I am sure Prof. Gemmill will agree with me as to the desirability of researches on the development and metamorphosis (and, not least, the postembryonal development) of many more forms than those few, which have been studied up to now. Not even the development and metamorphosis of Asteropecten has been studied by means of modern methods, the researches of Joh. Müller and Metchnikoff still remaining the only base of our knowledge of this subject. I hope very sincerely that Prof. Gemmill will extend his admirable studies to this and many other Asteroids, as I also hope that both he and Prof. MacBride will agree that my efforts to widen our knowledge of the development of Echinoderms are not entirely without value, and that the views expressed in my work, however much they may disagree in them, are not entirely without reasonable foundation.

Th. Mortensen.

Zoological Museum, Copenhagen,
January 22.

I shall summarise the points at issue between Dr. Mortensen and myself as briefly as possible.

He complains that I made an "unprovoked personal attack" on him. Nothing was further from my intentions. The so-called attack was a criticism of certain views attributed to Dr. Mortensen by Dr. Bather in a review of one of Dr. Mortensen's recent works in Nature. Dr. Bather seemed to think that Dr. Mortensen believed that after all the development of Echinoderms might be an alternation of generations as Johannes Müller originally suggested. As Dr. Mortensen has unreservedly repudiated this view there is nothing more to be said on this point.

But Dr. Mortensen did say that the fixed stage in the development of Asteroids (discovered by me in 1893) was of secondary character, because it was absent in two families (Astropectinidæ and Luidiidæ) classed together as Paxillosa. I had a perfect right to comment severely on statements such as these, because (1) the fixed stage is found in the most widely diverse families belonging to two of the great primary divisions of Asteroidea. (2) The fixed stage regarded as an ancestral reminiscence, enables us to understand how and why the ancestors of Asteroidea passed from the stage of free-swimming bilaterally symmetrical animals to the stage of radially symmetrical forms creeping over the bottom. (3) If Dr. Mortensen had known what he as a specialist in Echinoderms might reasonably be expected to know, namely, what has been determined as to the physiology and habits of Luidia and Astropecten, he could never have regarded them as primitive, but would have recognised them as what they are, the most specialised of all Asteroidea.

It is not a question of the ground on which particular starfish can be dredged up. Every marine biologist knows that sporadic individuals of rock and gravel-inhabiting species can be dredged on sand or mud. The dredge, indeed, gives no precise information as to the habitat of a species, for the bottom is usually "patchy." But Luidia and Astropecten *when observed in life* are found to be *burrowing species*, which when at rest are almost completely buried in the sand or mud in which they live like many Ophiuroids, and the structure of the arms is modified in relation to such habits. A fixed stage in the ontogeny of such forms would be an impossibility, for in such an environment the larva would find nothing to which it could attach itself. By a happy coincidence I received a few days ago Part V. of W. K. Spencer's "Palæozoic Asterozoa." In this work I read "The existence of large marginals throws no light on the affinity of extinct species, but it does throw light on the shape of the arm" (*i.e.* it is adaptive). When the arm is flat and the dorsal skeleton reduced to a flexible membrane the borders of the arms must be strengthened.

Dr. Mortensen accused me of referring contemptuously to certain specialist students of external features only. I am afraid I must plead guilty on this count. I have spent weary time in going through the ponderous works of Sladen and Ludwig, and so far as any attempt to correlate structure with function is concerned, these authors might just as well have been describing postage stamps as Asteroidea. The distinction between Phanerozonia and Cryptozonia was made by Sladen. The Phanerozonia were stated by him to be the original and primitive group (*a*) because fossil starfish were all phanerozonate, (*b*) because cryptozonate forms when young are phanerozonate.

I have never been able to find the evidence on which (*b*) is based. I have often seen young imagines of Asterias and Asterina, but there is certainly nothing "phanerozonate" in their appearance. Statement (*a*) is absolutely inaccurate. If Dr. Mortensen is open to conviction on this point let him study W. K. Spencer's monograph, where he will find every fossil form from Palæozoic strata carefully described, and further, an attempt made to correlate its structure with its probable habits. He will learn that Cryptozonia are just as old as Phanerozonia, and that the oldest starfish of all are neither Cryptozonate nor Phanerozonate and have no plates corresponding to the marginals of Astropecten at all.

Lastly, as to the accusation that I belittled Dr. Mortensen's work. I have no wish to depreciate his work, but with the exception of the treatise on the Crinoids (Comatulidæ), which is irrelevant to the point at issue, it is not what I regard as embryology at all. By that term I understand the attempt to follow through the development of the organs of the adult from their beginnings in the embryo or larva with a view of obtaining light on the ancestry of species. Dr. Mortensen's researches on Echinoderm larvæ have been purely classificatory, and he has done valuable work in determining which larval forms belong to certain adults. His recent work on Comatulidæ, it is true, is embryological: he has confirmed the results of Bury and extended them to other species; but he dismisses the conclusions of other embryologists without sufficient consideration of facts.

Medical Education.

I AM sorry Prof. Dakin (NATURE, February 3, p. 151) should think my letter (NATURE, January 13, p. 50) merely an attempt to open another discussion on evolution. I do not know how I could have expressed myself more clearly. Manifestly, a knowledge of such things as the anatomy of frogs and dog-fish cannot persist in the minds of medical students or be useful to them intellectually or professionally unless linked with other studies. They can be so linked only through truths about development, variation, heredity, and evolution. But here the naturalist is in conflict with the physiologists, psychologists, pathologists, and medical men into whose hands the students pass and whose opinions, abundantly supported by evidence, they always adopt.

It is one thing to demonstrate that evolution has occurred, and for this none are better qualified than naturalists. But evolution is not disputed by medical men, though, owing to the biology they learn, few give it a thought. It is quite another thing to demonstrate the method of evolution. Here, to say the least, naturalists are not in a position to ignore evidence derived from other sciences. For example, they have very diverse opinions about fluctuations. But did ever a naturalist see a fluctuation in a living being existing under natural conditions, other than man (*e.g.* a sparrow or house-fly, the most familiar of all)? If he did, was he able to follow that being throughout its career and test the influence of that fluctuation on its life? If he did, was he able to note the effect on offspring and descendants?

Very obviously our whole *immediate* knowledge of fluctuations, natural selection, and the method of evolution is derived from human beings, among whom alone we are able to observe with that sufficiency and minuteness which extreme familiarity confers. Thus every man (not only Prof. Dakin's superman) knows that powers of resisting the carnivorous bacillus of tuberculosis occur in all shades between wide extremes (therefore they are fluctuations); that they tend to run in families (therefore they are inheritable); that the less resistant tend to perish and the more resistant to survive (therefore there is natural selection); that every race is resistant n proportion to the length and severity of its sufferings (therefore natural selection is the antecedent of evolution); and that what is true of tuberculosis is true also of every lethal and prevalent disease (therefore the instances are in thousands and include all the world and all humanity—indeed every case in which we are able to observe closely).

Naturalists, unable to observe either fluctuations or natural selection among plants and lower animals, must get their ideas about the method of evolution either from observations on man or else through mere guessing. Apparently they prefer not only to guess but to claim scientific status for their guesses. After all, man is an animal. I do not know why he should be thought unworthy of study.

What does Prof. Dakin mean by "it is highly desirable that first-year medicals, raw youths from school, should make their first acquaintance with the animal world through less expensive material than human bodies"? Expensive in what—money or time? Does Prof. Dakin suppose that raw youths dissect fewer humans because they dissect more frogs?

I gather that he disapproves of attempts by me to discuss evolution, "for his letter indicates a very imperfect acquaintance with biologists and their work." I think by biologists he means zoologists and botanists. But, if I be incapable, why not end the nuisance by indicating my errors. A jury always grows suspicious when not the evidence, but only the opposing attorney is attacked. There has been much of this hinting at my ignorance—doubtless with reason, if not with proof. Nevertheless, I know some elementary facts which, it seems, are outside the range of the average naturalist, *e.g.*, that events do not happen (characters do not develop) without antecedents (nature) and exciting causes (nurture); that living beings are bundles of adaptations; that the multicellular organism springs from a germ in which are none of the characters it afterwards develops, and therefore, inherits nothing but its nature (the sum of its potentialities for development), and develops nothing except in response to nurture; that our powers of observation are proportionate to our familiarity with the objects of study; that whenever we are able to observe sufficiently closely we always find natural selection in full swing; that the variations selected by Nature are always fluctuations; that the result is always adaptive evolution; that man, unlike Nature, frequently selects mutations; that therein lies the difference between natural and artificial selection; and so on.

On these elementary facts I have founded some equally elementary questions. Why are some characters supposed to be more innate, or acquired, or inheritable than others? What precisely was the great Lamarckian controversy about? Was it founded on anything but a play on words? Why is the word inherit used with two directly contrary meanings? What is meant by the statement that "Nature is five perhaps ten times stronger than nurture," and what by the statement that "mutations, but not fluctuations, have their representatives in the germplasm"? Why, in the face of enormously massive evidence, is it supposed that there is no natural selection, or that natural selection is merely a preserver, not a creator, of adaptations? Why in the face of equally massive evidence is it maintained that the inheritance, not merely the reproduction, of mutations is independent? And so on. I notice that the erudite people who are so ready to proclaim my ignorance are not equally ready to face these facts and answer these questions. Nevertheless, both facts and questions, however elementary, are fundamental. Unless they be met, posterity will regard a page of Darwin, who always met his difficulties with candour and without arrogance, of more value than all the thousand publications of those who bark at the dead lion.

As Prof. Dakin has been good enough to suggest that I am ignorant, may I supply him with proof and the readers of NATURE with a test? I do not know what naturalists (the biologists of Prof. Dakin) mean by their key-words "innate," "acquired," and "inherited" when applied to characters. Does Prof. Dakin know? Will he tell us?

G. ARCHDALL REID.

A Relativity-predicted Mechanical Effect in the Electromagnetic Field.

THE present writer would certainly starve if his bread depended on supplying a certain experimental verification here asked for. It should, however, be mere Boys' play to those who measure the gravitational constant with a little pile of sovereigns and a quartz fibre, or who photograph the wake of a flying bullet. The mathematical argument leading to the prediction indicated below is sent to England by the mail carrying this letter, for publication, but I cannot say where and when it will appear.

A body, say a crystal, at rest in an electromagnetic field should experience a force per unit volume, in Maxwell's notation and in E.M. units, equal in magnitude and direction to

$$\mathrm{VKB} - \mathrm{ES}\nabla\mathrm{D} + \frac{d}{dt}\mathrm{V}(\mathrm{DB} - \mathrm{EH}/4\pi c^2),$$

where K is conduction current and c the velocity of light *in vacuo*. It is possible that the third term has been given before, but I have not seen it anywhere. The verification here asked for is that of the existence of this term. VEH is in the direction of a light ray and VDB is normal to the corresponding front. In an isotropic transparent body, VDB $=k^2(\mathrm{VEH}/4\pi c^2)$, where k is the index of refraction.

Unfortunately, $4\pi c^2$ is about $10^{22} \times 1{\cdot}131$, but my son, Dr. A. L. M'Aulay, tells me that the magnitude of VEH may readily be made equal to 10^{16}, so that the effect may be detectable.

The term indicates that when a wave-train traverses a point the matter at the point is always urged along the ray *towards* the nearest wave-crest or wave-trough, and normal to the front *from* the nearest crest or trough. Can any reader suggest a plausible physical reason why this should occur?

I may remark that Maxwell's expression for the force per unit volume is

$$\mathrm{V}(\mathrm{K} + d\mathrm{D}/dt)\mathrm{B} - \mathrm{ES}\nabla\mathrm{D},$$

and that probably most relativists would drop the $d\mathrm{D}/dt$ from this expression. Let the physicist tell us which, if any, of the three expressions is verified experimentally.

ALEX. M'AULAY.

The Measurement of the Rates of Oxidation and Reduction of Hæmoglobin.

WE have recently been engaged on the determination of the velocities of the chemical reactions of hæmoglobin. These are of interest both to the physiologist because of the important part played by this pigment in respiration, and also to the physical chemist because this pigment is an almost unique example of a large complex protein molecule which combines with gases in a simple chemical manner. Some of the results that we have obtained and the methods we have used may therefore be of interest to readers of NATURE.

In order to measure the rate of reduction two solutions were prepared: (*a*) a 1·5 per cent. solution of whole blood in tap water, (*b*) a solution of sodium hyposulphite ($Na_2S_2O_4$) in tap water which was rendered neutral to brom-thymol-blue by the addition of sodium carbonate solution. These two solutions were by suitable means forced under a pressure of, roughly, 500 mm. of mercury into the mixing chamber of the measuring apparatus through conical jets of small bore, so that the two solutions underwent vortex motion at a high rate of speed. Preliminary tests of the measuring apparatus, using as fluids a sodium hydroxide solution containing phenol phthalein and a rather stronger solution of acid, showed that mixing and chemical combination were complete with one measuring apparatus in less than 0·0055 sec., and with another apparatus in less than 0·0005 sec. The mixed blood solution and reducing agent passed from the mixing chamber of the apparatus in use down a glass tube with known velocity, being examined at different positions by means of the reversion spectroscope, by which we could ascertain the ratios of those amounts of hæmoglobin still combined with oxygen and those in the reduced state.

We thus obtained the concentration of oxyhæmoglobin (O_2Hb) at a series of instants, the intervals between which could be readily obtained from the rate of linear flow of the solution down the tube, and the positions of the points examined by the spectroscope.

Experiments on the rate of reduction of oxyhæmoglobin (O_2Hb) by the reducing agent ($Na_2S_2O_4$) have shown that with increase of concentration of the latter the rate of reduction increases to a maximum, beyond which it cannot be raised by a further increase. This we take to mean that the process consists of two stages:

(1) Reduction of oxyhæmoglobin, *i.e.*
$$O_2Hb \rightarrow O_2 + Hb.$$
(2) Removal of O_2 (liberated from O_2Hb) by combination with the reducing agent.

As the concentration of the reducing agent is increased, the free oxygen formed from O_2Hb by stage 1 is removed more quickly, until a concentration is reached at which the "free" oxygen is removed so quickly that the reaction $O_2Hb \rightarrow O_2 + Hb$ is not appreciably opposed by the reverse reaction $O_2 + Hb \rightarrow O_2Hb$. Further increase in concentration of the reducing agent cannot therefore further accelerate the velocity of the reduction of the O_2Hb, the latter being now solely determined by the velocity of the reaction $O_2Hb \rightarrow O_2 + Hb$. We have other evidence in support of this view, which we hope to present at length elsewhere. The time taken for complete reduction of O_2Hb when the concentration of $Na_2S_2O_4$ was sufficient to secure the "maximum" rate of reduction was about 0·5 sec. at 12° C. This rate of reduction is such as to be a factor of importance in considering the conditions which determine the rate of uptake of oxygen by organs within the body. We found further that the logarithm of the concentration of O_2Hb when plotted against time gave a straight line relationship, as should indeed be the case if the reduction of O_2Hb is a monomolecular process.

The measurements of the velocity of oxidation of hæmoglobin required the preparation of large quantities of reduced hæmoglobin solution. This was obtained by spraying a solution of blood in tap water heated to 50° C. into a large vacuous container, thus causing the gases combined with the hæmoglobin to be liberated. This reduced blood solution was mixed with water containing dissolved oxygen by forcing both fluids into the mixing chamber of one of the observing apparatus described above. It was found that the combination was a very rapid one, the reaction being complete in one hundredth part of a second at 10° C. At body temperature it is probable that the velocity would be even higher. This gives some idea of the intense rapidity with which oxygen entering the blood, as the latter passes through the lungs, becomes chemically combined with hæmoglobin. It seems to us possible that similar methods might be useful for determining the velocity of other rapid chemical reactions.

Stages of Golgi Bodies in Protozoa.

IN the *Anatomischer Anzeiger* (47 Band, 1914) Jan Hirschler, in his paper "Ueber Plasmastrukturen in den Tunicaten-, Spongien-, und Protozoenzellen," gives a description of the trophozoite of *Monocystis ascidiæ*, in which he figures Golgi bodies. This has never hitherto been confirmed, nor are any other stages known.

For some time we have been carrying out work on an Adelea, and after considerable difficulty succeeded in getting excellent preparations of the Golgi apparatus in many stages of the life cycle. In the accompanying illustration (Fig. 1) is the young

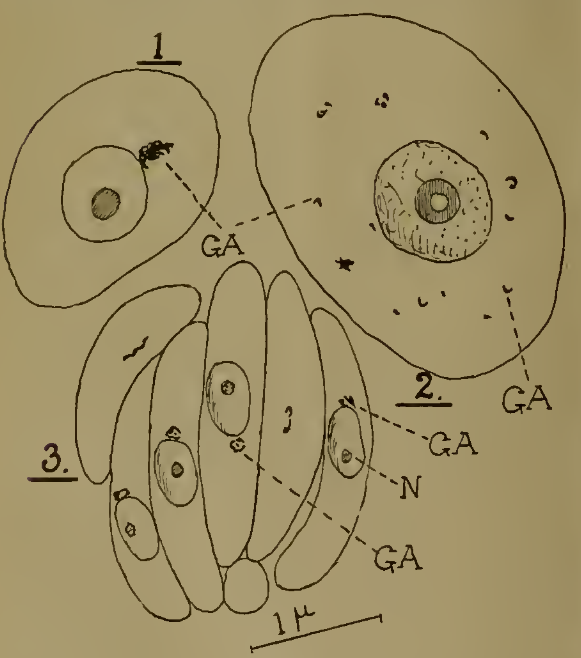

FIG. 1.

trophozoite showing an excentric and juxta-nuclear apparatus (GA); 2, the older trophozoite has a scattered apparatus, and in the "corps en barillet" stage in 3 the apparatus in each cell is again juxta-nuclear and excentric. The work is still proceeding in several species, and this is merely a preliminary announcement.

Selective Interruption of Molecular Oscillation.

MR. FAIRBOURNE (NATURE, February 3, p. 149) has reopened a subject which I believed was certainly closed; but since the fallacy is practically the same as before, though a little less easy to detect, I feel that I cannot then have been sufficiently clear for him.

None of Mr. Fairbourne's arguments has yet disposed of the validity of the ordinary treatment to be found in any text-book on the kinetic theory; for the elementary kinetic treatment of gaseous pressure is independent of the diameters of the gas-molecules, and would be perfectly valid if they were, as for the first approximation they are assumed to be, particles of a finite mass but zero radius; in this case, however, the mean free path would be infinite at every pressure, so that Mr. Fairbourne has introduced no new factor by confining himself to the case of long free paths.

This being so, it is not to be expected that space can be found in these columns for a disproof of whatever inadequate alternative to the accepted methods of analysis may be brought up; but I suggest that in this particular case he has not proved that he has satisfied a condition which he admits is vital, namely, that the numbers of molecules crossing XY and AD *in unit time* must be shown to be not proportional to their lengths. Many of the "superfluous" molecules which ultimately cross XY spend first a long time in the cone; there is nothing in his treatment which prevents such molecules being counted a very large number of times, since all points on their long paths may equally be taken as centres of small spheres O. Mr. Fairbourne's treatment is inconvenient; but it is obvious, since it does not discount the classical method, that, if carried out correctly, even it would have given the classical result.

I have always maintained that the length of the mean free path is irrelevant; I observe that he now admits this ("Subsequent intermolecular collision in the cone cannot destroy the excessive downward bias," etc.). The inevitable conclusion, as I pointed out last July, is that the pressure is without any influence except on the *magnitude* of the effect. It being granted that the molecules do not interfere with one another in any relevant way, the effect must be directly proportional to their number, *i.e.* to the total pressure. At atmospheric pressure, therefore, perpetual motion should be an accepted phenomenon even if the effect were measurable only with ambiguity at the pressures used by Mr. Fairbourne.

A Biochemical Discovery of the Ancient Babylonians.

AT a lecture given recently in Cambridge by Prof. Okey my attention was directed to a passage written by Galileo in 1623 in which this pioneer of scientific method attacks the doctrines of the classical philosophers with his usual irony and vehemence. I refer to a section of his "Il Saggiatore," in which Galileo replies to his contemporary Sarsi, who had quoted Suida to the effect that the Babylonians used to cook eggs in an emergency and when no fire was available, by rapidly whirling them in slings. ("Babylonii iniecta in fundas ova in orbem circumagentes, rudis et venatorii victus non ignari, sed iis rationibus quas solitudo postulat exercitati 'etiam crudum ovum impetu illo coxerunt.' " Suida, Lessicografo. Bizant., x.)

Galileo makes the following caustic comments: " Se il Sarsi vuole che io creda a Suida, che i Babilonii cocesser l' uova col girarle velocemente nella fionda, io lo crederò; ma dirò bene, la cagione di tale effetto esser lontanissima da quella che gli viene attribuita, e per trovar la vera io discorrerò così: Se a noi non succede un effetto che ad altri altra volta a riuscito è necessario che noi nel nostro operare manchiamo di quello che fu causa della riuscita di esso effetto, e che, non mancando a noi altro che una cosa sola, questa sola causa sia la vera causa. Ora, a noi non mancano uova, nè fionde, nè uomini robusti che le girino; e pur non si cuocono; anzi, se fusser calde, si raffreddano più presto; e perchè non ci manca altro che l' esser di Babilonia, adunque l' esser Babiloni è causa dell' indurirsi l' uova e non l' attrizion dell' aria: che è quelo ch' io volevo provare." (If Sarsi *commands* me to believe on the authority of Suida that the Babylonians used to cook eggs by swiftly swinging them in slings—I will. But I will certainly say that the cause of such results is far from that which he attributes; and in order to discover the true cause I will reason in the following way: If we do not succeed in obtaining a result which was successfully obtained at another time, some one factor at least must be lacking which is necessary for the successful production of the result. Now, we have no lack of eggs, nor slings, nor strong men to swing them, *and yet they do not cook; on the contrary*, if already warmed the swinging would cool them more quickly. Since the only factor that is lacking is that we are not Babylonians, therefore the fact of being a Babylonian is the cause of the eggs solidifying, and not the friction of the air: and this is what I set out to prove.) (Galilei, Opere, vi. Also in " Frammenti e Lettere " (1917), p. 66).

If Galileo had actually put his experiment to the test he might have written otherwise. Within the last few years it has been " discovered " that egg white under mechanical strain such as *vigorous shaking* or very high hydrostatic pressure undergoes coagulation (*vide* Robertson, " Physical Chemistry of the Proteins," 1918). In a paper to be published shortly in the Proc. Roy. Soc. (read at the meeting of February 15), I show that chemical changes which occur on heat-coagulation also occur on coagulating an egg by mechanical means.

The myths and anecdotes of the ancients are almost invariably built on some foundation of fact; and it seems highly probable that the Babylonians were aware that eggs could be coagulated by vigorous movement (such as swinging in slings). If this be so, the phenomenon of mechanical coagulation proves to be another example of a former observation rediscovered—in this case after the lapse of thousands of years!

Use of Yeast Extracts in Diabetes.

We have recently shown (*Journ. of Physiol.* 57, p. 100, 1922) that there is present in the blood of normal persons a sugar of a reactive nature, which gives the same osazone as glucose, but has a lower rotatory power. In the blood of persons suffering from severe diabetes mellitus, this sugar is not present in amounts capable of detection. In conjunction with Dr. Devereux-Forrest, we have found that, after administration of insulin to diabetic persons, whereas the quantity of sugar in the blood is decreased, the amount of normal blood sugar is increased.

We have also shown (Proc. Physiol. Soc., December 16, 1922) that extracts of pancreas and liver together alter the rotatory powers of glucose and fructose *in vitro*. It was suggested that the absence or inactivation of either the pancreatic or liver factor was the cause of diabetes. Since the pancreatic and liver factors were markedly accelerated by the addition of phosphates, it seemed possible that one constituent of the pancreatic factor might be a sugar-phosphoric acid complex. As an essential step in the metabolism of sugar by yeast is held to be the formation of hexose-phosphoric acids, it seemed possible that an extract of yeast might take the place of the pancreatic factor.

We have obtained a solid preparation from yeast which would appear to have similar properties and effects.

When a solution of this substance is injected into rabbits, a very definite lowering of the blood sugar occurs, in every way comparable to that which we have found after injections of insulin. Rats when injected die in convulsions similar to those caused by insulin.

Some properties of insulin and of this extract of yeast are very similar. Both contain organic phosphorus and carbohydrate. Seliwanoff's reaction is positive in each case after hydrolysis.

We are at present engaged in a further investigation of these extracts.

Meteorological Nomenclature and Physical Measurements.

In reply to Sir Napier Shaw's kindly rejoinder in Nature of February 17, p. 218, to my meditations on the progress of meteorology, I prefer to his simile of a boat-race that of boats striving to tow the not yet quite ship-shape bulk of meteorological research forward on its destined course. Although Sir Napier Shaw's was the best equipped of the boats, in which he was able to experiment with new modes of propulsion, I am sure he recognises that I was pulling with all my strength, if independently, at least in the same direction as himself. That I pulled in grim earnest with the result of long disablement accounts for my present position (which strikes me as more desolate than dignified) on the shelf, from which I see the now graceful lines of the new meteorology moving ahead with Sir Napier's new engines installed, and though almost out of hearing I listen to their beat in order to form an opinion as to how they act. I should be sorry indeed if anything I said were to retard or discourage any one on board that craft or cast a shadow on the laurels with which Sir Napier Shaw has been crowned by the scientific world to the joy and pride of every British meteorologist.

Dropping metaphor, there is surely large room for helpful difference of opinion as to terminology and the relative value of facts and formulæ. I do not dislike the metric system in spite of its occasional awkwardnesses, nor would I hesitate to embrace the millibar if it seemed to me to be making for unity instead of adding a new ramification to diversity. In the works I was reviewing I failed to see the signs of the coming of the millenium of the millibar; but if it is on its way, " come it will for a' that."

The Origin or Basis of Wireless Communication.[1]

By Sir Oliver Lodge, F.R.S.

Finsbury Technical College has done splendid work throughout its short history. It fills a distinct niche, it supplies a felt want in the education of the Central metropolis, and I hope that any idea of closing it has now subsided. It has had, moreover, a brilliant array of teachers, men who appeared specially adapted to serve the needs of its special kind of students. I will here only mention three contemporaries who worked together after 1885, when the initial start had been made, and the early traditions settled, by Ayrton and Perry. Silvanus Thompson became principal in 1885, and had as his colleagues John Perry and Raphael Meldola. John Perry was remarkable as a teacher, and did his best to cultivate a wider interest in the rather narrow technically trained students who came under his paternal supervision, encouraging them to read novels, to take an interest in literature, and—even in mathematics—to take a broader outlook than most teachers thought it worth while to cultivate. As for Silvanus Thompson, the breadth of his outlook and width of his interests are almost proverbial. He represented a rare combination of scientific aptitude and high artistic faculty, together with a fondness for literary study among archives, and he became in the eyes of all his contemporaries—including Lord Kelvin and Lord Rayleigh—a recognised historian of science. He had a keen love of the past and of discoveries in their nascent stages. Old documents and records were of real interest to him: and he used to do his best to dig out of obscurity some of the pioneers and early workers towards developments which afterwards became famous.

Early pioneering work is too often overlooked and forgotten in the rush of a brilliant new generation, and amid the interest of fresh and surprising developments. The early stages of any discovery have, however, an interest and fascination of their own; and teachers would do well to immerse themselves in the atmosphere of those earlier times, in order to realise more clearly the difficulties which had to be overcome, and by what steps the new knowledge had to be dovetailed in with the old. Moreover, for beginners, the nascent stages of a discovery are sometimes more easily assimilated than the finished product. Beginners need not, indeed, be led through all the controversies which naturally accompany the introduction of anything new; but some familiarity with those controversies and discussions on the part of the teacher is desirable, if he is to apprehend the students' probable difficulties. For though he does not himself feel them now, the human race did feel them at the new fact's first introduction; and the individual is liable to recapitulate, or repeat quickly, the experience of the race.

A large number of people now interested in the most modern developments of wireless have but little idea—perhaps none at all—of the early work, in apparently diverse directions, which preceded and made such developments possible. Even those who are high authorities in wireless telegraphy, and know nearly all that can be known about it—like the distinguished dean of this college, Dr. Eccles—can scarcely know the early stages quite as well as Silvanus Thompson and I knew them; no one, indeed, can afterwards feel in touch with the history so closely as those who have lived through the period covered by it. Only those who have survived the puzzled and preliminary stages of a discovery can appreciate fully the contrast with subsequent enlightenment. It may suffice to say that the term "inductance" or "self-induction," which we now use so glibly, did not at first exist; and that so late as 1888 Sir William Preece still spoke of it as "a bug-a-boo": whereas it is the absolute essential to tuning, and even to electric oscillation. Faraday was the first to direct attention to it, under the name "electrotonic state;" and he treated it experimentally with his usual skill. Lord Kelvin, who first introduced it as a mathematical coefficient, without any explanation, called it "electrodynamic capacity." The name self-induction was given to it by Maxwell, though it was long before it was understood or utilised, and the name "inductance" is a nomenclature of Heaviside.[2]

I wish in this lecture to say practically nothing about anything to do with wireless later than 1896. What I have to deal with is the early pioneering work apart from practical developments. Let me here say at once, to avoid misunderstanding, that without the energy, ability, and enterprise of Signor Marconi, what is now called wireless would not have been established commercially, would not have covered the earth with its radio stations, and would not have taken the hold it has upon the public imagination. Before 1896 the public knew nothing of its possibilities: and for some time after 1896, in spite of the eloquence of Sir William Preece and the demonstrations by Signor Marconi, the public thought it mysterious and almost incredible; and still knew nothing about the early stages. Indeed, I scarcely suppose that Signor Marconi himself really knew very much about them. He had plenty to do with the present; he felt that the future was in his hands; and he could afford to overlook the past.

It may be doubted whether the younger generation, who are so enthusiastically utilising, and perhaps improving, the latest inventions, will care much about the past either. Incidentally, however, I want to say two things to those who are occupied with the subject to-day. First, do not hesitate to speak and think of the *ether of space*, as the continuous reality which connects us all up, and which welds not only us but all the planets into a coherent system. Do not be misled by any misapprehensions of the theory of Relativity into supposing that that theory dispenses with the ether, merely because it succeeds in ignoring it. You can ignore a thing without putting it out of existence: and the leaders in that theory are well aware that for anything like a physical explanation of light or electricity or magnetism or cohesion or gravitation, the ether is indispensable. The ether has all these functions, and many more. We are utilising it every day of our

[1] From the first Silvanus P. Thompson memorial lecture delivered at Finsbury Technical College on February 1.

[2] Silvanus Thompson wrote a pamphlet on the early history of wireless, in connexion with a successful application before Lord Parker for the extension of my fundamental tuning patent of 1897. This pamphlet has never been published, but it ought to be. I had not time to quote from it.

lives; and it would be ungrateful, as well as benighted, if we failed to render due homage to its omnipresent reality and highly efficient properties. It lies at the origin of all electrical developments, and forms the basis for this new and broadcast method of communication.

That is one thing: the second is to congratulate all those whose wonderful and rapid advances have rendered possible the astonishing feat of, in any sense and by whatever means, carrying the human voice across the Atlantic. When Signor Marconi succeeded in sending the letter "s" by Morse signals from Cornwall or Ireland to Newfoundland, it constituted an epoch in human history, on its physical side, and was itself an astonishing and remarkable feat. The present achievement of changing over from Morse signals to ordinary speech, made possible by the valves of Prof. Fleming and Dr. Lee de Forest and others, is a natural though still surprising outcome and development of long-distance transmission, and must lead to further advances, of which at present we can probably form but a very imperfect conception.

Well now, I must go back to very early times. In or about the year 1875 Mr. Edison observed something, which at that time could by no means be understood, about the possibility of drawing sparks from insulated objects in the neighbourhood of an electrical discharge. He did not pursue the matter, for the time was not ripe; but he called it "Etheric Force"—a name which rather perhaps set our teeth on edge;—and we none of us thought it of much importance. Silvanus Thompson, however, took up the matter in a half-hearted sort of way, and gave a demonstration to the Physical Society of London in, I believe, June 1876—a paper which I have had a little difficulty in finding in the Proceedings of that Society. Nothing much came of it, however, though his argument tended to show that the sparks could be accounted for on known principles. The value of this is merely that it must have rendered Thompson susceptible to methods of detecting real electric waves, when they were discovered later.

It was found afterwards that Joseph Henry, at the Smithsonian Institution in Washington, had observed something of the same kind so early as 1842. He seems to have had an intuition of the possible importance and far-reaching consequences of his observation, for he speaks as follows (I quote from a passage cited in my "Modern Views of Electricity," an appended lecture "On the Discharge of a Leyden Jar" [1]):—

"It would appear that a single spark is sufficient to disturb perceptibly the electricity of space throughout at least a cube of 400,000 feet of capacity, and . . . it may be further inferred that the diffusion of motion in this case is almost comparable with that of a spark from flint and steel in the case of light."

That is to say, so early as 1842 Joseph Henry had the genius to surmise that there was some similarity between the etherial disturbance caused by the discharge of a conductor and the light emitted from an ordinary high temperature source.

In the light of our modern knowledge, and Clerk Maxwell's theory, we now know that the similarity is very near akin to identity. Both sources emit ether waves, though prodigiously differing in length.

Subsequent to these early stray observations, a suggestive semi-private observation, of a partially similar kind, was made by that singular genius and brilliant experimenter, David Hughes, the inventor of the microphone or telephonic transmitter, and of the Hughes printing telegraph still used in France. He was a man who "thought with his fingers," and worked with the simplest home-made apparatus—made of match-boxes and bits of wood and metal, stuck together with cobbler's wax and sealing-wax. Such a man, constantly working, is sure to come across phenomena inexplicable by orthodox science. As a matter of fact, Hughes unknowingly was very nearly on the trail of what was afterwards discovered, in a much more enlightened manner, by Hertz. Hughes, too, got sparks in the course of his experiments, but he also got something very like coherer action by means of his microphone detectors. They enabled him to get actual galvanometer deflexions—such as Hertz never got.

I cannot at the moment fix the date, but it was early in the 'eighties and before either Hertz or me. Hughes was a telegraphist, and though he would never have worked out the subject mathematically as Hertz did, and would not have been interested in matters of theory, he might well have stumbled, even at that early date, on something like a rudimentary system of wireless signalling, had he been encouraged. But he was not encouraged. He showed his results to that great and splendid mathematical physicist, Sir George Stokes; and Stokes, alas, turned them down, considering that they were explicable either by leakage or some other known kind of fact.

That is the danger of too great knowledge; it looks askance at anything lying beyond or beneath its extensive scope; whereas an experimenter operating at first hand on Nature may quite well occasionally stumble on a fact which lies outside the purview of contemporary science, and which accordingly neither he nor any one else at the time understands. Crookes himself had a similar experience. In his pertinacious and systematic way he explored many unfamiliar and untrodden regions; and he also invited the attention of Stokes to a simple and easily investigated case of abnormal movement; Stokes, however, perceiving that such motion was physically impossible, declined to take any interest in it or even to see it. His reason told him (and the reason he gave was) that on recognised principles the asserted phenomenon could not happen. But that was precisely its point of interest, and that was why Crookes with his instinctive sagacity conceived that such things held within them the germ of a great science of the future.

In Crookes's case the germ still remains unfructified by orthodox science. In Hughes's case the germ was rediscovered and has borne fruit a million-fold. But this is to anticipate. Suffice it now to direct attention to the collection of Hughes's apparatus now unearthed by the energy and piety of Mr. Campbell Swinton, and exhibited in the Science Museum at South Kensington. Let us try, however, to avoid imitating the mistakes of our revered scientific ancestors: though I admit it is a difficult task. So much rubbish is brought to our

[1] See also NATURE, vol. 39, pages 471-474

notice that we are bound to run the risk of neglecting a jewel among the chaff.

These spasmodic observations, however, are not exactly discoveries: they were more akin to vague intuitions. The first and gigantic step in the real discovery was made by Clerk Maxwell, in or about 1865: and he made it in mathematical form, not in experimental actuality, by one of those superhuman achievements which are only possible to our greatest mathematical physicists. He did not discover either the way to generate ether waves, or to detect them; but he did give their laws: he legislated for them before they were born. He knew the velocity with which they must move, and gave implicitly, though without elaboration, the complete theory of their nature.

Up to his time the nature of light was unknown. All the other theories of light had attempted to explain it on mechanical principles, like the vibrations of an elastic solid. Light was known to consist of transverse waves: the wave-length and the frequency of oscillation could be determined. But no one knew what was oscillating, nor what the mechanism of propagation was. With extraordinary genius Fresnel and MacCullagh had explained the phenomena of light in all detail as regards reflection, refraction, diffraction, interference, and polarisation. But the nature of the waves was unknown; and the elastic solid theory, though fascinating, was felt by those who dived most deeply into it to contain some flaw, and to be, strictly speaking, unworkable. Light did not seem explicable on dynamical principles—the principles which were so fruitfully devised by Galileo and Newton for dealing with ordinary matter.

MacCullagh's theory indeed was not dynamical, and in that respect had some advantage. But it was also vaguer and less definite on that account; though, being thus indefinite and yet enabling results to be achieved, it was less liable to be upset and replaced by future discovery.

To Clerk Maxwell we owe the epoch-making discovery that light was not a mechanical oscillation at all, that the ordinary mechanical properties of matter did not apply to it, but that it was explicable solely and wholly in terms of electricity and magnetism. It is impossible to sum up his discovery in a few words; but roughly we may say that the most obvious outcome was:

(1) That if electric waves could ever be generated they would travel with the velocity of light.

(2) That light was essentially an electromagnetic and not a mechanical phenomenon.

(3) That the refractive index of a substance was intimately related to its dielectric coefficient.

(4) That conductors of electricity must be opaque to light.

Maxwell showed further, though he did not then express it in language of this character, that the ether had two great and characteristic constants, of value utterly unknown to this day, though guessed at by a few speculators like myself;—one of them the electric constant of Faraday called K; the other the magnetic constant of Kelvin called μ. It was impossible then, and it is impossible now—though it is not likely always to remain impossible—to determine the value or even the nature of either of these constants. But Maxwell did perceive a way of measuring their product; and he was the first to measure it. Their product is known; and it is equal—as he showed it must be—to the reciprocal of the square of the velocity of light.

Well now, this great discovery aroused in us young physicists the keenest enthusiasm. In the early seventies of last century—I think about 1871 or 1872—I remember discussing it with the man we all now know and honour, J. A. Fleming, who at that time was a fellow student with me in Prof. Frankland's advanced chemical laboratory at the brand-new College of Science, South Kensington. A year or two later, at Heidelberg, I studied Maxwell's treatise pretty thoroughly, and formed the desire to devote my life if possible to the production and detection of Maxwell's electric waves.

I used to discuss the possibility of producing these waves with my great friend, G. F. FitzGerald, whose acquaintance I made at the meeting of the British Association in Dublin in the year 1878; and he wrote some mathematical papers discussing the possibility of producing such waves experimentally. I myself also spoke at the British Association about them, in 1879, 1880, and again in 1882 at the Royal Dublin Society. FitzGerald, as I say, examined mathematically what then seemed the abstruse question of electric wave production; and after some hesitation came to the conclusion that direct artificial generation of waves was really possible on Maxwell's theory, in spite of certain recondite difficulties which at first led him to doubt it. (See "Scientific Writings" of FitzGerald, edited by Larmor, pp. 90-101.) Indeed one of his papers on the subject was originally entitled "On the Impossibility of Originating Wave Disturbances in the Ether by Means of Electric Forces." The prefix "im" was subsequently dropped; although his first, or 1897, paper concluded thus:

> "However these [displacement currents] may be produced, by any system of fixed or movable conductors charged in any way, and discharging themselves amongst one another, they will never be so distributed as to originate wave-disturbances propagated through space outside the system."

In 1882 FitzGerald corrected this erroneous conclusion, and referred to some early attempts of mine at producing the waves. ("Scientific Writings," p. 100.) I state all this in order to emphasise the difficulty which in those early days surrounded the subject on its theoretical as well as on its practical side.

In 1883, at the Southport meeting of the British Association, FitzGerald took a further step and surmised that one mode of attaining the desired result would be by utilising the oscillatory discharge of a Leyden jar—the theory of the oscillations of which had been worked out, partly by Helmholtz and more fully by Lord Kelvin, 30 years before—if only we had the means of detecting such waves when they were generated.

PRODUCTION OF WAVES.

In 1887 and 1888 I was working at the oscillatory discharge of Leyden jars (initially in connexion with the phenomena of lightning), and—with the assistance of A. P. Chattock—I then found that the waves could be not only produced but also detected, and the wave-length measured, by getting them to go along guiding wires adjusted so as to be of the right length for sympathetic resonance. Thus I obtained the phenomenon of electric nodes and loops, due to the production of stationary waves by reflection at the distant end, and in my own mind thus verified Maxwell's theory. (I gave a brief account of this work, with calculations of wave-length, in *The Electrician* for September 21, 1888, page 623. Many other passages of early history can be found in the same volume about that date. It was an important year.)

Transmission along wires popularly sounds different from transmission in free space, but it was well known to me that the process was the same, and that the waves travel at the same speed, being only guided by the wires, much as sound is guided in a speaking-tube, without the velocity of transmission being to any important extent altered. The theory is given near the end of my paper—an important one as I think, and as Silvanus Thompson agreed—in the *Philosophical Magazine* for August 1888, where the experimental production of much shorter waves is also foreshadowed.

The beginning of my experiments was reported to the Society of Arts in April 1888; they are recorded, as said above, in the *Phil. Mag.*, and they were more completely described orally at the British Association at Bath that year. (See the *Electrician*, vol. 21, pp. 607-8, September 1888.)

In that year, also, I heard for the first time of Hertz's brilliant series of experiments, where, by the use of an open-circuit oscillator, he had obtained waves in free space, and by reflection had also converted them into stationary waves and observed the phenomena of nodes and loops, and measured the wave-length.

Attention was directed to these experiments of Hertz by FitzGerald in his presidential address to Section A of the British Association meeting at Bath in 1888. No wonder they interested him; for they showed that his method of utilising the oscillatory discharge of a Leyden jar was effective; and, to the surprise of all of us, including Hertz himself, that the waves from an opened-out condenser had sufficient power to generate sparks in an insulated conductor upon which they impinged; the detecting conductor, as generally used by Hertz, being in the form of a nearly closed circle with a minute spark gap at which the scintilla appeared. The radiating power of even a small Hertz oscillator was calculated by me in a subsequent paper (*Phil. Mag.* for July 1889, p. 54), and was found to be 100 horse-power, while it lasted. The duration was excessively short, for, at that rate, practically all the energy was expended in a single swing (about the 100-millionth of a second), but its power of producing little sparks was explained.

This work of Hertz was splendid. He was then professor at Carlsruhe, still quite a young man. He had been trained under Helmholtz; and I had made his personal acquaintance in Berlin when I went to call on Helmholtz in 1881, on a tour of the universities of the Continent. He was then Helmholtz's demonstrator, and was thought highly of by that great master. He could speak English, and was very friendly. I did not see him again till some time after the publication of his great discovery.

Hertz was not at that time fully acquainted with Maxwell's theory, although he knew his equations better than any other German except Helmholtz. Maxwell had not then made any serious impression on the Continent. Even Hertz does not seem at first fully to have realised what he was doing, and did not use the words "electric waves." That title was attached to his subsequently translated book at the suggestion of Lord Kelvin. He spoke about the *out-spreading of electric force*; somewhat as Joseph Henry had done. That was the title of his book. He worked out the phenomena he observed with extraordinary skill, both experimentally and mathematically, rapidly perceiving that Maxwell's theory could be applied to them, and that it might be elaborated in detail so as to include the whole of his phenomena. He it was who drew those accurate diagrams of the genesis of the waves, showing what is happening near the oscillator at every phase—diagrams which now appear in most text-books and of which the upper half is represented as scouring across the country. He knew that true waves were not emitted till beyond a quarter-wave length from the source. He knew how they were polarised, and how their intensity differed in the equatorial and polar directions, and how it varied with what may be called latitude. In fact he rapidly came to know all about these waves. As to us, we knew not which to admire most—his experimental skill when working with a tiresome and irritating mode of detection; or his mathematical thoroughness in ascertaining the laws of their propagation. A synopsis of his equations will be found clearly cited in Preston's "Theory of Light," as well as in other books. I translated some of his papers into Nature. Never was there the smallest iota of jealousy between us, or anything but cordial and frank appreciation. Maxwell and Hertz are the essential founders of the whole system of wireless. That is to say, they constructed the foundations solidly and well. Of the super-structure—splendid as it is now—we are as yet far from seeing the completion.

In March 1889 I lectured to the Royal Institution on "The Oscillatory Discharge of a Leyden-jar," and incidentally exhibited many of the effects of waves, both on wires and in free space, with overflow and recoil effects. But there was nothing akin to *signalling* exhibited in this lecture, as there was in the subsequent lecture in 1894.

Nevertheless, Sir William Crookes, on the strength of these experiments—which he mentions—wrote a brilliant article in the *Fortnightly Review* for February 1892 (vol. 51, p. 173) in which he foreshadows actual telegraphic accomplishment by that means, and indicates also the possibility of tuning or selective telegraphy, which was not actually born till 1897. He is evidently impressed with the experiments both of Hertz and of myself, and he quotes from my *Phil. Mag.* paper of August 1888 in confirmation and illustration of his prevision. For he says—after speaking of choosing wave-length with which to signal to specific people—"This is no dream of a visionary philosopher. All the requisites needed to bring it within the grasp of daily life are well within the possibility of discovery, and are so reasonably and clearly in the path of researches now being actually prosecuted in every capital of Europe, that we may any day expect to hear they have emerged from the realm of speculation into that of sober fact." Then he goes on—evidently referring to the experiments of D. E. Hughes, at which he must have been present[3]—" Even now indeed telegraphy without wires is possible within a restricted radius of a few hundred yards, and some years ago I assisted at experiments where messages were transmitted from one part of a house to another, without any intervening wire, by almost the identical means here described."

That article appeared in 1892, and was an anticipation of genius. Too little appreciation is felt to-day for the brilliant surmises and careful and conscientious observations of a great experimental worker like William Crookes; and on some of his researches orthodox science still turns its weighty and respectable back.

OTHER METHODS OF DETECTING WAVES.

In 1889 I had come across the effect of cohesion under electric impetus, and employed it to ring a bell under the stimulus of the overflow of a Leyden jar, as described in my paper to the Institution of Electrical Engineers in 1890 (vol. xix. pp. 352-4, where D. E. Hughes's comment on it is also recorded). In 1893 I heard—through a demonstration by Dr. Dawson Turner at Edinburgh—of Branly's filings-tube—an independent discovery of M. Branly, which really constituted an improvement on the first rough coherer idea. What I had called a coherer was not this, but a needle-point arrangement, or the end of a spiral spring touching an aluminium plate, which was and is extremely sensitive, but rather unmanageable.

With a Branly's filings-tube I made many more experiments, developing the subject; and on the untimely death of Hertz I determined to raise a monument to his memory by a lecture at the Royal Institution on these experiments (Friday, June 1, 1894), which I styled "The Work of Hertz"—meaning that it was a direct outcome and development inspired by that work. I soon found that the title was misleading, so that in the next edition I changed it into "The Work of Hertz and some of his Successors," and afterwards changed it still further into "Signalling across Space without Wires"; for that, of course, is what was being done in laboratory fashion all the time. The depression of a key in one place produced a perceptible signal in another—usually the deflection of a spot of light—and, as I showed at Oxford, also in 1894, employing a Thomson marine speaking galvanometer lent me by Alexander Muirhead, a momentary depression of the key would produce a short signal, a continued depression a long signal;—thus giving an equivalent for the dots and dashes of the Morse code—if the filings-tube were associated with an automatic tapper-back. One form of such tapper-back was then and there exhibited—a trembler or vibrator being mounted on the stand of a receiving filings-tube. This was afterwards improved, with Mr. E. E. Robinson's help, into a rotating steel wheel dipping into oiled mercury. Our aim was to get signals on tape, with a siphon recorder, and not be satisfied with mere telephonic detection. We succeeded; but more rapid progress would have been made had we stuck to the telephone, as wiser people did.

[3] Colonel Crompton now tells me that the experiments to which Crookes was probably referring were conducted not by Hughes but by Willoughby Smith, who seems to have demonstrated that some sort of communication was possible in this way.

TELEGRAPHY 1894 TO 1896.

My Royal Institution (1894) lecture was heard by Dr. Muirhead, who immediately conceived the desire to apply it to practical telegraphy. When my lecture was published—as it was in the *Electrician*, with diagrams roughly depicting the apparatus shown, drawn (some of them) skilfully but not always quite correctly, by the then editor of the *Electrician*, Mr. W. H. Snell—it excited a good deal of interest; stimulating, to the best of my belief, Capt. (now Admiral Sir Henry) Jackson, Prof. Righi, and Admiral Popoff to their various experimental successes which have been elsewhere described.

I was too busy with teaching work to take up telegraphic or any other development; nor had I the foresight to perceive, what has turned out to be, its extraordinary importance to the Navy, the Merchant Service, and indeed Land and War service too. But fortunately in Italy there was a man of sufficient insight to perceive much of this, and with leisure to devote himself to its practical development. In 1896 Signor Marconi came to this country—and the rest is public knowledge.

Man and the Ice Age.[1]

By Prof. W. J. SOLLAS, F.R.S.

THE great advance recently made in our knowledge of the Quaternary epoch begins with the observations of General de Lamothe on the ancient shore-lines which run along the coast of Algeria at heights of about 100, 60, 30, and 20 metres above the existing sea-level. They maintain their course with such remarkable uniformity that M. de Lamothe was unable to regard them as due to elevation of the land, and consequently attributed them to changes in the level of the sea, and was thus led to predict that similar shore-lines would be discovered on the opposite coast of the Mediterranean and particularly in Provence; a prediction which was subsequently verified by Prof. Depéret.

Next Prof. Gignoux, a friend and former pupil of Prof. Depéret, made a detailed investigation of these shore-lines and their associated deposits in the Western Mediterranean, and embodied his results in a masterly monograph.

Finally, Prof. Depéret himself extended these investigations to the Eastern Mediterranean and the west coast of the North Atlantic Ocean. In a comprehensive review of the whole subject he proposed the following classification of the Quaternary deposits, based on the four marine terraces of de Lamothe.

1. SICILIAN (Döderlein). Coast-line at from 90 to 100 m. The most perfect example of this stage is afforded by the Conca d'Oro or basin of Palermo, an ancient bay of the Mediterranean now filled up with Quaternary deposits. They commence with a blue clay containing near its base the famous fauna of Ficarazzo, which points to cold conditions and a depth of 90 metres. Traced towards those localities where the sea was clearer, the clay passes into a Polyzoonal

[1] A lecture delivered to the Geological Society of London on January 10.

limestone resembling our Coralline crag, while towards the shore it becomes sandy. Ascending in the series, the sand increases and finally passes into conglomerates, which at the summit (90 m.) extend over a rocky platform bored by Lithodomus and encrusted with barnacles—to end against the foot of steep cliffs which are undercut and penetrated by sea caves.

The Sicilian stage is sharply marked off from the Calabrian (Upper Pliocene) by a stratigraphical unconformity and a fauna which is distinguished by the disappearance of many Pliocene mollusca, and the advent of many "cold" species from the North Atlantic. These were brought probably by a cold marine current. At Reggio the Sicilian terrace has yielded an entire skeleton of *Elephas antiquus*.

2. MILAZZIAN (Depéret). Coast-line at from 55 to 60 m. The deposits of this stage are chiefly littoral with a fauna indicating a temperate climate, but warmer than that of the existing Mediterranean.

3. TYRRHENIAN (Issel). Coast-line at 28 to 30 m. This includes the well-known Strombus beds (*Strombus bubonius*) which are found all round the Mediterranean. The fauna is characterised by "warm" species, such as still live off the coast of Senegal and the Canary Islands.

4. MONASTIRIAN (Depéret). Coast-line 18 to 20 m. This is named from the city of Monastir in Tunisia, adjacent to a locality very rich in fossils of the stage. The fauna is almost identical with the Tyrrhenian, but on the north coast of the Mediterranean contains no "warm" species.

THE FOUR CORRESPONDING RIVER TERRACES.

General de Lamothe has shown that the four Quaternary beaches or shore-lines of Algeria correspond with the four Quaternary terraces of the river Isser in Algeria, and Prof. Depéret has similarly identified the Quaternary river terraces of the Rhone with the ancient beaches of Provence.

Thus the river terraces were determined by the base level of erosion, *i.e.* in the first place by the position of the sea-level at the time of their formation.

They are thus liberated from their supposed dependence on the four glacial episodes of Prof. Penck. This distinguished investigator had, as is well known, attributed the transport of the material of which they consist to the action of the comparatively feeble rivers which issued from the moraines of the glaciers at their full extension during a glacial episode,—a view scarcely inconsistent with palæontological evidence.

Commont has correlated the four terraces of the Somme with those of the Rhine, and de Lamothe has correlated them with the four Quaternary sea-levels. But the three lower terraces of the Somme, *i.e.* the first or Monastirian, second or Tyrrhenian, and third or Milazzian, all contain in their lowest deposits a warm fauna, which in the case of the lower two includes Hippopotamus—an animal which certainly was not swimming in the Somme at a time when Switzerland and the Baltic buckler were covered with ice and ice was floating in the English Channel. Messrs. Hinton and Kennard have further shown that a warm mammalian fauna characterises the greater part of the terraces of the Thames.

Thus both marine and river terraces unite in proclaiming a warm climate and so far, apart from the Sicilian, we have encountered no signs of an Ice Age.

CONNEXION OF THE TERRACES WITH THE MORAINES.

We turn then to the moraines which afford evidence of the intercalation of glacial episodes in the otherwise genial climate of the Quaternary age. Prof. Depéret considers that he has proof of the association of the Milazzian terraces with the external moraine of the Rhone (Mindel), of the Tyrrhenian with the intermediate moraine (Riss), and of the Monastirian with the internal moraine (Würm). This association by no means implies synchronism, but it enables us to assign the several moraines to their respective stages.

From the point of view we have now reached it will be perceived that the term "Great Ice Age" is a misnomer, and that instead of speaking of a glacial age interrupted by genial episodes, it would be far more in accordance with fact to speak of a genial age interrupted by glacial episodes.

Since these glacial episodes were quite certainly intercalated it will naturally be asked why they are not more obviously represented in the fauna of the Quaternary age. The answer to this is that the remains of a cold fauna are by no means infrequent, but the gravels at the base of a terrace are not the place to look for them. It is to the slopes between the terraces that we should turn, for it is these which correspond with glacial episodes, and when, as generally happens, they are covered with löss we find in it the bones and teeth of such cold-loving species, as we might expect.

It may further be pointed out that terraces, both marine and fluviatile, mark a stationary level of the sea when deposits were accumulating, in which the contemporary warm mammalia might easily be preserved.

In the intervals when the sea-level was changing the work of denudation ruled supreme and undisturbed deposits were formed but sparingly. Now and then no doubt the bones of some animal belonging to the cold fauna might escape destruction and find burial in a marine terrace along with the warm fauna proper to it, and thus possibly have arisen some of those perplexing anomalies of distribution with which we are only too familiar.

REGRESSIONS.

The movement of the sea-level does not appear to have been a simple fall from the Sicilian to the Milazzian

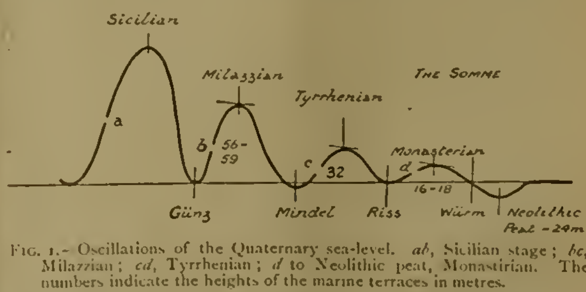

FIG. 1.—Oscillations of the Quaternary sea-level. *ab*, Sicilian stage; *bc*, Milazzian; *cd*, Tyrrhenian; *d* to Neolithic peat, Monastirian. The numbers indicate the heights of the marine terraces in metres.

coast-line and from the Milazzian to the Tyrrhenian; there is evidence to show that it fluctuated (Fig. 1), first sinking from the Sicilian to somewhere not far from the existing sea-level and then rising to the Milazzian, and similarly for all the succeeding stages.

Chronology of the Human Family.

The researches of Mr. Reid Moir have made us familiar with the existence of some member of the Hominidæ in the Red Crag, *i.e.* in the Calabrian stage of the Pliocene system, and if Prof. Depéret is right in referring the Forest Bed to the Sicilian, man seems to be also represented in this stage.

In the Milazzian (third terrace of the Somme) human artefacts are found associated with a warm fauna. Some of them are primitive forms of the Chellean boucher, and the industry as a whole is known as the Strepyan or Pre-Chellean.

The Tyrrhenian (second terrace of the Somme) affords the typical Chellean industry. It was indeed from this stage at Abbeville that Boucher des Perthes obtained the so-called "coup de poing" by which he established for the first time the existence of man at this remote period.

In the Monastirian, represented by the lowest gravels of the first terrace, the Chellean attains its final stage of evolution. It is still associated with a warm fauna. But these gravels are "ravinées" by a later one which brings with it Acheulean implements and the mammoth. If our preceding correlations are correct, the Acheulean must evidently be referred to a later stage of the Monastirian when the Würm glaciation was beginning to make itself felt. The Mousterian and all the succeeding industries of the Upper Palæolithic would then belong to the closing days of the Monastirian and the final retreat of the ice.

The interpretation seems to represent the present state of our knowledge, but it is not without its difficulties; one of the most perplexing is suggested by the "warm" Mousterian of Commont. More than one explanation may be offered of this, but the question may well be left to future research.

Comparison of the Coast-Lines of the Northern and Southern Hemisphere.

A eustatic movement of the sea-level is by itself unproved and unlikely, but a general deformation of the globe might well produce effects involving such a movement. That epeirogenic movements cannot be excluded is shown by the fact that the Tyrrhenian coast-line is deformed by local disturbances so that in the Strait of Messina it stands at 100 m. instead of 30 m., and in the Isthmus of Corinth even reaches 300 m. The Quaternary age was indeed by no means so reposeful as seems to be generally assumed; it includes movements of the earth's crust affecting wide areas and on no inconsiderable scale, as is shown by the recent observations of Prof. Bosworth in Peru, and Dr. Molengraaff in the East Indies.

This immensely complicates our problem. Prof. Depéret has sketched in bold outline a remarkable and suggestive history of the Quaternary age. To work it out in all its details will be the arduous task of more than one generation of geologists.

That a general deformation of the globe was in progress during Tertiary and Quaternary times is suggested by the general presence of raised beaches on both sides of the equator. On the north, General de Lamothe determined the existence of ancient coast-lines in Algeria at 325, 255, 204, 148, 108, 60, 30, and 18 m. On the south, they have been observed in Mejillones Bay, Chile, at 320-300, 225, 133, 111-108, 40, and 15-18 m.

It looks as though the earth accomplished its contraction by pulsations.

Obituary.

Prof. Paul Jacobson.

On January 26 the death occurred at Berlin of Prof. Paul Jacobson, who was widely known as the general secretary of the German Chemical Society and as the editor of important chemical works. He was born on October 5, 1859, at Königsberg in Prussia, and he studied under A. W. Hofmann at Berlin and Victor Meyer at Göttingen. In that university he became a lecturer, and followed Victor Meyer to Heidelberg, where he became professor. Jacobson carried out a number of researches in the field of organic chemistry, especially on azo- and hydrazo-compounds, which earned him the reputation of a careful and original research worker. At the same time he began with Victor Meyer the "Lehrbuch der organischen Chemie," in which these two workers have put on record an immense amount of knowledge and experiences. After the early death of Victor Meyer, Jacobson continued to work alone, unfortunately without being able to finish it.

In 1897 Jacobson removed to Berlin as editor of the Berichte der Deutschen Chemischen Gesellschaft and general secretary of the society. He transacted the business of this society with indefatigable industry and perfect tact until September 1911. He then became scientific editor of the Abteilung für Sammelliteratur, which was founded by the society for the purpose of re-issuing F. Beilstein's "Handbook of Organic Chemistry" and M. M. Richter's "Lexicon of the Carbon-Compounds," and between 1900 and 1906 Jacobson edited five supplementary volumes to the third edition of Beilstein's Handbook. Then he commenced the fourth edition of this standard work, which is to be completed in the near future. The new editions of M. M. Richter have been continued under the supervision of Jacobson by R. Stelzner, as "Literaturverzeichnis der organischen Chemie."

The death of Paul Jacobson will be deeply regretted by all who came to know him in the meetings of the Society and at international congresses. Scientific research suffers a great loss by his death.

Prof. W. N. Parker.

The death occurred on February 22, at the age of sixty-five, at his residence at Cardiff, of Prof. W. N. Parker, emeritus professor of zoology at the University College of South Wales and Monmouthshire.

Prof. Parker was a pupil of Huxley and for a time acted as his demonstrator. During 1881 and 1882 he was lecturer in biology at University College, Aberystwyth. He joined the staff of the University College of South Wales and Monmouthshire when it opened its doors in 1883, and retired in September 1922. He came of an illustrious family, being a son of the late Prof. W. K. Parker, and a brother of the late Prof. T. J. Parker. He married a daughter of the late Prof. August Weismann, who survives him, and leaves a family consisting of a son and two daughters.

Prof. Parker was for many years president of the biological section of the Cardiff Naturalists' Society and a member of the science committee of the National Museum of Wales. To the latter institution he presented a valuable collection of zoological material a few months prior to his death. In collaboration with his brother he wrote Parker and Parker's "Practical Zoology." He also translated into English Weismann's "Germ Plasm" and an abbreviated form of Wiedersheim's "Vergleichende Anatomie der Wirbeltiere." In addition, he published original papers on the following subjects: "Anatomy and Physiology of Protopterus," "Poison-organs of Trachinus," "The Structure of the Young of *Echidna aculeata*," "Persistence of the Left Posterior Cardinal Vein in the Frog, with Remarks on the Homologies of the Veins in the Dipnoi," "The Respiratory Organs of Rhea," "On some Points in the Anatomy of the Indian Tapir (*Tapirus Indicus*)," "The Anatomy of the Cæcum in the Rabbit (*Lepus cuniculus*) and Hare (*Lepus timidus*)"; in collaboration with F. M. Balfour, "On the Structure and Development of *Lepidosteus*"; and in collaboration with T. H. Burlend, "On the Efferent Ducts of the Testis in *Chimæra monstrosa*."

Prof. Parker devoted himself for nearly forty years to the interests of the College and University and to the development and organisation of the zoological department. It is impossible to speak too highly of the courage and determination which he brought to bear upon his work in the face of great difficulties in the early days of the College. He will be sadly missed by a large body of former students who passed through his hands, in whose personal welfare, both in the department and outside, he always took the keenest interest. The news of his death will be received with great regret by a large circle of friends and former colleagues.

