinguished visiting brethren R. H. McChord, of Lebanon, and J. S. Lock, of Barboursville. The meeting was called to order at 2 P. M., and there being no special business outside the program, it was called. The first on the program was a paper by **S. P. Miller** on "Diphtheria." It was a very exhaustive paper, well received, well prepared, and very much appreciated, and discussed by all the members present, and the two visiting members. The next paper was by **R. C. McChord** on the "so-called non-operable cases of cancer of the cervix." It was a splendid paper, and well illustrated. It was freely discussed, and all the members were much pleased at the doctor's fine success that he reported from his manner of treating this terrible disease.

At night there was a public meeting at the court house, with a full program, and all who were on it present. But in view of the fact of the importance of the subject assigned to Dr. Lock, all the others gave way to him, and he occupied the entire evening on "Preventive medicine" and gave one of the best lectures that has ever been heard in Columbia. There was a good audience but not half what it ought to have been. But every one present was pleased and benefitted. He gave much of his own experience in the Kentucky Mountains, illustrated by stereopticon views. It was unfortunate that the fiscal court could not be present, and had he lecture, they would have been more liberal to the health work than the courts we have heretofore had. It certainly did great good to the people of Columbia, and they will be a long time forgetting it.

U. L. TAYLOR, Secretary.

Carter—The Carter County Medical Society met in regular session at the office of Dr. G. B. O'Roark in Grayson, May 11, 1914, with Dr. J. L. Lyons in the chair. After drafting resolutions of respect and condolence relative to the death of our honored friend and fellow doctor, D. B. Wilcox, who departed this life on April 25, the society transacted its regular business. Talks were made by the members on various topics. Typhoid, and its prevention, was discussed at length by Dr. J. W. Kincaid, of Catlettsburg, who was kind enough to honor us with his presence. He also gave an interesting talk on alley cleaning and the disposition of animal car-

cases which we think it would be well to publish in pamphlet form and distribute widely over the state.

But the paper of the day was the one he read on "A Plea for Greater Accuracy in Diagnosis." We have never heard anything better or more appropriate. It was so highly appreciated that the society, on motion of Dr. J. W. Strother, tendered to Dr. Kincaid a vote of thanks and requested him to forward his paper to the Journal for Publication.

No further business appearing, the society adjourned to meet at Stamper Hotel, June 16. Every one went away feeling richly rewarded for having taken a day off.

Resolutions.

Whereas, God in His infinite wisdom has called from among us our beloved confrere, D. B. Wilcox who for several years has been a busy, successful practitioner, Therefore, be it

Resolved That in the death of our esteemed associate the Carter County Medical Society has lost one of its most loyal and useful members, the community one of its most progressive and valuable citizens and the bereaved family a devoted husband and an affectionate and indulgent father.

Resolved, That the society tender to his wife and children our deepest sympathy and for consolation, commend them to Him who doeth all things well.

Resolved, That we manifest the esteem in which we held our departed fellow practitioner by presenting a copy of these resolutions to the bereaved family and sending a copy to the local paper and the Journal of the Kentucky State Medical Association for publication.

W. A. HORTON,
J. W. STROTHER,
J. L. LYON,

Committee.

G. B. O'ROARK, Secretary.

Cumberland Valley—The Cumberland Valley Medical Society met at the Majestic Opera House, Corbin, on Thursday, March 26, 1914, with about 500 members of the laity present at the afternoon session and the following members of the society: W. F. Bogness, Louisville; W. L. Heizer, Bowling Green; A. D. Wilmoth, Louisville; T. J. Ballard, J. F. Wilder, J. H. Parker, B. J. Edwards, G. G. Edwards, W. C. Bryant, J. F. Bryant, W. M. Cox, of Corbin; H. S. Pitman, East Bernstadt; J. W. Parker, Grays; O. P. Nuckols and J. G. Foley, Pineville; C. A. and E. S. Moss, L. O. Smith, Williamsburg; J. S. Lock, Barboursville; P. E. Bryant, J. B. Mason, H. V. Pennington, and G. S. Brœck, of London; P. E. Giannini, Dorothy; L. M. Scott, J. L. Heferman, and Jim Richmond, of Jellico, Tenn.; F. R. Burton, Watlick; J. S. Owsley, Lilly; L. S.

Siler, Woodbine; M. Pennington, Bertha; George Corum, Wilton

The program was opened by a speech of welcome by B. J. Edwards of Corbin, and was followed by a response by O. P. Nuckols.

W. F. Boggess then gave an excellent talk on "The Relationship of the Physician to the Public," showing us how to eliminate worry and were a perpetual smile. Discussion by H. V. Pennington and others.

And though we were very much disappointed that Dr. McCormack could not be with us, we were more than pleased with W. L. Heizer, whom he sent to represent him. Dr. Heizer gave us a very instructive talk on some of the needs of the times, especially in regard to the present system of education in our schools which teaches the student practically nothing of the laws of health and the need of the medical inspection of schools and an all-time health officer, and was enthusiastically responded to by the laity when he requested that those who would be willing to pay ten cents a head for an all the time health officer to rise to their feet. Discussion by A. D. Wilmoth, E. S. Moss and J. G. Foley.

J. H. Parker then gave us a paper on some of the finer points in "Appendicitis," which was one of the best papers of the day. Discussion by J. L. Hefferman, E. S. Moss, A. D. Wilmoth, W. F. Boggess and by J. H. Parker in closing.

At this time the afternoon session was adjourned to the banquet hall at the Wilbur Hotel where the Corbin Medical Society entertained the visiting doctors with the usual Kentucky hospitality. J. H. Parker acted as toastmaster, then, after several "new ones" we got down to business again and saw the unseen with J. B. Mason in his paper, "Some Uses of the X-ray as a Diagnostic Agent," and the excellent pictures accompanying it. Discussion by L. M. Scott and T. J. Ballard.

D. M. Pennington, in the next paper, established his reputation as an artist in word painting in his paper, "The Country Practitioner and Cut Fees," his paper was heartily enjoyed by every one. Discussion by B. J. Edwards, C. A. Moss, L. S. Siler and J. W. Parker.

A. D. Wilmoth read the next paper, "Diagnosis of Cancer of Breast." It was an unusually good one, and contained a wealth of information and instruction mined from the storehouse of a wide experience and close observation. Discussion by W. M. Cox and others.

Those present decided to make this a permanent organization, with June 4, 1914, Corbin as the time and place of next meeting. The following officers were elected:

President, J. H. Parker, Corbin, First Vice President, J. G. Foley, Pineville; Second Vice-President, H. S. Pitman, East Bardstadt; Secretary and Treasurer, C. A. Moss, Williamsburg.
C. A. MOSS, Secretary.

Henderson—The Henderson County Medical Society met in regular session at the rooms of the Commercial Club and a good attendance was on hand. Dr. Poole presided over the meeting.

J. W. Cooper read an interesting paper on "Intestinal Indigestion." This timely subject was handled well by the reader. The most prominent feature was "Milk supply as related to infant feeding" and "the excessive infant mortality." The paper elicited a free and full discussion by the following members: Drs. Dixon, Royster, Letcher, Galloway, Poole, Ligon, Forwood, Floyd, Hancock, Neary. Dr. Cooper in closing said he hoped the health officer would exert more immediate supervision in the matter of milk supply. The meeting then adjourned to re-assemble on May 25th, 1914.

B. J. NEARY, Secretary.

Graves—The Graves County Medical Society met at H. A. Shelby's office Tuesday, March 31st, with a very large attendance of the physicians of the county.

The meeting was called to order by President Jno. L. Dismukes. The minutes of the last meeting were read, approved and adopted.

G. T. Fuller read a paper on "Lobar Pneumonia." This was a most excellent paper and was received with much interest by the doctors. It was discussed by Drs. Hunt, W. E. Merritt, Shelby, Puryear and Dismukes.

H. A. Shelby read a paper on "Veratrum." The doctor handled his subject very thoroughly and brought out some points that will be worth while to remember. General discussion of this subject by the society.

Mrs. Cora Beck, Registrar, read a paper on "Vital Statistics." This was a very interesting paper. The essayist brought out some very important thoughts, urging the doctors of the county to co-operate with the registrars and to make their reports of death and births promptly and with the greatest care as to the cause of death. Mrs. Beck bears the distinction of having the best report of any registrar in the State, and she said this was due to co-operation of the physicians in her district.

Next came the election of officers for the year 1914, as follows:

J. H. Shelton, President; M. W. Hurt, Vice President; G. T. Fuller, Treasurer; H. H. Hunt, Secretary.

Committee on Credentials, Drs. G. T. Fuller, chairman, J. C. Puryear and W. J. Shelton.

Delegates to Convention—Drs. J. L. Dismukes; M. W. Hurt, alternate.

Upon invitation of Dr. W. E. Merritt, the society is to meet at Fancy Farm, Thursday, May 28, 1914.

The society extends to Hale & Gilliam, the popular druggists, their sincere thanks of appreciation for their kindness while in session.

There being no further business the society then adjourned.

H. H. HUNT, Secretary.

Greenup—The Greenup County Medical Society was held at Russell, on May 7, 1914.

A. J. Bryson, of Fullerton, read a paper on "Incipient Pulmonary Tuberculosis."

E. E. Fitch, of Russell, read a paper on "Tuberculosis of the Hip Joint."

A. P. HUNT, Secretary.

Greenup—The Greenup County Medical Society was held at the Davis Hotel, at Fullerton, on April 2, 1914, at 3:00 p. m.

Members present, H. T. Morris, A. S. Brady, C. E. Vidt, E. R. Fitch, M. W. Meadows, A. J. Bryson, W. E. Nichols and A. P. Hunt.

H. T. Morris read an excellent paper on the "Symptoms, Diagnosis and Medical Treatment of Pleurisy."

A. P. Hunt read a very interesting paper on the "Surgical Treatment of Pleurisy."

The discussion was opened by A. S. Brady, followed by C. E. Vidt, A. J. Bryson, W. E. Nichols, E. R. Fitch, M. W. Meadows, and closed by H. T. Morris and A. P. Hunt.

"How To Make a Better Society," was discussed by all members present.

After the meeting was over the members were served with luncheon at the hotel.

A. P. HUNT, Secretary.

Harrison—The Harrison County Medical Society met in regular session May 4, in the office of Drs. Givens, Wells & Moore. At this meeting twenty members were present. The minutes of the last meeting were read and approved.

N. W. Moore, reported a case of pneumonia treated with hypodermic injections of camphor and oil with apparent relief from toxemia and reduction of temperature, after two or three doses had been administered.

W. H. Carr reported two cases of difficult labor that were delivered with forceps. These cases were discussed by Drs. Rees, Wells, Carr and Moore.

W. H. Carr read a paper on "Prevention and Control of Contagious Diseases in Children."

L. S. Givens read a paper on "Influence of the Olfactories on Digestion."

These papers elicited a lively discussion in which Drs. Wells, Martin, Rees, Wood, Smiser, Moore and Carr participated.

The meeting adjourned to enjoy an elegant smoker-lunch, the guests of Dr. Givens. This feature was very much enjoyed. Dr. Givens is a past master in entertaining and every one departed with a warm spot in his heart for the genial doctor.

W. B. MOORE, Secretary.

Muldraugh Hill—Meeting called to order by President Pope in the City Hall at 10:20 a. m., about twenty members being present. Reading of the minutes being dispensed with, the Society heard the report of the Committee on Constitution and Geographical change. After the Committee had read the Constitution as a whole it was adopted, article by article, and finally as a whole. It is understood that this Constitution binds the Society and takes precedence over all former Constitutions and By-Laws. The Committee further recommended that as the doctors of Meade and Breckinridge took no interest in the Society, and as they had no way of conveniently attending the meetings, that these counties be dropped from the roster and the Counties of Warren and Barren added. Upon a vote this recommendation was adopted. The Secretary was instructed to notify the doctors of these two counties of this fact.

A. O. Pfingst reported an interesting case of a very large naso-pharyngeal polyp that extended down into the pharynx. Discussed by Drs. Hall and Hester, and in closing by Dr. Pfingst.

A. D. Willmoth reported a case of a large infected kidney containing a large stone.

G. C. Hall presented pictures of two cases of unilateral trachoma, one a case of a boy eleven years of age with well developed granulations, the other a young lady whose disease had existed over six years. Discussed by Dr. Pfingst.

C. W. Hibbitt reported a case of tubal pregnancy seen in consultation, in which operation was done before rupture. Discussed by A. D. Willmoth, who made point that when hemorrhage occurs patients do not usually bleed to death as was once feared.

H. N. Leavell spoke of ectopic gestation first on one side, then on the other. Temperature due to absorption of fibrin ferment or fibrinogen.

J. H. Peak thought tube had ruptured, but that it had been held intact by folds of broad ligament. Pain due to distention. Thought complete absorption could occur and complete restitution take place. Care should be taken in making an examination as rough handling may cause rupture. Patients may bleed to death.

G. W. Hibbitt in closing took issue with Dr. Peak, first that this had ruptured and been inclosed in broad ligament. Thought that also tubes are capable of large distention. Thought cases of severe hemorrhage were due to rupture of tube.

J. H. Hester read a case report of Steel in eyeball and method of removal. Discussed by Dr. Hall, who thought Dr. Hester's method similar to that reported by Dr. Jackson, of Denver. In doubtful cases in poor people with large families enucleation was preferable, while in patients of considerable means who can afford to take the time, conservative treatment should be adopted.

A. O. Pfingst thought that outlook after giant

magnet operation was gloomy, and reported cases of late degeneration. Thought eyes with injuries of ciliary body should be enucleated.

Curran Pope explained the methods of localization in cases of foreign body in the orbit.

Adjournment at 12 N. for dinner.

Society re-assembled at 1:30 P. M. for scientific work.

A. D. Willmoth read an essay on the diagnosis and early removal of cancer of the breast demonstrated with lantern slides in natural colors.

Discussion opened by Dr. Peak. Must remember that all tumors of breast must be dealt with as if they were malignant. Must make a very wide incision to avoid recurrence and without regard to closure of wound. One should pay particular attention to the removal of all fascia of muscles. Skin grafting in slow healing wounds. Begin at axilla and work downward and inward. Advantages in control of hemorrhage and preventing metastasis. One should never have any instruments, hands, or any material that has touched the growth touch the wound surface.

H. N. Leavell acknowledged the compliments paid, by the essayist and previous speaker, to his brother-in-law, Dr. Rodman. He detailed the incision as now practiced by him. Made a practically bloodless field. Condemned the Jackson incision.

With the mortality of this disease so high and the results of delay so disastrous one should act promptly and carefully; clean out all tissue at all suspicious. Make the diagnosis afterward if necessary. If case is malignant you are on safe side. If innocent your operation has done no harm.

C. W. Hibbitt asked if there were any reason why any tumor of breast should be left. We should be very careful in cleaning out axilla.

Curran Pope spoke of the efficacy of the massive high frequency current in preventing recurrence or treating the wound to promote closure. Spoke of the high frequency current in removal of papillomata and similar growths in the closed cavities. Spoke of the Abderhalden sero diagnosis of malignancy. Has had good results with applications of the X-ray with a very hard high tube. Thinks it does a great deal of good after operations not before.

A. D. Willmoth in closing spoke of the transplantation of cancer cells to other parts of the body of the patient if the same knife were used that made the primary decision. Make a complete removal at the one operation. It is a mistake to do a secondary operation in but a few days afterward. Pathologist should be on hand to make frozen sections and give an immediate report. Must always clean out axillary space. Thought that it was an advantage to leave pectoral muscles. Objected to by Drs. Leavell and Peak who asked of what good it would do to remove part of the fascia as metastasis occurred

through that channel. Spoke of Dr. Bambridge's work with high frequency currents and fulguration. Also the implantation of radium gelatin in the wound. Injection of aseptic fluid in cases of cancer had done very little good.

Charles Hibbitt read a paper on the Complications of Pelvic Operations.

J. H. Peak in opening the discussion thought vomiting much less frequent than formerly. Frequently neurotic or psychic. Doesn't believe in fasting patients and gives water to within five or six hours after operation. Believes in washing out stomach frequently. Has never had hemorrhage following abdominal operations. Gas pains are very troublesome, thought fasting made it worse. Advocated early use of rectal tube. Had seen acute suppression of urine following even simple operation. Thought it due to the ether. Thought it practically impossible to prevent infection if patient had to be catheterized often. Did not like boric acid in cystitis.

A. D. Willmoth spoke of the vomiting following operation due to acidosis and one should fill patients' stomach with weak lemonade.

In post-operative peritonitis mop out with 2 1-2 per cent. solution alcoholic of Iodine and put patient in Murphy position.

Curran Pope called attention to the fact that whiskey is not a stimulant, but is toxic, depressant, and anaesthetic.

C. W. Hibbitt in closing still maintained that whiskey had a place as a stimulant; thanked the members for their discussion.

E. F. Horine read an essay on the Duties of the Anaesthetist.

H. N. Leavell opening the discussion spoke of the change in medical practice since he first graduated and at the present day when there is the specialist in anaesthesia

A. D. Willmoth spoke of the importance of this subject and the importance of selecting a competent man to give the anaesthetic and let him select his drug. Spoke of the importance of the quiet personality of the anaesthetist and careful watchfulness of the anaesthetist of the blood pressure.

J. H. Peak thought the subject of extreme importance; spoke of the decorum to be maintained in the operation. Avoid loud talking, joking, etc., about the operation.

G. C. Hall complimented the paper of Dr. Horine and bore testimony to his skill as an anaesthetist as Dr. Hall had taken an anaesthetic administered by him the previous summer. It was quiet and easy, without a single disagreeable symptom or remembrance such as some people complain of. Neither did the ether have any disagreeable after effect when he again got back to work and began operating. Thought these happy results largely due to Dr. Horine's skill and training in handling the anaesthetic.

A. O. Pfingst told some personal experiences of

anaesthesia. Thought it could be made very disagreeable by an untrained man. Though easy manners, quiet decorum was great importance to the patient.

H. N. Leavell again spoke, explaining that in rural districts one man should be selected and trained to give anaesthetics.

Curran Pope interpreted the psychology of the patient's mind during the period of anaesthesia. Anaesthetic room should have quiet, appealing furnishings. There should be no crowd and no talk. Anaesthetist should have a quiet, appealing voice while every effort should be made to lull the patient into a sense of security, avoiding all sight of instruments, etc.

E. F. Horine in closing stated that in answer to Dr. Pfingst that while chemically the purified products should be the same he had found that it seemed to take less of the Squibb products than of other makes.

In small towns one man should be trained as an anaesthetist. Hearing is last sense to be abolished but is so in complete surgical anaesthesia.

At the close of the discussion the names of Drs. J. H. Peak and E. F. Horine were regularly presented to the Society and unanimously elected members.

There being no further business before the society adjourned to meet again in August

G. C. HALL, Secretary.

CONSTITUTION OF THE MULDRAUGH HILL MEDICAL SOCIETY.

Article 1.—Name.

The name of this Society shall be the "Muldraugh Hill Medical Society."

Article 11.

The object of the Society shall be, first, to promote good will among its members.

Second, to stimulate and maintain an active interest in the science of medicine and surgery and to encourage among its members careful and conscientious work along those lines.

Article III.—Officers and Their Duties.

Section 1. The officers of the Society shall consist of a President, one Vice-President for each county composing the Society, and a Secretary-Treasurer, elected for one year or until their successors qualify.

Sec. 2. It shall be the duty of the President to preside at all meetings of the Society; to call special meetings at any time he may deem proper or at the written request of seven members of the Society.

Sec. 3. It shall be the duty of the Vice-Presidents, one to preside in the absence of the President; this Vice-President to be selected in alphabetical order of counties; to keep alive an active interest in the Society, particularly in his own county, and to endeavor to enlist the sym-

pathy and active support of all reputable physicians who come within his sphere of influence. He shall co-operate with the Secretary in arranging for program for the meetings by personally seeing members in the county and endeavoring to get them to prepare papers or case reports.

Sec. 4. It shall be the duty of the Secretary-Treasurer to keep all records of the Society; to preserve an accurate copy of the minutes and transactions and see that same are published regularly in the Kentucky State Medical Journal.

He shall keep an accurate account of moneys of the Society received by him as dues or in payment of advertisements in the program, such money to be used by him in defraying the legitimate expenses of the Society.

He shall each year at the annual meeting submit a written report of the financial affairs of the Society which shall be submitted to the Executive Committee for auditing and approval.

Article IV.

Section 1. There shall be an Executive Committee consisting of the President of the Society and two other members elected by the Society.

Sec. 2. It shall be the duty of the Executive Committee to exercise general supervision over all the affairs of the Society: to lay before the entire membership from time to time such matters as in their judgment require its action; to look after the interest of the Society and exert themselves for its benefit and advancement; to audit the accounts of the Secretary-Treasurer following his annual report.

Sec. 3. Vacancies in the Executive Committee shall be elected by the Society at its next regular meeting.

Sec. 4. One member of the Executive Committee shall be elected for three years, and one for two years.

Article V.

Section 1. The meetings of the Society shall be held on the second Thursday in April, August, and December.

Sec. 2. The meeting place of the Society shall be Elizabethtown provided, however, that upon invitation to meet in another town the meeting for that invitation may be changed by a two-thirds vote of the members present.

Article VI.

Section 1. The annual meeting of the Society shall be in December at which time an election of officers shall be held and the annual reports of the former officers presented.

Sec. 2. Election of officers shall be held in the following order. President, Secretary-Treasurer, member of the Executive Committee.