J. H. L.

Mr. F. J. Lloyd.

The death of Mr. Frederick James Lloyd on February 8 removes an interesting figure from the ranks of the older workers in agricultural science in this country. Mr. Lloyd was born at Sketty, near Swansea, in 1852, and was educated at Bristol Grammar School. After leaving school he proceeded, for family reasons, to study law, but, showing a natural aptitude and interest in science, he soon rejected a legal career and found an opening in the laboratory of the late Dr. Voelcker. The training received there during the next four years was supplemented by evening studies at King's College, London, and subsequent experience in chemistry during a sojourn in Germany. On his return to England he became successively chief assistant to Dr. Thomas Stevenson, of Guy's Hospital, and at the laboratory of the Royal Agricultural Society, ultimately setting up in practice on his own account as an agricultural chemist.

Mr. Lloyd's knowledge of physiology and agricultural chemistry thus acquired led him naturally to a special interest in the subject of dairying, with which he became still more closely identified on the death of Dr. Voelcker by his appointment as consulting chemist to the British Dairy Farmers' Association. His close connexion with that body lasted throughout his life and directed his attention to questions of milk production and the feeding of dairy stock in relation thereto. In due course he began a series of investigations on the manufacture of Cheddar cheese, undertaken on behalf of the Bath and West and Southern Counties Agricultural Society, which proved very helpful to cheese-making farmers of the West of England and brought him into contact with the special agricultural interests of that area. Cider-making particularly attracted his notice. In association with Mr. Neville Grenville, and again on behalf of the Bath and West Society, he started experiments designed to improve the methods of manufacture then current on farms. These extended over some ten years and resulted in the establishment of the National Fruit and Cider Institute at Long Ashton in 1903, Mr. Lloyd acting as director until 1905. This Institute, now associated with the University of Bristol, and serving as its Agricultural and Horticultural Research Station, has been developed by the Ministry of Agriculture to function as the senior Fruit Research Station for this country, and stands as a direct result of Mr. Lloyd's work.

Mr. Lloyd lived also to see the establishment of the Research Institute for Dairying at Reading. His pioneer studies on both the subjects with which he was so closely identified have thus found fitting recognition.

Much of Mr. Lloyd's work was published by him in the form of a series of reports in the Journal of the Bath and West Society, of which for some twenty years he was associate editor. Those relating to cider were republished later by the Ministry of Agriculture. He also, while holding an appointment as lecturer on agriculture at King's College, London, published his lectures in book form under the title of "The Science of Agriculture," a volume which has been translated into several languages.

We regret to announce the following deaths:

Prof. A. S. Butler, lately professor of natural philosophy in the University of St. Andrews, on March 2, aged sixty-eight.

Sir Ernest Clarke, until 1905 secretary of the Royal Agricultural Society of England and the first lecturer in agricultural history in the University of Cambridge, on March 4, aged sixty-seven.

Prof. B. E. Fernow, emeritus professor and dean of the faculty of forestry at the University of Toronto, and first chief forester of the United States, on February 6, aged seventy-two.

Prof. G. Lefevre, professor of zoology in the University of Missouri, on January 24, aged fifty-nine.

Prof. Vladimir M. Shimkevich, professor of zoology in the University of Petrograd.

Rev. William Wilks, for twenty-five years secretary of the Royal Horticultural Society and the producer of the well-known Shirley poppies, on March 2, aged seventy-nine.

Current Topics and Events.

MUCH excitement was recently created all over the world by the sensational headline, "Cause of influenza discovered at Rockefeller Institute, says Dr. Flexner." The announcement was given a prominent position in the daily papers and everywhere was lauded as one of the greatest medical discoveries known. Almost alone among our contemporaries we stated the actual facts of the work of Olitsky and Gates, the reputed discoverers of the long-sought-for microbe of influenza, and we recommended the adoption of a cautious reserve until further data were revealed. Some of the inner history of this latest American press boom are now published in an editorial in the *Journal of the American Medical Association* (February 10), which has the greatest circulation of the medical papers of the United States and is a journal of the highest repute. It seems that after the sensational announcement above, the *Journal* telegraphed to Dr. Simon Flexner, who replied that his announcement was merely a summary of papers already published by Olitsky and Gates in the ordinary way in the *Journal of Experimental Medicine*. The summary was prepared for the New York State Department of Health. Dr. Flexner states that some one in the State publicity department had headlined the summary without his knowledge. Now that the actual statement of Dr. Flexner has appeared in the Health News Service, it is seen to be nothing that has not been known for the last three years, and as the *Journal of the American Medical Association* points out, the "organism cannot be said to have been conclusively shown to be the cause of the condition known as epidemic influenza," a view which we ourselves independently printed. In justice to the Press it is stated that in this instance it was not to blame, but it is not stated who was. The *Journal* deprecates this method of publication, leading as it does to false hopes for thousands of sufferers, and to the ultimate discredit of real advances in medical science.

TELEGRAMS from New York appeared in several newspapers of February 28, announcing the discovery of a fossilised human skull in the province of Santa Cruz, Patagonia. The *Times* of March 1 published particulars relating to the skull, which were obtained by its correspondent at Buenos Ayres from the discoverer, Dr. Wolf, formerly of the Canadian Geological Survey. The skull, it appears, was found not by Dr. Wolf but by a settler seven years ago in sand-hills in the pampas lying some twenty miles to the west of the port of Santa Cruz. The discoverer reports it to be "petrified" and "probably of tertiary origin." As regards its characters, all that is to be learned is that it is "long in proportion to its width," that its "frontal eminences are well marked," and that it may be a woman's skull. It is true that there exist in Patagonia deposits of the right age to yield fossil remains of Pliocene man, and on numerous occasions, during the past twenty-five years, claims of his discovery have been made. None has stood the test of inquiry; when the remains proved to be human, it was found that a mistake had been made concerning their geological antiquity; when their antiquity was upheld, the remains proved not to be human. Whether the discovery now announced will prove an exception remains to be seen.

IT is reported that excavations now being carried on at Ur of the Chaldees on behalf of the British Museum and the University of Pennsylvania have brought to light a temple of the Moon God. As Ur was the seat of the worship of deified kings and one of the greatest centres of ancient theology, its further investigation is likely to add considerably to our knowledge of the religious and social life of early Mesopotamia. The site and the purpose of the temple were first identified through the interpretation by Rawlinson of four cylinder seals discovered in 1854 by J. E. Taylor, who located the temple tower and excavated an adjacent building and burial mound. Further excavations were carried out by Mr. R. Campbell Thompson in 1918 and by Dr. H. R. Hall, on behalf of the Trustees of the British Museum, in 1919. Dr. Hall also investigated a neighbouring site at Tell el-Obeid, where he found much copper, including several lion heads and a large relief, in a pre-Sargonic building (*circ.* 2900 B.C.) beneath a platform of unburnt brick, probably of Dunghi of Ur (*circ.* 2450 B.C.). The site of Ur itself was occupied from neolithic down to quite late times, the temple having been restored by Nabonidus in the sixth century B.C. As regards its early inhabitants, Mr. Campbell Thompson, in the *Times* of March 1, points out that the present excavations may be expected to throw light upon his suggestion that the people of this area differed in race from the Sumerians. This view is based upon the character of the fragments of hand-made, painted pottery found by himself and Dr. Hall at Ur, Eridu and Tell el-Obeid, which is identical with that discovered by de Morgan at Susa in Elam. This latter, in turn, is referred to a similar, but rougher, type found at Anau in Turkestan.

A WELL-PRESERVED dolmen has been discovered by workmen while excavating at the back of a house at St. Ouens, Jersey. Associated with the dolmen was a kitchen midden full of limpet shells and containing an ancient human skull and a round stone for grinding corn. The skull is very much flattened in the frontal region, and it is no doubt on this ground that a very high antiquity, exceeding that of *Pithecanthropus erectus*, has been attributed to it locally, as is stated in a highly coloured report which appeared in the *Daily Mail* of February 26. It is also suggested that the kitchen midden is of mesolithic age. Although the find is of considerable interest, neither supposition appears to be well founded. Shell-fish must always have been, as they are still, an important element in the diet of the islanders, and therefore does not necessarily indicate a mesolithic culture, while the association with the dolmen and a stone for grinding corn would suggest that a very early date in the neolithic period for the skull is not probable. The flattened appearance of the skull, upon which stress is laid in the report of the discovery, may be due to pathological causes, but more probably is, as often happens, a case of flattening due to post-mortem pressure after burial. Further details of the measurements of the skull will be awaited with interest, as it will be important to note whether, notwithstanding its distortion, it is to be ascribed to the Mediterranean long-headed type.

On February 12, Prof. Otto Pettersson, director of the Swedish Hydrographic Biological Commission, Gothenburg, celebrated the seventy-fifth anniversary of his birth, and both chemists and oceanographers in this country, to whom his genial personality is so well known, will wish to join in offering him their congratulations and their good wishes for his future prosperity. Having in early life made a European reputation as a chemist, Prof. Pettersson turned his attention to the study of oceanography, and much of the work in that subject during the last thirty years has owed its success to his initiative and inspiration. His name is particularly associated with the foundation in 1902 of the International Council for the Study of the Sea, of which organisation he was president for a number of years. It was largely owing to Prof. Pettersson's influence and efforts that the Council survived the trying period of the European war and has since renewed and extended the valuable co-operative researches which it is conducting in the interests of the fisheries. We rejoice to know that in spite of his advanced age, Prof. Pettersson's zeal for scientific work is in no way abated, and that he remains an active and energetic investigator, more especially of problems affecting the sea.

The sixth Silvanus Thompson memorial lecture of the Röntgen Society is to be delivered on Tuesday, May 1, by Dr. C. Thurston Holland.

The gold medal of the Astronomical Society of the Pacific was presented to M. B. Baillaud, director of the Paris Observatory, at the American Embassy in Paris on February 26.

Dr. Christopher K. Ingold was awarded the Meldola medal of the Institute of Chemistry, for the second time, at the annual general meeting of the Institute held on March 1.

An excursion to Devizes and Salisbury Plain, extending from May 18 to 21 inclusive, particulars of which are obtainable from Mr. B. H. Cunnington, Wiltshire Archæological Society, Devizes, has been arranged by the Prehistoric Society of East Anglia.

The Medical Research Council has appointed the following scientific committee to organise an investigation into dog's distemper: Sir William B. Leishman (chairman), Mr. J. B. Buxton, Capt. S. R. Douglas, Prof. F. Hobday, and Dr. C. J. Martin. A member of the Council's staff will act as secretary to the committee, and communications should be addressed to the Secretary, Distemper Research Committee, 15 York Buildings, Adelphi, W.C.2.

The British Association recently acted in co-operation with a number of other "travelling" societies in requesting the railway companies to revert to the pre-war practice of granting return tickets at single fare and one-third to members attending meetings, on presentation of a voucher. The Association has now been informed that in connexion with its next annual meeting, in Liverpool, September 12–19, this concession will be made by the companies.

At the meeting of the Franklin Institute of the State of Pennsylvania, Philadelphia, held on February 21, Dr. Lee de Forest received the Elliott Cresson gold medal awarded to him by the Institute for his invention of the three-electrode audion. In presenting Dr. de Forest for this award, his invention was characterised as one of the most important ever made in the field of the electrical transmission of intelligence, and one which through its development has marked a profound revolution in the art of radio communication.

The tenth annual general meeting of the Institution of Petroleum Technologists will be held at the House of the Royal Society of Arts on Tuesday, March 13, when an address will be delivered by Prof. J. S. S. Brame, the retiring president. The president-elect for the ensuing session is Mr. Herbert Barringer, and the vice-presidents are Mr. Alfred C. Adams, Sir George Beilby, Sir John Cargill, Viscount Cowdray of Cowdray, Mr. Arthur W. Eastlake, and Sir Thomas H. Holland.

At the annual general meeting of the Optical Society, held on February 8, the following officers and council were elected: *President*: Prof. A. Barr. *Vice-Presidents*: Sir Frank Dyson, Mr. T. Smith, and Mr. R. S. Whipple. *Hon. Treasurer*: Maj. E. O. Henrici. *Hon. Secretaries*: (*a*) Business Secretary, Prof. Alan Pollard, Imperial College of Science and Technology, South Kensington, S.W.7; and (*b*) Papers Secretary, Mr. F. F. S. Bryson, Glass Research Association, 50 Bedford Square, W.C.1. *Hon. Librarian*: Mr. J. H. Sutcliffe. *Editor of Transactions*: Dr. J. S. Anderson. *Council*: Dr. J. S. Anderson, Instr.-Comdr. T. Y. Baker, Mr. W. M. Brett, Prof. F. J. Cheshire, Mr. R. W. Cheshire, Dr. R. S. Clay, Mr. H. H. Emsley, Mr. P. F. Everitt, Dr. J. W. French, Miss L. M. Gillman, Mrs. C. H. Griffiths, Dr. L. C. Martin, Prof. A. W. Porter, Mr. F. Twyman, and Mr. A. Whitwell.

A new meteorological observatory at Santa Cruz, Teneriffe, Canary Islands, was sanctioned by Royal Decree in July 1921. It is now announced that the building has been started, and will probably be completed shortly. The fact is noted in the *Meteorological Magazine* for February, and it is stated that the Island of Teneriffe already has a first-class observatory at Izana, situated 2307 metres above sea-level. Being on the direct route from Lisbon to Rio de Janeiro, these two observatories will be of great service to transatlantic aerial navigation. The note adds that a hydroplane station is also to be established on the island.

A memorandum on the probable character of the weather in north-west India in January, February, and March 1923 was prepared by Dr. G. T. Walker, director-general of Indian observatories, and submitted to the Government of India on January 5. The data which control the amount of rain and snow to be expected are:—(*a*) The recent weather conditions in Persia and north-west India; these are slightly favourable. (*b*) The seasonal change in the upper air in northern India, which is slightly adverse. (*c*) The atmospheric pressure over India in the previous October and November, which is neutral, October being above normal and November below normal. (*d*) Rainfall at Seychelles and Zanzibar; rainfall at Seychelles was in defect in November and December, and at Zanzibar it was in excess in December. On the whole the indications point to a slight defect in the winter precipitation, but the indications are said not to be sufficiently pronounced to justify a forecast of a deficiency.

Referring to the obituary notice of Prof. George Lunge in Nature of February 17, p. 228, a correspondent has pointed out the last paragraph might give the impression that Dr. Hurter was of German nationality whereas he was a native of Schaffhausen, Switzerland. The writer of the notice was concerned rather with the influence exercised at the time by the German universities in providing opportunities, not necessarily for Germans alone, for scientific training as chemists, some of whom came to England to acquire knowledge and experience of the practical applications of the science.

We have received from Messrs. A. Gallenkamp and Co. a catalogue of "Electrometric Apparatus for determining Hydrogen Ion Concentrations." This includes an apparatus for determining hydrogen ion concentrations both for work of high accuracy and for routine industrial work.

Messrs. Bowes and Bowes, 1 Trinity Street, Cambridge, have just issued a very useful catalogue (No. 417) of second-hand books, journals, and portraits of scientific interest offered for sale by them. It contains 1158 titles, which are classified under the following headings: Journals, etc.; Agriculture; Anthropology and Ethnology; Biography; Biology; Botany (including Forestry and Gardening); Geology; Microscopy; Zoology (including Ornithology and Entomology); General Science; Chemistry; Physics (including Einstein Theory); Medical (including Physiology); Portraits.

Our Astronomical Column.

Increase of Brightness of Beta Ceti.—There appears to be no reason to doubt the news that this star has brightened by more than a magnitude in the last week or so. The change was first observed by a British schoolboy named Abbott, resident in Athens; being a member of La Société Astronomique de France, he telegraphed to M. Camille Flammarion at Juvisy, whose assistant, M. Quénisset, confirmed the brightening. Apparently further confirmation has been received from the United States. Unfortunately the star is observable in England only by day or in very bright twilight, and the skies have not been propitious for studying it. Data for drawing the light curve are not yet to hand, so that it is premature to speculate on the probable cause of the increase of light. The news hitherto available comes through the daily press; the Astronomical Bureau at Copenhagen has made no communication.

The Zodiacal Light.—Mr. W. F. Denning writes:—During the period from about March 8–20 and April 4–18, the zodiacal light may be well observed on clear evenings in the absence of moonlight. It will be visible about two hours after sunset as a faint glow extending upwards, obliquely, through the constellations of the Zodiac, and broadest at its base on the western region of the horizon. It apparently varies from night to night, for its visibility is evidently influenced by atmospheric conditions. Careful observations of the degree of luminosity, positions, and boundaries of the light on successive evenings will be valuable. The most probable explanation of the phenomenon is that it is due to the sun's reflected light on myriads of meteoric particles belonging to systems of little inclination and situated at moderate distances from the sun.

The Spectra of Visual Double Stars.—Mr. F. C. Leonard publishes in the Lick Observatory Bulletin (No. 343) an important contribution to the study of the spectra of visual double stars. If the components of a double star had a common origin, a knowledge of the spectral relationships existing in different systems, presumably at various stages in the course of evolution, might be expected to disclose the general trend and the comparative rates of development of these stars. It was with the intention of gaining more knowledge on this subject that Mr. Leonard commenced this investigation in 1920. From a study of eighty visual double stars specially observed for this work, he finds that the spectrum of the secondary component of a dwarf star is generally of a later class and that of a giant star is of an earlier class than the primary. In both giant and dwarf stars the greater the difference in magnitude between the primary and secondary the greater is the absolute difference in spectral class.

The spectrum of each component of a double star appears to be a function mainly of its absolute magnitude; or in other words, the spectra of the components of double stars are so related to each other that, with but few exceptions, these systems conform to the Hertzsprung-Russell arrangement for individual stars, plotted according to spectral class and absolute magnitude. In this configuration, the fainter component normally precedes the brighter one, regardless of whether the latter be a giant or dwarf in the order prescribed by the Lockyer-Russell theory of stellar evolution. The two earlier conclusions are special phases or necessary consequences of this generalisation. Thirteen binary systems, all stars of which were dwarfs, indicated that as the sum of the masses of the components increased, their disparity in spectral class approached zero. Of any two stars of unequal mass but of otherwise identical physical properties, that with the less mass will in general pass through its life history in advance of the more massive one.

Research Items.

The Oldest Christian Tomb in India.—Agra, which possesses, in the splendid mausoleum known as the Taj, one of the finest sepulchres in the world, claims also the oldest Christian grave in northern India. It is known as the Martyr's Chapel, the tomb of a rich and very pious Armenian merchant called Martyrose, who died at Agra in A.D. 1611. The inscription on the tomb, now for the first time translated by Mr. Mesrovb Seth in the Journal of the Asiatic Society of Bengal, vol. xvii., 1921, runs: "In this tomb rested the pilgrim Martyrose son of Pheerbashi of Julfa. He died in the city of Agra and gave his goods to God for his soul. 1060 of the Armenian era." The Archæological Department has now restored the tomb of this worthy, a member of the important Armenian community of Julfa in Persia, who came to India as a merchant. An inscription in Persian to his memory has been placed on the tomb.

The Ismaili Sect of Islam.—The important sect of the Ismailis or Assassins, the doctrines of which were preached by the Old Man of the Mountain, has exercised wide influence in Persia. The scattered material collected by historians, travellers, and theologians cannot compare in value with the genuine documents of the sectarian literature, but for five hundred years, when these materials came to an end at the time of the Mongol invasion which destroyed the power of the Assassins, the life of the sect is a blank. Mr. W. Ivanov, who has spent seven years in investigating the beliefs of the sectarians in Persia, has published under the title of "Ismailitiia," a translation of an important text which throws much light on the subject. This has been issued by the Asiatic Society of Bengal as part 1, vol. viii. of its memoirs. It will be interesting to European readers, as the leader of the sect is the Agha Khan of Bombay who did notable service to the Indian Government in the War, and has since devoted himself to the task of calming the agitation which has arisen in India on the Caliphate question.

The Indian Tribes of California.—The University of California, in its series of publications on American archæology and ethnology, has issued a large number of valuable memoirs, but a general survey of the inter-relations of the culture of these tribes has hitherto been wanting. This want has now been supplied by Mr. A. L. Kroeber, an ethnologist to whom we owe several of these tribal memoirs, who has prepared a general sketch under the title of "Elements of Culture in Native California," for the University series (vol. xiii. No. 8), in which he describes the arts of life, social organisation, religion, and ceremonies. This memoir, which gives an excellent survey of the industrial, social, and religious life of a primitive people, will be a valuable book of reference to ethnologists. It is provided with sketch maps, but unfortunately a general index is wanting.

Microbic Transmissible Autolysis.—One of the most interesting developments of modern bacteriology has been in relation to what is now called the Twort-d'Hérelle phenomenon. This has recently been the subject of the Cameron prize lecture given by Prof. J. Bordet, of Brussels, and published in the *Brit. Med. Journal* of February 3. In this lecture the main facts are clearly set forth and particularly the views of Bordet and his co-workers. For those who have not been following the subject specially it may be stated that in 1915, F. W. Twort, Director of the Brown Institution, London, described a peculiar glassy-like change which appeared in colonies of certain micrococci which he had isolated from calf lymph. A minute trace of the glassy agent added to a cultivation of bacteria dissolved the latter, and strange to say, the glassy agent could traverse fine porcelain filters without detriment. In 1917 d'Hérelle observed similar phenomena and regarded them as due to the activity of a living agent which he called "microbe bacteriophage" on account of its power of devouring bacteria. This view he has continued to defend with great vigour. Bordet and Ciuca adopted an entirely different explanation. They do not believe the active substance is a living agent at all but as a product of the bacterium itself induced in the first instance by some external influence and subsequently capable of indefinite transmission. A full treatment of the subject will be found in Bordet's lecture referred to above.

The Spleen.—The functions of this organ are somewhat obscure. It is generally recognised, however, that it has something to do with the destruction of effete red blood corpuscles. A certain proportion of the corpuscles in general circulation are more fragile than the rest, in the sense that when distended by osmosis in hypotonic solutions they burst in solutions of a higher concentration than do the younger, more distensible ones. A recent paper by Bolt and Heeres, in the *Biochemical Journal*, vol. 16, p. 754, shows that after passing through the spleen, blood corpuscles are rendered less resistant, so that a larger proportion become hæmolysed when placed in the stronger salt solutions, that is, the less hypotonic solutions. Thus they withstand distension to a smaller degree than normally. This property is due to the adsorption of some substance supplied by the spleen and can be removed by washing with Ringer's solution. The previous work of Brinkman and van Dam had shown that the fragility of red corpuscles depends on the relative proportion between cholesterol and lecithine in their outer membranes, the former conferring stability, the latter, fragility. Apparently the spleen adds lecithine in larger amount than it does cholesterol.

Curing Sleeping Sickness.—In the *Empire Review* for February Dr. Andrew Balfour has an interesting article entitled "Cure of Sleeping Sickness." He deals largely with the claims of the new German remedy "Bayer 205" and admits that it is the most powerful destroyer of the parasites of the disease so far tested. For a time sleeping sickness and other trypanosome diseases were looked upon as absolutely fatal, while later on partial success was achieved by more than one remedy containing arsenical or antimonial bodies. "Bayer 205" contains neither of these in any form, and although its exact composition is not known, it is suggested that it belongs to the benzidine dye series. It is a white powder, easily dissolved in water, neutral in reaction, without smell, and does not deteriorate on heating. It possesses extraordinary parasitotropic action on trypanosomes, and in minute doses can produce a *sterilisatio magna* in animals heavily infected with these parasites. These results worked out by Haendel and Joetten have been confirmed in man by Mühlens and Menk in Germany and by Wenyon and Manson Bahr in London. Dr. Balfour emphasises the need for chemical research in this country, and lays stress on the necessity for persistence, time, money, and far-sightedness. Ehrlich was fond of summing up the success of scientific researches in what he termed the four G's, *Geld, Glück, Geduld, Geschick*, which comes to the same thing.

RECENT PENTACRINIDÆ.—In the Journal of the Washington Academy of Sciences of January 4 Mr. A. H. Clark publishes a revision of the recent representatives of the crinoid family Pentacrinidæ. For many years the name Pentacrinus has ceased to be applied to any crinoid now living, and now Isocrinus, to which genus most of the modern species were for a time referred, is also considered to be entirely extinct. For the only species that remained—the Atlantic *Pentacrinus wyville-thomsoni*—Mr. Clark founds the new genus Annacrinus.

A NEW BRITISH ENTEROPNEUST.—In the current number of the *Quarterly Journal of Microscopical Science* (vol. 66, part iv.) Prof. Alexander Meek records the discovery of an interesting addition to the British marine fauna. The Enteropneusta have hitherto been represented in British seas, so far as known, only by two species of the genus Dolichoglossus, from the west coast of Ireland and Scotland respectively. The newly discovered species is apparently referable to the genus Glossobalanus, and the name proposed by Prof. Meek is *Glossobalanus marginatus*, the species being regarded as distinct from any previously described. Unfortunately only a single imperfect specimen was obtained, off the coast of Northumberland at a depth of 52 fathoms. It is further suggested that a Tornaria larva sometimes met with in the North Sea plankton may be referable to this species.

POMOLOGY.—A few years ago Mr. E. A. Bunyard, of the well-known Maidstone nurseries, upon his own initiative started a *Journal of Pomology*, in which contributions of very great scientific interest have been published. With its third volume this journal commences its career anew as the *Journal of Pomology and Horticultural Science*, with a powerful publication committee to support the original editor, the financial responsibilities now being transferred to the three horticultural research stations at Long Ashton near Bristol, Cambridge, and East Malling, Kent. In a foreword, Sir A. D. Hall expresses his interest in the new journal and his hope that while providing a medium for the publication of the results obtained by the investigators at these research stations, it may also "gather together new knowledge and experience from all kinds of public and private workers connected with fruit-growing in Great Britain." From the beginning the format of the journal has been good and many of its photographic reproductions exceptionally fine. The first number of the new volume contains a valuable series of papers upon the raspberry. The genus Rubus has long been a stumbling-block to systematists, and Mr. N. H. Grubb appears to have commenced for *Rubus Idæus* the task which the late Rev. Moyle Rogers carried out so thoroughly for *Rubus fruticosus*. Upon a series of characters the large and confusing number of varieties of raspberry grown in Great Britain are arranged within groups and a key given to permit the determination of some of the more important varieties. First importance is attached to the surface characters of the young canes, which fall into two groups, one pubescent, the other glabrous or nearly so; the colours of the spines then provide another valuable character. This important work is certainly a necessary preliminary to any cultural or experimental work with the raspberry. W. Boyes describes the characters of different types of apple-tree shoots, based largely upon the current nomenclature of the French horticulturist. F. V. Theobald describes the apple and plum case-bearer and its treatment. Herbert W. Miles discusses the control of the apple-blossom weevil, and G. S. Peren the value of spraying for the control of the logan beetle.

SURVEYS IN THE EASTERN KARA-KORAM AND KHOTAN.—A detachment from the Survey of India, under Maj. H. Wood, was attached to Dr. F. de Filippi's expedition of 1913 to undertake exploration and geophysical researches in the little-known regions of the Kara-koram at the headwaters of the Shyok and Yarkand rivers. Maj. Wood's report, which was delayed by the war, is now published ("Exploration in the Eastern Kara-koram and the Upper Yarkand Valley. Dehra Dun: Office of the Survey, 1922. 6*s*.). The work included the survey of the Depsang plateau, the San Remo Glacier, from which the River Yarkand proves to drain, and the upper valley of that river. Maj. Wood shows how he ascended what he believes to be the line of an old route leading across the head basin of the Oprang, but Dr. Filippi was forced to abandon his project of exploring that valley. An appendix contains a discussion of historical evidence bearing on certain disused or forgotten routes through the Kara-korams. The report is accompanied by a series of photographic plates and a coloured map, on a scale of 1 to 250,000, of the area surveyed by Dr. F. de Filippi's expedition.

MAN AS AN AGENT IN GEOGRAPHICAL CHANGE.—Some of the ways in which man modifies the surface features of the earth were discussed in a lecture by Dr. R. L. Sherlock, given to the Royal Geographical Society on February 19. Mining and quarrying assist the natural agents of denudation and transform scenery. A calculation of the amount of rock removed in various kinds of excavation by man in Great Britain since the earliest times shows the significance of this work. The total excavation spread over the British Isles would amount to 3·83 inches. This may be compared with Geikie's estimate of the rate of erosion in the British Isles, which is 2·72 inches in 2000 years. Surface subsidence is an important effect of mining operations. Dr. Sherlock showed how this might be prevented or delayed by leaving pillars to support the roof, or by the method frequently adopted in the collieries of Upper Silesia of stowing waste materials in the cavities produced. The accumulation of waste on the surface may be utilised to fill up a foreshore as at Middlesbrough, where 4270 acres have been reclaimed in this manner; or it may form artificial hills. In the Black Country of Staffordshire some 230 million cubic yards of waste have been deposited on 23 square miles. Yet in this case subsidence has probably more than counterbalanced the gain. Under the site of London some 50 million cubic yards have been excavated, but brick or other linings have prevented subsidence. In fact, the level of London has actually risen by the accumulation of domestic and other waste. Excavations have shown this to be the case. On its own debris the height of London grows about one foot a century. It is probable that in three centuries the waste from the coal used in London has amounted to more than 42 million tons. Most of this directly, or indirectly, in the form of bricks and artificial flagstones, has been incorporated in the site of London. Dr. Sherlock also gave examples of man's interference with rivers, and, by means of pumping, with the circulation of underground waters.

OIL IN LACCOLITHIC DOMES.—Of the many geological structures in which petroliferous sediments may be involved, elevated, dome-like masses of rock, resulting from igneous intrusion of the laccolithic type, are rarely productive of oil on a commercial scale, save possibly in certain cases in Mexico. There is, however, no reason *prima facie* why such a structure should not be favourable, unless secondary mechanical or thermo-dynamical effects on the superincumbent strata seriously influence the stability of organic material within the sediments. Thus it is not surprising to find that the United States Geological Survey is turning its attention to such possibilities in certain areas in the Western States, and a brief paper (Bulletin 736-F) dealing with oil accumulation in laccolithic domes in the Little Rocky Mountains region of Montana (the work of Messrs. A. J. Collier and S. H. Cathcart) is one of the first results of this inquiry. In the cases described, the uplifts are due to intrusions of porphyry, some of which are exposed, others, in the less denuded tracts of country, being still covered by sediments of varying ages, principally Upper and Lower Cretaceous. Of the former, the Eagle sandstone and the Mowry shale are both possible oil-bearing horizons, while the Kootenai formation (Lower Cretaceous) is well known to be favourable elsewhere. One or other of these horizons could be reached by drilling in at least two pronounced domes, the Guinn and the Grouse-Alder domes, within the area described, to the south of the Little Rocky Mountains. The authors do not of course prophesy commercial success for any fields which may be opened up here, but they have indicated the most likely areas in an otherwise discouraging region, and it will be interesting to observe, both from the scientific and industrial points of view, the results of any trials which may ultimately be made as a consequence of their report.

Lighting in Mines.—A striking illustration of the value of good illumination in enabling output to be increased in industrial operations is afforded by some experiments in coal mines described by Messrs. E. Farmer, S. Adams and A. Stephenson in the Journal of the National Institute of Industrial Psychology. The report of the Miners' Nystagmus Research Committee, issued last year, confirmed the impression that this disease is due mainly to inadequate illumination. The present research shows how the miner's work is hampered and his output affected by deficient lighting. There are two chief drawbacks to most existing miners' lamps, the low illumination afforded and the exposure of the filaments, which, in such dark surroundings, give rise to highly inconvenient after-images on the retina. The authors describe a form of cylindrical shield which has a useful effect in avoiding this form of glare, and also give the results of work for an eight-hour period with the ordinary standard miners' lamp and with a special "porch-light" giving six times as great an illumination. It was shown that the improved illumination led to an increase in output from 2·47 to 2·83 tons, an increase of 14·57 per cent. The experiment serves to show the wide field for improvement existing in lighting conditions in coal mines and the benefits that might be secured by a moderate expenditure on research.

Meteorology at Southport.—Results of meteorological observations at Southport for the year 1921, and the annual report of the Fernley Observatory of the Corporation of Southport, compiled by the meteorologist, Mr. Joseph Baxendell, have recently been issued. The report is published in two editions, copies being circulated by the Southport Corporation, and by the Meteorological Office, Air Ministry. The Borough Observatory of Southport is the longest municipally-maintained meteorological station in the British Isles, observations having continued for the past 50 years. Daily, weekly, and monthly returns are supplied to the Meteorological Office. Much time has been devoted to the comparisons involved in the investigations of meteorological periodicities; among the clearly indicated cycles is one of 5 years, while a rainfall cycle of 53 years is said to be the chief. An appendix gives monthly averages, for 10 years, of the amount and duration of rainfall under different wind directions. It is shown that winds from southerly points are pre-eminently those of the rainy quarter. The most remarkable year during the half-century's existence of the observatory is stated to be 1921, although in the north-west of England it was not so dry as several previous years; the total deficiency of 4 inches of rainfall was trivial in comparison with the extraordinary drought over south-eastern England. For general fine-weather factors there is no known predecessor to equal it, the outstanding feature being the remarkably high mean atmospheric pressure. The underground water-level remained extremely low until the substantial winter rains in the latter part of December. Taken as a whole, the meteorological results will serve well as a guide for observations made by other municipal bodies.

Distance Thermometers.—Messrs. Negretti and Zambra have introduced a type of distance thermometer which appears to get over many of the difficulties and errors to which such instruments have been subject in the past. The new instruments depend on the expansion of mercury in a steel bulb to which a capillary tube of the required length is attached. This tube ends in a coiled Bourdon tube with the free end of which the pointer of the instrument gears directly. The pointer moves over a circular dial about 300° of which are occupied by the scale. The effect of change of temperature of the connecting capillary is eliminated by a wire of invar running down the tube and reducing the volume of mercury to such an extent that the change of its volume with change of temperature is identical with the change of volume of the steel tube. The errors of such an instrument tested at the National Physical Laboratory from 0° to 50° C. at no point of the scale exceeded 0·05° C.

Photo-elastic Research.—In a recent number of the Memoirs of the Society of French Civil Engineers (Bulletin de juillet-septembre 1922) Prof. E. G. Coker gives the text of a lecture, delivered by him last summer in Paris, which contains an up-to-date account of the method of exploring stresses in structures by means of celluloid models examined in polarised light, a method which is at present making rapid progress both here and on the Continent, and bids fair to become indispensable to every scientific engineer. Besides giving a sketch of the method and its general applications, Prof. Coker obtains new and interesting results concerning the testing of cement briquettes under tension, and compares the standard forms of such test-pieces adopted in Britain and France respectively. In particular, he shows that the standard briquettes adopted in both countries for cement tests lead to a strikingly unequal distribution of tensile stress across the middle section of the test-piece, and thereby to serious error in the deduced tensile strength. He suggests, as the result of photo-elastic research, a new shape of standard briquette which is free from this defect. Further illustrations of the method include a discussion of contact stresses and an investigation of the stresses arising from the action of cutting tools, both in the work and in the tool itself. This part of the lecture is partly a restatement of results previously described by the author and Dr. Chakko in the Proceedings of the Institution of Mechanical Engineers in April 1922, but various novel points are introduced.

The British Science Guild.

The Mansion House was an appropriate *venue* for the great meeting organised by the British Science Guild on February 27 to acknowledge and proclaim the importance of scientific method, scientific knowledge, and scientific research as factors in promoting "national and Imperial interests." In the Egyptian Hall, with its high curved roof, its brilliant stained-glass windows, its serried banners recalling battles and heroes of long ago, the Lord Mayor presided over a distinguished company of representatives of modern science and industry. The first citizen of London is the honoured custodian of many great traditions, among which not the least precious is the city's historic generosity in promoting education and science. The City and its Companies have in the past given freely of their wealth in aid of these great causes, and it is fitting therefore that their faith in science, so amply proved, should stimulate the new crusade for its increased national recognition. Not less significant was the King's message of encouragement which Lord Askwith read to the meeting, welcoming the efforts of the Guild "to stimulate the scientific spirit, and to secure that application of science to industries, commerce, and, indeed, in all fields of human activities, so essential to efficiency and to the closer fellowship of all parts of the Empire."

The Lord Mayor, in his introductory remarks, emphasised the usefulness of the Guild's work of propaganda. When, he said, the British Science Guild was founded in 1905, its first object was stated to be to convince British people, by means of publications and meetings, of "the necessity of applying the methods of science to all branches of human endeavour, and thus to further the progress and increase the welfare of the Empire." Modern civilisation is so closely bound up with the advance of scientific knowledge that all progressive citizens can realise the service which a body like the Guild is able to render to this country and to Imperial development. This is an age of science, when such wonders as X-rays, radium, and wireless telephony, which have added so greatly to human powers and communication, are accepted almost as commonplace parts of our daily life. More scientific work is being carried on now than ever before, and we may expect results which will be of even greater value than those already achieved. British science in several directions leads the world, and it is right that this fact should be more widely recognised. Science stands not only for new devices and powers, but also for accurate knowledge and the right use of man's capacity and individuality. Scientific method must, therefore, be applied to social problems if the true principles of progress are to be determined. The Guild stands for national service in a wide sense: it includes representatives not only of pure and applied science, but also of industry and capital. After the Napoleonic wars, the nation found itself exhausted and impoverished. Our national position was re-established through the steam-engine and the industrial development which followed. We have now to look to the science laboratory to restore our economic position, and even to improved agricultural production. Later in the meeting the same note was sounded by Sir Joseph Cook, High Commissioner for Australia, who pointed out that a vast amount of capital had been wasted through the war, but the loss would soon be made good if two blades of grass could be made to grow instead of one or if the speed of steamships and other forms of transport could be doubled.

The principal resolution was moved by Lord Askwith as president of the Guild and accepted unanimously in the following terms:

"That this meeting, convinced that the progressive use of scientific knowledge is essential to industry and commerce, and that the application of scientific method to all public affairs would ensure increased efficiency and economy, pledges itself to support the efforts of the British Science Guild to promote national and Imperial interests by means of these powerful factors."

A letter of apology for absence was read from Sir Joseph Thomson, which stressed the need for the popularisation of science on the widest possible basis. "It seems to me," Sir Joseph said, "that the remarkable increase in the opportunities for scientific research which has taken place in the last thirty or forty years has not been accompanied by a proportionate increase in the means of bringing matters of scientific interest before the great mass of the people. . . . I do not forget the work of some of the great newspapers in spreading an interest in science by the admirable articles they publish at frequent intervals, but the public I am thinking of does not read the *Times* or the *Morning Post*." A more urgent need was to arouse an interest in science in the bulk of the population, which would facilitate the passage of measures to promote the progress of science in this country. Lord Askwith endorsed this plea and urged also that a great deal more might be done to endow discovery. It was of immense importance, he considered, that men of science without the hope of immediate reward should probe the mysteries of Nature, and that new discoveries should be brought quickly into general knowledge.

The appeal for some further endowment of "problem-solvers"—the elder men of science who devoted their lives to research as apart from the young trained laboratory workers—was vigorously pressed by Sir Ronald Ross. It might be supposed that the discoverer of the cause of cancer or tuberculosis would soon become a millionaire, but he pointed out that Sir David Bruce, who solved the problem of sleeping sickness, was now in Madeira unemployed, and there were three or four others whom he could name. He suggested that the nation should pension scientific discoverers of pre-eminent worth, and allow them to go on working as they pleased.

The vote of thanks to the Lord Mayor and the other speakers was proposed by Lord Askwith and seconded by Lord Bledisloe, who made an interesting speech on the application of science to agriculture. It appears that Continental agriculturists use the results of the researches on fertilisers and plant diseases at Rothamsted more than we do ourselves.

The meeting was a prelude to the launching of a national appeal by the British Science Guild for increased personal and financial support, and an appeal committee has been appointed, of which Lord Askwith is president. The list of members includes many distinguished representatives of science and public life. The director of the appeal is Commander L. C. Bernacchi, physicist of Scott's first Antarctic Expedition. A comprehensive plan of objects and methods has been drawn up and will be widely circulated in due course. The details of the scheme were not announced to the meeting, but the Lord Mayor said at the conclusion of his speech that whatever support was given to it would be returned a hundredfold in national honour and profit.

Research in the Scheme of Higher Education.[1]

By Dr. Herbert H. Hodgson, The Technical College, Huddersfield.

The present time is exhibiting none other than a break in the continuity of civilisation. No longer must the production and recognition of supermen be left to chance, since unusual genius, in whatever quarter it may be found, must have a field provided for its activities if our place as a leading nation has to be maintained. It is the province of higher education to discover this genius, a province, which, owing to haphazard evolution, is largely at the mercy of the dilettante, and, as a consequence, not yet in a condition to evolve those power stations of mind without which the necessary creative atmosphere remains ungenerated. The practical results of the German system of higher education have been the creation and development of key industries wherever possible, these ensuring an industrial system which afforded the security of continuous employment of an extremely varied character. This conferred a measure of national stability which was stout enough to defy the whole world for four years, and, but for lack of psychological balance, might have retired the actual winner of an apparently drawn battle.

The industrial exploitation of chemical science by Germany has entirely changed the international situation, inasmuch as a flourishing all-round chemical industry is now essential to the continued success and progress of all great manufacturing activities. This industry dominates the whole trade situation, and no country, however friendly at present, must ever be in a position to dictate by means of it such terms as can spell eventually our decadence and commercial annihilation. An unemployment problem of so vast a magnitude as ours demands the exploration of every reasonable avenue which may provide economic work, a demand which leaves no room for the neglect of key industries to be used against us. This in itself is an answer to the query as to whether the material importance of the organic chemical industry warrants its foundation in Britain. Recent combinations in other countries between firms engaged in key industries are ominous portents for the future.

The greatest key industry is that of synthetic dyestuffs, which, once established permanently, will prove the greatest source of well-being to our nation yet conceived. Its potentialities are bewildering in their immensity and can create and fashion the very future itself, so it becomes imperative that no external nation must be allowed to possess such a weapon as a monopoly. The war demonstrated the temperamental fitness of our countrymen for the dyestuffs industry, and, in spite of the current hostile criticism, I hold with Sir William Pope that only a few years are required for the organisation of a perfect lattice of fine chemical industries.

No industry dependent upon men of science for its progress will be able to survive external competition of a kind which Germany, the United States, and Japan are capable of exerting, unless a creative atmosphere is generated within the walls of our schools and our standards of intellectual attainment are raised to a much higher level than at present obtains. It is not sufficiently realised how much research work has to be done before any tangible results accrue, and therefore a multiplication of agencies is necessary, a practical proposition only to be realised by means of our higher educational system.

Any comparison of pre-war British and German chemical ability which attempts to exalt the German as one apart, even as something chemically occult, must take the fact into account that so much of our best intellect as revealed by scholastic agency is absorbed into the civil service that the essence of Britain's research ability has never yet taken part in the industrial competition. In Germany the contrary has obtained. The British chemical mission to Germany after the Armistice found that industry there is systematically linked with the universities, and concluded that if our industries are to succeed in the future it is in this direction probably more than in any other that improvements must be effected.

It must be realised that higher education with respect to science and technology is at the parting of the ways, and whether the future is to emphasise the mediocre and the mechanical or to reveal latent genius will also decide whether the chemical industry, with its quota towards the solution of our unemployment problem, will also take root in this country. Our educational programme, therefore, must include a readjustment of the aims of technical education and the evolution of a new branch of the teaching profession to deal with the higher standard of student attainment necessary. No chemical department should be without a definite and distinct research section in which, at the earliest stage possible, students should be initiated into the methods of scientific inquiry. This was the practice of the great Hofmann, and it is as practicable to-day as it was in his brilliant period. The entire staff should also have service in the research section as part of their duties but with safeguards for individual expression. By this means a network of research colonies will be brought into existence, and the pivotal principle must be insisted upon that directors of research must not be prevented by details of organisation from actual personal participation. A large amount of individual responsibility will thus be generated with a greater resultant effort. As the late Prof. Meldola said, "I have not the least hesitation in declaring the belief that a school of chemistry which is not also a centre of research is bound to degenerate and to become a mere cramming establishment not worth the cost of maintenance." There should also be research centres on the lines of the Emperor William Institutes in Germany, an ideal proposed by Sir David Brewster seventy years ago for providing research careers for worthy men.

I would also suggest that patents should be examined by research organisations, and, where dishonest, the fact broadcasted, so that the intending fraudulent monopolist can be banished from our midst.

Another factor of far-reaching importance to industry is the establishment of English as a language for scientific publications at least co-equal with German. This can be secured on a stable basis only by the quality and quantity of our scientific output.

Only by the development of British research ability can our security as a nation be maintained and our prosperity advanced, since by it a lattice of industries will result, which, by reciprocity with the research agencies, will promote the extension of each. We shall then face the future with the determination to produce results in chemical science not inferior in quality or quantity to those in realms of knowledge where our leadership has never been in dispute.

[1] From a paper read at the Annual Meeting of the Association of Technical Institutions on March 3.

Physics in Industry at the Wembley Laboratories.

THE General Electric Company, Ltd., is now a very large organisation, which employs some twenty thousand workers. It has engineering works at Birmingham, where it manufactures all kinds of electrical machines. At Stoke, near Coventry, telephones are manufactured. At the Osram lamp works at Hammersmith, lamps and valves of all kinds are made. At Erith, the company took over a few years ago the works of Messrs. Fraser and Chalmers, which manufacture steam turbines and mining plant. At Southampton, electric cables of all kinds are manufactured, and the company has glass works at Lemington-on-Tyne. Mainly on the initiative of Mr. Hugo Hirst, the managing director, it was decided some six years ago to establish a central laboratory to carry out the scientific and industrial researches which are essential for the progress of industry. Mr. Clifford Paterson, who was then the head of the electrotechnical department of the National Physical Laboratory, was appointed superintendent, and he is now helped by a staff of physicists and engineers many of whom have world-wide reputations.

The opening of the research laboratories on February 27 was a very interesting function. Lord Robert Cecil, speaking at the opening ceremony, said that the immediate task of the country is to repair the waste of the war. To do this the first and most essential requirement is to use every endeavour to increase the output of human energy and skill. This can only be done in two ways, namely, by reducing expenditure and by increasing the efficiency of production. Research, by making every man's skill go further, adds to the world's wealth. Science has no territorial boundaries. By promoting research the relations between this country and the world are improved. Sir J. J. Thomson, who also spoke, pointed out that it is absolutely necessary that a research laboratory should have a highly efficient staff. The capacity for the highest kind of research is rare. Training may increase the efficiency of a researcher, but it cannot put insight and originality into him. It is also certain that no research laboratory can guarantee delivery. The output of such a laboratory is always highly irregular and spasmodic. Sir Joseph Thomson also dwelt on the importance of cultivating the thinking powers of the community to the utmost.

The research laboratories are situated near Wembley and have a total floor area of 80,000 square feet, but they have ample room for expansion. The building has a north-light roof and nearly all of it is only one storey in height. The upper floor galleries carry most of the electric cables and the hydraulic pressure, steam, gas, and vacuum pipes required by the experimenters.

These galleries carry the arterial system essential for the laboratory without the necessity for conduits or ducts. This greatly increases the flexibility of the whole system.

The machinery in the central sub-station supplies the electric power, keeps the gases in circulation, and maintains the vacuum in the vacuum pipes throughout the building. Power at a pressure of 2850 volts and on the three-phase system is supplied by the North Metropolitan Electric Supply Co., and is converted into various pressures, both direct and alternating, for the distributing mains by means of motor generators and transformers. The lighting system is permanent, and is not touched for experimental purposes. The method of arranging the experimental distributing system is an extension of that which Mr. Paterson used at the National Physical Laboratory.

In addition to the electric machinery the substation contains the vacuum and compressor plant. Two rotary compressors feed into a horizontal boiler placed in the gallery, and this stores the compressed air which is required for experimental purposes. There are also three vacuum pumps driven by motors which are in continuous operation. These exhaust a fine vacuum main to the low pressure of 0·5 mm. of mercury and rough vacuum mains to pressures down to 6 mm. of mercury. There are also high-pressure hydraulic mains, compressed-air mains, and a one-inch hydrogen main.

There are two splendidly equipped workshops, one for metal and one for wood. These make the special apparatus required by the staff. They also engage in research work of their own, devising and improving automatic machinery and suggesting means of accelerating and improving the methods of production.

In the vacuum physics laboratory, X-ray analysis and analyses for detecting traces of gases are made. A novel question that is being investigated is the X-ray danger that may exist in connexion with the use of valve tubes at high voltages. For example, when these tubes are being exhausted, pressures of 10,000 volts and upwards are sometimes applied. Ordinary bulb glass which contains about 18 per cent. of lead is impermeable to these rays, but the special silica tubes often used in valve work are permeable; it is therefore necessary to know whether the work is dangerous or not. The problems produced by the static charges and other high voltage effects produced in bulbs are also being studied.

Some of the laboratories, for example the one for measuring the life of lamps, are used for routine testing. There were 800 lamps undergoing life tests simultaneously. They were of all kinds, carbon filament, metal filament, neon lamps, etc. Some of the neon lamps produce very novel effects and they are in great demand at present in physical laboratories. In photometry the equipment is very complete, and the various problems of illumination are being investigated by most scientific methods. A novel photometer was shown in operation which measured the absorbing power of various surfaces for light. By the use of this instrument the "blackness" of the inside coatings of lamp bulbs tarnished by use can be measured.

A specially novel and interesting feature of the laboratories is that they contain four small experimental factories for making electric lamps, tungsten wire, thermionic valves, and primary batteries, and these laboratory factories are regarded as tools which any of the research staff can use in connexion with the further development of a research. It is inadvisable to specialise research to too great an extent. Lamp research, for example, is not confined to the intensely interesting work on vacuum physics. It is equally concerned with metallurgical research, glass research, radiation from solids and gases, and high tension electrical phenomena in general. In a research laboratory it is necessary that the staff should be interested in practically every kind of research.

Many other interesting researches are being carried out at Wembley, and some of the work done has already proved of great commercial value in the factory. The importance of physics in electrical development may be illustrated by the case of the ordinary switch for the electric lamp. In the old days, an ominous bluish light sometimes made its appearance when the switch was turned off, and occasionally a switch was burnt out. The base of the switch was sometimes made of wood, which is a very poor insulator. Electricians then improved matters by accelerating the rate at which the terminal pieces separated when the current was broken. Later on it was found that a double air break was a vast improvement, and the base is now made of the best vitreous porcelain, which is practically a non-conductor. Those who use switches nowadays seldom if ever consider the thought that has been expended on their development. Every device in a progressive factory is undergoing continual improvement, and practical men recognise the value of an experimental and theoretical study of the physical laws which govern its development.

The new laboratory at Wembley is one of the largest research laboratories in this country. Compared with American standards, however, it is not large. The research laboratory of the Western Electric Co., Inc., of 463 West Street, New York, has a 13-storey building on a floor area of 400,000 square feet, and employs 1600 full-time researchers under the able guidance of Dr. Jewett, president of the American Institution of Electrical Engineers. The results obtained, however, are seldom in proportion to the size of a research laboratory, and we were much impressed by the ability of the staff at Wembley.

University and Educational Intelligence.

Aberdeen.—The honorary degree of LL.D. was conferred, *in absentia*, on the Duke of Richmond and Gordon, Chancellor of the University, at a meeting of the Senatus Academicus held on Tuesday, February 27.

Prof. W. Mitchell, vice-chancellor and Hughes professor of philosophy in the University of Adelaide, South Australia, has been appointed Gifford lecturer for the sessions 1924–25 and 1925–26.

Cambridge.—The Grace approving the regulations for the admission of women students of Girton and Newnham Colleges to titular degrees in the University has now been approved and one stage of a long-drawn-out controversy has been completed. Among the other privileges granted to women students by the new regulations is included the right to be admitted to instruction in the University and to University laboratories and museums, though the number receiving such instruction at any one time is limited to five hundred. Women are now admitted as research students on the same footing as present candidates for the degrees of M.Litt., M.Sc. and Ph.D.

The Right Hon. T. Clifford Allbutt, Gonville and Caius College, Regius professor of physic, has been appointed as delegate to the celebration next June of the 800th anniversary of the foundation of St. Bartholomew's Hospital and the Priory Church of St. Bartholomew the Great.

The opening of the new chemistry section of the Technical High School of Stockholm is announced in the *Chemiker Zeitung* of February 10. The building cost 3,300,000 kroner, and has four large laboratories for inorganic, organic, technical, and electrochemistry, and a smaller for the study of fermentation. The Director is Prof. W. Palmaer. It is stated that in size the building is exceeded only by that of Boston.

A report on the development of adult education in rural areas has been issued (H.M. Stationery Office, 6*d*.) by the Adult Education Committee constituted in April 1921 by the Board of Education. The report reviews the work in this field of existing organisations—Local Education and other County Authorities, Women's Institutes, University Extension Committees, Workers' Educational Association, Association of Village Clubs, Y.M.C.A., Educational Settlements, and County Unions of village organisations,—the conditions of State aid, and the available sources of supply of books, and concludes with several practical suggestions. Among the opinions formulated by the Committee are: schemes of rural education properly organised can secure immediate and notable success provided village initiative and co-operation are encouraged; some form of county organisation, such as the Oxford Rural Community Council, is essential; national organisation is desirable and has been provided for by the recent establishment of a representative council by the National Council of Social Service; pioneer lectures and short courses of lectures are a necessary prelude to formal classes and merit State aid; the full development of the Carnegie Trust Rural Library Scheme will solve most difficulties as to the supply of books. As regards this last point, it is explained in a highly interesting memorandum appended to the report that it is the policy of the trustees to promote the establishment of county schemes controlled by County Council Education Committees, and 192,000*l*. was set aside by the trustees in February 1920 to enable every county to inaugurate one. By January 1922 thirty-eight were in operation. The key-stone of the whole system is the Central Library for Students (London and Dunfermline), from which any good-class modern book on a serious subject can be obtained through the county librarians.

Statistics of 670 Universities, Colleges, and Professional Schools, published by the United States Bureau of Education as Bulletin, 1922, No. 28, shows a total student enrolment for 1919–20 of 521,754, of whom rather more than one-third were women; by departments—preparatory 59,309, collegiate 341,082, graduate 15,612, professional 57,131. Of the 670 institutions, 109 were under public and 561 under private control: 82 were independent professional schools. Of 586 universities and colleges with undergraduate students, 354 were co-educational, and reported 162,558 men and 96,908 women; 117 were maintained exclusively for men and 115 exclusively for women. Enrolments in the professional schools were: law 20,992, medicine 14,242, dentistry 8809, theology 7216, pharmacy 5026, veterinary medicine 908. The percentage of women students ranged between 14 in pharmacy and 0·01 in veterinary medicine. Engineering schools enrolled 51,908 students, almost all men, distributed as follows: general engineering 10,231, civil 8859, mechanical 11,789, electrical 9469, mining 3048, chemical 5743. The number of engineering students more than doubled itself in the decade 1910–20. The total amount of benefactions—excluding government grants—was 65 million dollars. The total income per student—363 dollars in 1920—has risen steadily since 1890, when it was only 68 dollars. During the same period the percentage of receipts derived from the Federal Government, the State, and the city has increased from 12 to 27 and of student fees from 22 to 26, while the percentage from productive funds and private benefactions has decreased from 65 to 38. The following figures relate to universities and university colleges (excluding Oxford and Cambridge) in Great Britain in receipt of annual Treasury grants in 1920–21: income per student 54*l*., percentage of income from endowments 11, parliamentary grants 34, grants from local authorities 9, tuition fees 32.

Societies and Academies.

London.

Royal Society, March 1.—A. **Mallock**: The effect of temperature on some of the properties of steel. The period of torsional vibration and the length of a steel wire were automatically and continuously recorded in terms of time, while the temperature was varied between 15° and 1000° C. The results show (1) that the variation of the rigidity of steel between ordinary temperature and a dull red heat is small (less than 1 per cent.); (2) that above the critical temperature (about 800° C.) the rigidity decreases rapidly; (3) that the temperature coefficient of expansion does not show any marked change as the metal passes through the critical temperature; but (4) that a comparison with the cooling curves of iron and steel proves that the specific heat of the high temperature form of the metal is much less than it is at temperatures below the critical point.—C. H. **Lees**: Inductively coupled low-resistance circuits. The oscillations in each of two circuits of low resistance coupled by their mutual inductance can be simply expressed in terms of a certain product of capacitance and inductance. The expressions for the currents lead to a simple graphical solution of the problem.—Lord **Rayleigh**: Studies of iridescent colour, and the structure producing it.—(1) The colours of potassium chlorate crystals. The structure of the iridescent potassium chlorate crystals investigated by Stokes and the late Lord Rayleigh is examined microscopically. The periodic twinned structure inferred by the latter is clearly shown in the photographs taken under the microscope with polarised light. Some crystals have exceedingly complex structure, showing many groups of evenly spaced twin planes and a very complex reflection spectrum. This results from high interference from twinned layers situated a considerable distance apart. Chlorate crystals, giving a silvery reflection, were obtained by Madan, who heated the ordinary colourless crystals to about 250° C. A complex twinned structure is induced, and photographs of the structure of the crystal and of the reflection spectrum show corresponding irregularities in each, resulting from want of flatness in the twin planes. (2) Mother-of-pearl. The results generally confirm those of Brewster and A. H. Pfund. Micro-photographs show the grating structure of a pearl oyster shell and the structure of parallel layers of an "ear" shell. The absorption spectrum of the latter shows that in agreement with the spacing of the layers the reflection is of the second order. (3) The colours of Labrador felspar. The colours seen by reflection arise from two distinct origins:—(*a*) Specular reflection from tabular inclusions, which show the colours of thin plates and are often 0·2 mm. in dimensions; they are distributed parallel to one of the cleavages. (*b*) Diffuse reflection from a plane about 15° away from the cleavage mentioned; this is the source of the striking colours observed. When the diffuse reflecting plane is examined microscopically under conditions which ensure that the light only comes from a very thin stratum, it is found that the plane of reflection is patchy. The patches are of irregular outline. The diffuse character of the reflection is accounted for by the small diameter of these reflecting surfaces, regarded as independent optical apertures. Their size (0·005 mm.) accounts approximately for the angular diameter of the diffuse image of a point source seen by reflection. The colour of the reflection is not sharply limited to special regions of the spectrum, and can be explained by the interference of streams of light from the two surfaces of each patch. The patches may be fissures in the material, and there is evidence that their thickness is not absolutely uniform. The brightness of the colour is explicable by the large number of reflecting patches adding their effects, without definite phase relation such as would give rise to regular interference.—L. V. **King**: On the complex anisotropic molecule in relation to the dispersion and scattering of light.

Society of Public Analysts, February 7.—Mr. P. A. Ellis Richards, president, in the chair.—E. **Griffiths-Jones**: Titanium in Nile silt. Titanium is determined by a colorimetric method after freeing the sample from silica; 1·3-2·55 per cent. of titanium oxide was found. Egyptian straw showed only 0·4 per cent. of titanium oxide on the ash.—Osman **Jones**: Notes on the examination of preserved meats, etc. The presence of a trace of zinc chloride in the tin container (which sometimes arises through the use of this salt as a soldering flux) causes a more rapid absorption of tin by the food contents; the use of sealing fluid containing a high boiling-point solvent also causes a disagreeable flavour to be imparted to the food material. The absorption of tin by the meat contents of a can is greatest at the time of processing and almost ceases after about 4 months. A dilute solution of iodine in potassium iodide gives a crimson colour with agar, while with gelatin an orange-coloured precipitate is produced.

Optical Society, February 8.—F. W. **Preston**: On the properties of pitch used in working optical glass. Pitch as a material for mounting lenses for polishing possesses many remarkable advantages. Its colour is valuable; the dull black surface in contact with the lens prevents reflection of light at the second face of the glass. Its coefficient of expansion approximates to that of glass, it melts at a relatively low temperature, and remains plastic through a considerable range. Pitch, being an undercooled liquid, may be made sufficiently solid to resist deformation by external pressures during the polishing operation, and yet left sufficiently plastic to yield to internal stresses, so as to be self-annealing at ordinary temperatures. The alteration of properties on prolonged heating is its most serious disadvantage.—T. Y. **Baker**: Prismatic astrolabe designed and made at the Admiralty Research Laboratory, Teddington. This instrument, used for accurate geodetic survey work, is a modification of that designed by MM. Claude and Driencourt, which has been extensively used in Egypt. The modifications are: (i.) The prism can be rotated about an axis parallel to its edges, and the angles of the prism are allowed to depart slightly from 60°; by using each edge of the prism in turn as the front edge, three observations of the star can be made instead of only one, the mean of the measured altitudes being exactly 60°. (ii.) A refracting prism of small angle is mounted to cover one quadrant of the object glass and a duplicate image of one star is thus produced in the field of view. The duplicated images are on the same horizontal level. Observation for contact is made by noting the instant when the descending image is on a level with and between the duplicated images. Laboratory trials show that whereas the mean error of observation with the old scheme was 0·2″, with the new arrangement it is 0·12″.

Aristotelian Society, February 19.—Prof. Wildon Carr in the chair.—C. E. M. **Joad**: The problem of free will in the light of recent developments in philosophy. It is generally admitted that on the basis of the Materialist and Mechanist theories, the conditions which must be satisfied if free will is possible are not fulfilled, since causation is conceived as proceeding always from the material to the mental. It is not generally recognised, however, that the Vitalist theories, for which the ultimate reality is life or spirit, also preclude the possibility of free will. There are two difficulties in regard to the theory of a vital principle or spirit. (1) How can a homogeneous unity differentiate itself into individual manifestations which are in some sense less real than itself, unless it contains in itself the principle of difference *ab initio*, that is to say, unless it is a plurality and not a unity? (2) Assuming that this difficulty could be surmounted, how can the individuals so formed act, desire, or will with a motive force, other than that derived from the underlying vital principle? If the energy with which they desire is that of the vital principle, and the will with which they suppress the desire, if they do suppress it, is also that of the vital principle, it follows that they are responsible neither for their desires nor for their suppression. These difficulties cannot be solved on the basis of a reality which consists of an initial unity, but the problem of free will, if not actually soluble, takes an entirely different complexion if an initial dualism or pluralism be assumed.

Association of Economic Biologists, February 23.—Prof. E. B. Poulton, president, in the chair.—Sir John **Russell**: Partial sterilisation of soil. The discovery that partial sterilisation increased the bacterial activity of soil was accidental, but when followed up it showed protozoa were present in the soil depressing bacterial numbers. It also showed that certain soil bacteria have the remarkable power of breaking the benzene ring, decomposing such unlikely substances as benzene, toluene, naphthalene, phenol, etc., and utilising them as food. Partial sterilisation kills or reduces disease organisms: here, however, heat is the only certain agent, the various chemical substances having specific properties rendering their general use difficult. A knowledge, however, of disease organisms to be suppressed and of the substances toxic to those organisms, allow the costly heating process to be superseded by the much cheaper chemical treatment. Finally, partial sterilisation produces chemical changes in the soil, some of the products of which have important effects on the plant. Thus, heating soil produces something which stimulates root development. At present partial sterilisation is used by the scientific worker to open up new fields of investigation, and by the practical grower to obtain better crops as the result of the increased bacterial activity, the freedom from disease organisms, and the presence of the root-stimulating substances.—H. G. **Thornton**: The destruction of aromatic antiseptics by soil bacteria. Soil antiseptics fall into two groups: those resembling toluene in mode of action, and those resembling phenol. The second group produces a sudden and great increase in the bacterial numbers in the soil, which is only temporary and is not accompanied by any considerable increase in ammonia production. The effect suggested that organisms fed on this group of compounds. Phenol, cresol, and naphthalene, when added to ordinary manured soil, disappear rapidly, due largely to a biological cause, and bacteria were found which in pure culture were able to derive the energy necessary for growth by decomposing these compounds. These organisms fell into three groups, non-motile resembling *B. phloei*, large rods producing clostridial sporangia, and short oval pseudomonads. The Pseudomonas group is of chief importance in producing phenol destruction in the soil.

Paris.

Academy of Sciences, February 12.—M. Albin Haller in the chair.—C. **Guichard**: Two triple orthogonal systems which correspond in such a manner that the second tangent of one shall be the polar reciprocal of the third tangent of the other with respect to a linear complex.—A. **Andant**: The application of photography to the study of critical opalescence. The phenomenon was studied by means of a Hilger spectrograph, and the opacity measurements were made with a Fabry and Buisson microphotometer. Curves are given showing the variation of opalescence in ethyl acetate with temperature and with the wave-length.—M. **de Broglie** and J. **Cabrera**: The K absorption spectrum of element 72 (celtium). Some specimens containing zirconium show a feeble band with wave-length $\lambda = 0{\cdot}1905$Å. From corresponding spectra of ytterbium ($N = 70$) and lutecium ($N = 71$) this line would belong to the element of atomic number 72.—Mlle. Irène **Curie**: The distribution of length of the α-rays.—L. J. **Simon**: Viscosity, neutralisation, and isomorphism. The gradual neutralisation of arsenic and phosphoric acids has been followed by viscosity measurements. NaH_2PO_4 is indicated by a well-marked viscosity minimum: Na_3PO_4 shows a viscosity maximum. The arsenate and phosphate viscosity curves are very similar.—H. **Colin** and Mlle. A. **Chaudun**: The diastatic hydrolysis of the glucosides of alcohols. Determination of the molecular weights. An experimental method of fixing the molecular weight of a glucoside by measuring the quantity of enzyme for which the glucose set free from a fixed weight of glucoside no longer increases with the amount of the enzyme. Measurements of propyl, isopropyl, butyl, and isobutyl glucosides are given.—P. **Job**: The complex ions formed by silver salts and aqueous solutions of ethylenediamine.—Marcel **Delépine**: The potassium irido-dipyridino-dioxalates.—Marcel **Godchot**: The 1 : 2 cyclohexanediols and ortho-chloro-cyclohexanol.—Paul **Pascal** and M. **Garnier**: Two definite combinations of nitrogen peroxide and camphor. The melting-point curve of camphor-nitrogen peroxide indicates two definite compounds, $5N_2O_4 + 4C_{10}H_{16}O$ and $2N_2O_4 + 3C_{10}H_{16}O$.—Charles **Baron** and Albert **Verley**: Contribution to the study of a national petrol. Study of the miscibility of alcohol (94-100 per cent.) with ordinary petrol.—F. **Diénert**: Contribution to the study of the circulation of water in the chalk. Results of experiments with fluorescin. Water circulation in the chalk takes place by fissures only and not by filtration. A detailed experimental study of each region is necessary to determine the course of the water underground.—Pierre **Bonnet**: The existences of limestones containing Ural Fusulina in southern Transcaucasia.—Raoul **Blanchard**: The terraces of glacial closing.—Sabba **Stefanescu**: The contraction of the lower maxillary of mastodons and elephants.—Emile F. **Terroine**, A. **Feuerbach**, and E. **Brenckmann**: The unit of energy metabolism and the active mass of organisms.—Albert **Lécaillon**: The tendency to albinism in the hybrids of *Dafila acuta* and *Anas boschas*.—Jules **Amar**: The law of minimum in biology.

Diary of Societies.

SATURDAY, MARCH 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (4).

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—Conversazione.

MONDAY, MARCH 12.

VICTORIA INSTITUTE (at 1 Central Buildings, Westminster), at 4.30.—Rev. Prof. A. S. Geden: Value and Purpose of the Study of Comparative Religion.

ROYAL SOCIETY OF MEDICINE (War Section), at 5.—Col. J. F. C. Fuller: Problems of Future Warfare; to be followed by a discussion on The Medical Problems of Future Warfare.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (4) (Hunterian Lectures).

ROYAL SOCIETY OF ARTS, at 8.—J. E. Sears, jun.: Accurate Length Measurement (2) (Cantor Lectures).

SURVEYORS' INSTITUTION, at 8.—C. G. Eve: The Re-valuation for Landlord's Property Tax, Schedule A.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—O. G. S. Crawford: Air Survey and British Archæology.

TUESDAY, MARCH 13.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. C. G. Seligman: Rainmakers and Divine Kings of the Nile Valley (1).

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section), at 4.30.—Prof. F. R. Fraser, Dr. A. N. Drury, Dr. A. E. Clark-Kennedy, and Dr. T. F. Cotton: Discussion on the Action of Quinidine in Cases of Cardiac Disease.

ROYAL SOCIETY OF MEDICINE (General Meeting), at 5.—J. E. Adams: The Urgent Need for Education in the Control of Cancer, to be followed by a discussion by Dr. C. P. Childe, Lord Dawson, Dr. H. Spencer, and others.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. G. Evans: The Nature of Arterio-sclerosis (3) (Goulstonian Lectures).

INSTITUTION OF PETROLEUM TECHNOLOGISTS (Annual General Meeting) (at Royal Society of Arts), at 5.30.—Prof. J. S. S. Brame: Presidental Address.

MINERALOGICAL SOCIETY (at Geological Society of London), at 5.30.—A. Hutchinson: A Graphical Method of correcing Specific Gravity Determinations.—C. E. Tilley: Genesis of Rhombic Pyroxene in Thermal Metamorphism. Mineral Associations and the Phase Rule.—C. S. Garnett: A Peculiar Chlorite-rock from Ible, Derbyshire. The Dissociation of Dolomite.—A. Brammall and H. F. Harwood: The Dartmoor Granite: (a) Porphyritic Felspars, and Biotite; (b) Andalusite, Sillimanite, Cordierite, and Spinellids.—J. G. C. Leech: Some Occurrences of Titanium Minerals on St. Austell Moor.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—H. Gordon: The Effect of Schooling on Intelligence Tests.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—W. A. Dexter: The Development of the Air Pump for High Vacuum.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Annual General Meeting.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—C. H. Caffyn: Rocks under the Microscope.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Miss M. Edith Durham: "Bird-men" and related Customs in the Balkans.

SOCIOLOGICAL SOCIETY (at Leplay House, 65 Belgrave Road), at 8.15.—J. A. Hobson: Bias in the Social Sciences.

ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. C. S. Myers: The Association of Psychoneuroses with Mental Deficiency.—Dr. H. J. Norman: Genius and Insanity.

WEDNESDAY, MARCH 14.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (5) (Hunterian Lectures).

GEOLOGICAL SOCIETY OF LONDON, at 5.30.

FELLOWSHIP OF MEDICINE (at Royal Society of Medicine), at 5.30.—A. J. Walton: The Differential Diagnosis of Surgical Dyspepsias.

INSTITUTION OF AUTOMOBILE ENGINEERS, at 7.45.—Major T. G. Tulloch: Multiple-wheel and Track Motor Vehicles.

ROYAL SOCIETY OF ARTS, at 8.—Sir William Warrender Mackenzie: Industrial Arbitration.

THURSDAY, MARCH 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lt.-Col. E. A. Strange: Japanese and Chinese Lacquer (1).

ROYAL SOCIETY, at 4.30.—G. C. Steward: Aberration Diffraction Effects.—Lord Rayleigh: Further Observations on the Spectrum of the Night Sky.—Lord Rayleigh: Studies of Iridescent Colour, and the Structure producing it. IV. Iridescent Beetles.—Prof. J. W. Nicholson: Oblate Spheroidal Harmonics and their Applications.—Prof. J. W. Nicholson and Prof. F. J. Cheshire: The Theory and Testing of Right-angled Prisms.—Prof. J. C. McLennan and D. S. Ainslie: The Fluorescence and Channelled Absorption Spectra of Cæsium and other Alkali Elements.—Dr. W. Stiles: The Indicator Method for the Determination of Coefficients of Diffusion in Gels, with special reference to the Diffusion of Chlorides.—H. T. Flint: A Generalised Vector Analysis of Four Dimensions.

LINNEAN SOCIETY OF LONDON, at 5.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. A. J. Hall: Encephalitis Lethargica (Epidemic Encephalitis) (1) (Lumleian Lectures).

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—Prof. B. Melvill Jones: The Control of Aeroplanes at Slow Speeds.

INSTITUTION OF MINING AND METALLURGY (at Geological Society of London), at 5.30—Annual Meeting.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Sir Richard Gregory: The Position and Character of Science in Schools.

INSTITUTION OF ELECTRICAL ENGINEERS AND ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 6.—F. Hooper and J. W. Beauchamp: Co-operation between the Architect and the Electrical Engineer.

CHEMICAL SOCIETY, at 8.—E. H. Usherwood and M. A. Whiteley: The Oxime of Mesoxamide (*Isonitrosomalonamide*) and some Allied Compounds. Part III. Ring Formation in the Tetra-substituted Series.—H. H. Morgan: The Preparation and Stability of Cuprous Nitrate and other Cuprous Salts in the presence of Nitriles.—F. Challenger, A. L. Smith, and F. J. Paton: The Interaction of Hydrogen Sulphide, Thiocyanogen, and Thiocyanic Acid with Unsaturated Compounds.—Prof. T. M. Lowry: The Polarity of Double Bonds.

INSTITUTE OF METALS (London Local Section) (at Institute of Marine Engineers, Inc.), at 8.—W. B. Clarke and others: Discussion on The Heat Treatment of Non-Ferrous Metals.

CAMERA CLUB, at 8.15.—C. P. Crowther: The Man Behind the Camera.

FRIDAY, MARCH 16.

ROYAL SOCIETY OF ARTS (Dominions and Colonies and Indian Sections), at 4.30.—Lt.-Col. Sir Leonard Rogers: Recent Advances towards the Solution of the Leprosy Problem.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 5.—Dr. F. M. R. Walshe: The Symptomatology of Eighth Nerve Tumours.—W. Trotter: The Surgical Treatment of Tumours of the Eighth Nerve.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (6) (Hunterian Lectures).

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Second Report of the Steam-Nozzles Research Committee.

RADIO SOCIETY OF GREAT BRITAIN (at Institution of Electrical Engineers), at 6.30.—L. F. Fogarty: Accumulators, Dry Cells, and the Currents used in the Reception of Radio Telephony, illustrated by Experiments.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—C. H. Woodfield: Comparative Power Costs.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group Meeting, in conjunction with the Affiliation of Photographic Societies), at 8.—R. H. Lawton: A Criticism of the Prints in the Affiliation Print Competition.

ROYAL SOCIETY OF MEDICINE (Electro-therapeutics Section), at 8.30.—Prof. Gosta Forsell: Some Observations on Movements of Gastro-intestinal Mucosa.

SATURDAY, MARCH 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (5).

PUBLIC LECTURES.

SATURDAY, MARCH 10.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. N. Milligan: The Great Sea-serpent.

MONDAY, MARCH 12.

INNER TEMPLE HALL, at 8.—Dr. C. Porter: The Principles and Practice of Sanitary Legislation (Chadwick Lecture).

TUESDAY, MARCH 13.

LONDON SCHOOL OF ECONOMICS, at 5.—Sir Henry Reid: Food Supplies (Statistics, before, during, and after the War) (4).

UNIVERSITY COLLEGE, at 5.15.—Prof. E. T. Whittaker: Electric Fields in Atomic Physics (succeeding Lectures on March 15, 20, and 22).

WEDNESDAY, MARCH 14.

KING'S COLLEGE, at 5.30.—Sir Richard Gregory: The Influence of Science.

THURSDAY, MARCH 15.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 5.—H. S. Goodhart-Rendel: Architecture—a Necessity or a Luxury?

CENTRAL LIBRARY (Fulham Road), at 8.—A. H. Page: Architectural and Record Photography.

FRIDAY, MARCH 16.

UNIVERSITY COLLEGE, at 5.30.—Sir Gregory Foster: Lectures—their Use and Abuse.

CHELSEA POLYTECHNIC, at 8.15.—Prof. A. C. Seward: A Summer in Greenland.

SATURDAY, MARCH 17.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. A. Abram: Travelling in the Middle Ages.

Editorial communications to the Editor.

A National Water Policy.

THE Minister of Health has recently appointed a Standing Advisory Committee "to confer with representatives of the Ministry on questions of water supply." From a reference in the public announcement of this appointment to the final report of the Water Power Resources Committee of the Board of Trade, it would appear at first sight that the step is the outcome of one of the recommendations put forward by that Committee in its report of November 1921, which was reviewed in NATURE of February 9 last year (vol. 109, p. 161). The proposal therein made, it may be recalled, was for the formation by Act of Parliament of a controlling water commission having jurisdiction over England and Wales, with statutory powers and duties. In commenting on such a far-reaching and momentous proposal, we felt it desirable to deprecate the idea of setting up a fresh department with a retinue of officials and an additional burden of salaries for the taxpayer.

Our first impression, therefore, was one of gratification that apparently the departmental proposition had been dropped and that, in place of it, there was to be a "Standing Committee," presumably honorary, with advisory functions. On further consideration, however, we became less confident that the announcement covered all that it implied, and whether, in fact, it was in any degree a materialisation of the Water Power Committee's findings. Inquiry has confirmed the suspicion that the Ministry of Health is only concerned with the water question as regards supplies for domestic use, and that the terms of reference of the Advisory Committee, though unspecified, cannot possibly be stretched to cover functions which lie within the province of the Board of Trade.

An inspection of the list of the committee shows it to comprise the names of six gentlemen connected with municipal waterworks administration in various official capacities. With one exception, we miss altogether any name which appeared as signatory to the very full and comprehensive report of the Water Power Resources Committee. There is, indeed, a marked absence of that representation of broadly national, scientific, and industrial interests which should, in our opinion, form a prominent, if not a predominant, element in a committee dealing with the policy of development of the water resources of the country.

This is the more disappointing in that, according to the Press, the first meeting of the committee has already been held, and it is announced that it discussed two matters which were in the forefront of the Water Power Resources Committee's recommendations, and have been the subject of earnest advocacy by NATURE for a number of years past. These are (1) the formulation of the outlines of a national water policy, and (2) the survey of the water resources of England and Wales. We are not in possession of information as to the views of the members of the Advisory Committee on these points, but we conceive that they must have been somewhat seriously handicapped by the absence of assistance from the compilers of the very valuable report to which we have alluded. In regard to the second point, we note that the survey is already in hand, and is being made by the Engineering Department of the Ministry of Health. We confess that we are puzzled by this statement. Conservation and control of water power resources for industrial purposes is not very obviously a question of health, or of physical well-being. We are therefore at a loss for an explanation, unless it be, that the survey is limited to sources of water supply for domestic use. If so, this is not only regrettable as making it an inquiry of inadequate scope, but it is also inconsistent with the announcement that the survey is being prosecuted "on lines recommended by the Water Power Resources Committee in their final report." Turning to that report, we find the recommendation expressed as follows:

"That in view of the importance in the national interest of the utilisation of water power, wherever this is commercially practicable, the Board of Trade, or the Electricity Commissioners, should be charged with the duty of studying, supervising, and promoting the development of all water power. The (Water Power) Department should collect data concerning, and cause surveys to be made of water power resources, and they should give the widest publicity to the results of their inquiries."

Clearly it is not within the province of a Ministry of Health to prosecute such a research, which must lie outside the education and training of its officials. Our own suggestion was that the work might be done as a branch of the Ordnance Survey, as it is done in the United States by the Geological Survey.

A matter of such outstanding importance as national water power control demands the most careful and competent handling. It has been the subject of a searching and painstaking investigation by a committee thoroughly representative in character, the recommendations of which, after several years of exhaustive study and the issue of three reports, were to the effect that the matter did not admit of procrastination or delay, and that it should be dealt with on a generous and effective scale. They were "thoroughly convinced of the necessity of such action if the national water resources are to be properly conserved and fully and systematically utilised for all purposes, and that the work should be proceeded with unremittingly." We therefore urge that the matter should be entrusted to a committee with a scientific and technological element of adequate proportions, and that the survey should be placed in the hands of a department closely associated with this particular class of work.

The Gas Industry.

(1) *The Administration and Finance of Gas Undertakings: with Special Reference to the Gas Regulation Act*, 1920. By G. Evetts. Pp. xi + 374. (London: Benn Bros., Ltd., 1922.) 32*s*. 6*d*. net.

(2) *Modern Gasworks Chemistry*. By Dr. G. Weyman. Pp. x + 184. (London: Benn Bros., Ltd., 1922.) 25*s*. net.

(3) *Gasworks Recorders: their Construction and Use*. By Dr. L. A. Levy. Pp. xi + 246. (London: Benn Bros., Ltd., 1922.) 35*s*. net.

(4) *The Distribution of Gas*. By W. Hole. Fourth edition, rewritten and enlarged. Pp. xv + 699. (London: Benn Bros., Ltd., 1921.) 50*s*. net.

THE gas industry had its modest origin in the researches of William Murdoch, the "incomparable mechanic" to whom the Royal Society awarded its Rumford medal for his work in the production and utilisation of illuminating gas. Its rapid growth owes much to the co-operation of the scientific workers, although in the early days, even as now, there were not lacking prominent and distinguished men of science prepared to wail a Jeremiad over the industry. While to-day the nature and magnitude of its operations entitle the gas industry at least to contend for pride of place among applied sciences, whether chemical, mechanical, or physical, it cannot be too strongly emphasised that the industry is the child of pure science, and its present-day problems the problems of pure science. The industry asserts that pure and applied science are one and indivisible.

Scientific literature, apart from technical journals and the Transactions of various institutions, dealing with the fundamentals of the processes and control of manufacture of towns' gas is not at present very extensive. The volumes under review, together with Meade's "Modern Gasworks Practice" in the same series, and Prof. Bone's "Coal and its Scientific Uses," constitute practically the only modern English works dealing specifically with the scientific and other problems of the gas industry.

(1) Consider the magnitude of the industry. We learn from Mr. Evetts's book that in the United Kingdom the public supply of gas is in the hands of about 1630 undertakings. About 20 million tons of coal and 65 million gallons of oil are employed annually in the manufacture of gas in the country. By-products of

carbonisation amount to 10 million tons of coke, 180 million gallons of tar, 170,000 tons of sulphate of ammonia, and 45,000 tons of sulphur annually. About 87 per cent. of street lamps in the country are lit by gas. The annual make of gas is approximately 1200 million therms supplied to consumers through about 8 million meters. The figures are clamant for the maintenance of a due sense of proportion in criticism of the industry. We commend them to the notice of any inclined to regard the gasworks as the original home of the three-card trick, and the gasometer as the present-day residence of the Borgias.

Mr. Evetts has produced an extremely clear and readable account of the legislative and administrative aspects of the gas industry. Primarily intended to meet the requirements of the student, the junior assistant, and others desirous of qualifying for high administrative posts in the industry, the book will be welcomed by a much wider circle of readers.

The provisions of the Gas Regulation Act, 1920, enabling gas to be supplied and sold on the basis of its potential thermal value, are set out in Chapter 2. Although from the date of the publication by the Board of Trade of the brochure on Gas Standards the gas industry generally welcomed the suggested new method of supply (p. 34), it should be remarked that at a somewhat earlier date such suggestions were regarded favourably only by a very small minority of representatives of the gas industry considering the subject. The supply and sale of gas on the only conceivable scientific basis, namely, on a thermal basis, having regard to present-day uses of gas, we owe to the Board of Trade. The electrical unit of energy supply is termed the Board of Trade Unit. We suggest that correspondingly the unit of supply of gaseous energy should be designated the Board of Trade Therm.

Among the matters dealt with by Mr. Evetts are: the sliding scale of gas charges, parliamentary procedure when applying for a Bill, the model Bill, repairs and depreciation, hirings and fittings, arbitration and other workaday matters. Chapter 8, dealing with financial aspects of the sale of gas by therms, is a clear statement of the numerous facts to be taken into consideration before a calorific value is declared. Advocates of the supply of low-grade gas should ponder well the tables on p. 242, giving the costs of mains and the pressures necessary to deliver a definite quantity of energy in the form of gases of various calorific values. In this connexion we may remark that such changes in declared calorific value as have recently occurred have all been in the direction of supplying gas of higher calorific value.

(2) Dr. Weyman's book on modern gasworks chemistry describes the methods employed in the control of plant and processes employed in the manufacture of towns' gas. Chapters are devoted to coal, carbonisation, coke, refractory and insulating materials, tar, ammonia, oxide purification, steam raising, water supply, and lubricants. A great amount of work has gone to the collection of the very large number of analytical and other tests comprised in the volume We regret that frequently these are not sufficiently detailed or clearly described to afford working instructions. Occasionally, and more especially in regard to what would be regarded as essentially physical tests, the descriptions are inaccurate or meaningless. As examples, we would refer to the calorimetric radiation correction (p. 27), the standardisation of the Wanner pyrometer (p. 56), and the determination of thermal conductivity (p. 74). It is certain that the methods described for the determination of the thermal conductivities of materials will not yield results of much value in the hands of the works chemist. This class of work should, we think, for the present, until the gas industry is equipped with its own large central testing establishment, be allocated to the National Physical Laboratory. In any case, if this section of the book is to be retained in later editions, it should include a description of the simpler flow methods, developed at the National Physical Laboratory for the determination of thermal conductivity, and probably more suitable for adoption in industrial laboratories.

(3) Dr. Levy's work on gasworks recorders is the complement of Dr. Weyman's. Control of chemical processes can be based upon the results of snap-tests or the indications of recording devices. There is much to be said for both methods. Painful experience with some recorders forces the present writer to the unfortunate conclusion that generally the former method is to be preferred to the latter. Individual observers suffer from their "personal equations." Recording devices are not without their idiosyncrasies. Their value and trustworthiness are to be determined by the "acid test": How far is the record influenced by, and *only* by, variation in the characteristic to be recorded? Frequently the influence of disturbing factors, such as friction, temperature, and the rest, are completely overlooked in the design of such instruments.

Pressure and vacuum gauges, pyrometers, gravitometers, gas analysis and volume recorders, and densimeters are among the recorders discussed in this volume. The activity, born of the Gas Regulation Act, 1920, among makers of scientific instruments is evidenced by the chapter devoted to recording gas calorimeters. Prof. Boys's instrument, incorporating many novel features and points of geometric design, is worthy of the close attention of scientific instrument makers generally. Incidentally it may be mentioned that an important feature of this recorder, namely, that the calorific value is recorded in strict relation to the chart ruling, however the chart may be displaced on the drum, is omitted from the description of the chart on p. 127. The electrical flow meter of C. C. Thomas described on p. 208 *et seq.* is finding extensive application in industry, more especially in America. In all descriptions of this instrument with which we are acquainted, it appears to have been overlooked that the device is merely an application of the constant flow method of calorimetry introduced by Prof. Callendar, and is one more in the lengthy and lengthening list of contributions—not always acknowledged—made by pure to applied science. Considering that the platinum resistance thermometer is among the most accurate of all indicating or recording instruments, it is disappointing to find its calibration inaccurately described on p. 62 and the variation of the resistance of platinum with temperature wrongly given in Fig. 56.

The main defect of the present volume is what we may be pardoned for describing as its apparent partisan character. About one-third of the instruments described are the products of a single firm. This is certainly unjustifiable in a work claiming, according to the preface, to describe all recording instruments of utility in gas engineering. We are acquainted with at least five types of recording pyrometers which go unmentioned although they are of utility at least equal to that of any described. Scant justice is done to certain forms of carbon dioxide recorders, to depth gauges, to water or steam meters. The recording specialities of one firm are referred to in the advertisement pages included in the volume but are not found in the text! We register our protest against this growing tendency in English scientific literature of a certain type.

(4) Under the Gas Regulation Act of 1920, the gas undertaking is interested in the supply of gas right up to the point of combustion of the gas in the burner. Mr. Walter Hole, from his experience as superintendent of the City of Leeds Gas Mains and Distribution Department, is, we think, as well qualified as any one within the industry to undertake the task of compiling a standard work on the subject of gas distribution. That a fourth edition of his work has been called for is eloquent testimony that it supplied a need felt in the industry. We would suggest, however, that the subject of gas distribution is so large that a treatise to be adequate must be the result of the co-operation of a number of experts in its various branches. In these days of specialisation it is not to be anticipated that a single individual will be able to deal adequately with, *e.g.*, the jointing of steel mains and the laws of flow of gases in pipes. The result of such an attempt might be foreseen and is evident in the present volume. The section devoted to main-laying is excellent and constitutes the best part of the volume. That devoted to a theoretical discussion of the flow of gases in pipes is inaccurate and altogether inadequate. It would be well, we think, to include the work of Stanton and Pannell and the empirical formula deduced by Lees from their results in this section.

New chapters on inferential meters and gas for industrial purposes have been included. The former is not entirely adequate. The form of Pitot tube developed as the result of work carried out at the National Physical Laboratory is quite incorrectly attributed to Griggs. This error will serve to illustrate the author's apparent general lack of acquaintance with the more strictly scientific aspects of the subjects of gas distribution. The chapter on gas for industrial purposes is wholly commendable and illustrates the great development which has occurred within recent years in this direction, a development very much accelerated by the call for munitions during the War.

Summing up our impressions after carefully reading the four volumes, we would say that the gas industry has at long last started on the way to provide itself with a scientific and technical literature which shall be in some measure adequate to its needs and deserts. The four volumes here briefly reviewed stand in serious need of overhauling, and we suggest that when a further edition of any of the volumes is called for, the proof-reading should be a little more carefully done. Grammatical errors and split infinitives are in some of the volumes almost as thick as "leaves in Vallombrosa," and we are tempted to infer that the gas industry has its own peculiar variant of Kings' English. The prices of the volumes are, even in these days of inflated index figures, exceedingly high. A considerable portion of the text and illustrations in Mr. Hole's and Dr. Levy's volumes is available gratis in the form of trade circulars, and we believe that these circulars will, owing to the high price of issue of the volumes, continue to be the main source of information consulted by the great majority interested in gas distribution and gas-works recorders. J. S. G. THOMAS.

The Earth under the Rule of Man.

Man as a Geological Agent: An Account of His Actions on Inanimate Nature. By Dr. R. L. Sherlock. Pp. 372. (London: H. F. and G. Witherby, 1922.) 20*s.* net.

THE Human period of the Quaternary era has set in. Disregarding epochs of the Pleistocene or of earlier periods in which man has left traces of his existence, his activity may be said to have begun when a clear field was given for migration. His rule on the earth's surface was assured by the disappearance of continental glaciation from the temperate zones. Henceforward, he began seriously to modify the earth. The improvement of the entrance to a cave was probably his first essay in denudation; the building of a barricade against wild beasts foreshadowed the vast works of transport and accumulation that are traceable in the Pyramids or in Cuzco.

By turning up the soil with pointed sticks, and later with some primitive form of plough, man assisted natural agents in the disintegration of hard rocks. As the soil developed under culture, with a constant renewal of its air-ways and water-ways, the subsoil in humid climates became modified in an opposite direction. Its interstices were choked by fine material washed in from above. There was a greater retention of water in the overlying soil, and acres that at one time were liable to run dry became available for the continuous growth of plants. When a patch became poor and temporarily exhausted, the early and unskilled cultivator moved to some adjacent area, just as the Berber of the Tell, with his camel-plough, or the Bantu in some forest-clearing, with his wooden hoe, is apt to do at the present day. In this way the earth was primarily and profoundly influenced by man. Let us remember that if our "civilisation" comes to us from the crowded life of cities, our "culture" reaches farther back, and was born with the first tillage of the fields.

This widely spread and continuous attack upon the land-surface does not appeal to Dr. Sherlock so much as might have been expected. He is more concerned with the localised and spectacular results of engineering pertinacity in recent centuries. These lend themselves to statistical treatment, and they can be compared with the slowly cumulative effects of natural, that is to say non-human, agents. Dr. Sherlock has brought together a large amount of curious information, and is able to tell us (p. 24) the total output of coal from Great Britain between 1500 and 1913 A.D., the area (p. 110) of England and Wales under pavements in 1908, and the height of the brick structure (p. 236) that forms the famous mound of Babylon. A fine example of his zeal for calculation appears on p. 73, where, by the use of average specific gravities, he records the output of quarries of eleven types of material during nineteen years in cubic yards in place of tons; 2·75, however, seems a slip for 2·25 in the case of gypsum; and is it scientific to use for quarried ironstone a factor so precisely stated as 4·017?

It was well worth while to direct attention to the enormous bulk of the artificial hills of slag or shale that are still growing in our mining areas. The illustrations facing pp. 203 and 207 are convincing evidence of the activity of man. The modification of an area of complex structure by the spread of a city over it is excellently typified in the chapter on London. The story of the origin of Moorfields in water that was banked up against the Roman Wall, and of the replacement of the alluvial mud of the Wall Brook and the Langbourne Water by the subterranean floors of some of our most monumental city buildings, might have been told in even greater detail. Dr. Sherlock, however, is not to be lured into the picturesque. He does not step aside to mention the lining of corridors in modern offices and hotels with the spoils of Egypt and Numidia, with slabs of imperial porphyry, "fiammeggiante come sangue," and with pale marbles voluptuously veined; or the accumulation of exotic blocks, exceeding in variety and length of travel the erratics of an ice-age, which man has brought together to deck, say, San Paolo fuori le Mura, even in an epoch of nineteenth-century restoration. The amount of Caen stone in the south of England, or of the corresponding oolite from Portland in the grey limestone areas of Ireland, suggests similar reflections. A conspicuous example of man's energy in geological transport is to be found in the Portuguese stone that was brought in carracks round the Cape to build the jutting fort on the coral shore at Moçambique.

Though the reader's imagination is not touched by Dr. Sherlock, plenty of facts are given on which to found an outlook. A sense of accurate hard work pervades the volume. The material has been quarried out, and the result of its accumulation is neither a slag-heap nor a cathedral. We have noticed only one misprint ("Berschlag" for "Beyschlag"), and few matters that the geologist could reasonably question. We wish that we could agree with the optimistic statement on p. 112 that "no sooner is a part of the road-covering destroyed than more material is brought from a quarry to replace it." In illustration of the denuding effect of ordinary traffic, a photograph of one of the deeply cut by-ways in the Folkestone Sand of Surrey would have been welcome as a touch of rural England. It would refresh one after reading of the 156,000,000 cubic yards of comminuted quartz-conglomerate on the Rand.

The construction of the volume is such that its main lines suggest attractive by-ways. The amazing transference of rock-material for agricultural purposes from Chile, Christmas Island, or the desert-edge of Gafsa, might well deserve a mention. The destructive action of man-made sulphuric acid in the atmosphere of our industrial towns has been pointed out by Mr. J. A. Howe. Dr. Sherlock, however, has provided us with ample material for developing the subject along such paths as may appeal to us most nearly. GRENVILLE A. J. COLE.

Comparative Psychology.

Handbuch der vergleichenden Psychologie. Herausgegeben von Gustav Kafka. Band 1: *Die Entwicklungsstufen des Seelenlebens.* Pp. viii + 526. Band 2: *Die Funktionen des normalen Seelenlebens.* Pp. viii + 513. Band 3: *Die Funktionen des abnormen Seelenlebens.* Pp. viii + 515. (München: Ernest Reinhardt, 1922.)

THE present is often said to be a psychological age, and certainly the recent rapid multiplication of psychological books and lectures would seem to justify the above statement. One happy result of the stimulus which popularity has given to the production of psychological literature has been to make that literature extensive and varied. Nevertheless a survey of that literature shows that the psychologist's library is by no means adequate to his needs. There are at least two regrettable deficiencies, deficiencies which are more obvious in English than in German psychological literature. There is, on one hand, no large-size and generally accredited work on theoretical or pure psychology, a work sympathetically mediatory between the several divergent schools of contemporary psychological thought, a work which provides a basis of theory for the co-ordination of the as yet somewhat scattered results reached in the various fields of psychological research. There are in existence many first drafts of and essays towards such a work, but none is detailed and comprehensive enough, apart from the fact that none of them can claim anything like general agreement; and this deficiency, however unavoidable, however much a symptom of scientific health, is obviously very disconcerting to students.

The second deficiency, the one most in question here, is the absence of a sustained and comprehensive attempt to describe the world of living beings from the psychological point of view. Twenty years ago this would have seemed an impossible, if not a thankless task. To-day it is at least possible to make a beginning. For one of the many indications of the psychologicalness (if the word may be permitted) of this age has been and still is the rapid and unresting invasion of one realm after another of concrete experience by the psychologist. From the somewhat supermundane and, to many, jejune science, closely associated with metaphysics, which it was in the last century, psychology has developed into a science which touches practical interests and activities at a thousand points. Education and industry, art and society, war and peace, all have begun to be at least discussed and often treated from the psychological point of view. And one result of this successful ramification has been the accumulation of material for such a description of the world.

What a fascinating gazetteer that would be, a psychological gazetteer of the world! A survey of the world through the eyes and from the vantage point of the psychologist! What tantalising glimpses one has of a psychological description of politics, of business, of courtship and marriage. . . . Those preserves of opinion which, as Mr. Trotter says, are deemed too lofty for knowledge and are reserved for conviction, would no longer be able to keep their sacrosanct aloofness. One would seek to understand not only the origin and persistence of the opinions but also the taboo itself. All phenomena, oaths, and tea-parties, morality and social rank, would be approached from the point of view of psychological interpretation. Ethical and æsthetic prejudgments would neither deter nor mislead, they would be explained. One would psychologise on a cosmic scale, never stopping till the psychology of the psychologist himself had been written.

There is scant prospect, alas, of anything of the quality and scale of the above for a very long time to come. Intensively and extensively contemporary psychology is not equal to such a task. On one hand, psychology, despite its recent advances, has not yet explored, much less cultivated, the full extent of its territory. Progress has been ragged, and while here the workers are many and progress rapid, there it is well if a bare seisin has been taken. On the other hand, psychological theory is as yet too limited and too sketchy, neither strong enough nor comprehensive enough, for the organisation and interpretation of the vast mass of data with which it would have to grapple.

But half a loaf is better than no bread, and if even relative finality cannot be looked for, yet a beginning is feasible. If no beginning has so far been made, with the possible exception of the late Wilhelm Wundt's obsolescent and inadequately conceived "Völkerpsychologie," the fault must lie with the necessary specialisation of contemporary psychology. The individual psychologist has been marooned, as it were, in his own field of work, ample though that field has often been; his tentatives towards communication and co-operation have been baffled by the immensity of the science, and few have had the courage and the vision even briefly and imperfectly to envisage that science as an articulate whole. So that even the little that was possible has been left undone, and the reader who wishes to gain even a cursory and incomplete conspectus of psychological experience must pursue his purpose through scores of ill-related and narrow volumes.

The student's labours have been considerably lightened, and the present unfortunate and unnecessary state of affairs significantly improved, by a recently published work. This is the "Manual of Comparative Psychology" edited by Prof. Gustav Kafka, of Munich, to which twelve psychologists, including himself, have contributed. The work itself is divided into twelve sections, each section constituting a specific department of psychology and being written by a specialist in that department. These sections are grouped, somewhat unequally, into three groups, each group corresponding to a volume of some five hundred pages. The three groups are: The Evolution of Mind (Animals, Primitive Mankind, and Children); the Functions of the Normal Mind (Language, Religion, Art, Society, and Vocational Psychology); and the Functions of the Abnormal Mind (Psychopathology, Sex, Dreams, and Criminals).

This list sufficiently indicates the scope of the work. It is easy to find omissions: law, industry, and morality are inadequately represented, for example, while the editor himself deplores the absence of a section on the psychology of science, an omission due to his inability to find any one to write the section. It is easy also to find fault with the arrangement of the subject-matter. To mention one point only, it is surely not justifiable to give the impression that sex and dreams are abnormalities. One might again stress the occasional overlapping, the occasional unevenness of treatment and of point of view, and the more than occasional stodginess of manner, due largely to excessive compression on the one hand, and to theoretical incoherence on the other hand. But this is a pioneer work and must be judged leniently. If the reader brings an active and organising mind to its perusal, then the defects will be neutralised and the solid qualities of the work appreciated. For this reason one hesitates to recommend the work to the general reader, above all to the general reader who knows little or no psychology, and to whom an overloaded and viscous style is repellent. To those better versed in psychology its comprehensiveness, its accuracy, and its excellent bibliographies will make their appeal. They will be grateful for the compact account of the psychology of language. They will be glad to have Sante de Sanctis' views on dreams, inasmuch as they are the views of a man who began the study of dreams before Freud published his "Traumdeutung"; and they will be appreciative of and grateful for much else in this timely work. The fact that it is written in German will constitute but one more reason for regret that an international language for science has not long since made the peculiar aptitude of the German for this type of work the common property of mankind.

Our Bookshelf.

Handbuch der Pflanzenanatomie. Herausgegeben von Prof. K. Linsbauer. II. Abteilung, 1 Teil: Thallophyten. Band 6: Bakterien und Strahlenpilze. Von Prof. Dr. Rudolf Lieske. Pp. iv+88. (Berlin: Gebrüder Borntraeger, 1922.) 4*s.* 6*d.*

The purpose of this handbook, which is to be comprised in a series of monographs by specialists in the various branches of the subject, is to give, in brief compass, a critical presentation of the present state of our knowledge of plant anatomy and cytology. In the volume before us, Prof. Rudolph Lieske, of the University of Heidelberg, has brought together, in a commendably brief and useful form, a critical digest of what is at present known of the morphology of the bacteria and ray-fungi (Actinomycetes). The first part of the book contains an account of the bacteria. In reference to the nuclei and nuclear structures which have been so frequently described, it is concluded that, although there can be no doubt about the existence of minute granules with nuclear characteristics, the presence of true nuclei in the bacteria has by no means been proved. The author has some interesting observations upon the recently described symplastic stage in bacterial development, and on the so-called sexual reproduction of bacteria. Among other topics dealt with are pleomorphism and variability, filtrable viruses, and mycobacteria.

In the second part of the volume the ray-fungi are dealt with. In discussing the systematic position of the group it is pointed out these organisms have certain characteristics in common both with bacteria and fungi, and that they must be looked upon as an independent group standing between the two. The various forms of the Actinomycetes present an astonishing variability both in morphological and physiological peculiarities, and the characters which have been used by various observers to discriminate species are so inconstant that no dependence can be placed upon them.

A literature list accompanies each part of the work, and there is a good index.

Mathematics and Physical Science in Classical Antiquity. By D. C. Macgregor. Translated from the German of J. L. Heiberg. (Chapters in the History of Science, II.). Pp. 110. (London: Oxford University Press, 1922.) 2*s.* 6*d.* net.

This volume gives a general survey of the science of classical antiquity, laying special stress on the mathematical and physical aspects. It opens with an account of the Ionian natural philosophy, pointing out that science is the development of early attempts of man to see his way in the world outside. Next there is a chapter on the achievements of the Pythagorean school, followed by two others on the progress made in the fifth century B.C. One of these is on mathematics, still under the influence of Pythagoras, and the other on medicine, which then reached a level not surpassed before the Alexandrian age. The work of Plato and Aristotle is adequately dealt with, while the longest chapter in the book is assigned to Euclid, Archimedes, and the Alexandrian school. In the period of decline which followed (second and first centuries B.C.)

only medicine made any real progress, and a four-page chapter is sufficient to record the work of the Romans. The last chapter, a long one, is devoted to Greek scientific literature of the Byzantine empire, it being stated that the founders of modern science, such as Galileo, Copernicus, and Newton, learnt from the Greeks not only particular results but also the very meaning of science.

Naturally Prof. Heiberg's little book makes no pretence of being a complete history of science in classical antiquity. It puts the achievements of the different schools of thought into a true perspective, and the language throughout is free from technicalities. The book would be improved by the insertion of more dates, even when these are only known approximately. (A companion volume deals more fully with the medical and biological sides of the subject.) W. E. H. B.

Tested Methods of Metallurgical Analysis (Non-Ferrous). By S. Pile and R. Johnston. Pp. 128. (London: H. F. and G. Witherby, 1922.) 7*s.* 6*d.* net.

In referring to the literature of metallurgical analysis the student, and even the worker of experience, frequently finds himself at a loss to select, from the mass of alternative detail offered, a method suited to his immediate requirements. The authors of the present work, while disclaiming any novelty in the methods given, have collected together a series of well-tried methods of which they have had personal experience. The book deals mainly with commercial metals and their more important alloys. It opens with a few introductory remarks on general analytical procedure, and on sampling. In the latter no mention is made of the frequent necessity for rejecting the first few drillings of a bar to avoid the introduction of skin impurities, as distinct, of course, from segregated elements. The suggestion of dissolving up a large quantity of metal, and working on an aliquot portion of the solution, is a good one, and worthy of more general adoption. The metals are dealt with in alphabetical order, several good methods being given for each metal, and special attention is paid to details of manipulation. The inclusion of "moisture" among the determinations is rendered possible by the somewhat "scrappy" reference to fuels and oils. A similar extension in the case of sulphur is treated at greater length. No mention is made of gold or its alloys.

With some exceptions, perhaps of secondary importance, the book is a sound and careful compilation, and should meet all the requirements of those needing, at the working bench, a trustworthy guide to assays coming within the scope of the book, familiar or otherwise.

Faune de France. 4: *Sipunculiens, Échiuriens, Priapuliens.* Par Prof. L. Cuénot. Pp. 31. (Paris: P. Lechevalier, 1922.) 3 francs.

To this excellent series, promoted by a federation of the French natural history societies, Prof. Cuénot, of Nancy, contributes an account of the curious marine animals that used to be classed together as Gephyrea. Nowadays it is supposed that the resemblances between the three groups mentioned in the title are due to convergence, and that each group was derived independently from some primitive ancestor of the annelids. Prof. Cuénot, whose writings of twenty years ago on some of these creatures are well known to zoologists, has here given a clear, interesting, and well-illustrated summary of the species living round the coasts of France. British zoologists, though they have the works of Shipley and the more recent paper by Southern, may none the less welcome this convenient aid to the study of a remarkable assemblage. F. A. B.

Manuel de filature. Par F. Rubigny. (Bibliothèque Professionnelle.) Pp. 366. (Paris: J. B. Baillière et fils, 1922.) 10 francs.

The volume under notice is one of a series of technological works, written primarily for the use of workers in the several industries, and deals with the spinning of all kinds of fibres, including asbestos and artificial silk, and also with the spinning of paper yarn. The treatment follows similar lines to those adopted by other writers on spinning, but with rather more attention to function and less description of machinery details than is the case with English works on the subject. Though this book cannot, any more than similar works on spinning technique, be taken as a trustworthy guide with respect to the raw materials, yet considering the wide field covered in less than 400 octavo pages, the treatment is otherwise remarkably adequate; and the book should be found a useful supplement to the usual works on spinning.

Cours de physique mathématique de la Faculté des Sciences. Par Prof. J. Boussinesq. Compléments au tome 3: Conciliation du véritable déterminisme mécanique avec l'existence de la vie et de la liberté morale. Pp. xlviii + 217. (Paris: Gauthier-Villars et Cie, 1922.) 30 francs.

This book is in the nature of a supplement to a complete course of mathematical physics by the University of Paris professor. It contains an extraordinary variety of matter, not very well arranged, but its main purpose is to round off a natural philosophy course by including, or rather by reconciling, the mechanism of physical nature with the indeterminism of life and consciousness. To a certain extent this has been the intellectual problem since Leibniz. Prof. Boussinesq can scarcely be said to claim to bring forward anything distinctively new, but he discusses the problem with full scientific knowledge and keen philosophical interest.

Smith's Intermediate Chemistry. Revised and rewritten by Prof. J. Kendall and E. E. Slosson. Pp. xv + 566. (New York: The Century Co.; London: G. Bell and Sons, Ltd., 1922.) 8*s.* 6*d.* net.

There can be no doubt that this book, the first edition of which was reviewed in Nature of October 14, 1920, p. 208, has been greatly improved by revision. It is now more balanced in treatment, is very well printed and bound, and is probably the best elementary treatise on chemistry of the day. The inaccurate historical note on oxygen (p. 28), which was mentioned in the former review, has been toned down, but is still somewhat incorrect. Apart from the very clear and modern account of the chemistry of the common elements, the book contains a large number of brief notes on important matters (vitamins, enzymes, atomic structure, isotopes) not often met with in elementary manuals.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Origin of Radioactive Disintegration.

IN a letter to NATURE of September 16, 1922 (vol. 110, p. 379) R. N. Pease directs attention to the possibility that the radioactivity of the heaviest elements may be due to the disturbing effect of the electrons in the atom. This view may be traced back to the time of the discovery of radioactivity (cf. J. J. Thomson, *Phil. Mag.* 7, 265, 1904, and Lord Kelvin, *Phil. Mag.* 8, 525, 1904). The problem, however, has been seriously complicated by the circumstance that, on the basis of ordinary mechanics and electrodynamics, the outstanding difficulty has not so much been to understand that radioactive disintegration can occur as to understand the simple law of radioactive decay. For the latter question, it seems that the development of the quantum theory has prepared the way to a deeper insight in the sense that the same law may be shown to apply to transition processes between stationary states of quantised systems.

On the basis of the quantum postulates alone it is an open question whether the nuclear instability is a strictly spontaneous process solely dependent upon the state of the nucleus itself, or whether external influences also play an essential part. A tentative argument in favour of the latter view is perhaps afforded by the fact that the life-periods of the elements at the beginning of the disintegration series are very large. This fact suggests the idea that the nuclei may be intrinsically stable and the radioactivity of these elements induced by the action of an external field of force, the origin of which may be looked for in the surrounding electrons. The regular variation in the life-period of successive elements in the disintegration series seems to indicate that the disintegration, when once initiated, proceeds spontaneously until a stable element is reached. On the other hand, the occurrence of radioactivity in the elements of low atomic numbers (rubidium and potassium) might be due to an enhanced efficiency of the perturbations due to some sort of resonance in the interaction between the nuclear and the electronic motion.

The force exerted by the electrons at a point in, or close to, the atomic nucleus will increase rapidly with increasing atomic number on account of the decreasing dimensions of the electronic orbits belonging to a permanent group. It will, however, in addition, depend intimately on the nature of the electronic configuration. If this configuration at every moment exhibits central symmetry, the forces from the electrons will to a large extent neutralise each other. The case is essentially different in the recent theory of Bohr, according to which the electrons belonging to a particular group and moving in eccentric orbits will approach the nucleus in succession. The shortest distance from the nucleus will be attained by the electrons moving in orbits with azimuthal quantum number equal to 1, and will then be given by

$$d = \frac{d_0}{2N}(1 - \alpha^2 N^2) \quad . \quad . \quad . \quad (1)$$

approximately. Here N is atomic number, d_0 the radius of the orbit in the normal hydrogen atom, and $\alpha = \frac{2\pi e^2}{hc} = 7{\cdot}2 \times 10^{-3}$ is the constant occurring in the theory of the fine structure of hydrogen lines. For the uranium atom the above formula gives $d = 15 \times 10^{-12}$ cm. On the other hand, the inferior limit for the diameter of the uranium nucleus, derived from the energy of the α-particles from uranium on assuming this energy to be due to the electrostatic repulsion of the nucleus, comes out of the same order of magnitude as the above value of d. At the moment of closest approach these electrons will thus exert forces upon the individual particles of the nucleus which may be of the same order of magnitude as the electrostatic attraction or repulsion between the particles themselves. For still larger atomic numbers, d will rapidly decrease while the nuclear dimensions will be expected to increase. It is therefore seen that for some atomic number not far ahead of that of uranium the electrons in question would have to pass quite close to the nucleus, and thus exert large perturbing forces on the nuclear particles. For still larger atomic numbers a motion for which the nuclear field is treated as due to a point charge would become impossible as the electrons in question would have to collide with the nucleus. On the whole, it does not appear excluded that the presence of radioactivity among the heaviest known elements as well as the apparent absence of elements of higher atomic numbers may be connected with some sort of interaction between the nuclear and the external electrons.

The efficiency of this interaction will be expected to depend intimately on certain resonance conditions, as is the case for ordinary mechanical systems. The frequencies of the motion of the nucleus must in general be expected to be of an altogether higher order of magnitude than the frequencies in the motion of the electrons; but there remains the possibility that the nucleus as a whole will rotate and this rotational frequency may in some cases be comparable with some electronic frequency. The case when the nucleus rotates with an angular momentum equal to $h/2\pi$ is of special interest, as this value appears to be associated with the most stable state of quantised systems. The rotational frequency w may then be estimated from the expression

$$w = \frac{h}{4\pi^2} \cdot \frac{1}{Ma^2}, \quad . \quad . \quad . \quad (2)$$

where M and a are the nuclear mass and radius of gyration about the axis of rotation. Assuming the nuclear dimensions to increase from about 8×10^{-13} cm. in helium (Rutherford and Chadwick) to about 6×10^{-12} cm. in uranium (cf. above) this frequency is found to decrease from about 10^{20} sec.$^{-1}$ in helium to about 10^{16} sec.$^{-1}$ in uranium. The latter value is essentially larger than the value to be expected for valency electrons. This is also necessary in order to understand the fact that the radioactive properties hitherto on record are independent of chemical combinations. It will further be found compatible with the assumptions regarding the nuclear dimensions to assume the frequencies of nuclear rotation in potassium and rubidium to be of the same order of magnitude as the electronic frequencies of the K and the L electrons respectively in these elements.

The above considerations, however, are to be regarded merely as tentative suggestions, and our knowledge of nuclear structure is probably far too scanty to permit of any definite conclusions concerning these questions at present.

The New Marine Biological Research Station of the Bergen Museum.

FOR close upon one hundred years researches regarding marine fauna have been a prominent part of the work carried out by the Bergen Museum. The first biological station in Norway was built in the year of 1891 and was attached to the museum. On account, however, of the expansion of the city of Bergen, the pollution of the salt-water supply for the station gradually increased to such an extent that the biological work there had to be abandoned.

By the generosity of private donors, who realised that the fine traditions of the maritime research work carried out at Bergen should be maintained, the Trustees of the Bergen Museum have been enabled to build a new station. The biological station (Fig. 1) is now situated on the island of Herdla, about seventeen miles from Bergen. The station is thus right in the centre of one of the richest and most promising fields for research of the west coast of Norway, well known also through the investigations of such British naturalists as Norman, Jeffreys, Harmer, Punnett, and others. The open sea, the deep fjords, and the narrow sounds with their strong currents, offer here the most varied and changing conditions of life for marine fauna, which accordingly is extraordinarily rich and well represented.

FIG. 1.—Marine Biological Station at Herdla, seen from the fjord.

Any biological condition typical of the west coast of Norway may be reached within less than two hours' sail from the station. The salt-water supply is taken from a depth of approximately 25 metres, which guarantees salt water of excellent quality and without appreciable changes in temperature and salinity. Thus are present the best conditions for experimental and embryological research.

The object of the station is to serve as a basis for scientific investigations, as well as for the international courses in marine biology which were held at the Bergen Museum for a number of years until 1914, and with a large participation from abroad. The station is open to naturalists of all nations. During the period in the summer when no courses are held, the station has tables for ten scientific workers besides the staff. During the winter there are tables for five only. Being situated close to the open sea, which never freezes, the station can be kept open all the year round, and thus offers good opportunities for collecting material during the winter months. The station contains the necessary accommodation for housing naturalists visiting it.

A 25-ton research vessel, the *Herman Friele*, is attached to the station, and is equipped with appliances for research down to a depth of 1500 metres. Moreover, the station is provided with a smaller open motor boat and various rowing-boats.

By the opening up of this new station, facilities are afforded for utilising again the particularly favourable conditions for marine biological investigation offered by the west coast of Norway. I shall be glad to reply to any inquiries regarding the station or the reservation of tables.

A. BRINKMANN.
(Director.)

Museet, Bergen, Norway.

Industrial Applications of the Microscope.

WHILE one reads with satisfaction in NATURE of February 17, p. 239, of the ever-increasing examples of the application of the microscope to industry, the fact remains that the use of the mineralogical microscope with the small amount of knowledge of crystal optics necessary has up to the present been practically disregarded.

In 1918 a considerable amount of work was done in this connexion dealing particularly with explosives, but the results were never published, and hence it is thought that the following example may be of interest.

It was proved quite definitely at the Ardeer Factory of Nobel's Explosives Company that the degree of nitration in guncotton and nitrocellulose could be ascertained directly by the optical properties of the product. Thus it was found that the birefringence of ordinary cotton fibre before nitration was strong and of a positive character. The same cotton after being fully nitrated showed strong birefringence but of a *negative* character, while cotton with an intermediate degree of nitration was shown to be practically isotropic.

It was found afterwards that a corresponding work had been carried out by Dr. Phil Hans Ambron in Germany, and he published a table giving the actual values and character of the birefringence of nitrated cellulose and also nitrated ramie or China grass. It is, of course, true that the degree of nitration can be obtained quicker and more accurately by means of a nitrometer, but the two lots of information differ widely. The nitrometer gives the average nitration of the whole sample while the microscope gives the actual nitration of separate fibres, and is therefore a valuable test of the homogeneity of the sample.

During the War, when acetone was unobtainable, a substitute had to be found as a solvent for nitrated cellulose in the making of cordite. Ether-alcohol was the substitute used. Now, while cellulose and almost any form of nitrated cellulose are soluble in acetone, ether-alcohol will only dissolve nitrated cellulose of a certain percentage nitration, and the homogeneous nitration of large samples of cotton was by no means easy or altogether certain, and hence the microscopic method should have been invaluable. The results of these experiments were obtained too late to be used on a large scale, but they certainly show an example of the class of information obtainable.

Another application of a rather humorous nature can also be cited. A large consignment arrived in the factory of what was called ground silica. This was sent to the analytical department and its percentage of silica ascertained. It was pointed out, however, that the value of ground silica did not lie in the purity of the material but in its fineness and homogeneity. This was tested both by elutriation and the microscope. The microscope revealed the fact that the material was nothing but an inferior sand, with very little grinding. Ground silica must, of course, always show conchoidal fracture and not rounded grains. This sample was also shown to contain the mineral glauconite actually replacing the tests in small fragments of foraminifera, and hence had during its formation been closely connected with the sea. The price per ton indicated that the material was supposed to have been obtained by the grinding of vein quartz.

The identification of asbestos has been published before, but it bears repeating. Platinised asbestos was extensively used in the sulphuric acid plant. The asbestos was originally supplied from the continent, but during the war this supply was not available. The South African asbestos or the mineral crocidolite was used as a substitute with very disastrous results. It was decided, therefore, that the nature of the original asbestos must be obtained by chemical analysis and all samples similarly tested. The chemical analysis of a complicated silicate like asbestos is a long and by no means easy process, as the asbestos is seldom free from other complicated silicates. Now, it was found by a very simple mineralogical test that the original sample was the mineral chrysotile, and by similar tests it was quite easy to ascertain which of the other samples was also chrysotile and to pick out the purest. In this way, a dozen samples were tested in two hours, whereas the chemical analysis had already been in hand for three months, and was likely at the same rate to take another six and give no information whatever.

The simple test for chrysotile was mounting it on a microscopic slide in mononitrobenzene and rotating it between crossed nicols. The refractive index was obtained by the Becke method. The refractive index together with the birefringence and optical character render the mineral quite distinct from any other sold as asbestos. These are three of the very many occasions that cropped up so frequently.

ASHLEY G. LOWNDES.

Marlborough College, Wilts.

Factors of Odorous Strength.

IN the letter from Mr. J. H. Kenneth published in NATURE of February 3, page 151, a relation is indicated between the odours of certain substances and specific gravity. If, however, we examine the boiling-points of the odorous constituents of the four oils mentioned, we find that in order of increasing vapour pressure the oils stand as follows: sandalwood (305), cedarwood (280), origanum (230), and terebene (160), the figures in brackets being the approximate boiling points. This order is precisely that represented by the specific gravity quoted by Mr. Kenneth.

I scarcely think the phenomenon with which Mr. Kenneth's letter deals, can safely be ascribed to the specific gravity of the oils, although possibly in this instance the specific gravity is a property concomitant with volatility. Volatility alone, however, does not afford a completely satisfactory explanation of this and many other phenomena connected with the smell of an odoriferous substance. There are at least four factors concerned, namely: (1) Volatility; (2) solubility in the aqueous layers in the nose; (3) solubility in the lipoid fats of the nose, and (4) chemical reaction with osmoceptors in the nose.

A substance which fails to satisfy any one or more of these factors is odourless, and it is obvious that variations in the factors will produce variations in both the strength and the quality of the odour.

T. H. DURRANS.

The Dyson Perrins Laboratory,
South Parks Road,
Oxford, February 6.

WITH reference to Mr. Kenneth's letter in NATURE of February 3, p. 151, I should like to point out that, if the "votes" be counted on a sort of proportional representation scheme by adding to the first votes for each substance half the second, a third of the third, and a quarter of the fourth, we get the following results in votes:

S.	C.	O.	T.
18·66	11·56	9·33	6·33

This result seems to me to enforce Mr. Kenneth's argument.

The Life-Cycle of the Eel in Relation to Wegener's Hypothesis.

IN NATURE of January 27, p. 131, under the title "The Distribution of Life in the Southern Hemisphere, and its Bearing on Wegener's Hypothesis," an account is given of a discussion at a recent meeting of the Royal Society of South Africa on this question. Opinions were divided, the geologists suspending judgment, while the hypothesis was opposed on botanical and entomological grounds as being unnecessary. On the other hand, it was said that the most important zoological evidence in support of Wegener's theory was provided by the distribution of the isopod, Phreatoicus.

It seems to me that strong evidence in favour of Wegener's hypothesis is to be found in the life-history of the European freshwater eel, as revealed by the brilliant researches of Dr. J. Schmidt, of Copenhagen. For something like eighteen years Dr. Schmidt has been engaged on this subject. He has published numerous papers and has summarised his results in the Philosophical Transactions, published a year ago, and quite lately in NATURE (January 13). It will be sufficient for the present purpose to allude only to certain of his results.

Of the two freshwater eels of the North Atlantic, the American species spawns somewhat to the south and west of the spawning region of the European species, and the larvæ attain full size and, after metamorphosis, enter the freshwaters of the American coast when about one year old. On the other hand, the larvæ of the European species, originating more to the east but still in the same region, are transported by the Atlantic Drift and its continuations, aided perhaps by their own efforts, it may be for thousands of miles, as shown in the chart, p. 51 of the article in NATURE of January 13. Still more to the point, the larvæ are about three years old when they become transformed into elvers and enter freshwaters. A larval life so extremely prolonged, as Dr. Schmidt points out, is quite unique. The rate of growth, moreover, is extraordinarily slow. At full size, after about three years' growth, the larvæ are approximately three inches long, although the temperature of the water in which they are immersed is comparatively high. In our own waters with much lower temperatures most young fishes would attain a corresponding length in as many months. The extremely slow growth of the larvæ of the European eel is thus an adaptation to the prolonged journey.

It is scarcely possible to understand this unique phase in the life cycle of the European eel on the hypothesis that the geographical conditions were formerly the same as now exist. But if Wegener's theory be accepted, the explanation is simple. As the coasts slowly receded from one another the larval life of what became the European species was more and more prolonged by natural selection in correspondence with the greater distance to be traversed. T. Wemyss Fulton.

The Stoat's Winter Pelage.

Sir Herbert Maxwell's letter on the above in Nature of February 17, p. 220, raises points of great interest. Presumably if his glacial explanation be correct, stoats taken from the Scottish Highlands to the south of England will still become white in the winter; whereas stoats brought from the southern counties to the north of Britain will remain the same colour the year round. Has this ever been put to the test?

It would be instructive to know whether winter coats intermediate in shade between brown and cream-white are ever assumed. I ask this from the point of view of mutation, which is so much to the fore at present. Have, for example, circumpolar white animals arisen from coloured ones through chance albinos being preserved and increased by Mendelian segregation, or have they appeared through the selection of paler and paler forms leading eventually up to white?

Then again, taking Sir Herbert Maxwell's explanation as correct, have we not here an example revealing how slowly evolution may work? The elimination of the arctic winter garb of the stoat in Britain is not yet complete, though some thousands of years at least must have elapsed since the last ice age.

One more point: Is the British stoat as regards its pelage reverting to the pre-glacial condition, and if so, how does this harmonise with the view that evolution is irreversible? John Parkin.

The Gill, Brayton, Cumberland.

Sir Herbert Maxwell's attractive thesis (Nature, February 17, p. 220), that latitude and not winter temperature regulates the seasonal change of the stoat's pelage from brown to white, does not meet all the facts of the case. Islay is farther north than Monreith, and yet in Islay a large proportion of the stoats retain their summer colour throughout the winter.

Having made arrangements some time ago to obtain specimens of the Islay stoat, regarded by Mr. Gerrit Miller as a distinct race, I was struck by the fact that individuals killed in December and February were in summer coat. This suggested inquiry as to the usual course of events in the island, and Mr. Macdonald reported that there white winter stoats are rather the exception than the rule: that of more than 20 stoats he had killed during the winter of 1921–22, only one was entirely white, although in the previous winter the proportion was higher, about six being white; but that only in exceptional years did the proportion of white individuals attain to about half of the total number killed.

Now the latitude of Edinburgh is not far off that of Islay, yet my impression is that here almost all the stoats become white in a normal winter.

These and other facts strengthen the old idea that climate is somehow involved in the colour-change, which seems also to depend to some extent on the condition of the individual animal.

James Ritchie.

The Royal Scottish Museum,
Edinburgh, February 21.

Sir Herbert Maxwell, in Nature of February 17, p. 220, directed attention to what he considered the conditions determining the winter change of colour in stoats, and inferred that the tendency to undergo such a change is usually the inherited characteristic of some particular strain or breed, rather than the outcome of any special present local severity of climate. He said the effect was most marked in the Highlands of Scotland and diminished regularly as one travelled south, until on reaching Cornwall the winter blanching seemed almost entirely in abeyance.