Sec. 3. Election shall be by ballot except by unanimous consent. A majority of all votes cast is necessary for election. In the event that more than two men are nominated for an office after

first ballot low man will be dropped.

Sec. 4. Nominations for office are made orally.

Article VII.—Membership.

Section 1. Applications for membership. Any member may propose the name of a reputable physician for membership. It must be submitted in writing and seconded by another member. The name is then presented to the Society and a ballot taken. Three negative votes shall exclude a candidate.

Sec. 2. Membership in the Society shall be of two classes, active and honorary.

Sec. 3. Active membership. Any reputable physician residing in the counties of Jefferson, Bullitt, Hardin, Nelson, Larue, Grayson, Marion, Taylor, Green, Hart, Barren and Warren, may be elected an active member of the Society.

Sec. 4. Honorary members are such physicians who distinguished by prominence in the medical profession or long and faithful work in the Society the Society desires to honor by electing to that order.

Honorary members are elected by a three-fourths vote of the members present. They are entitled to all the privileges of the society except the right to hold office and are exempt from dues.

Sec. 5. Active members shall pay to the Secretary-Treasurer one dollar a year as dues in January of each year.

Article VIII.

The fiscal year of the Society extends from January 1st to December 31st.

Article IX.

Section 1. Ten members present in person at a meeting shall constitute a quorum for the transaction of business.

Sec. 2. Special meetings may be called by the President at his discretion and must be called by him when requested in writing by seven or more members.

Article X.

Amendments of this Constitution and By-Laws must be submitted in writing at a regular meeting of the Society, after which all members shall be notified in writing of the proposed amendment, which shall be brought up for consideration at the next regular meeting. A two-thirds vote of the members present shall be necessary for adoption.

Article XI.

Section 1. The following order of business shall be observed at all meetings of the Society. Call to order; reading of minutes; unfinished business; (reports of officers; reports of Committees; election of officers, at annual meeting); new business.

Sec. 2. Scientific Program. Presentation of new instruments. Presentation of clinical cases or specimens. Case reports. Essays. Miscellaneous business. Adjournment.

Sec. 3. Case reports and essays must be submitted in writing, preferably typewritten, on one side of the page only. In short, articles presented to the society must be in shape for publication. After being read they are the property of the Society.

Pendleton—The Pendleton County Medical Society met at the Day House in Falmouth, with the following members present: P. N. Blackerby, Chipman, Clark, Daugherty, Ecklar, McKenney, J. Ed Wilson Woolery.

The meeting was called to order by J. Ed Wilson president, and after roll call and a reading of the minutes of previous meeting, we proceeded to the business of the day. After transacting the routine of business, we had a report of Clinical Cases, as there was no essayists ready. We had some very good reports of clinical cases.

We then adjourned.

W. A. McKENNEY, Secretary.

BOOK REVIEWS

A Treatise on Diseases of the Skin.—For the use of advanced Students and Practitioners. By Henry W. Stelwagon, M. D., Ph. D., Professor of Dermatology, Jefferson Medical College, Philadelphia. Seventh edition, thoroughly revised. Octavo of 1250 pages, with 334 text-illustrations, and 33 full-page colored and half-tone plates. Philadelphia and London: W. B. Saunders Company, 1914. Cloth \$6.00 net; Half Morocco, \$7.50 net.

It is hardly necessary to remind the readers of this review that seven editions of Stelwagon's Diseases of the Skin speak more for its popularity and practicability than any original review. This language is clear, simple and easily understood. The symptoms are given in detail and differential diagnosis is made comparatively easy. The treatment is carefully considered and practical. It is unhesitatingly recommended to the general practitioner and specialists.

The Principles of Pathologic Histology.—By Frank B. Mallory, M. D., Associate Professor of Pathology, Harvard Medical School and Pathologist to the Boston City Hospital. Octavo of 677 pages, with 497 figures containing 683 illustrations, 124 in colors. Philadelphia and London: W. B. Saunders Company, 1914. Cloth, \$5.50 net.

Pathology has come to occupy such a prominent part in the consideration of cause of diseases and their cure that this book most likely will supply a long felt want. An accurate conception of the pathology of any tissue en masse can only be acquired by an intimate and thorough knowledge of the changes in its cellular composition. The purpose of this book is to supply such a knowledge of pathologic histology that comprehension

of lesions fully or partially developed become plain.

A Text Book of Physiology.—By Isaac Ott, A. M., M. D., Professor of Physiology in the Medico-Chirurgical College of Philadelphia, etc. Fourth edition, revised and enlarged, illustrated with forty-three half tones and other engravings, many in colors, by F. A. Davis Company, Philadelphia.

The chapters on blood circulation and metabolism have been entirely revised. Respiration and glands with an external secretion have been revised to a considerable extent. It is a standard text book on Physiology.

Materia Medica, Pharmacology, Therapeutics and Prescriptive Writing.—For Students and Practitioners. By Walter A. Bastedo, Ph. G., M. D., Associate in Pharmacology and Therapeutics at Columbia University. Octavo of 606 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1913. Cloth, \$3.50 net.

This book is a compilation of lectures delivered at Columbia University, with certain editions. Considerable stress being laid upon those things that have a direct bearing on practice. It is not too technical and is of real worth to the practitioner.

Medical Gynecology.—By S. Wyllis Bandler, M. D., Adjunct Professor of Diseases of Women, New York Post-Graduate Medical School and Hospital. Third Thoroughly Revised Edition. Octavo of 790 pages, with 150 original illustrations. Philadelphia and London: W. B. Saunders Company, 1914. Cloth, \$5.00 net; Half Morocco, \$6.50 net.

In these days of gynecological surgery the general practitioner is made to feel at times as if there was nothing left for the doctor to do and yet it is well known that the medical gynecologist has a great field of usefulness if the physician will but prepare himself for this work. This book is entirely fair to the surgeon but gives to the general practitioner his right and just due. It is certain that the general practitioner can increase his practice of diseases of women materially by making himself more familiar with this subject and this volume seems to contain about all that is needed.

Principles of Surgery.—By W. A. Bryan, A. M., M. D., Professor of Surgery and Clinical Surgery at Vanderbilt University, Nashville, Tennessee. Octavo of 677 pages with 224 original illustrations. Philadelphia and London: W. B. Saunders Company, 1913. Cloth, \$4.00 net.

This book forms a clear exposition of the subject; is well illustrated, practical, not too technical and an all-around good book.

The Practice of Pediatrics.—By Charles Gilmore Kerley, M. D., Professor of Diseases of Children, New York Polyclinic Medical School and Hospital. Octavo of 878 pages, 139 illustrations. Philadelphia and London: W. B. Saunders Company, 1914. Cloth, \$6.00 net; Half Morocco, \$7.50 net.

This book is the outgrowth of a demand upon Dr. Kerley for more extensive work on diseases of children. It is in every way equal and even superior to his former book on diseases of children and doubtless will find its way into many more doctors' libraries than its predecessor.

Development and Anatomy of the Nasal Accessory Sinuses in Man.—Based on 290 lateral nasal walls, showing the various stages and types of development from the sixtieth day of fetal life to advanced maturity. By Warren B. Davis, M. D., Corinna Borden Keen Research Fellow, Jefferson Medical College, Philadelphia. Octavo of 172 pages with 57 original illustrations. Philadelphia and London: W. B. Saunders Company, 1914. Cloth \$3.50 net.

This is a splendid volume. The illustrations are superb, the text comprehensive and it is of special value to specialists and contains a great deal of real benefit to the general practitioner.

A Text-Book of Physiology: for Medical Students and Physicians.—By William H. Howell, Ph. D., M. D., Professor of Physiology, Johns Hopkins University, Baltimore. Fifth Edition Thoroughly Revised. Octavo of 1020 pages, fully illustrated. Philadelphia and London: W. B. Saunders Company, 1913. Cloth, \$4.00 net; Half Morocco, \$5.50 net.

Recently we had occasion to review the fourth edition of this book. It was then strongly commended. The fifth volume is a decided improvement and brings the subject matter entirely up to date. It is probably the last word in its treatment of principles of Physiology.

The Text-Book on Anatomy and Physiology for Nurses.—By Amy E. Pope, with 135 illustrations, published by G. P. Putnam's Sons, New York. Price \$1.75.

This book of 500 pages is chock full of facts essential to the practice of nursing and doubtless will receive, as it deserves, a ready sale.

Volumes 7, 9 and 10, Practical Medical Series, 1913.—Published by Year Book.

Volume 7 on Obstetrics by DeLee, deals with the physiology, diagnosis and pathology of pregnancy, abortion, pathology of labor and operative obstetrics. It is worth while.

Volume 9 on Skin and Venereal Diseases, miscellaneous, by Baum and Moyer. This deals with dermatoses in constitutional infections, therapeutics of the dermatoses, gonorrhoea and syphi-

lis and genito-urinary medicine. In the back appears literature on medical history, sociology and eugenics.

Volume 10 by Patrick Bassoe, on Nervous and Mental Diseases. This volume deals with the neuroses, diseases of the brain, meninges, the cord, the peripheral nerves, dementia precox and parietic dementia and traumatic insanity.

Posture of School Children, with its Home Hygiene and Efficient Methods for School Training.—By Jessie H. Bancroft, Assistant Director Physical Training Public Schools, New York City, published by the McMillan Company, New York. Price, \$1.50.

This book is so full of practical suggestions of useful information that it would be difficult to specialize in a short review. It should be in the hands of every school teacher and parent that they might be fully efficient in caring for the health of the children by securing better cooperation between the home and school. Physical training especially in the cities is left largely to the schools which sometimes fail in their duty with the result that the health of the child is seriously handicapped.

The illustrations alone teach valuable lessons.

A Text-Book of the Practice of Medicine.—By James M. Anders, M. D., Ph. D., LL. D., Professor of Medicine and Clinical Medicine, Medico-Chirurgical College, Philadelphia Eleventh Edition Thoroughly Revised. Octavo of 1335 pages, fully illustrated. Philadelphia and London: W. B. Saunders Company, 1913. Cloth, \$5.50 net; Half Morocco, \$7.00 net.

The popularity of Anders Practice of Medicine warrants this the eleventh edition. A review of its treatment of the diseases, knowledge of which has undergone a change in recent months, shows that it has been thoroughly revised and brought up to date.

Case Histories in Pediatrics.—By John Lovett Morse, A. M., M. D., Boston, and published by W. M. Leonard, Boston. A unique book, arranged under twelve headings. The first, "Normal Development and Physical Examination of Infants and Children," takes up 62 pages, and is well written.

When you read on page 50 this sentence, "They are, moreover, not a sign of an admixture of negro blood, but merely of the persistence, in a rudimentary form of a functional layer of pigment cells in our ancestors, the monkeys," don't become disgusted and shelve the book for by so doing you would miss a great deal of useful information. Under the other eleven headings, i. e. "Diseases of the Gastro-Enteric Tract," "Dis-

eases of Nutrition," "Specific Infectious Diseases," etc. etc., 200 cases are reported giving full history, physical examination, diagnosis, prognosis and treatment in every case. If you read the book through carefully you will be as well prepared to practice medicine among children as you could be from reading books. For the beginner the book is a boon, for the older practitioner quite a help. The type is all that could be desired.

J. J. RODMAN.

Gonorrhoea in Women—By Norris. Published by W. B. Saunders Company, Philadelphia. This book is a complete exposition of the subject and embraces practical treatments from a medical and surgical aspect

Glycosuria and Diabetes—By Allen. Published by W. M. Leonard, Boston. This large volume contains a great deal of technical and difficult research in determining the etiology and various phases attending these conditions and is entirely too technical to be appreciated by the average practitioner

"**A Practical Treatise on the Treatment of Sexual Impotence and Other Sexual Disorders in Men and Women,**"—By William J. Robinson and published by the Critic and Guide Company. A great many practical suggestions are found in this volume and it is presented in an interesting and plausible manner. Any one interested in this special line would do well to consult this work.

Pharmacology, Clinical and Experimental.—Halsey's translation of Meyer and Gottlieb's pharmacology. Price \$6.00. By J. B. Lippincott Company, Philadelphia. This volume of 590 pages by these recognized specialists is probably as complete and accurate a text as can be found. In eighteen chapters are considered pharmacology of the motor nerve-endings, central nerve system, sensory nerve-endings, vegetative nervous system, eye, digestion, reproductive organs, metabolism, heat regulation, inflammation, the various organs of the body and factors, influencing pharmacological reactions. 64 illustrations supplement the text.

Electricity in Diseases of the Eye, Ear, Nose and Throat—By W. Franklin Coleman, Chicago, and published by the Courier-Herald Press. So many of our profession using electricity in their practice that this book will be of interest by reason of its practicability and intrinsic worth. Too much time is not given to fanciful details and fine spun theories but most of the attention is directed to telling how the work is done and why. The book is profusely illustrated and makes much of the text clearer. Price, \$4.00.

Stammering and Cognate Defects of Speech.—Second Volume. Price \$5.00. By C. S. Blumel and published by G. E. Stechert & Company, New York. Insufficient attention has been given to the sufferers from these physical incapacities. It is a revelation to one who has not given it much study to find how much real information of benefit to the patient is secured by a perusal of these two columns.

Case Histories in Pediatrics.—Second Edition by Dr. John Lovel Morse. Price \$3.00 Published by the W. M. Leonard Company, Boston. This book is in its second edition; is very much improved and is brought up to date in extended review of this first edition in March 1st, 1911, Journal. Again we commend it to the medical profession.

The Clinics of John B. Murphy, M. D.—At Mercy Hospital, Chicago. Volume III, Number 1 Octavo of 190 pages 91 illustrations. Philadelphia and London: W. B. Saunders Company, 1914. Published Bi-Monthly. Price per year: Paper, \$8.00. Cloth, \$12.00.

In the absence of a personal visit to the Murphy clinic, a copy of one of these volumes is the next best thing. Presented in Dr. Murphy's clear, convincing style of teaching and with abundant illustrations, it gives the reader the impression that he is present in the Hospital. It is worth while and recommended to the readers of this Journal.

History of Medicine—With Medical Chronology, Bibliographic Data, and Test Questions, by Fielding H. Garrison, A. B., M. D. Principal Assistant Librarian, Surgeon General's Office, Washington, D. C., Editor of the "Index Medicus," Octavo of 763 pages, many portraits. W. B. Saunders Company, Philadelphia and London, 1913. Cloth, \$6.00; Half Morocco, \$7.50, net.

This work supplies the practitioner with abundant historical material relative to his profession and to its development and progress. It furnishes the basis of more extended study of the history of medicine. For the medical essayist, it is invaluable. The reputation of the Author is a sufficient guarantee that the subject matter and facts are dependable and they are arranged in such a way as to give one a clear conception of the history of medicine. The large number of references in the footnotes provides the student and medical speaker or writer with an encyclopedia of information that is within reach by reason of their logical and careful arrangement. It should be in the library of Kentucky physicians.

The Diagnosis and Treatment of Digestive Diseases.—By Geo. M. Niles, M. D., Professor of Gastro-Enterology and Clinical Medicine at Atlanta Medical College. Published by P. Blakiston Sons & Company, 1012 Walnut Street, Phila-

delphia. Price, \$5.00. This book of 570 pages deals with diagnostic methods, examination of feces, the digestive organs and the discussion of the differential diagnosis for the medical and surgical cases, stomach tube, gastric lavage, various methods of local treatment of the stomach and intestines. Diet and drug therapy, psycho-therapy and hydro-therapy are given under separate chapters. In part second, there are considered special diagnosis and treatment of diseases, including the neuroses, the gastrites, motor insufficiency, hematemesis, tumors of the stomach, ulcerations, diarrhoea, dysentery, constipation and intestinal parasites. The arrangement is splendid, text clear and method of treatment are rational and altogether is quite an addition to the library of the general practitioner, particularly interested in the diseases of the alimentary tract.

Treatment of Chronic Leg Ulcers, a Practical Guide to Its Symptomatology, Diagnosis and Treatment.—By Dr. Edward Adams. 122 Pages. Cloth \$1.00. Published by The International Journal of Surgery Company, 100 Williams Street, New York City.

This little book of 110 pages is replete with suggestions and measures for the relief and treatment of these particular lesions which are so difficult to handle.

Chestnut Toxemia?—T. C. Merrill, Washington, D. C., (*Journal A. M. A.*, January 24), calls attention to certain toxic symptoms that have been observed in persons after eating chestnuts from trees affected from the so-called chestnut blight due to a fungus which has been destructive in some of the New England States. Chestnuts from healthy trees are not considered toxic, but it should be remembered that during germination they are remarkable for enzymic activity and it is possible that liberation of toxic substances may then occur. The fungus of chestnut blight (*Endothia parasitica*) affects the nutrition by destroying the bark and while infection of the nut has been observed, such chestnuts are not likely to be eaten. Influences affecting the eatable portion may be due to perverted sap in the diseased trees. He gives a table of the symptoms observed in twenty-one cases which cannot be easily reproduced here but which is instructive. No positive claim is made that the symptoms are due to the eating of chestnuts. The post hoc, though present, is not here intended necessarily to mean propter hoc. It may take several chestnut seasons to determine this question. Food-poisoning, aside from the chestnuts, is excluded in the series. The cases seem to be accompanied with gastro-enteric symptoms and great prostration and slow recovery seemed to be almost the rule. The term "great prostration" is used as indicating an effect disproportionate to any known cause.

ELIGIBILITY OF NON-PROPRIETARY MIXTURES.

Physicians and publishers of journals who wish to adhere to the recommendations of the Council on Pharmacy and Chemistry of the American Medical Association, are herewith reminded that non-proprietary mixtures are deemed by the Council as eligible for prescribing and advertising, without the necessity of being admitted to New and Nonofficial Remedies.

Strictly non-proprietary mixtures of official substances, etc., (for instance, morphin and atrophin tablets) are generally sold without any special claims which would make them subject to investigation by the Council; while the number of these combinations listed by the various manufacturers is so great that that even their mere enumeration in New and Nonofficial Remedies would be practically impossible. The intelligent physician is the best judge of the advisability of prescribing ready-made non-proprietary mixtures of this type. The danger is that he may not always be able to discriminate clearly, on the one hand, between these non-proprietary mixtures that are not listed in New and Nonofficial Remedies because their admission would be superfluous, and on the other hand, the proprietary mixtures which do not appear in New and Nonofficial Remedies because they have been refused admission. The appended definition of "proprietary mixtures" shows where the line is drawn by the Council.

PROPRIETARY MIXTURES.—A mixture will be considered as proprietary, and therefore requiring consideration by the Council and admission to the book or appendix, if it contains any proprietary article, if it is marketed under a name which is in any way protected or if its manufacturer claims for it any unusual therapeutic qualities.

All mixtures to which this definition applies are deemed proprietary and will be listed by name in New and Nonofficial Remedies, if they comply with the rules of the Council.

In all doubtful cases, the secretary of the Council will gladly supply specific information.

W. A. PUCKNER,
Secretary of the Council on Pharmacy and Chemistry, 535 North Dearborn Street, Chicago.

Brass-Poisoning.—A case of brass-poisoning in a worker in brass but not a brass founder is reported by C. A. Pfender, Washington, D. C., (*Journal A. M. A.*, January 24). The frequent attacks were first interpreted as malaria, but blood examination failed to reveal the parasite. Quite by accident, the patient observed that his attacks would occur only after he had been brazing, never after forging or welding with the acetylene-oxygen torch. He would feel apparently well until he reached fresh air, when, as he expressed it, he was suddenly "knocked out," sometimes hardly able to get home. He would experience a general lassitude akin to exhaustion, pain in chest and rawness of lungs, and a taste as of blood in the mouth and accompanied by a sharp rigor and general contraction of the muscles of the chest, arms and legs. Dyspnea was pronounced at times. When the attacks were severe—which was always the case when he had been exposed to the fumes for several hours—he would be literally stricken dumb, unable to move or call for help. He describes the sensation as being "similar to lockjaw." The worst attack he had lasted four hours. His distress was so great that I resorted to morphin, 1-4 grain, and atrophin, 1-100 grain which afforded relief. Sweat did not always follow the chills, nor was fever always present and at no time did it exceed 101 F. The pulse was rapid and fairly strong, but he would tremble for hours after the paroxysm had subsided. As soon as Pfender found that the brass fumes were the cause of the trouble he cautioned the patient accordingly. Installation of better ventilation in the workshop was recommended and the patient was advised to intermit his work between jobs with some other employment. He was given iron and arsenic for a considerable time and was greatly improved. An annoying nervousness and tremor of the hands and arms which occasionally troubled him afterward was relieved by from fifteen to thirty minutes autocondensation treatment with about 600 to 800 miliamperes of the D'Arsonval current. It struck Pfender that the repeated attacks which the patient suffered might affect the lungs and a careful physical examination of the chest showed a number of minor changes which might predispose to tuberculosis. In conclusion he advises more care than is usually given in inquiring about a patient's occupation especially if the disease is refractory to treatment.

Paralysis General.—Treatment. Hexamethylenamine, gr. x (0.6 Gm) thrice daily, found effectual in preventing retention of urine and avoiding necessity for catheterization.—Baird.

Pancreatitis, Subacute.—Treatment. 1. Rest 2. Limitation of diet. 3. After acute attack of pain has passed off, cholecystostomy.—Archibald and Mullally.

MANUAL REMOVAL OF PLACENTA AND MEMBRANES.

By WALKER B. GOSSETT, Louisville.