Since his observations appear to be confined to the island of Great Britain, Sir Herbert may be interested to learn that as a boy at Jersey, about the year 1880, I happened to come across a white stoat. This was shot by a neighbour, in St. Lawrence valley, and, after being stuffed, kept by us for some years. It represented a perfect ermine, the fur being pure white except for a black tail. I never heard of, or saw, any other specimen in Jersey, either white or brown. The case seems interesting, for the stoat belonged to a breed which must have been free from any extraneous admixture, particularly from the north, since that remote period in the past, when the French coast (on which the Channel Islands are situated) was finally separated from Great Britain by the English Channel. Further, the climate being mild and uniform, the tendency to assume a winter pelage can only have resulted from very ancient inheritance.

Exeter College, Oxford.

The Subject Index to Periodicals.

May I add a few words of information to the appreciative review of the above publication which appeared in Nature of February 17, p. 214. Our headings are "The Subject Headings used in the Dictionary Catalogues of the Library of Congress" to which an annual supplement is published. These are linked up with the corresponding classes in the shelf-classification of that library. The advantage of this type of catalogue is that, if properly compiled, it combines system and uniformity with the property of immediate reference. It is in fact a class catalogue in which the headings are arranged in "index" order. Your reviewer's suggestion that we should print a list of the journals indexed in each Class List will be certainly adopted when our funds admit of it. Our Class Lists for 1915-16 contained such Lists as well as Authors' Indexes, and it was with the utmost regret that we were compelled to discontinue these features.

The following extract from an official letter now being circulated widely throughout the British Empire may interest some of your readers:

"In assuming responsibility for the Index the Council of the Library Association was actuated by the following considerations:

"(1) That, in view of the rapid growth of the periodical press, the analytical indexing of periodicals could be carried out with due regard to efficiency and economy only by co-operative effort.

"(2) That such co-operative publication should be controlled by a British professional body rather than be left to the enterprise of a foreign publisher.

"(3) That the Index should be compiled by trained library workers on a voluntary basis, and that the price should be fixed as nearly as possible to the cost of production, and without any idea of profit."

Every effort will now be made to bring the Subject Index up to date. We hope to complete the 1920 Class Lists this summer and commence the publication of the 1921 Lists in the autumn. For further particulars application should be made to the Hon. Secretary of the Library Association, Westminster Public Libraries, Buckingham Palace Road, S.W.

E. W. HULME,
Editor of "The Subject Index to Periodicals."

Gorseland, North Road, Aberystwyth,
February 23.

Time Relations in a Dream.

I HAVE read with much interest Dr. Atkin's letter in NATURE of January 27, and also Mr. Barcroft's letter in the issue of October 23, 1919 (vol. 104, p. 154) to which he refers. My own observations, made in various degrees of semi-consciousness, appear to show that there is no such thing as a definite time relation, as it depends entirely on the degree of consciousness, the time scale being enormously shortened in the semi-conscious state most remote from wakefulness, so that the images produced by the mind must succeed one another with extraordinary rapidity when in that state. As wakefulness increases, the time scale seems to expand, and the succession of events proceeds more and more slowly, until it practically stops or becomes normal as wakefulness resumes absolute control. I have been led to believe that the mind is *always* active—just like the heart always pulsates—whether we are asleep or awake, and that control and memory are the features of our waking condition, so that we do not remember the images it calls forth, except when we are beginning to awaken, and the degree of activity of our memory in our dreams and the extent of the dream memorised merely depend on the rapidity with which we reach wakefulness.

I have made a number of observations of hypnopompic pictures, or optical illusions, which occur while sinking into slumber or during gradual awakening. I described my first observations in the Journal of the Society for Psychical Research for April 22, 1921, but since then I made several curious observations, some of which concern the case in point.

The hypnopompic pictures which I have observed are generally landscapes passing *slowly* before one's closed eyes, when in an *almost awake* condition, one being fully aware of one's wakefulness, and having one's full reasoning powers *while the illusion proceeds*, so that one can make precise observations and experiments as to the effect of volition, etc. The pictures, which are extraordinarily sharp and full of detail, appear as an endless panoramic band or film passing *slowly* before one's mind's eye, so to speak. The film may pass in any direction, right to left, or the reverse, or vertically downwards, or obliquely. A film may snap, but it invariably slows down as consciousness increases, till it becomes motionless and *then* gradually fades.

It seems as if several such bands or films could exist at the same time, passing one in front of the other, and sometimes in different directions, the uppermost alone being visible of course, and its sudden ending by snapping allowing the one underneath to be visible. This would explain the sudden changes which are often noticed in dreams. The fact that the film is panoramic (and not cinematographic, that is, without perception of translation) is remarkable, as one would have expected it to be cinematographic in character. Once, attaining consciousness very rapidly, I glimpsed, for a couple of seconds, a blurred mass of lines such as one sees from an express train on a wall quite close to the track lines caused by the persistence of vision of the details on the wall, combined with their motion relatively to the train. I have no doubt whatever that I had witnessed the hypnopompic "film" nearly at its normal speed, but with a mind already "slowed down" by the return to consciousness, and unable to cope with its speed and see the details which otherwise I am persuaded—by the agreement of all my observations—would have been visible.

The latter observation bears directly on the question of duration. At such a high translation speed, hundreds of times faster than the usual speeds I had hitherto observed, a whole panoramic view must pass in an extraordinarily short time. Moreover, at such a speed, cinematographic effects are possible, but I fail altogether to imagine by what mechanism they could take place, and so far my observations have given me no clue, although I have once or twice witnessed variations in the process which prevent me from despairing of getting further insight into this mysterious working of our minds. It seems as if control and memory slowed down the working of the mind so that the speed of succession of the images is an inverse function of the degree of wakefulness. M. GHEURY DE BRAY.

40 Westmount Road, Eltham, S.E.9,
February 10.

The Social Influence of Science.

IN his article in NATURE of February 17, p. 209, Mr. F. S. Marvin says: "When in the sixteenth century the mind of Ancient Greece awoke again . . ." The advent of modern science is here considered as a revival and continuation of Greek knowledge; an opinion very commonly held, but entailing some difficulty—a millenary period of stagnation and even retrogression. This is inconceivable; the very essence of science is progress, continuous but not steady, because the rate is increasing. This characteristic of science was pointed out in the Harveian Oration for 1897 by Sir William Roberts ("Science and Modern Civilisation," NATURE, October 28, 1897, vol. 56, p. 621).

Antiquity has been artistic, literary, philosophical with deductive reasoning; but is markedly deficient in the objective study of Nature and the inductive mentality. The philosophers' knowledge of things was part of their system, based on *a priori* principles. Their opinions were many and conflicting, with various degrees of credulity, a few of them by chance right. The influence, if any, on the birth and growth of modern science has been very limited; the method of working, by patient observation and experimenting, is exactly the reverse. The rise of the experimental inductive method was like a botanical mutation and inaugurated a new era in the evolution of mankind. AD. K.

Antwerp, February 17.

It is true that progress was made in certain directions during the "millenary period of stagnation," for example, the improvements in mathematics due to the Arabs. Yet the main fact in the re-birth of science in the sixteenth century is the discovery of the work of the Greeks, especially in geometry, astronomy, and geography. Descartes goes back to Pappus, Copernicus to Aristarchus, Toscanelli to Ptolemy. There is no question that in the general spirit with which the medieval mind regarded Nature there was retrogression, and that the Greek mind did come to life again at the Renascence, partly in its broader quality of rational inquiry, partly in the actual works of Greek thinkers.

F. S. MARVIN.

German Book Prices.

IN reference to Prof. Browning's letter in NATURE of December 23 (vol. 110, p. 845), I should like to point out an added difficulty in India and Burma. Not only are exorbitant prices charged for German books, but to the majority of our students such books are useless owing to their ignorance of the language. The Indian or Burmese student already has to learn English in order to study chemistry, and to ask him to learn German as well is too great a handicap and should be unnecessary.

The appearance of certain recent works on inorganic chemistry shows that British chemists are capable of compiling exhaustive treatises, and a dictionary of organic chemistry in English would be invaluable. The Society of Dyers and Colourists is preparing a colour index, and the combined strength of the Chemical Society and Institute of Chemistry should be able to produce a work on organic chemistry which would enable Indian or Burmese students to carry out research in organic chemistry without constant reference to German works.

Single Crystals of Aluminium and other Metals.

THE brilliant account given by Mr. G. I. Taylor at the Royal Society (February 22) of the deformation of single crystals of aluminium leads me to direct attention to work done in this laboratory ten years ago by Mr. B. B. Baker and Dr. E. N. da C. Andrade. Mr. Baker showed that sodium and also potassium cylinders when stretched contracted laterally so as to lead to an approximately elliptical section, and when they broke they did so at a chisel edge. The surfaces are marked with a double set of slip lines. A photograph of the appearance is shown in the Proceedings of the Physical Society of London for 1913.

Dr. Andrade, who was experimenting at the same time on the traction of metals, showed that similar results were obtainable with tin and lead, and also with frozen mercury (*Phil. Mag.* 1914). He concludes that they are due to large uniform crystals of a size comparable with the diameter of the rod. From the regularity of behaviour over a length of several centimetres it may be concluded that both were dealing with single crystals several centimetres long in the case of each of these materials—at any rate in the same sense as that in which the crystals of aluminium are spoken of as being single.

The crystals of sodium are still in my possession, having been carefully preserved in anhydrous paraffin. They show the characteristics, even the fine surface markings, practically as well as when they were drawn.

Paradoxical Rainfall Data.

AT Blue Hill careful measurements of rainfall have been made for thirty-seven years. There is no break in the record and the amounts are checked by more than one gauge. Data for the entire period 1886–1922 are given in Blue Hill Meteorological Observations. The average monthly values are :

January	101·1 mm.	July	104·1 mm.
February	101·0 ,,	August	100·8 ,,
March	109·2 ,,	September	103·1 ,,
April	94·1 ,,	October	96·4 ,,
May	94·0 ,,	November	97·7 ,,
June	86·3 ,,	December	97·9 ,,

Year . . . . . 1185·7 mm.
Month . . . . 98·8 mm.

The driest month is June and the wettest is March. Yet the driest month in the whole period was March 1915, when the total rainfall was only 1 mm. What is equally remarkable, the wettest month was June 1922, when 274 mm. fell. It is difficult to explain these rainfalls on any theory of probability. The June rainfall was not due to abnormally heavy showers.

Atmospherics.

MANY who have "listened in" must have been much interested by the peculiar sounds the telephone generally emits, in addition to those produced by the waves from the broadcasting station. Although atmospherics are produced by the electric discharges during thunderstorms, many would appear to have a very different origin.

In the discussion of a paper on "The Study of Radio-telegraphic Atmospherics in Relation to Meteorology," by C. J. P. Cave and R. A. Watson Watt (Journal of Meteorological Society, January 1923, pp. 35-42), Mr. L. F. Richardson asked Mr. Watson Watt "if he could explain the origin of the peculiar atmospherics which were experienced at Eskdalemuir on the telephone, which was connected with an overhead wire in a lonely valley. In addition to the ordinary clicks there was a 'swishing' sound. The frequency of the vibration diminished as the swish went on. This property was characteristic of the sound of a shell passing high overhead. Mr. Richardson had the idea, perhaps a mad one, that the swish might be produced by a meteorite."

Many of the atmospherics I have heard have had this character, and it may be suggested that the idea that they are produced by very small meteorites is not quite such a mad view as would at first appear.

In the higher atmosphere, there may be a very considerable electric potential gradient, and if a meteorite, entering it, ionised a path in it, an electric discharge might occur along this ionised path sufficiently strong to give off electric waves. There is indeed reason to suppose that the direction from which the waves come is influenced by variations in the sun's position (R. A. Watson Watt, Proc. Roy. Soc., vol. 102, 1923, p. 460).

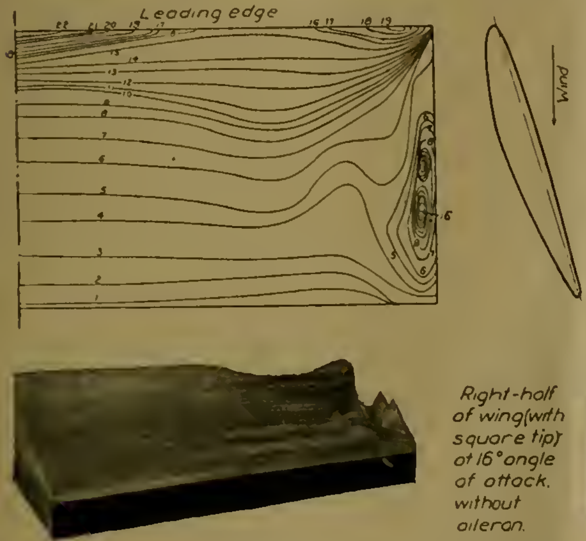
Recent Aeronautic Investigations and the Aeroplane Industry.[1]

By Prof. JOSEPH S. AMES, The Johns Hopkins University, U.S.A.

FEW industries offer better illustrations than the manufacture of aeroplanes of the intimate relation between purely scientific investigations and the practical application of their results. As an example of this fact, attention may be directed to three experimental researches in progress at the laboratories and flying-station of the National Advisory Committee for Aeronautics at Langley Field, Virginia. These researches were begun and are being conducted in order to add to our knowledge of the science of aeronautics, but their results are of the utmost importance to the industry and also to the art of aviation. Other illustrations might well have been selected, but these are, in many respects, of "actual" importance.

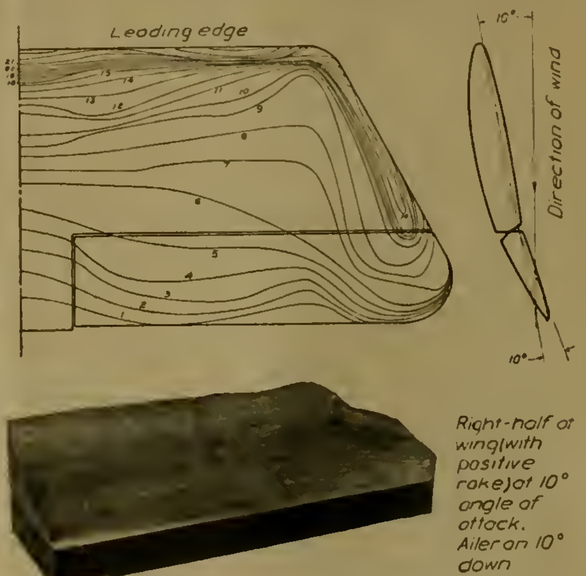
The first research deals with the pressure distribution over the wings, tail-surfaces, etc., of an aeroplane—an old problem, studied with marked success by the staffs of the British establishments at Teddington and Farnborough. What is novel in the present investigation is the extension of the problem to aeroplanes making manœuvres, and to wings of different plan form, varying the angle of attack and the aileron angle. The method adopted is simple: numerous series of small openings are made in the surface to be investigated; each of these is joined by a rubber tube to a capsule containing a metal diaphragm, to which is attached a tilting mirror; a beam of light is reflected from this on to a photographic film which may be shifted, thus permitting a series of observations to be made. The apparatus in use records the pressures existing at sixty points simultaneously. All the diaphragms are, of course, standardised and calibrated. (In the case of wind-tunnel experiments a number of liquid manometers are used.)

Among the questions already investigated are: the change in pressure distribution produced by a loop, a roll, etc.; the effect of the shape of the wing-tip, square corners, elliptical, raked off, etc.; the influence of the air-stream from the propeller. In all cases the pressures are measured quantitatively, and the results are shown in two ways: by making plaster or wooden models, like a relief map; and by drawing contour lines of pressure (Figs. 1 and 2). From the knowledge thus obtained, the aeroplane engineer can decide upon the best shape of wing or elevator, etc., and upon the relative strength required in different parts of his structure; and further, if a breaking sand-load test is thought necessary, he can so distribute the load as to make it correspond to actual flying conditions.



Plan and elevation showing contour lines. and built-up model.

FIG. 1.



Plan and elevation showing contour lines and built-up model.

FIG. 2.

The second research was undertaken to learn the actual motion of an aeroplane in alighting, taking off, making oscillations and manœuvring, and at the same time to record the motions of the control surfaces and the forces exerted by the pilot (Fig. 3). A large number of instruments are required, all of which were newly designed with special reference to lightness and compactness, as well as to accuracy. The central instrument is a photographic film wrapped on a cylinder which is in rotation, for all records are made upon this by beams of light reflected from mirrors which form part of all the various instruments. When in actual use on an aeroplane, the pilot simply presses one button at the beginning of a manœuvre, and this starts everything. The instruments in use at the present time are as follows:

(*a*) Chronometer, consisting of a constant speed

[1] Substance of a lecture delivered before the Franklin Institute, Philadelphia, on November 23, 1922.

motor, properly governed. Lines of light are recorded at definite intervals, *e.g.* two seconds.

(*b*) Air-speed recorder, simply a Pitot-Venturi nozzle attached to suitable pressure-recording capsules.

(*c*) Single component accelerometer, consisting in the main of a damped steel spring, one end of which is free.

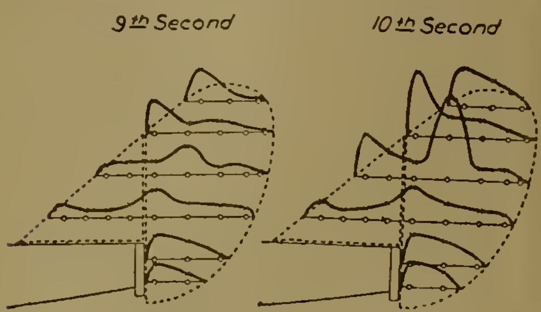


FIG. 3.—Showing the curves of pressure on the entire surface of the rudder at various intervals during a left turn.

(*d*) Three-component accelerometer, a combination of three of the previous instruments. The sensitiveness of the three is adjusted corresponding to the amount of the acceleration to be expected.

(*e*) Angular velocity recorder, making use of a high speed electric motor as a gyroscope. The curves obtained by this give, when integrated, angular displacement, and when differentiated, angular acceleration.

(*f*) Three-component angular velocity recorder, a combination of three of the previous instruments.

(*g*) Control position recorder, consisting essentially of three spring-controlled spools threaded on an axial screw, each spool actuated by a wire leading to the horn of the control surface.

(*h*) Force recorder, using a carbon pile resistance method.

Of course all these instruments are not used at the same time, but only as many as are needed for the study of each particular question.

From a practical point of view these instruments allow the performance of an aeroplane to be recorded accurately, in a manner quite free from the personal impressions of the test-pilot; and, further, the records taken in any manœuvre tell a story which is perfectly plain. Numerous questions, often raised by pilots, have already been answered, and pupil pilots have received great assistance.

The last research to be mentioned is one which is only beginning, but the apparatus has been carefully tested, and a few preliminary readings have been made. This refers to a new method of investigating the "scale effect." In the ordinary wind tunnel the forces and moments on a model of about one-twentieth the full scale are observed, and from these measurements deductions are made as to the promised performance of the full-sized aeroplane, or part thereof. It has been known for many years that in order for these deductions to be justified it would be necessary to have in the tunnel and in the flight of the actual aeroplane the same Reynolds's number, as it is called. This number is the fraction $\rho VL/\mu$, in which ρ is the density of the air, V is the relative velocity of the air-stream, L is a linear dimension of the aeroplane (or part), and μ is the coefficient of viscosity. It is clear that the Reynolds's number in the tunnel is about one-twentieth, or less, that of the aeroplane in flight. To obviate this, a complete wind tunnel has been installed inside an elongated steel tank—35 feet long, 15 feet in diameter—in which the air is kept compressed to 20 or 30 atmospheres (Fig. 4). The walls of the tunnel proper are hollow, and in this space the balances are installed, so as to be out of the air-stream. The attitude of the model in the tunnel may be varied, and the balancing weights may be shifted, etc., by small electric motors, controlled from outside the tank. Readings consist in viewing through suitable small windows a number of Veeder counters. The importance of this apparatus from the point of view of aerodynamics is sufficiently obvious, and from that of the aeroplane designer even more so.

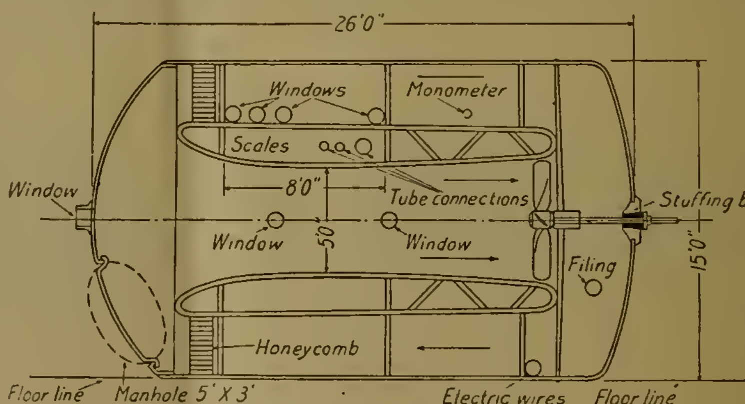

FIG. 4.—Compressed air wind-tunnel.

Radiography and Physics.[1]

By Dr. G. W. C. KAYE.

THE frail, untrustworthy X-ray tube of 1895 and the more robust and dependable tube of the present day do not differ in principle. The X-ray tube still remains a device for generating high-velocity electrons and suddenly depriving them of that velocity by hurtling them against a target. In fact, the tube possesses all the characteristics of a battlefield, except that as yet we lack the ability to give our shells speeds of the order of 50,000 miles a second. Then, just as a flash of flame accompanies the sudden stopping of the shell, so do the X-rays set out in all directions from the target, travelling in straight lines just as

[1] Abstracted from the opening address to the Society of Radiographers, October 31, 1922.

light rays radiate from a lamp. The X-ray tube is, indeed, an X-ray lamp in which the applied voltage is analogous to the temperature of a luminous lamp. If we raise the temperature of the latter, we shorten the average wave-length; so with the X-ray bulb, if we raise the voltage the average wave-length is diminished.

In the light of present-day knowledge, what do we know to be the factors which control output from an X-ray tube? The radiographer is concerned more with the general or continuous spectrum of X-rays than with the superposed rays characteristic of the target. In regard to the former the factors are three: (*a*) The number of the cathode rays or electrons which strike the target; (*b*) the speed of the electrons; (*c*) the massiveness of the atom of the target. (*a*) is represented by the current through the tube, (*b*) by the voltage across the tube, (*c*) by the atomic weight or, more precisely, the atomic number of the metal of the target.

To what extent do these several features come in? To settle these points let us call in the aid of the X-ray spectrometer and vary each of the factors one by one. The spectrometer spreads out into a continuous fan of rays all the various wave-lengths present, and tells us, moreover, the amount or intensity of each wave-length. So that if we plot wave-length against intensity, we get a curve which clearly reveals the composition of the beam. Furthermore, the area of the curve is a measure of the output. If we do this, we find that the several spectral curves show that the X-ray output is proportional to the current, to the atomic number of the target, and to the square of the voltage.

We notice that the voltage comes in as a second-power term, and the importance of measuring voltage by the radiographer not sporadically but as a routine procedure day in and day out should be stressed. For the applied voltage has a dual importance: it not only dominantly affects the output, but it is the sole arbiter of quality or penetrability or wave-length.

The time is approaching when we must gradually relinquish the use of the terms "hard" and "soft" X-rays and accustom ourselves to speak of wave-lengths. For example, in deep therapy we can say that the spectrum of rays employed lies between 0·06 and 0·2 Å.U., the mean effective wave-length being about 0·15 Å.U. or less. The radiographer who uses point spark-gaps up to, say, 6 inches long employs a spectrum of rays ranging from about 0·12 to 0·4 Å.U., the mean effective wave-length generally lying between 0·2 and 0·3 according to the filter and nature of the high potential generator. We might make a beginning by agreeing, for example, that "hard" rays refer to rays with wave-lengths shorter than 0·1 Å.U., and that "soft" rays have wave-lengths longer than 0·3 Å.U., the intervening rays being of "medium" hardness.

Let us consider the career of an electron in an X-ray tube impelled towards the target with a velocity which it owes to the applied voltage V. The chances that that electron will ultimately come into suitable conflict with one or more atoms in the target and so generate X-rays are slight—about 1000 to 1. The energy of the electron is, in fact, much more likely to be frittered away as heat. Assuming that the unlikely happens, one of two things may occur: the electron may lose all its energy at one encounter or it may do so by instalments in a succession of encounters. In other words, if we agree to think of its energy in terms of the original driving voltage (V), then it may lose the whole of V in one step or do so in a number of steps.

Now Planck's quantum relation tells us that whenever an electron has its speed altered the wave-length of the X-ray produced is inversely proportional to the energy given up by the electron; that is, to the equivalent loss of propelling voltage. It will be noted that no question arises of the nature of the target. To put it another way:

$$\left(\begin{array}{c}\text{Loss of propelling}\\ \text{voltage on electron}\end{array}\right) \times \left(\begin{array}{c}\text{Wave-length of}\\ \text{resulting X-ray}\end{array}\right) = \text{const.}$$

In those encounters where the whole of the energy of the electron is transferred in one fell swoop, the shortest-waved X-rays possible to that voltage will be generated. They will be accompanied by a variety of longer waves depending on the varied experience of other electrons, but always a short-waved limit is set by the magnitude of the full exciting voltage.

We are led to appreciate a number of other results. It is seen at once why we do not get (as was once imagined) homogeneous X-rays when a tube is excited by constant potential, and where all the electrons reach the target with the same velocity. Nevertheless, we should expect that the proportion of short waves would be greater with constant potential than it would be with fluctuating potential, the peak value of which is equal to that of the constant potential. Furthermore, from what is known of the effect of voltage on output, we should anticipate a greater X-ray output (and less heating of the target) with a constant voltage than when that voltage is diluted with lower voltages. Both these surmises as to the superior efficacy of constant potential are confirmed by the X-ray spectrometer.

With reference to the existence of a minimum wave-length or boundary to every spectrum of general X-rays, this is fully borne out by spectrometer measurements and photographs. Numerically, Planck's relation becomes:

$$\left(\begin{array}{c}\text{Minimum wave-}\\ \text{length in Å.U.}\end{array}\right) \times \left(\begin{array}{c}\text{Maximum}\\ \text{voltage}\end{array}\right) = 12{,}350.$$

This very simple relation provides us with a scale of quality which, if not perfect, is more exact than any which the radiologist has been in the habit of using. If we glance at typical spectral curves of X-ray emission, we see that they are not symmetrical—the centre of gravity of the curve is well towards the quantum limit—the shortest waves are the dominating ones, and still more so if the rays are subjected to normal type filtering. The mean effective wave-length of a spectrum of rays is seen to approximate to the wave-length of the peak of the curve; that is, the wave-length of maximum intensity. Now, there is some evidence that the "peak" wave-length is proportional to the limiting or quantum wave-length, and this fact enables us so to identify very fairly the quality of a mixed bundle of X-rays. No doubt something depends on the wave-form of the exciting potential, but the effect of this is probably less important as the voltage is raised. The precision of the method would be enhanced if steps were taken to standardise apparatus and technique, so that all work could be done by the use of, say, three or four spectra the distinctive features of which, including energy distribution, could be determined and specified.

Among the other interesting aspects of the X-ray tube is the distribution of the rays in different directions from the target. With the usual 45° target the rays are most intense at right angles to the cathode ray beam. For radiographical purposes it is often better to mount the target face more nearly at right angles to the cathode beam and thus employ a pencil of rays which leaves the target face at a relatively small angle. The width of the focal spot is thus foreshortened and definition enhanced.

If penetrating power is the important factor, then we may well endeavour to utilise the X-rays leaving the tube in the direction of the cathode rays, which X-rays are of appreciably shorter wave-length than in other directions. Thus a tube in which the target also served as a metal window would offer advantages on this score.

The proper choice of filter may do much to increase the effectiveness of a tube. For example, it is known that, weight for weight, silver is relatively more transparent than lead to short waves, but is relatively less transparent to longer waves. Again, copper is relatively superior to aluminium in letting through short waves, but relatively inferior as a filter if long waves are required.

What has the future in store for us as regards X-ray tubes? Higher voltages are coming—one hears rumours of 500,000 volt tubes in Germany; and both the United States and Germany have, I understand, developed transformers giving 1 million volts. The life of 200,000 volt tubes is none too long; there will be many difficulties to overcome before a 500,000 volt tube will become a practical proposition.

A crying need is more robustness in the X-ray tube, which must become more of an engineering job. The portable Coolidge tube with lead-glass walls ¼ inch thick and a window of soda-glass for letting out the rays is to be commended on this score. Equally robust is the new miniature dental tube of similar design which measures only 4 to 5 inches long and has a diameter of about 1½ inch. It is operated at 45,000 volts and 10 milliamperes, is mounted in the same oil-tank as the transformer, and gives excellent definition. It also contributes substantially to the protection which the radiographer has a right to demand. In this connexion we may confidently look forward to a time at no very distant date when, in the interests of the operator, all protective material and apparatus shall be certified by the National Physical Laboratory. This will be realised when I mention that different makes of lead-glass on the market differ by 100 per cent. in protective value. The same remark applies to lead-rubber.

What should be our ideal in radiography? To make the process as simple and noiseless as taking an ordinary photograph. The patient should hear nothing untoward, the apparatus should look no more formidable than a camera. Spark and brush discharges should be taboo; the rumble of rotating machinery anathema. Standardised technique must be the order of the day for much of the radiographer's work. The number of variables must be cut down.

It is possible that the future may witness the fuller development of the metal X-ray bulb of a design radically different from the present. Much work is being done on them at the present time. But in almost every section of a radiographer's X-ray equipment there is room for great improvement. How low the efficiency is may be gathered from the following. We may take it that the efficiency of the high-tension generator is of the order of 50 per cent., that of the X-ray bulb 1/1000. We may assume that half the rays emitted by the bulb are utilised, that half these useful rays are arrested by the object, and that 1 per cent. of the remainder is recorded by the photographic plate or screen (rather more, say 5 per cent., if an intensifying screen is used). Thus the overall efficiency of an X-ray equipment is of the order of 1 in 800,000.

An Inquiry into Dog Distemper.

FOR some considerable time it has been felt in this country that an investigation might be undertaken with advantage on the mystery of dog distemper, and the matter has recently been brought to a head by an appeal from the editor of the *Field* to dog lovers. A considerable sum of money has been promised, and the Medical Research Council has undertaken to organise an experimental inquiry with a view of finding out the causal agent of the disease and possibly a prophylactic. As announced in NATURE of March 10, a committee has been appointed under the chairmanship of Sir William Leishman, the other members being J. B. Buxton, S. R. Douglas, F. Hobday, and C. J. Martin. Other workers, it is suggested, will be co-opted for special investigations later on.

Distemper is an acute highly contagious disease, presenting symptoms somewhat analogous to measles in man. While some have regarded it as specific for the dog, others consider that it occurs in cats, young foxes, wolves, jackals, hyænas, and even monkeys. From its contagiosity it is certain that the cause is a microbe of some kind, which, however, has hitherto remained unmasked. Indeed, there is very little real scientific knowledge extant on the disease. This is in part, at any rate, due to the fact that what veterinary surgeons and the laity call distemper is almost certainly not one but several different diseases. That one of these is the specific disease distemper is, however, very probable.

At present the concept of "distemper" is entirely clinical. Thus, one finds descriptions in the literature of catarrhal, gastric, nervous, and exanthematic types of the disease. There is a great body of evidence to show that one attack of the malady confers a durable immunity on the survivor. The disease occurs in all countries and was apparently known in antiquity. On the other hand, there is a tradition—it is little more—

that distemper was introduced into Europe from South America in the seventeenth century. There have been many researches on the probable cause, and from the time of Semmer (1875) down to the present, every known type of microbe has been incriminated, many authors with great assertiveness having maintained that they had found the specific micro-organism.

Many have believed that Carré came nearest the truth with the idea that the *causa morbi* is an invisible microbe which can traverse bacterial filters. With filtrates obtained from nasal secretions he obtained lethal effects which were claimed to be identical with true distemper, and he regarded the visible bacteria found by others as of the nature of secondary invaders, which obtained a hold on the tissues as a result of the depressing effect of the real filter-passing virus.

This view is largely accepted without criticism, and is said to be the line along which the new committee will work. It may be pointed out, however, that Carré's work, which is not given in any great detail, has been adversely criticised by Galli-Valerio, and especially by Kreganow, who worked under the direction of Frosch, himself a known and successful worker on the filter-passer of foot-and-mouth disease. Filter-passers have been suggested or proved for a number of pathological conditions, notably the mosaic disease of tobacco plants, foot-and-mouth disease, Cape horse sickness, fowl plague, molluscum contagiosum, etc. These filter-passers have much in common. They are highly infectious, invisible, filterable, and non-cultivable. The causes probably constitute a new group of living things, which, if discovered in the case of distemper, may throw a flood of light on many unknown causes of disease in man, and it is for this reason that the work now being undertaken on distemper will be watched with unusual interest.

W. B.

Obituary.

Prof. E. E. Barnard.

It may safely be said that the whole astronomical world is mourning the death of Edward Emerson Barnard, which occurred on February 6, and very many will feel it as the loss of a personal friend even more acutely than as the removal of one of the world's most remarkable observers.

Prof. Barnard was born at Nashville, Tennessee, on December 16, 1857; he was left fatherless and destitute by the Civil War, and had to go out to work in a photographic studio in Nashville at the age of nine, after the most meagre opportunities of education. But his subsequent career is a remarkable proof of the adage that "where there is a will there is a way." He worked most faithfully for his employers, and at the same time devoted his evenings to private study; it was not till the age of nineteen that his attention was directed to astronomy by perusal of Dr. Dick's "Practical Astronomer." The next year he had saved enough to buy a 5-inch telescope, with which in 1881 and 1882 he discovered the first two of his large family of Comets.

In 1883 Prof. Barnard obtained a fellowship in astronomy at Vanderbilt University, which gave him the opportunity for perfecting his education and the use of a 6-inch equatorial, with which he did useful work on comets, nebulæ, and double stars.

In 1888 Prof. Barnard went to the Lick Observatory, where he had the advantages of a giant telescope and a splendid climate. Three years later he made the sensational discovery of the fifth satellite of Jupiter, the first addition to the retinue of that satellite since the days of Galileo. In 1889 he had observed an eclipse of Japetus by Saturn and the ring which gave important information on the transparency of different parts of the crêpe ring. He was also doing very useful photographic work, photographing the Galaxy and the tails of comets with the Willard lens. These photographs showed interesting detail, in particular the shattered tail of Brooks's Comet of 1893. He demonstrated the value of a lantern lens for depicting faint diffused nebulosity; in particular, he discovered a huge nebula with many wisps that wandered over the greater part of Orion, the former "great nebula" of which was but a pigmy compared with it. Besides discovering very many new comets, he was frequently first in the field in detecting periodic ones on their return: for example, Pons-Winnecke in April 1921, the position of which had only been roughly predicted. In 1896 he left the Lick Observatory for the Yerkes Observatory, but the change involved no real break in his work.

Prof. Barnard took up a new and fruitful line of work in recent years, making a minute study of the light changes of all the Novæ that have appeared in modern times. Many of them had become excessively faint and difficult objects, but he was able to prove that some of them were still varying in a more or less regular manner.

Mention should also be made of Barnard's discovery of the star of largest known proper motion; this was no mere accident, but a well-earned fruit of careful study of numerous photographs.

Prof. Barnard was both a fellow and an associate of the Royal Astronomical Society, and was awarded its gold medal in February 1897.

It is pleasant to record that Prof. M. Wolf named two of his minor planet discoveries Barnardiana and Rhoda after Barnard and his late wife. It is a testimony to the universal sentiments of affection and esteem that were felt towards them.

A. C. D. Crommelin.

Prof. J. Radcliffe.

Prof. Joseph Radcliffe, head of the department of Municipal and Sanitary Engineering in the Municipal College of Technology, Manchester, died on February 16 at his residence in Crumpsall after a brief illness, at the age of sixty-six years.

A native of Rochdale, Prof. Radcliffe was forced by circumstances to commence to earn his own living at a very early age, but managed to attend evening classes with such success that he was one of the first scholarship students sent by the Rochdale Pioneers' Co-operative Society to the then Owens College at Manchester. After serving an engineering apprenticeship in Rochdale, he passed into the Waterworks department, where he gained a special experience, which led to his later appointment as engineer to the Todmorden waterworks. In 1891 he commenced his career as professor in the Manchester College of Technology, where he had previously devoted untiring energies to founding the department by holding evening classes. In 1906, the Victoria University of Manchester conferred on him the degree of M.Sc.Tech.; and practically all the institutions and societies interested in his subjects had recognised his great abilities.

It is no exaggeration to say that the death of Prof. Radcliffe will be sincerely mourned all over the globe by former students, the numbers of which must literally run into thousands. Apart from his sound teaching, his wonderful kindness and modest, genial disposition have made his one of the most regretted losses his college and profession have ever sustained.

MR. T. W. STRATFORD-ANDREWS.

MR. T. W. STRATFORD-ANDREWS, who died on February 17, was a director of many companies connected with electrical industries. He was born in 1870 and educated at King's College, London, and his practical training in engineering was obtained at the works of Siemens, Schuckert, in Berlin.

Mr. Stratford-Andrews succeeded his father as managing director of the Indo-European telegraph line in 1899, but before assuming his new duties he took part in the expedition which went 800 miles up the river Amazon to lay an extension of the Western Brazilian telegraph cable. In 1897 also he rode on horseback through Russia and across the Caucasus to Teheran to inspect the route of the Indo-European land line. This journey he described in a little book entitled "Overland to Persia." In 1913 he covered the same ground again in a motor car accompanied by his wife and his sister. He was decorated by the Shah of Persia for his services, and received the thanks of the Russian Government.

Mr. Stratford-Andrews was the first to introduce direct automatic Wheatstone working on the Indo-European system. He also initiated, in conjunction with Sir Henry Kirk of the Indo-European (Government) department, direct operation at high speed between London and Karachi, a distance of 5600 miles. In his later years he took the greatest interest in radio-telegraphy and telephony, and he was chairman of the Radio Communication Company. His wide knowledge and technical insight were much appreciated by his numerous colleagues.

PROF. IGNAZ VOGEL.

THE death occurred on December 29 last of Prof. Ignaz Vogel, a well-known agricultural bacteriologist and mineralogist. He was born on April 15, 1871, at Altenkunnstadt in Franconia, and after studying chemistry under Emil Fischer at Würzburg he graduated in 1893. Taking up physiological and bacteriological research work, he became assistant to Prof. Dunbar at Hamburg, where he remained till 1900. He was then appointed to the position of bacteriologist at the agricultural experimental station of Posen, being transferred five years later to the Emperor William Institute at Bromberg. In 1914 he was called to Leipzig as director of the bacteriological department of the Agricultural Institute of the University of Leipzig, where he succeeded Prof. Löhnis, who had received an appointment as agricultural expert in the United States.

Prof. Vogel published at Marburg a number of researches on the occurrence and the transformation of the various kinds of sugar in the bodies of plants and animals, most of which appeared in the *Zeitschrift für Biologie*. Later he turned his attention to the study of the bacteria of the soil, and of solid and liquid manure. He published numerous papers concerning the fixation of atmospheric nitrogen in the form of ammonia, and the transformation of this substance into nitrates and albumen, most of which appeared in the *Zentralblatt für Bakteriologie*. In the "Handbuch der Milchwirtschaft" he edited the agricultural section.

The researches of Vogel have contributed greatly to the increase of agricultural production by showing how the various methods of manuring can be properly adjusted to the qualities of the soil. In his university work he trained a number of able pupils, being always willing to communicate his great knowledge to his colleagues. All those who have been able to enjoy his teaching and society greatly regret the loss that agricultural science has suffered through his premature decease.

PROF. A. N. FAVARO.

ON September 30 of last year, there passed away at Padua, Antonio Nobile Favaro, widely known for his numerous contributions to the history of mathematics and physics. Born at Padua on May 21, 1847, educated at the University of Padua and at the engineering schools at Turin and Zurich, he entered in 1875 upon his long career as professor of projective geometry at Padua. His "Lezioni di statica grafica" (1877) were soon after translated into French. So early as 1873 he began the study of the history of science by a contribution on the evolution of planimeters. For nearly half a century he worked assiduously on questions dealing with the history of mathematical instruments, with papers and letters of Tycho Brahe, N. Tartaglia, Leonardo da Vinci, and others.

The researches for which Favaro is best known, and which mark the crowning effort of his long career, are on the life and work of Galileo and his friends. In 1887, Favaro received a commission from the Italian Government to edit the complete works of Galileo. He devoted nearly thirty years to this task and brought out the "Edizione Nazionale" of Galileo's works in twenty volumes, which serves as a model to other governments as to what can and should be done in editing the works of great men of science. As by-products Favaro brought out a series of publications, "Amici e corrispondenti di Galileo Galilei," consisting of more than forty parts and constituting an important contribution to our knowledge of science in Italy during the sixteenth and seventeenth centuries.

FLORIAN CAJORI.

WE regret to announce the following deaths:

Dr. Norman Dalton, senior physician to King's College Hospital and formerly professor of pathological anatomy in King's College, London, on March 9, aged sixty-five.

Prof. J. D. Van der Waals, professor of theoretical physics in the University of Amsterdam, on March 8, aged eighty-five.

Current Topics and Events.

It is fitting that some reference should be made in these columns to the fact that it was just fifty years ago that Mr. Edward Clodd, the veteran scientific thinker, happily still with us, published his first book, "The Childhood of the World." In 1920, at the advanced age of eighty, he published his "Magic in Names." In the period which elapsed between the appearance of these two books, Mr. Clodd devoted the leisure of a busy life of affairs to scientific research in branches of study connected with the physical and mental evolution of man. The results were embodied in a number of volumes dealing with various aspects of this central problem, of which the principal are: "The Childhood of Religion," 1875; "Myths and Dreams," 1885; "The Story of Creation," 1888; "The Story of Primitive Man," 1895; "A Primer of Evolution," 1895; "Tom Tit Tot," 1898, perhaps his best known and most enduring work; "The Story of the Alphabet," 1900; and "Animism," in 1906. In addition he produced monographs on his friends and associates—Bates, of Amazon fame, Grant Allen (1900), Huxley (1902), and a volume of "Memories" published in 1916. Mr. Clodd was one of a band of workers, of whom Huxley and Tylor were the best known, and who now, unfortunately, have nearly all passed away. To their untiring efforts to promote and popularise anthropology, its present position as a serious branch of scientific study is almost entirely due. Those of a younger generation who were first introduced to the evolutionary point of view in the study of man and of his religion and mental concepts through the lucid exposition and power of logical demonstration of which Mr. Clodd is a master, owe to him a debt of gratitude which is not likely to be forgotten.

Further details of the progress of excavations at the Temple of the Moon God at Ur of the Chaldees, to which reference was made in these columns last week (see p. 336), are now to hand. Information given in a telegram published in the *Times* of March 7 indicates the relation of the present discoveries to those made by Dr. Hall in the course of his investigations—a point which previously was not clear. It would appear that the portion of the Temple discovered by Dr. Hall was the terrace of the main building which lay underneath. In the course of the present excavations, which have been made mainly in the south-east corner of the mound, one chamber has been found, which it is conjectured may be the innermost shrine, containing a valuable hoard of jewelry including many bracelets and necklaces, mostly of gold, and a tiled courtyard in which a gutter, such as was habitually used for collecting and carrying off the blood of a victim, suggests that it was the place of sacrifice. The cult of the Moon God was evidently re-established by Nebuchadnezzar, who made his daughters priestesses of the Temple, which he restored in the sixth century B.C., as is shown by an inscription. The upper bricks of the ruins were of this period, but those underneath were much earlier, and it is clear that in the restoration of the Temple the original foundations were, so far as possible, left untouched.

Dr. Charles Hose's lecture on Sarawak at the Royal Colonial Institute on February 27 was opportune in affording material for a comparison in methods of administration and development with British North Borneo, an area which has attracted some little attention recently. Sarawak, a territory of some sixty thousand square miles, is perhaps best known in connexion with the romantic history of the Brooke family and as an independent native state under British protection, which has been ruled for nearly a century by a family of white men. It is, as Dr. Hose said, "perhaps the greatest achievement in state-making of the nineteenth century." It was founded by Sir James Brooke in 1840, and came under British protection in 1888 when its population numbered 600,000. The inhabitants include Malays, Dayaks, Kenyahs, Kayans, and a number of primitive tribes, still pagan, whose customs and beliefs have furnished, as readers of that valuable book "Pagan Tribes of Borneo," by Dr. Hose and Prof. McDougall, will remember, much material for the comparative study of religion, especially in connexion with their methods of divination and their belief in a spirit helper in animal form. The policy of the Brooke family has been to preserve, under an autocracy, as much of native custom as possible, retaining the great offices of state held by Malay nobles at the time of Sir James Brooke's accession to power, and associating the natives with the administration. As Dr. Hose pointed out in his lecture, several chiefs in bygone days endeavoured to establish peace through wide areas, but failed. To achieve enduring success the unifying influence of a central authority was needed. This has been furnished by the Rajahs, who, without breaking up old forms of society, have supplied elements lacking in the old system.

Information has been received that an All Russian Agricultural Exhibition will be held in Moscow on August 15–October 1. In a circular issued by the Russian Trade Delegation it is stated that foreign firms, institutions, and private persons are invited to participate in the exhibition, and that all privileges granted to Russian exhibitors will apply equally to foreign exhibitors. Special arrangements will be made to facilitate the delivery of exhibits, all such goods being given preferential treatment on the railways and waterways of the Republic, and for convenience of transit all foreign exhibits will be exempt from Customs examination at the frontier, provided that the goods bear regulation labels. Provision will be made for the insurance and safeguarding of exhibits, both during transit and at the exhibition itself. A fixed tariff of charges for space in the foreign section has been drawn up, all charges being payable in advance and not to be refunded if exhibitors renounce their allotted space or finally abstain from exhibiting.

The Council of the Institution of Mining and Metallurgy has made the following awards: The gold medal of the Institution to Mr. Edgar Taylor, president, 1909–1911 and 1916–1918, in recognition of his services to the Institution since its foundation in 1892 and as an evidence of appreciation of his honourable record of work in connexion with the development of the mining industry, particularly in India; "The Consolidated Gold Fields of South Africa, Ltd." gold medal to Dr. Leonard Hill, in recognition of his valuable researches on ventilation and for his paper on "Ventilation and Human Efficiency," contributed to the Transactions; and "The Consolidated Gold Fields of South Africa, Ltd." premium of forty guineas to Mr. H. F. Collins, for his paper on "The Igneous Rocks of the Province of Huelva and the Genesis of the Pyritic Ore-bodies," contributed to the Transactions, and in recognition of his researches on the subject.

An invitation is extended to Farmers' Clubs, Chambers of Agriculture and Horticulture, and other bodies interested in agriculture or market-gardening, to visit the Rothamsted experimental fields during the coming summer. The guide demonstrator is Mr. H. V. Garner, who for the past two summers has very successfully served in this capacity and has been able to make the visits both useful and interesting to farmers. Among important items of interest are: experiments on the manuring of arable crops, especially wheat, barley, mangolds, potatoes; manuring of meadow hay; effect of modern slags and mineral phosphates on grazing land, hay land, and arable crops; crop diseases and pests; demonstrations of good types of tillage implements, tractors, etc. At any convenient time between May 1 and October 1, there is sufficient to occupy a full day, and there is provision for assuring that the time shall not be lost, even if the weather turns out too bad to allow of close investigation of the fields. The director of the Station, Sir John Russell, will be happy to arrange full details with organisations of farmers, farm-workers, and others wishing to accept this invitation. Small groups of farmers are specially welcomed; if possible, arrangements should be made beforehand, but it is recognised that farmers' movements must often depend on the weather, and no one need stay away because he has been unable to write fixing a date.

The departmental committee recently appointed to consider the present system of charging for coal gas on a thermal basis has now issued its report as a White Paper (Cmd. 1825, 6*d*.). The main recommendation is that the method of charging for gas on the thermal basis should be continued and extended to all statutory gas undertakings within the scope of the Gas Regulation Act. Thus is vindicated the really scientific method of asking the consumer to pay according to the amount of heat he receives. In the days of Argand and the flat-flamed fish-tail burners, light was produced by the combustion of the particles of gas in the surrounding air, and gas supply was then maintained at an illuminating standard. With the advent of the incandescent mantle, and the increasing use of gas fires, illuminatory properties in gas became of secondary importance to its heating values, and a calorific standard was introduced in 1916. The heat unit in common use in Great Britain for expressing the value of fuels has been, for many years, the British thermal unit, which is the amount of heat required to raise the temperature of 1 lb. of water 1° F. under appropriate conditions. This unit was used in gas calorimetry, and a gas was said to have calorific value of 500 British thermal units when 1 cubic foot gave out, when burned, sufficient heat to raise the temperature of 500 lb. (about 50 gallons) of water through 1° F. To obtain a conveniently practical unit, the therm, which is equal to 100,000 British thermal units, was adopted.

The *Weekly Weather Report* for the week ending March 3, issued by the Meteorological Office, Air Ministry, gives a summary of the weather for the several districts of Great Britain for the past winter, comprised by the thirteen weeks from December 3, 1922, to March 3, 1923. The daily mean temperature for the period ranged from 40·1° F. in the east of Scotland to 46·9° F. in the Channel Islands. During the winter the extreme readings ranged from 61° in the Midland Counties to 15° in the east of Scotland, while in England the lowest temperature recorded was 22° in the Midland Counties and the south-east of England. Total rainfall was greatest in the north of Scotland, where the measurement was 18·52 in., which is 2·17 in. more than the normal; but the greatest excess on the average was 5·47 in., which occurred in the south-west of England. There was an excess of rain everywhere, the minimum excess being an inch in the east of England, where the total measurement was 6·53 in. Rain fell with greater frequency than the normal over the whole of Great Britain: the largest number of days with rain was 74 in the north of Scotland; the least, 53 in the north-east of England. The duration of sunshine was fairly equal to the normal in all districts. At Greenwich the mean temperature for the winter, December, January, and February, was 42·4° F., which is 2·9° above the normal for thirty-five years; temperature ranged from 57° to 24°. Rain fell on 49 days, which is 4 days in excess of the normal, and the total measurement was 6·60 in., which is 1·08 in. more than the average for thirty-five years. The duration of bright sunshine at Greenwich was 118 hours, which is 11 hours fewer than the normal.

News received in Christiania, according to the *Times*, reports the arrival of Capt. R. Amundsen on December 15 at Nome, Alaska, from Wainwright, on the north coast, where he is wintering. His visit to Nome was to ascertain news of the *Maud*, which is now drifting across the polar basin. Capt. Amundsen expects to leave Wainwright or Point Barrow on his flight across the Pole to Spitsbergen in the middle of June. On March 6 a wireless message from the *Maud* reported her position as lat. 74° N., long. 170° 30′ E. The ship has drifted about half a degree north and three degrees west of her position in the middle of December. Her speed of drift is about the same as that of the *Fram* at the same time of year, but the *Maud* is still well to the east of the New Siberia Islands and has not passed beyond the shallow and partially charted waters of the continental shelf.

H.M. THE KING has approved the grant of a Royal Charter of Incorporation to the Institution of Royal Engineers. The Institution, then known as the Royal Engineers Institute, was established as a voluntary association in the year 1875 for the general advancement of military science, and more particularly for promoting the study of such subjects as are of importance to the military engineer. In pursuance of its objects, the Institution has directed its efforts to the advancement of the science and art of engineering, especially in relation to their application to military purposes, and has thus been able to afford material assistance to those engaged in dealing with the important problems of defence connected with the British Empire. The Institution has during the past 47 years published 950 occasional, as well as other, papers on military and other scientific subjects; these papers, except those which are of a "Secret" or "Confidential" character, are available to the general public. *Inter alia*, the Institution now administers an important fund established in connexion with the award of scholarships to the children of deceased officers and other ranks who have fallen in the performance of their duties while on active service.

IN an article in the *Fortnightly Review* for March, Sir Charles Bright discusses the relation between the Empire's telegraphs and trade. He concludes that it is of national importance that there should be a great all-round reduction in cable tariffs. As this would doubtless result in greatly increased traffic it would necessitate laying many additional cables on different routes. He also dwells on the importance of the immediate completion of the Imperial "wireless chain," as well as alternative wireless chains. On March 5, Mr. Bonar Law announced that the Government is to proceed with the erection in this country of a state-owned and operated station capable of communicating with any part of the Empire. At the same time licenses are to be issued to private companies for the erection of stations in this country for radio-communication with any part of the world, subject to the conditions necessary to secure British control. The Marconi Company has thus been granted the license for which it has long asked, and it intends immediately to erect five large power stations to communicate with the Dominions and South America, and five smaller stations for more local traffic. The cost of these stations will be about two million pounds. It seems to us that this extension of long-distance communication will be of immediate benefit to this country, and the ensuing reduction in the tariff may induce the cable companies to co-operate with the radio companies. As Sir Charles Bright points out, this country has considerable leeway to make up; America, for example, uses 3400 kilowatts for its radio stations, and France 3150, while the British Empire only uses 700 kilowatts.

THE Spring Foray of the British Mycological Society will be held at Bristol on April 20–23. Headquarters for the meetings will be at the botany department of the University.

AN exhibition of Carboniferous corals has just been completed by Dr. W. D. Lang and Dr. Stanley Smith in the Geological Department of the British Museum (Natural History). Polished specimens and transparent sections have been prepared to illustrate the structure of each genus, and explanatory diagrams have also been added.

THE second annual general meeting of the National Institute of Industrial Psychology will be held in the rooms of the Royal Society on Tuesday, March 20. Among the speakers will be the Earl of Balfour, Sir Lynden Macassey, Dr. C. S. Myers, Sir Robert Hadfield, and Sir Charles Sherrington.

AT a representative meeting of botanists held at the Linnean Society's rooms on Friday, March 2, it was decided to hold an Imperial Botanical Conference of British and Overseas botanists in 1924 about the beginning of July. An executive committee was appointed, with Sir David Prain as chairman, Mr. F. T. Brooks as honorary secretary, and Dr. A. B. Rendle as treasurer. An invitation to attend the conference will be sent at once to Overseas botanists.

PROF. JOSEPH S. AMES, who gives an account of recent aeronautic investigations in the United States elsewhere in this issue, has been chosen to deliver the eleventh annual Wilbur Wright memorial lecture of the Royal Aeronautical Society. The lecture, the subject of which will be "The Relation between Aeronautical Research and Aircraft Design," will be given at the house of the Royal Society of Arts on May 31.

THE Royal Irish Academy devoted its meeting on February 26 to a commemoration of the centenary of Pasteur. Addresses were delivered by Dr. W. R. Fearon, Prof. A. C. O'Sullivan, and Prof. Sydney Young (president of the Academy), dealing with various aspects of his work, and an address in French by Prof. R. Chauviré dealt with Pasteur as a typical Frenchman.

A SCIENTIFIC superintendent under the Fishery Board of Scotland will shortly be appointed. He will conduct and supervise the scientific fishery investigations which the board may consider necessary, and be in charge of the board's laboratories at Aberdeen. Applications for the post, accompanied by copies of any published papers of the applicants, if deemed desirable, and the names of at least two referees, must reach the secretary of the board, 101 George Street, Edinburgh, by, at latest, March 31.

THE Ministry of Agriculture and Fisheries will shortly appoint an inspector in connexion with agricultural and horticultural education and research. Applicants for the position must have taken a course in science or agriculture at a university or college of agriculture, and should have had special training in the science and practice of dairying. Forms of application and copies of the regulations governing the appointment may be had from the Secretary of the Ministry, 10 Whitehall Place, S.W.1. Application forms must be returned by March 26.

WE have received intimation of the opening at Lake Trasimeno of a laboratory for the study of the biology of the lake, including researches on the fresh-water fishes. The lake, which is about thirty miles in circumference, offers many opportunities for limnological work. It is to be hoped that this new station will receive the support which will justify its continuance. The premises have been provided by the University of Perugia, and Dr. Osvaldo Polimanti, professor of physiology in the University, has been appointed director, and intending workers should communicate with him.

MR. G. M. B. DOBSON will deliver a lecture to the Royal Meteorological Society on March 21 on "The Characteristics of the Atmosphere up to 200 km., as obtained from Observations of Meteors." Meteorological observations in the free atmosphere by means of *ballons-sondes* have not been carried to heights much greater than 30 kilometres, but Prof. Lindemann and Mr. Dobson have recently put forward a method of determining the temperature at much greater elevations by means of observations of meteors (see NATURE, December 9, 1922, p. 794). Those interested are invited to attend the meeting, which will be held in the Society's rooms at 49 Cromwell Road, South Kensington, London, S.W.7.

AT the annual general meeting of the Institute of Metals held on Wednesday, March 7, the following officers for the year 1923–24 were elected :—*President* : Mr. Leonard Sumner. *Past-Presidents* : Sir Gerard A. Muntz, Bart., Engineer Vice-Admiral Sir Henry J. Oram, Sir George Beilby, Prof. H. C. H. Carpenter, and Engineer Vice-Admiral Sir George Goodwin. *Vice-Presidents* : Sir John Dewrance, Mr. W. Murray Morrison, Sir Thomas Rose, Dr. W. Rosenhain, Sir William E. Smith, and Prof. T. Turner. *Honorary Treasurer* : Mr. A. E. Seaton. *Members of Council* : Mr. W. H. Allen, Mr. L. Archbutt, Mr. G. A. Boeddicker, Mr. T. Bolton, Dr. H. W. Brownsdon, Engineer Vice-Admiral R. B. Dixon, Prof. C. A. Edwards, Mr. S. Evered, Dr. R. S. Hutton, Mr. F. C. A. H. Lantsberry, Sir Charles A. Parsons, Mr. H. A. Ruck-Keene, Dr. R. Seligman, Mr. James Steven, Mr. F. Tomlinson, and Mr. H. B. Weeks.

Our Astronomical Column.

GREAT FIREBALL IN NORTHERN INDIA ON DECEMBER 28, 1922.—Mr. W. F. Denning writes that "letters have been received reporting a splendid fireball which appeared over the Punjab at about the time of sunset on December 28. It was observed by a great number of people, and accounts published in the *Civil and Military Gazette* (Lahore) include descriptions from Simla, Peshawar, Balloki, Moghalpura, Sargodha, Jhelum, Rawalpindi, Bakloh, Dharamsala, Lahore, Sharaqpur, Murpur, and other stations.

Many of the accounts are of little service, but Col. W. E. Pye and Lieut. Stephenson at Shagai, Khyber Pass, North-West Frontier, give an excellent description of the phenomenon. The observed path at the latter place was from 6°-43° to 20°-48°, and the fireball exhibited moderately slow motion. It left a long white streak which endured about fifteen minutes. A large number of the observers allude to the streak as perfectly straight at first, but it soon assumed a zig-zag shape, and drifted away from the place of its early projection. At one station the streak, which appeared to be vertical when formed, became horizontal in twelve minutes, the lower end having moved the required distance. At Sargodha, six minutes after the great illumination due to the meteor, loud rumbling sounds were heard, caused by the disruption of the object. These would indicate a distance of 75 miles.

From a comparison of the observations the fireball seems to have been an early Quadrantid with a radiant at 234° + 55°. The height was about 54 to 29 miles, and velocity about 25 miles per second. The luminous course was directed from N.N.W. to S.S.E. It crossed the river Chenab, and ended about 100 miles N.E. of Mooltan.

These results are only approximate. The object was one of great splendour, and it is hoped that further observations will be forthcoming.

STELLAR SPECTRA OF CLASS S.—In the current number of the *Astrophysical Journal* (December 1922) Mr. Paul W. Merrill directs attention to a number of red stars having spectra similar to that of R Geminorum, which differ from any of the well-known types of spectra which form the Harvard classification. In this classification the red stars are known as M and N types and each of these is subdivided, but no stars are known which have a spectra intermediate between them ; M stars have characteristic titanium flutings and N stars carbon flutings. This peculiarity has led to the adoption of a break in the main series of stellar evolution types of spectra.

Thus an M star of increasing temperature becomes consecutively in the evolutionary series a K, G, F, etc., type star, while an N star, also a giant, becomes an Ro, G, F, etc., type star in its progressive stages. Mr. Merrill shows in this paper that the stars he has discussed should properly form a third division of the giant series joining on to the main sequence of evolutionary stages between the types Ma and K. This progression may be likened to three sets of railway lines joining up at two positions near each other and continuing as a single line. Thus :

```
           ↙ Ro    Na    Nb    Nc
B A F G K    Ma    Mb    Mc
  ←———      ↖ S    Se
```

It is interesting to note that the Harvard classification is based to a great extent on the replacement of metallic lines by ionised lines, and eventually by gaseous lines, the higher the temperature ; but Mr. Merrill points out that while some M stars show ionised lines, so also do the S stars ; this presents, as he says, "an anomalous circumstance which invites investigation."

Research Items.

African Sign Writing.—Mr. C. W. Hobley in the Journal of the East Africa and Uganda Natural History Society, No. 18, March 1923, has given some examples of sign writing collected in East Africa. It includes reproductions of the large fauna of the country, giraffe, elephants, and the like, and their spoor, supposed to indicate to the friends of the artist the presence of game in the vicinity. Others seem to be marks of locality and property. The custom of using signs still survives among the natives. In Togoland, if a man calls on a friend and finds him absent, he will pull a little grass from the roof of his hut and attach it to a stick outside the door to announce to the owner that a visitor has called. Wemba hunters make marks on their arms to record the number of the bigger animals they have killed, and in some parts of Kavirondo the birth of each child is marked by a cicatrisation on the abdomen, possibly with some magical object. The facts collected by Mr. Hobley and the illustrations he has provided are interesting in connexion with the origin of writing.

The Catholic Christians of Eastern Bengal.—Little has hitherto been known of the remarkable community known as the Firingis or "Franks" of Eastern Bengal. The late Dr. James Wise gave some account of them in the very rare volume entitled "Notes on the Races, Castes, and Trades of Eastern Bengal," of which only twelve copies were privately printed in London in 1883, and even libraries like those of the British Museum, the University of Cambridge, and the Royal Anthropological Institute do not possess a copy. Some of the information was, however, copied by Sir H. Risley in his "Castes and Tribes of Bengal." Some fresh details of this curious people have now been collected by Mr. H. E. Stapleton, special officer of the University of Dacca, and published in vol. xvii., 1922, of the Journal of the Asiatic Society of Bengal. They are believed to be descended from the Portuguese pirates who infested the Delta of the Ganges in the sixteenth and seventeenth centuries. They undoubtedly include many converts from the local races, they speak nothing but Bengali, are indistinguishable from Bengalis in dress and means of livelihood, and until recently they made no claim to Portuguese descent. They now number about 8500, but of these, 2000, under the French Fathers, are converted natives and have no claim to the name Firingi.

Productivity of Hill Pastures.—An inquiry conducted into the productivity of hill pastures in Exmoor, Wales, and Northern England ("University of Oxford Institute for Research in Agricultural Economics: The Productivity of Hill Farming," by J. Pryse Howell, London, Oxford University Press, 1922. 1s. net) has shown the value of artificial manuring of pasture and of more intensive cultivation in increasing the production of mutton, wool, and beef per acre. Much improvement in this direction is possible on the lower-lying ground, but it is less practicable on farms with an extensive range of high sheep-walks. The improvement of the latter will always be difficult owing to the considerable cost involved, but the committee of inquiry make certain recommendations which could well be carried out. Much depreciation of flocks occurs, especially in Wales, from the practice of allowing the rams to roam at will over the unenclosed sheep-walks, and it is recommended that a more efficient system of control of rams be instituted and enforced. The management of the "Commons" with grazing rights is very unsatisfactory, and joint action by the commoners is essential if matters are to be improved. Bracken, heather, and gorse are too often allowed to grow unchecked, thus reducing the feeding value of the land, and the systematic burning of heather and gorse, and the eradication of bracken, would prove most advantageous. The mortality among the flocks from various diseases is very heavy, and causes great monetary loss, and the committee emphasise the fact that a systematic inquiry into the diseases affecting sheep is a matter of the most urgent importance.

Rusts in South Africa.—The great economic importance of rusts, owing to the considerable loss in crops that they cause, renders it essential to determine the life history of as many types as possible in order to discover the second host where unknown. Infection experiments have shown that the common rust on *Vigna angustifolia* produces spermagonia and æcidia on this species from October to January, and then infects the Besem gras (*Tristachya rehmani*) by means of æcidiospores (M. Pole-Evans, Union of S. Africa, Science Bull., Nos. 1 and 2 of 1923). Uredospores and teleutospores are produced on the second host, the winter being passed in the latter stage, and with the fresh growth of the Vigna in spring, infection occurs by sporidia developed from the resting teleutospores. This rust on sweet pea and Besem gras is a new species of Puccinia which has not yet been described and named. A similar life cycle has been established for the mealie rust (*Puccinia maydis*), of which the spermagonia and æcidia occur from October to December on *Oxalis corniculata*. This connexion was originally established by Dr. Pole-Evans, and has now been confirmed by these infection experiments. Other species of Oxalis tested proved to be quite immune.

Colour Inheritance in Seeds and Flowers.—In a paper showing the inheritance of certain brown and red pigments in the seeds of soy bean and rice varieties, Mr. I. Nagai (*Journ. Coll. Agric.*, Imp. Univ., Tokyo, vol. 8, No. 1) has also made experiments on the physiology of the pigments involved. They are in two groups, the anthocyanins and the reddish-brown phlobaphenes. The whole subject of the genetic physiology of these pigments is discussed, and the limitations in our knowledge of the relations between genes, chromogens, and enzymes in colour production are pointed out. In the same Journal, Dr. S. Ikeno describes the genetics of flower colour in *Portulaca grandiflora*. The condition of colour inheritance resembles that in various other genera, the factor C producing an orange colour, C + G yellow, C + R red, while magenta, which is probably the original colour, is produced by C, R, and a blueing factor B acting together. R and B generally show complete linkage, but occasional crossing over produces red-flowered plants. Reverse mutations were also obtained, from white to magenta or red, as well as bud mutations, which were already known. Drs. K. Miyake and Y. Imai (*ibid.* vol. vi. No. 4) similarly analyse the flower colours of *Digitalis purpurea*. The purple colour is due to the presence of two factors C and P. When P is absent the flower is white with red spots, while in the absence of C it is white with yellow spots.

The Strength of the Plant Cuticle.—Botanists have recognised the importance of this question since the investigations conducted at the Imperial College of Science under the direction of Prof. V. H. Blackman have led to the conclusion that some parasitic fungi pierce the cuticle of the uninjured plant purely by pressure. They will therefore find considerable interest in the conclusion drawn by recent writers in the Journal of the Textile Institute as to the surprising strength of the cuticle surrounding a cotton hair. From different lines of investigation this result is arrived at by R. S. Willows and his co-workers in the Research Department of Tootal, Broadhurst Lee Co., Manchester, in their experiments upon mercerisation (Journ. of the Text. Inst., xiii. pp. 229-40, December 1922), and by H. F. Coward and L. Spencer upon the absorption of caustic soda solutions by cotton (Journ. of the Text. Inst., xiv. pp. 832-45, Jan. 1923). All these investigators conclude that the swelling of the cotton hair in alkali may be considerably restricted by the resistance to expansion of the cuticle and give cogent grounds for this conclusion. Such a strong cuticle upon a hair which has largely matured within a closed fruit is at first sight a surprising phenomenon. It is interesting to note that H. J. Denham, in his study of the destruction of the cotton hair by micro-organisms (Journ. of the Text. Inst., xiii. pp. 240-48, Dec. 1922), inclines to the view that some of these organisms can penetrate the healthy cuticle. This cuticle resists cold alkalis at high concentration and its hydrolysis by any organism has yet to be detected; but in view of these studies upon its strength, the actual method by which the uninjured cuticle is penetrated would seem to deserve close investigation.

Impounding Water for Mosquito Control.—In Bulletin 1098 of the U.S. Department of Agriculture, 1922, Mr. D. L. van Dine describes a method of controlling the breeding of malaria mosquitoes in the lower Mississippi Valley. In this region the bayous or shallow streams of the delta, with their accompanying vegetation, greatly facilitate the breeding of anophelines. The topography renders drainage impossible, and a trial was therefore made of clearing a section of the bayous and impounding the water so as to convert what was practically a marsh into a lake. The essential points in this method are the preliminary clearing of all vegetation, the provision of a sufficiently high permanent level of water, to suppress the further growth of aquatic and semi-aquatic vegetation, and the maintenance of a clean margin. The experiment thus carried out is stated to have given good results.

Growth of Cassava Plants.—T. G. Mason has an interesting note in the Scientific Proceedings of the Royal Dublin Society, vol. 17, N.S. Nos. 11-13, pp. 105-112, December 1922, upon the growth of some Bitter Cassava plants in St. Vincent, West Indies, under equivalent conditions save that half the plants were ringed through the phloem near the base of the stem, measurements of growth being made both before and after the operation. The experimental results show that this ringing did not affect the growth in length of the shoots for several weeks and then only to a relatively small extent; the fleshy roots, on the other hand, accumulated far less weight of reserve material upon the ringed plants. The author scarcely appears to put the simplest interpretation upon these experimental results when he declines to assume that the normal channel for the passage of this food to the root has been interrupted by cutting through the phloem, but assumes instead that the ring has blocked the passage of some mysterious correlating agency from the dominant apical shoot bud, and that in the absence of this unknown factor normal transmission of organic solutes in the xylem is impossible.

Origins of Petroleum.—In an important paper on the marine kerogen shales from the oil-fields of Japan (Sci. Rep. Tohoku Imp. University, Ser. 3, vol. 1, No. 2, 1922, Maruzen Co., Tokyo), Mr. Jun-ichi Takahashi describes a number of interesting deposits of Miocene and Pliocene age from various islands of the Japanese group, including a series where radiolaria, sponge-spicules, and diatoms are associated with what was originally sapropelic matter. The author concludes that the kerogen has arisen from "nectons and kelps" which have "been repeatedly buried by ash and detritus from submarine volcanoes." He illustrates the memoir by photographs of rocks and marine fossils, and of a remarkable series of thin sections of the sapropelic ooze.

Cannel Coal, Lignite, and Mineral Oil in Scotland.—The Geological Survey has published recently volume xxiv. of its special Reports on the Mineral Resources of Great Britain, which gives an account of a number of minor occurrences of cannel coal, lignite, and mineral oil in Scotland outside the recognised Scottish oil-shale fields. The work has been done by a number of members of the staff of the Geological Survey, and the publication is edited by Dr. W. Gibson. It is of course important that all such occurrences should be put on record, although, as is pointed out in the memoir itself, they have little or no economic value; nevertheless they are of interest to the geologist, and the information here given may prevent waste of money and energy in attempts to develop them.

The Warialda Meteorite of New South Wales.—The Warialda meteorite, which is defined as a fine variety of hexahedrite, has been described, figured, and its analysis given by J. C. H. Mingaye (Rec. Geol. Surv. N.S. Wales, vol. x. part 1). It is identical in crystallographic structure with the Bingera and Barraba meteorites which were found in the same district, and the three are probably products of the same fall, of which it is hoped further specimens may yet be discovered.

Orthopterous Insect Wing in a Selenite Crystal.—In the Mount Elliott Copper Mine, North Queensland, at a depth of 260 feet from the surface, and embedded in a large crystal of selenite, enclosed in the actual copper lode worked in that mine, there has been found a portion of the wing of an Orthopterous insect. This interesting fragment forms the subject of a paper by Dr. R. J. Tillyard in the Records of the Geological Survey of New South Wales, vol. x. part 2. The crystal must have been formed by percolating waters long after the lode itself came into being; its age is, consequently, very uncertain, but the author inclines to the view that it is late Tertiary. The conclusion reached after a careful study of the fossil is that it represents an archaic type belonging to the family of long-horned grasshoppers (Tettigoniidæ), and does not belong to any genus known to exist in the world to-day. Accordingly it has received the name of *Austrodictya corbouldi*, n. gen. et sp., the trivial name commemorating the manager of the mine through whose instrumentality the specimen was saved from destruction and forwarded to the Survey.

New Brunswick Oil-shale and Gypsum Deposits.—Memoir 129 of the Geological Survey of Canada records the geology of the Moncton Map-area, which includes parts of the counties of Westmorland and Albert lying in south-east New Brunswick. Besides giving an account of the general geology of the district, incidentally the geology of the Carboniferous rocks for the most part, the memoir gives some new facts relating to the oil-shale deposits. These shales are associated with certain horizons in the Carboniferous sequence, and an effort has been made to elucidate the structures accurately to enable the extent of the resources available to be calculated. Actual oil and gas possibilities are practically negligible, but the shales at places like Albert Mines and Rosevale are both well known and valuable, while several other localities offer good prospects. Since May 1921, the D'Arcy Exploration Co. (a subsidiary of the Anglo-Persian Oil Co.) has been operating at Rosevale, mainly on experimental lines with a special type of retort (Wallace), and the results have so far proved quite satisfactory. The average recovery of oil from a ton of shale is about 30 gallons, the specific gravity of the product varying from 0·893 to 0·903. This compares favourably with that obtained from the Scotch retort on the same material, where the yield is less and the gravity of the oil usually higher. Some gypsum and anhydrite deposits described from the region also form interesting and economically valuable occurrences: these are in the Hillsborough Series of Mississippian age and are at present being worked in the Demoiselle and Hillsborough basins. The relationship of the gypsum to the anhydrite deposits appears to be obscure here, as is frequently the case elsewhere; but the theoretical problems to be solved have a direct bearing on the future working of the deposits.

CLOUD FORMATION.—The Royal Magnetical and Meteorological Observatory of Batavia, in Verhandelingen, No. 10, gives a discussion by Dr. C. Braak on cloud-formation, nuclei of condensation, haziness, and dimensions of cloud-particles. The data were determined by means of Aitken's dust counter. In addition to the observations made in the East-Indian Archipelago an appendix is given on observations made in the Indian Ocean during a voyage from Java to Europe. Observations were also made on dry fog in the Archipelago as well as in other regions. Individual observations are published, so that the details can be examined. The differences between land and sea are given, and the variations with height above sea-level. The number of nuclei in the open sea under humid conditions was 120 per c.cm., and in the open sea in the dry season 1620 per c.cm.; in the neighbourhood of the land the mean number was 2560. The variation with height above sea-level shows a great decrease in the number of nuclei with increased height. Seasonal variations are considered, dealing chiefly with observations in Java and Sumatra. Much of the haze experienced is attributed to smoke from forest and prairie fires. The size of the particles is said to have a larger influence than their number on the density of haze, careful observations being made with a microscope to test this view. Valuable generalisations have been made on the subject, and these will doubtless be tested by other observers. This paper was taken as the subject for discussion at the evening meeting at the Meteorological Office on February 5, and is referred to in the *Meteorological Magazine* for February.

THE ELECTRICAL CONDUCTIVITY OF GLASS.—The February issue of the Journal of the Franklin Institute contains a communication from the director of the Applied Science Section of the Nela Research Laboratories, giving the results of the research of Mr. L. L. Holladay on the conductivities of glasses at temperatures up to 500° C. Between 20° and 75° C. the resistance from the inside to the outside of the glass tubes used was measured, and at higher temperatures the resistance of a length of the tube. In all the eleven glasses tested the conductivity could be expressed as the product of a constant into a power of the temperature centigrade about $-\frac{1}{2}$, into ϵ, the base of the Napierian logarithms, to the power $-A/T$, where A is a constant and T the temperature centigrade. A table of values of the constants for the glasses tested is given.

HEATING IN ELECTRIC CONDUCTORS.—An important research on the heating of buried cables has just been communicated to the Institution of Electrical Engineers by Mr. S. W. Melsom and Mr. E. Fawssett. Most of the tests were made at the National Physical Laboratory, but some were made under actual working conditions, the cables being laid in all kinds of soils. The rating of a cable depends on the rate at which it can dissipate the heat generated in it by the electric current, and hence it was necessary to calculate what current it could carry under different working conditions. Apparently the thermal conductivity of the insulating material of the cables does not vary appreciably with temperature, and thus the solutions of the thermal problems which Fourier gave in his "Théorie analytique de la chaleur," published in 1822, apply. The thermal constants of various kinds of soil are given, and so by the help of formulæ the maximum permissible currents in the various cases can be readily computed. It was found that in certain cases existing cables could carry greater currents safely, and hence economies can be effected. The research, which was a costly one, has taken several years, and was carried out on behalf of the British Electrical and Allied Research Association.

A RECORDING SACCHAROMETER FOR BREWING.—Messrs. Negretti and Zambra have constructed an instrument known as a hydrograph or recording saccharometer, which is compensated for temperature. It has been designed and constructed to provide a simple and practical means of showing and recording the specific gravity of wort flowing to the under-back, copper, etc. It consists of a cylindrical vessel on the lower portion of which is a ¾-in. pipe, through which the wort is admitted. To prevent eddies in the vessel, an inlet pipe leads into an annular ring, which distributes the flow evenly round the vessel. A cylinder and copper gauze is also provided through which the wort percolates. An outlet pipe at the top of the external cylinder is provided, and here again there is another annular ring over which the wort flows, with the object of preventing eddies. Within the inner copper gauze cylinder a hollow float of thin nickel heavily coppered is suspended. The hollow float is completely filled with the liquid, and is connected with the recording instrument by means of a chain immediately above the vessel. The chain is connected with a grooved quadrant mounted on a knife-edged axis. On the opposite side a weight is provided to balance the float when it is in the liquid, the zero adjustment being provided by an adjustable weight. The indications of the instrument are rendered independent of temperature from the fact that the wort in the cylinder and in the float are at the same temperature. The clock carrying the chart revolves once in six hours, and the graduated portion of the chart is marked from 1000 to 1100° specific gravity, and subdivided to 2° specific gravity, which on the chart is equal to $\frac{1}{20}$th of an inch. The pen marks in a continuous ink line on the chart, and the readings can be made to ½° specific gravity with the greatest accuracy. In an ordinary mash tun, however, the wort from the various taps are often running at different temperatures and at a different specific gravity, so that the measurements made with the wort from one tap will not of necessity give the average specific gravity of the whole wort. The objection does not apply if the wort is drawn off through one spend pipe or is running from the under-back to the copper.

Humanism in Technical Education.[1]

By Sir THOMAS HOLLAND, K.C.S.I., K.C.I.E., F.R.S.

VERY few questions have been more discussed than that of education, and the reason for it is quite obvious; for educational methods are as varied as the students who have to be educated, and perfection can be reached only when a system is designed to meet the special circumstances of each individual. Some plants want pruning, others require fertilising, to produce their best results. One pedagogue thinks discipline should be the cure for all students' evils; others preach the importance of making the work attractive. The clash of ideals is heard most in our technical schools. One authority wants full-scale machinery, another says that the college workshop is merely a misleading caricature of a commercial factory. We are told that the student of science and technology can never become an educated man without a dose, and a fairly large dose, too, of the so-called "humanities"; he must always be narrow otherwise, if not absolutely lopsided, and can never be prepared in an institute of science and technology efficiently to undertake the full duties of citizenship.

In a community of science workers discordant notes are similarly heard. One presses for pure science as the main requirement of the practical technologist; another urges training in purely technical methods. The practical man thinks he has used a very hard word indeed when he calls the science student a theoretical idealist, a dreamer. The student of science pretends to despise the practical man as a mere rule-o'-thumb worker, often, however, because he fails to grasp the principles which underlie, and the long process of expensive research that has evolved, the so-called rule-o'-thumb. The doctrinaire student of science very often is, as some one has said of the early riser, conceited all the morning and stupid for the rest of the day.

It is, however, impossible to lay stress on any one truth without apparently being unfair to some other truth. Somewhere between these extremes the maximum of truth is to be found. It is too often so that where science is taught, the student is crammed with the facts instead of trained in the methods. The product of the science class is sometimes handicapped by what Prof. Huxley, the greatest of my predecessors at South Kensington, called "precocious mental debauchery"—the result of too many bouts of book-gluttony and lesson-bibbing.

I do not intend this evening to follow up any of these apparently divergent doctrines. We have learnt now, if we never appreciated it fully before, that a country cannot defend itself in war, or fight the relentless battles of peace, without science and technology. But the technologist will not remain only an expert in the workshop. He has duties as a citizen and must face relations, and competitive relations too, with other human beings, with most of whom he is unable to communicate in technical terms alone—the technical terms that he learns in the class-room. To be appreciated, he must understand and be understood by others: he wants the "humanities."

Now what is meant by the "humanities"? A dictionary will tell you that classical learning is intended by the same word that we also use for a study of the dispositions and sympathies of man. Sure enough, the study of classical literature once had this meaning. Late in the middle ages the study of the classics revealed to the world the long-buried wisdom, especially of the Greeks—their art, their religion, and, more important, their science. That discovery gave rise to the great movement which we speak of generally as the Renaissance—the revolt of intellect from previous feudalism and theological bondage—resulting not only in the revival of literature, art, and that religious freedom which is generally known as the Reformation, but in the development also of scientific curiosity, what, to avoid the secondary meaning of curiosity, we now call research. It gave us the Copernican for the Ptolemaic reading of the solar system; it gave us also in practical form the mariner's compass and, with the exploratory spirit which accompanied it, the discovery of the Americas, of South Africa, India, and the Far East; it gave us the invention of gunpowder and that of paper and printing, which facilitated the distribution of the new learning to a wide world.

How many of these developments, which succeeded one another with the speed of a revolution, were due to independent origin and from other sources, and how many were quickened by the rediscovery of buried philosophies, we need not stop to inquire; but it is obvious that what would otherwise have been but slow combustion developed, because of this discovery, at the speed of an explosion. That discovery was specially the discovery of humanism in Greek literature. Greek literature acted on medieval scholasticism like nitric acid on a combustible cellulose; cotton was converted into gun-cotton.

The lesson to be learnt from the Renaissance is strengthened by a consideration of what happened afterwards to classical studies. With the passage of time, classical learning like an organism went through a period of vigorous youth, vitalising the world with new energy and new ideas, until it reached the stage of adolescence, and, with it, specialisation.

That is the life-history of every organism. With specialisation the study of the classics became narrowed to its linguistic, grammatical, and purely rhetorical aspects: its main object became obscured and stricken with a formalism and a pedantry that "has given us false ideas, and the narrow spirit of a mutually admiring coterie, that wrote Latin and Greek verses to one another and to no one else. It has engendered a wild form of pedantry that regarded a false concord or a false quantity in Greek, not at all as we should regard a similar mistake in French, but as a shock to the higher order of things, which deserved scorn and reprobation when committed by a man, cruel punishment when committed by a boy."

These are not the words of a prejudiced and jealous scientific man, but the judgment of a distinguished classical scholar, the present Vice-Chancellor of Oxford. Reviewing the situation in this way before the Congress of Universities in 1921, Dr. Farnell pleaded for the revival of humanism in classical studies, and I wish similarly to direct attention to the importance of humanism in science and technology, for we also are exposed to the very same danger that Dr. Farnell says has now nearly strangled classical scholarship in our public schools and younger universities. We can thus learn something from the classics; we can profit by their mistakes, knowing that it is never so easy to recognise our own as the mistakes of others.

[1] From an address delivered at the Sir John Cass Technical Institute on January 31.

During the middle two quarters of the nineteenth century, science went through what we might call its Renaissance period. In its philosophical aspects, it was a revolt in part against a widespread misinterpretation of theology, and, in educational policy, it was a revolt against the dominance of what we regard as a perverted and senile form of the classical humanities. We do not object to the humanities, but to that devitalised residue of the humanities that is without humanism.

I am not now going to discuss the relative merits of science and classics as educational media, but I want to bring home to you the danger of defeating the very end of science itself. Scientific men are also liable to succumb to that form of pedantry which in classics exchanged humanism for grammar and rhetoric, and that homologue of pedantry in most religions which tends to kill doctrine by ritual. Do not let us claim that science can give mental training as good, when really we mean as bad, as that afforded by classics. You may remember what Huxley said of Peter Bell, whose dead soul, according to Wordsworth, saw nothing in Nature :

> " A primrose by the river's brim,
> A yellow primrose was to him,
> And it was nothing more."

Huxley asked if Peter Bell's apathy would have been roused one whit by the information that the primrose is a dicotyledonous exogen, with a monopetalous corolla and central placentation. This additional information would have added no more to the humanising influence of the primrose on Peter Bell than any form of exegetical analysis of a Greek text in exchange for Greek philosophy and Greek art.

Let us take an illustration from one of the departments of this Institute—that of metallurgy. The syllabus of this subject refers to " Bessemer and open-hearth plant and processes." A fair summary of what I, as a junior student, had to learn under this head would be as follows : " The original Bessemer process, as conducted in a ganister (silicious) lined converter, does not effect the elimination of phosphorus from the pig-iron ; but by using a basic (dolomitic) lined converter, Thomas and Gilchrist found it possible to eliminate the deleterious element that affects the quality of the resultant steel, so it is now possible to use a phosphoric pig-iron for steel making." Later, coming under the influence of a professor with a wider outlook of the world, I learnt that this so-called basic process changed the whole of our international relationships. It opened up the enormous phosphoric ores of Germany, Belgium, and America. It resulted, therefore, in a challenge to British supremacy in the steel business. Just think of what that meant to railway development, shipbuilding, machinery, and dozens of dependent industries ! Obviously, realisation of this, to me, quite unforeseen meaning in a purely technical fact opened up a new world of human interest.

Who was Thomas and who was Gilchrist ? Those were the first questions that occurred to one. Thomas, I found, was a magistrate's clerk who attended evening science classes at the Birkbeck, a college having an object similar to that of the Sir John Cass Institute, and named for the same good reason after its founder. Gilchrist was his cousin, and he proved to be much more interesting to me, for he was an old School of Mines student and a Murchison medallist.

Thomas and Gilchrist made, by their invention, a greater impression on the history of civilisation than any two Prime Ministers we have ever had, a greater influence than the sum-total of that exercised by one devoted to optimistic militancy and his counter-irritant, the apostle of tranquillity. Thomas had what the great Mr. Gladstone described, in reviewing his memoirs, as " an enthusiasm of humanity." I am ready to assert that a review on these lines of the way in which the basic process of steel-smelting has affected history, especially when so touched with the human relations of the two men to whom it is due, is all that is necessary for the student. He will soon satisfy his own curiosity about technical details ; he will soon be studying the question himself in the library and the workshop.

This stirring of that form of curiosity that Dr. Johnson called " the thirst of the soul " and " the characteristics of a vigorous intellect " will give human, living interest to a student's work. The teacher's task is three parts done and faithfully fulfilled when he has inspired the student sufficiently to impel him to find out the rest for himself. Nothing appeals to a man like humanity.

In a thoughtful paper read before the Congress of Empire Universities in 1921, Prof. Cecil Desch advocated the adoption of the historical method in science teaching. But history consists of innumerable biographies. As Emerson said, " There is properly no history, only biography." History, divorced from biography, can be as dull and deadening as either Greek grammar or descriptive technology. The educational balance is not secured by requiring students to attend a formal course of classics or history as well as of science. That would be merely to double the offence. A physician does not apply a counter-irritant if he can get at the seat of the disease. It is not separate courses of history and science—a mechanical mixture—that are wanted, but the history of science itself, that is, a chemical compound. Giving two separate doses of two unrelated subjects to act as mutual correctives is equivalent to giving a man a metallic sodium pill with a sniff of chlorine gas, when what he wants is merely a pinch of common salt.

But for the power unwisely given to examiners to make or mar a student's career, I would like to try the experiment of covering a syllabus of, say, metallurgy or chemistry by lectures on biography alone. I believe students could be trusted to fill in the historical frame-work on their own account, and to find out for themselves all that is required in the way of technical details. They shall succeed, of course, in varying degrees just as they do now ; but whether they succeed partially or wholly, all shall be better men for having made an effort inspired by a natural and healthy curiosity ; they shall have had the very training which lays a sure foundation for what the scientific man calls research ; and what the scientific man calls a training for research is the very kind of training which qualifies a man to face the problems of after life, when every difficulty that the student has to face after he has left the institute shall have no apparent resemblance to any question previously treated, either in the lecture-room or the laboratory. Every problem that the student meets with afterwards shall be a piece of new research to him.

Sir Richard Gregory, in his address to the British Association last year, defined education as the " deliberate adjustment of a growing human being to its environment ; and the scope and character of the subjects of instruction should be determined by this biological principle." I agree, and as the technical student's environment will be human beings, with little or no familiarity with his own pet technical terminology, he wants to go into the world with a full appreciation of the human aspects and importance of his special subject.

The Flora of an Indian Island.[1]

As a preliminary to the faunistic study of Barkuda, one of several islands in the Chilka Lake, Dr. N. Annandale has investigated its climate, physical structure, palæontology, and vegetation. The lake is a maritime one in the extreme north-east of Ganjam, and is connected with the Bay of Bengal. The island, some three hundred acres in extent, though isolated for terrestrial animals, is within the range of insects of feeble flight and that of dispersal for many seeds. The climate is that of the coasts of the Circars to the south and Orissa to the north. The physical structure is simple and the geological formation uniform; the rocks are the quartz schists of the Ganjam Malias. The changes in the shore water-level, though of faunistic importance, scarcely affect the vegetation. The rocks contain no fossils, but sub-fossil molluscan shells abound in the soil of the island and the sand of its shores. These shells indicate that the island, as such, is recent; the age of the rocks has no bearing on its existing biological features.

Though the vegetation is restricted, several types occupy different areas. Much of the surface has been colonised primarily by species of Ficus, mainly *F. bengalensis*, with an undergrowth of Glycosmis and a partial thatch of woody climbers. This is gradually replaced by other species of Ficus accompanied by trees like *Melia Azadirachta* and *Strychnos Nux-Vomica*, while the undergrowth is reinforced by Capparis and Zizyphus. The foreshore vegetation is scanty. Where the coast is rocky the species present, though fewer than on sandy or gravelly sections, are arboreal and therefore more conspicuous. Behind the foreshore comes a Pongamia belt, broken in places by intruding Cratæva and Melia. Within this zone, besides surviving Ficus groves with Glycosmis undergrowth, are areas where the latter is replaced by *Weihea ceylanica*, the former by Cratæva, Odina, and Albizzia. Stony areas have a scanty plant-covering; the rock-flora of the interior includes masses of two arboreal Euphorbias, *E. antiquorum* and *E. neriifolia*. The commonest tree on the island is *Melia Azadirachta*; perhaps the most abundant herb indigenous there is *Oldenlandia Heynei*.

Dr. Annandale's ecological sketch is supplemented by a plant-list prepared from his specimens by two members of the Botanical Survey staff. This important adjunct to the paper is somewhat marred by typographical errors, and shows want of uniformity in citation. Messrs. Narayanaswami and Carter have not supplied an analysis of the vegetation from the point of view of plant-distribution to correspond with Dr. Annandale's discussion of the subject from the point of view of plant-association. Their carefully prepared list provides all the material required for the purpose, but they have made it more troublesome for those desiring to ascertain the facts by adopting a taxonomic system which, whatever its academic merits, has the inconvenience of differing from that used in the "Flora of British India."

The affinities of the Barkuda flora are South Indian. The list enumerates 139 plant-forms, of which two may be new while five remain undetermined. The remaining 132 include twenty-one, nearly 16 per cent., not reported from Orissa north of the lake, and seventeen, nearly 13 per cent., never found north of the Dekhan. One species, *Riccia crispatula*, has hitherto only been known from Ceylon; two, *Selaginella tenera* and *Weihea ceylanica*, have only been reported from Ceylon and from India south of the Dekhan. Thirty-five, more than 32 per cent., of the Barkuda species reported from North-eastern India, are themselves indicative of South Indian affinity. Seven are littoral plants that are North-eastern Indian only, because they occur on the Orissa coast and in the Sundribuns. The remaining twenty-eight include ten reported only from Orissa, which is a northward continuation of the Circars, and eleven reported only from Chutia Nagpur, which forms a north-eastern extension of the Dekhan, while the remaining seven have been met with both in Orissa and Chutia Nagpur but not in the Gangetic Plain.

The Sed Festival of Ancient Egypt.

At a meeting of the Royal Anthropological Institute held on February 20, Mr. P. E. Newberry presented a paper on "The Sed Festival of Ancient Egypt." This was perhaps the most ancient of all the many Egyptian festivals: it was certainly the most important. There are representations of it on monuments from the beginning of the Ist Dynasty down to Ptolemaic times.

Various interpretations of the festival have been given, but none of them are entirely satisfactory. According to the Greek version of the Rosetta Stone, it was a festival marking a period of 30 years, but there are records of it being celebrated in the 2nd, 15th, 22nd, and 25th years of different kings' reigns. It appears to have been a repetition of the festivals of a coronation and its celebration seems to have procured for the king a new lease of life. It certainly had something to do with the king's assumption of responsibility for the protection of Egypt. It should be especially noted that the king's daughters take a prominent part in the festival. On the mace head of Narmer-Menes is the earliest representation of it: here there is a princess seated in a palanquin and behind her are three men in the act of running: this scene is also found in the Sed festivals of Neusere (Vth Dyn.), of Amenhotep III. (XVIIIth Dyn.), and of Osorkon (XXIInd Dyn.), although in the later examples young princesses standing replace the figure in the palanquin. This ceremony is probably the most primitive one of the Sed festival and represents, Mr. Newberry believes, a *race*, and a race for no less a prize than the Kingdom. Frazer in his "Lectures on the Early History of Kingship" (p. 260 *sq.*) notes that something, apparently the right to the hand of the princess and to the throne, has been determined by a race, and he quotes instances from classical and other sources. "Such a custom," he says, "appears to have prevailed among various peoples, though in practice it has degenerated into a mere form or pretence."

Although it is often assumed that the kingship was hereditary, in the male line—that the son regularly succeeded his father on the throne—it is certain that in Egypt the king claimed his right to the kingship, not because he was the son of his predecessor on the throne, but because he married the hereditary princess who might be the widow or daughter of his predecessor. It is obvious, therefore, that the marriage ceremony must have been a very important one in ancient Egypt. Egyptian women marry early in life, sometimes at 10 or 11, oftener at from 12 to 14 years of age. No doubt the same custom prevailed in ancient times. At 13, or even earlier, a girl may be a mother, and from 40 to 45 she becomes incapable of bearing children. When she becomes incapable of bearing children the husband often takes a new wife: this may perhaps explain why the Sed festival was called the 30 years' festival; for if a girl is married, say at 12, she ceases to be able to bear children at 42, just 30 years after her marriage, and her husband takes another wife.

If the hereditary princess predeceased her husband, then it must have been necessary for the king to marry again so as to retain the kingship: this would explain the fact that the Sed festival was sometimes celebrated in years earlier than the 30th year of a king's reign. It also explains why a king sometimes married his own eldest daughter. If the hereditary princess survived her husband, then Mr. Newberry's theory explains why she is sometimes married to her husband's successor. This theory would also give a reason for it being a kind of repetition of the king's coronation and for its procuring for the king a new lease of power.

There is yet another fact which suggests the theory that the Sed festival was a marriage festival. It was celebrated in a booth or tent (called *Sed*) raised high above the ground; and with Semitic peoples the tent plays a very important part in marriage ceremonial, as Robertson Smith notes in his "Kinship and Marriage," p. 198 ff.

Chemistry in Industry.[1]

NATURAL science—and in this connexion chemistry must be given a position of great prominence—is by far the most important dynamic factor in human progress. Notwithstanding its liability to abuse, its discoveries have, on the balance, made enormously for the greater good and greater happiness of the human race.

The direct utilisation by the State of the services of the professional chemist is a matter not only of immediate concern to chemists themselves, but also of high importance to the community at large, and it is one of the functions of the Institute of Chemistry to ensure that the relations between the appointing authorities and those who hold official chemical positions are of a satisfactory character. Unfortunately, some public bodies do not appear to be aware of the lengthy and expensive nature of the chemist's training or of the difficulties and responsibilities connected with his work, and consequently the advertised conditions of some public posts are not commensurate with the importance of the services demanded. There is a tendency on the part of local authorities to utilise the services of unqualified or imperfectly trained persons for carrying out what are regarded as simple routine processes, a practice against which the council of the Institute has protested vigorously on the ground that it constitutes a serious danger to the community and involves a waste of public money.

The disinterested zeal of the scientific worker is without parallel in the whole world, but it is not wise for any country to presume too much on this disinterestedness. Science is one of the greatest and freest of all givers, but it has a right to demand that recognition in the councils of the nation to which it is entitled. The indirect effect of proper State treatment is very great and the rulers of Germany know this well. A leading German industrial chemist said recently that notwithstanding Germany's position of virtual bankruptcy, the State, at the instigation of the commercial committee of the Reichstag, had come to the help of the great chemical and physical societies, particularly to that of the Kaiser Wilhelm Institute, and if the State could not continue financial aid, the German people themselves must give their last mark to maintain science.

Although the supply of qualified chemists exceeds, for the moment, the demand, there is no cause for serious alarm. The profession attracted a larger number of young men during the last four years than in any previous corresponding period. Notwithstanding the increased output from the colleges and the intense industrial and commercial depression, the new members of the profession are being steadily absorbed. This absorption may be taken as a definite indication that chemistry is more highly valued by the manufacturer than formerly, and that the leaders of industry and commerce are turning more and more to science to assist them in the solution of their various problems.

[1] From an address delivered to the Institute of Chemistry at the annual general meeting on March 1, by Mr. A. Chaston Chapman, F.R.S.

An Intestinal Parasite of Man.

WE understand that Sir Ronald Ross is engaged at the Ministry of Pensions in the investigation of *Giardi intestinalis*, often known as *Lamblia intestinalis*, which, of the three or four common flagellates inhabiting the intestine of man, has the greatest claim to pathogenicity. Moreover, it differs from the others in being an inhabitant of the duodenum and upper part of the small intestine instead of the large intestine. It is probably the first parasitic protozoan to have been observed, for, as Dobell has pointed out, the famous Dutch observer Leeuwenhoek saw it in his own stools so long ago as 1681. From that time down to the present day there has been much controversy as to the significance of its presence in the human intestine. Some regard it as a definitely harmful organism, while others believe that it does not damage its host in any way.

The frequent occurrence of the flagellate in enormous numbers in certain cases of mucous enteritis seems to suggest that it may sometimes be pathogenic, though, like parasitic amœbæ and bacteria which are known factors in disease, it often occurs in perfectly healthy individuals, who are to be regarded as carriers. American workers have brought forward evidence that *Giardia intestinalis* may invade the bile duct and gall bladder and cause irritation in these organs. Flagellates belonging to the same genus occur in domestic animals, such as dogs, cats, rats, and mice, but it appears that these are distinct from the human form, though Grassi and others believed that human beings became infected by ingesting the encysted forms of the flagellate which escape in large numbers in the dejecta of these animals. Careful experiments have, however, shown that it is not possible to infect animals with the human parasite, and slight morphological differences point to the existence of a number of distinct species.

Reproduction of the flagellate is by a complicated process of binary fission. The organism also becomes encysted in ovoid cysts within which division into two takes place. These cysts are found in the dejecta, and are responsible for the spread of infection. It is only during periods of diarrhœa that the free-swimming flagellates occur in the stool, so that infection of human beings is generally recognised by the discovery of the cysts. There is no known method of ridding a human being of infection, and if it is correct that the flagellate may sometimes damage its host, the outlook for these unfortunate individuals is not a bright one.

University and Educational Intelligence.

Belfast.—At the recent meeting of the Senate of the Queen's University, it was announced that the bequest of 57,000*l.* from the late Henry Musgrave, a well-known benefactor of the University, had been paid. Of this sum 30,000*l.* is left to the absolute control of the Senate, to be used and applied for such purpose as the Senate shall consider necessary. Mr. Musgrave directed that 7000*l.* be invested, and the income applied towards paying an additional reader in connexion with the chair of physics. The sum of 20,000*l.* is to be invested, and the income applied in perpetuity for the promotion and encouragement of research in pathology, physiology, physics, biology, and chemistry. The income is to be applied in founding and maintaining studentships for promoting research in these subjects. Each studentship shall be held for one year, but if the electors are satisfied with the work of the student he may be elected for a second year but no longer. If at any time there shall not be any suitable candidate, or if in any year there be a surplus, such surplus shall form a fund out of which special grants may be made to graduates of the University engaged in research. The Senate has agreed that the annual value of the studentships shall be 200*l.*, and has appointed Prof. Ashworth, Prof. Lorraine Smith, Sir Joseph Larmor, and Prof. Collie, together with Prof. Symmers, Prof. Milroy, Prof. Morton, Prof. Small, and Prof. Stewart, to be the electors of the above studentships.

Mr. R. C. Johnson, Balliol College, Oxford, has been appointed lecturer in physics in succession to Dr. Gray, who resigned his appointment in December; Mr. S. P. Mercer, head of the Seed Testing Department of the Government of Northern Ireland, has been appointed lecturer in agricultural botany and plant diseases.

Bristol.—The Long Fox lecture will be delivered by Prof. F. Francis on Tuesday, March 27, at 5 o'clock. The subject will be "The Relation between Chemistry and Medicine."

The Coombe Memorial Scholarship, of the annual value of 60*l.* and tenable in the faculty of engineering of the University of Bristol, will be offered for competition for the first time this year. The scholarship has been established by the Engineering and the National Employers' Federations (West of England Association) as a memorial to a former president, and will be open to candidates who habitually reside within the area of the Association, which includes the counties of Gloucester, Somerset, Wilts, Devon, and Cornwall, as well as the city of Worcester and the towns of Hanley Castle, Malvern, Malvern Wells, Pershore, and Newport, Mon. The examination will be held at the Merchant Venturers' Technical College on Wednesday, July 4 next, and applications must be sent to Mr. A. Storey, director of the Association, not later than July 1.

Cambridge.—The Adams prize for an essay on "The Theory of the Tides" has been awarded to Mr. J. Proudman, Trinity College, director of the Liverpool University Tidal Institute. The essay submitted by Mr. H. Jeffreys, St. John's College, is highly commended.

Prof. H. A. Lorentz, of Haarlem University, will on May 15 deliver the Rede lecture on "Maxwell's Electromagnetic Theory."

On the conclusion of the last of the courses for naval officers held in the University since the termination of the war, the First Lord of the Admiralty has written to express the thanks of the Board of the Admiralty for the great service which the University has rendered the Navy. He expresses the hope that in some shape or other the intimate association between the two may still be kept alive for the mutual benefit of both.

Mr. M. B. R. Swann, University demonstrator in pathology, has been elected fellow and lecturer at Gonville and Caius College.

Edinburgh.—On Thursday, March 1, the Right Hon. David Lloyd George delivered his address as Lord Rector to the students.

Mr. Lloyd George was afterwards entertained at lunch in the Union, and in replying to the toast of his health referred to the fact that seven of his colleagues in the late Government were graduates of Edinburgh. He dealt in an impressive manner with the relation of the universities to the War. He confessed that although he had known the part played by the universities in building up national efficiency, he never realised till the days of war what a national asset a great university was. He doubted very much whether the rich men of this country quite realised at the present moment what a national reserve a university is. After referring to the new kind of warfare developed by an enemy which was the most highly trained intellectual machine probably in the world, Mr. Lloyd George said the moment came when we called upon our universities, and they came to our rescue and poured out their trained minds—in the War Office, at the Admiralty, at the Ministry of Munitions—bringing the whole resources of their scientific knowledge, and, what was still more, knowing where to place their hands on people who had the training to enable them to take up the problems. He continued—"I don't know, I tell you now, what would have happened to us if we had not had the universities to fall back on in those dark days. I will tell you more. In the end our university brains beat theirs. War, you may say, is not what universities are for. I agree, but war is the great test of the nerve of a nation, of the muscle of a nation, of the heart of a nation. It tests every faculty of the human mind as well as the human body, and the test came; and in every particular, on land and sea, where scientific knowledge was required, where trained ingenuity was needed, we defeated the foe. That was due to the universities. Therefore I regard universities not merely as the great training-ground . . . I regard them as the fourth arm of defence for the security of this land."

Mr. Lloyd George warmly eulogised the services rendered by Principal Sir Alfred Ewing at the Intelligence Department, and stated that the work he did there gave information which ultimately brought America into the war.

Leeds.—The Honorary Degree of Doctor of Laws was conferred upon Major the Right Hon. Edward Frederick Lindley Wood, president of the Board of Education, on March 5. Prof. Barbier, in presenting Mr. Wood, said: "The University desires to do honour to one who, the scion of a Yorkshire family of high distinction, is himself 'commended for the gifts that come from learning.' Mr. Edward Wood has won the respect of his fellow countrymen by the grave sincerity of his judgment. He holds an office of onerous responsibility in our public education. And by his unselfish generosity he has given to the transfer of an historic mansion the grace of a great benefaction to the city of Leeds."

London.—Applications are invited by the senate for the Ramsay Memorial chair of chemical engineering tenable at University College. Particulars are obtainable from the Academic Registrar, University of London, South Kensington, S.W.7.

Sheffield.—At the meeting of the Council on March 9 the following appointments were made: Mr. G. Grant Allan, to be assistant bacteriologist; and Mr. H. P. Lewis, to be assistant lecturer in mining geology.

Societies and Academies.

LONDON.

Royal Society, March 8.—A. B. **Wood**, H. E. **Browne**, and C. **Cochrane**: Determination of velocity of explosion-waves in sea-water; variation of velocity with temperature. An accurate determination of the velocity of explosion-waves in the sea gives:

(*a*) $V = 4955 \cdot 5$ (± 1) ft./sec., at $16 \cdot 95$ ($\pm 0 \cdot 1$)° C. and salinity 35 per cent.

(*b*) $V = 4836$ (± 2) ft./sec., at $6 \cdot 0$ ($\pm 0 \cdot 1$)° C. and salinity $35 \cdot 1$ per cent.

(*c*) $V = 4847$ ($\pm 1 \cdot 5$) ft./sec., at $7 \cdot 0$ ($\pm 0 \cdot 1$)° C. and salinity $35 \cdot 2$ per cent.

In the new technique developed, it is unnecessary to know the exact position of charge relative to receivers. The results lead to a mean value of $10 \cdot 9$ ft./sec. per ° C. as the temperature-coefficient of velocity in the range 6° C. to 17° C. The following expression represents the velocity at any temperature t° C. within this range, and at any salinity S (parts per thousand):

$$V = 4627 + 13 \cdot 7t - 0 \cdot 12t^2 + 3 \cdot 73S.$$

The salinity-coefficient is approximately 3 to 4 ft./sec. per 1 per cent. increase of salinity, the theoretical value being $3 \cdot 73$ ft./sec. per 1 per cent. No change was detected for charges varying in weight from 9 oz. to 300 lb. of explosive and no variation with depth. The coefficient of adiabatic compressibility of sea-water at $16 \cdot 95$° C. and 35 per cent. is $C_p = 42 \cdot 744$ $(\pm 0 \cdot 02) \times 10^{-6}$. Combining this with Ekman's value of C_θ, the ratio of the specific heats of sea-water under these conditions of temperature and salinity is $\gamma = 1 \cdot 0094 \pm 0 \cdot 0005$, in good agreement with $1 \cdot 0090$, deduced from thermo-dynamic data.—P. M. S. **Blackett**: The study of forked alpha-ray tracks. Forked alpha-ray tracks obtained by the Wilson condensation method were studied. The lengths of the tracks of the recoil atoms yield information concerning the relative ionisation due to different kinds of ionising particles, and of the average charge carried by them. Measurements of the angles between different parts of the tracks gave the masses of the recoil atoms in three particularly favourable cases.—A. **Egerton**: On the vapour pressure of lead.—I. The vapour pressure is measured by effusion of vapour at low pressure through a hole of measured area. Temperature is maintained constant by a selenium cell relay arrangement within 1/3° C. for many hours at about 800° C. Pressures were measured to 10^{-5} mm. The vapour pressure of ordinary lead between 1200-600° absolute is expressed by the equation $\log p = 7 \cdot 908 - 9932/T$. The latent heat of vaporisation of lead (λ_0) is $47{,}000 \pm 1000$ cal. The chemical constant of lead is $1 \cdot 84 \pm 0 \cdot 2$, agreeing well with the theoretical value ($1 \cdot 853$) obtained from the relation $3/2 \log M - C_0 = C$. The vapour pressures of lead and the uranium-lead isotope appear to differ by 2 per cent., but the result is rendered uncertain by an unexplained lowering of vapour pressure which lead undergoes on prolonged heating *in vacuo*.—A. C. **Egerton** and W. B. **Lee**: (1) Some density determinations. The Archimedes method of determining densities is rendered more accurate by utilising certain mobile and heavy organic liquids which avoid air bubbles and damping difficulties, and increase the weight of liquid displaced. Ethylene dibromide and carbon tetrachloride were employed with accuracy. A satisfactory sample of metal for density determination is prepared by filtering, casting, and heating *in vacuo*. The density of lead is $11 \cdot 3437$ at 20° C. The probable error of the nine determinations on three different samples is 1 part in 100,000. The maximum departure from the mean value for any single determination is less than 1 part in 12,000. A sample of uranium-lead would have an atomic weight of $206 \cdot 26$ from the density obtained. (2) Separation of isotopes of zinc. Two sets of distillations of pure zinc have been carried out in high vacuum, under conditions to obtain a slightly different concentration of the isotopes in the final residue of the final distillate. The samples are cast *in vacuo* and seeded with a particular kind of zinc. The first distillations gave a residue of slightly increased density, but the distillate possessed the same density as the original zinc. The second distillations gave a residue of increased density (about 1 part in 3700) and a distillate of decreased density (about 1 part in 3000). Determinations on seven samples of ordinary zinc give the density of zinc (prepared in the described way) as $7 \cdot 1400$ (the probable error being less than 1 part in 100,000). Flaws, allotropes, different physical conditions, and impurities are improbable. The amount of the separation agrees with Dempster's observations of isotopes of weights extending over six units (namely, 64-70), but is not so great as might be found for equal parts of 64 and of atoms of weights 66, 68, and 70.—E. **Hatschek** and P. C. L. **Thorne**: Metal sols in non-dissociating liquids. I.—Nickel in toluene and benzene. Very stable sols of nickel in a medium free from ions can be produced by decomposing nickel carbonyl dissolved in mixtures of toluene and benzene, containing a small amount of rubber, at 100° C. In the electric field the particles of disperse phase move to, and deposit on, *both* electrodes. Electrophoresis in fields of different strengths, all other factors being equal, shows that the amounts deposited are proportional to the first, or a lower, power of the potential gradient. Therefore positively and negatively charged particles are originally present in the sol. The sol resembles typical protected aqueous sols, inasmuch as it is coagulated by liquids which are not solvents for the protective colloid, *i.e.* rubber. The coagulum is only very imperfectly peptised again by rubber solvents, such as toluene or benzene.—H. **Hirata**: Constitution of the X-ray spectra belonging to the L series of the elements.

Zoological Society, February 6.—Sir S. F. Harmer, vice-president, in the chair.—Oldfield **Thomas**: (1) A new rock-kangaroo, *Petrogale godmani*, sp. n. It is like *P. assimilis*, but with a whitish tail, broader nasals, and larger secator. Its habitat is Black Mountain, near Cooktown, N. Queensland. (2) Skull of a pygmy fruit-bat from Sumatra. The generic name Æthalops is proposed.—C. A. Adair **Dighton**: Coat-colour in greyhounds.—E. G. **Boulenger**: The experiments of Dr. Kammerer and others upon amphibians and insects.—E. Leonard **Gill**: The Permian fishes of the genus Acentrophorus.—Charles F. **Sonntag**: On the vagus and sympathetic nerves of the terrestrial carnivora.—E. P. **Allis**: The postorbital articulation of the palato-quadrate with the neurocranium in the Cœlacanthidæ.—G. S. **Giglioli**: On the linguatulid arachnid, *Raillietiella furcocerca* (Diesing, 1835), Sambon, 1922.—Mrs. Rita **Markbreiter**: Some Microfilaria found in the blood of birds dying in the Zoological Gardens, 1920–1922.

February 20.—Dr. A. Smith Woodward, vice-president, in the chair.—D. **Seth-Smith**: Sexual display of the Magnificent Bird-of-Paradise (*Diphyllodes magnifica hunsteini*).—Einar **Lönnberg**: Remarks on some palearctic bears.—E. W. **Shann**: The embryonic development of the porbeagle-shark, *Lamna cornubica*.—Robert **Gurney**: Some notes on *Leander longirostris*, M.-Edwards, and other British prawns.

Faraday Society, February 19.—Sir Robert Robertson, president, in the chair.—A. W. **Porter** and J. J. **Hedges**: The law of distribution of particles in colloidal suspensions with special reference to Perrin's investigations. Pt. ii. The behaviour of particles specifically lighter than the medium has been examined in regard to distribution with height, using for the purpose emulsions of paraffin in water. The change of concentration occurs only at the bottom of the containing vessel. There is an increase of concentration with height reckoned from the bottom. A type of curve is suggested which fits closely the experimental results.—D. B. **Macleod**: On a relation between surface tension and density. The empirical relation $\gamma/(\rho_l-\rho_v)^4=C$, where γ is the surface tension at any temperature, ρ_l and ρ_v the densities of the liquid and the vapour at the same temperature and C is a constant for each liquid, fits the experimental figures with remarkable accuracy for temperatures ranging from the melting-point to the critical temperature.—D. B. **Macleod**: (1) On a relation between the viscosity of a liquid and its coefficient of expansion. If x_0 be the volume of the free space in 1 c.cm. of a liquid at 0° C. and $1-x_0$ the volume occupied by the molecules, it is assumed that at a temperature t° C. the volume of the free space is $x_0+\alpha t+\beta t^2+\gamma t^3$—the volume of the molecules remaining constant. The viscosity of liquids is expressed as a function of the free space, thus $\eta_t x_t^A=C$. For normal liquids A is nearly unity. For associated liquids it has a higher value. The values obtained for the free space for various liquids at their boiling-points are practically constant and of the order required by Van der Waal's theory. An expression is given for the viscosity of liquids at different temperatures and pressures. (2) On the viscosity of liquid mixtures showing maxima. The viscosity of liquid mixtures is a function of the free space of the constituents and of the mixture. In the case of liquid mixtures showing a maximum, the increase of viscosity is due mainly to the increase of density, which in turn is due to the chemical affinity between the constituents. It is probable that complexes which are formed further reduce the free space and consequently increase the viscosity.—F. H. **Jeffery**: Electrolysis with an aluminium anode, the anolyte being (1) solutions of sodium nitrite, (2) solutions of potassium oxalate. With solutions of sodium nitrite probably the primary product of reaction at the anode is aluminium nitrite which is hydrolysed rapidly to hydrated aluminium oxide and nitrous acid, the latter giving rise to nitric oxide and nitric acid. With solutions of potassium oxalate the product of reaction at the anode is a complex anion derived from aluminium. The salt $K_3\{Al(C_2O_4)_3\}\cdot 3H_2O$ can be derived from the anolytes after electrolysis. It is probable that the salt is a true complex salt comparable with potassium chromioxalate, and if this be true, the alumini-oxalate complex can be represented in three dimensions just as Werner represented the chromioxalate. The isolation of a complex salt from an anolyte does not imply necessarily that the constitution of the anionic part of this salt is identical with that of the complex anion present in the anolyte after electrolysis.—Maurice **Cook**: Crystal growth in cadmium. Evidence has been obtained that unworked crystals can grow under certain conditions. The usual methods of preparing metallic specimens for microscopic examination are useless, since the specimen cannot be regarded as unworked after it has been sawn off the original, ground, and polished. In these experiments the metal is cooled in such a way as to be free from the stresses usually set up during solidification. The results obtained indicate that during annealing considerable crystal growth has taken place. Irregularity in the shape of the grains is probably a factor greatly facilitating crystal growth.—S. D. **Muzaffar**: Electric potential of antimony-lead alloys. Measurements of the electric potential of the antimony-lead alloys were made by means of a quadrant electrometer against a calomel electrode in N KOH, N $Pb(NO_3)_2$, and tartar emetic with tartaric acid solutions. The results reveal an identity of potential up to 98 per cent. antimony with that of lead, which show the formation of no solid solution and no chemical compound between the two metals.

Royal Microscopical Society, February 21.—Prof. F. J. Cheshire, president, in the chair.—Sir W. M. **Bayliss**: Colloids and staining. The histologist is concerned with the staining of particles, large or small, sometimes present in the living cell, sometimes formed by fixing agents. The process is a complex one; but, as would be expected from the heterogeneous nature of the systems concerned, adsorption is the chief factor, especially in its electrical aspect; chemical combination seems to be of less importance. Thus, surfaces with a positive charge take negative (" acidic ") dyes, those with negative charge take " basic " or positive dyes. The degree depends on the magnitude of the charge, as shown by the effect of electrolytes, alcohol, heat, isoelectric point, etc. The removal of the amino groups from proteins has no effect on the process. Adsorption can be distinguished from chemical combination in certain cases, such as silk dyed with the acid of Congo-red. The fixation of stains by heat is difficult to explain. The action of mordants is also obscure; chemical combination as " lakes " is only a partial explanation, since these are stated to be resistant to acids. Differentiation appears usually to be a process of colloidal dispersion of the " lake." In a few cases, as the staining of fat by Soudan III., partition in accordance with solubility is the main factor. A. **Mallock**: The resolving power and definition of optical instruments. Resolving power is taken as indicating the least distance (angular or linear) at which two points can be seen as separate in the field of the instrument; definition is the ratio of that area of the field over which the resolving power is maintained to the whole area, or, shortly, the dimensions of the least objects appreciable and the range over which the appreciability extends. Optical images are formed when and where a number of paths from one point to another have the same optical length, in which case either point may be considered as the image of the other. By optical length is meant the length measured in wave-lengths in the medium through which the path proceeds. The constancy of this length causes all the waves emanating from one of the points to arrive at the other in the same phase, and this condition may be used to determine the form of the reflecting or refracting surfaces required to make one point the image of another. Resolving power depends on the rapidity with which the length of the optical path varies as the distance from the geometrical focus is increased: the more rapid the variation the greater is the concentration of the light and the smaller the luminous area which forms the image of a point. For telescopes where the angular aperture of the lens is small the variation is proportional to the diameter of the object glass, and a perfect lens one inch in diameter should have a resolving power of 4 in. of arc. For microscopes where the angular aperture of the lens is large the least appreciable distance is about $\lambda/2$ or 1/100,000 in. with ordinary light. Test plates for microscope objectives consist of groups of fine lines ruled on films of anilin colour, the thickness of which is only a small fraction of a wave-length of light.

Paris.

Academy of Sciences, February 19.—M. Albin Haller in the chair.—G. **Urbain**: Celtium, element of atomic number 72. A discussion as to the priority of Coster and Hevesy. The author cites the earlier work of Dauvillier and himself, and concludes that Coster and Hevesy were not the discoverers of element 72, but have only found a material in which it is present in a relatively high proportion. The author claims that the name celtium has priority over hafnium for this element.—J. L. **Breton**: Spark-gaps in which the spark in a gaseous dielectric is deflected by a strong air current. Two types of spark-gap are described. The simpler of the two consists of a conducting disc of metal or graphite rotating with a high velocity in a hermetically closed cylinder filled with coal gas or the vapour of alcohol. The sparks play between this disc and two graphite electrodes. Long uninterrupted working is secured by water-cooling or by a fan. The apparatus has been successfully applied to the working of a high-frequency-induction furnace.—Jules **Andrade**: Isochronism and quadratic friction.—Georges **Friedel**: Cholesteric bodies.—C. **Sauvageau**: The prolonged quiescent state of an ephemeral Alga (Mesogloia).—M. W. C. Brögger was elected a foreign associate in the place of the late M. Schwendener.—A. **Myller**: Systems of curves on a surface and the parallelism of M. Levi-Cività.—M. **Juvet**: A generalisation of Jacobi's theorem.—M. **Malaval**: Permanent deformations by extension and compression.—M. **Mesnager**: Observations on the preceding note.—P. **Dumanois**: An aerodynamical arrangement for testing motors. The usual fan resistance does not permit of continuous variation. The author encloses the fan in a cylindrical drum closed by two plane parallel walls, one of which is constructed of radiating shutters. By partially opening the shutters, when fixed to a 12 h.p. motor, the number of turns per minute can be varied between 950 and 1470, a sufficient variation for practical conditions of use.—M. **Rateau**: Remarks on the preceding communication. M. Dumanois' apparatus has advantages over the Froude brake.—A. **Weinstein**: The unicity of sliding movements.—Charles **Bohlin**: The autologous series belonging to the problems of two and three bodies.—Ernest **Pasquier**: A simple expression of the acceleration of mercury in the case of the problem of two bodies, taking into consideration the movement of the perihelion of the planet.—Thadée **Peczalski**: The relation between Young's modulus and the ratio of density to atomic mass. The relation $E = B(\delta/M)^2$ is deduced, in which E is Young's modulus, δ is the density, M the atomic mass, and B a constant (8×10^5 kilograms per sq. mm.). The calculated and experimental values are compared for nine metals.—A. **Marcelin**: Superficial fluids. The unlimited extension of oleic acid. A study of the "superficial pressure" exerted by a thin layer of oleic acid on water. When the layer of oleic acid is one molecule thick the acid may be regarded as being in an intermediate state between the free and dissolved states, to which the name of "superficial solution" is given.—St. **Procopiu**: The appearance of the flame, arc and spark lines in the arc-spectra of metals in a vacuum.—Albert **Portevin** and François **Le Chatelier**: A phenomenon observed during the test by extension of alloys in course of transformation. The peculiarity observed was confined to aluminium alloys of the duralumin type with or without the addition of other metals (manganese, zinc). The elongation of the test pieces, instead of increasing continuously with the pull, progressed by repeated oscillations of an amplitude amounting to 4 per cent. of the load and with a frequency of several oscillations per second. The phenomenon attained its maximum amplitude immediately after tempering.—A. **Bigot**: The action of heat on kaolins, clays, etc. Black pottery. A study of the black pottery from the Bouchets Cave (Ardèche), from Basutoland, and of Etruscan black vessels.—André **Brochet**: The hydrogenation and dehydrogenation of castor oil and its derivatives. Castor oil with active nickel was treated with hydrogen at 150° C. under pressure. The pressure showed a series of oscillations which can be interpreted by assuming a series of hydrogenations and dehydrogenations. The fully hydrogenated product gave off hydrogen on heating with nickel to about 280°, but the product finally obtained did not correspond with the original oil.—René **Locquin** and Sung **Wouseng**: the hydration of the dialkylethinylcarbinols and the preparation of the α-hydroxymethyl ketones. Tertiary acetylenic alcohols of the type $RR.C(OH).C\equiv CH$ are readily converted into the ketones $PR.C(OH).CO.CH_3$ by Denigès' reagent (acid sulphate of mercury). Details of the method are given and a description of five ketones prepared by this general method.—Henry **Joly**: Stratigraphical observations on the Oxfordian and Lusitanian at certain points in the Celtiberic chain (Spain).—Léon **Bertrand** and Antonin **Lanquine**: The large Provençal sheets of Audibergue and Cheiron (Maritime Alps).—E. **Schnæbelé**: The present structure of the primary Vosges. The application to the whole of the Vosges of observations made especially to the north of the valley of Villé.—L. **Giraux**: The geological position of the neolithic workshops of the forest of Montmorency.—J. **Beauverie**: The relations existing between the development of wheat rust and climate. The sharp contrast between the climatic conditions in 1921 and 1922 showed that *Puccinia triticina* is especially the rust of dry seasons and *P. graminis* is the rust of wet seasons, the latter doing the most damage from the point of view of yield of grain.—M. **Rose**, J. **Dragoiu**, and F. **Vlès**: The reversibility of the phenomena of arrest by lowering the *p*H in the evolution of the eggs of the sea urchin.—M. and Mme. G. **Villedieu**.—The action of insoluble oxides on the mildew of potato (*Phytophthora infestans*). It is generally admitted that for a substance to act on a living organism it must first be rendered soluble. Experiments on the toxic action of the insoluble oxides of various metals (magnesium, cadmium, nickel, cobalt, zinc, copper, mercury) on the conidia of potato mildew are in direct contradiction with this hypothesis.—R. **Herpin**: Comparison between the sexual behaviour of some nereidians from the coasts of the Channel.—Ch. **Gravier**: Remarks on the preceding communication.—Auguste **Lumière**: The possibility of realising intestinal disinfection. An account of some experiments with sodium argentothioglycerine sulphonate, $AgS.CH_2.CH(OH).CH_2.O.SO_3Na$. Experiments on a dog showed that while a dose of 1 gm. of benzonaphthol per day had no effect on the number of organisms in the fæcal matter, the administration of the same weight of the silver compound sterilised the intestine in four days.

Labour and Science in Industry.

THE statement issued by the Trade Union Congress on February 19 entitled "The Attack on Labour Standards" calls for notice from those interested in the scientific organisation of industry. It is stated quite truly that "During the last 150 years industrial conditions have been revolutionised. Labour-saving devices have been introduced: steam and electric power have been developed, and the increased productive capacity of industry following innumerable inventions and scientific discoveries has enabled those who work by hand and brain to increase enormously their output." But if this increase in mechanical power is to be labour-saving, it must not, they go on to say, be at the expense of those who labour, and they have some fear that an attempt is being made "to utilise the present 'slump' for the purpose of degrading conditions of employment to the lowest possible point." In particular it is claimed that a reduction in the hours of labour is the only means of enabling the workers to share in the triumphs of civilisation and industrial peace, and that a firm front must be maintained on that point.