In a normal delivery of placenta and membranes, we find that the uterus remains retracted and quiescent. In a short time, five to fifteen minutes, active contractions begin and then at regular intervals. The separation of the placenta occurs especially during the contractions, also the period of quiescence. We know that different views are held regarding how the separation occurs, to retraction of the placental site, to relaxation of the uterine walls after contraction, and to Schultz's view of the formation of a retro-placental haematoma. We know it takes time for the separation to take place and contraction of the uterus to expel it. We cannot put a time limit upon the third stage, any more than we can to the first and second stages. I condemn the practice of the forcing of the placenta out immediately after the end of the second stage. Also, do not begin the immediate kneading of the uterus after end of second stage, unless for some cause. It is good practice to place the hand over the uterus to see that it does not become overdistended. The uterus should have a period of rest before it begins to contract to expel the placenta. Kneading too quickly may set up a tetanic contraction of the uterus, especially the lower part of the body, also destroy the quiet formation of the retro-placental haematoma. I follow the custom of keeping the hand resting quietly upon the uterus, or even

have the nurse or patient, for at least fifteen minutes, then begin the kneading of the uterus every three to five minutes. When the placenta has passed from the body into the lower segment of the uterus, diagnosed by the altered shape of the uterus, fundus rising higher and uterus less globular, then make pressure for the expulsion. If the placenta is not expelled in thirty minutes, then use the Crede's method, we all know what that method is.

When the placenta appears at the vulva orifice and does not readily drop into the hand, then carefully remove by direct traction or twisting.

After having tried Crede's method and find I have an adherent placenta, I then introduce my hand into the uterus and manually remove placenta and membranes. Be absolutely surgically clean. Always re-wash your hands or dip your rubber-gloved hands into a lysol solution before the introduction of the hand into the uterus, also have the vulva thoroughly cleansed. It is customary to have your patient anaesthetized but I have performed this operation without this being done. The fingers should be passed up between the uterine wall and the placenta, and the placenta stripped off, then make your wide sweep to get all portions, then grasp the placenta and membranes in your hand and the uterus made to force the hand and placenta out together. Keep the external hand upon the uterus to steady it and work along with the internal hand. Some operators advise an intro-uterine douche of boiled water, hot, to stimulate contraction and wash out any debris, but this is not absolutely necessary. If in hospital practice, it is very good,

but at private homes I do not make a practice of doing this. Ergotole given, hypodramatically, in all cases.

After a normal placenta has been expelled by nature, examine it to see if the membranes and the whole of the placenta have come away. Now if you find that the bulk of the membranes has been retained, then introduce the hand and remove same. If only a small portion is retained, it is a wise course to leave this alone and trust to nature to expel it, but no portion of the placenta should be left behind and left to nature to safely expel it. It should be removed.

DISCUSSION:

Edward Speidel: I think we are sometimes a little too hasty in the removal of the placenta. All of the modern text-books, as well as Crede himself, state that his method should not be resorted to within a period of half an hour after labor. Repeated attempts to secure the expulsion of the placenta within a shorter length of time are very injurious, especially squeezing the uterus before it has become firm and hard. The proper time for the expression of the placenta, when it is not expelled by nature is, of course, after it has become detached from the upper segment of the uterus and is in the lower segment. This can be determined in either of the two ways mentioned by the essayist. First, by elongation of the uterus, which can be noticed if the hand is kept lying upon the fundus. Another and more positive means of recognizing this condition, is to place a pair of arteryforceps on the portion of the cord protruding from the vulva after the cord has been cut. If, within fifteen or twenty minutes, the forceps have moved three or four inches, it is an indication that the placenta has slipped down into the lower segment of the uterus, and the time for expression has arrived.

As to manual removal of the placenta, I think the physician should wait a considerable length of time before resorting to this extremely dangerous operation. I read quite an interesting article in a recent number of the American Journal of Obstetrics and Diseases of Women on the third stage of labor, describing the custom in the Rotunda Hospital in Dublin, with respect to the removal of the placenta. No attempt is made at removal of the placenta until half an hour has elapsed after labor. If the attempt is then unsuccessful, they wait an hour, or an hour and a half, or sometimes two hours, before resorting to operative removal.

When we are compelled to undertake operative removal of the placenta, it should be carried out under rigid precautions, because it is one of the most dangerous operations for the mother in the realm of obstetrics. It should be done under rigid asepsis and, in my opinion, with gloved hands.

It has always been my custom, and I think it is a good one, to irrigate the uterus after manual removal of the placenta with a large quantity of hot water. It serves a double purpose, not only removing any infection present, but it assists in bringing about firm contraction of the uterus and prevents any bleeding from the placental site.

John K. Freeman: I hope the essayist will bring out a little more definitely, in his closing discussion, his idea as to the time we should interfere. It has been my rule never to attempt manual removal of the placenta unless there is a hemorrhage or some other special indication for it. I have often waited a long time for the placenta to be delivered, and I have never regretted the waiting. I remember hearing the late Dr. Anderson read a paper on the management of the third stage of labor, in which he stated that it was his practice to wait as long as two hours, and that he had no reason to regret it. We are often a little too hasty and, if you will pardon me gentlemen, I think some obstetricians are, strictly speaking, meddling; they are in too big a hurry to deliver the placenta and get away and they do not give Nature a fair chance. The woman has been under chloroform say half an hour or an hour, or sometimes two hours and is exhausted, and Nature, after the uterus has been emptied of its contents, must react. Therefore, as long as there is no hemorrhage, I think we should wait and give Nature a chance. I have delivered many women at full term—possibly more than a thousand—and I have never, with but one exception, resorted to manual extraction of the placenta. I am speaking of deliveries at full term understand.

The method described by the essayist is the one that should be carried out. I have only recently begun to use gloves in obstetrical work. Of course we can extract the placenta very much better, especially in premature delivery, with our bare fingers than with gloved hands, and we sometimes have to do this where we have hemorrhage and have not our rubber gloves with us.

The essayist has written upon a very practical subject and I have enjoyed it very much indeed.

Simrall Anderson: I would like to ask the essayist if he does not think there is a difference between an adherent placenta and a retained placenta.

I remember reading in an old book on obstetrics that I picked up some time ago, of the injection of cold water into the umbilical cord with the object of securing separation of the placenta from the uterus. I would like for the doctor in closing to tell us whether he knows anything about the merits of this procedure.

Harry J. Phillips: This subject is one of which the medical student is taught but little during his term at college. It occurs to me that I saw my first obstetrical case after I was en-

gaged in active practice. The average student does not have an opportunity of seeing cases of this kind in clinics.

Every one of us in the course of time, adopts a routine procedure that he carries out in his own practice. I would like to know just how many of us make traction on the cord in a case of retained placenta. I have known, and have seen old practitioners, with thirty-five or forty years of experience, make traction on the cord to liberate a retained placenta. Of course, that is contrary to our views now, and I daresay no one here would think of doing this—yet it is often done. It might not be amiss to say here that in twenty years practice, I have never had a post-partum hemorrhage or a case of sepsis. It is remarkable what amount of abuse the uterus can stand. I have never worn rubber gloves in a single obstetrical case and, like my colleague, Dr. Freeman, I have delivered a great many babies in the past twenty years. I have been careful—just as careful as can be, but I have not waited thirty, or fifty or sixty minutes for the delivery of any placenta, nor shall I ever do so. I have made it a practice to keep my hand upon the fundus of the uterus as the child is being born, allowing the child to remain on the bed for two or three minutes while the nurse gets the silver solution ready to place in the child's eyes, meanwhile keeping my hands upon the fundus of the uterus. Then, after I have tied the cord, I occasionally step to the bedside and gently knead the uterus, getting it firmly contracted and the placenta in the lower segment. Then, after having waited possibly twenty minutes, I place my forefinger in the vagina to see if I can feel the placenta and, if so, I immediately employ the Crede method and expel it. I never make direct traction upon the membranes, but invariably twist them into a rope, and in that way bring them all away. My personal experience has taught me that this is the best plan and, after all, we learn things best by personal experience. I have never had a case of post-partum hemorrhage or sepsis, nor have I ever lost a woman in child-bed from any condition.

T. K. Van Zandt: I wish to congratulate Dr. Phillips; he has made a record.

In regard to the point he made about the membranes, I believe the modern teaching is that this method should not be employed.

I am surprised to hear that Dr. Phillips has never used gloves. I note that Dr. Gessett states in his paper, that he used gloves in his case, and I am glad to see that he is coming to it.

Walker B. Gossett, (Closing): I must admit that I have not been in the habit of using rubber gloves, but I now use them frequently—especially when I wait on doctors' wives. One reason I did not use them was because I do no surgery; I am a general practitioner and obstetrician and

I do not handle pus and, under those circumstances, a man who practices strict asepsis will have no septic cases even if he does not use rubber gloves.

I agree with Dr. Phillips that twisting the membranes is a good rule, and I sometimes employ slight traction. However, each individual case is a law unto itself.

Answering Dr. Anderson's question, the difference between a retained placenta and an adherent placenta, is that the former is lying in the uterus without being attached, and a little traction will expel it. Under these circumstances the Crede method is a very good one. In septic cases where the placenta is adherent, we should give Nature more time to expel it. In such cases I wait as long as an hour, but I have never waited longer than that for the expulsion of an adherent placenta.

As Dr. Speidel has pointed out, manual expulsion of the placenta is one of the most serious operations in obstetrical practice, and it should be done only under the most rigid asepsis. For that reason I have not made it a practice to employ intra-uterine douching, because we are liable to infect the patient. Also in forceps delivery, I do not practice intra uterine douching because I am afraid of introducing septic material into the uterus along with the douche. Sterile water cannot be obtained as readily in the home as in the hospital.

In cases of retained placenta, I do not believe we should run the risk of introducing the bare hand into the uterus. While we may do obstetrical work safely without gloves, still I do not think we should go into the uterus after a retained placenta without gloves on.

The Call of the Child.—The Federal Children's Bureau is more than justifying itself according to Frances Bradley, Georgia, who gives (*Journal A. M. A.*, January 24), an account of the methods used by the bureau at the recent Conservation Exposition at Knoxville, Tenn. As a part of the Child Welfare Exhibit, a children's health conference was installed to determine the prospect of raising future healthy citizens. All parents were invited to bring their children but no scoring was done or prizes given, the natural incentive of parenthood and desire for the welfare of the child only being relied on, and the results justified the method. Husbands were as interested as wives and the parents were shown how they succeeded or failed to do their best for their offspring. The examinations were opened to all classes and conditions and to all ages under fifteen. Bradley gives a number of instances showing how valuable counsel could be given even when it seemed hardly needed as well as when the need was obvious.

SURGICAL JUDGMENT IN OPERATIONS FOR ACUTE MASTOIDITIS.

By GAYLORD C. HALL, Louisville.

Most surgical procedures are not manually difficult. Some, however, require a nicety of touch or delicacy of manipulation that places them in a class above the usual operation.

This is particularly true in those regions of the body where surgical procedures must be carried out within a small space which is surrounded by important structures: where the inadvertent slip of an instrument or an ill-chosen step in technique might result in serious injury to our patient. On such a plane we must place the mastoid operation. So much has been written along this line in the past twenty years it is unnecessary to mention the particular dangers that beset this procedure as they are doubtless well known to you all.

Unless one is sufficiently conversant with this technique to follow a diseased condition to the end, yet at the same time avoid these dangers, he is but illy prepared to pursue his special work.

Important, however, as this technique is to acquire, or however facile one may become in its accomplishment there are certain other qualities one must possess before one can hope to fulfill the highest ideals of surgery as well as be a safe and conscientious adviser. This particular quality is surgical judgment, by which I mean the sense that will enable one skilled in the knowledge of the condition to digest the symptom complex presented in any given case and arrive at a conclusion as to the necessity or not of operative interference. In short, it is a mingling of sound common sense with the special knowledge required in the work at hand.

With these preliminary remarks I wish to consider the subject this evening under two main divisions. First, the considerations that lead us to operate in acute cases. Secondly, some points in the method of operating.

Considering the first phase of our subject the first question to be answered is what constitutes mastoiditis. This brings us to a review of the chief symptoms. There is usually, though not invariably, a history of middle ear disease. The appearance of the ear drum varies greatly. It may be red, bulging, and unopen. Usually rupture has occurred or the ear has been opened. Looking through the rupture pulsation is usually present. The lips of the wound may be pouting or protruding which usually indicates too small an opening with deficient drainage. The position of the opening of the drum is of importance. If above or anterior it is much less favorable

than below and behind and much more apt to have caused trouble.

Finally there may be a hole of considerable size in the drum without swelling and apparently well able to take care of any discharge; as in those cases in which the discharge varies within wide limits. There may be no discharge or at best but slight moisture with white flakes in it as in the case just cited. In the very early stages the discharge may be profuse and sanguinous or if later purulent and thick. It may be so profuse as to constitute practically a continual flow into the canal interfering greatly with the inspection of the deeper structures.

In my opinion the extremes are more significant than the moderate discharge. The color and physical characteristics are of little importance.

Of greatest importance is the bacterial contents of this discharge, all being agreed that the streptococcus mucosus is the most dangerous organism, prone to marked destruction of tissue with but few symptoms. Next in importance the streptococcus pyogenes; following this the pneumococcus and staphylococcus. There are, however, rarer bacterial infections in this region that are far more destructive than the last named organism. We have occasionally a Krebs-Loeffler bacillus, Friedlander's pneumo bacillus, bacillus influenza, and meningococcus, bacillus pyocyaneus. There may be a mixed infection or a pure culture present.

One should obtain the secretion for examination direct from the middle ear if possible and not that which has lain an indefinite time in the external canal.

Another symptom of considerable value is the sagging downward of the posterior superior canal wall due to an edema or a superficial periostitis anterior to the mastoid antrum.

Pain may be absent or severe. It is apt to be worse in severe infections with an abnormal discharge and an inadequate opening of the ear drum.

The location of the pain is of importance. Tip pain is not particularly significant as it occurs in most cases of simple otitis media in the early stages. Its location high up or involving that side of the head, or referred to a point behind is much more characteristic of a mastoid infection. Finally it may be absent altogether or exist only as an indefinite something which the patient feels but can not adequately describe. The character of the pain may vary from the acutest suffering down through all stages and varieties to nothing at all.

Tenderness over the tip, as in pain, has no special significance. Deep tenderness over

the antrum or behind at the point of exit of the mastoid emissary vein is suggestive of mastoiditis.

Such further symptoms as swelling and edema over mastoid with displacement of the auricle outward, which symptoms occur particularly in children, are but confirmatory evidence and indicate a rupture outward through the cortex with localization of the infection.

The general symptoms of the disease present as wide variations as the local ones. The patient may be profoundly septic; unconscious, with high temperature; rapid pulse and all the attendant symptoms. On the other hand pulse and temperature may be normal and the patient show no evidences whatsoever of his infection.

The usual course is about as follows: An infection of the middle ear followed by rupture or opening of the drum has a temporary amelioration of symptoms with sudden recurrence. This may be ushered in by a chill; the patient feeling sick; all of the ear symptoms are accentuated though sometimes there may be a sudden cessation of the discharge with the advent of mastoid symptoms.

After reviewing these symptoms in detail one may pertinently ask at this point what symptoms point unmistakably to a mastoiditis.

I think no categorical answer can be given to this question. Any combination of three or four of the above mentioned symptoms if continued for twenty-four or thirty-six hours should convince one of such a condition, but this does not by any means dispose of the subject for there are undoubtedly cases of mastoiditis that occur with practically all of the classical symptoms absent.

I believe we have all seen such cases with no particular pain or tenderness; without drooping of the canal wall; without characteristic discharge, or redness, or swelling behind the ear, or any general symptom that would indicate a severe infection and found on operating a process greatly diseased with abundant pus to testify the necessity for operation.

In this connection I wish to report the following cases:

Case I.—W. S., age 33 years. Coal miner by occupation. One month before operation had suffered an acute abscess in the middle ear which had ruptured, with abundant discharge for several days after which all symptoms became better. Throughout the month in which he had had the trouble, however, there had been three different recurrences of the inflammatory symptoms all of which had subsided spontaneously.

On examination, pulse, temperature, and

respiration were normal. There was no tenderness at any point. The patient had an indefinite feeling of discomfort in the direction of the occiput and involving the muscles on that side of the neck. The drum was widely opened and contained but a moderate amount of discharge. No additional discharge could be obtained by suction. Infection showed streptococcus.

Operation was decided on from the character of the discharge, the indefinite pains in the head and the history.

Operation disclosed a tremendously developed mastoid process, foul pus in antrum under pressure; excavation backward revealing a large mass of granulations over the site of the sinus. This was so extensive and extended so far back that we at first thought we were dealing with a thrombosis of the sinus and removed the granulations with that thought in mind. The mass was finally dislodged, thicker around than the finger and fully an inch and a quarter long, under which could be seen the bluish sinus uncovered for that length practically from the knee down to the jugular bulb.

A very wide and thorough dissection was made in all directions finally excavating the largest cavity which I have ever seen in the skull. The wound was partly closed and the cavity lightly packed with iodoform gauze, rubber tissue being placed over the exposed sinus.

Recovery was prompt and uneventful except that for a few days following the operation there was daily excursions of temperature from 97 1-2 to 99 1-2, which, however, subsided without further interference and the patient went on through an uninterrupted recovery.

Case II.—H. S., age 24 years. Following tonsillitis and rhinitis developed an indolent infection of middle ear. This was promptly opened with the subsidence of all symptoms. After about three weeks, however, patient began to complain of pain, indefinite in character, coming on at odd times affecting that side of the head. There was no acceleration of pulse or temperature at any time. The patient was up and around. One feature, however, which developed somewhat later in the treatment was fainting every time the ear was dressed. The discharge was not abundant and was a mixed infection, pneumococcus predominating with staphylococcus.

A course of vaccine had been given without influencing the condition. Operation revealed abundant pus in the antrum under considerable pressure. This entirely relieved the condition and patient had an uninterrupted recovery.

In such cases the decision to operate is

fraught with many difficulties and no absolute rules can be laid down, as a decision often rests on the observance of a single symptom that is out of all proportion in severity and extent to the apparent disease process.

In such cases must we humbly bow to the years of experience of some of our older colleagues since long observation of the vagaries of a disease in a given locality certainly gives one a superior understanding of a doubtful condition.

I recently had the pleasure of assisting a gentleman, whose attainments we all admire and respect, in an operation for acute mastoiditis. The patient was an elderly lady past sixty and the only prominent symptom in this patient's case was dizziness.

Operation revealed pus under great pressure affecting chiefly the lower portion of the process with erosion of the bony covering of the lateral sinus.

I am informed that the operation was completely successful in relieving all symptoms and the patient made an excellent recovery.

Finally in some cases the answer must be left to the verdict of an exploratory operation as in certain abdominal conditions and as in such cases this exploration is as free from danger either to life or function.

The sooner that otology learns the lesson that surgery has been taught about appendicitis the better off it will be.

Waiving discussion regarding the three essential points in any infection, namely, virulence of infecting organism; size of dose; resistance of patient; we find broadly speaking there are two classes of cases.

One where the process burns itself out and remains strictly localized, the resistance of the patient being well marked. All of these patients should recover with operation. The other where there is no delimitation of the process, resisting power on the patient's part being feeble, the whole organism suffering from the onslaught of the infection. Such cases usually die.

There are two other possible outcomes that are subordinate to these two. In the non-resisting cases by very prompt resort to surgical means in ridding the patient of the great mass of infection we may be able to turn the tide in our favor, the operation having the effect of so diminishing the dose of the infection that even the feeble resisting powers at our command can cope with it. As in appendicitis so in mastoiditis it is possible to operate at a time when the line of defense is but partially developed the insult of the operation causing it to give way altogether and converting what would have been a localized process with safe operation later to a rapid-

ly spreading diffuse process the patients usually succumbing to meningitis.

Therefore, from the ineptness of any middle ear inflammation the strictest watch should be kept for the advent of signs of mastoid involvement. Such signs appearing the case should be submitted to operation at the earliest possible moment.

If seen late and the case is showing doubtful resistance reasonable delay in an endeavor to strengthen such resistance is justifiable.

I grant that the analogy is not so complete as in appendicitis for the reason that it has not been so thoroughly worked out. I believe, however, this postulate holds good. Either operate very early or in cases seen late in the development of the disease attempt by conservative means to stimulate resistance until you can convert the patient into a reasonably safe surgical risk.

Concerning the operative procedure I do not intend to describe its technique, all men are agreed that the proper thing to do is to uncover the mastoid antrum and work in all directions from this point; to remove all diseased tissue. Difference in the manner of arriving at this end is of no importance.

Difference of opinion as to what constitutes "all diseased tissue" is of importance since stopping short of this tends to delay convalescence or may be the starting point of further disease or necessitate another operation.

I therefore desire to call attention to two points that I think of importance in technique and which I believe renders recovery more certain and convalescence more rapid.

The first of these is the wide opening of the drum membrane. The reason for this is manifest. Presumably at least the mastoiditis itself arose because one was unable to maintain sufficient drainage from the middle ear through the drum. I usually make this incision at the beginning of an operation and pack the canal with cotton. It is a little point but one I think that is often neglected.

The second point in technique to which I desire to call attention is the excavation forward from the antrum of the zygomatic cells and in the direction of the aditus ad antrum. In fact these should be cleaned out until by means of a bent canula (Heath's) one can syringe from the antrum through the aditus into the middle ear. After excavating these cells I place the tip of the canula deep into the cavity with its mouth toward the middle ear. Hot saline is then washed through until a mass of pus and detritus precede this.