It would be impossible in a short article, and unsuitable in these columns, to enter on a discussion of the detailed questions involved in various industries at the present day; but the general question is one of the highest moment. Seeing that the application of science to industry has transformed society in the period referred to, and has indirectly affected politics, art, education—in fact every side of Western life—it behoves us to consider with the utmost care how far the mass of the workers has benefited by the change. By this it must ultimately be judged, for whatever may be the eternal value or eternal permanence of knowledge in itself, as soon as we apply it to the conditions of our life, it must be judged by the effects on the whole people and not on the few. As a human being, enjoying the products of industry, the happiness of the manual worker has an absolutely equal claim to moral or legal consideration with that of those who direct or organise his work.

This will scarcely be questioned nowadays on the employing side. Are not the "workers" on their side now ready to agree that, so far as we can judge in so difficult a matter, since the Trade Union action and legislation of the last three-quarters of a century, the conditions of the working-class are both happier, more intelligent, and more humane than they were before Watt invented the steam-engine?

But, it will be said, is not the betterment, if real, due not to science, but to legislation and other action necessitated by the evils which the industrial revolution had produced? Above all, have the "workers" received a fair share in the increased products?

On the latter point a decision commanding universal assent is impossible. There is no absolute standard of justice in such affairs. If we can be satisfied on the general question, that the condition of the workers has been appreciably improved by the applications of science to industry and life, it would be unreasonable to seek a mathematical proportion. Can we? Immediately after the introduction of big machines and factory production, we certainly could not. The herding together of crowds of poor people in hideous, hastily constructed, and insanitary town-dwellings was a monstrous evil. Even now these conditions too largely persist to allow a very roseate picture to be drawn. But, on the other hand, so much has been done to ameliorate them that it would be equally untrue to paint quite so black a picture as may be heard described from Labour platforms. Life has been transferred from country to town for the mass of our people, and that has its inevitable drawbacks. But it is not on the whole an unhappy or degraded life. Houses have been, and are being, vastly improved. Hours of labour have been reduced, and there is not the slightest prospect of their return to the condition of the early factory years. Facilities for education and enjoyment have been vastly increased, or rather newly created. Health is remarkably improved.

One result of the change in industry due to science is seldom noted in these discussions, and yet it is one of the most important. Mass production and scientific machinery have between them thrown up a large new class of men intermediate between the manual workers and the capitalist director. This class—the foreman, the shop-steward, the manager, the man with exceptional organising or mechanical ability who invents and sets up on his own account—is the most characteristic human product of the industrial revolution and one of the weightiest factors in modern society. Those estimating the share taken by "Labour" in the fruits of scientific industry cannot omit this, which is the best paid section and nearest to the mainspring. Moreover, in general we may note that those industries which have absorbed most brains in their development, notably engineering, also pay the highest wages. Agriculture, which has up to the present remained most primitive, pays the lowest.

The application of science to industry does not appear, therefore, to carry with it the wholesale degradation of the working-class as is sometimes contended, though the great mass who do purely mechanical work are rightly the chief concern of the social reformers and the Trade Union Congress.

F. S. M.

An Antarctic Saga.

The Worst Journey in the World: Antarctic, 1910–1913. By Apsley Cherry-Garrard. (In 2 vols.) Vol. 1. Pp. lxiv + 300 + 4 + 30 plates + 4 maps. Vol. 2. Pp. viii + 301–585 + 28 plates + 1 map. (London, Bombay, and Sydney: Constable and Co., Ltd., 1922.) 63*s*. net.

THIS is the sixth book to give the story, or part of the story, of Capt. Scott's last expedition, and it is in some ways the most remarkable of them all. Mr. Cherry-Garrard took part in three of the worst journeys ever made in the Antarctic or anywhere else, and the iron of his sufferings has entered into his soul and imparted a ferric quality to his recollections. He writes often with a forceful epigrammatic directness that makes one gasp; again he falls back into pages of rather heavy going, for his quotations from the other books on the expedition are very numerous, albeit they are well chosen. The very first paragraph of the preface sets the keynote of simulated cynicism and paradox.

"This post-war business is inartistic, for it is seldom that any one does anything well for the sake of doing it well; and it is un-Christian, if you value Christianity, for men are out to hurt and not to help—can you wonder when the Ten Commandments were hurled straight from the pulpit through good stained glass. It is all very interesting and uncomfortable, and it has been a great relief to wander back in one's thoughts and correspondence and personal dealings to an age in geological time, so many hundred years ago, when we were artistic Christians, doing our jobs as well as we were able just because we wished to do them well, helping one another with all our strength, and (I speak with personal humility) living a life of co-operation in the face of hardships and dangers which has seldom been surpassed."

This prepares us for the last sentence in the preface, which in turn illuminates the literary landscape of these volumes:

"My own writing is my own despair, but it is better than it was, and this is directly due to Mr. and Mrs. Bernard Shaw. At the age of thirty-five I am delighted to acknowledge that my education has at last begun."

An author possessed of so humble and hopeful a disposition should not take it amiss if a critic tries to help by suggestions of improvement as well as by hearty recognition of exceptional candour and artistic power.

To begin with, the historical introduction detracts from the value of the book, of which it occupies sixty-four pages. It ought to have been much shorter and focussed more directly on McMurdo Sound. Unfortunately, Mr. Cherry-Garrard went direct to Cook's "Second Voyage" and neglected to check his extracts in proof, otherwise he would not speak of "*sus*pissated juice," nor would he have quoted a longitude as "2° East" without adding Cook's essential words "of the Cape of Good Hope." On the other hand, he omitted to consult the *Challenger* "Narrative," but took from some uncited source the surprising statement that the *Challenger* "spent three weeks within the Antarctic Circle," the actual time having been more nearly three hours. Later history as summarised by Mr. Cherry-Garrard also requires revision. Borchgrevink should have been mentioned as the first man to land on the Ice Barrier and travel over its surface, and Armitage might have been named as the leader of the first party to ascend to and travel over the great polar Plateau.

Incidentally, the paging of the book reveals the fact that it was designed as one volume, for vol. 2 begins with p. 301, and as the exigencies of printing made it difficult to end vol. 1 on p. 300 four unnumbered pages had to be introduced, and so a singularly clear description of the embryology of the Emperor penguin by Prof. Cossar Ewart, which occupies those pages, has necessarily escaped the index.

As a general account of Scott's last expedition Mr. Cherry-Garrard's book surpasses all the others. Mr. Priestley's book on the northern party, Dr. Griffith Taylor's and Mr. Ponting's on the main wintering party, and Capt. Evans's account of his personal experiences are fine books, each in its way dealing admirably with special aspects but leaving the expedition as a whole unchronicled. The two great volumes of Scott's Last Journey giving the official account omit the preliminary arrangements for the expedition, of which Mr. Cherry-Garrard gives a racy account, and enter too fully into the fears and anxieties of the leader on the great southern journey to leave a clear impression on the mind. Again, the exquisite reproductions of Dr. Wilson's beautiful water-colours and the panoramic sketches of scenery give to the volumes before us a charm that in large part compensates for the very high price which their inclusion necessitates.

If poetry be indeed definable as "emotion recollected in tranquillity," Mr. Cherry-Garrard has given us a true epic of exploration. His emotion was strong and his recollection is sardonically calm. The description of the "worst journey in the world" from Cape Evans to Cape Crozier in winter darkness to obtain eggs of the Emperor penguin is the most vivid and moving we have met with in polar annals. The mellow nobility of Wilson's character and the dauntless cheeriness and resourcefulness of Bowers made them ideal companions in a desperate adventure, and despite the deprecatory references to himself we can see that Mr. Cherry-Garrard was not unworthy of his associates. To be sure, Bowers would not have worried if all the penguin eggs had been broken, nor would Wilson have taken offence at the superior aloofness (real or imaginary) of a museum official, which hurt the author severely. All the same, we think the Gilbertian humour and grotesque exaggeration of Mr. Cherry-Garrard's efforts to extort from the "Chief Custodian" an expression of the value of the objects for which three men had put their lives to the touch may well be passed by as a piece of friendly banter, for to the general reader it serves as an artistic relief to the grim horror of the quest.

The description of the main southern journey and of the ascent and descent of the Beardmore Glacier is a most valuable piece of first-hand narrative. Still more must one appreciate the story of the return of the last supporting party under Capt. Evans, which is told in large part in the very words of Lashley, one of the two "naval ratings" who saved the life of their leader by heroism as fine as ever was. The diary, given in its original lower-deck language, is a masterpiece of rugged prose that defies all rules of grammar and is incapable of imitation.

Mr. Cherry-Garrard conveys a good impression of the scientific aims of the expedition in untechnical words; but in our opinion the real value of the book is as a contribution to polar psychology. Priestley has treated of this aspect of the expedition more formally; but here we have a quarry of the raw material with which psychologists will know how to deal. As a rule, official reports fail in a candid treatment of the human element in an expedition, while the unauthorised records of subordinates usually fail in trustworthiness. Yet we know more of the mental state of Cook's companions in 1773-75 from Forster's ill-natured volumes than from the great navigator's own calm narrative, and we get delightful sidelights on Sir James Ross from M'Cormick's "Polar Voyages" in spite of the conceit and short-sightedness of the writer. We cannot view Mr. Cherry-Garrard's analyses of the character of his leader or his comrades as ill-natured, while he is certainly totally free from any suggestion of claiming superiority for himself, and, save in the case of the "Chief Custodian" referred to above, he is obviously sincere.

To future students of polar travelling this book will prove invaluable whether all the opinions put forward in it are accepted or not. We are reluctant to raise controversies that would no longer serve a practical purpose; but no future explorer can afford to pass by the criticism of the rations used for sledge-travelling or the inquiry into the real cause of the collapse of Scott's party. While the immediate cause was, as Scott stated, the shortage of paraffin for heating and the totally unexpected low temperature of the air on the Barrier surface in March, Mr. Cherry-Garrard indicates that an unfortunate dietary had led to the slow and gradual undermining of the health of all the members, lowering their vitality to a point which made the struggle hopeless. The discussion of this subject is painful; but it is scarcely likely that the views put forward will be accepted by the survivors of this or other polar expeditions without very careful scrutiny. It must be remembered that only experience can test the sufficiency of any diet, and that the best theoretical views are open to revision in the light of new knowledge. The War included so many large-scale experiments on mal-nutrition that any one criticising Scott or his advisers for their views in 1909 must be careful to do so with respect only to the state of knowledge at that time.

Capt. Scott was a great leader, and it may be that the wave of hero-worship which rose to so unprecedented a height when the news of his fate became known overshadowed the merely human side of his character. Even if all that Mr. Cherry-Garrard says of the strength and of the weakness of his late leader stands the test of time, the question cannot but arise whether the time for such a characterisation has yet come. In the future it will be a valuable piece of comparative study to contrast one great leader with another, but it will never be fair to compare the searching analysis of Capt. Scott with the more conventional presentment of other leaders whose qualities have been dealt with, let us say, with the reticence dictated by Victorian standards of consideration for the feelings of surviving relatives.

We think that it may be possible to combine fearlessness with good taste by placing on record in some safe keeping for future study the most intimate personal criticism of explorers by those who have been most closely in contact with them; and we should like to see all personal diaries of all the expeditions secured from the risk of destruction, especially from the risk of destruction by the writers themselves in after years, by deposit with a responsible institution in trust for posterity.

HUGH ROBERT MILL.

Indian Irrigation.

Triennial Review of Irrigation in India, 1918–1921. Public Works Department of the Government of India. Pp. v+222. (Calcutta: Government Printing Office.) 5 rupees.

INDIA is a land of many problems, and not the least difficult and perplexing is that of irrigation. The meteorological conditions vary there more than anywhere else in the world, within an equivalent area. The country contains alike the locality (Cherrapunji) with the greatest recorded average annual rainfall (460 inches) and arid tracts where rain is practically unknown. More troublesome than these extremes is the general irregularity of the incidence of precipitation, its unequal distribution, its capricious periodicity, its liability to entire failure. Drought and famine are ugly visitants to a country, but they are only too familiar to the unfortunate inhabitants of the land of the Moguls.

There is no need, therefore, to enter any plea or make any justification for irrigation works in India. Not merely the happiness and comfort but the very existence of many thousands of lives depends upon the provision of supplies of water by artificial means to the crops during the dry season.

The volume before us contains a record of the irrigation works carried out during the triennium 1918–21 by the Public Works Department of the Government of India. It also embodies an extremely interesting review of the inception and progress of various undertakings of the kind during a period of some forty years. The 10½ million acres irrigated by Government Works in 1878–79 have grown to 28 million acres in 1919–20. Perhaps a better method of forming an idea of the works themselves is to speak in terms of channels constructed. By the year 1900–1 there were 39,142 miles of Government channel in operation. In 1920–21 this length had increased to 55,202 miles. Every year there has been an average addition of 800 miles.

From an agricultural point of view, the triennium 1918–21 consisted of a central prosperous year between two lean years. In the first year the average deficiency in the rainfall throughout the plains was greater than in any preceding year since 1877. In 1919, on the other hand, the precipitation for the whole season was 5 per cent. above the normal. In the following year another set-back occurred, and the percentage below the normal ranged from 13 in the United Provinces to no less than 83 in Sind. Commenting on these facts and their relationship to the irrigation works already in existence, the report truly says: "But for the works, on millions of acres the crops would never have come to maturity; on millions more, no crops at all could have been sown. . . . It is safe to say that even 20 years ago, many tracts would have suffered from widespread famine which, owing to the facilities now afforded for irrigation, passed through the triennium unscathed."

The review of the triennium period includes a notice of the great Triple Canals project in the Punjab, commenced in 1905 and finally completed in 1917. It consists of 433 miles of main canals and branches and 3010 miles of distributaries, in connexion with which nearly 20,000 miles of watercourses have also been constructed. The total area commanded is 6250 square miles, and it is proposed that 1,675,000 acres shall be irrigated annually. Another notable undertaking referred to is the Divi Island project in the delta of the Kistna river in Madras, which is an attempt to effect irrigation on a large scale by pumping. The installation comprises eight double-cylinder Diesel engines, each of 160 h.p. and driving a centrifugal pump capable of discharging 73 cu. ft. per second on a 12-foot lift. Another engine is to be added shortly.

Among the works now in hand is the Sarda Canal in the United Provinces. The decision to construct this canal finally settles what has probably been the most contentious question in the irrigation of India. The controversy over the matter has lasted for more than half a century. The canal when constructed will irrigate the North-Western districts of Oudh. It will comprise 478 miles of main canals and branches and 3370 miles of distributaries.

Space does not admit of reference to other interesting schemes which are described in the report. Its 222 pages are replete with useful information, which will repay study by those interested in the subject. There is a helpful series of maps and diagrams, many excellent photographs, and some tabular statements showing the financial results of the various irrigation operations throughout India.

BRYSSON CUNNINGHAM.

Scientific Societies in the British Isles.

The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland: a Record of the Work done in Science, Literature, and Art during the Session 1921–22 by numerous Societies and Government Institutions. Compiled from Official Sources. Thirty-ninth Annual Issue. Pp. vii + 374. (London: C. Griffin and Co., Ltd., 1922.) 15*s*. net.

THE appearance once more of Messrs. Charles Griffin's well-known Year-Book affords us an excellent opportunity for taking stock of the position of science in the British Isles. The volume is arranged in the customary style, the various bodies dealt with being divided among fourteen sections according to the nature of their activities. In each section again, there is a further grouping according to the location of the society, institution, or department in London, the Provinces, Scotland, or Ireland. As is only to be expected, most of the more important entries appear in the London groups. In each case, some particulars of the society or institution are given, together with a list of its publications during the year when available.

The total number of societies, research departments, etc., appearing in the 1922 Year-Book exceeds 550, of which it is fair to say that some 480 are concerned, directly or indirectly, with science. The remaining 70 are accounted for by literature, history, and law. In addition to these, there are long lists of local societies and clubs interested in photography, law, or medicine. The distribution of the societies among the various sections is also interesting. Section 1, including bodies dealing with all branches of science, has 75 entries; sections 5 and 7, covering biology and mechanical science respectively, have 90 each; section 13, on archæology, has 63, while section 14, on medicine, has 54 entries apart from the long list of local medical societies.

The various societies and bodies of a similar nature appearing in the Year-Book can be divided fairly sharply into two distinct groups; those which exist for the publication of research, and those which are better described as functioning for the popularisation and spread of knowledge. Of the five hundred or so entries appearing, about one hundred seem to fall into the former group; and of these 14, including the Geological Surveys, the National Physical Laboratory and the Royal Observatory at Greenwich, are supported by Government.

A mass of similarly interesting information exists in this valuable publication, and it may seem ungracious to ask for more. That is, however, the penalty of providing good fare. The sub-title of the volume states that it deals with the year 1921–22, but, for example, it is somewhat late in the day to find information on the British Association brought up only to the Edinburgh meeting of 1921. Further, we would suggest the inclusion of the numerous Research Associations now in existence, while it would add much to the interest of the volume if the number of members of each society could be indicated. A few errors in classifying the entries have been noticed; for example, the Nature-Study Society and the School Nature-Study Union appear in the section headed Psychology. These are, however, minor blemishes in a most valuable publication, which we believe is the only single volume providing an outline survey of the activities of most, if not all, the learned societies of the British Isles.

Aluminium and its Alloys.

(1) *Aluminium and its Alloys.* By Lieut.-Col. C. Grard. Translated by C. M. Phillips and H. W. L. Phillips. Pp. xxiii + 184 + 16 plates. (London: Constable and Co., 1921.) 17*s*. 6*d*. net.

(2) *The Institution of Mechanical Engineers: Eleventh Report to the Alloys Research Committee: on Some Alloys of Aluminium (Light Alloys).* By Dr. W. Rosenhain, S. L. Archbutt, and Dr. D. Hanson. Pp. ii + 256 + 24 plates. (London: Institution of Mechanical Engineers, 1921.) 42*s*.

(1) LIEUT.-COL. GRARD'S book is essentially a treatise on the mechanical properties of aluminium and some of its commercial alloys. The extraction of the metal is described in two pages, and no more detail is given than in an elementary textbook,

although there are several plates showing the power houses of Continental works. The account of the economic position of the industry is also too meagre to be of much use. The valuable part of the book consists of a long series of diagrams of mechanical properties of metal that has been subjected to various thermal and mechanical treatments, and of a corresponding series for certain of the light alloys and for the aluminium bronzes. Tensile strengths are given in metric and British units—an excellent practice.

The lack of any theoretical discussion deprives these sections of much of their value. The ageing of duralumin and similar alloys is a puzzling phenomenon when presented in the form of a mere record of tensile and hardness tests, but becomes comprehensible when considered in the light of microscopical and electrical evidence, and interpreted by means of the theory of solid solutions. Most of the photomicrographs represent the copper-aluminium alloys, commonly called aluminium bronzes. The writer appears to be unaware of the work that has been done in this country, at the National Physical Laboratory and at the Royal School of Mines, which has thrown so much light on the properties of this metal and of the light alloys. The book will be found useful chiefly for reference, when information is sought as to the strength, hardness, cupping quality, etc., of the alloys with which it deals.

(2) The latest report of the Alloys Research Committee is of a very different standard. The recent work carried out at the National Physical Laboratory has led to the preparation of several new alloys of technical importance, the most remarkable being the alloy "Y," which retains its strength and resistance to alternating stresses at elevated temperatures, and is also resistant to corrosion. This alloy contains copper, nickel, and magnesium. The report includes studies of the constitutional diagrams of several of the binary and ternary systems, and an investigation of the causes of age-hardening in aluminium alloys. In this connexion the importance of magnesium silicide as a hardening agent is shown, and the changes of hardness with time and temperature are correlated with the changes in solubility of this compound in the solid solution. The principal casting alloys are found, from measurements extending over long periods, to be stable in dimensions, and there is no doubt that these researches have added to the range of structural materials of high quality available to the engineer, and that a great future lies before light alloys, suitably heat-treated. The photo-micrographs illustrating the volume are remarkably clear, and their beauty will be appreciated by all who have had occasion to prepare these alloys for examination. C. H. D.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr. E. Abderhalden. Abt. V: Methoden zum Studium der Funktionen der einzelnen Organe des tierischen Organismus. Teil 3A, Heft 3, Lieferung 69: Entwicklungsmechanik. Pp. 441–538. 630 marks. Abt. IX: Methoden zur Erforschung der Leistung des tierischen Organismus. Teil 1, Heft 2, Lieferung 71: Allgemeine Methoden. Zoologische allgemeine Methoden. Pp. 97–438. 2160 marks. (Berlin und Wien: Urban und Schwarzenberg, 1922.)

THE number of subjects included in these two parts of Abderhalden's great "Handbuch" precludes, in a short notice such as the present, anything beyond a mention of the chief topics discussed.

Lieferung 69 is devoted to "Entwicklungsmechanik." Here Herbst discusses methods of artificial parthenogenesis; Günther Hertwig, the method of irradiation of the germ-cells by radium and Röntgen rays; Romeis, the technique of investigations on the action of organic extracts, such as muscle, thyroid, and suprarenal extracts, on invertebrates, anuran tadpoles and urodele larvæ; and Braus, the methods of tissue cultures *in vitro*.

Lieferung 71 is more extensive. Przibram is responsible for a chapter of about 90 pages on "Living Material for Biological Investigations." In this he considers the choice of species to be employed in biochemical researches, how and whence to obtain them, their transport and maintenance, the terrarium, the aquarium (including the setting up and aeration of seawater aquaria), and the insectarium. In addition, there is given some account of the application of chemical agencies, the means of obtaining and maintaining various degrees of moisture and of pressure, the application of mechanical agencies, and the alteration of the action of gravity. The subjection of the animals to the action of electricity and of magnetism, the application of heat and of light (measurement of the degrees of light, coloured light, ultra-red and ultra-violet rays), and the isolation and marking of the subjects of the experiments are also dealt with.

Two sections of 40 pages each are devoted to methods of preservation of zoological preparations and to zootomical technique. The methods of reconstruction by means of wax or paper plates are fully explained, while shorter but useful sections deal with the preparation of simple text-figures by the author, and with the production of transparent museum preparations.

Oxidations and Reductions in the Animal Body. By Dr. H. D. Dakin. Second edition. (Monographs on Biochemistry.) Pp. ix+176. (London: Longmans, Green and Co., 1922.) 6*s*. net.

THE complex chemical compounds taken as food by animals are not brought by a single reaction of oxidation to their final states of water, carbon dioxide, and urea. They pass through many intermediate stages, which are of great interest and importance, not only from the purely chemical aspect, but also on account of the fact that many of them play a part in the production of substances which have a profound influence on physiological processes. It is the object of Dr. Dakin's monograph to describe these intermediate stages, and the reader may be satisfied that he will obtain the latest information on the subject. The book is to be highly recommended. It has a good index and a complete bibliography. The section on carbohydrates has been almost entirely rewritten since the previous edition. The description of oxidations which can proceed with the aid of water without free oxygen is of interest in itself, but such processes are of subsidiary importance in the higher animals, since these cannot exist without free oxygen.

With reference to certain views held as to the significance of catalase, the author concludes that there is no evidence that this enzyme has any connexion with oxidation; it may, however, be of use in decomposing excess of hydrogen peroxide, produced in the course of autoxidation, into inactive oxygen. The author points out that he is not concerned with the thermodynamics of the various reactions, nor with the catalytic mechanisms by which they are brought about, although he devotes a few pages to autoxidation and the peroxide systems, and to the important glutathione system of Hopkins. This omission is not to be regarded as a serious defect, because the object of the monograph is of a different kind. It reminds us, however, that there is an urgent need for a monograph dealing with the thermodynamics and general physical chemistry of the oxidation mechanisms of the living organism. W. M. B.

A Treatise on the Integral Calculus: with Applications, Examples, and Problems. By J. Edwards. Vol. 2. Pp. xv+980. (London: Macmillan and Co. Ltd., 1922.) 50*s*. net.

IN the second volume of his large treatise on the integral calculus, Mr. Edwards deals with multiple integrals, gamma functions, Dirichlet integrals, definite integrals in general, contour integration, elliptic functions, the calculus of variations, Fourier series and integrals, mean values and probability, and the harmonic analysis. The volume contains an immense collection of formulæ and questions extracted from examination papers and from the older literature of the subject, which may prove useful for reference to the sophisticated reader, but are more likely to repel than to inspire the students for whom the book appears to be intended.

Mr. Edwards is confessedly out of sympathy with modern tendencies in mathematical education, and thinks that students do not learn enough skill in manipulation. He prefers that they should devote their energies to acquiring proficiency in methods which are in many cases obsolete, rather than that they should obtain the same results by a systematic application of a few powerful general theorems. This tendency is particularly obvious in the chapters on definite integrals and on elliptic functions. In consequence, that residuum of problems for which the older methods are still the most suitable receives rather less than justice. His use of the methods of differentiation and integration under the integral sign, change of the order of integration, etc., is uncritical, and is not likely to conduce to clear thinking on these important subjects. His definition of a function of a complex variable is unsatisfactory, and entirely misses the point in failing to emphasise the crucial importance of the existence of a unique derivative. In the bibliography of the chapters on the calculus of variations he refers the reader to a number of obsolete treatises, but ignores the important modern works of Hadamard and Kneser.

The teacher of to-day may use this work for reference himself, but he will scarcely wish his pupils to make their first acquaintance with the processes of analysis from its pages. E. G. C. POOLE.

Farm Buildings. By W. A. Foster and Deane G. Carter. (Agricultural Engineering Series.) Pp. xv+377. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 15*s*. net.

THE little work under notice is intended to guide the American farmer and agricultural student in designing and constructing farm buildings. It is stated that farm buildings have had their most rapid development in America in the years since 1910. Prior to that one could, and indeed still can, find the early buildings put up by the first settlers, made of logs, if trees were abundant, or of sods or boards if they were not, as happened on the prairies. Now, however, these rough constructions have largely disappeared, or remain only as stores of subsidiary importance, and their place is taken by large new and characteristic-looking structures of steel and concrete. The change is not only one of convenience: it represents a great saving on the farm. It is estimated that at least 100,000,000 dollars is lost annually to American farmers through depreciation of farm machinery due to lack of proper housing; that 200,000,000 dollars are lost annually owing to the consumption of badly stored food by rats; and further, that considerable increases in milk and meat production could be obtained if the animals were better housed.

The authors discuss the best types of barns, stables, cowsheds, pigstyes, etc., and give many illustrations showing how to adapt the design to the available situation or space, and what materials should be used in construction.

The English agricultural student will find the volume of particular interest for its sections on silos, pigstyes, and cattle-sheds, and for a fund of information showing how the American farmer, suffering from even greater shortage of labour than his British confrère, has nevertheless succeeded in putting up buildings of undoubted utility.

British North Borneo: An Account of its History, Resources and Native Tribes. By Owen Rutter. Pp. xvi+404+plates. (London, Bombay, and Sydney: Constable and Co., Ltd., 1922.) 21*s*. net.

ALTHOUGH Sir West Ridgeway, the chairman of the British North Borneo Company, contributes a preface to this volume, it is in no sense an official publication. This will be appreciated by those who are conversant with recent criticisms of the company's methods of administration. The author is both fair and unbiassed.

The story of North Borneo is not without stirring incident. In the last century its coast was infested with pirates, whose extermination was first undertaken seriously in 1845 at the instigation of Rajah Brooke of Sarawak. Their subjugation was completed only in 1879, the year the British North Borneo Company was formed. Of the numerous native risings with which the company has had to deal, the most formidable was that headed by the redoubtable Mat Saleh, who was defeated and killed in 1899.

Mr. Rutter gives a very complete account of the geography and economic resources of the country, of which, however, the greater part is still undeveloped. The native population offers many points of interest to the ethnologist. The Dusuns and Muruts, the up-country agricultural population, are of Indonesian stock. The coastal peoples, Bajau, Illanun, and others, represent an incursion of Malayan stock. The latter are Mahommedans, while the former are pagan. A remarkable feature in the religious beliefs of some of the Dusuns is the cult of the sacred jar, in each of which a small company of relatives has a joint ownership.

Incandescent Lighting. By S. I. Levy. (Pitman's Common Commodities and Industries.) Pp. x+129. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 3*s*. net.

THE author has produced an interesting and well-written book which gives a good historical account of the development of artificial lighting; particular attention being given to incandescent lighting. A chapter is devoted to the growth of the rare earth industry. The dramatic discovery of rich deposits of monazite in the British Empire, and notably at Travancore in India during the War, was a great help to this country; the sands at Travancore contain more than 45 per cent. of monazite. The processes of extracting pure thorium compounds from monazite demand great ingenuity, and they are well described. Descriptions are also given of the recent great improvements in the manufacture of incandescent mantles. The author gives a very fair comparison of the costs of oil, gas, and electric methods of lighting. The average candle-power (formerly called the mean spherical candle-power) should, however, have been taken as the basis of the comparison and not the mean horizontal candle-power.

Lubrication and Lubricants: a Concise Treatment on the Theory and Practice of Lubrication; the Physical, Chemical, and Mechanical Properties and Testing of Liquid and Solid Lubricants; with Notes on Recent Developments and Examples from Practice; for Engineers, Chemists, and Students. By J. H. Hyde. (Pitman's Technical Primers.) Pp. x+114. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 2*s*. 6*d*. net.

ALTHOUGH very uneven, the little book under notice is interesting. The definitions are usually rather carelessly given, if at all. Thus, in the chemical section (which is not very satisfactory) neither the iodine nor the acetyl value is explained, although both are quoted. Langmuir's name is incorrectly spelt throughout the book. The chapter on recent developments is of interest, and deals among other matters with the variation of efficiency with temperature and the effect of adding vegetable to mineral oils. We have previously commented on the very ambitious titles of the small books in this series; the remark applies in the present volume, and any one who expects what he might from the title will be disappointed.

Molybdenum Ores. By Dr. R. H. Rastall. (Imperial Institute: Monographs on Mineral Resources with Special Reference to the British Empire.) Pp. ix+86. (London: J. Murray, 1922.) 5*s*. net.

THE molybdenum minerals, their origin and mining, are dealt with, and an account of the metallurgy of molybdenum is also included in this work. The account of the electrical treatment on p. 5 does not seem complete, as no mention is made of the furnace charge. The sections on the sources of supply appear to be exhaustive, nearly every reported occurrence of molybdenum being mentioned, together with the production, if any. The table on p. 12 indicates that the demands for the metal are limited; the production in 1918 was equivalent to about 800 metric tons of metal; that in 1921 was only 7 tons. The principal use is in the preparation of special steels; a lower amount of molybdenum will replace tungsten in a high-speed tool steel, and a small amount of molybdenum is said to improve a mild structural steel.

History of Chemistry. By Dr. F. P. Venable. Pp. vii+169. (London and Sydney: D. C. Heath and Co., 1922.) 5*s*. net.

DR. VENABLE'S "History of Chemistry" is a second edition of a book that appeared in 1894. A history of chemistry which contains no illustrations or diagrams, and in which formulæ are used only in the few passages where their historical development is under consideration, must be subject to serious limitations and in the nature of things cannot be much more than a sketch. It is not quite clear to the reviewer what type of reader will be attracted by such a sketch; but it is likely that the well-read student of chemistry will find some interest in this brief outline, and may be led by it to follow up the history of his science in some volume in which more details are given.

The Elements of Scientific Psychology. By Prof. Knight Dunlap. Pp. 368. (London: Henry Kimpton, 1922.) 18*s*. net.

THE author has here produced one of the best and most useful of the many text-books now available on psychology. He is a good experimentalist, and is thoroughly alive to the importance of a knowledge of physiology to the psychological student. He shows himself able at the same time to maintain a distinctively psychological point of view. The main faults of the book are that it attempts to cover too much ground, and that occasionally it presents, as text-book material, conclusions which require to be subjected to much further research.

Grundzüge einer Physioklimatologie der Festländer. Von Dr. Wilh. R. Eckardt. Pp. v+123. (Berlin: Gebrüder Borntraeger, 1922.) 4*s*. 6*d*.

DR. ECKARDT has produced a useful little book, which aims at giving an outline, according to the most recent investigations, of the distribution of temperature, pressure, and precipitation in the main land-masses. Particular attention is paid to Europe. There are a number of sketch maps and diagrams, and a short bibliography. The book gives in a convenient and authoritative way information that is not generally accessible in a collected form. It should prove very acceptable to students of geography.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Wegener Hypothesis of Continental Drift.

THE chief value of the discussion on the Wegener hypothesis is that it has given rise to a reconsideration of the problems presented by the configuration and relations of the major features of the earth's surface.

The elaborate structure of theory built up by Dr. Wegener, and so effectively criticised by Mr. Lake (see NATURE, February 17, p. 226), will have few, if any, thorough-going defenders in this country, but some of its leading features cannot be lightly dismissed. Mr. Crook (NATURE, February 24, p. 255) has recalled to our notice the suggestions put forward by Osmond Fisher, and later by W. R. Pickering, that the separation of the moon from the earth, which Sir George Darwin believed to have resulted from tidal action, took place in the region now occupied by the Pacific; that our satellite took with it three quarters of the earth's crust, and that the remaining quarter, from which our continents trace their descent, has since split up into fragments which have drifted apart over the heavier fluid magma below, leaving channels between them, the most important of which is now the Atlantic Ocean. Here we have an interesting approximation to certain of the assumptions of the Wegener hypothesis; but both Osmond Fisher and Pickering, it will be noticed, considered the separation of the continents to be the result of a general drift towards the Pacific. In this they differ from Wegener, who attributes it to a varying lag of the earth's crust relatively to its interior, so that one portion became separated from another.

If the former view is well founded there should be a certain amount of symmetry about an equatorial diameter drawn to the centre of the Pacific from its antipodes in Africa. It is therefore interesting to note that Prof. Sollas in a communication to the Geological Society in 1903 (Q.J.G.S., vol. 59, pp. 184-8) declares that "an axis of terrestrial symmetry" "passes through the middle of Africa on the one side, and the Pacific Ocean on the other," a depression in the Pacific corresponding to a dome in Africa. He is inclined to accept Osmond Fisher's hypothesis, that the Pacific owes its origin to the birth of the moon, and suggests that the African dome represented an unsuccessful attempt on the opposite side of the world to give birth to a second satellite. This symmetry is, it is true, obscured by the east and west folding, which is such a frequent feature in the earth's crust, and is attributed by Wegener to a drift away from the poles towards the equator, but is not improbably the result of a movement from the equatorial region to the poles due to the slowing down of the earth's rotation and consequent decrease of the ellipticity of its figure and of the equatorial protuberance.

Like Mr. Crook, Prof. Sollas follows Suess in believing that the Atlantic owes its origin not to continental movement but to the foundering of the tract which it now occupies. My principal object in writing is to point out that the hypothesis of the drifting apart of North and South America from Europe and Africa is quite consistent with that of a subsidence and submergence of a great part of the ocean area that now separates them; and that the latter is in fact the consequence of the former.

The evidence, based on similarity of lithological characters and fossil contents of the rocks, that South America east of the Andes and the Falkland Islands were once in much closer proximity to Africa, is to my mind conclusive, and scarcely less is that of a former association of a great part of India and of Australia with Africa. There seems, too, every reason to believe that, although masked in places by other tendencies, there has been a general movement of the lighter continental crust or Sial from Africa towards the Pacific. This appears to be a drift from a region of a comparatively low gravity to one of higher gravity.

As we have seen, Wegener and others believe that the earth's crust lags behind the solid core as a result of tidal retardation, and that this lag varies from point to point. If this is the case, the folded mountains that have their roots deep in the earth's interior will, no doubt, have a smaller lag than other portions of the earth's crust, and therefore, as Prof. Joly suggests, a relative movement from west to east. How far such movements are of importance it is at present impossible to say.

Whatever may be the ultimate causes of the relative movement of continents, they can only be effective when they operate in a direction in which the earth's crust does not possess sufficient rigidity to oppose them. We can no longer suppose that there is a fluid substratum to the earth's crust. It is probable that the solid crystallised zone below the oceans is usually fifteen to twenty miles in thickness, and at those depths the enormous pressure of 90 to 120 tons to the inch will give a comparatively high rigidity at the temperature of about 800° C. that may there prevail, even to an uncrystallised magma. Where, however, a great thickness of sediment has accumulated in the neighbourhood of a continent on a sea-bottom, it will—as Dana was the first to point out—by acting as a blanket, cause the temperature of the rocks beneath to rise and become less rigid, especially if they are basic in composition. In this rise of temperature, Prof. Joly believes radioactivity plays an important part. At the same time the area concerned will sink slowly to satisfy the requirements of isostasy, forming a trough parallel to the coast line. If a period of compression in a direction at right angles to the coast supervenes, the rocks will yield to it and the trough will be laterally compressed and deepened while the sedimentary accumulations are thrown into folds. In this way the land masses surrounding the Pacific have been enabled gradually to advance inwards from its circumference, their progress being marked by folded mountain ranges. Yet the Pacific, as a whole, apart from the marginal portions, being comparatively free from sedimentation, has preserved its rigidity and successfully resisted compression.

On the other hand, there seems reason to believe that Africa is in the main the centre of a region of tension, due to the outward drift of continental masses in the circumstances already described. It is obvious that the separation caused by such a movement must involve a deficiency of material in the separating tract, and a loss of stability on the margin of the separated masses. Sometimes the blocks into which they are divided by jointing will fall forward one upon another like a succession of bricks and so give rise to a number of faults dipping away from the rift. Examples of this are seen in Skye and Caithness. More usually the slow subcrustal movement towards the line of fracture will carry the solid crust with it. The result will be a series of faults hading towards the region of tension and with a downthrow in that direction. In North Devon and Cornwall I have shown that there is evidence that there has been a general debacle of the rocks towards the west in Tertiary times. North-west and south-east faults occur every few yards with a considerable hade to the south-west; but the slickensides show that the movement was oblique, partly down the fault planes and partly parallel to the strike of the faults to the north-west, the latter component being the more important, so that the total movement to the west must have been considerable. At the same time there has been a general tilt of the country in that direction. I am given to understand that somewhat similar faulting occurs in the South of Ireland, and, no doubt, it exists elsewhere on the eastern shores of the Atlantic. The total westward movement visible on the land does not amount to more than a few miles, but the downward displacement that accompanied it must have resulted in the submergence of a large area to the west, and the same structures, no doubt, extend still farther in that direction under the sea. In the actual neighbourhood of the rift (to use the convenient term employed by Prof. J. W. Gregory) there may well be a complete absence of the Sial, so that the Sima would be found close below the abysmal deposits of the deep sea, as Wegener supposed to be the case. There is, however, no reason to suppose that the opposite shores of the continents represent the actual margins of the rift, and we cannot expect to find the close correspondence between them which he endeavours unsuccessfully to demonstrate. Submarine plateaus rising in the midst of greater depths may represent portions of Sial submerged between two rifts.

The solution of these problems should be regarded as an urgent task for the immediate future. There is little doubt that further information with regard to the density of rocks below the sea-bottom would result from the systematic measurement of the variation of gravity at sea with concurrent determination of its depth. The new methods that are now available are at once more rapid and more trustworthy than those previously employed, and might well be carried out either by the Navy or the great ocean liners. Valuable information, too, will be yielded by the Eötvös balance with respect to the rocks below the sea in the immediate neighbourhood of the shore.

John W. Evans.

The Function of Mendelian Genes.

In Nature of March 3 there appears a letter from Mr. Julian Huxley on "The Function of Mendelian Genes," in which he criticises a paragraph in a review of mine published in Nature of January 20. As I think that the difference between Mr. Huxley and myself is due to a certain extent to a misunderstanding of my meaning, perhaps you will allow me space to make a brief reply.

Mr. Huxley's main point is that in treating Mendelian genes as measures of pathological damage to the hereditary substance, I forgot that each discovery of a presumably pathological mutant gene implied the existence of an allelomorphic normal gene in the type, and that in this way we were enabled to analyse the hereditary machinery of the type.

The paragraph to which Mr. Huxley alludes was a small item in a review devoted to vitalism. Mr. Huxley and I had a prolonged battle in *Science Progress* last year, and perhaps before long we may have another friendly encounter in the same journal. As he alludes to this contest in a footnote, I may here say that he is incorrect in stating that he forced me to admit that not all mutations were pathological. All I said was that I could not make such a universal statement without examining each case, but I may add that I have yet to meet with the Mendelian mutation which is not pathological. My answer to Mr. Huxley is that of course I recognise the existence of hypothetical allelomorphic normal genes, which taken together make up the hereditary machinery of the type, but I doubt the value of the analysis of this machinery into genes at all. The only analysis of the hereditary complex which seems to me to be at all interesting or fruitful, is its dissociation into the factors out of which it was actually historically built up. I regard this complex as the solidification, so to speak, of the reactions of the race to the varying experiences through which they have gone during past ages. New habits have been superposed on old ones, with accompanying modifications of structure; and when we have unravelled this history completely, we have given as exhaustive an account of the origin of the hereditary machinery as is possible.

The normal "gene" is an imaginary section of this machinery invented to account for the damage which a mutant gene introduces. Mr. Huxley alludes to the existence of multiple allelomorphs as *proving* that the recessive mutant gene is not the mere absence of something which we call the dominant gene. I think that a series of multiple allelomorphs inevitably suggests a graded series of varying degrees of damage, or, as we may phrase it, a series of increasing intensities of defect. Such a series is given by the mutants of the red eye of the wild Drosophila. These are listed as vermilion, scarlet, cherry, pink, eosin, cream, and white! What other plausible explanation can be given of these than the gradual disappearance of the dark red pigment of the normal eye?

One of the mutant genes of Drosophila produces a variation termed "balloon wing." In insects showing this variation the two layers of ectoderm forming the wing are widely divaricated from each other, the space between them being occupied by a bubble of air. Now there is a general consensus of opinion based on palæontology, embryology, and comparative anatomy as to the evolutionary history of insects' wings. They began as slight lateral extensions of the dorsal terga of the thorax, at first in all three segments; but later they were confined to the posterior two segments. In the beginning they served merely as parachute planes to break the fall of the insect when it leaped into the air; later, as they grew longer and flexible, they became capable of independent movement, and so developed into the varied types of wing found at the present day. On what phase, one may ask, of this history of progressive functional evolution does the existence of the balloon wing mutant throw the smallest light?

We are gradually learning to recognise that the body of an animal is built up by the co-operation of the semi-independent growths of a number of tissues and organs which, however, mutually limit and determine the extent of each other's growth. The compromise which is arrived at, is expressed in the normal specific or racial structure of the animal, and may be expressed by the term "regulatory balance." When the race is exposed to new surroundings, the regulatory balance is altered and a new race is evolved. This accounts for the fact noticed by Sturtevant that allied species differ from one another in numbers of minute points affecting all the organs of the body, whereas mutations are characterised by marked differences affecting only one or two organs. Mutations may be defined as pathological disturbances of this regulatory balance; if they are so severe as to produce a noticeable effect on the offspring when introduced by only one parent, they are dominant; if their effects are only apparent when both parents are affected, they are recessive.

Mr. Huxley's comparison of the mutant black mouse to the melanic local races of wild species is unfortunate. The black mouse (which I have often reared) is covered with a fur of so uniform colour as to make it exceptional among mammals. It may be compared to the various melanic sports which occur in other species of mammal, such as the black leopard. I have seen a black individual among a litter of the common Canadian squirrel.

On the other hand, a melanic local race implies a new regulatory balance. As an example of the relation of racial character to the environment, I may mention the common red grouse of Scotland, supposed to be the only species of bird peculiar to Britain. In Europe there is the allied species of willow grouse, differing in having the tips of the primaries white and in turning white in winter. When a Scotch landowner imported the willow grouse he found that in two or three generations they became indistinguishable from the red grouse; and when red grouse were introduced into Norway, they reverted in a few generations to a form indistinguishable from the willow grouse.

E. W. MacBride.

Definitions and Laws of Motion in the "Principia."

In his recent interesting article (Nature, February 17) on the Definitions and Laws of Motion in the "Principia," Sir George Greenhill reopens a very old discussion (Nature, vol. 39, 1888-9). It might have been expected that the lapse of one-third of a century would have been sufficient for reconciliation of the engineer and the physicist. Every scientifically trained engineer knows, as Sir George Greenhill knows, that no confusion is introduced by the employment of a given multiplier or divisor in every term of an equation.

The only new feature now given in the mathematical discussion lies in his equation (1),

$$Wv/g = Ft,$$

in which it is insisted that the g as a divisor *must* be attached to the v and not to the W. But, in the weight problem, this merely makes the equation an identity with W = F; and, if we introduce F as a non-gravitational force, say by the use of a spring-balance, or a column of compressed air, etc., still giving t its old value, we find a different average F, and therefore a different W, at different localities. It is this local variation of W which reveals to the physicist an absence of that aspect of invariance, the existence of which he, as a scientific man, feels compelled to search for. And his search is not in vain; for he finds that, with v, t, and average or actual F (non-gravitational) all constant, W *is* proportional to g, and therefore the attachment of g to W is justified, in his belief, by Nature. In fact, he has come into contact with the *materiae vis insita*.

I have never known any student of engineering who, having first had a normal training in physics, felt compelled, in his engineering studies, to alter his ideas. He knows that his "factor of safety" in constructional details is large enough to cover such variations of g as he meets with in practice. The real quarrel (if it still exists) is only one regarding the use of the word "pound," and the context in the engineer's or the physicist's statement usually prevents confusion, even if it were not the case, as I have always found it to be, that the student of engineering is quite willing to speak, when clearness requires it, of the mass of a pound and the weight of a pound.

I do not agree with Sir George Greenhill that Mach was right in saying that Newton's Def. I. is only a definition of density. I regard it as presuming that the meaning of density is known, so that the definition is really one of the *quantitas materiae*, to which the *materiae vis insita* or *inertia massae* is proportional. It then implies the physical law that inertia is independent of the form of aggregation, and depends, for a specific material, only on the extent of the aggregation. Nor do I agree with him that Newton's use of many different words for the name of the same thing was undesirable. We must remember that Newton was the pioneer, introducing new ideas, and requiring therefore to use every form of phraseology or nomenclature that might help to make them understandable.

Sir George Greenhill disagrees with Tait, and credits him with the honour of introducing innovations. Now Tait was a modest man, and a loyalist towards Newton. He gives the honour to Newton, whose interpreter only he was. The further statements on this point made in Sir George Greenhill's second article do not alter the position.

Tait's wise words (*l.c.*) of a third of a century ago are well worth attending to to-day, apart from electrons. He said ". . . mass is the personal property of a body, one of the invariable things in nature:—and not an accidental property dependent, for its amount and even its very existence, on the momentary surroundings. The letter M has hitherto been used by Newtonians in this sense. If anyone has since attached to it another and different sense, *he* is responsible for the consequent confusion. Would it not be well if Prof. Greenhill, and the School to which he has attached himself, would kindly leave to Newtonians their M, as defined for them by their Master; and (with severely logical consistency) turn it upside down (thus, W) when they wish to embody their own revolutionary definition? No Newtonian will refuse to recognise $Wv^2/2g$ as a correct expression for so much energy:—though he will probably think it both clumsy and complex, and will prefer to write as usual his $Mv^2/2$."

W. Peddie.

University College, Dundee.

In his article under the above title in Nature of February 17, Sir George Greenhill expresses the opinion that it would be worth while to examine the previous state of the theory of dynamics to see what laws were current before the statement as given by Newton. The evidence of Newton on this point is often overlooked, though it is noted by Tait. In the scholium to Corollary VI. on the Third Law of Motion, Newton freely acknowledges the work of his predecessors.

"Hactenus principia tradidi a mathematicis recepta et experientia multiplici confirmata. Per leges duas primas et corollaria duo prima Galilaeus invenit descensum gravium esse in duplicata ratione temporis et motum projectilium fieri in parabola; conspirante experientia, nisi quatenus motus illi per aeris resistentiam aliquantulum retardantur."

In these days of the Fletcher trolley and Atwood's machine it would be interesting to know what were the experiments Newton had in mind as confirming dynamical principles. Mach has pointed out the great achievement of Galileo in arriving at the First Law of Motion, but he does not assign him credit for a knowledge of the Second Law. It is quite apparent from the above quotation that in the time of Newton there existed a tradition that Galileo's teaching of dynamics embodied the Second Law as enunciated in the "Principia." This is borne out by Lagrange in his introduction to the second part of his "Mécanique Analytique," in which he states that the Second Law is contained in the note added by Viviani at the suggestion of Galileo to the "Dialogues of Two New Sciences" (Eng. Trans. Crew and De Salvio, p. 184), deducing that the speeds falling down planes of different inclinations but of the same height are equal. In this note it is assumed as self-evident that the accelerations of a given body are as the forces producing them. This result combined with the fact that all bodies have the same gravitational acceleration corresponds to the form ($F/w=a/g$) recommended for elementary teaching and favoured by Sir George Greenhill.

The acknowledgment which Newton makes to Wren, Wallis, and Huygens for the discovery of the laws of impact is generally known in connexion with his description of his own experiments on impact. His attitude towards these experiments is different from that of the critical exposition of dynamics of to-day, in which the Third Law is placed in the position of honour from which the Second Law is derived by observation or experiment. With Newton, however, the Third Law requires justification, as shown by the conclusion of his description of his experiments on impact, "atque ideo actionem et reactionem esse aequales."

One other extract is worthy of attention. Under Definition III. of *materiae vis insita* Newton remarks, "Per inertiam materiae fit ut corpus omne de statu suo vel quiescendi vel movendi difficulter deturbetur." This objective view of inertia is better adapted for the general qualitative introduction to inertial mass than the innate view consequent on an initial statement of the First Law. This objective view frequently finds expression in elementary text-books, but might receive greater emphasis in view of the electromagnetic theory of inertia, and the initial discrimination between inertial mass and gravitational mass forced on us by the modern theory of relativity. The quantitative definition of mass as a measure of inertia merely interprets "difficulter deturbetur" in terms of acceleration. We may say then, as a preliminary to a more exact definition, mass is a measure of the difficulty of accelerating a body.

The Resonance Theory of Hearing.

I HAVE been reading with great interest various accounts of ingenious models made to illustrate the resonance theory of hearing, but I have been unfortunate enough to miss any clear reference to any structure in the cochlea which could respond on a physical basis to all vibrations which are capable of being appreciated by the human ear, or rather nervous system.

I have before me a pianoforte with a register of seven octaves, containing wires which vary from about 150 cm. in length and more than 0·4 cm. in diameter to wires 10 cm. long and tightly stretched. If the range were continued to the eleven possible octaves the extreme dimensions would be proportionately modified, being lengthened in the one case and shortened in the other. This, I take it, is the best pianoforte manufacturers can do, and that if they could have used shorter or finer wires they would have done so.

Let us turn then to the human cochlea and form some idea of its dimensions relative to such an instrument. It consists of a tube coiled two-and-a-half times, about 35 mm. in length, and varying from 4 mm. to 1 mm. in diameter. The total cubic contents of the cochlea, according to Sir Arthur Keith, are 70 cubic mm. The third canal of the cochlea has a diameter varying from 0·5 mm. to 0·8 mm. The basilar membrane has, according to Keith, a diameter varying from 0·17 mm. to 0·4 mm., with an average area of 13·2 sq. mm.

If the cochlea as a whole be considered, it can be likened in size to a stout silk thread 35 mm. in length. If the third canal of the cochlea alone be considered it can be likened to a silk thread 35 mm. in length, with an average width of 0·5 mm.

How is it possible to imagine structures of this order of magnitude capable of differential resonance to the vibrations of sound? From the ability of the investigators who have been dealing with the problem, I am certain that such an elementary difficulty cannot have escaped them for a moment, but I shall be grateful to any physicist who will throw light on a problem which is as difficult as it is fascinating. If the presence of anatomical resonators capable of responding to vibrations of the varying length indicated can be demonstrated, the resonance theory can well be considered. Otherwise it must be abandoned.

JAMES W. BARRETT.

105 Collins Street, Melbourne,
January 5.

SIR JAMES BARRETT'S letter expresses a difficulty in the way of acceptance of the resonance theory which I believe to be more generally felt than perhaps any other, namely, the difficulty of conceiving that a structure so minute as the cochlea, which may be compared in size to a small split-pea, can contain a series of resonators capable of responding to some 4000 separate tones extending over about 11 octaves. When we compare the suite of strings of a piano, which will respond only to 85 separate tones in 7 octaves, although they occupy with their case a space of 10 to 15 cubic feet, and weigh several hundredweight, the whole conception seems indeed bizarre and absurd.

This difficulty may be considered under two headings:

(1) How to account for the minuteness of the scale.

(2) How it is possible to have such a wide range of tones within so small a cubic space.

(1) *Scale.*—If it be granted that we are to look for our resonating elements in the transverse fibres of the basilar membrane, the scale of the cochlea will be determined by the length of these fibres. This again will be determined by the formula

$$\text{Number of vibrations per sec.} = \frac{1}{2 \times \text{length of string}} \sqrt{\frac{\text{tension in dynes}}{\text{mass of unit length of string}}}$$

or

$$n = \frac{1}{2l}\sqrt{\frac{t}{m}}.$$

It is obvious that in this formula, for any particular value of n, l can be given any value we choose by assigning suitable values to t and m. Theoretically, there is no reason why the resonators should not be 10 or even 1000 times smaller than they are in the cochlea. Practically, the limits of what is possible are set by the strength, fineness, and flexibility of the materials available. The particular factor which renders this extraordinary reduction of scale possible is, that in the cochlea the factor m is large out of all proportions with what obtains in any of our stringed instruments. This result is attained by the beautiful mechanical device of loading the strings each with a definite mass of cochlear fluid.

(2) *Differentiation.*—The fibres of the basilar membrane are differentiated for length, tension, and mass just as are the piano strings. Accepting Keith's measurements, the differentiation for length is sufficient to account for 1½ octaves; that for mass (as determined by the "fluid load") for about 2½ octaves. The remaining six to seven octaves of the audible scale must be due to variations of tension, as applied by the spiral ligament. This means a proportion of something like 1 to 5000 or 10,000 between

the lowest and highest tension. In a good section of the cochlea the spiral ligament will be seen to exhibit a progressive differentiation in bulk and closeness of texture not inconsistent with such extremes of tension. Further, the upper and lower limit of tension can be roughly calculated, and the resulting values are possible ones. The highest is only about a quarter of the breaking strain of tendinous structures of the same fineness.

Helmholtz recognised quite clearly the bearing of the "load" on the basilar fibres in rendering possible the small scale of the cochlea, though he failed to realise the *progressive differentiation* of the fibres for mass thereby effected. He says, "That such short strings should be capable of corresponding with such deep tones must be explained by their being loaded in the basilar membrane with all kind of solid formations; the fluid of both galleries in the cochlea must also be considered as weighting the membrane, because it cannot move without a kind of wave motion in that fluid" (second English edition translated by A. J. Ellis, p. 146).

No doubt if Helmholtz had known the anatomical structure of the spiral ligament, which was described by Albert Gray in 1900, the whole mechanism of the cochlea would have been clear to him.

Stirling's Theorem.

In starting from $dn=1$ and then making dn infinitesimal, Dr. Satterly's demonstration in Nature of February 17, p. 220, is scarcely convincing, and the error introduced by this step is represented in his answer by the absence of the factor $1/\sqrt{n}$ or the term $\frac{1}{2}\log n$, neither of which is entirely negligible when n is large. I suggest the following adaptation of his proof, which avoids, I think, the inconsistency referred to above.

$$\operatorname{Log} \overline{n+1} - \log n = \log (n+1).$$

$\therefore$ by Taylor's theorem

$$(D + D^2/\underline{2} + \ldots)\log n = \log n + 1/n + \ldots$$

all terms on the right being negligible after the first when n is large.

$$\therefore \log n = \frac{1}{D + D^2/\underline{2} + \ldots}\log n$$

$$= \frac{1}{D}(1 - D/2 + kD^2 +)\log n$$

$$= \int \log n\, dn - \tfrac{1}{2}\log n + k/n + \ldots$$

$$= n\log n - n - \tfrac{1}{2}\log n + C.$$

The constant can readily be evaluated by the use of Wallis's expression for π.

Echinoderm Larvæ and their Bearing on Classification.

Though loth to prolong this discussion, I wish, in fairness to Dr. Mortensen and myself, to say that I did not accuse Dr. Mortensen of regarding the echinoderm metamorphosis as a case of metagenesis. What I did write in Nature for December 8, 1921, seems to agree entirely with Dr. Mortensen's statement on March 10, 1923—a statement accepted by Prof. MacBride.

Against Dr. Mortensen's view, that the sucking disc of Brachiolaria is a relatively recent acquisition, Prof. MacBride would cite me as in substantial agreement with himself (Nature, January 13). That agreement extends to our common belief that all groups of echinoderms have passed through a fixed stage at some time in their ancestral history. On the precise relation of that fixed stage to the adult structure in the case of the starfish, we do not agree. Dr. Mortensen, it appears, is one of those who support my particular view. The sucking disc of the Brachiolaria has certainly been regarded by me, as by Prof. MacBride, as confirmatory evidence of the general theory. But if, as Dr. Mortensen now suggests, it be a secondary development, the theory does not necessarily fall, and Dr. Mortensen distinctly says that it does not. On the other hand, assuming Dr. Mortensen to be correct in his assertion that the forms with such a larva are only the more specialised, the sucker may none the less perpetuate an ancestral structure.

Until the geological history of the starfishes has been more fully worked out along the lines followed by Dr. W. K. Spencer, it is safer to express no opinion on the classification of the forms now living.

Constitution of Black Maketu Sand.

We have made a careful chemical and X-ray analysis of the black sand from Maketu, N.Z., from which Dr. Alexander Scott believed he had isolated the oxide of a new element. We are able to confirm Prof. Bohr's conclusion that no new element is present.

Starting with 1000 grams of the sand we obtained 1·7 grams of material free from silica, and insoluble in sulphuric acid. Fusion with sodium bisulphate did not bring this into solution, thus confirming Dr. Scott's experience, but it is interesting to note that on fusion with *potassium* bisulphate the residue went into solution completely, and was found by both chemical and X-ray analysis to consist of about equal parts of iron and aluminium. Prof. Bohr found an appreciable quantity of titanium in the residue, while we found no more than a trace; but as our residue was only 0·2 per cent of the ore our extraction was probably more complete.

Scientific Periodicals for Czech Students.

I have recently received a most earnest and pathetic request from a group of Czech students at the University of Prague asking me whether this Society could send them an English scientific periodical. Unfortunately we have no funds for this, but it has struck me that it might be possible for some of your subscribers, who perhaps do not have their copies of Nature bound, to let me have them to send to these students. It would be a really kind and charitable act, and would be helpful in promoting the good feeling between ourselves and the Czecho-Slovaks, which is so useful at the present time.

If the papers were to be sent from London, I could arrange to call for them at stated times, so that no trouble of packing or postage would be involved.

The Egyptian World in the Time of Tutankhamen.

By Dr. H. R. HALL.

THE name of Tutankhamen, king of Egypt, whose reign may with comparative certainty be placed in the decade 1360–1350 B.C., is now a household word, and is probably known to many who have never heard of Thothmes or Rameses. The discovery of his tomb at Thebes by Lord Carnarvon and Mr. Howard Carter, with its wealth of funerary furniture and the magnificent state which probably enshrines the actual body of the king, has made Tutankhamen familiar to all; so that, at any rate for the time, we regard him as the typical Egyptian pharaoh of his age. But, as a matter of fact, he was an ephemeral and undistinguished monarch personally, and his short reign is only remarkable for one fact, the return of Egypt to the polytheistic faith of her forefathers after the short episode of the Disk-worshipping heresy of his father-in-law, Akhenaten, the artist, poet, and pacificist, one of the most extraordinary figures of the ancient world.

Akhenaten is the outstanding figure of his century, but he, again, is not the typical great king of his time: it is his father, Amanhatpe or Amenhotep III., the Memnon of the Greeks, who can rightly claim that position. Akhenaten was too strange and unconventional a figure. Tutankhamen began by following the heresy of his father-in-law, but in his day the reaction came, and the great god Amen of Thebes, king of the gods and head of the imperial pantheon, returned to his own. It is probably on this account that Tutankhamen was buried in the magnificent splendour that we see: Amen-Ra and his triumphant priests saw to it that the returned prodigal received fitting burial, with all the provision that the old religion could give him to ensure his dignity and well-being in the next world.

It is at the moment of his return to the national religion's fold that we survey the state of the world as known to the Egyptians, for to go further afield would bear us into endless paths of speculation. Egypt and Mesopotamia give us the only known chronological bases for real history at this time; to go outside their world, into the Bronze Age of Western Europe, for example, would be to cast loose from the control of known dates and events and to speculate merely as to the probable growth of civilisation, not to write history.

What was the world like outside Egypt, as known to the Egyptians, in Tutankhamen's day?

About 1580 B.C. the Syrian and Canaanite invaders who had dominated Egypt for at least two centuries, the Hyksos or Shepherd-Kings, had been expelled by force, and the Egyptians, filled with the spirit of *revanche*, had in their turn imposed their rule on the lands of their oppressors. The raids of the earlier kings of the XVIIIth Dynasty, which now occupied the throne of Thebes, had crystallised under Thutmases, or Thothmes, III. into a settled policy of conquest and empire, and Amenhotep III. was the undisputed ruler of Syria, Palestine, and Phœnicia.

These countries were regarded by the kings of Babylon and Assyria as the rightful domains of the king of Egypt, their peoples as his subjects. He was their lord in peace and war. Egyptian residents and generals controlled the native princes. The Egyptian frontier ran from the Amanus and north of the Aleppan district to the Euphrates near Carchemish, and thence down the river for some distance, till it turned off and ceased in the undefined wastes of the desert, reappearing at the head of the gulf of Akabah, in the land of Edom. The great historical cities of Syria, Aleppo, Carchemish, Damascus, and Jerusalem; the Phœnician cities of the coast from Arvad in the north, past Byblos, of old an Egyptian centre, Tyre, and Sidon to Akko in the south; the towns of the Philistine coast, from Dor to Gaza; had already existed for centuries. But though the Phœnicians were there, the Philistines were not yet in the land which afterwards bore their name, Palestine. They did not arrive in Canaan till nearly two centuries later.

Outside the Egyptian border to the west, in the days of Amenhotep III., the ancient kingdom of Babylonia existed in august but somewhat faded and inert majesty, as old as Egypt and as proud, but weak and querulous, trusting to the power of old renown as her protection against attack rather than to warlike prowess. Officially she now bore the name of Karduniyash, an appellation given her by the kings of her foreign Kassite dynasty, a race of conquerors, probably of Indo-European origin, who had come from beyond the Zagros some four centuries before.

North of her, on the Tigris, was Assyria, also an ancient power, but younger; Babylonian in culture, but more purely Semitic in race; and rejecting the claim to suzerainty which Babylon sought to impose on her. To the west of Assyria was the ill-defined kingdom of Mitanni, the land of Northern Mesopotamia between the Khabūr, the Euphrates, and the mountains of Diarbekir, inhabited by an intrusive race of uncertain origin ruled by kings probably, like the Kassites, of Aryan origin.