The importance of this is manifest if one but considers the anatomy of the parts. The determination of a mastoid infection is not the mere presence of pus behind the middle

car but the presence of pus that can not drain out through the natural channel which is the *aditus ad antrum*; therefore, in every case of mastoiditis there is a time when by reason of pus or swelling of the membrane the *aditus* is blocked and drainage between the antrum and middle ear is cut off. Hence the necessity of clearing out this passage which is but following the disease to its source and removing it.

Trivial as these two points may seem I believe they are the answer to a short convalescence and the man who neglects them and stops his operation after opening the antrum and tip sentences his patient to a long convalescence and the possibility of a second operation.

DISCUSSION.

J. M. Ray: I have enjoyed Dr. Hall's paper very much indeed. First in regard to diagnosis. I think any case of acute suppurative middle-ear disease, with a persistent discharge and pain continuing for three or four weeks is evidence of involvement of the mastoid. While a great many of these cases will get well without operation, still I think they should be operated upon, for the sake of safety if nothing else. A simple mastoid operation does not amount to so very much, while if the condition is allowed to go on for some time, it may amount to a great deal. I do not believe that mastoid disease develops in three or four days from a suppurative middle ear. Every once in a while some one calls me up and tells me to go see a patient that has the mastoid disease, and in many instances I find that the diagnosis has been based upon a little tenderness over the mastoid.

I believe in thorough operative procedure. When I go in I do not stop until I am fairly sure that all of the diseased structures have been removed. A gentleman was in my office a few days ago upon whom I had done a double mastoid operation, first on one side and then on the other, at different times. This man was over seventy years old when I operated upon him. In the operation I opened the lateral sinus and there was considerable hemorrhage, which was easily controlled and he got well. He was in my office the other day bragging on how good he was feeling. If I had cut the operation short in this old man, before having removed all of the disease, there is hardly any doubt that he would have had a sinus thrombosis which would probably have terminated fatally.

In acute mastoid cases, let the middle ear alone as much as possible. If it has good drainage, let it alone; do not probe into the middle ear because of the danger of dislocating the ossicles and producing permanent deafness. I like to see the middle ear dry within three or four days after operation, letting the drainage come from behind.

Adolph O. Pängst: I think the point of practical interest to a society of this kind, the majority of whose members are engaged in general practice, is the fact that there are symptoms other than the so-called cardinal symptoms, which indicate mastoid operation; in other words, that it is not always necessary to wait for the typical symptoms of swelling and bogginess behind the ear and sagging of the ear canal—symptoms anybody can recognize—before opening the mastoid. Dr. Hall brought out this point, but it is worth repeating. One of the symptoms he spoke of is sagging of the ear canal. The presence of this symptom is a fairly good indication that the mastoid is involved, although its absence does not indicate the reverse. I would pay considerable attention to the amount of pus. In my opinion, persistent and copious discharge of pus is one of the most important symptoms we have of involvement of the mastoid bone. I think attention was first called to this by Politzer, but he placed the limit of time at a little longer than it is now. He believed that in the presence of a profuse discharge, persisting for four or five weeks, operation should be done even in the absence of other symptoms of mastoid involvement. However, according to Dench and others, operation should be resorted to earlier than four or five weeks. I have operated in cases where the only symptom was profuse discharge and elevation of temperature in the absence of pain, bogginess, or any other of the so-called cardinal symptoms.

I do not believe an elevation of temperature is in any degree indicative of mastoid involvement, because we may have this in ordinary middle ear disease.

Dr. Hall spoke of making microscopic examination of the pus to determine the species of organism present, as an aid in telling when to operate. I have never been able to carry this out with any degree of satisfaction. I do not believe I would go into the mastoid simply because of the presence of a streptococci infection in the middle ear, unless there were other clinical symptoms tending to confirm the diagnosis. In Dr. Hall's case, however, the discharge was sufficiently profuse to indicate operation, regardless of the microscopic findings.

C. T. Wolfe: Just a word on this subject from a prophylactic standpoint. Most of these conditions start with a simple ear-ache; or, rather, a great many simple ear-aches terminate in mastoid involvement. A great many of us, especially those who do general practice, are prone to use sweet oil and laudanum, or other similar remedies, with the idea of controlling the pain, when a simple incision of the ear-drum would relieve the trouble by releasing the pus, which, under pressure, causes the pain. It behooves every one of us to be thoroughly familiar with the anatomy of the ear-drum because, in my opinion, a

great many mastoid operations could be avoided by early incision of the drum.

C. H. Harris: I believe if I had mastoid disease, I would want my mastoid opened. I would like for Dr. Hall to answer one question in closing. The late Dr. Wm. Pusey, who operated upon two or three children for me, took the position that free incision of the ear drum, cutting down through the periosteum over the mastoid, would relieve mastoid abscess. I remember one child, a little over a year old, that he operated upon. He cut down through the periosteum, and said if that did not relieve it in a little while, he would do a radical mastoid operation. I did not have a great deal of faith in it, but much to my surprise the symptoms were relieved and the child had no further trouble.

Gaylor C. Hall, (Closing): I wish to thank the gentlemen who have discussed the paper. During the season just past, we have been seeing a great many cases of mastoid involvement without any of the usual symptoms. I believe I would be safe in saying that, of the cases I have operated upon this season, the majority have been without the classical symptoms of mastoid involvement. Whether this was a seasonal incident, or whether it was due to the type of infection prevalent, I do not know, but certainly the season just past has been very unusual in that respect.

As to Dr. Ray's remarks, regarding probing the middle ear, I want to say in defense of myself that I never put a probe into the middle ear, or attempt any surgical procedure whatever there, except for the purpose of securing a very wide opening of the ear drum, for the reason, as stated in the paper, that mastoid infection is at least partly determined by the fact that there is inadequate drainage through the opening already existing, which is proof that the opening is insufficient.

In regard to the species of organism as an indication for operation, that was one of the features of the particular case I mentioned. This man had suffered three spontaneous attacks following the initial lesion, and they had all subsided spontaneously. He had come a distance of more than two hundred miles, and he expected radical relief. While he had a very moderate discharge, it proved to be a streptococcal infection, and in view of this fact, together with the history, I felt justified in operating upon him, the result of which speaks for itself.

Dr. Harris' question is, as usual, a very difficult one to answer. He refers to the Wild incision. The only explanation I can give of the relief afforded by this operation is that in the first place, the mastoid of a child is very poorly developed, the antrum is high, and the cortex is there. It is simply one of the means by which nature enables children to resist infections. The incision in the direction of the antrum deter-

mines the outlet of pus in that direction, and nature is able to take care of it. In older children, with a better development of the mastoid, I do not believe such an incision would be adequate. In fact, I would not care to practice it at all, but those cases in which it does the work are very young infants, with an absence of tip cells, the antrum high up, and cartilaginous substance between the posterior canal wall and the anterior surface of the mastoid antrum; thus the incision determines the infection forward and nature takes care of it.

CLINICAL CASES

EXCISION OF THE TARSAI CARTILAGE AND CONJUNCTIVA IN OLD TRACHOMA.

By C. T. WOLFE, Louisville.

In view of the fact that a recent investigation of the trachoma situation in our schools, by men connected with the United States Public Health Service, has shown that 2 per cent of all the children have trachoma, we are necessarily confronted with the problem of its elimination or at least means must be devised to prevent its further progress. While I had the pleasure on several occasions of being associated with these officials in the work they did in Louisville and though large numbers of cases were reported, I am still of the opinion which opinion I expressed some months ago in a paper before this society, that trachoma does not constitute a serious problem in this city. We have in Louisville all the facilities that medical science has invented, our physicians and surgeons are of the best and in goodly numbers, and though this disease, which as a rule is found to be most prevalent among the poorer classes, they need not suffer as a consequence, for our clinics are numerous and well taken care of. If a like condition to this existed e.g. in Eastern Prussia, trachoma would not there be considered, as it is now, a national problem. Further their social and economic conditions predispose to trachoma and are necessarily far below our level, and their sanitation is an unknown quantity. What we do need in Louisville is a campaign of education to bring the matter before the public.

It may be of interest to note that in dealing with trachoma we are dealing with a disease of great antiquity. Hirschberg assures us that it existed fully three thousand years ago. Though from that early age to the present it has been attacked both medicinally and surgically, no one has yet discovered a medication or devised a surgical procedure that will

act either as a pumacea or as a phophylactic agent.

The very early surgeons realized the all too frequent inefficacy of medical measures in the treatment of this most intractable disease and resorted to surgical procedures that indeed seem crude at the present day.

The Arabians are given credit for first attacking trachoma from a surgical standpoint more than a thousand years ago. Their method consisted of rubbing the trachomatous conjunctiva with a fig leaf until blood appeared.

According to Wood the modern treatment of trachoma, both medical and surgical, dates from 1812, when the French troops, returning from Egypt, imported the disease into the continent of Europe. At a period when bleeding was regarded as a *sine qua non* of correct therapeutics is not surprising that surgeons should have practiced depletion of the conjunctiva in the hope of checking the disease. It is stated that great quantities of blood, even up to several pints, were abstracted. In addition leeches were used, and blisters were applied.

Other methods were brought to light at different times and heralded over the world as apparent steps such as scarification, eurette and brossage and while all are useful, a tremendous impetus was given methods of this type by Knapp in 1891, when he introduced his ingenious roller forceps.

Though all of these methods are advantageous they nevertheless have their shortcomings in that they do not prevent recurrences and none of them will cure trachoma *per se*.

Thus it can be readily seen that the treatment of trachoma, especially in its latter stages, has ever fallen far short of our expectations. There has been but little to offer in the way of encouragement to individuals so unfortunately afflicted, for the disease at this stage responds but little to the usual medications, and if at all, is so slow that our patients through discouragement become wandering habitues of the various clinics until nature ultimately arrests the disease. But the end she gains hardly justifies the loss the patient sustains. For there results a complete obliteration of the retro-tarsal folds, a shrunken and distorted cartilage, with its attendant evil effects, a pannus that is usually dense and permanent and a dry and shrunken conjunctiva.

Therefore, from the standpoint of theory it was reasoned that since the disease will not subside until these tissues are destroyed, why not remove them before nature has had to and save the patient the time and suffering which must necessarily cover years. Thus

the operation in question was attempted consisting of an excision of the upper retro-tarsal fold of conjunctiva and the superior tarsal cartilage, obliterating entirely the trachoma bearing area in the upper lid.

In the hands of its originator, Dr. Heisrath, and his assistants, Drs. Vassius and Kuhnt, of Eastern Prussia, it has yielded 50 per cent to 60 per cent of cures and in addition has afforded practical immunity from reinfection. In view of these facts it is indeed surprising the indifference with which the American surgeons have regarded it, for it has not been adopted universally in this country.

The indications for this operation, according to Wootton, are in the severe trachoma of adults with corneal complications and in all stages except the cicatricial. Claiborne believes it is indicated in all cases of trachoma in which cicatrization has commenced and panus and keratitis are present. On the contrary he thinks it should not be performed in any case in which granulations are sufficiently abundant to justify expression unless the disease has several times repeated itself after the operation. As to its being contra-indicated in the cicatricial stage, I am inclined to take exception, since such striking results were obtained upon one of my patients who had a very pronounced cicatricial process. The results of my experience corroborate those of Claiborne and I believe as he does that if there is one class of cases in which the excision is indicated it is in the purely cicatricial or the cicatricial form combined with granulations.

While my experience covers but six cases, the results have been very gratifying, and I believe that when indicated this procedure fills a long want in the alleviation of this most troublesome malady.

DISCUSSION.

J. M. Ray: I have enjoyed Dr. Wolfe's report very much indeed. There are just two points that I want to discuss; first the trachoma problem. It seems that attention has been most vividly directed to the supposed prevalence of trachoma by the recent inspection of our city schools. I have practiced medicine here a good many years, and I constantly have several cases of trachoma under my observation; yet I have never been impressed that we have more cases of trachoma here than exist in other cities of the same size. I am sure that the relative proportion is not as large as it was when, as a young man, I was an interne in an Eye Hospital in New York. At that time I had in one eleemosynary institution, more than one hundred cases of trachoma out of a total of three hundred and fifty children.

Any one who has practiced medicine here as

long as I have, and is familiar with the State of Kentucky, knows that there are a number of places located throughout the State that might be termed trachoma areas, of communities. I remember that, while a hospital interne in New York, I made a visit to my old home in Nelson county, Kentucky, and while there a doctor friend of mine told me that he wanted me to see a family that he was treating for sore eyes. I went with him, and found a mother and three children all suffering from trachoma. I told them it was contagious, and warned them against using the same basin, towel, etc. Since then I have seen nearly all this family, and they have the disease. I do not believe that trachoma is contagious in the sense that it can be contracted through the air, but constant association, using the same wash-basin and towel, sleeping on the same pillow, etc., will sooner or later result in every member of the family contracting the disease. Since I have been practicing in Louisville, I have operated on two or three members of that family for trachoma, and I think I have treated seven or eight other members and several neighbors for the same condition. Altogether, I have seen probably a dozen cases, outside of this family, from that same community.

I think the newspaper notoriety given to the recent inspection of our schools has unduly excited a lot of people with respect to trachoma; many of them seem to think that we have a new disease to deal with and one that is highly contagious. I do not believe that one child can contract trachoma from another simply through association at school, unless they are intimate enough to use the same handkerchief, wash in the same basin, or something of that kind. I had an illustration of the effect of this inspection to-day. A mother sent her child to me with one of these little slips from the inspector, together with a note from the teacher to the effect that unless the child was treated, it would not be permitted to return to school. This child had a very mild infection in the culdesac. I hardly believe that child is dangerous from the standpoint of association at school. We need a little education along the line of diagnosis, because everything that is called trachoma is not really trachoma. I have seen cases that had been recommended for operation that were not trachoma.

In regard to the operation described by Dr. Wolfe, I am sure he does not intend to be understood as bringing it forward as a new operation. I have been doing it, off and on, for a good many years. In the late stages of trachoma, in certain cases, it is a very valuable operation. When I left the hospital as an interne, I went abroad, and in Paris I saw Galezowski do this operation. He operated on these patients under chloroform. With forceps and a pair of scissors he takes out the culdesac, and never put in a stitch, and after seeing this I became less afraid of operations on

the culdesac. I heard some one say last summer, "what is the use of fooling with this operation? Turn over the lid, cut out the culdesac, put the lid back and get along just as well as with sutures.

Adolph O. Pfingst: I had the pleasure of seeing Dr. Wolf operate on one of these cases, and of seeing one of them after operation, and I wish to compliment him on the results. One of these was a very interesting case. The man had marked pannus and a corneal ulcer. In this case there was marked improvement within ten days after the operation, although prior to the operation practically every remedy recommended for this condition had been used without results.

As to the operation itself, it is the rational procedure in advanced cases. The principle involved is that it exposes that part of the conjunctival surface where we have the most trouble and where recurrence most frequently takes place; namely, the culdesac, above the margin of the upper lid. All of us have operated on these cases by other methods and sent them home apparently well, only to have them return in six or eight months with a recurrence starting from this culdesac. This is also the place most frequently neglected by the practitioner in following up the treatment. In the operation reported by the essayist the cartilage is cut away with its conjunctival surface, and the conjunctival of the culdesac drawn to the edge of the lid, making it amenable to treatment.

As to the indications for this operation, I do not believe Dr. Wolfe intended to convey the idea that it does away with the roller forceps and other methods that we have carried out in the past. We all use roller forceps to get rid of granulations on the conjunctiva, but in advanced cases, where there is pannus, ulceration or scar tissues with its deformity, it is certainly a valuable operation.

C. T. Wolfe, (Closing): Just a word in regard to suturing. I do not believe Dr. Ray would operate on a case of this kind without putting in sutures. Without them we do not accomplish what we desire from the operation; namely, to bring the conjunctiva forward and make a new lid and thus do away with the irritation that results from granulation in the lid.

This operation was formerly done on the lower lid also, but most operators have now abandoned that. The lower lid is not the one that is responsible for the symptoms and sequelae of trachoma; it does not give rise to corneal ulcers or other irritations of that kind.

VESICAL CALCULI,

(REPORT OF CASE.)

By ELLIS SAUNDERS ALLEN, Louisville.

Vesical calculus is a concretion of the solid urinary constituents. Calculi may be generally grouped under the following headings:

1. Those formed from the normal constituents of the urine,—uric acid, the phosphatic, the mixed, and the urate calculi.

2. Calculi formed of salts found in normal urine, but never present in excess except in disease, the oxylates and carbonates.

3. Concretions formed from elements entirely foreign to normal urine,—cystin, indigo, and xanthic oxide.

The large majority of stones are formed of uric acid and the urates, the phosphatic and mixed calculi come next in order of frequency; and last come the oxalates and rarer forms,—indigo, xanthic oxide, etc.

Uric Acid Calculi are formed in acid urine. Originating in the pelvis of the kidney, they descend through the ureter to the bladder, usually causing that form of violent and paroxysmal pain which is termed renal colic. Once in the bladder their further growth is due to accretion of uric acid alone, or they may form nuclei for the deposition of other elements. Uric acid calculi are generally smooth, spheroidal moderately hard, and yellow to reddish brown in color.

High living and a gouty diathesis are factors predisposing to the formation of these concretions. They occur at the extremes of life.

Urate Calculi. The sodium, potassium, and ammonium urates, though rarely forming large stones, are constantly and copiously deposited as sediment in febrile affections, and when, from any cause, the urine becomes markedly concentrated. The urate calculi are observed almost exclusively in children. In the adult they may form the nuclei or large concretions made up of divers elements. They are grayish yellow in color.

Phosphatic Calculi follow the uric acid and urate concretions in order of frequency; there are three varieties:

1. The amorphous calcium phosphate rarely forms a calculus of itself. It is commonly deposited in layers about calculi of other salts, or is intermingled with them, sometimes reaching considerable size. It crumbles easily; its color is a dirty brown or white.

2. The triple phosphates (ammonio-magnesian phosphates) are commoner in calculus formation than calculi phosphate. Such calculi are crystalline and of a whitish color. Formed in ammoniacal urine only, they are

vesical in origin and frequently complicate cystitis.

Mixed fusible calculi, being composed of the triple phosphates and calcium phosphate, are not uniform throughout, forming about a nucleus of calcium oxalate, uric acid, foreign bodies, etc. They appear as masses which resemble white friable mortar, and are formed in ammoniacal urine.

Calcium Oxalate Calculi, like those of uric acid, are of renal origin, and occur most frequently in patients suffering from oxaluria, a diathesis associated with indigestion and neurasthenia. These are the hardest of all stones, and are usually small or of medium size, spheroidal in shape, dark brown or black in color, and have a tuberculated surface, giving rise to the name of mulberry calculus. Amorphous urates and phosphates are often deposited between the tuberculations.

Calcium Carbonate Calculi are rare. When found they have been multiple, small, weighing from thirty to forty grains, each, and hard and lamellar in structure, similar to the calcium oxalate calculi.

Cystin calculi. Cystin as a major constituent of calculus is extremely rare.

Those suffering from vesical calculus as a rule present the following symptoms; pain, frequent urination, hematuria and very frequently pyuria and bacteriuria. And when they present themselves for an examination the diagnosis of cystitis is made, and the usual treatment for this condition instituted, which consists principally of urinary antiseptics irrigation and, of late days, vaccine therapy.

The patient is generally more or less free from symptoms as long as the treatment is kept up, but as soon as there is a lapse in treatment, the old symptoms present themselves. Such was the history of the cases I am about to report.

Case I. Mr. W., age 50, white, family history negative, lives in the country, under the best hygienic surroundings. For 20 years been suffering with what was regarded as a chronic cystitis; obtains partial relief at times by rest in bed, medication and irrigation. Twenty years ago, he consulted the late Dr. Yandell of this city, who irrigated the bladder a number of times, placing him on urinary antiseptics. After each visit to Dr. Yandell he obtained temporary relief; however, at intervals the spasm and vesical tenesmus was so intense, as to require large doses of opiates to obtain relief. At no time within this interval of twenty years has he been able to go more than a couple of hours without emptying the bladder and at times for months he could not go longer than 20 minutes. About four years ago, his suffering was so intense

that he consulted Dr. Hugh Young of Baltimore. Dr. Young did his punch operation, removing a small portion of the middle lobe of the prostate. He was cystoscoped a number of times with negative findings, except an infected and contracted bladder. He remained under Dr. Young's care for five months, the treatment consisting principally of irrigation and instillation with an attempt to dilate and increase the capacity of the bladder. No relief was obtained, and the patient returned home suffering as usual. Two years ago he returned to Dr. Young and similar treatment was carried out. At this time he remained under Dr. Young's care for two months, with very little relief. In December, 1913, he consulted me. I sent him to the hospital where I could investigate his case thoroughly. A laboratory report of the urine showed blood, pus, colon bacilli, staphylococci, and numerous mole fungi. An autogenous vaccine was given and injections of a 20 per cent solution of argyrol into the bladder. The capacity of the bladder at this time was not more than an ounce; there was marked vesical tenesmus causing the patient to empty the bladder every fifteen or twenty minutes; this kept up through the night. The patient told me that he never slept longer than 20 minutes at one time, so I sat up with him one night and recorded the intervals at which he was disturbed. Only one time during the entire night did he go longer than twenty minutes and at this time he went twenty-four minutes. He told me that this had kept up for ten years. In about a week's time under the treatment mentioned above he was able to go as long as three hours without being disturbed, and with an irrigation of boric acid solution I demonstrated a capacity of six ounces. I then sent him home for a week to see if his symptoms would return. He remained away for ten days, upon his return he was suffering as usual. I then passed a sound and demonstrated a foreign body from which could be elicited a distinct click.