Farther west, beyond Taurus, was the confederation of tribes of the Anatolian Hittites, who owed allegiance to an overlord, the "Sun" of Khatti, reigning in central Anatolia, at a city represented by the modern Boghàz Köi, east of the Halys. The ancient Semitic population of Cappodocia no longer existed, having been destroyed or expelled by the Hittites.

Hittite tribes had already crossed the Taurus, inhabited the districts of Aleppo and Carchemish, and had even pushed outposts down as far south as Palestine, where they lived under Egyptian rule, side by side with the Canaanites and with Aryans from Mitanni.

South of the Anatolian Hittites was Cilicia, inhabited by a kindred race, of whose culture we know little, but that it owed much, probably, both to the Hittite and to the Syrian.

The island of Cyprus, the people of which also were racially related to the Anatolians, probably, had recently been conquered by Ægean tribes from Rhodes and Greece itself, who brought with them the Mycenæan culture, now beginning in Greece to take the place of the Minoan civilisation of Crete from which it was derived. The Minoan civilisation was now eclipsed on account of the collapse of the dominion of Knossos, which had sent ambassadors to Egypt in the days of Thothmes III.

This was, leaving out of account the Sudan in the south and the wild Libyan tribes to the west, the world as known to the Egyptians. Of Italy, they probably had as yet no knowledge.

Towards the end of the reign of Amenhotep III. a revolution broke out in Syria and Palestine. Shubbiluliuma or Suppilulius, king of the Hittites, a monarch full of guile, aspired to oust Egypt from the control of Syria and to destroy Mitanni. He found tools ready to his hand in certain discontented and rebellious Amorite princes of the Lebanon and in the Phœnicians of Arvad, and stirred up strife. Amenhotep quelled the revolt for a time, but it broke out again, and when his extraordinary son, Akhenaten, ascended the throne, the whole country seethed with turmoil.

The new king was interested only in his project of reforming the Egyptian religion; he was a man of art and of peace, and for the first time in history, perhaps, a great king refused to go forth to war, and allowed his dominions to fall away from him.

Palestine and Syria were in chaos. Wandering tribes, among them those Khabiri who have been credibly identified with the Hebrews, overran the land, the Hittite princes of the south revolted, and with them certain chiefs of Aryan (? Mitannian) origin who also had settled there under the Egyptian dominion. The Canaanite chiefs and Phœnician princes who remained faithful were gradually borne down in the absence of help from Egypt, and at the end of Akhenaten's reign the whole country had fallen away from the king.

In Tutankhamen's day the great prince Huy may represent himself on the walls of his tomb, as he does, bringing Semitic chiefs to offer tribute to his majesty, but we see that this can have been but a farce: the king's writ ran no farther than the coast of the Shephelah, probably. In the north the Amorites had but exchanged one master for another, for they now became the vassals of the Hittites, albeit under a looser control than that of Egypt. The Hittite control of Syria continued unchallenged till the days of Seti I. and Rameses II., fifty years later, when Egypt essayed to reimpose her yoke on the Semites. Long wars ensued, waged directly by Egypt against the Hittites, until about 1279 B.C. a peace of exhaustion was concluded between the protagonists, a peace of which we have the full protocol, signed and sealed by the Great King of Egypt and the Great King of Khatti, couched in diplomatic and legal phraseology that might have issued from a modern chancellery. It was a compromise: of her old Asiatic dominion Egypt retained only Palestine; Syria fell to the Hittites and remained theirs till, eighty years later, the invasion of the Philistines and their seafaring allies from the North overthrew the Hittite kingdom and tore Palestine itself from Egypt.

Tutankhamen, then, was confronted across his attenuated frontier by a far more formidable foe than the Babylonian could ever be. Mitanni was gone—destroyed by Shubbiluliuma after all help from Egypt had proved vain. Assyria, trusting in the prowess of her soldiers, kept her independence of both Babylon and Khatti; Shubbiluliuma seems prudently to have let her be. Her king, Ashur-uballit, was a long-lived and probably a politic as well as a doughty ruler. Somewhat later, in the time of Rameses II., Shalmaneser, king of Assyria, was a much more powerful monarch than the Babylonian Kadashman-turgu, and it was partly in apprehension of his power, probably, that Rameses and Khattusilis, the Hittite ruler, finally compromised their differences.

The collision of different national civilisations at this time produced none of the mutual approximations that might have been expected. Only Egypt began to show signs, more accentuated later, of Semitic influence in her culture. Babylon, however, shows no signs of Egyptian influence, the Hittites perhaps a little, the Mycenæans more. But there is no landslide in any direction anywhere. Each people remained faithful to its traditions. There were colonies of Mycenæan artists, as of Semitic and even Hittite craftsmen in Egypt. But though the Egyptians prized and used Greek products, we find no direct imitation of Minoan art even in the free and untrammelled Egyptian art of Akhenaten's time, though the works of the Minoan artists must have appealed to the realistic and truth-loving king. There is no trace of Minoan or of Mesopotamian influence yet in any of the objects of Egyptian art discovered in Tutankhamen's tomb of which photographs have been published: the weird heads, for example, of one of the gilded couches that have been thought to be Mesopotamian in aspect are merely heads of the Egyptian goddess Thoueris in her fierce and typhonic character. We should, in fact, expect Mesopotamian influence less than Minoan or even Hittite. The Thoueris-head was adapted by the Minoans for the heads of their water-demons.

Such, in brief survey, are the main characteristics of the outer world known to Tutankhamen and his people, and of Egypt's relations with it.

Recent Advances in Photographic Theory.[1]

By Dr. C. E. K. Mees.

The study of the physico-chemical relations on which depend the form in which a precipitate is produced has been developed by a number of workers in recent years, and its application to the precipitation of silver halide has been studied by Sheppard and Trivelli. In his earlier work Trivelli made a large number of photomicrographs of emulsions taken from standard photographic plates and films, one of which is reproduced in Fig. 1. It will be seen that the silver bromide grains, of which the emulsion is composed, are of very varied sizes, there being present a large number of small grains, down to the limit of those visible with a microscope, and a smaller number of large grains, including some of very much greater area than the smallest grains present. The largest grains are all polygons, with angles of 60° and 120°. There is a tendency to round off the corners and edges of the small grains, so that the smallest grains appear to be more or less spherical.

[1] Communication No. 165 from the Research Laboratory of the Eastman Kodak Company. From a lecture delivered before the Franklin Institute of Philadelphia on December 7, 1922.

A study of these small spherical grains by R. B. Wilsey, however, using the methods of X-ray crystal analysis, shows that even the smallest grains are still definitely crystalline and have the same structure as the large grains, the crystalline form being a cubic lattice.

So long ago as 1915 it was realised that the distribution of the different sizes of grains in an emulsion might play a very important part in determining the characteristics of that emulsion. The problem was to measure the distribution of the grains; that is, the number of grains of a given size which occurred in an emulsion and the variation of the number with the size of the grain. This problem has often arisen in scientific work. It has been studied in connexion with suspensions of all kinds. Various indirect methods of attacking the problem have been suggested. It is possible to get determinations by settling the emulsion, taking advantage of the fact that the larger particles will settle most rapidly according to Stokes's law, but the direct method is, clearly, to spread out

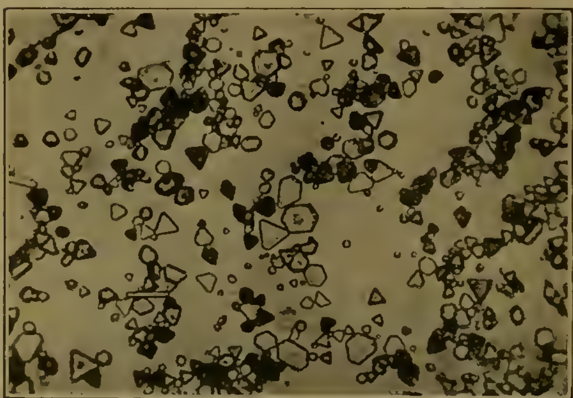

FIG. 1.

a thin layer of the emulsion and to count the different sizes of grains occurring in it. Trivelli photomicrographed a thinly coated emulsion at an enlargement of 2500 diameters, enlarged the negatives to 10,000 diameters, outlined all the grains of these enlargements, and then planimetered the grains and obtained tables showing the areas of the different grains present, at least a thousand grains being counted for each emulsion. Sheppard and Wightman obtained the same results by the use of the camera lucida instead of photomicrography. From these tables curves were obtained showing the relation between the size of grains and the number present for several standard emulsions. Fig. 2 shows the results for the portrait film and slow-lantern emulsions. It will be seen that the curve shows a distribution of sizes of grain which corresponds approximately to a probability curve, the maximum number of particles being of a diameter of approximately 0·5 μ, the particles both smaller and larger than this being fewer, until we have very few particles indeed of larger size than 2·7 μ and also few of smaller size than 0·2 μ. On this small side no particles can be measured less than 0·2 μ, because this is the limit of the resolving power of the microscope.

It is probable, however, that curves showing diameters will not be of real value, because the controlling factor will not be the diameter of the particles, but their projective area, as shown in Fig. 3.

Svedberg investigated systematically the relation between the size and sensitiveness of grains in photographic emulsions. He prepared emulsions so thinly

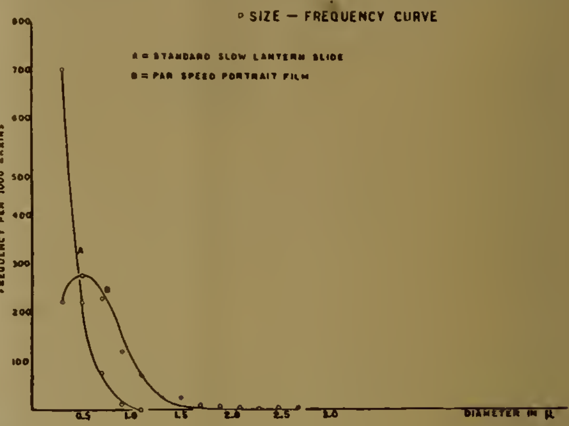

FIG. 2.

coated that the grains were all in single layers, and counted the grains of different sizes by classifying them into four classes. The emulsions were then exposed and developed, and the developed silver removed, the remaining grains, representing those which had not been made developable by the action of light, being counted. In this way curves could be obtained showing the sensitiveness of the grains of each class, and it was found, as might be expected, that the larger grains were much more sensitive than the smaller grains.

Svedberg next assumed that the product of the light action in the halide grain—that is, the substance of the latent image—consists of small centres distributed

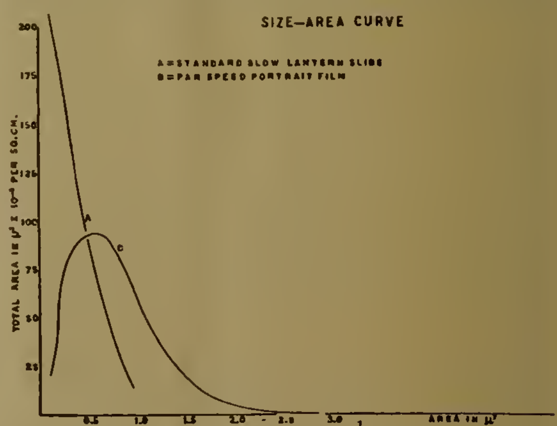

FIG. 3.

through the grain or through the light-affected part of the grain, and that these centres are distributed according to the laws of chance. If a plate be developed for a very short time the grains show these centres as small black spots upon them. This was shown by Hodgson as early as 1917 (Fig. 4).

Not only did Svedberg demonstrate the existence of these centres, but he also made plain their relation to the silver bromide grains by photographing the grains before development by deep red light, then developing for a short time and removing the undeveloped halide. On the plate there are then left small dots, and comparisons with the first plate showed these to correspond with the silver halide grains originally present.

Svedberg has shown that the number of centres produced in this way by initial development increases with the exposure in accordance with the usual photographic laws, and it might be assumed that the discovery of these centres produced during development is a proof of discreteness in the action of light upon the grain, and that they must result from a structure in the silver bromide grains existing either before exposure or produced during exposure, and corresponding, for example, to spots of sensitiveness. While the evidence for this seems very great, it must be remembered that we know nothing about these centres until development takes place, and that even if the whole grain were equally affected by the action of light and changed to the same extent, we should still expect development to take place first at some local spot corresponding to slight surface differences in the grain. A sheet of metal immersed in acid, for example, will not be attacked uniformly all over the surface. Because of the impurities, action will start at individual points.

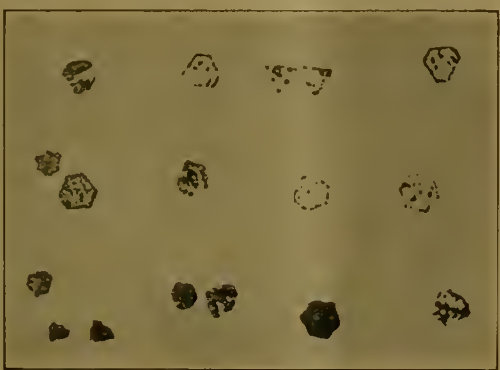

Fig. 4.

In a very important paper, Toy has given measurements showing that the number of nuclei produced on initial development are proportional to the number of grains which become developable on complete development, and that the larger grains not only have more nuclei on account of their size, but that these nuclei are also more sensitive to light than those in the smaller grains, the sensitivity of a grain being the sensitivity of its most sensitive nucleus. Svedberg considers that the number of developable centres per unit area of grain surface is a measure of the light sensitivity of the silver halide of the emulsion. From Toy's work it would seem to be doubtful whether we can speak of the light sensitivity of the halide itself in terms of the nucleus theory, since this will vary with the size of the grain.

Recently, a number of phenomena have been observed which are very difficult to explain by the use of the classical wave theory of light, and it seems not unlikely that it may be necessary to turn to a theory having some analogy to the corpuscular theory. As a first step towards this, Max Planck suggested his now well-known quantum hypothesis, according to which an atom radiating energy liberates it in discrete quanta, the amount of energy corresponding to each quantum being a constant multiplied by the frequency of the light. Bohr adopted Rutherford's theory of the structure of the atom, considering the atom to consist of a nucleus containing an electron carrying a positive charge of electricity, and to be surrounded by one or more electrons carrying a negative charge, the electrons revolving about the positive nucleus itself. He imagined that the electrons revolve without radiating, but that when an electron suffers some violent shock it gives up energy, and this energy is radiated and has the value of Planck's quantum. Thus, if an electron, by the sudden impact of another electron, for example, is thrown out of an atom and is attracted back to its place by the nucleus, then, as it falls back, it will send out a pulse of energy, and it will be seen at once that, if light is produced by such a behaviour of electrons, it is inherently probable that it will be radiated in pulses rather than continuously. Since, according to Bohr, the frequency of the vibration emitted is exactly proportional to the energy which the electron releases, Planck's quantum condition is fulfilled, and we have the famous equation,

$$Ve = h\nu,$$

where V is the voltage acting on the electron charge e, ν is the frequency, and h is Planck's constant.

In an X-ray tube the discharge of electricity is in the form of a stream of corpuscles travelling with a very high velocity, which depends upon the voltage of the electric current applied to the tube. When these corpuscles strike the target their energy is radiated in the form of X-rays, and we know that these X-rays partake very closely of the nature of light, except that the length of the waves is about one-thousandth of those of light, or, what is the same thing, their frequency is a thousand times as great. It is to this that they owe their great penetrating power.

On the classical wave theory of light, then, we should imagine that an X-ray tube having its target bombarded by the stream of corpuscles produced by the current would emit waves of X-rays spreading into space, just as waves of light are imagined to spread from a source; but now comes a great difficulty. When these X-ray waves travelling out pass through a gas and are absorbed, they cause the molecules of the gas to emit electrons, and these electrons are emitted with almost exactly the same velocity as the electrons in the tube which produced the X-rays themselves. The extraordinary nature of this phenomenon is well illustrated by Sir William Bragg in a recent article. He takes as an analogy the dropping of a log of wood into the sea from a height of one hundred feet. A wave radiates away from where it falls; the wave spreads; its energy is more and more widely distributed; the ripples die away; at a short distance, a few hundred yards, perhaps, the effect will apparently disappear. If the water were perfectly free from viscosity, and there were no other causes to fritter away the energy of the waves, they would travel indefinitely, always diminishing in their height. Now, at some point, say a thousand miles away, these now microscopic ripples encounter a wooden ship. We should expect that they would produce no effect, especially as they may have passed many other ships without having affected them, but, for some reason, as these tiny ripples reach the ship, a plank of the same weight as the log is hurled out of the ship to a height of exactly one hundred feet, and the whole energy which was originally supplied by the log falling into the water is concentrated upon the ejection of the plank. It will be seen at once how inadequate the wave theory is to account for this phenomenon. Similar difficulties occur in connexion with photo-electricity or the liberation of electrons under the influence of light.

The method by which a photographic emulsion adds up light during a long exposure has always been a great problem when it is considered from the point of view of the classical wave theory. If we accept the idea that the grains of silver halide in an emulsion are exposed to a continuous flood of light from a distant star, for example, then each grain must be imagined to be integrating light until it has received enough to make it developable. Since the exposure required in astronomical photography is frequently very long, we must consider that the grains continue to integrate the light for many hours, and it is difficult to imagine any mechanism which would enable them to do this. The difficulty is enhanced by the fact that even a very brief exposure continues to produce an effect after an interruption of a long period, so that if all the grains have been affected by the first exposure, they must be capable of storing energy quite insufficient to make them developable and to hold this energy for a long period, and then resume its accumulation at the level where the interruption occurs. In the same way, when we study the exposure of the individual grains, even if we could imagine some mechanism by which the grains could store up the energy falling upon them until they became developable, we should expect that all the grains of the same size would become developable at the same time, unless, indeed, we assume the process of exposure to be autocatalytic in nature. When grains are examined under the microscope, however, some of them are found to have been affected before others. If we imagine that they all have become exposed to a uniform flood of light, we must consider that these grains differ in sensitiveness among themselves, and that the possibility of change on exposure, so that they become developable, is due to the presence of a sensitiser. This may be either concentrated unequally in the different grains or may form centres of sensitiveness similar to those supposed to exist by Svedberg and other workers in the field, who think that the centres found at the beginning of development are the origin of sensitiveness, and are present from the time of making the emulsion.

If we had no prior knowledge of the wave theory of light, however, it is clear that the simplest explanation of the sensitiveness of different grains would be that, instead of a continuous flow of light in the form of waves on to sensitive films, the light was falling upon it as a rain of projectiles, and that these projectiles made developable any grains that they hit, the grains that were missed not being developable, but being hit later if they continued to be exposed to the radiation. Naturally, the bigger the grains the more likely are they to be hit, so that a calculation can be made of the relation between the size and the percentage number of grains which will become developable after a given exposure.

Silberstein suggests that the projectiles, rather than being called "corpuscles," which gives the idea that they are round, should be called "light darts," and should be imagined to consist of a long train of waves of very small diameter travelling with the velocity of light.

It is obvious that this theory of light darts would meet the difficulties which are offered by the phenomena of X-rays and photo-electricity to the idea of a continuous wave front, while not excluding the possibility of the formation of interference and diffraction effects. At first sight it would seem to offer a solution of the problem of the integration of exposure by the silver halide grains of the emulsion, since we might assume that, instead of a grain integrating energy falling upon it until it had received enough to make it developable, it was not affected at all until struck by a quantum of light, and then became developable completely. If this was so, however, we should expect that the amount of energy necessary to make a grain developable would be, on the average, one quantum, and at most a few quanta, more than one being necessary because of the chance that a fresh grain would not be struck by every "light dart" falling upon the emulsion, some falling between the grains and others striking grains which were already developable.

In some work which has just been started in our laboratory we are getting results from which I think we may conclude as a preliminary statement that, for high-speed emulsions, several hundred quanta of violet light are necessary per grain in order to make the grain developable. If this is confirmed, the light dart hypothesis would seem to be scarcely sufficient by itself to explain the integration of energy by the emulsion, and we are thrown back on to the idea of differential sensitiveness among the grains, or of spots of limited area on the grains, so that of the hundreds of quanta striking a grain only one may be considered to be operative, the rest falling upon the insensitive portions of the grain. Suppose that the fraction of a grain which is sensitive is ϵ, and this consists of an average of $\bar{K}$ spots of ω area, then

$$\bar{K}\omega = \epsilon a.$$

Now, if a grain has no spots, it will be quite insensitive and will not be developable, no matter how long it is exposed, so that the value of $\bar{K}$ and ω can be determined experimentally by counting the grains left over after a very prolonged exposure.

In any case, a question of great importance in connexion with the latent image is the amount of energy required to make the silver halide developable. If the new determinations show that several hundred quanta of violet light per grain are necessary, then a revision of ideas relating to the latent image itself will follow, as compared with those ideas derived from the belief that the energy available is only one quantum per grain, in which case it is clear that the latent image must depend upon a change occurring in a single atom of silver or halogen, since the only work we can imagine one quantum capable of doing is to release a single electron from an atom. If several hundred quanta per grain are available, then it is clear that not one atom of silver per grain may be affected, but that several hundred atoms may be changed, and that an appreciable, though very small, amount of chemical decomposition may be effected by the energy available.

More important still, quantitative differences in the amount of latent image present in a grain become possible. If only one quantum per grain is available, a grain is either exposed or not exposed, but if energy corresponding to an amount of several hundred quanta is used, we might imagine that a grain could become partly exposed, so that, for example, it might be developable by a developer of high reduction potential but not by one of lower potential. Moreover, grains might clearly be of different degrees of sensitiveness—that is, they might require different amounts of energy to make them developable—and the whole idea of quantitative differences in sensitiveness and exposure, which is so difficult if we imagine one quantum of energy per grain to be sufficient to produce a complete change in the grain which will make it developable, becomes perfectly intelligible. On the other hand, the division of the sensitive area into a number of small sensitive spots, which accords with the ideas both of Silberstein and those of other workers such as Svedberg who have located sensitiveness in "centres," would still enable us to retain the idea that a single quantum of energy is sufficient for exposure if it reaches one sensitive spot.

Obituary.

Dr. James Gow.

THE lamented death on February 16 of Dr. James Gow, formerly headmaster of Westminster School, and author of "A Short History of Greek Mathematics," calls for notice in NATURE. Educated at King's College School, Gow went to Trinity College, Cambridge, in 1871, and was 3rd Classic and Chancellor's classical medallist in 1875. He was elected fellow of Trinity in 1876, the year in which it was observed as a curiosity that the four fellows of Trinity then elected all had monosyllabic names and mustered no more than fifteen letters between them: Cox, Hicks, Lord, Gow. Three of them, including Gow, rowed for the historic Second Trinity Boat Club, now extinct.

Gow's mind was alert, quick, and versatile; he could have succeeded at almost anything he undertook. The son of an artist, he had himself decided talent in the same direction; he was, as an undergraduate, devoted to music. But his main work was in classics, and even there his interests were very varied. His fellowship dissertation was on the origin of grammatical gender; he edited the Odes and Epodes and the Satires of Horace; and he produced one of the most useful books ever written for schoolboys, a "Companion to School Classics"—a pioneer work which gave a lead to more ambitious and bulky handbooks since issued from the University Presses and elsewhere.

The "Short History of Greek Mathematics" is another proof of Gow's versatility. His original intention was to write a history of the city of Alexandria. He contemplated a chapter in that work which should deal with the mathematical school from Euclid to Diophantus. But this project led him insensibly to more general mathematical topics, such as the development of numeral systems, Egyptian arithmetic, Greek calculation and Greek theory of numbers, with the result that the material accumulated became too extensive for a chapter in a more general history, and he decided to make Greek mathematics the subject of a separate work. Such a book was very much wanted; here, too, he was breaking new ground. There were three recent and important German works by Bretschneider, Hankel, and Moritz Cantor, but no book in English at all comprehensive. The undertaking was the more arduous in that Gow had made no special study of mathematics since his schooldays, and it is no small proficiency in mathematics that is required for the compilation of such a history. The work proved a little uneven owing to the fact that the arithmetical portion was written on a scale too large to allow of the history of geometry being treated with equal fulness if the whole work was to be in a reasonable compass; and Gow realised that with "a history like this . . . the utility will no doubt vary as the brevity" (p. 145).

The best possible test of a book is, perhaps, the impression that it makes upon a reader who takes it up thirty or forty years after its publication. This book stands the test well. It is true that the mass of the material that must be included appeared to Gow at times to be overwhelming: for he speaks in his preface of the labour having often been dreary. But this certainly would not be gathered from the finished work, which is from first to last anything but dreary. Many things in it have necessarily been superseded as the result of subsequent researches, but the book can still be read with the same pleasure as it aroused on its first appearance.

T. L. H.

Rev. William Wilks.

HORTICULTURE is the poorer by the sudden death on March 2 of the Rev. William Wilks, vicar of Shirley, Croydon, 1879–1912. The son of Dr. G. F. Wilks, born at Ashford, Kent, on October 19, 1843, William Wilks was educated at Clapham and Pembroke College, Cambridge, where he took his degree in 1864. He was intended to follow his father's profession, but forsaking that course, after studying at Wells, he took orders, and was appointed curate of Croydon in 1866. The rest of his life, except for his annual holiday on the Continent, or latterly in Scotland, was spent in that neighbourhood, and when in 1912 he resigned his vicarage he went to live and garden next door at the "Wilderness" which he had built, and where he died.

There is no need to speak here of Mr. Wilks's parish work—the concourse of local people at his funeral at Shirley showed how it was appreciated—but rather of his work in and for horticulture. For nearly sixty years he was intimately connected with the Royal Horticultural Society. His grandfather and father had both taken a keen interest in gardening at Charing and Ashford, and the curate of Charing, the Rev. J. Dix, for some time chairman of the Royal Horticultural Society's Floral Committee, was an intimate friend of his youth. His love of Nature and gardening was still further fostered by his education under Prof. Pritchard, and by his vicar at Croydon, Canon Hodgson, so that when he went to Shirley he was well equipped to follow his bent in the large garden of the vicarage. He became a member of the Royal Horticultural Society's Floral Committee about 1880, and at the great reconstruction of the Society in 1888 he was appointed honorary secretary. He filled the post of secretary until 1920, when he retired and was elected to the council.

In 1888 the Society was in very low water; its liabilities were great, its finances low; it had less a horticultural than a social policy; it seemed doomed to early wreck, after weathering the storms of eighty-four years. With its new secretary, Sir Trevor Lawrence, Sir Daniel Morris, Sir William Thiselton-Dyer, Sir Harry Veitch, Mr. George Paul, Sir Michael Foster, Dr. Masters, and others, a determined return to a horticultural course was made, and in steering that course William Wilks took a leading part. He was a great secretary. A man of wide vision, a fine judge of men, courteous, tactful, able to bend men and things to the policy the new council had determined upon, cautious but ready to seize opportunity, loyal to his council and inspiring loyalty, ready with encouragement, kindly in restraining excess of zeal, an able organiser, under him the Society progressed from potential bankruptcy to financial prosperity, from a membership of about 1000 to more than 16,000, to the possession of its fine hall and offices, its Journal (which he edited from 1888 to 1906), its great garden at Wisley, with its school of horticulture and the development of research into gardening problems which all along he had seen to be essential to sound progress, and which, as soon as finance permitted, he fostered with all his power. His aim all through was to further British horticulture in its widest sense, and for his work for the Society, until it had been placed upon a sound financial footing, he took not even the most modest remuneration. The Society to-day is a monument to his work.

The gardens of the world, large and small, even into the Arctic regions, are the richer for Mr. Wilks's own gardening efforts, for from an aberrant field-poppy he raised the wonderful strain of Shirley poppies, and freely distributed seed every year to all comers. As with his poppies and foxgloves, he deemed no pains too great to spend upon the selection and increase of beautiful hardy things, and no pleasure to exceed that derived from sharing his beautiful things with others. His writings in the Journal were of these things. In his quiet garden he grew the choicest of hardy fruits, for he was a pomologist of no mean order, and he cared for and studied there the plants and animals it contained and attracted, with all the love of a true naturalist.

Sir Ernest Clarke.

Sir Ernest Clarke, a man of singular ability, and gifted in many different directions, was perhaps best known as secretary of the Royal Agricultural Society of England from 1887 to 1905.

Himself a Suffolk man, born at Bury St. Edmunds in 1856, Clarke had a special interest in East Anglia, and contributed largely to the enrichment of its archæology, literature, and folklore. In especial he showed himself an adept in unearthing the truth and in demolishing many of the erroneous statements that had found their way into past records. This same power marked his treatment of agricultural history and literature when, as the first Gilbey lecturer, he gave, in 1896, his series of lectures at the University of Cambridge, from which, in 1894, he had received the degree of Hon. M.A. Indeed, one may say that he was the first serious student of this subject since Arthur Young.

After service in the Local Government Board, and then as assistant secretary in the Share and Loan Department of the Stock Exchange, Clarke was selected in 1887, out of 106 candidates, to be secretary of the Royal Agricultural Society of England in succession to the late H. M. Jenkins. As secretary of the Society he distinguished himself by his great activity and powers of organisation. He had great ideals as to the position which such a Society as his should occupy as the leading authority both at home and abroad, and such he worked constantly to make it. For more than eighteen years he acted in this capacity, receiving the honour of knighthood in 1898. Later, however, came the disastrous days (1903–6) arising from the decision of the Council to abandon the peripatetic Shows and to have a permanent Showground at Park Royal, and this resulted in Clarke's resignation in 1905. He then returned to the City, and was associated, to the close of his active career, with various commercial enterprises.

Following on the death of his wife in 1918, Clarke was struck down with a paralytic seizure, and for the last four years of his life was unable to leave his room. But he retained to the end the clearness of intellect, and the interest in all around him, that had marked his active days.

Though he could never be called an "agriculturist," Clarke contributed largely to its history and literature, and the Journal of the R.A.S.E. contains many admirable reports of his, chiefly memoirs of noted agriculturists, such as Philip Pusey, Sir James Caird, the Duke of Richmond, etc., besides the "History of the Board of Agriculture," "Agriculture and the House of Russell," etc. To the series of King's Classics he contributed, in 1903, a new edition of "The Chronicles of Jocelin of Brakelond," an account of monastic life in the days of Abbot Samson, and he made many other contributions to archæological, historical, and folklore societies. He was an original member of the "Confrères"; and one of the "Sette of Odd Volumes"—being the "yeoman" in that body, and president in 1898. He was also a past-president of the Chartered Institute of Secretaries. Clarke was, in addition, a gifted musician, a brilliant conversationalist, and a man of much reading and wide general knowledge.

J. A. Voelcker.

Current Topics and Events.

By Clause 9 of the "Fees (Increase) Bill," the Government proposes to confer upon the Trustees of the British Museum a power which they have never sought and which, we are certain, they do not desire—a power to charge fees for admission to the Exhibition Galleries both at Bloomsbury and South Kensington. Of course, if the power is granted by Parliament, the Treasury will take good care that the Trustees exercise it. The precise proposal is to charge a fee of 6*d*. on Monday, Tuesday, Thursday, and Friday. How much better will anyone be for this? The probable receipts seem to us to be ridiculously overestimated by the Geddes Committee, since they only allow for a reduction in the number of visitors of less than one-half. Speculation on such a matter is rather idle. We know only that a charge of 6*d*. on three week-days at the Victoria and Albert Museum brought an average yearly return of 1000*l*. Against a possible income of, say, 1200*l*., have to be set expenditure on the installation of turnstiles and a considerable diminution in the receipts from the sale of publications, which has been greatly extended of late in both sections of the Museum. But this sort of haggling is beside the mark. The condemnation of this retrograde proposal depends on no nicely calculated less and more, but on the disservice that will thereby be done to popular education in its widest and highest sense. The nation will lose and the Museum will lose, for we may be sure that gifts in money and in kind will not flow so readily to a half-closed establishment. It seems, too, as though the Government would lose whatever popular support it now possesses. The British Museum has become in a very real and living sense a national possession, and the nation will refuse to be robbed of its free enjoyment.

The reluctance to discuss the monetary value of their services is a tradition which dies hard among the brain-workers in this country and abroad, and is in large measure responsible for the unenviable position of many salaried workers during and since the War. In the legal and medical professions, which occupy a legalised privileged position and are further safeguarded by the needs and the attitude of the community, professional unity is possible and demands for improved conditions of service and better remuneration for these classes are generally successful. The success of medical men in this country in particular has given an impetus to other professional workers towards combination, and various organisations now exist having for their avowed object the improvement of the economic position of the professional classes. In France, after approaching first the Confédération Générale du Travail, and later the General Association of Employees—both organisations of manual workers—the brain-workers have decided to form their own independent Confédération des Travailleurs Intellectuels. It is already in a position to exert considerable influence in the Chamber of Deputies and the Senate, and its success has provoked the creation of similar bodies in several other European countries. In this country there is an organisation, the National Federation of Professional Technical, Administrative, and Supervisory Workers, founded in 1920, having similar aims. Hitherto it has not been able to obtain the support of the medical, legal, engineering, teaching, or scientific associations. These may join the federation later, but, in the first instance, they will probably find it better to form their own federation. The time is certainly opportune for a movement to be made in this direction.

The sum of 1,000,000*l*. provided for agricultural research and education under the Corn Production Acts (Repeal) Act, 1921, has now been provisionally allocated for the furtherance of various schemes, and the details are outlined in the current issue of the Journal of the Ministry of Agriculture. The suggested grants cover a wide field, and in several cases are intended to be supplemented by certain moneys raised by the institutions benefiting therefrom. Dairying, silver-leaf research, and fruit growing are to be aided in various centres by the provision of building and maintenance funds, and a scheme is under consideration for the establishment of an Animal Pathology Research Station at Cambridge University. Support is also being given to the National Poultry Institute scheme, with special provision for research in various directions, for commercial experiments and for higher instruction in poultry keeping. On the educational side additions are being made to the research scholarships and travelling fellowships, the advisory services are to be completed and strengthened, while a considerable sum has been provisionally allocated for grants in aid of capital expenditure at university departments of agricultural colleges. County agricultural education will benefit in a similar way. The approximate allocation under the above headings is as follows: Research and Advisory work, 465,000*l*.; Higher Agricultural Education, 84,000*l*.; County Agricultural Education, 170,000*l*.; Scholarships for the sons and daughters of Agricultural workers, 117,000*l*.; Miscellaneous Schemes, 74,000*l*. Some re-arrangement of the above sums may, however, prove to be necessary as the schemes are more fully investigated and begin to be worked out.

The Retail Pharmacists' Union, in a recent announcement with regard to the subject of the accurate dispensing of medicines, describes the training required for the profession of pharmacy. The announcement is, however, headed with the words "The Chemist," and this has led Mr. A. Chaston Chapman, president of the Institute of Chemistry, to suggest again that the time has come for the pharmacist to relinquish the use of the term "chemist" in favour of those who definitely practise chemistry. Mr. Chapman points out that "the Institute of Chemistry, as the representative chartered professional body of chemists, numbers upwards of 4000 fellows and associates, whose qualification demands a four years' university course, or the equivalent, and the majority of whom are engaged in the many branches of industry on which the science has a bearing. In other countries the strict equivalent of the word 'chemist' signifies, as it should, one who professes chemistry, and not in any case the pharmacist, druggist, or dispenser of medicines."

THE summer meeting of the Institution of Electrical Engineers will be held at Manchester and Liverpool on June 5-8. Visits have been arranged to important electrical works in the locality.

A CONFERENCE of the Women's Engineering Society will be held at the University of Birmingham on April 11-14. Particulars can be obtained from the general secretary, Miss C. Haslett, 26 George Street, Hanover Square, London, W.1.

IN the new edition of Zittel's "Grundzüge der Paläontologie," lately published, Profs. Broili and Schlosser refer to the tooth of the supposed ape-man, Hesperopithecus, from Nebraska, U.S.A., as being a problematical specimen. They state that it may perhaps be the first milk-molar of a primitive horse.

THE Geological Department of the British Museum (Natural History) has just acquired the palæobotanical collection of Dr. Dukinfield H. Scott. It comprises more than 3000 microscope slides, chiefly of British Carboniferous plants, on which most of Dr. Scott's own researches have been based. It is a direct continuation of the Williamson collection which was acquired by the Museum in 1896.

IT is stated in the *Chemical Age* of March 10, that at the annual meetings of the American Chemical Society to be held next month, Prof. F. G. Donnan and Principal J. C. Irvine will be among the British delegates. The subjects for discussion will include motor fuels, the history of coal tar dyes, insecticides and fungicides, and the chemistry of cellulose.

IT is stated in a Press dispatch from Oklahoma City appearing in *Science*, that an amendment prohibiting the purchase of books or copyrights teaching the theory of the evolution of the human race was inserted in the State Free Text Book Bill which passed the lower house of the legislature on February 21. Only one dissenting vote was cast against the anti-Darwinian section.

THE Mueller medal and fund have been awarded to Mr. J. H. Maiden, Government Botanist of New South Wales and director of the Botanic Gardens, Sydney, in recognition of his botanical work. The medal was founded in memory of the late Baron von Mueller, Government Botanist of Victoria, and is awarded at each meeting of the Australasian Association for the Advancement of Science, which, in 1923, sat at Wellington, New Zealand. It has been awarded previously for botany, zoology, geology, and ethnology.

PROF. HORACE LAMB, late professor of mathematics in the Owens College and University of Manchester; Lord Meston of Agra and Dunottar, formerly Lieut.-Governor of the United Provinces of Agra and Oudh; and Mr. G. Gilbert Scott, Royal Academician, have been elected members of the Athenæum Club under the provisions of Rule II. of the club, which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

A SYMPOSIUM and general discussion on alloy resistance to corrosion will be held at the Department of Applied Science of the University, Sheffield, on Friday, April 13. The meeting is being organised jointly by the Faraday Society, the Sheffield section of the Institute of Metals, and the Manchester Metallurgical Society, and the scope of the discussion will include the new non-corrodible, non-ferrous alloys, such as stainless nickel silver and the nickel chromium alloys, as well as stainless iron and steel. A general introduction to the discussion will be given by Prof. C. H. Desch. Further particulars may be obtained from Mr. G. R. Bolsover, Brown-Firth Research Laboratory, Princess Street, Sheffield, or from the secretary of the Faraday Society, 10 Essex Street, Strand, London, W.C.2.

FARMERS' Clubs, Chambers of Agriculture, and other bodies or individuals interested in agriculture are invited to visit the headquarters of the National Institute of Agricultural Botany, Huntingdon Road, Cambridge, during the coming summer. They will be able to see trials of new varieties of wheat and barley in progress on the trial ground, and a collection of different varieties of various farm crops growing in the field. The buildings of the Institute will also be open to inspection; these include the Official Seed Testing Station for England and Wales, where testing of seeds is always being carried out. The most interesting period for inspecting the Institute is from June to August, and all who wish to take advantage of the invitation should communicate with the director of the Institute, Mr. W. H. Parker.

MR. T. SHEPPARD, the energetic Curator of the Hull Municipal Museum, by the publication of a series of pamphlets describing the collections in his charge, has done much to popularise the study of science and archæology, and has given an example to those in charge of similar collections. A recent publication is a list of the specimens of natural history, antiquities, and applied art. The museum dates from 1823, and the specimens collected by the Literary and Philosophical Society finally passed to the Hull Municipal Museum in 1902. Since then the collections, particularly of local scientific objects and antiquities, have been largely extended, and the museum now holds a high place among similar institutions. Its value has been largely increased by Mr. Sheppard's continuous efforts to bring the collections to the notice not only of local visitors but of those from a distance.

THE British Non-Ferrous Metals Research Association has adopted a somewhat novel way of communicating the results of its recent investigations to its members. Lectures are arranged at one or more centres to which only the members of the Association itself are admitted. Two objects are served in this manner: first, early confidential communication of the results of the research is assured to those who have given it financial support; and secondly, the investigator gets into close and immediate contact with that section of the industry chiefly interested in his work. This private lecture system has so far been applied to two subjects. Dr. W. Rosenhain has reported on the investigation on copper, and the influence upon its properties of small quantities of impurities, which is being carried out for the Association by Dr. D. Hanson and others at the National Physical Laboratory; and Mr. E. A. Bolton has described work on the cause and prevention of red stains on brass, which he is carrying out at the University of Birmingham.

THE Staff Association of the British Museum (Natural History) held, on March 8 in the Museum Board Room, a scientific reunion which was attended by about seventy members and visitors. Round the room were arranged a large number of interesting objects. Among the geological exhibits may be specially mentioned the portions of the fossilised skeleton of Baluchitherium, a gigantic perissodactyl ungulate from Baluchistan, recently described by Mr. Foster-Cooper. This species is closely related to the rhinoceros, and is the largest land mammal at present known. An exhibit of the fauna of submarine cables attracted much attention, particularly the portion of a cable, brought up from a depth of 750 fathoms, showing a shark's tooth broken off in the wire sheath. A series of mounted specimens of animals acquired by the aid of the Rowland Ward bequest were shown. The flattened crystal of diamond and the well-formed ruby crystal, both formerly in the John Ruskin collection, were on view. It being the intention of the Trustees to adapt a bay in the Central Hall for the purpose of displaying the South African elephant in its natural surroundings, Capt. Guy Dollman had prepared a model on a one-eighth scale to demonstrate the effect; artistically designed and executed and efficiently lighted, this model was exhibited, and proved very popular. Messrs. C. Baker demonstrated their most recent microscopes and accessories.

AN International Air Congress will be held in London on June 25-30 this year under the presidency of the Duke of York, when opportunities will be provided for the reading and discussion of papers on every aspect of air matters. The Congress will be divided into four groups (each again divided into sub-groups) which will meet simultaneously. Group A will deal with methods of research, aerodynamics, controllability, structural methods, materials, and alighting gear. Group B is subdivided into sections on fuels and lubricants, motive-power plant, air-screws. Group C will discuss air transport and navigation problems, and in Group D airship design and construction will be discussed. Further particulars can be obtained from Lt.-Col. W. Lockwood Marsh, General Secretary, International Air Congress, London, 1923, c/o The Royal Aeronautical Society, 7 Albemarle Street, London, W.1, England.

UNDER the title of "The Claim of Antiquity," the Councils of the Societies for the Promotion of Hellenic and Roman Studies and of the Classical Association have issued an interesting bibliography of books for those who know neither Latin nor Greek. It provides a list of the best books, originals or translations, dealing with the general subject of classical literature; the most important authors; philosophy and religion; history; geography; science; art and archæology; and social life, giving the prices of each publication. The volumes published in the excellent Loeb Library have done much to spread the knowledge of classical literature among those who are ignorant of or have forgotten their classical learning, and the present publication, compiled by experts, will do much to advance the objects which these classical societies have in view. It will furnish an acceptable addition to all school libraries.

THE Secretary for Mines invites applications for a research post under the Safety in Mines Research Board. Candidates must possess high general scientific qualifications and experience in engineering, with, if possible, a knowledge of coal mining. The person appointed will be required to advise on questions of research on the safety problems of coal mining, to prepare programmes of research, and to organise and superintend research work. Applications for the position must reach the Under-Secretary for Mines, Mines Department, Dean Stanley Street, S.W.1, by, at latest, April 30.

THE tricentenary of the birth of Blaise Pascal occurs on June 19, and preparations have been made for celebrations in France on July 8-9. The President of the French Republic will attend the meetings, the chief of which will be a commemoration gathering, to be addressed by the Minister for Public Instruction and other members of the French Academy. There will also be a meeting at the summit of the Puy de Dôme, when a member of the Academy of Sciences will speak on the famous experiment carried out there, at Pascal's suggestion, of observing the barometric height at the summit and comparing it with that at the base of the mountain. A difference of three inches in the height of the mercury column was observed, giving Pascal justification for his conclusion that the column of mercury in the barometer is supported by the pressure of the atmosphere.

AT the annual general meeting of the Geological Society held on February 16, the following officers and members of council were elected:—*President*: Prof. A. C. Seward. *Vice-Presidents*: Dr. J. W. Evans, Mr. R. D. Oldham, Dr. H. H. Thomas, and Prof. W. W. Watts. *Secretaries*: Mr. W. C. Smith and Mr. J. A. Douglas. *Foreign Secretary*: Sir Archibald Geikie. *Treasurer*: Mr. R. S. Herries. *Other members of council*: Dr. C. W. Andrews, Mr. F. N. Ashcroft, Prof. P. G. H. Boswell, Prof. W. S. Boulton, Dr. Gertrude L. Elles, Dr. J. S. Flett, Dr. F. H. Hatch, Prof. O. T. Jones, Mr. W. B. R. King, Dr. W. D. Lang, Prof. S. H. Reynolds, Sir Aubrey Strahan, Sir Jethro Teall, and Mr. H. Woods.

At the general meeting of the Asiatic Society of Bengal on February 7, the following officers and members of council were elected :—*President* : Dr. N. Annandale. *Vice-Presidents* : Sir Asutosh Mukhopadhyaya, Mr. Mahamahopadhyaya Haraprasad Shastri, Dr. J. Coggin Brown, and Lieut.-Col. J. D. W. Megaw. *General Secretary* : Mr. Johan van Manen. *Treasurer* : Prof. C. V. Raman. *Philological Secretary* : Dr. D. R. Bhandarkar. *Joint Philological Secretary* : Mr. S. Khuda Bukhsh. *Natural History Secretaries* : (*Biology*) Dr. P. J. Bruhl and (*Physical Science*) Mr. P. C. Mahalanobis. *Anthropological Secretary* : Ramaprasad Chanda. *Medical Secretary* : Major R. Knowles. *Honorary Librarian* : Dr. T. O. D. Dunn. *Honorary Numismatist* : Mr. C. J. Brown. *Other Members of the Council* : Dr. Upendra Nath Brahmachari, Mr. Kumar Sarat Kumar Roy, Sir R. N. Mookerjee, Mr. Pramatha Nath Banerjee, and Dr. W. A. K. Christie.

The Australian National Research Council is making preparations for holding an important Pan-Pacific Science Congress in Australia in August next. The sympathy and support of the Commonwealth Government has been secured, and it is expected and sincerely hoped that scientific workers representing all the countries bordering, or having interests in, the Pacific will send representatives to this congress. Already the Commonwealth Government has issued cordial invitations to the countries concerned, inviting them to join in making this congress a success. It is well known that in international matters the Pacific must play an important part in the near future, and a fuller knowledge of its peoples, its products, and its natural phenomena, from a scientific point of view, is urgently desirable. The first Pan-Pacific Science Congress was held at Honolulu in August 1920, and it is proposed that the Australian meeting should be opened at Melbourne on August 13, 1923, and on August 23 be transferred to Sydney, and terminate there on September 3. Arrangements are being made to deal with the following subjects : (*a*) agriculture and veterinary science ; (*b*) anthropology and ethnology ; (*c*) biology, including botany, entomology, zoology ; (*d*) geography and oceanography ; (*e*) geology ; (*f*) hygiene and climatology ; and (*g*) physics, including geodesy, geophysics, radiotelegraphy, and seismology. Among the office-bearers are the following : Australian National Research Council—Sir David Orme Masson, The University, Melbourne (*President*) ; R. H. Cambage, Royal Society, Sydney (*Hon. Secretary and Treasurer*) ; Prof. A. C. D. Rivett, The University, Melbourne (*Joint Hon. Secretary*). Pan-Pacific Committee — Sir Edgeworth David, The University, Sydney (*Chairman*) ; E. C. Andrews, Mines Department, Sydney (*Hon. Secretary*).

The projection of light in optical lanterns and kinema apparatus, discussed before the Illuminating Engineering Society on February 20, is a problem that evidently deserves more study. It appears from the results of recent tests that in most optical lanterns only about six per cent. of the light furnished by the source is usefully applied on the screen. In the kinema projector, with its small aperture and shutter, the percentage is even less. Moreover, even the light reaching the screen is not all profitably used, for much of it is reflected on to walls and ceilings and never reaches the eyes of the audience. Some attempts to utilise gas-filled incandescent lamps in place of arcs were also described, and the results of investigations seem fairly promising. Other items of interest in the discussion included a demonstration by Major Adrian Klein of his new colour-projector, and a three-phase alternating current arc shown by Mr. J. Eck. From a scientific point of view the Klein projector is particularly interesting, as the colours are not produced by means of filters, but by the aid of a train of prisms. When these spectrum colours are projected on painted scenery very vivid changes are produced.

The annual report of the Meteorological Committee to the Air Council for the year ended March 31, 1922, has recently been issued. It is the sixty-seventh year of the Meteorological Office and the second report submitted to the Air Council instead of to the Treasury as formerly. The meteorological service now comprises many meteorological organisations which in past years have been carried on separately and independently. In all, the total staff aimed at to complete the organisation is 375. Retrenchments undertaken, however, by all Government departments have led to some modified programmes for the meteorological service, and reductions in the staff have taken place instead of the wished-for augmentation. The total whole-time staff of the Meteorological Office and its out-stations has changed during the year from 266 to 261. The year has seen a great increase in the interest of seamen in weather information, and the report mentions that it is greatly to be regretted that this increased interest should coincide with conditions which have made it imperative to reduce rather than to extend the activities of the Marine Division. Data now being received are gradually getting back to pre-war conditions, when it was equally felt that excessive observations were costly. For forecasting work the report states that, although certain messages are still received by cable, almost all European countries have now adopted the use of wireless telegraphy, and it is growing evident that it will shortly be possible to dispense entirely with the exchange of messages by cable. Much information is given relative to aviation and the upper air, new developments entailing much organisation. The British Rainfall Organization is now controlled by the Meteorological Office, and among many other branches of work may be mentioned atmospheric pollution and the oversight of attached and subsidiary observatories.

The Journal of the British Science Guild for February contains a summary of the proceedings at the annual dinner in May last year. In proposing the toast of the British Science Guild, Sir Arthur

Mayo-Robson mentioned the interesting fact that Lord Curzon had distributed 500 prospectuses of the Guild's "Catalogue of British Scientific and Technical Books" to His Majesty's Consuls abroad. He also pointed out the thirst for scientific knowledge that was developing in various parts of the Empire he had recently visited, where fruitful opportunities for the work of the Guild appear to exist. Among others who spoke, Mr. H. G. Wells pleaded for a wide view of science, which should not be regarded as a monopoly for any nation, though they naturally hoped that the British Empire would make a worthy contribution to the general store of knowledge. The late Mr. F. W. Sanderson, whose genius as a schoolmaster is the subject of appreciatory editorial reference, emphasised the value of scientific methods in schools in developing a desire among boys to "get at the truth." He added that a catalogue of the British Scientific Products Exhibition had been of great interest to the boys. Other contributions to the journal cover wide ground. There are extracts from recent articles in the press on the Guild's national appeal. Prof. Flinders Petrie and Admiral Ballard have contributions on "The Science of Sailing." Dr. J. A. Harker deals with "The Fixation of Nitrogen," Mr. A. P. M. Fleming with "Radio-Telephony," and Mr. Leon Gaster with "Illuminating Engineering." Dr. R. S. Clay furnishes a note on "The British Pianoforte Industry." As usual the Journal also contains a series of readable notes illustrating the application of science in daily life.

Commander Hilton Young makes to us the suggestion that insects may be able to appreciate the proximity of a solid body by detecting the pressure differences which would be set up by air currents impinging on the latter. He asks whether this possibility has been examined, and a distinguished naturalist to whom we submitted the inquiry states that various entomologists have referred vaguely to insects being affected by changes of air pressure. Forel speaks of the sensitiveness of insects to slight movements in the air and to slight vibrations in his "Le Monde social des fourmis," vol. 2 (1922), and Folsom in his "Entomology" (1906) suggests that the sensillum placodeum may be affected by air pressure. Another work by Forel, "Sensations des insectes" (1886), and Berlese's "Gli Insetti," should also be consulted.

The firm of Mr. C. Baker, of 244 High Holborn, London, W.C.1, has issued the January number (No. 77) of its well-known classified list of second-hand instruments and scientific works. The catalogue is arranged in sections, each confined to a specific class of apparatus, and contains a number of useful items. Those in need of physical apparatus, microscopes, cameras, etc., would do well to consult this list.

Many students to whom Dr. A. Holmes's "Petrographic Methods and Calculations" is of interest and value will be glad to learn that the work, hitherto available only in one volume, will in future be obtainable in three separate parts dealing respectively with Specific Gravity, Separation and Determination of Minerals, and Detrital Sediments; Thin Sections; and Chemical Analyses and their Interpretation. The publishers are Messrs. Thomas Murby and Co., 1 Fleet Lane, E.C.4.

Messrs. H. K. Lewis and Co., Ltd., 28 Gower Place, London, W.C.1, are now issuing monthly lists of additions to their scientific and technical circulating library, instead of quarterly lists as previously. Every effort is made to meet the needs of workers in laboratories connected with the manufacturing industries, and the latest works on scientific research on all kinds of raw material and manufacturing processes are freely added to the library. These may also be seen in the technical books department, or a list will be sent to any inquirer.

With the assistance of prominent specialists in many parts of the world, Mr. Jerome Alexander, 50 East 41st Street, New York City, is preparing a comprehensive book on "Colloid Chemistry: Theoretical and Applied." British contributors include Dr. E. F. Armstrong, Prof. H. Bassett, Sir W. M. Bayliss, Dr. E. F. Burton, Mr. W. B. Hardy, Prof. F. G. Donnan, Mr. F. E. Lloyd, and Dr. A. E. Dunstan. Mr. Alexander invites any one who may have information of interest on experimental facts and practical applications of colloid chemical principles to send him a brief statement for inclusion in the book.

Messrs. Longmans and Co. have in the press "Friction," by Dr. T. E. Stanton, of the National Physical Laboratory, in which work the attempt is made to deal concisely with the whole subject of the mechanical friction which exists between bodies in contact, solid, liquid, or gaseous, under forces producing, or tending to produce, their relative motion. Attention is given to friction due to the flow of fluids over solid surfaces, with special reference to the dimensional theory; also to the lubrication theories of Osborne Reynolds, Michell, and Sommerfeld, and to the recent researches at the National Physical Laboratory on lubrication. The section on solid friction includes the theories of rolling friction and of the stability of structures on soft earth, together with the results of some modern experiments on materials used for brake blocks, and the final chapter is devoted to a discussion of Reynolds's theory of the relation between the heat transmitted to solid surfaces by fluids flowing over them and the frictional resistance of the surfaces due to the flow, and an examination of the experimental data bearing on this theory.

The spring announcement list of Messrs. Chapman and Hall, Ltd., contains many books of scientific interest, among which are: "Vital Factors of Foods: Vitamins and Nutrition," by C. Ellis and Dr. Annie Louise Macleod, aiming at furnishing all essential facts regarding vitamins, and at bringing together the literature on the subject; "Perfumes and Cosmetics: with Special Reference to Synthetics," by W. A. Poucher; and "Electric Lift Equipment for Modern Buildings," by R. Grierson, which deals with the selection, installation, operation, and maintenance of modern electric passenger, goods, and service lifts. The same publishers will also issue a new and completely revised edition of "Electrical Engineering Practice," by J. W. Meares and R. E. Neale, in two volumes, the first of which will be ready shortly.

Research Items.

THE PYRAMIDS OF MEROE AND THE CANDACES OF ETHIOPIA.—A new chapter in the history of Egypt has been disclosed by the work of the Harvard-Boston Expedition in the Sudan, of which a summary is given by Prof. G. A. Reisner in *Sudan Notes and Records*, vol. v. No. 4. About 900 B.C. a Libyan family occupied Napata and seized the roads from Egypt to the mines and the southern markets. Ethiopia was then a province of Egypt, and for the first time they made it an independent kingdom and Egypt one of its provinces. They were not negroes, but of a mixed brown race which had previously lived in Ethiopia. For about 80 years they ruled 3000 miles of the Nile valley, and they were finally driven back to Ethiopia, ruling at Napata and building their pyramids there. In the end the branch settled at Meroe became the more powerful, and this kingdom persisted uninterrupted for another 650 years. Thus it has fallen to the lot of the expedition to trace the history of this family through more than twelve centuries.

HEAD-HUNTING IN PAPUA.—In the March issue of *Man* Mr. E. B. Riley gives an account of the method of preparing the heads of enemies practised at the village of Dorro in Papua. After the flesh and brains are removed a piece of rattan cane is fixed to the bottom of the mummified skull to take the place of the lower jaw and to act as a support for the packing of the neck. It was difficult to ascertain why the lower jaw is not replaced. The explanation seems to be that they prefer to hang this up in the house, and keep it as a mark or token of the owner's prowess in war, when the mummified head is discarded on account of natural decay; but the lower jaw is sometimes replaced, being tied to the zygomas, as in the case of the rattan cane above described. Finally, the head is dried, being fixed on a wooden framework over a fire lighted for that purpose, and the hair is pulled out on the second day as decomposition of the skin advances. Following this paper is a description by Dr. A. C. Haddon of stuffed human skulls from the Fly River District, Papua, two of which are preserved in the Cambridge and Manchester Museums.

CRIMINAL TRIBES OF INDIA.—The problem of dealing with the nomadic, predatory tribes of India has been considered for many years by the Imperial Government. All sorts of repressive measures have been put in force; the tribes have been proclaimed and attempts have been made to segregate them in settlements under police control. This system has always broken down, and these people, including the Sansias of the Punjab, the Doms of the United Provinces and Bihar, the Yerukalas and Korachas of Madras, have continued to be a pest to the country, and much violent crime was committed by them. Some twenty years ago a proposal was made by the Salvation Army to take charge of these people, and the result of the experiment is described in a paper by Commissioner Booth Tucker, read before the Royal Society of Arts (vol. lxxi. No. 3661). The Salvation Army has collected some of these people in settlements, each in charge of a European, where the more respectable members act as police, industries are taught, and efforts made to raise their moral character. In the debate which followed the reading of this paper several experienced Indian administrators, including Sir E. A. Henry, Sir John Hewitt, and Lord Pentland, bore testimony to the success of the experiment, which may be said to have solved one of the most difficult problems of Indian administration.

FATIGUE IN LAUNDRY WORK.—Miss May Smith is to be congratulated upon her recent Report (No. 22) to the Industrial Fatigue Research Board (H.M. Stationery Office, price 2s. 6d.), embodying "Some Studies in the Laundry Trade." Owing to the great variety of articles dealt with in laundries, the measurement of output, so as to serve as an index of the relations between working conditions and the human factor, proved unusually difficult. Nevertheless, she has been able to show that there is a reduction in efficiency in laundries towards the end of the day, which tends to be greater during a ten-hour than during a nine-hour day. These conclusions are strikingly corroborated by the data afforded by the interposition of "dotting" tests, which, in addition, reflect passing variations in the health and mental state of the worker. Miss Smith finds clear evidence of the beneficial effects on efficiency which occur after a fifteen minutes' rest pause has been introduced into the morning spell, but the greatest influence on the laundresses' output appears to be due to the vast individual differences in the workers' efficiency. Apparently the atmospheric conditions of laundries compare very unfavourably with those in potters' shops, boot and shoe factories, and cotton-weaving sheds. But when conducted under good conditions, Miss Smith believes that laundry work is not detrimental to the health of the workers. The variations in health due to excessive standing, faulty movements, and improperly designed machinery receive attention, and recommendations are made in regard to supervisors, the provision of seating, unsuitable footwear, change of occupation, etc.

OUR OLDEST SETTLEMENT IN AFRICA.—Dr. Frank Dixey has followed up his physiographic description of the colony of Sierra Leone (see NATURE, vol. 105, p. 689, 1920) by a complete petrographic survey of the main promontory (Quart. Journ. Geol. Soc. London, vol. 78, p. 299, December 1922). The peninsula forming the colony proper has been carved out of a remarkably uniform and unusually large stock of norite, the fine-grained character of which indicates that the present surface follows that of a dome of intrusion. Veins of coarser norite, and some of aplite, cut this mass, which is regarded as post-Cambrian, but of ancient date. The only strata on its surface are post-Pliocene gravels. This extensive occurrence of basic igneous rock furnishes further evidence of the existence of a West African petrographic province of strongly magnesian character.

SURVEYS OF THE SAHARA.—A new map of the western Sahara, between the Atlas to the north, and the Senegal and Niger to the south, and the meridian of Paris on the east, is published in *La Geographie* for January. The map, which is on a scale of 1 : 2,000,000 is based on information collected by the French military posts in the Algerian Sahara, Mauretania, and the Sudan, and particularly the explorations of Capt. Augiéras who, in addition to various journeys in the Sahara between 1913 and 1917, crossed the desert with a small column in 1919–20 from Algeria to Senegal. This crossing, which is briefly described in an article accompanying the map, was from the French outpost of Tabelbala, south of Colomb Bechar, in a south-westerly direction to the outpost of Atar, whence by a circuitous route Bogue on the Senegal was reached. This entailed, from post to post, a total march by camel of some 1500 miles, which was accomplished, excluding rests, in 78 days. In such a survey there must obviously be inaccuracies and Capt. Augiéras regrets his inability to get more satisfactory longitudes, but the map shows great improvements on former maps of this part of the Sahara.

DISTRIBUTION OF ICE IN ARCTIC SEAS.—The publication by the Danish Meteorological Institute of "The State of the Ice in the Arctic Seas, 1922," directs attention to a somewhat unusual year, but unfortunately information is almost entirely lacking from Siberian waters and very scanty from the Beaufort Sea. By April the extent of pack in the Barents Sea was much smaller than usual. Bear Island, which had been free from ice all winter, was clear and open water almost reached to Novaya Zemlya. The edge of the ice continued to retreat. In July the whole west coast of Novaya Zemlya was clear, and in August Franz Josef Land was probably accessible by open sea. Early in the year conditions in Spitsbergen were about normal. In May and early June an unusual amount of ice drove round the South Cape before continuous easterly winds, but this resulted in the west coast being practically free from ice for the remainder of the summer. On the north coast conditions were particularly favourable, and a vessel reached lat. 81° 29′ N. Some sealers circumnavigated Spitsbergen, a feat that is not possible in most years. In the Greenland Sea the belt of pack lay more westerly than usual, and though the east coast of Greenland does not appear to have been clear of ice, open water touched the coast in about lat. 74° N. during August. Jan Mayen and the coast of Iceland were free from pack from May onwards throughout the summer. On the Newfoundland banks both pack and icebergs were abundant in early spring, but July was clearer than usual. In Davis Strait the winter ice was thinner and the "west ice" less abundant than usual. In Bering Strait conditions were fairly normal, but along the north coast of Alaska the pack pressed hard and navigation was much hindered.