I suggested a cystoscopic examination which was beautifully done by Dr. Bronner, discovering a stone. At the same time Dr. Bronner called my attention to an orifice of a pathological nature and location. This man very readily consented to an operation which was performed on the 7th of January of this year, extracting the stone that I present to you. The suprapubic operation was done; the bladder was thoroughly explored and a diverticulum was found located on the left side of the bladder about an inch lateral to the trigone. This diverticulum was filled with a tenacious mucus. As there was no constriction of the neck of the diverticulum I made no interference. The bladder was closed with a double row of No. 2 catgut sutures

a small wick drain being inserted into the space of retizius, and a retention catheter was placed in the bladder. This patient had no symptoms nor leakage from above until on the eighth day while having his bed changed the catheter was accidentally jerked out and as I was out of town, the patient began to leak through the incision as the orderly was unable to reinsert another catheter. The suprapubic wound was about a month in closing and the patient had considerable tenesmus and an enormous accumulation of mucus in the bladder which was so tenacious as to completely occlude a large sized catheter. This patient left the hospital at the end of about six weeks not entirely relieved from the tenesmus, having had several attacks of rather severe muscular spasm of the neck of the bladder but informs me to-day that he is very much better.

Case II. Mrs. B., age 55; married; family history negative, who for five years has presented symptoms of a chronic cystitis with acute exacerbations presenting the urinary findings of an abundance of pus, blood, mucus, and colon bacilli. She has been treated during the last five years by a half a dozen different men for cystitis. One man of ability stated that she had a tumor of the bladder, which was probably malignant. She came under my care in November, 1913, she was given the same treatment as the other case, i. e. urotropin autogenous vaccine and argyrol injections which for a time gave practically complete relief, the urine showing only a few pus cells, an occasional blood cell, and very few bacteria. However, when treatment was discontinued for a couple of weeks all of the trouble returned as severe as before. I then suggested a cystoscopic examination, which was admirably done by Dr. Brennan, demonstrating a large stone. This patient too, had suffered so very much and been so inconvenienced that she readily consented to an operation. The bladder was opened January 7th by the suprapubic method, and the larger of these two stones removed. The retention catheter was introduced. This patient went home on the 10th day, suprapubic wound entirely closed and all symptoms cleared up.

As vesical calculi are so very common and as their removal is rather a simple procedure, I would have little excuse for reporting these cases other than to suggest that there would probably be a good idea to have an early cystoscopic examination made in order to determine whether or not we are dealing with an uncomplicated case of cystitis, for as long as there is a foreign body which continues to irritate the mucosa of the bladder there will be recurrence of vesical symptoms with all of its annoyances.

DISCUSSION.

Herbert Bronner: Owing to Dr. Allen's splendid preliminary treatment in this case, the bladder was very tolerant to the cystoscope and it was comparatively easy to obtain a very clear view of this oblong-shaped argyrol-stained stone, as well as the orifice of the diverticulum on the left side of the bladder. I was unable to be present at the operation, but I understand the doctor did not find it necessary to do anything for this diverticulum other than thorough dilatation of the orifice.

The after-symptoms in this case have been explained by Dr. Allen. I believe the patient developed an attack of acute cystitis, probably largely brought on by trauma. It is barely possible, however, that some infectious material may have accumulated in this diverticulum and caused another attack. From the appearance and shape of this stone, I believe it had its origin in the diverticulum.

The second case is also of interest. Stones within the urinary bladder of the female are comparatively rare; men of large experience have operated upon only a few cases. The reasons for this rarity are plain. Primary stones pass out very easily on account of the shortness and dilatibility of the female urethra. Secondary, or phosphatic stones are seldom found because the exciting causes such as occur in the male-stricture, enlarged prostate and other obstructions—do not occur in the female.

A. C. L. Perceful: It appears to me, from the shape of this stone, that it might have been encysted in the diverticulum, and the diverticulum closed up, which would account for the other men not being able to find it.

I would like to ask Dr. Allen if he has ever seen a record of a case of stone in the bladder without a history of pain at any time. I have a case under observation at the present time, with symptoms similar to Dr. Allen's case with the exception of the pain.

E. O. Grant: Just one point about dealing with the diverticulum. The main difficulty is in getting a sufficient hold: it is difficult to hold it with either forceps or a hook. In the past few months, Dr. _____ of Cleveland, has brought out a new operation for these cases. His procedure is to entirely pack the diverticulum with a strip of thin gauze, such as we use for mopping out the bladder, making a semi-solid tumor out of it and cutting the diverticulum around that. It makes an easier operation than by holding with forceps or a hook, and it would probably be well to give it a trial in these cases.

Geo. H. Day: I would like to ask Dr. Allen if this patient had ever been X-rayed by Dr. Young? It does not seem to me that he has followed his usual technique in this case. However, it serves to emphasize the fact that such cases should be X-rayed. While it is a fact that vesical

stones will often escape the X-ray, still it should be done as a matter of routine.

W. C. Dugan: I wish to emphasize the point brought out by Dr. Day in regard to the employment of X-rays in these cases, bearing in mind, however, that not finding it does not mean that the stone does not exist. We should be very careful in our criticism of men who overlook stones with a searcher. No one who knew the late Dr. Yandell will question that he was a past master with the sound, and yet he occasionally overlooked them, as was done in this case.

As to the diverticulum, I agree with Dr. Grant that the best plan is to take it out and get rid of it, and the method he mentioned is a good one.

E. S. Allen, (Closing): It seems to me that this stone must have been in the diverticulum or it would not have been overlooked. It was also overlooked by Dr. Wheeler of Lexington, but upon the introduction of the cystoscope by Dr. Bronner, the stone was very easily seen. Both of these men are good men, and they have had far wider experience than I have, and it is not my intention to criticize them. The point I particularly wanted to bring out is that we frequently treat these old chronic cases of cystitis over long periods of time with antiseptics, irrigations, vaccines and so on. I believe that in such cases after a certain length of time, when the symptoms have cleared up, we should make a thorough investigation, either with the cystoscope or the X-ray, or both.

In regard to Dr. Perceful's question, I think we very frequently have stone existing in the bladder without giving rise to much symptomatology, depending a great deal upon the formation or shape of the stone. I think I have such a case on hand now. This patient three years ago, had an attack of renal colic, and has never passed a stone or had any symptoms since then. In looking up the literature this afternoon, I found a number of cases in which the first symptom was a haematuria. Very frequently this is the only symptom until infection develops, which increases the hypersensitiveness in the bladder. When this man came to me he had retention of urine. This stone had gotten into the mouth of the urethra and caused complete occlusion. By means of a large syringe I forced argyrol into the bladder and very probably dislocated the stone. Upon attempting to urinate he passed a small stone, and if it had not been for the passage of this small piece of stone, I would probably not have discovered the stone in the bladder. He would begin to urinate and the stone, because of its shape, would become engaged in the neck of the bladder and occlude the passage.

W. C. Dugan: Suppose you had found nothing with the cystoscope, would you have gone ahead and opened the bladder for diagnostic purposes?

E. S. Allen: I would probably have drained it peritoneally.

FRACTURE OF THE PELVIS AND SEPARATION OF THE SACRO-ILIAC JOINT.

By W. BARNETT OWEN, Louisville.

Because of the similarity of symptoms and treatment of sacro-iliac separation strain and disease will include in this case report eight cases of sacro-iliac strain and one case of tuberculous disease of the sacro-iliac joint.

As the symptoms of these conditions are in the main identical, will briefly state them: Pain (referred to the side of the pelvis or radiates over the buttock or thigh, sometimes straight through, greatly resembling pain of appendix disease), a peculiar feeling of insecurity and weakness about the pelvis and hip joint on the affected side, the trunk is inclined toward the sound limb, as the result of which the pelvis is tilted causing an apparent lengthening of the limb on the affected side. There may be a sensitiveness to direct pressure over the sacro-iliac joint. Pain is aggravated by lateral pressure on the pelvis or by any manipulation that disturbs the articulation.

Sacro-iliac strain is frequently mistaken for sciatica, lumbago or disease of the hip or spine. Upon examination with the pelvis fixed the freedom of motion and lack of muscular spasm would usually rule out hip or spine involvement. However, with the primary involvement of the acetabulum, the findings upon examination are very similar and it frequently requires very close study to differentiate the two conditions. The symptoms of local sensitiveness to point pressure and to manipulation usually exclude sciatica or lumbago.

Case I.—Tuberculous disease of the sacro-iliac joint, was a young lady, twenty-two years of age, unmarried, family and personal history negative, present condition of three month's duration, was admitted to the Hospital for Ruptured and Crippled, New York City, Dec. 1904. The above diagnosis was verified by X-ray pictures. Treatment consisted of the application of plaster spica, with the limbs abducted to about thirty-five degrees. The dressing was changed every two months for one and a half years. The Thomas hip-splint was applied and the patient allowed to walk. The disease did not progress after the first dressing was applied. The case was lost sight of one year later but until that time was able to walk comfortably with a slight limp. Should an abscess form (and this happens in the majority of such cases because early treatment is rarely instituted), it may burrow into the pelvis and present itself above the crest of the ilium. It may pass through the sciatic notch or appear

in the ischio-rectal fossa, and may rupture into the rectum.

The eight cases of the sacro-iliac strain are all adults, six females and two males. Classification as to occupation—two nurses, one colored laundress, one dress-maker, three house-keepers, two railroad employees, one worked in a shop and the other a conductor. Their ages were from 22 to 53. Seven of these cases gave a history of a definite over-strain or injury and the diagnosis was comparatively easy. A belt about four inches wide and of heavy material was snugly buckled around the pelvis. Seven of these cases were immediately benefited and eventually cured.

In one case, female, age 40, housekeeper, fell from step-ladder and felt something give way in her back. A belt was applied but the support was not sufficient. A plaster of Paris spica was applied for two weeks, the limbs being abducted to about 35 degrees. She was relieved of pain after the first day. The belt was again re-applied and worn continuously, there being no recurrence of pain or discomfort for the past five months. There being nothing out of the ordinary in the other cases, will not go into detail.

TREATMENT.

The ordinary sacro-iliac strain can be successfully treated by the application of a belt about four inches wide around the pelvis to be worn continuously. Advanced and obstinate cases of sacro-iliac strain, and all cases of sacro-iliac separation or disease should have a double plaster spica applied, with the limbs abducted to the normal range. The bandage should be snugly, evenly and comfortably fitted around the pelvis and molded over the crests, giving sufficient support behind. The sacro-iliac joint gets considerable support from the application of the belt, but in cases which can not be relieved by its use, would immobilize, support and protect by the application of a plaster spica, applied in the manner previously mentioned.

The case of fractured pelvis and separation of the sacro-iliac joint is as follows:

Mrs. M. B., age 39, married, admitted to City Hospital October 16, 1913. Family history negative. Personal history: had pneumonia, frequent attacks of pleurisy between ages of 16 and 30. Has had articular rheumatism following an attack of pneumonia. Had three miscarriages, all between one and three months. Made uneventful recovery from each—last one three years ago. Present History: jumped from second story window on picket fence October 16, 1913, fractured ramus of pubis on both sides, separated left sacro-iliac joint and lacerating labia. The

immediate attention consisted of catheterization of bladder, sixteen ounces of urine being obtained. Labial laceration repaired and broad adhesive straps were applied snugly about the pelvis.

Patient suffering tremendous shock was in a highly nervous state, a morphine fiend, and attempted suicide.

Morphine was continued for two weeks. X-ray pictures were taken by Dr. Louis Moir which showed the condition above mentioned. The case developed typical pneumonia, involving both lungs, and lasted about ten days. On October 31, under gas-oxygen anesthesia, lasting six minutes, both limbs forcibly abducted, and the sacro-iliac separation was reduced. Apparently no union had taken place in the left pubis. The right was in good position and was not felt to move at time of reduction.

A plaster spica, including both limbs, was applied, and another X-ray picture was taken by Dr. Moir the following day, this time, the pain was especially severe in the sacro-iliac region. After the reduction, the pain in this locality ceased, although she complained of pain in different parts of the body at times, we attributed that to the withdrawal of the morphine which she had been taking regularly for several years.

At the end of four weeks, this dressing was removed and a wide belt applied. After the patient had been walking about the hospital for about two weeks, we allowed her to go home. The records show that, in spite of many complications and drawbacks, she was fortunate enough to get a good result. Being greatly interested in this case, I instructed her to report at my office every month for an examination. She came one time and upon examination found that she had continued to improve and was able to walk comfortably with a very slight limp.

In conclusion, (1) Many cases of sacro-iliac involvement are treated for sciatica, lumbago, rheumatism, etc.

(2). Sacro-iliac strain and disease should be excluded by a thorough examination of every case of persistent or recurrent pain in the back.

(3). The best results in the shortest time are obtained by early treatment of sacro-iliac involvement as in all joint conditions.

DISCUSSION:

Guy P. Grigsby: More than anything else I wish to verify Dr. Owens' statement in regard to the X-ray plates. Unfortunately, he was unable to have them here to-night.

I was in service at the City Hospital when this woman was brought in. One thing that struck me as remarkable was the fact that, notwithstanding

the nature of the injury and the fact that she had sixteen ounces of urine in the bladder, she did not have rupture of the bladder.

The position of abduction certainly placed the fragments in the most perfect position possible. This was shown very distinctly by the plates, and I am sorry that Dr. Owens could not get them to show here to-night.

Jno. J. Moren: I am very glad indeed that Dr. Owen has brought up the subject of sacro-iliac strain. It is a very interesting one, because a great many cases that are treated for sciatica, neuritis, etc., are really due to this source. I have seen cases of supposed sciatica which had resisted practically every form of treatment recommended for this condition, and which yielded promptly under proper support of the pelvis. Recently I saw a gentleman from the country, who had been suffering for several weeks from so-called sciatica, or lumbago. He had curvature of the back, very large hips, and he could not walk a square without suffering the most excruciating pain. I procured a belt, about four inches wide, and placed it around his pelvis at the sacro-iliac joint. In less than two days he walked from the Tenth Street depot to my office without any discomfort whatever. I have heard from him since then and he is getting along very nicely.

This afternoon a gentleman was sent to my office complaining of a peculiar pain down his leg. In stepping over anything he could make it all right, but when it came to stepping down, he could not bend his back. He could not make an ordinary stride, because when he did it caused tension on the ham-string muscle, giving rise to the pain. Another good diagnostic feature is that these patients cannot lift the affected leg as easily as they can the unaffected side. I remember one patient that I had under observation suffering from typical strain and sciatica, who got in the middle of a street car track, and to save his life he could not step over the rail; he had to get down and practically roll out.

To come back to the young man who was in my office this afternoon, I put an ordinary belt around his waist and then told him to lift his foot. He did so, and one could tell from the expression on his face that he could do it better than he had before. I then told him to see if he could strike his regular stride, and he could, but when he took off the belt the former condition returned.

Geo. A. Hendon: I would like for Dr. Owens to tell us what method of treatment he pursues in cases of tuberculous disintegration of the sacro-iliac joint. This is a proposition that is quite different from traumatic strain. I have always believed that in those cases, the mechanical support should extend to the limitation of motion in an up and down direction as well as laterally, and that we should insist upon their putting a high shoe on the good foot and using

crutches. I would like for Dr. Owen to mention, in closing, the direct treatment of the lesion itself; whether he aspirates the joint and injects some antiseptic medium, or whether he depends upon the influence of rest to effect a cure, or whether he advocates opening and curetting the joint.

W. Barnett Owen: I wish to thank the gentlemen for their discussion. As to Dr. Hendon's question in regard to the treatment of tuberculous involvement of the sacro-iliac joint, I think the first thing to do is to get an X-ray picture in order to determine the extent of the infection. If the focus is sufficiently accessible and the patient's condition will permit it, a radical operation for its removal should be done. Unfortunately, most of these cases are so far advanced when we see them that it is not safe to carry out this latter procedure. In such cases I would depend more upon protective dressings. In the abduction position the joint is more nearly at rest, and a tuberculous focus is supposed to be more or less self-limited if protected and the patient is properly nourished. I believe I would treat these cases along that line.

RUPTURED OVARIAN CYST.

(REPORT OF CASE.)

By B. F. ZIMMERMAN, Louisville.

I thought that this specimen, being in a fresh state, might be of interest to the society.

I saw this patient a week ago to-night, at about nine o'clock, with a history of severe pain in the abdomen, beginning at four o'clock that afternoon, and she was still suffering when I saw her, although not so severely. Pulse 100; temperature nearly normal. She said that, following the severe pain in the abdomen, her bowels had moved, as they had done the other times during the day. She had considerable pain in the region of the rectum, and an uncomfortable feeling in the bladder upon the passage of urine. Her menstrual history gave no suggestion of pregnancy. She had menstruated about two weeks prior to this time, and it had been free, as it usually was; in fact, she had been troubled with menorrhagia for a number of years, and had frequently complained of pain in the right side since an attack of typhoid eight years ago. At times decided swelling had been noticed in the right side. She was very tender over the lower part of the abdomen, but as her condition did not seem serious I gave her something to relieve the pain and told her I would examine her the next morning. Upon examination I could make out nothing definite except uterine displacement with tenderness in the right side. The patient weighed more than 250 pounds and it was difficult to make a satisfactory examin-

ation. My diagnosis lay between an extra-uterine pregnancy and an ovarian twisted on its pedicle. I advised operation and she went to the Infirmary and was operated upon Friday morning, four days after the beginning of her trouble. During this time as long as the woman remained quiet, she had no pain.

Operation. Cutting down upon the peritoneum I found blood in the peritoneal cavity and at once concluded that I was dealing with an extra-uterine pregnancy. Then I went into the pelvis and found the right tube small, as you see it here, and somewhat distorted about this longitudinal band on the appendix. In the pelvis I found a double handful of clots and there were clots adherent to the ovary. These were removed, suspension done, a small cyst taken from either ovary and the appendix removed. The uterus was curetted. It was enlarged to the size of a two-months' pregnancy, and there was more than the usual amount of endometrium. The clots, which were very adherent, were submitted to Dr. Allen for examination and he reports that he was unable to find any embryonic tissue.

I take it that this was an ovarian cyst that had ruptured, and possibly some cases of ovarian pregnancy that have been reported were of this character.

FRACTURE OF INTERNAL CONDYLE OF FEMUR TREATED WITH WIRE NAILS.

(REPORT OF CASE.)

By C. B. SPALDING, Louisville.

During the evening of Saturday, the 7th of December, 1912, I was called by Dr. Elmore, to see Mr. T. O. H., who had been injured in a car accident. Upon a superficial examination by Dr. Elmore and myself, we were able to make out a fracture in the right knee, but due to the extreme swelling, coupled with the shock and pain present, we could not be sure of the extent of damage so applied a temporary splint, and ordered the patient to be moved to St. Joseph's Infirmary the following morning, an X-ray picture to be made by Dr. Morr, en route to the infirmary.

This X-ray picture showed a complete fracture, irregular in contour, of the internal condyle of the right femur, a few small fragments of bone being entirely separated near the proximal end of the line of fracture.

We explained the condition to the patient, advising him of the probability of a stiff, useless joint; and also, the possibility of loss of limb, from pressure, due to the extreme tension within the joint from haemorrhage.

He was advised of the possibilities; as well as the risk of opening the joint and attempting to repair the injury. Holding out to him, in case of success, the hopes of a fairly useful joint, and telling him plainly what might happen in the event of the operation being unsuccessful, he promptly accepted our opinion, and gave us freedom to use our judgment.

The operation was delayed until Monday, the 9th, to insure the cessation of all active hemorrhage.

At the time of operation, the patient's general and local conditions were as follows: Age 47, white, male, weight about 160 pounds, height about 5 feet 9 inches. Family history negative. Personal history showed that he had sustained a fractured rib, in the April preceding, which repaired rapidly.

HABITUAL BEER DRINKER.

Examination of lungs was negative, heart action, normal, pulse 68, blood pressure 170. Temperature 99 1-5 degrees, urinalysis showed a specific gravity 1038, trace of albumen, a few hyaline casts, an occasional pus cell, no blood; and sugar reaction, negative.

The local picture presented a greatly swollen knee, superficial veins engorged, and the soft structures putting on pressure well up to the middle third of the thigh.

Dr. Hein administered the anesthetic, using gas-oxygen preliminary, with a total of 215 gms. of ether. Anesthetic started at 1:10 and stopped at 2:46; operation began at 1:32 and was completed at 2:40. Blood pressure during operation varied from 170 at the start to 130 at the finish. Pulse ran from 120 at start to 132 at the finish. Respiration 28 to 30.

The operation consisted of an incision about five inches long, along the anterior border of the sartorius muscle, extending above and below the adductor tubercle. Extravasated blood was encountered immediately under the skin, and throughout. When the sight of the fracture was reached approximately a pint of black blood and synovial fluid escaped from the joint and surrounding structures. Four small fragments of bone were removed; and the line of fracture was found to be very irregular, the inner condyle being pulled well up toward the shaft of the bone and firmly held there by its muscular attachments.

Two wire nails, (a 6 and an 8 penny) were started into the fragment. The one, entering below the adductor tubercle and pointing outward and upward, the other, above the tubercle, and directed downward and outward. When these were well planted in the substance of the fragment, two fingers of my left hand pressed firmly downward on the fragment while two assistants pulled on the lower extremity. Thus exerting all the means at

hand to replace the fragment downward, which was very difficult, and at that, we were unable to place it perfectly. When it had been lowered as much as possible the nails were driven into the opposing bone. The fascia and muscles were sewed in place, and the skin closed without drainage. Catgut was used throughout. The leg was dressed in plaster, on a double inclined plane, leaving the joint free for dressing, if necessary.

Convalescence was uneventful, patient having a normal temperature in the morning and running a fever of 99 degrees to 99 4-5 degrees in the afternoon, for two weeks. Patient left hospital January 6, 1913, and was visited at his home until March 6, 1913. Cast was removed January 20, 1913, and quite a little stiffness was present. Dr. Elmore took charge and with frequent treatments, succeeded in accomplishing much for the motility of the joint.

At present the patient has about a right angle flexion and almost perfect extension, with quite an outward bowing due to the inability to fix the fragment in exactly its normal plane with its fellow.

This gentleman has a very useful leg and is maintaining his position with the school board and has been since early fall. The operation having been performed one year and nearly three months ago.

DISCUSSION.

F. T. Fort: This report should not be allowed to go without discussion. Very brilliant results have been obtained along this line. In fractures of the internal condyle of the humerus, the inner condyle of the femur and the neck of the femur, it is almost impossible to hold the bones together unless we fix them by some means, and the best method of accomplishing this seems to be the use of wire nails. One thing to remember is that, in wiring these fragments in close proximity to a joint, we must be very careful not to allow the head of the nail to enter the joint cavity. By a thorough knowledge of the anatomy, and an X-ray picture as a guide, one can in most instances introduce the nails without entering the joint cavity. If the technique has been good, one need not fear infection from leaving the nails in there. However, more care is demanded in these cases than in the ordinary run of cases, because an infection seems to be much more easily started. One should always use gloves and handle the materials as little as possible. If more of this kind of work was done, we would have fewer cases of deformity and more useful limbs.

W. C. Dugan: I would like to indorse what the preceding speaker has said. If there is any place that the use of wire nails is indicated, it is in fracture of the condyles. In the knee joint,

leaving out the use of wire nails entirely, opening up the joint and draining it will be a very potent factor in an early recovery.

I believe the doctor would have had better result and less trouble in approximation, if he had cut the tendon of the abductor muscle. I see no reason why that could not have been done and it would have averted the sliding upwards of the fragment, making approximation easier.

C. B. Spalding, (Closing): I wish to thank the gentlemen for their discussion.

To all who are engaged in the practice of medicine, there come times, more or less frequently, when we are called upon to assume very great responsibility. So far as I know, this procedure has never before been carried out in this city, and in attempting it I subjected myself to the possibility of utter failure and subsequent criticism. It was rather a hard position, and without the co-operation of the physician and the patient, the results might not have been so good.

In regard to Dr. Dugan's suggestion, as to cutting the abductor muscle, I agree with him that this would be a very good thing to do. The only possible objection would be the possibility of interference with the blood supply, and I do not believe that would be sufficient to do any great amount of harm.

Dr. Murphy originated this procedure, and he claims that even in cases where the bone is entirely black from lack of blood supply, if nailed back in position it will derive a blood supply from the adjacent bone, and regeneration will take place.

I believe it would have been better to have cut the tendon, as it was almost impossible, with all the strength we could use, to get it in position. The edge of the fracture was very jagged and widely spread, making it a very difficult thing to secure approximation, as I am sure Dr. Elmore, who saw the case, will agree.

Had this patient in the least degree resisted the suggestion we made, or if the physician, Dr. Elmore, had not cooperated with me in every possible way, this procedure could not have been carried out. On the other hand I believe that, without it, the patient would have had a stiff joint, although not necessarily a locked joint.

Dr. Fort has suggested to me the advantage of using two nails rather than one. In some cases one is sufficient, but in a case like this, where we have the condyle broken off in a position like that (illustrating on blackboard), the muscles will pull one nail out. After getting it through the shell of the bone, it is like driving it in soft structures. My idea in introducing two nails and crossing them was to get a wedge, so that the small fragment will pull against this wedge and it will not pull out.

ECLAMPSIA.

(REPORT OF CASE.)

By B. J. O'CONNOR, Louisville.

My reason for reporting this case lies chiefly in the fact that the condition was anticipated early in the pregnancy. The patient, a primipara, 21 years of age came to me in the early stages for a diagnosis of pregnancy. Her family history was excellent and personal history good with the exception of an attack of scarlet fever in her twelfth year, which was followed by a dropsy. She also suffered occasionally with rather severe headaches. Her blood pressure was 140 but she was other wise in good physical condition.

On the succeeding day her husband brought me a specimen of her urine, which showed a moderate albuminuria, with numerous hyalin and a few granular casts. The probability of serious trouble was explained to the husband in order to emphasize the necessity of frequent examinations of the urine and proper prophylactic measures. A partial explanation was made to the patient in order to impress her with the importance of a restricted diet, proper regulation of her habits, free elimination and the avoidance of mental and physical irritants.

She reported regularly at the office with a specimen of her urine during the first six months and continued in good shape. Every specimen of urine examined however revealed a persistence of the albumen and casts. Her blood pressure varied from 136 to 148. Beyond the hygienic and dietetic measures, nothing was given during this time except an occasional compound cathartic pill and salts, and several pints of Basham's mixture.

From this time onwards she showed a gradually increasing dropsy commencing in the feet and later becoming distinct in both the hands and face. Despite enforced rest, carefully restricted diet and active elimination no decided improvement could be attained in either the reduction of the albuminuria or the oedema. The quantity of urine voided and the total solids were satisfactory. The blood pressure at no time exceeded 150, ranging usually from 140 to 150. She had several moderately severe headaches during this time but they invariably promptly yielded to free elimination. No other symptom of uraemia or the anticipated eclampsia became manifest until about 12 days prior to the date on which we expected labor.

The evening before her eclamptic attack she had some gossips as company, who entertained her to a late hour with narratives of the difficulties and dangers of labor and how various acquaintances had suffered, aye, even died. She spent a restless night full of hor-

rible dreams and arose with a terrific headache. As I had directed she telephoned me immediately. I was unable to make the call immediately but I ordered the druggist to send her a half dozen powders, each containing 2 1-2 grains of calomel and 5 grains of aspirin, one to be taken every half hour until relieved. I saw her about two hours later, she had taken three powders but was still suffering. Her blood pressure was 185, pulse rate 96 and her general expression unfavorable. I gave her another powder and followed it with a bottle of magnesia. Veratrum viride was ordered in ten minim doses every 30 minutes to be continued until the pulse rate was reduced. Although anticipating an eclamptic attack I felt fairly safe with ten grains of calomel and a bottle of magnesia under the patient's belt. I left the nurse in charge and told the family I would return in about three hours.

About an hour and a half after my departure my patient became unconscious and had a hard prolonged convulsion. The nearest physician, Dr. Heman Humphrey, was called and administered chloroform. I saw her toward the end of the convulsion, she was pale, but deeply cyanotic, and mild spasms continued for about 30 minutes. This was followed by deep stupor which continued for three hours. She had a few labor pains prior to the convulsion and an examination showed a moderate dilatation of the cervix, I resorted to manual dilatation during this stupor and finally with the patient still in a semi-stuporous and semi-delirious condition. About eight ounces of urine were removed with a catheter and the patient had several watery evacuations. The pulse rate dropped to about 80 and the pressure to 160. The progress of the labor was satisfactory until the head reached the perineum. After a reasonable wait forceps were applied after the patient was anaesthetized and the labor completed without difficulty. It was somewhat difficult to establish free and easy respiration in the infant but it seemed to be perfectly healthy. Even after the completion of the labor the patient still remained somewhat somnolent and her mind was cloudy.

Hot drinks were given during the night and hot packs used on the patient. On the following morning the kidneys acted freely and the mental haziness cleared. The puerperium and convalescence was perfectly normal but the bed rest was continued until all the oedema had disappeared. Several examinations of the urine since that time showed neither albumen or casts, the patient nursed the baby and the youngster now about six months old weighs close to twenty pounds.

As stated in the beginning my reason for

reporting this case is to emphasize the advisability of routine urinary examinations in every case and the frequent use of the sphygmomanometer during every pregnancy. In this instance, as well as in others, we can obviate many difficulties and minimize many of the dangers in this trying time of a woman's existence.

DISCUSSION:

Edward Speidel: I desire to make a statement, and I would like to know whether it can be corroborated by the experience of other members of the society.

I take the blood pressure of every case of pregnancy that comes to me and, as a rule, I find very little difference in the blood pressure of the pregnant woman and that of the healthy non-pregnant woman. Another thing I have noted is that, in toxemic cases, presenting albumen in the urine, the blood pressure, until near labor, is rarely above 150, whereas in those cases of toxemia which present no kidney symptoms, the blood pressure is, as a rule, very high. I have seen it as high as 210 and 220 before labor. I would like to know the experience of other members in this respect.

The case reported by Dr. O'Connor, before the onset of labor, before the patient had the first convulsion, would have been a splendid one for venesection. I believe that had a half a pint of blood been drawn from this patient, followed by the injection, intravenously, of normal saline solution, the convulsions and coma might have been avoided.

As to the after-treatment, I think the doctor followed the right plan. The patient went into labor and almost delivered herself. If anything at all was indicated, it would have been to dilate the cervix manually and effect delivery more rapidly.

I think it should be impressed upon every one that the anesthetic of choice in these cases is ether, because it has been conclusively demonstrated that chloroform will produce changes in the liver corresponding to those produced by the toxemia of pregnancy. Consequently, of all forms of anesthesia, ether is the one of choice.

As to viratrum viride, I have used it but I am somewhat afraid of it. It is exceedingly depressing. Although it is highly recommended by many authors, I prefer venesection and the introduction of normal saline.

Another thing that might have been used with benefit in this case is a method that I use in City Hospital cases, principally on account of nerve tension—that is, small doses of morphia. In some instances I also use morphin, but in this case morphin was not indicated because of the kidney condition, but a half grain of apomorphia every four hours would probably have been of benefit.

Ben Vaughan: In this connection I wish to briefly mention a case that came under my observation.

I delivered a woman on the 22nd day of April, and on the 23rd day of May following, I was called to see her and found her in typical eclamptic convulsions. The history in this case was that the woman had borne one child previous to this one, and she had suffered eclampsia at that time. I had seen the woman only once or twice prior to delivery, and had given her advice in regard to her diet, a few cathartics, and so forth, and she had a normal labor as far as I was able to judge. After the fourth or fifth day following the delivery, I did not see her any more until the 23rd day of May, when she had some fourteen or fifteen typical eclamptic convulsions. I looked up the literature, but could find no mention of any case in which the condition had come on so late.

This case impressed upon me the fact that this condition would occur more frequently if it were not for treatment. I am inclined to believe that this woman would have had eclamptic convulsions during labor if it had not been for the treatment she received. I noticed, in looking up the literature, that the frequency of eclampsia varies from one in every two hundred cases of labor, according to some authors, to one in two thousand. I have had four cases in my own practice and I have not delivered anything like six or eight hundred woman. I have been practicing eight years and average probably twenty-five deliveries a year, which would make it about four in two hundred cases.

Milton Board: I wish to call attention to the mental symptoms in puerperal eclampsia. They are due to the condition of the kidney. I wish to take occasion to emphasize the fact that, not only in this but in other acute toxic mental conditions, we have to deal with a diseased kidney, and when this is treated the symptoms will clear up. Now, how are we going to bring that about? Irritative diuretics will probably produce a little more urine, but when you get through you have a good deal less kidney. Hence diuretics that are in any degree irritative should not be employed. The ingestion of large quantities of water will do no harm and may do much good. The point I wish to emphasize is that by attention to diaphoresis much can be done for these patients. While I do not practice obstetrics and know very little about it in latter years, I believe that, in a city of this size, with convenient and adequate hospital facilities, it is entirely feasible and practicable to place these patients in a hospital where diaphoresis can be brought about by the proper means. I mean in advance of the eclamptic state six weeks or two months preceding labor. Give them Turkish baths, or electric light baths—something that will produce good diaphoresis and relieve the strain on the kidney without employing irritating diuretics. I know that it

works wonders in other mental conditions due to a diseased kidney, and eclampsia is the same thing in the respect that it is caused by a toxemia.

Walker B. Gossett: In regard to the anesthetic to be used in labor, I favor chloroform. I do not know of a single instance of a woman dying under the use of chloroform in labor. It is claimed that ether is much easier on the liver, but there is no doubt that chloroform is much easier on the kidneys and bronchial tubes.

I saw a case in consultation last week, in which the doctor had been called suddenly to deliver the woman. He did a version and delivered her very quickly. I do not know whether she was conscious after delivery or not, but when I was called she had been unconscious for some hours and had oedema of the lungs. In this case ether was the anesthetic used and the doctor had had no chance to ascertain anything about the condition of the woman's bronchial tubes; she might have been the subject of bronchitis. Therefore, particularly where we are called upon suddenly to deliver a woman, I think chloroform is much safer than ether. I have never used ether in my obstetrical work, and I believe that chloroform is far safer.

C. H. Harris: Two or three statements have been made here to-night with which I cannot agree. We were formerly taught that ether should not be given where the kidneys are involved. Therefore, I have always stuck to chloroform in labor cases, and have never had any trouble from it.

I think Dr. Speidel hit the keynote when he said that venesection is the thing in eclampsia. On two or three occasions I have been forced to resort to venesection in these cases, and it is marvelous how we can stop an eclamptic convulsion by withdrawing a pint of blood. Just why it is I do not know—whether it is because it lowers the pressure or drains out the toxine; at any rate, it does good.

Dr. Vaughan has reported a case in which the patient developed eclampsia a month after delivery. The present-day teaching is that eclampsia is due to some toxin generated by the foetus and that pressure on the kidney has nothing to do with it, the high tension being merely a symptom of the toxemia that exists. I think it is quite unusual to see eclampsia developing a month after delivery, due primarily to puerperal toxemia. No doubt in Dr. Vaughan's case, there were chronic changes in the kidney that produced the condition.

I have never given any one *viratrum viride* or *aeonite*. They are two drugs that I am almost as much afraid of as I am hydroseyanic acid. Tincture of *aeonite* depends upon tartaric acid to hold the *aeonitin* in solution, and is never a reliable drug. It is good for a liniment, or to drop in the ear, but we can never depend upon the

ordinary drug-store preparation being held in solution. *Viratrum viride* I am afraid of because its effect is cumulative. We may get no effect whatever from either of the first few doses and then get the cumulative effect of all of them at one time, causing the blood pressure to become very low and the patient to become cyanotic.

In regard to Dr. O'Connor's treatment of this case, it seems to me that it was a little risky to give aspirin and calomel at the same time; it is rather a bad combination to put into the stomach. I am inclined to believe that the heat produced in the stomach by the aspirin, together with the high temperature in the liver—say 107 degrees F.—would have a tendency to change that calomel into acetate of mercury.

Bernard J. O'Connor, (Closing): In regard to Dr. Harris' remarks, I have given calomel and aspirin together often, and have never seen any harmful effects from it. My object was to relieve her headache as soon as possible and to secure active catharsis, and it was due to the fact that I could not reach her immediately that I took this course. When she complained of headache, I immediately suspected an eclamptic condition.

Venesection is all right, but in view of the fact that this patient had had ten grains of calomel and a bottle of magnesia, I did not believe venesection was necessary. The bowels began to move about the same time that the convulsions came on, and it is possible that, if she had received this treatment a day or two beforehand, the convulsions might have been averted. In certain cases, however, I think venesection is indicated.

The point I wish to emphasize is the necessity of observing the blood pressure in these cases. Most authorities hold that a blood pressure of more than 165 in pregnancy is a danger sign, and one that demands attention, as it practically indicates the onset of convulsions. Certainly it did in this case. This woman had a blood pressure of not more than 150 until that morning, when it went to 180.

In my opinion, chloroform does not increase the blood pressure. Furthermore, in the presence of kidney involvement, it is less irritating to the kidney, and in eclampsia due to nephritis, chloroform is a much safer anesthetic.

Veratrum viride is a drug that I have used very little. It slows the pulse and reduces the blood pressure. One of the Eastern authorities, who has used it considerably, now decries its use. I do not know whether the experience of others will bear this out, but there are many phases of this subject that are debatable.

TWO CASES OF HODGKIN'S DISEASE.

By F. C. ASKENSTEDT, Louisville.

The recent research of Bunting and Yates, which has demonstrated the power of a diphtheroid bacillus to produce Hodgkin's disease, or pseudo-leukaemia, has added new interest to the study of this disease. These men have isolated from the affected lymph glands an acid-fast, Gram staining, polymorphous bacterium, at times resembling the diphtheria bacillus, at other times assuming the morphological characters of a staphylococcus, both forms occurring in the same gland. Those glands farthest advanced pathologically have been shown to present the largest number of bacteria, the staphylococci form predominating, while in the more recently infected glands the diphtheroid type prevails. Monkeys inoculated with cultures of these organisms have developed the pathological evidences of Hodgkin's disease and have proven capable of transmitting the infection to other monkeys by direct inoculation. Thus the pathogenic power of the bacterium is established in full accord with the accepted postulates of Koch. Hodgkin's disease is therefore now recognized as an infectious disease due to a specific organism, and this knowledge insures a more intelligent treatment, both prophylactic and therapeutic, in the future management of the disease.

While not rare in occurrence, Hodgkin's disease is overlooked often enough, at least in its earliest stage, to merit a more careful consideration by general practitioners, and this has induced me to report the two cases which follow, although neither presents features of peculiar interest.

Case I. Mr. M., came to consult me in June, 1911, for backache and pains in the right side of the abdomen, which he attributed to an attack of "la grippe" during preceding March. He also complained of distension of the abdomen, with inability to pass gas either up or down, as she expressed it. At night he was restless, and a sense of weakness was present at all times. During previous years he had been enjoying unusually good health. At the time of the examination he was 59 years of age, weighed 182 lbs, and measured 5 feet 5 inches in height. A considerable swelling of the left side of the neck, due to enlarged cervical glands, was observed. There were also a few enlarged glands in left groin and in both axillae. These glands felt rather hard to touch, were not adherent to the skin or surrounding structures, and were not tender. On the left tonsil a caseous mass, about the size of a pea was noticed. After removing this mass with a cotton applicator, the tonsillar surface beneath it appeared perfectly

normal. The patient had a dry cough, but physical examination of the lungs and a von Pirquet test applied proved entirely negative. Respiration was 32, pulse 88, and a temperature would rise each day to 100 degrees. Blood pressure taken while patient was lying, was 122 m.m., systolic, and 90 m.m. diastolic; while in the standing posture it was much lower—systolic 90, diastolic 70. second dorsal, first, fourth and fifth lumbar vertebrae were tender to pressure. The bowels moved regularly, and urination was normal. The urine was free from albumin, sugar, and excess of indican. A blood count showed 4,976,000 red cells, 88 per cent hemoglobin, and 23,166 white cells, distributed as follows: small lymphocytes, 4 per cent; large lymphocytes and transitional, 3 2-3 per cent.; polymorphonucleated leucocytes 92 1-3 per cent. No abnormal cells were discovered. The spleen was not palpable at this time upon deep inspiration. Examination of the heart failed to reveal an apex beat, largely because of the adiposity of the patient; relative dullness extended 3 inches to left and 1 1-2 inches to right of midsternum. The sounds were normal, except deficient in muscular tone.

During the following month the patient lost steadily in weight and strength. Anorexia developed and a constant dull pain in the abdomen annoyed him greatly. The glands in the right side of the neck also became involved and proved slightly tender. Both groins, Scarpa's triangles, both axillae, and the left side of the neck presented large masses of enlarged lymph glands, extending in a chain under the clavicle. Sometimes he complained of tinnitus aurium. When lying his pulse rate registered 100, systolic blood pressure 104, diastolic 85; while on standing his pulse rose to 118, and his systolic blood pressure fell to 92, diastolic to 75. Vomiting set in and became so obstinate, in conjunction with complete anorexia, that nutrient enemata were resorted to. In addition there developed a marked ascites, requiring paracentesis owing to the increased embarrassment to the respiration occasioned by the distension. The tapping yielded 1 1-2 gallons of a reddish white fluid of a specific gravity of 1016, and containing numerous red cells, a few leucocytes and 1.8 per cent. albumen. After removal of the ascitic fluid a number of enlarged glands could easily be made out in the epigastric region and the spleen became easily palpable. Rapid return of the ascites necessitated twice a removal of the tapping, with removal each time of almost a gallon of fluid, which presented a milky appearance but no longer blood. A fall of 8 m.m. blood pressure was noticed after the completion of the aspiration. As the disease progressed and the cir-

culuation became impaired general anasarea ensued, complicated by a severe and exhausting diarrhoea. The urine was now scant (450 c.c. per 24 hours), highly acid, presented sediment of urates, and contained a considerable amount of diacetic acid, with an excess of ammonia. Albumen, sugar, and an excess of indican were never present. The blood pressure, which proved refractory to the influence of adrenalin administered hypodermatically, sank to 72 after the last aspiration, two days before death, which occurred about four months after the first appearance of the symptoms.

This case presents a few unusual points to be noted: (1) The caseous mass upon the tonsil, suggesting this organ as the avenue of infection; (2) the rapid involvement of distant glands; (3) the development of ascites due, as indicated by the appearance of the fluid, to pressure upon the thoracic duct by enlarged retroperitoneal or mesenteric glands; (4) the rapid course of the disease.

Case II. Mrs. S., age 63. Spare build, weight 107 pounds. Came to the office in May, 1913, complaining of loss of strength and flesh since preceding February, and, more lately insomnia and attacks of sudden prostration. In March she had first detected an enlarged gland in left groin, and later others in different regions. At the time of the examination there were several enlarged glands in the posterior and anterior cervical regions, in both axillae and in both groins. Examination of the blood revealed 4,888,000 red cells, 95 per cent hemoglobin, and 8,700 white cells. A differential count gave 3 1-2 per cent. small lymphocytes, 3 per cent. large lymphocytes and transitional cells, 82 1-2 per cent. polymorphonucleated neutrophiles, and 1 per cent eosinophiles. There was a moderate amount of fever, intermittent in character, and the pulse rate varied from 95 to 100. The urine was free from albumin and sugar, and indican was present in but normal amount.

During the month which followed the temperature ranged from 98 to 103 degrees. There were severe and shifting pains in the chest, head, back, and limbs, and hypnotics were required to produce sleep. Appetite was lost and nausea became frequent. Axillary, inguinal and cervical glands continued to enlarge, forming considerable masses. Under the right clavicle a chain of glands showed an extension into the thorax. That the mediastinal glands were also involved was apparent from a turgescence of the veins of the chest. Notwithstanding this marked and general involvement of the lymph glands the spleen failed, even after deep inspiration, to be palpable, while the patient remained un-

der observation. A mitral regurgitation accounted for a moderate degree of hypertrophy and dilatation of the heart. Systolic blood pressure was 132 m.m., diastolic 95. Respiration 22, and pulse varied from 88 to 112.

The subsequent course of the case was without interest. Diarrhoea alternated with constipation; fever, pains and gastric symptoms showed considerable fluctuations; and a general decline was noticed. In July the patient removed from the city, and died the following September.

This case ran a subacute course of about six month's duration, with the symptoms of a typical febrile form of pseudo-leukaemia, if we except the absence of palpable spleen and of hemorrhages or petachia.

The treatment of these cases was not limited to the resources of any one school, but no tangible influence upon the course of the disease can be claimed by any agent we employed. X-ray exposures were considered in the second case reported, but on account of the rapid and extensive involvement of so many different regions, the radiologist consulted did not deem such applications advisable.

To-day a ray of hope is heralding a brighter day for the future treatment of such cases. The discovery of the specific cause of the disease, the bacterium *hodgkini*, has led to the employment of autogenic vaccine, which, though failures are frequent, has afforded some encouraging results in the few cases so far reported. I refer to a paper by Drs. Billings and Rosenow, published in the issue of Dec. 13, of the *Journal of the American Medical Association*. The early surgical removal of the focus of infection has also given favorable results in some cases.

Fully realizing the shortcomings of this report, I hope nevertheless, in closing, that one lesson of practical value has been conveyed, viz: In the diagnostic consideration of all enlarged lymph glands remember the possible presence of an incipient Hodgkin's disease.

DISCUSSION.

Carl Weidner, Sr.: Dr. Askenstedt stated in his report that in this case the disease ran a course of only about six months. This was rather a rapid course. Most of those that I have seen extended over a period of two or three years.

In a number of post-mortems that I have made in these cases, I have found practically every gland in the body enlarged, resembling, as I once made the comparison, the bunches of garlic that we see hanging in the stores, varying in size from a hazelnut to a large walnut.

I have tried the arsenical treatment in a number of cases and, while it seemed to bring about

temporary improvement, the terminations of my cases have been uniformly fatal.

I notice that recent investigators have discovered what they believe to be the specific organism of Hodgkin's disease, but I am inclined to doubt that it will prove to be the true cause.

One very interesting phase of the subject that has been discussed a great deal, is whether or not Hodgkin's disease is tuberculous in character. Some authors claim to have traced a good many cases to this source, but whether or not the tuberculous trouble in such cases is a secondary infection is a question that remains to be settled. The main difference between the ordinary tuberculous process and Hodgkin's disease, is that in the latter condition the glands do not become broken-down; they remain more isolated. The blood pictures of the two conditions are also distinctly different. However, some of the recent authors have described cases where a tuberculous condition of the glands existed and which had been diagnosed as Hodgkin's disease.

Wm. A. Jenkins: Just a word regarding the etiology of Hodgkin's disease. I do not believe it can be considered an accepted clinical fact that it is due to a specific organism. However, the evidence seems to be accumulating in this direction, and the trend of modern text-books and among the best clinicians seems to be to classify Hodgkin's disease among the infectious granulomata. Most of them believe that, sooner or later, it will be conclusively demonstrated to belong to that class. The rapid course of the disease and the febrile curve are distinctly suggestive of an infectious process. Upon section of the glands removed we find two conditions that are strongly suggestive of an infectious process. One, more or less characteristic, is eosinophilia, and the other is the presence of giant cells. Both, from the standpoint of histology, are indicative of an infectious process. Differential diagnosis, when modern laboratory methods are employed, should not present great difficulties. The blood picture will at once differentiate Hodgkin's disease from true leukemia, either of the myelogenous or lymphatic type. So far as tuberculosis is concerned, it is now generally accepted that those cases supposed to be of tuberculous origin, are really cases in which an intercurrent tuberculous infection has taken place. Therefore, the tuberculous condition is secondary rather than primary. For the purpose of differential diagnosis, we have the family history and the various reactions for tuberculosis; likewise for syphilitic conditions we have the therapeutic test and the Wasserman reaction.

Just a word in regard to the case of myelogenous leukemia reported by Dr. Grigsby. There are three things to use in this type of the disease; (1) arsenic; (2) exposure to Roentgen rays, and (3) the benzole treatment. Of these, the latter is perhaps the most theatrical in its results,

When there has been a marked reduction in the number of white blood cells, it is time to discontinue the benzole treatment. In the cases in which I have seen this remedy used, it has certainly exerted a marked influence in bringing about a reduction of the number of white blood cells, with a corresponding increase in the number of red blood cells and hemoglobin percentage. It is usually administered in doses of ten drops, in a soft gelatin capsule, followed by a glass of milk, three times a day for two weeks, then a rest of two weeks, and then resuming the treatment, and so on, making intercurrent examinations of the blood at intervals of ten days or two weeks, and when the white cell count has been materially reduced, then, after a period of rest, switch over to some of the arsenical preparations and give it in increasing doses.

I believe the concensus of opinion among foreign observers at the present time is that the improvement following this treatment is temporary rather than permanent. This will have to be settled in the future.

Leon K. Baldauf: I would like to ask Dr. Askenstedt if he made diagnosis on the clinical symptoms alone in this case?

F. C. Askenstedt: Yes, sir.

Leon K. Baldauf: While I do not mean to imply that the diagnosis in this case is not correct, I believe the safest method of making diagnosis of Hodgkin's disease is to take out a gland and examine it microscopically. Histologically, the picture of Hodgkin's is perfectly distinct; no other glandular lesion presents a picture like it. Dorothy Reed gave probably the first and most careful description of the glands in Hodgkin's disease, and she believed that some of the cases that Hodgkin himself described were not really Hodgkin's disease.

While, as Dr. Jenkins has stated, the evidence seems to indicate that Hodgkin's disease belongs under the classification of infectious granulomata, there is still some question about it. It is true that we find giant cells, eosinophiles, a great increase in the fibrous tissue, etc., but the giant cells differ from those found in other infectious granulomata, such as syphilis and tuberculosis. Dorothy Reed emphasized the point and it is now generally accepted, that where we find (as we frequently do) tuberculosis co-existent with Hodgkin's disease, the tuberculous infection is secondary; that when the glands are removed in the early stages of Hodgkin's disease, they show no tuberculous infection, whereas in many cases of Hodgkin's disease, examination of the glands in the latter stages will show tuberculous lesions, demonstrating that the tuberculous infection is secondary rather than primary.

Hodgkin's disease does not act exactly like an infectious condition; it acts more like malignant disease. These patients have a definite

anemia. Dr. Askenstedt's cases do not show quite enough anemia.

Carl Weidner, Sr. Is it not a fact that these cases sometimes do not show marked anemia even after the disease has existed for some time? I have found as many as three or four million blood cells after the condition had existed for a considerable length of time.

Leon K. Baldauf: That shows anemia, but a hemoglobin percentage of ninety-five does not show an anemia at all.

F. C. Askenstedt, (Closing): As pointed out by Dr. Weidner, the duration of the disease in these cases was unusually short; as a rule, it averages from one to two years.

As to the diagnosis, I believe with Dr. Baldauf that to obtain absolute proof, a microscopical examination of the glands should be made, but practically it seems unnecessary in many cases. In private practice we do not always have the same facilities that we have in hospital cases, and microscopical examinations of the glands in my cases was not possible. I am, however, convinced that these were cases of Hodgkin's disease. In the first place, I know of no disease other than Hodgkin's disease, except leukemia, that would bring about involvement of as many sets of glands in as short a time as occurred here. The progressive debility, emaciation, diarrhoea and cough showed involvement of the intestinal and bronchial mucous membranes, which, together with enlargement of the spleen in the first case, and the absence of excess of mononucleated white cells, made up a typical picture of Hodgkin's disease. Both cases had fever, which does not always occur in Hodgkin's disease. Here, however, it accounts for the increased numbers of polymorphonucleated white cells. As to the red cells, it not infrequently happens that these will not show a decline in the beginning of the disease. I read an article some time ago in which a number of cases was reported, and I was surprised to note that one-half showed a normal blood count. In my cases, if the blood count had been repeated a few months later, I should probably have found a reduction in the red blood cells. In each case, however, the blood count was made about a month after the inception of the disease, so I do not think that the findings speak against the diagnosis.

In regard to the etiology of Hodgkin's disease, in 1910 Fraenkel and Much first advanced the theory of a diphtheroid bacillus as the cause, and the question has been one of more or less dispute since that time. However, the researches of Bunting and Yates in the past few years have furnished positive evidence. They succeeded in cultivating a diphtheroid bacillus which, upon injection in pure cultures, into monkeys, produced the typical pathological lesions of Hodgkin's, and the enlarged glands upon examination presented a histological picture identical with

those of Hodgkin's disease. Furthermore, inoculation of other monkeys with these glands reproduced the disease. Not only that, but Billings and Rosenow of Chicago, have treated twelve cases of Hodgkin's disease with the autogenous toxin of these patients, and all but one showed improvement. One case made a complete recovery. It is something we may well take notice of.

MEDICAL PROGRESS

DEPARTMENT OF MENTAL AND NERVOUS DISEASES.

By T. J. CRICE, Louisville.

Since Lambroso enunciated his views as to the physiognomy of criminals which caused him to place them in a class by themselves, he has gained many adherents with views modified and also extended. There has developed naturally enough an opposing army of thinkers, who may be divided into those who place the blame for criminal offenses entirely on the social environments of the offender; including his training or rather lack of training from birth to maturity; and those who regard him as wilfully vicious even though morally defective and therefore responsible for his actions.

It would seem that in the course of the controversy the latter view has steadily been losing ground. While the former has not as yet made good in the minds of many, it has lost many from its camps, because of disappointing results, following half-hearted attempts at prison reform without any practical knowledge of the material dealt with. Some of this so-called prison reform for political advertisement and to be able to secure some character of institutional "job" has been practiced to some extent in this state. More and more champions of the Lambrosian idea in its essence, namely that the criminal is inherently abnormal, has come to the front with evidence more or less, and criminology at the present time is fast becoming a medical science rather than a legal one.

There appeared an article written by Dr. Bruce Thompson, 1870, Resident Surgeon in one of Scotland's prisons which argued from the medical point of view in strong terms.

"On the borderland of lunacy lie criminal populations." It is a debatable region, and no more mixed problem comes before the medical psychologist than this, viz., where madness ends and madness begins. The inmates of asylums and of prisons are so nearly allied that thin partitions do their walls divide. The following propositions I believe are well worth our consideration:

1. There is a criminal class distinct from other civilized men.
2. The criminal class is marked by peculiar mental and physical characteristics.
3. The hereditary nature of crime is shown by the family history of criminals.
4. The transmission of other nervous disorders with crime in this class proves the alliance of hereditary crime with other diseases of the mind, such as epilepsy, dipsomania, etc.
5. The incurable nature of crime in the criminal class goes to prove its hereditary nature.

With these propositions, justified or not, they go to show the impression that a close study of the criminal made on a careful observer before the days of modern psychiatry and psychoanalysis before the realm of the sub-conscious mind had been explored by Charot, Freud and Judin, but this new school or phase of the subject is by no means on a footing sure enough to convince either the public at large or the legal profession of the justification for its point of view, nor has it received often enough that respectful hearing in the courts which would have prevented injustice being done not only to the prisoner at the bar of justice, but also to society. Nevertheless, complete justice to both offender and society is slowly on the way and even those who oppose or take no thought of the newer doctrines are unconsciously following in line with them by their attempts to ameliorate the conditions of the convict by agitating for prison reform.

Indeterminate sentences, the parole system and the changing of the prison into an institution for correction and custody rather than punishment. True enough, more of sentiment than of science is back of these methods, and therefore in many individual instances harmful injustice to society and ultimate harm to the offender against society is wrought. This is inevitable in any period transition from an erroneous to a more correct method of dealing with social problems, because of a contact gradually growing more intimate.

Justice to all will come nearer, and it is the psychiatrist, with his collaborator, the psychologist on whom the responsibility may rest most heavily if the newer ideas of the crime as a disease of the criminal as a sick man are to prevail. There is no longer any credited opposition to the view that criminal offenses, petty or otherwise are the product of individual and social disease. With the latter aspect of the subject I am not at present concerned. While the influence of the environment for those most charitably inclined, excuses the offender from responsibility for his condition;

it does not excuse him from responsibility for his acts. But if any offender is a diseased person in the psycho-physiologic sense, his responsibility must come into question before the courts of justice.

Question of Responsibility. Many a medico-legal battle has been fought over this question. The issue has been confused usually because the legal mind has ever thought of consciousness as synonymous with sanity. Because a man knew what he was doing the lawyer has held him responsible, but a man's mental make-up is a very complex thing; it is a bundle of psychic forces and habits which may be summed up in three divisions.

1. Intellect, or consciousness.
2. Emotion, that is, impulse to act.
3. Will, that is, action itself. No two persons are alike in the strength or weakness of one or the other of these forces.

To take the view that consciousness of the wrongfulness or illegality of an act at the time of its commission makes the offender responsible for it and legally sane is inconsistent with the well-founded knowledge of mental functions which we now possess. Conduct is not dependent chiefly on knowledge, but much more on impulse or emotion and a will, capable or incapable of controlling and directing impulse in a way to harmonize with knowledge; that is consciousness. It is just because this complexity of function that so many different kinds of crimes are committed and so many different types of criminals exist and the more or less inadequate classification of criminals that have been attempted by various writers will show when analyzed that consciously or unconsciously the classifiers have characterized the objects of their study according to the mental function most involved in them. Classification:

1. The criminal by instinct who is the born criminal.
2. The passionate criminal who commits crime under the influence of passion.
3. The criminal from chance.
4. The criminal from habit.
5. The insane criminal.

In the first group would be placed those who by reason of some inherent defect involving the intellectual and emotional functions are incapable of developing the sense of love, self-sacrifice, pity, honor, altruism or remorse. Persons whose standard or right and wrong can never be the same as that of the average member of society in the period in which he lives.

These are cases of arrested development in the ethical sphere and represent reversions in this faculty to primitive types. Illustrations of the brute instinct which we all possess, are seen in the class of criminals, whose acts are

due to passion, becoming of sufficient provocation, beyond control, because of weakness of will in the nature of a deficiency or inhibition power in the nervous system. Now it is known from physiologic investigation that it is a function of certain nerve cells and fibers in the cortex of the cerebrum.

In the case of the criminal from choice, we are confronted with a feeble-minded person who is easily made the subject of suggestion, because of deficiency of judgment and who responds to the criminal suggestion because of deficiency of inhibition. Persons of this kind are the tools of the more intelligent in crime, and harmless in themselves, in an environment in which they are safe-guarded from temptation, they lead normal lives. They are children all of their lives in so far as their faculty of judgment and power of will are concerned.

In the class of habitual criminals are to be found those who by reason of environment, especially early environment, lead criminal careers in response to the association of ideas which their environment has aroused, or which has been aroused by psychic shocks during the age prior to that of mature judgment. These shocks have affected the subconscious mind in a way to make it seek relief in periodical reaction, usually of a resentful retaliative nature. Such a career is for them the path of least resistance.

The first crime has relieved the depth of the sub-conscious mind from tension and thus aroused in it sufficient pleasure or desire to cause disassociation of emotion from intellect at the time when the opportunity to commit the crime again occurs. Persons of this kind from the class of recidivists or repeaters and it is noteworthy that prison officials have reported that the subsequent offense of the repeater is exactly like or similar to the preceding one. Their condition may be compared in a measure to that of the kleptomaniac in whom, however, there is a much wider disassociation of consciousness and who is more definitely insane. They may also be compared or likened very closely to the hysterical patient as regards the essence of the disorder. In the definitely insane group of criminals, that is, those having one of the clear-cut psychoses, there are all grades of mental disintegration involving, as in the borderland cases, one or more, or all of the functions of mentality.

Those most prone to commit statute offenses are the paranoiacs. With his disruption of judgment, the epileptic, in whom consciousness is almost entirely split off and who at the time of the act is almost entirely a sub-conscious automatic personality; the kleptomaniac, the dipsomaniac and other drug ha-

bitnes, especially the cocaine fiend, who may commit violence in reaction to hallucinations. Responsibility for crime, committed by persons of this kind can be at once dismissed. But when there are offenders of the first four classes enumerated, to consider, we are brought face to face with the borderland cases, these in psychiatry. These comprise that vast number of unfortunates who are psychopathic, but are rarely committed to hospitals for the insane and are so disposed of only in their episodal periods of excitement or quarrelsomeness. When they recover to their usual level, they are again discharged into society; no more fit than before to cope with its complexities. Among these are the ones who commit petty offenses for which they are sent to jail, workhouse or reformatories for short terms; after their release they soon are returned because of inability to get along in any environment in which they are not closely subjected to organized discipline. They behave very well in custody and if kept so for prolonged periods, would gradually develop habits of self-control, concentration of mind and industry, which would make them self-supporting in occupations fitted for their capacities. The vagrant, the browler, the gangster, the prostitute, the ne'er-do-well all belong to this group. They have been called by several writers "Constitutional Inferiors" and this is a correct term to apply to them. If the particular function of mentality in which they are inferior is designated, otherwise the term is unsatisfactory, for in some of their capacities many of them are found to be exceptionally brilliant or at least superior to the average; that is, in music, drawing, literature and inventions. For these, one writer prefers the term "Constitutional Abnormality." All offenders indeed may be characterized by one or more of the following attributes:

1. Exaggerated suggestibility.
2. Exaggerated egotism.
3. Emotional instability.
4. A lack of altruistic or unselfishness.
5. Lack of the power of sustained energy that is abnormal nervous fatigue.

6. A tendency to the easy disintegration of consciousness which permits the brutal or inferior qualities of the subconscious mind easily to become dominant when temptation occurs and to be uncontrolled by the critical quality of the conscious mind; even when the critical function is sufficiently aroused, the power of direction by the will is in abeyance. Here is again some of the similarity in mental make-up of these persons to that of one affected with hysteria.

Treatment of the Criminal Insane. Are we to abolish prisons and penitentiaries and take

the pessimistic view that all crime is incurable? Shut up all offenders in asylums for the remainder of their lives? Abolishment of punishment is certainly called for and it seems it is gradually coming as the prison is gradually changed into a house for correction and custody, into a colony for abnormal people where they may live as nearly normal a life as possible. Where their individual characteristics and capacities are studied and their lives arranged accordingly. The same change has already occurred in the methods of dealing with the insane as may be seen by a visit to some of our up-to-date State Hospitals.

If these methods are worth while in the case of the chronically insane, they are still more so in the treatment of criminal offenders who though mentally abnormal, are in the majority of instances, amenable to much greater improvement in habits of thinking, feeling and acting; however, such treatment cannot be accomplished without the supervision and co-operation of the medico-psychologic profession. It is perfectly possible for those who have associated for a long time in a professional capacity with psychopathic persons to determine who is amenable to this, that or the other form of correction and to tell when the person is sufficiently corrected in his neuropsychic functions to justify his parole into normal society. It is also perfectly possible for those of the legal profession to determine who should be kept in permanent custody. It is not possible for those of the legal profession to determine these questions justly unless they also have had the training of the physician and the psychiatrist, nor is it possible for them to frame just laws as to penalties. The question of trained physicians I think should especially apply to our insane asylums instead of the courageous politicians dictating who should treat our sick insane in the state of Kentucky.

It is not unreasonable therefore, to foresee the time when the function of the lawyer and the judge will be restricted to the determination of the guilt of the offender and the function of prescribing what is now called the "sentence or penalty," but which some day will be called the therapy or treatment, will be taken over by physicians well-trained in mental diseases who are in the service of the State and consequently free from bias judgment.

namine, gr. x (0.6 Gm) thrice daily, found effectual in preventing retention of urine and avoiding necessity for catheterization.—Baird.

TYPHOID FEVER.*

By J. F. ADAMS, Bagdad.

Typhoid fever is an acute, infectious disease, the cause of which is the bacillus of Eberth. Pathologically it is characterized by hyperplasia and sloughing of the solitary follicles and Pyer's patches of the intestines, associated with parenchymatous changes in the principle viscera.

Typhoid fever may occur at any age but is especially frequent between the ages of 15 and 25 years. It is less frequent later in life although it has been known to occur in persons over 70 years of age.

MODE OF INFECTION.

In most cases the germ is swallowed, but I believe it is conceded that it may reach the circulation through the respiratory organs, then again it is admitted that they may develop some initiatory lesion in the lungs, pleura or the tonsils then pass into the circulation.

The period between the time the germ enters the system and the development of active symptoms is usually 10 days to 3 weeks, though sometimes longer and occasionally not so long. During this period the patient may not experience anything aside from his normal constitution, but in most cases he complains of headache, languor, muscular pains in the back and limbs and a lack of disposition to work. This condition may last from a few days to a week or even two weeks. Now in a typical case (which I shall confine myself to in this article as it would take too much time and space to speak of all the different types of this disease) we find three distinct stages: first; stage of development, second; stage of fatigium, third; stage of decline. The stage of development is as a rule very gradual, patient usually complaining of chilly sensations and hot flashes with increased prodromal symptoms. We seldom see typhoid ushered in by a distinct rigor and often about this time when we are greatly in doubt as to the nature of the patient's trouble, nose bleed may occur and thus clarify the diagnosis. These symptoms are soon followed by prostration of patient so severe as to cause him to go to bed. Again the disease may be ushered in by severe nervous symptoms as spasm especially in children, or some pulmonary symptoms as bronchitis.

As the initial period progresses the symptoms assume a more severe type; we find a gradual rise of temperature each day showing an increase of from 1.2 to 2 degrees over the preceding day. This condition usually exists for about a week when the temperature reach-

es its fastigium, which marks the beginning of the second stage, which usually lasts about two weeks. During the first week of the second stage the symptoms become more severe, patient suffers more from the continued high fever, the evening temperature usually reaching 103 or 104; pulse usually rapid, but not dicrotic. The headache, which was so marked in the beginning usually ceases, but we usually find mental dullness or mild delirium, especially at night.

The tongue is coated and may be dry and cracked; the abdomen is often tender and distended and about the tenth day we find rose-colored spots on the abdomen or chest or perhaps both. The spleen may be enlarged.

About the end of this week we may have serious complications as perforation or intestinal hemorrhage.

During the second week of the fastigium the previous symptoms continue in severe form. the pulse becoming more rapid and maybe diaerotic, but the temperature may become remittent in type; this is the stage during which we are more fearful of complications as hemorrhage or perforation or hypostatic congestion of the lungs or lobar pneumonia and even if we do not have these complications, the condition of the patient is frequently serious.

This stage of the disease varies in duration according to the severity of the infection.

STAGE OF DECLINE.

We generally find or expect to find on or about the 21st day of this disease in favorable cases the fever declining and the other symptoms improving; this is usually followed by true convalescence, but sometimes we find the disease runs on through the fourth week with symptoms more severe than previous, the patient suffering from diarrhoea, stupor and delirium, feeble pulse, great tympany and even involuntary discharges from the kidney and bowel with the fever continuing into the fifth week or even longer.

CLINICAL SYMPTOMS.

To speak briefly I will say we usually find general in disposition, headache, muscular pains, stepladder type of temperature, until its full height is reached—abdominal tenderness and nose bleed.

DIAGNOSIS AND PROGNOSIS.

I base my diagnosis on the preceding symptoms, especially when the temperature resists full dose of quinine for 24 to 48 hours.

The prognosis depends largely upon the severity of the type of fever, but it should always be guarded, even in the cases seemingly the mildest, as we may have a fatal hemorrhage or perforation when least expecting it.

*Read before the Shelby County Medical Society.

TREATMENT.

As typhoid fever is a self-limited disease, characterized by ulceration of the intestine, I think the chief indications for treatment are to support the patient and keep the intestinal tract as thoroughly disinfected as possible, in order to give nature a chance to repair the ulcers. First I place my patient in a large well-ventilated room, preferably on a mattress protected by a rubber sheet and in all cases I advise them to secure a trained nurse if possible. Then as cleanliness is the first step toward disinfection and in order to cleanse the entire tract and produce a free flow of bile, which is nature's antiseptic, I prescribe calomel combined with bicarbonate of soda in 2 gr. doses for an adult until three such doses are taken and follow this up in 5 or 6 hours with oil or salts, preferably the former, and after the bowel has been well cleansed I give some intestinal antiseptic, of which I prefer salol, in doses from 3 to 5 grs. every 4 hours, according to the age of the patient.

For the high temperature I use either the warm or the cold bath, followed by an alcohol rub as indicated by the condition of the patient. I find in plethoric patients the cold bath to be the best, but in the thin, nervous cases or with children, I prefer the warm bath on account of the lessened liability of shock to the patient. I bathe for a temperature of 102 or over.

In order to assist in the expulsion of gas and thereby relieve tympany and so lessen the danger of perforation and hemorrhage, I use an enema of normal salt solution one day and give oil or salts the next. I support the heart as soon as indicated and often before. I believe it well to begin our precautionary treatment against cardiac weakness about the middle of the second week of the disease by using Strychnia in doses of 1-60 to 1-40 gr. every 4 to 6 hrs. as needed, digitalis when the pulse is rapid or diacrotic. I encourage patient to drink quantities of water and keep him on a strictly liquor diet, as buttermilk, egg albumen with lemon or orange.

I keep my cases in bed for ten days after the entire disappearance of all fever. I feed at regular intervals of 3 or 4 hours, according to amount taken and the way it is absorbed. I have patient use the bed pan every time, if possible, and have him turned frequently to prevent any pulmonary complications or bed sores and I have all body or bed linen kept perfectly clean; when soiled I have them removed and thoroughly boiled, and all discharges from the bowel, kidney, vomited matter or sputum thoroughly disinfected by using bichloride mercury 1-500 chlorinated lime 5 or 6 oz. to the gallon or a solution carbolic

acid 5 to 10 per cent; also the vessel should be kept clean and disinfected.

While I have had no experience with the Serum treatment, except as a preventative, I am heartily in favor of it.

For the delirium I depend on opium in some form, preferably morphine hypodermatically. For intestinal hemorrhage I depend on morphia as required to quiet peristalsis and elevate the foot of the bed, apply ice locally over the abdomen and after the bleeding ceases I usually wait from 48 to 72 hours and move the bowels by enema of normal saline and keep patient in recumbent position till all danger of a recurrence of the bleeding has passed. In severe hemorrhage I use normal saline subcutaneously or intravenously. For perforation, while we have had some brilliant results from surgery, I have always been very successful in letting my cases all die, but I try to let them die as easily as possible by keeping them under the influence of opium.

For the dry, cracked tongue I give turpentine in 5 to 10 drop doses, 3 or 4 times a day and mop the mouth often with some alkaline preparation.

I think we often discharge our patients too soon after convalescence begins, I believe we should keep them under our care until all danger of relapse from indiscreet feeding has passed and after they are discharged, the room and all the clothing and carpets exposed should be fumigated.

THE RELATIONSHIP OF THE PHYSICIAN TO THE PUBLIC.*

By W. F. BOGGESS, Louisville.

It is always a matter of positive pleasure for me to meet with the profession of the towns and country. Those magnificent specimens known as the country physician, those men who have made the profession what it is, who are, next to the ministry, and along with the educator, the back-bone and sinew of American civilization.

It is also a peculiar pleasure for me to come in contact with the clientele of such men. The people who hold up the hands of the physician, who assist him in every way possible in his wonderful unselfish work of saving life, relieving pain and preventing disease. Such altruism as is exhibited by the physician is not shown in any other phase of human life and human activity.

With all this pleasure, however, I always feel somewhat embarrassed in determining my line of thought before an audience of physicians and laymen. It is somewhat difficult to

*Public address at a meeting of the Cumberland Valley Medical Society, Corbin, Ky., on March 26, 1914.

make a professional subject so plain that even a child can understand and appreciate it, and at the same time not appear purile to my erudite professional friends. Yet the layman and the doctor meet on such intimate and important ground, the one so dependent upon the other, and so closely associated not alone in matters of life and death, but in the more sacred confines of home and its protection that I feel there are many subjects, such as the White Plague, the Venereal Peril, Infant Mortality, The Abortion Evil, the Decreasing Birth Rate, The Divorce Mill, Child Labor, The Prevention of Blindness, The White Slave Traffic, Physical Conservation and many other of like importance, about which the profession and laity should meet on a more confidential and intimate plane. In my mind there is so much about which I should like to have a heart to heart talk with my brethren, all practical, all important, and all worthy of a better mind to present, yet it is not my purpose to confine myself to any one line of thought, but shall present in an uncongruous way some thoughts with the hope of exciting present interest and present facts and ideas for future elaboration and study.

Permit me, again to pay a tribute, so deserved, to these splendid professional characters of your county, these noble general practitioners who, with their splendid manhood, that every physician should have, are striving with an altruistic spirit to come in closer touch with you, the people, in our modern warfare against disease and death. For it is through you, the layman, that we can hope to obtain such results. In the battle of life there are, or can be no hired substitutes—an axiom and a truth that no one can appreciate better than a physician. Permit me here also to say that while the layman is carried away by the wonderful and spectacular achievements of modern surgery and specialism, which is oftentimes purely mechanical, dealing only with the material and tangible in life, yet does not grasp, nor fully appreciate his family physician as he should. With acknowledgement of all credit for the wonderful strides of surgery within the past two decades, I must impress upon you that the innermost,—the general practitioner,—deserves as much credit and as much honor, and his achievements have been just as wonderful. He deals with the hidden and the occult. He does the scientific part of the work, makes the diagnosis. While not overlooking or underestimating the wonderful strides of surgery, I must insist that the advancement of internal medicine is even more wonderful. The painstaking pathologist and bacteriologist, the erudite and careful chemist, the scientific and experimental therapist have made di-

agnosis almost an exact science. The physician of to-day is no longer held by the shackles of empericism, but should, and is practicing an intelligent scientific medicine. One of the most wonderful advancements of modern medicine is along the line of prophylaxis, or preventive medicine. The quietness of modern achievement in medicine is the finding and determining the cause of disease and then its prevention.

The country was horrified recently by the terrific and sudden destruction of seventeen hundred lives in the sinking of the Titanic. The whole world was in mourning, and our own fair land was particularly grieved at the untimely and unexpected destruction of so many of our splendid citizenship. Yet, in the United States alone more than seventeen hundred of her citizens are dying daily from preventable and needless diseases. Over these no funeral pyres are built, no loud protestations of sympathy and condolence are uttered. The physician stands out as a beacon light crying out to the laymen for help and assistance, looking to you laymen as his only means of turning the great army of ignorance and selfishness and superstition back with the powerful forces of education and enlightenment that these public talks are given by the physician.

Without going into details I only mention here the magnificent and monumental work that the medical corps of the United States Army and Marine Service are doing to protect our country against the ravages of the Bubonic plague, which is a constant menace to our Western shores, to the protection of our citizens against cholera from the cesspools of Europe, against the yellow plague where the South American countries are in eternal danger to our fair land. The establishment of quarantine stations and leprosy colonies, health inspection of immigrants are all means and measures to keep out diseases, contagion and death. Against the ravages of smallpox and other epidemic and contagious diseases of serious character, our state, county and our municipal health officers, in conjunction with the National Government, when necessary, offer protective measures and means of great value.

Our list of infectious, contagious and preventable diseases are rapidly increasing, owing to our more thorough knowledge of the causation of disease. Disease is never accidental, suffering always has pathology, causation of disease is not always determinable, for we have not only to look to the patient's present condition and surroundings, but also to his past history, method and mode of living, and even go back beyond his birth to his progenitors and ancestors.

Let us consider a few of the conditions by which laymen can do so much for their own preservation, for the protection of themselves and their offspring, for the protection of their state, for the economic value of human life to a State is hard to estimate, and for the help and glory of their physician.

First, the Prevention of Consumption. There is no disease that quite reaches the importance and prominence at this time in the minds of the profession, as well as the laity, as does the great white plague, that awful scourge that is almost as wide spread as humanity itself, certainly as wide spread as the bounds of civilization. A scourge that comes right to the doors of every home and almost to every individual to such an extent that a consideration of any phase of the subject is of great importance.

The last census, which is in itself very incomplete, shows that one million, seven hundred and fifty thousand people in the United States are tubercular. One out of every sixty of our population is tubercular and that one hundred and seventy-five thousand persons die annually from consumption in the United States alone.

Since the discovery by Koch, in 1882, of the infectious nature of the disease the positive demonstration of the cause and the subsequent knowledge of its true pathology and etiology our ideas as to the preventability, as well as the curability of the disease have been materially changed and revolutionized. That it is an absolutely preventable disease is no longer questioned. We have been shown by positive statistics, as well as personal experience that it is not only preventable but in its early stages, curable, possibly as much so as pneumonia and typhoid fever, and at any stage except the last, capable of being arrested and checked.

So it is for a consideration of the possible prevention of tuberculosis that I come to you, not with the hope of bringing new or original ideas, but with the desire that I can awaken in my audience, both professionally and the laity, a more sincere effort to use every means and measure to prevent the further inroads upon humanity by the awful ravages of consumption. If I can awaken any one from the apathetic lethargy that comes to us from something we have always with us, something that because it is so common, so usual, we pay little attention to it, I will feel that my little talk has not been in vain. How wide awake, how excited we become in even the threatened approach of yellow fever or smallpox or some other epidemic, none of which diseases are nearly so fatal, nearly so vital and wide spread in their epidemicity as consumption, yet in the terrible scourge of

consumption we sit supremely quiet and if perchance a few of these unfortunates get well, by the grace of God, we formerly felt that we of the profession have done our whole duty by humanity. The time has come when we should wake up to the realization of not only the absolute preventability of the disease, but also our duty as citizens in bringing about that millenium so earnestly desired.

There are many phases to be considered in presenting this phase of tuberculosis. In the first place let me impress upon you the fact and a fact it is, that heredity plays no part in consumption. The disease is not transferable through the ovum from parent to child to whip up in future years. It is not heredity, but environment that is to be considered.

Only twenty-five per cent. of our consumptives show any inherited predisposition whatsoever, and in these it was not inheritance, but association with the disease, living in a tubercular atmosphere and surroundings. There are only two factors necessary for the development of tuberculosis in any individual. One is the presence of the tubercle bacillus to which we are all more or less exposed. The other is lowered vitality in the individual. The tuberculosis bacilli will not grow in healthy tissue. It will not thrive on tissue whose vitality is up to par. Anything that lowers vitality renders the individual subject to tuberculosis bacilli. Modern civilization, present methods and modes of living, fashion, dress, contention for mammon and social prominence are all destroying human vitality and resisting power. The strenuous times in which we live, the departure from the simple life are not only rendering the present generation candidates for tuberculosis, but are a menace to future generations and progeny as well. For without strong sound parentage, posterity will consist of weaklings. If the human race showed as much concern, knowledge and science in its own propagation as it does in the development of its stock and cattle, humanity would present a different picture. So in the prevention of consumption we must go back to the very beginning of a human life and the child of frail nature or one born of tubercular parents or in an atmosphere that is tubercular, must be brought up with the greatest care and guarded most zealously against any possible lowering of vitality, as well as association with any possible focus of infection.

Tuberculosis is essentially a house disease and when savages give up their rude out-door life and pass the greater part of their time between walls and under the roofs, it soon makes its appearance among them. Yet civilization will march on and the houses will always be a part of civilization, but they need

not necessarily be breeders of consumption. If we have smallpox or scarlet fever or diphtheria in a house we would not think of having a new family move into that house without thoroughly disinfecting it, and yet landlords and owners of tenant houses pay no attention whatever to the infection of a house or a room by tubercle bacilli and this just as infections under the circumstances as any of the other contagious diseases. Until we wake up to the realization of the danger from infected houses, our prevention will be worthless. It has been positively shown that the dust of rooms, hospital wards and other localities by patients with pulmonary tuberculosis contains myriads of bacilli and is infective. The infectiousness in this way is so clearly shown in that the death rate of phthisis is estimated at fifteen per cent. of the total mortality. While in prisons and sanitariums the number of nurses and attendants who are attacked are in direct ratio to the stringency in which sanitary precautions are carried out. Cornet has given us an axiom in "The consumptive in himself is almost harmless and only becomes harmful through bad habits."

Now a few words in regard to the preventability of typhoid fever. A disease that so often plays such ravages in the country and in the smaller towns among the young and the middle age of your citizenship.

This disease is absolutely preventable. For without a preceding case of typhoid fever and the contamination of milk and water or food supplies directly with the typhoid bacillus we would have no typhoid fever. The bacteria of typhoid leave the patients sick with the disease only in the excretions, urine, feces and sputum. These bacteria are capable of living for quite a while under favorable conditions outside of the body. These infective excretions through natural drainage, surface or sub-surface are carried into your water supply and rapidly contaminate. These excretions are carried by flies, birds and insects to be deposited upon your food products, this to be carried into the gastric intestinal tract, or may be carried through the uncooked vegetable, oysters and shell fish.

In one of your neighboring cities a few years ago they had a severe endemic of typhoid fever caused by contaminated ice, made from the water of a creek which was the natural drainage of the town.

We have learned to look upon the common house fly as one of the great and dangerous purveyors of typhoid infection. It was possibly the cause of the great epidemic that was such a commentary upon our inefficient army regulations that they had in our military camps particularly at Chickamauga during the Spanish-American war. Swarming from

the sewer ditches to the kitchen and the dining room, and thus carrying the infection to the food. Hence, the constant cry through the magazines and newspapers and social circles of "swat the fly." To guard against the infection of typhoid, precautions must be taken to prevent the access of infected substances into the mouth. From the hygienic standpoint, especially in regard to typhoid, the pure water supply, inaccessible to contamination is one of the most valuable and important possessions of any community.

By preventing the infectious material being distributed from patients it is theoretically possible to stamp out and prevent typhoid fever in a given district. Not only should the water supply be looked into, but the milk supply is undoubtedly responsible for many cases. One drop of contaminated water in the milk can of warm milk fresh from the cow is capable of infecting many gallons in a few hours, and cause localized epidemics among the people who use this milk.

Our chief aim in prophylaxis, therefore, should be to prevent the distribution of bacilli by destroying them in the excreta as soon as possible after they leave the patient. In this way we not only can prevent contact and direct infection, but by lessening the total number of cases in the community, and so preventing the chance of the infectious agent entering general sources of food and water supply, we may aid in preventing epidemics. The greatest difficulty is in the early recognition of mild cases. These mild cases are especially likely to occur in young children. Correct diagnosis, therefore, becomes an important part in the prophylaxis of the disease. This is greatly facilitated by our present bacteriological methods, and when possible these should always be employed. But for prophylactic measures to be inaugurated it is not necessary to wait for exact, positive diagnoses, but these measures should be put into execution in all cases where there is a suspicion that typhoid fever exists.

Whenever you have a case of typhoid fever in the country or in the town, you should at once give all persons who are likely to have been exposed to the same source of contamination, the typhoid vaccine, for by this artificial immunization it is possible to prevent the infection of persons exposed to the contagion.

I will not take time to call your attention to the wonderful positive results of typhoid vaccination. It is very close to the marvelous, it is without danger, it can be given with absolute immunity, and should be given in all cases where a possibility of exposure to infection is assured. It is also a remedy of much value in the typhoid carriers in whom the ty-

phoid bacillus lives for years, who go about the country spreading the infection from place to place. Typhoid vaccines given in sufficient quantity and sufficiently frequent will render the carrier immune.

I regret that my time will not allow me to go fully into the methods and disinfection of the excretions of typhoid fever patients. I leave that to the intelligence of your physicians who have the cases in charge.

The prophylaxis of venereal diseases is also a question of extreme importance and of paramount interest, not only to the present generation, but for the generations to come. It is a question that we hesitate to handle in a mixed audience, yet whose business it is to instruct in this matter of venereal diseases and their prevention? It should be, but is not, the business of parents to instruct their children, for parents themselves are ignorant. It is not the business of teachers—for such subjects are not embraced in their curriculum, for most of the teachers are themselves young and ignorant and are not capable of handling the subject before a child in a way that it would be educational.

It seems not to be the business of politicians or judiciary or so-called statesmen, for they seem afraid of injuring their political chances, and in the plans of the practical politician, the Utopian dreams of enthusiastic reformers have no place. It seems not to be the business of preachers for they oftentimes know little of the world's ways, and are too often concerned with the "soul's eternal salvation," forgetting that there are sins against the body as well as against the spirit, for which the divine Creator holds us equally responsible. The strange paradox which requires of the ministers of at least one great branch of the church that they refuse absolutely to marry persons who have been divorced, and yet permits them unhesitatingly and cheerfully to proceed to unite in holy wedlock the pure, innocent, unsuspecting young girl, with the gay young man about town, whose blood at that moment is reeking with deadly virus of specific disease, is worthy of thoughtful consideration. The ignorant father of such a girl asks no questions, the shortsighted and improvident state which grants the license asks no questions, the man of God, as he stands in the presence of high heaven before the contracting parties and their assembled friends, does ask a most vital and significant question, which, in its form and upon its face, is apparently an earnest appeal for important information but as he waits for one brief ominous moment after repeating the solemn charge "speak now or forever after hold your peace" he does not expect an answer. So when it revolves itself a

question for the physician to decide this problem of the control and limitation of venereal diseases and to be educator and instructors to the great mass of people who are both ignorant and take not time to consider the welfare of their children and grandchildren.

All of this in regard to venereal diseases brings us to that splendid field for socialistic and economic propaganda which we term eugenics, which simply means proper and right race propagation.

Let me reiterate if the human race showed the same care and concern and science in its own propagation as it does in its cattle and fowls and hogs, and even in the vegetable life, the human race would show a very different and more magnificent picture than it is showing.

Not only in the problem of clean parentage and consequently clean and wholesome physical children, but the development and growth of the mind and character requires the same careful instruction and handling as the cultivation of the most delicate plant and flower.