EARLY HISTORY OF THE BLACK CURRANT.—The *Gardeners' Chronicle* has recently commenced a very interesting series of notes under the heading "Early Botanic Painters." In the issue of February 17, the figures of the Black Currant reproduced from the paintings by Jean Bourdichon (1457–? 1521) are extremely interesting, and raise the query whether the cultivation of the black currant may not be of longer date than is usually supposed. R. G. Halton of the East Malling Research Station has recently described existing varieties of the Black Currant, and to judge from his brief account of its early history (*Journal of Pomology*, vol i. No. 2, p. 68), it receives scant notice from the earlier chroniclers of horticultural effort.

A NEW CULTURE MEDIUM FOR BACTERIAL COUNT WORK.—For bacterial counting work, in which the plating method is used, a first essential of accuracy is that the medium used in plating should give uniform results. There are two respects in which a medium should display this uniformity. In the first place, it should be reproducible, that is to say, different batches of medium should give similar results. In a medium recently developed at Rothamsted (H. G. Thornton, *Annals of Applied Biology*, vol. ix. p. 241, 1923), this reproducibility has been achieved by using pure chemical compounds as food constituents and especially by selecting those compounds that were found not to alter the reaction of the medium during sterilisation. In the second place, parallel platings of a suspension of organisms made on a *single* batch of medium should develop the same number of colonies (within the limits of random sampling variance). Uniformity in this respect involves the independent development of each colony on the plate, and on agar media this is frequently prevented by the development of bacteria that form rapidly spreading colonies which interfere with the development of other bacteria. A special study was therefore made of a common "spreading" organism with a view of limiting its growth. It was found that the organism spread over the agar surface by active motility and that the factors controlling its spread were (1) the existence of a surface film of water on the agar, and (2) the rate of multiplication previous to the drying of this film. In the present medium this rate of multiplication has been much reduced, so that spreading colonies are greatly restricted.

SILKWORM DISEASES IN INDIA.—The subject of silkworm diseases is not a new one in India, but notwithstanding the fact that sericulture is probably a much older industry in that country than in Europe, there are no corresponding early records of disease. The whole problem is very fully discussed in a recent memoir by Dr. A. Pringle Jameson (Report on the Diseases of Silkworms in India, Calcutta, 1922. pp. 165 and 8 plates). It appears that all the recognised diseases are prevalent, and those of the mulberry, muga, and eri worms are the same. Pebrine is only of importance in mulberry worms: losses are still heavy, mainly because the majority of rearers use unexamined eggs or "seed." Muscardine is almost confined to mulberry worms and is a most serious complaint, whole rearings being frequently lost. Flacherie is of less importance in mulberry worms, while grasserie is stated to cause loss to all species. Conditions in India make the control of disease considerably more difficult than in temperate countries, but there is no reason why the industry should not be placed upon a surer footing. The crux of the whole question lies in the "ryot," and, if improvement is to be effected, the village rearer must be instructed as to the causes of disease and induced to go in for better methods of rearing. Since the industry is carried on by cottagers, the latter should be encouraged to use disease-free "seed." The extension of the Government nursery policy will avail little unless the rearer can be induced to educate himself to adopt better methods. The most important work of the Government sericultural officers should be instruction and supervision, while sericultural schools should be established. The sericultural department officials themselves should conduct research work on a practical scale, and an attempt should be made to provide them with the chief literature on this subject in order that they may keep abreast with sericultural research. Improvements are to be looked for from the work of the provincial sericultural departments being extended among the villages.

FIBRES FROM THE TROPICS.—A noticeable feature of journals recording activities in tropical agriculture is the interest at present being taken in the subject of fibre production. The *Tropical Agriculturalist*, issued from Peradeniya, records promising experiments with cotton, and in its December issue (1922) devotes considerable space to a paper by E. Mathieu, superintendent of the Government Plantation, Kuala Kangsar, upon the cultivation of the "Kapok" tree, *Eriodendron Anfractuosum*. In the fruits of this plant, hairs grow freely on the inner side of the valves of the capsule but not upon the seeds themselves, so that the separation of the fibre from the seed is a relatively easy matter. The export of this fibre from Java in 1912 exceeded 10,000 tons, and owing to the increasing demand from Europe and America, its cultivation seems likely to extend in Ceylon.

The same number of this journal has a note by A. P. Waldock upon the "akund" fibre, obtained from the shrubs *Calatropis gigantea* and *C. procera*, which the writer considers may have industrial possibilities as a village industry. In *Industrial India*, vol. i. No. 12, the possibilities are discussed of the "roselle" fibre, obtained from the bark of *Hibiscus Sadariffa*, particularly var. *Altissima*, which is said to have given good yields of fibre in Malaya, in regions with rainfall between 90 and 120 inches. For dry tropical regions there is "sisal," the fibre from the leaf of *Agave rigida*, var. *sisalana*. In *Tropical Life* for January Major L. A. Notcutt begins an interesting discussion of the possibilities of the cultivation and extraction of sisal, more particularly with reference to the problem whether the East African product may hope to compete with the Mexican in cost of production. At present our knowledge with all these fibre plants as to what conditions in cultivation favour maximum fibre development in the plant is entirely empirical, but such recent researches as those of Dr. W. L. Balls and H. A. Hancock (Proc. Roy. Soc., 93 B, 426-439, 1922) upon the growth of the cotton hair, and the numerous investigations upon cotton and flax, now being published in the Journal of the Textile Institute, arouse hopes that we may soon have a deeper insight into the problem of wall formation and thickening in the plant, and this should prove the first step towards the control of cultivation with the view of facilitating the formation of fibre.

FORAMINIFERAL SANDS IN CORSICA.—Messrs. E. Heron-Allen and A. Earland (Bull. Soc. Sci. hist. et nat. de la Corse, 1922, p. 100, Bastia) find that the red sands of the Gulf of Ajaccio, which were supposed to owe their colour to derivation from adjacent granite rocks, are in reality largely composed of foraminifera. Some ten per cent. of their volume is composed of the rose-pink *Polytrema miniaceum*, a species having a wide distribution in the Mediterranean, with which Mr. Heron-Allen was concerned in his recent report for the *Terra Nova* expedition. The authors, in an inserted fly-sheet, show that they have much cause to complain (as was remarked in the famous "Printers' Bible") that printers have persecuted them without cause.

DEPOSITION OF SILICA IN SEDIMENTARY ROCKS.—In such cases as the famous Devonian cherts of Rhynie, or the silicified forest of Arizona, geologists have urged the probability of an invasion of silica in solution from volcanic magmas. In suitable climatic conditions, however, much silica must be set free during laterising processes, and this may wander far from its original source. In the Proceedings of the Rhodesia Scientific Association, vol. 20, p. 9, 1922, Mr. H. B. Manfe records the interesting case of the silicification of a fairly recent freshwater shale at the base of the Kalahari Sands at Gwampa. Mr. T. B. Lawler of Princeton University (*Amer. Journ. Sci.*, vol. 205, p. 160, 1923) describes the sheets of chalcetory that traverse the Oligocene strata of S. Dakota, passing alike through the sands and the included fossils. He attributes the vertical cracks in which they have been deposited to the squeezing out of water during the settling down of the beds, as the humid conditions of Oligocene times in the Dakota area were succeeded by an arid climate in the Miocene period.

EARTHQUAKE PERIODICITY AND TIDAL STRESSES.—Recent numbers of the Bulletin of the Seismological Society of America (vol. 12, 1922, pp. 49-198) contain a memoir by Mr. Leo A. Cotton on earthquake periodicity with special reference to tidal stresses in the lithosphere. A welcome feature is the sympathetic examination of Perrey's neglected laws (of greater frequency about the syzygies, perigee, and the lunar passages of the meridian); the author considers that the first and second are supported by a high degree of probability, while the third is unsound. The second part of the memoir deals with the effects of tidal stresses in the earth's crust, with special reference to the geological aspects of the subject, such as the position of the originating faults. The author considers 316 world-shaking earthquakes from 1899 to 1903, and shows that earthquakes are more frequent when the sun or moon is near the horizon, and that there is a very high maximum of frequency when the sun and moon are so situated that they exert their tidal stresses in the same direction.

METEOROLOGY AT LIVERPOOL.—Results deduced from the meteorological observations taken at the Liverpool Observatory, Bidston, in the years 1920 and 1921, have recently been published by the Mersey Docks and Harbour Board. The report and discussion was prepared by Mr. W. E. Plummer, director of the observatory. Observations are supplied three times daily to the Meteorological Office, which also receives monthly and annual returns. Daily results are given for the two years and the total and means are grouped for each month and each year. For 1920 the mean atmospheric pressure was 29·942 in. (printed in error as 29·924 in.); the mean was above 30 in. in 5 months. The mean air temperature was 49·6° F., which is 0·5° F. above the normal, the absolute maximum was 78° F. and the minimum 21° F. The total rainfall was 33·34 in., which is 4·82 in. more than the normal; the duration of sunshine was 1257 hours, which is 222 hours less than the normal. For 1921 the mean barometric pressure was 30·045 in., which is more than a tenth of an inch higher than in 1920; in a similar report for Southport especial mention was made of the exceptionally high barometric pressure which characterised 1921. The mean at Liverpool was above 30 in. in 7 months. The mean air temperature was 51° F., which is 1·9° F. above the normal; the absolute maximum was 86° F. and the minimum 28° F. The total rainfall was 22·47 in., which is 5·95 in. less than the normal; the duration of sunshine was 1585 hours, which is 99 hours more than the normal. The general modification of scales for the several elements which is being uniformly adopted by the Meteorological Office is not as yet being followed at the Liverpool Observatory.

THE SCATTERING OF LIGHT BY LIQUIDS.—When a beam of ordinary light passes through a liquid its intensity gradually diminishes according to the exponential law owing to the scattering of the light by the molecules of the liquid. The light scattered in a direction transverse to the beam should be completely polarised. According to a paper in the March issue of the *Philosophical Magazine*, Prof. C. V. Raman and Mr. Rao have examined nine liquids to determine to what extent the theories of scattering are in agreement with the facts, and find that the Einstein-Smoluchowski theory is the most satisfactory. According to it the scattering should be proportional to the compressibility and absolute temperature of the liquid and inversely proportional to the fourth power of the wave-length of the light used. They find that the transverse light is only partially polarised, but, on applying the correction specified by Cabannes, which is due to the non-symmetrical molecules, the theory gives correctly the amount of the scattering. As the critical temperature of the liquid is approached, the scattering becomes very large and the polarisation of the scattered light more complete.

The Indian Science Congress.

THERE is a real danger that the severe retrenchment in public expenditure now in progress in India may lead to a curtailment of activities in those departments in which such restriction is least desirable, namely, the educational and scientific services devoted respectively to the training of workers and the investigation and development of the resources of the country. It was therefore very opportune that the presidential address delivered at the Indian Science Congress which has completed its tenth session at Lucknow (January 8-13) emphasised the danger of apathy towards scientific knowledge and the immense problems bearing upon the welfare of India still awaiting solution. The president, Sir M. Visvesvaraya, himself a distinguished engineer and for many years the successful administrator of one of the largest and most progressive of the Indian States, rightly laid stress on the appalling state of destitution in which quite 100 million out of the total population of 320 million in the country live, and the necessity for scientific research to increase the food supply, raise the standard of living, develop resources and train the people for citizenship. The address contained constructive suggestions towards stimulating research, promoting co-operation and concentration of effort and making the results of scientific work both in India and abroad more readily available.

The sectional presidents dealt with a variety of subjects and their addresses were mostly of a general character. A few words regarding each must suffice, and those who are interested will no doubt refer to the complete report which will before long be published by the Asiatic Society of Bengal. In his discourse to the Section of Physics and Mathematics, Dr. S. K. Banerji reviewed recent theories regarding the origin of cyclones and discussed in particular the cyclones of the Indian seas, their origin, movements and disappearance. He favoured the view that counter currents having their origin in differences in temperatures over large geographic areas initiate the conditions that give rise to a system of gyrating winds in these storms, and that the condensation of water vapour supplies the energy necessary to maintain them for a long period of time. Dr. Meldrum in a brief opening address to the Section of Chemistry made out a case for regarding the study of this subject as a liberalising influence.

Mrs. Howard in her address to the Botanical Section dealt with the rôle of plant physiology in agriculture and indicated a number of directions in which botanical research is desirable, such as the factors underlying high quality in agricultural produce, the scientific interpretation of field experiments, the precise nature of various agricultural practices which come under the head of mutilations, the relations between physiology and the incidence of disease, and the basis of acclimatisation and change of seed. It was suggested that investigators in the Indian universities would find in these subjects many problems of great scientific interest and practical importance.

Dr. Pillai in his address to the Section of Agriculture epitomised recent researches in soil science. Prof. G. Matthai gave the Section of Zoology a very interesting survey of recent oceanographical research, with special reference to the Indian Ocean, dealing very fully with the physical and chemical factors influencing marine life and its distribution. Especially noteworthy was the reference to recent work on the colour of the light that penetrates by transmission and scattering into the depths of clear ocean water and its possible influence on the coloration of marine fauna and the development of their powers of vision. In the Section of Geology, Dr. Pascoe dealt with the palæography of Burma. Major Acton discoursed on the aims and economic value of medical research to the section devoted to this subject. The importance and interest attaching to the study of cultural anthropology was well emphasised by Dr. J. J. Modi in the section over which he presided.

A general survey of the work of the Congress indicates that scientific investigations in India are to a considerable extent directed by the special needs of the country, and indeed perhaps even more attention should be given than at present to subjects such as the chemistry of Indian natural products and problems arising therefrom. As an example of the kind of work being accomplished at present in this direction may be mentioned an interesting paper by J. L. Simonsen and M. Gopala Rao in which they showed that an exceedingly small proportion of pyrogallol added to Indian turpentine inhibits its tendency to oxidation for some months and thus adds greatly to its value. The practical side of research was also emphasised in a symposium of the Sections of Agriculture, Botany and Chemistry, in which a whole morning was devoted to the discussion of the nitrogen problem in Indian agriculture, and in another joint meeting, of the Sections of Botany and Agriculture, devoted to the improvement of fodder and forage in India. The same tendency is also found strongly reflected in the proceedings of some of the sections, notably in those just mentioned and in the Section of Medical Research.

Fundamental research as distinguished from applied science was strongly represented in the physics section of the Congress, and this was largely owing to the influence of the Calcutta school which has grown up during the past few years. Among some of the papers which dealt with new fields of research may be mentioned one by Mr. K. Seshagiri Rao on the scattering of light in fluids at low temperatures. A remarkable fact elicited by recent work (see Proc. Roy. Soc., November 1922, p. 159) is that the light transversely scattered in liquids which at ordinary temperatures is very imperfectly polarised increases in intensity and at the same time becomes more and more completely polarised as the temperature is raised towards the critical point. In Mr. Seshagiri Rao's work, the study of the scattering is carried down to low temperatures, and an effect of the opposite kind is noticed. The quantitative results promise to throw light on the nature and magnitude of the thermal agitation of the molecules at low temperatures. An analogous investigation by Mr. Lalji Srivastava on the scattering of light in crystals was also presented to the Congress.

There is scarcely space to refer here in detail to the numerous other papers dealing with subjects so varied as vortex motion in fluids, formation of ripple-marks, earthquake coda, chromatic emulsions, acoustics of the pianoforte, whispering galleries, theory of band-spectra, temperature ionisation of gases, and α-ray tracks in argon and helium, to mention only a selection, presented to the section at Lucknow. A reference may, however, be made to a paper which evoked a most animated discussion at the meeting, that is one by the writer putting forward a new theory of the well-known blue colour of clear ice in glaciers (see NATURE, January 6). In reply to some of the points raised, attention was directed to the very remarkable fact that during the process of artificial crystallisation involved in the manufacture of ice, the suspended matter originally present in the water is rejected by the crystals as they form and accumulates in a pocket. Ice which shows the blue opalescence is quite free from colloidal matter of any kind.

C. V. RAMAN.

The Exploitation of the Sea.

TWO very important documents bearing on the subject of the rational exploitation of fishing grounds have recently become available. The first is the report to the Minister of Agriculture and Fisheries of the British delegates who attended the meeting of the International Council for the Exploration of the Sea, held at Copenhagen in September last. The other is the Report of the Danish Biological Station (xxix., 1922). Both papers are of very great interest.

The British official report emphasises the practical nature of the work of the Council and gives an account of its organisation. There are four sections (hydrography, plankton, statistics, and fish). The work of the fish section is carried out by committees, and those which deal with the investigation of the herring, cod and haddock, and of the biology of the Atlantic slope are of great interest to British workers. Programmes of the investigations adopted by these committees are given in the report. One important committee, that on the plaice fisheries, has now completed its work, and the recommendations made by it have been approved by the Council and are given in full. These are that the parts of the North Sea situated (1) between the Continental coast and the 12-fathom line from N. lats. 52° to 56°, and (2) between the 12-fathom and the 15-fathom line, be closed to steam trawlers and motor vessels of more than 50 h.p., the inner zone throughout the entire year and the outer one during the months July to March. No size-limits with respect to the fish caught are recommended. The Council recognises the difficulty of enforcing these measures without the sympathetic support of the fishing industry, but it regards this as a matter for the concern of the governments of the participating countries. It is considered that the adhesion of Germany to such a scheme of regulation will be essential. The Council advises the continuance of observations and the review of the whole proceedings after three years have elapsed.

The meaning of the impoverishment of a plaice fishing ground is examined by Dr. C. G. J. Petersen in the second of the reports noticed. Since 1893 this distinguished Danish zoologist has studied the fisheries in the Limfiord and in the adjacent seas. In 1893 the old styles of plaice fishing were superseded by newer and more efficient methods, and Dr. Petersen thought then that this meant "the end of the golden day for the fishing industry," and he had similar thoughts about the North Sea plaice fisheries. Now he confesses that later developments have shown that he was wrong. What has occurred in the two areas is much the same; the quantities of plaice taken per day's fishing by the old types of vessels were much greater than those now being taken by the newer boats fitted with much more efficient gear. Why? In both areas there was an "accumulated stock" of fish. Vessels of low fishing capacity could do well on such grounds.

How to remedy this "impoverishment"? There are two theories of regulation: (1) to raise more young plaice either by protecting the breeding fish so as to allow them to reproduce at least once in their lifetimes, or by artificial hatching, and (2) to legislate and otherwise deal with the fishery so as to increase the *growth-rate* of the plaice, because it is not merely a vast quantity of fish on the grounds that is desirable but rather an increased rate of production of plaice-flesh. An overcrowded ground may harbour small old plaice or young and relatively big ones. Plaice which do not grow at all consume from three to four times their own weight of food. In the Baltic there are fish of 32-36 cm. in length which are 4-5 years old as well as others of the same sizes but of 9-18 years old. The best policy is so to regulate the fishing as to increase the proportion of the younger, more rapidly-growing fish.

How to do this? The conditions in the North Sea illustrate the difficulty—and the remedy. If the Dogger Bank were an island surrounded by shallow water, vastly more plaice would grow to good marketable sizes than do now. As it is, the fishing is probably too intense and plaice are caught more rapidly than they can migrate out from the overcrowded grounds just off the Continental coasts. The restocking of the deeper parts, where the fish will grow well, from the nurseries (where they grow slowly) must keep pace with the depletion of these grounds. This means two kinds of measures: (1) size-limits in fishing, and (2) transplantation, both being modified according to the circumstances. If young plaice do not migrate out into favourable parts of the North Sea they must be assisted. Dr. Petersen himself made successful transplantation experiments in the Limfiord long ago, and more recently, English investigators have shown, beyond all doubt, that the same measures were practicable, and sure to be highly successful, in the North Sea.

The rationale of a continued and still more intensive exploitation of the fishing grounds is indicated by the scientific investigations. The transplantation experiments show which are the favourable grounds; growth-rates are known, and the work now in progress by the English investigators is giving results of value in regard to the supplies of food on the various grounds. The difficulties belong only to the practical working of the regulatory measures. Something like a scientific "nationalisation" of the deep-sea fishing industry appears to be necessary in the interest of an increased food supply, should the apprehensions of a failing stock be justified. It seems like a revolutionary proposal to suggest that permission to exploit the offshore fishing grounds should become necessary and that this permission should be accompanied by certain conditions, yet something of the kind may have to come in the near future. Meanwhile the scientific work in progress is affording the data whereby such proposals can materialise when the administrations are ready.

J. J.

Solar Radiation.

VOLUME IV. of the Annals of the Astrophysical Observatory of the Smithsonian Institution contains the investigations on solar radiation made by the director, Prof. C. G. Abbot, assisted by F. E. Fowle, L. B. Aldrich, and others. The work in the Northern Hemisphere has been transferred from Mt. Wilson to Mt. Harqua Hala, Arizona; that in Chile from Calama to Mt. Montezuma. In 1914 pyrheliometers were taken up to a height of 25 km. by small balloons. The atmospheric pressure was 3 cm. of mercury; the value of the solar constant indicated was 1·84 calories per cm.², in good agreement with the adopted value.

Mr. Clayton compared the variations of solar radiation measured in 1913–14 with the temperature records in various parts of the world; he found a correlation that was positive in the Tropics and Polar regions, negative in the Temperate zones. He also found that the temperature in Argentina was correlated to the short-period variations of radiation observed in Chile, and he suggests that these changes have a tendency to recur in periods of 12 and 22 days. They are interpreted as being due to varying transparency of the solar atmosphere. Measures of the brightness of Saturn indicated similar variations, but with a time-interval proportional to the difference of longitude of Saturn and earth. This would be explained by the solar regions of high or low radiation being carried round by the sun's rotation.

The excess of radiation at sunspot maximum is explained by the greater activity of solar convection currents at that time; these bring hot matter from the interior to the surface, which more than balances the loss of heat in the spots themselves.

The mean state of transparency of the solar atmosphere is measured by observations of the radiation at different distances from the centre of the disc. The contrast between centre and limbs is found to be greatest when the solar spot activity is greatest. On the other hand, the short-period increases of radiation are associated with less contrast between centre and limb.

The work also gives information on the transparency to radiation of different layers of our own atmosphere. "The atmosphere above 11 km. contributes more than half the radiation of the earth viewed as a planet. . . . Nearly the entire output of radiation of the earth to space, more than $\frac{9}{10}$, arises from the atmosphere and clouds."

The albedo of a large white cloud in the sunshine was measured from a balloon above it and found to be 78 per cent. Prof. H. N. Russell's discussion of Müller's observations of the albedo of Venus gave the value 59 per cent. It is concluded that the clouds on Venus while general are not thick enough to give full cloud reflection except for oblique rays. The albedo of the earth seen from space is estimated as between 43 and 45 per cent.

Botulism in Scotland.

THE Scottish Board of Health has issued a very clear and interesting report on the circumstances attending the deaths of eight persons from botulism at Loch Maree in Ross-shire last year, and none of the vivid tragedy of the occurrence is lost in the telling by Dr. G. R. Leighton.

On August 14, 1922, a number of guests stopping in the hotel went out for the day, and within a week six of them, as well as two of the attendant ghillies, were dead. Once some sort of food poisoning was suspected, the distribution of the fatalities between these living in the hotel and those living in their own homes in the neighbourhood at once implicated luncheon, the only meal taken in common, as the source of the poison, and further inquiries appeared to bring particular suspicion on a glass jar of wild-duck paste out of which about a dozen of the sandwiches had been made. The empty jar was fortunately recovered, and Mr. Bruce White, at the University of Bristol, was able to show that the small fragments of paste left in it were intensely poisonous to mice, and from them to isolate the *Bacillus botulinus* itself. One of the ghillies was not hungry enough to eat all his sandwiches and took one home with him, when he fell ill next day and rumour suggested something wrong with the lunch his friends buried the sandwich, which was retrieved later and shown by animal experiment to be extremely toxic. A guest also failed in his appetite and threw the most part of a sandwich to a wagtail on the lake shore; a month later Dr. Leighton found the decayed remains of a small bird among the stones.

There has, indeed, seldom been an outbreak of food poisoning in which the facts were so clear and so plainly verified. The only point of interest which the report fails to elucidate—and perhaps the facts could not be ascertained with complete accuracy—is how many people ate any of the poisonous paste without having symptoms: it seems likely that there may have been about five.

As has lately been shown by Dr. K. F. Meyer of the University of California (NATURE, January 20, p. 95) *B. botulinus* is a widespread common inhabitant of the soil, and may often be found on fruits, vegetables, and other food-stuffs. Taken with food in any numbers that are reasonably possible it is harmless, and in this way differs sharply from the food poisoning bacilli of the Gaertner and Aertrycke group, which multiply inside the body and cause illness by producing a definite infection. *B. botulinus* is poisonous only if it has been able to grow for some time under favourable conditions outside the body and produce large quantities of its potent toxin: man is poisoned by the toxin, not infected by the bacillus. Laboratory experiments show that the resting spores are exceptionally difficult to kill by heating. Considering, indeed, the wide distribution of the bacillus in Nature, the rarity of botulism is a remarkable testimony to the care with which potted meats and so on are usually prepared. Really efficient sterilisation is a secure preventive. The difficulty is that the glass containers, which the public æsthetically prefers, cannot be heated to a sufficiently high temperature without an undue proportion of breakages. There seems to be no good reason why they should not be prohibited and tins made compulsory.

Building Construction Research.

THREE reports on investigations connected with house construction and allied subjects have recently been issued by the Department of Scientific and Industrial Research.[1]

In the first of these, Mr. W. H. Wainwright gives some details of the cost of cottage building, and at the present time, when the cost of building is a very vexed subject and development schemes have to be very carefully debated owing to financial stringency, such information should be valuable. It is only by careful analysis in the matter of outlay that organisation can be improved and economy effected, and those engaged in large building works will find in these tables much interesting matter. The diagrams are partly compiled from data collected by the Ministry of Health; some are calculating graphics which should save time and do something to popularise graphic methods among technicians, while others show the rise and fall of prices in labour and materials from 1914 to 1922 and are of general application.

Mr. Weller in his editorial introduction anticipates

[1] Department of Scientific and Industrial Research. Building Research Board: Special Report No. 6, "A Graphical Cost Analysis of Cottage-Building." By W. H. Wainwright. Pp. iv+8+20 diagrams. 2s 6d. net. Building Research Board: Special Report No. 5, "Building in Cob and Pisé de Terre: a Collection of Notes from Various Sources on the Construction of Earth Walls." Pp. iv+40. 2s. net. Fuel Research Board: Special Report No. 4, "Tests on Ranges and Cooking Appliances." By A. H. Barker. An Extract from the Report of the Building Materials Research Committee. Pp. vi+55+15 figs. 2s. 6d. net. (London: H. M. Stationery Office, 1922.)

an obvious criticism that the basis of calculation may be of changing value owing to changed conditions by stating that the percentage cost of materials in a cottage in 1914 and 1921 was found practically identical. From the diagrams the increased cost of a cottage due to variation in the market price of a material can be at once ascertained. We imagine that variations in human output are a good deal less amenable to graphic representation. Apart from this, however, a great deal of useful matter on relative costs and methods of calculation will remain truly recorded in this publication.

The notes which constitute the report on cob and *pisé* building form an interesting epitome of a subject which came into great prominence during and after the war, when bricks were prohibitive in price and the bricklayer was laying them at a minimum rate never contemplated. It is very unlikely that the methods of building described will ever become general, though in special local circumstances they will continue to have value.

The contributors to these notes write quite dispassionately, a fact which adds greatly to the value of the concise information given. Various methods used are explained in detail with dimensioned sketches of the simple shuttering and tools used in this construction, while photographs of cob and *pisé* cottages show how satisfactory a home it is possible to produce, even for two-storied buildings, direct from natural earths. Walls, which may be of lumps from a mould or formed *in situ*, are one or two feet in thickness and the houses are said to enjoy a very equable temperature and to remain dry, but a brick or concrete foundation about a foot high is necessary. The recent times of stress have produced a great many new types of building, but if we are to judge from American experience it would seem that, taking capital and current cost over a decade, the ordinary brick still holds its own against later competitors.

Houses or cottages having been constructed, it is necessary to provide heating appliances, and range-makers and others will find much useful information in the third of these reports. The necessity for the conservation of fuel energy during the war provided the stimulus for this useful investigation. It is common knowledge that the kitchen range is, in most houses, the main and most wasteful coal consumer, and it is surprising that range-makers have not before now turned their attention to the production of more efficient designs. This may be due partly, as the author points out, to the incompatibility of running economy and initial low cost of apparatus, but if capital and current costs were simply tabulated the purchaser would soon realise the ultimate cheapness of a range designed to utilise more heat units.

The purposes of a range for boiling, baking, water heating, and perhaps warming, render, the report tells us, a really economical design impossible, and attention should therefore be directed to the consideration of any means for separating these functions which might be practicable at least in large establishments. These functions were tested independently both from a broad physical and also from a purely culinary standpoint. Considered as separate functions, only $2\frac{1}{2}$ per cent. of the heat is transmitted to the oven, 12 per cent. to heating water, and 1·5 per cent. to the hot plate, as an average for commercial ranges. These figures were very largely increased in appliances designed during the tests. It has been stated that market conditions preclude the commercial success of many improved types of range.

Diseases of Plants in England in 1920–21.[1]

By Dr. E. J. Butler, C.I.E.

Most countries in the civilised world have been forced within the last twenty years to take steps to protect their crops from the menace of foreign parasites. During that period, with the growing recognition of the aid that science can give to agriculture by studying the cause and control of plant diseases and pests, has come a great increase in knowledge of the dangers of unrestricted traffic in plants. Many instances have occurred to prove how real is the risk of introducing plant parasites from other countries and how difficult to guard against. America has been the chief sufferer, but it is sufficient to mention gooseberry mildew and wart disease of potato to show that England has not escaped. Distances, as measured in time and in the amenities of transport, are constantly contracting between the continents, and the interchange of living plants—with their parasites—goes on in ever-increasing volume. Quarantine restrictions, at first imposed in a few special cases, have extended until at present the exporting seedsman or nurseryman is faced with barriers to his trade which are often extremely hampering. It is easier for a human being to enter the United States to-day than for a potato, unless it is accompanied by a sheaf of health certificates; while total prohibition of certain categories of plants is not uncommon.

Correspondingly heavy responsibilities have fallen on the official plant pathologists of the various countries. Produce for export has to be inspected and certified, and imports from each country have to be scrutinised for possible dangers. As an essential foundation for efficiency in what may be called the "Plant Protection Service," it is obviously necessary to know what diseases already exist in one's own country and what may be introduced from each of the countries from which imports are received. Plant disease surveys have been developed in nearly all the more advanced countries, that of the United States being the most complete, as is natural in view of the vast interests involved. So far as the fungous diseases are concerned, it is to Mr. A. D. Cotton, mycologist to the Ministry of Agriculture, that is due the organisation of the English survey. The present report is the third of the series for which he has been responsible, and will be the last in view of his appointment as keeper of the Herbarium, Royal Botanic Gardens, Kew. It is also by far the most complete that has yet appeared and is second to none in any European country.

The report covers the two years 1920 and 1921. These years offered an extreme contrast in their meteorological features, and not the least valuable of the results of the survey is the way in which the differences in the two seasons are reflected in the incidence of particular diseases. Potato blight, a lover of cool and damp conditions, was rampant in 1920, but could not withstand the hot, dry summer of 1921. The attack of crown rust on oats in Wales was unprecedented in the former year and singularly slight in 1921. The mildews, on the other hand, were unusually bad in 1921, and common scab of potatoes,

[1] Ministry of Agriculture and Fisheries. Report on the Occurrence of Fungus, Bacterial and Allied Diseases on Crops in England and Wales for the years 1920–21. (Miscellaneous Publications, No. 38.) Pp. 104. (London: H.M. Stationery Office, 1922.) 3s. net.

a disease that has recently been shown to prefer warm soils, established a record in virulence.

One may hope that the accumulation of such facts (of which the report contains many), and their correlation with the weather charts which are attached, will enable trustworthy forecasts of the intensity of particular diseases to be issued. It is unnecessary to emphasise the practical value of this to the grower.

Another point of the highest practical interest, and one that is best brought out by the methodical records of a survey, is that of varietal resistance to specific diseases. Such a year as 1920 is invaluable in establishing the behaviour of different varieties of potatoes to blight under optimum conditions for the latter. Kerr's Pink, for example, appears at or near the top of nearly all the lists of blight-resistant potatoes that are also immune to wart disease.

Equally valuable are the records of new crop parasites. No less than 136 names have been added to this report as compared with that for 1919, and several of these are diseases not previously known to occur in the country.

The report deserves a wide circulation at home and abroad, as it presents in a handy and convenient form a remarkably complete summary of the fungous and allied troubles with which the British grower has to contend.

Wave-power Transmission.

AN interesting paper has recently been presented to the North-East Coast Institution of Engineers and Shipbuilders, by W. Dinwiddie, on wave-power transmission. Wave-power machines are classified under three heads: (1) Continuous waves, where the generating plunger moves with simple harmonic motion. (2) Impulse waves, in which a single harmonic motion is transmitted in wave form at regular intervals, greater than the period of the motion itself. (3) Sychronous and asychronous motors, monophase or polyphase, in which direction research is proceeding.

Liquids such as oils and water are at present the media used, while the transmission of impulse along a steel wire has been used. A reciprocating pump plunger of small stroke is oscillated at a high speed at one end of a closed pipe line. Waves of compression and expansion are propagated through the pipe line. If the pipe line is completely closed at the other end, very high pressures can be generated in the pipe line; but if a plunger similar to the pump plunger is placed there, this will move in synchronism with the pump plunger, and is therefore able to do work on some type of machine. To prevent excessive rise of pressure in the pipe line when the sychronising plunger is stopped, capacity analogous to a condenser in an electric circuit is put in the pipe line, and if all machines are cut off a stationary wave is formed and theoretically no energy is given to the system by the generator. It is desirable that connexions to machines along the pipe line shall be made at ½ wave-length points. Machines tapped in at half wave-length points along the pipe will be self-starting and stable in running, while those at the quarter wave-length and three-quarter wave-length will not be self-starting. If, however, a machine is started at half wave-length along the pipe, then a machine at a quarter wave-length will start; and if a machine is started at a wave-length along the pipe, then machines at a quarter and three-quarter wave-length will start. That this is so can be seen by examining the changes of pressure that take place at these points, when there is a stationary wave, and when there is a progressive wave superimposed on the stationary wave.

The principle has been successfully applied to controls on aeroplanes, to the working of rock-drilling machines, and to riveters. A description of the special transmission pipes to resist the high pressures generated, and the mechanism for rotating the rock drill, is given in the paper.

University and Educational Intelligence.

ABERDEEN.—The University Court has agreed to refit the Botanical Museum in Old Aberdeen, prior to the occupation of the new botanical department which is at present being built there. It has also agreed to make provision for increased laboratory accommodation for the department of chemistry.

CAMBRIDGE.—Mr. T. M. Cherry, Trinity College, has been elected to an Isaac Newton studentship, and the tenure of the studentship of Mr. W. M. H. Greaves, St. John's College, has been renewed for one year.

Smith's prizes have been awarded to Mr. J. C. Burkill, Trinity College, for an essay on "Functions of intervals and the problem of area," and to Mr. A. E. Ingham, Trinity College, for an essay on "Mean value theorems in the theory of the Riemann Zeta-Function." Rayleigh prizes have been awarded to Mr. E. F. Collingwood, Trinity College, for an essay on "The formal factorisation of an integral function of finite integral order," to Mr. W. R. Dean, Trinity College, for an essay on "The elastic stability of a plane plate," to Mr. E. C. Francis, Peterhouse, for an essay on "The Denjoy-Stieltjes integral," to Mr. C. G. F. James, Trinity College, for an essay on "The analytical representation of systems of space curves," and to Mr. M. H. A. Newman, St. John's College, for an essay "On discontinuities of functions of a single real variable."

The subject proposed for the Adams prize for the period 1923–4 is "The physical state of matter at high temperatures." Investigation is suggested of the statistical equilibrium of an assemblage of atoms in various ionised and quantised states together with free electrons and radiation. The essay may deal, however, in any way with the simplifications or the complications which appear in the properties of matter at high temperatures.

The Special Board for Oriental Studies will proceed to the election of the Eric Yarrow student in Assyriology early next term.

The Board of Research Studies in publishing its third report announces that the number of research students has risen to 179. Of these about two-thirds are working on the scientific side; chemistry and physics have the largest number, followed by botany, agriculture, and biochemistry.

Grants from the Gordon Wigan fund have been made to Prof. Punnett for plant-breeding experiments, to the Museum of Zoology for cases, to Prof. Gardiner for a centrifuge and incubator, to Mr. Harker for sections of rocks, and to Prof. Seward for sections of fossil plants.

DURHAM.—The council of Armstrong College, Newcastle-upon-Tyne, invite applications for the chair of philosophy. The latest date for the receipt of applications and testimonials is May 1. They should be sent to the Registrar.

LONDON.—The following doctorates have been conferred:—*Ph.D. in Science*: Mr. M. V. Gopalaswami of University College for a thesis entitled "Economy in Motor Learning"; Mr. A. M. Mosharrafa of King's College for a thesis entitled "The Quantum Theory of Spectral Series"; Mr. W. S. G. P.

Norris of the Imperial College (Royal College of Science) for a thesis entitled "The Formation and Stability of Spirane Hydrocarbons"; and Edith H. Usherwood of the Imperial College (Royal College of Science) for a thesis entitled "(i.) The Formation of Heterocyclic Rings involving Reactions with the Nitroso- and Nitro-groups in their various Tautomeric Modifications; (ii.) Experiments on the Detection of Equilibria in Gaseous Tautomeric Substances."

A post-graduate scholarship in science of the yearly value of 125*l.*, for two years, is being offered to Bedford College graduates for award in June next. Further information will be furnished upon application, by the Secretary of the College, Regent's Park, N.W.1.

Manchester.—Mr. R. S. Adamson has resigned his post as senior lecturer in botany on his appointment to the Harry Bolus chair of botany in the University of Cape Town.

Mr. C. R. Christian has been appointed temporary demonstrator in pathology.

The Court of Governors has authorised the conferment of the following honorary degrees: *D.Sc.*: Prof. Niels Bohr, Copenhagen; Prof. F. G. Hopkins, Cambridge; and Mr. W. B. Worthington, president of the Institution of Civil Engineers, 1921–1922.

We have received from the newly constituted University of Lithuania, Kaunas (Kovno), a copy of a bilingual—Lithuanian and English—calendar. The University, which was opened in February 1922, has the following faculties: theology and philosophy, humanities, law, mathematics and natural sciences, medicine, and technical science (engineering, chemical technology, architecture, etc.). It has 45 professors, 37 docents, and 35 members of the junior teaching staff, while there are more than a thousand students. It appeals to cultural institutions to help in the establishment of a library by sending books and other publications.

Loughborough College celebrated its first presentation day on March 10, when the College diploma was conferred on some 250 students of the following departments: mechanical and civil engineering (69), electrical (31), automobile (32), pure and applied science (10), commerce and economics (88), training of teachers (31). The Minister of Labour, Sir Montague Barlow, who presented the diplomas and gave an address, remarked that the College is carrying out a very interesting experiment in undertaking a course which combines very closely theoretical studies and practical experience. This feature, to which we directed attention in our issue of October 21, p. 562, aims at securing for engineering students advantages comparable with those which a School Hospital gives to medicals. An essential principle of management of the instructional factory is that the output should be saleable. During the war the College trained more than 2300 munition workers, and at its close inherited the fine buildings erected for this work as well as valuable engineering equipment. Among the post-war students have been more than 500 enrolled under the scheme of grants for higher education for ex-service students; 237 of them have taken the diploma, and of these 138 have been satisfactorily placed in employment. The number of private fee-paying students enrolled is 343. There are students from Australia, South Africa, India, and many foreign countries. The College aims at a normal enrolment sufficient to enable the productive work scheme to be carried on as a commercial and economic enterprise.

Societies and Academies.

London.

Royal Society, March 15.—J. A. **Carroll**: Note on the series-spectra of the aluminium sub-group. In contradistinction to the alkali metals, the highest terms in the known series-spectra of the elements of the aluminium sub-group are the common limits of the sharp and diffuse series, and not the limits of the principal series. Measurements of the ionisation and resonance potentials for thallium suggested that there might be a yet undiscovered principal series in the far ultra-violet, the limit of which would be the greatest term and would correspond with the normal state of the thallium atom. Against this is the absence of positive evidence of such a series, and the easily reversible nature of the lines of the subordinate series in the arc spectra. Evidence as to the normal state of the atoms is afforded by an investigation of the absorption spectrum of the cool vapour of one of the elements in question, *e.g.* thallium. The lines were members of the subordinate series, thus confirming the original series arrangement. The results accord with the latest developments of Bohr's theory.—W. E. **Curtis**: The structure of the band spectrum of helium.—II. Seven of the doublet bands previously examined by Fowler have been studied in detail. The structure of the bands, in the main, is in agreement with the requirements of the quantum theory; some discrepancies are discussed in connexion with Kratzer's half-quantum hypothesis. Values for the moments of inertia of the molecules concerned are derived by a graphic method. Several perturbations are recorded (the first examples in this spectrum) and their significance is discussed.—G. C. **Steward**: Aberration diffraction effects. Diffraction theory would indicate that the image of a luminous point, given by a symmetrical optical system, should be a system of luminous rings, and this was investigated by Airy in 1834; geometrical theory leads to a consideration of several types and orders of aberration, and the modification of the "ideal" diffraction pattern produced by these geometrical aberrations is discussed. The method adopted depends upon the Eikonal function of Bruns. Aberration diffraction effects are dealt with, assuming that the stops of the optical system are circular, with centres upon the axis of symmetry. Other stops used, namely, the usual circular aperture, but with the central portion stopped out, one (or two parallel) narrow rectangular aperture, and a semi-circular aperture are also considered.—Lord **Rayleigh**: Further observations on the spectrum of the night sky. Specially designed spectrographs having a working aperture of $f/\cdot 9$ are described. The northern and southern horizons have been photographed simultaneously on the same plate, and the aurora line recorded almost down to the horizontal direction in each. There is no marked difference of intensity between them. The negative nitrogen bands appear fairly often in photographs taken in the north of England, but similar spectra taken in the south of England do not show them. They are always strong in the Northern Lights in Shetland. Two bright lines or bands in the blue and violet were always observed, the approximate positions, determined on the *very* small scale spectra, being 4200 and 4435. Their origin is not known. In addition, there is the aurora line 5578, also of unknown origin, and the dark Fraunhofer lines H and K.—Lord **Rayleigh**: Studies of iridescent colour, and the structure producing it. IV.—Iridescent beetles. Some of the iridescent beetles which have striking metallic colours show band systems in the spectrum of the reflected light.

That from *Pelidnota sumptuosa* shows a central maximum bordered on either side by subordinate maxima in exactly the way that reflection from a uniformly spaced assemblage of 34 thin plates would require. In the spectrum from one of the golden beetles, *Callodes parvulus*, the bands are accounted for on the supposition of two assemblages, each consisting of several reflecting planes, the distance between the assemblages being about 8μ.—J. W. **Nicholson**: Oblate spheroidal harmonics and their applications.—J. W. **Nicholson** and F. J. **Cheshire**: On the theory and testing of right-angled prisms.—J. C. **McLennan** and D. S. **Ainslie**: On the fluorescence and channelled absorption spectra of caesium and other alkali elements. Caesium exhibits a fluorescence and a channelled absorption spectrum in the neighbourhood of $\lambda = 8000$ when the vapour of the element is traversed by white light. In the absorption spectrum, bands separated by intervals that were simple multiples of 24 Å were found. Like sodium, potassium exhibits channellings in its absorption spectrum, in the neighbourhood of the second member of its doublet series. Indications have been obtained of channelling in the absorption spectrum of lithium in the near ultra-violet region.—W. **Stiles**: The indicator method for the determination of coefficients of diffusion in gels, with special reference to the diffusion of chlorides. The coefficient of diffusion increases at a greater rate per degree rise in temperature the higher the temperature; the relation between coefficient of diffusion and temperature in gels is thus not linear as is usually assumed for free diffusion in water. The coefficient of diffusion decreases with increasing concentration of gel and increases with decreasing concentration of the diffusing salt. Empirical expressions are given for these relationships.—H. T. **Flint**: A generalised vector analysis of four dimensions. An account is given of an invariant vector calculus in a notation which is the natural generalisation of that of Gibbs. Contravariant and covariant vectors are related by means of an operator—the extended idem-factor, and tensors are introduced as dyadics and polyadics. The expressions familiar in the tensor calculus of Riemann and Christoffel appear very simply in the analysis. Separated points are connected by the geodetics, and a simple definition of parallelism at two points leads at once to the Weyl parallel displacement relations.

Geological Society, February 28.—Prof. A. C. Seward, president, and, afterwards, Prof. W. W. Watts, vice-president, in the chair.—S. Hazzledine **Warren**: (1) The late glacial stage of the Lea Valley (Third Report). One new section found occurred at the level of, and in the area occupied by, the Middle or Taplow Terrace, whereas all the other sections were in the Low Terrace. It consisted of a bed of seed-bearing clay, in the middle of an old gravel-pit partly built over. The Taplow deposits yield a fairly temperate fauna and flora. The site is close to the head of a small streamlet, and it is assumed that the Arctic plant-bed is of Low-Terrace or Ponders-End date, and that it represents the silting of a stream which flowed across the Taplow Terrace. According to a report on the Arctic flora by Mrs. E. M. Reid and Miss M. E. J. Chandler, there is nothing to distinguish the flora from that of the previously-described localities of the Lea Valley. (2) The *Elephas-antiquus* bed of Clacton-on-Sea (Essex), and its flora and fauna. The deposit fills a deep, narrow, steep-sided, river-channel which apparently flowed into the Thames when that river occupied the deep channel now submerged off the coast of Essex. The Clacton bed yields evidence of an abundant flint-industry which is one of the best-known representatives of the Mesvinian series. This is of Late Chellean or Early Acheulean date, although it shows no cultural connexion with those industries, but it may be the precursor of Mousterian. The deposit is also rich in mammalian remains. Appended to the paper are detailed reports on the palæontology.

Linnean Society, March 1.—Dr. A. Smith Woodward, president, in the chair.—J. N. **Halbert**: Notes on the Acari, with descriptions of new species.—C. F. M. **Swynnerton**: Aspects of African woodland formations. Rain-forest, coppice, and thicket due to grass-fires, the means of prevention from injury by such fires, and the preservation of the forests by careful nurture, were dealt with.

Aristotelian Society, March 5.—Prof. A. N. Whitehead, president, in the chair.—E. S. **Russell**: Psychobiology. Physico-chemical method is applicable to many of the phenomena of life, but it fails of complete success because it cannot take account of the individuality and striving of the living thing, nor its flexibility of response. Also it cannot take into consideration, as an active factor, the past history of the organism, for it must regard past history as completely summed up in present state. The true alternative to the materialistic view is not vitalism, but a psychobiological view based upon a monadistic philosophy. Both the movements and the morphogenetic responses of the organism must on this view be interpreted as actions of a living individuality, carried out in response to its own sensed environment, in pursuance of the fundamental conative impulses which are the core of its being.

Zoological Society, March 6.—Sir S. F. Harmer, vice-president, in the chair.—Mr. **Caldwell**: A case of apparent melanism in Tippelskirch's Giraffe (*Giraffa camelopardalis tippelskirchi*).—H. G. **Cannon**: A note on the zoæa of the land-crab, *Cardisoma armatum*.—Miss L. E. **Cheesman**: Notes on the pairing of the land-crab, *Cardisoma armatum*.—C. F. **Sonntag**: The comparative anatomy of the tongues of the mammalia.—VIII. Carnivora.—T. H. **Ring**: The elephant-seals of Kerguelen Land.—R. **Kirkpatrick**: On the tunicate *Rhizomolgula globularis* Pallas. No. 24. Results of the Oxford University Expedition to Spitsbergen, 1921.

Society of Public Analysts, March 7.—Mr. P. A. Ellis Richards, president, in the chair.—A. **Lucas**: The examination of firearms and projectiles. A particular weapon may sometimes be recognised by the rifling marks imprinted on a bullet, while the nature of the fouling left in the barrel after the weapon has been fired may afford information as to the nature of the original powder and also, in some cases, the period that has elapsed since the last discharge. The composition, dimensions, and markings on bullets, slugs, etc., are described, and directions are given for the reproduction of rifling marks and for the chemical analysis of projectiles.—R. C. **Frederick**: The interpretation of the results obtained in the analysis of potable waters.—S. B. **Phillips**: Determination of the purity of vanillin. After reviewing the various methods proposed from time to time the author described two processes for estimating vanillin—one volumetric, and the other gravimetric.

Edinburgh.

Royal Society, March 5.—Prof. F. O. Bower, president, in the chair.—F. O. **Bower**: The relation of size to the elaboration of form and structure of the vascular tracts in primitive plants. Measurements of the diameters of the whole part (stem or petiole) and of the conducting tract (stele or meristele) in many living and fossil plants show that increasing size is accompanied by increasing complexity of structure. There is a tendency in the various organs of plants to decentralise their conducting tracts as the part enlarges, and to advance them in greater or less degree towards the periphery of the transverse section. This decentralisation is carried out homoplastically, with details differing in the several parts affected, in various primitive organisms. It is not inherent in any one organ. The final result may be a convergence of structure in different plants, and in different parts of the same plant. This is illustrated (i.) by the solenostele, (ii.) by the zygopterid petiole, (iii.) by the Dipterid petiole, (iv.) by the petiole of Anachoropteris. Stellation of the stele or of the xylem, medullation, decentralisation of the stele, and finally its disintegration, so far as they are functions of increasing size, must lose grade for comparative purposes.—Miss Margery **Knight**: The life history and cytology of *Pylaiella litoralis*. Development and the reproductive processes were described. This involved a detailed cytological study of the organism. In particular it is shown that there is no obligate relationship between cytological features, somatic characters, and reproductive organs. The object of the paper is to emphasise this fact, and thereby to reopen discussion on the value of cytological characters in phyletic study.—A. **Steuart**: An electric clock, with detached pendulum and continuous motion. The speed of the driving electric motor is controlled by a pendulum, without throwing any work on the latter. A gravity arm acts on the pendulum, and then short-circuits a resistance in the motor armature circuit. The motor raises the gravity arm, and so replaces the resistance. A powerful turret clock and a silent regulator clock were demonstrated.

SHEFFIELD.

Society of Glass Technology, February 21.—Prof. W. E. S. Turner, president, in the chair.—W. W. **Warren**: Organising for production from pot furnaces. The function of a furnace is to melt glass. For most purposes, circular gas furnaces, either regenerative or recuperative, are to be preferred to those of rectangular shape. Among the advantages of working to a time-table in the matter of founding and working during definite periods are: (*a*) the responsibility devolved on the producer and furnacemen to have glass ready in time for their co-workers; (*b*) mixing, filling pots, and all labour subsidiary to glass-making work smoothly in an appointed groove. Informal talks with the men's committee, with a blackboard for illustrating points and explaining figures, rarely failed to convince them that foreign competitors' methods and prices were a challenge to business sport. But if there were rewards at the end of the production programme, the men must share.—F. W. **Hodkin** and Prof. W. E. S. **Turner**: The effect of boric oxide on the melting and working of glass.—Violet **Dimbleby**, S. **English**, and Prof. W. E. S. **Turner**: Some physical properties of boric oxide-containing glasses. Prof. Turner presented these two papers. The new British chemical glass, American pyrex glass for chemical ware and cooking ware, and various forms of illuminating glasses, all contain boric oxide. Although the addition of boric oxide to a silicate glass brought a marked increase in the durability, this beneficial effect only holds good up to a certain point. Similar inversions in other properties, *e.g.* in the thermal expansion, the annealing temperature, the density, and refractive index, had also been found.

National Health and Medical Research.[1]

THE elaborately detailed report of the Medical Research Council for the past year gives much food for thought, whether we receive it in the spirit of the tax-payer, anxious to be assured that his contribution to the national health is being worthily expended, or in the spirit of the watchman, eager only for a sign, but untroubled by detail. We all have in us something of the tax-payer and, let us hope, something more of the watchman, so let us see how these respective parts of us are catered for in the Council's report. Whether we are able to appreciate its contents or not, we, as tax-payers, have always demanded this sort of governmental report. Does it not concern the disbursement of 130,000*l.*, or something like a halfpenny per head of the population, on the pursuit of new knowledge that is to alleviate human suffering? Unthinking lay and even medical critics might regard it as a perilous investment. Were they holders of cinema shares, they would probably accept without question a similar disbursement to the parents of a Jackie Coogan.

If, then, we expect to find definite assurance that new knowledge leading directly and immediately to improvement in the health of the community has been acquired, we shall be disappointed. The average newspaper, keen only for sensation, would vote it dull. But a closer study of the report, including its admirable introductory chapter by the special Committee of the Privy Council, is calculated to bring to the more responsive of us the conviction that inability to appreciate springs from our own ignorance and short-sightedness. We gather, in fact, that the machine which registers advance in scientific medicine resembles a piece of complicated clockwork, the wheels of which represent movements in all the biological and physical sciences, not excluding mathematics. We note, for example, how the Hill katathermometer—an instrument of precision for measuring the cooling power of the atmosphere—may be made to afford a most valuable index of conditions affecting the efficiency of the worker in factory and workshop. We note also recent progress in our knowledge of the biological action of sunlight, and its remarkable influence on diseases such as rickets. A new field is here opened.

The discovery of insulin by the Toronto workers is alluded to at length. We gather that a method of preparing a potent product of consistent uniformity has not yet been achieved, but doubtless this difficulty will yield to further research. It is worth reflecting that this new knowledge might still be withheld from us, were it not for the elaboration in recent years of

[1] Report of the Medical Research Council for the year 1921–22. (Published by His Majesty's Stationery Office.) 3*s.* 6*d.* net.

quantitative tests for sugar in the blood. It is probable that many a preparation of pancreas has failed, in the past, to become established because its physiological activity could not be satisfactorily tested and recourse was limited to casual clinical trials. When one considers the plethora of commercial pancreatic preparations already on the market, which claim to contain the specific sugar-destroying principle, it is comforting to know that the Medical Research Council has taken the action it has, and that its own experts are actively engaged in studying methods that may yield preparations of uniform potency. In connexion with these difficulties, we note with some interest Dudley's work at the National Institute in refining pituitary extract. Apparently, the further the purification was carried, the less potent the substance became physiologically. This is not the first time that such stumbling-blocks have interfered with attempts to refine biologically potent principles contained in organ extracts or in culture fluids which have served for the growth of micro-organisms.

It would be superfluous to attempt to enumerate the many lines along which research is being pursued, either by expert workers at the National Institute or by the many outside specialists whose work the Medical Research Council encourages or finances; nor can we mention even the terms of reference of the numerous committees and sub-committees which have taken upon themselves the task of co-ordinating attack upon a multitude of problems in all fields of scientific medicine and hygiene. Membership of these committees is no sinecure, and it is notorious that much self-denying work is performed. Verily, the appreciative tax-payer can have no reason to grumble at the way in which his exiguous contribution to the community's health is expended.

Now what has the report to say to the watchman seeking for a sign? We believe the organisation of research under the ægis of a responsible body of scientific advisors is a valuable national asset. Will such organisation interfere with the individual freedom of the research worker? Is there a danger that the extension of the team-principle and the laying down by a higher authority of precise research programmes may stifle what originality the worker may possess? The answer is, we believe, that there are men who work best in a team and men who prefer to work alone, and that there is ample room for both types. There are periods both in war and in peace when stocktaking of knowledge is essential if we are again to make advance into the unknown. The present is one of those times of national stocktaking in medical science. The very fundamentals of many departments of medical science require revision. A doyen of the chemical world recently referred to certain developments and proposals in biological chemistry as being simply re-search, with the accent and insistence on the first syllable.

The statement is both true and false. Simple reconstruction must inevitably form an integral part of modern research. Possibly the biological sciences, on which advance in scientific medicine mainly hangs, contain a greater proportion of inexact, un-coordinated, and incomplete statement than the so-called exact physical sciences. Every advance in the latter reacts on biology, necessitating re-search in some form or other. Co-ordinated investigation by teams is necessary in peace as in war, and the fruit will duly appear. The scientific investigation of deficiency diseases—a war-time necessity—has developed into something like a science of its own. The organised investigations on anærobic bacteria—another war-time necessity—which was perhaps a very typical example of a re-search, has already borne abundant fruit in recent exact studies of such diseases as botulism and braxy.

What of the night? The morning cometh.

J. C. G. L.

The Fourier-Bessel Function.

(1) *A Treatise on Bessel Functions and their Applications to Physics.* By Prof. A. Gray and G. B. Mathews. Second edition prepared by A. Gray and Dr. T. M. MacRobert. Pp. xiv+327. (London: Macmillan and Co., Ltd., 1922.) 36*s.* net.

(2) *A Treatise on the Theory of Bessel Functions.* By Prof. G. N. Watson. Pp. viii+804. (Cambridge: At the University Press, 1922.) 70*s.* net.

THE function to which these volumes are devoted received its name from the astronomer Bessel, 1824, on introducing it for the coefficients in the expansion of radius vector, and true or eccentric anomaly in a Fourier series of sines and cosines of multiples of mean anomaly or time. Two years before, in 1822, Fourier had encountered the same function essentially in his analytical theory of heat, and his variable is the square of the variable of Bessel.

The function is, however, first met in a dynamical problem, of the oscillation of a vertical chain, investigated by Bernoulli, 1738, and here the Fourier form is the natural one to use. The oscillation is replaced by a steady motion of permanent shape in a chain hanging down, and revolving bodily, and this is easy to realise experimentally; the plane oscillation is then seen in the shadow on a vertical wall.

Take the condition of relative equilibrium of a length x above the lowest point, where it is assumed that the displacement is small enough for vertical distance x

and the length of the chain to be undistinguishable, so that the tension $T=\sigma x$, as at rest, σ the line density.

Putting $g=\omega^2 l$, where l is the height of the equivalent conical pendulum revolving at the same rate ω, the equation of relative equilibrium is

$$T\frac{dy}{dx}+\int\sigma\frac{y}{l}dx=0,\quad x\frac{d^2y}{dx^2}+\frac{dy}{dx}+\frac{y}{l}=0,$$

having a solution $y=b\mathrm{F}(x/l)$, where $\mathrm{F}(x)$ is Fourier's function, defined by the series

$$\mathrm{F}(x)=\Sigma\frac{(-x)^k}{(\Pi k)^2}.$$

The sort called *Furniture Chain* is suitable for experiment: the links are small hollow brass spheres, joined up by rivet links, and it is sold in various sizes.

A length of the large size of about 4 feet is suitable for whirling round by hand, and producing a curve in 1, 2, 3, 4, . . . waves, showing to the eye the position of the first roots of $\mathrm{F}(x)=0$.

Standing up on a chair or the table, a length of 8 or 12 feet of the smaller size may be set in rotation by the dynamobile toy. The chain springs at once into a series of waves, where the higher roots are seen and their spacing, prolongation of the figure at the end of Gray.

The chain can also be used to show off a real catenary curve, instead of the string recommended in Routh—much too kinky and destitute of flexibility to form a good catenary. And dropping the chain from a height is a good problem on a steady blow, equivalent of a series of impacts of the discrete links.

With a rotating chain of variable density, σx^n, the tension $T=\sigma x^{n+1}/(n+1)$, and the equation changes to

$$T\frac{dy}{dx}+\int\sigma x^n\frac{y}{l}dx=0,\quad x\frac{d^2y}{dx^2}+(n+1)\frac{dy}{dx}+(n+1)\frac{y}{l}=0,$$

the solution of which may be written

$$y=b\left(-\frac{d}{dx}\right)^n\mathrm{F}(n+1)\frac{x}{l},$$

and l is the length of the subtangent at the lowest point.

For if $u=\mathrm{F}(x)$ is the solution of the equation

$$x\frac{d^2u}{dx^2}+\frac{du}{dx}+u=0,$$

differentiating n times, with $y=(-d/dx)^n u=\mathrm{F}_n(x)$,

$$x\frac{d^2y}{dx^2}+(n+1)\frac{dy}{dx}+y=0,\quad y=\mathrm{F}_n(x)=\Sigma\frac{(-x)^k}{\Pi(n+k)\Pi k},$$

the Fourier function of the nth order.

Here n may be changed into $-n$, and the differentiation into an integration, making $\mathrm{F}_{-n}(x)=x^n\mathrm{F}_n(x)$.

Gray's function $\mathrm{I}_n(t)$ (p. 20) is the equivalent of $\mathrm{F}_n(-x)$.

But with the variable $z=2\sqrt{x}$ of the Bessel form, the equation changes to

$$z^2\frac{d^2y}{dz^2}+(2n+1)z\frac{dy}{dz}+z^2y=0,$$

and this, with $y=(\tfrac{1}{2}z)^{-n}u$, into

$$z^2\frac{d^2u}{dz^2}+z\frac{du}{dz}+(z^2-n^2)u=0,$$

defining $u=\mathrm{J}_n(z)=(\tfrac{1}{2}z)^n\mathrm{F}_n(\tfrac{1}{4}z^2)$, and the simplicity disappears of the derivation of $\mathrm{J}_n(z)$ from $\mathrm{J}_0(z)$ by successive differentiation or integration; factors intervene of powers of z.

The interlacing of the roots of F_n and F_{n+1} is evident from the differentiation; and there is an infinite series of positive roots, but none are negative.

This chain of variable density could be imitated by a flexible lattice blind, of appropriate curvilinear outline, hanging vertically, and rotating bodily.

Lecornu's problem of the oscillation of a large weight, raised or lowered by a chain of which the density may be neglected, is seen in operation in the erection of the tall buildings springing up around; it gives rise to similar expressions.

A Fourier function of fractional order arises in the question of the stability of a tall mast or tree, or of a chimney stalk when it begins to flinch on the foundation, and starts to curl over from the vertical; illustrated experimentally by a thin steel wire clamped in a vice.

With uniform cross-section, the equation is

$$ek^2\frac{d^2p}{dx^2}+xp=0,\quad \frac{1}{p}\frac{d^2p}{dx^2}+\frac{x}{ek^2}=0,$$

where $p=dy/dx$, k is the radius of gyration of the horizontal section across the plane of flexure, and e is Young's elastic length of the material, quotient of the modulus of elasticity divided by the density.

Every linear differential equation of the second order is reducible, by a change of independent and dependent variable, to the canonical form

$$\frac{1}{u}\frac{d^2u}{dx^2}+\mathrm{I}=0,$$

and when the differential invariant $\mathrm{I}=kx^n$, any power of x, the form to which Riccati's equation is reducible, the equation is reduced to Fourier's form by a mere change of the independent variable to

$$z=\frac{kx^{m+2}}{(m+2)^2},$$

and becomes Fourier's equation for

$$u=\mathrm{F}_n(z),\quad n=-\frac{1}{m+2}$$

(Watson, p. 88).

Here with the uniform column on the verge of drooping from the vertical, $m=1$, $p=b\mathrm{F}_{-\frac{1}{3}}(x^3/9ek^2)$.

The smallest root of $F_{-\frac{1}{3}}=0$ is about 0·88, say $\frac{8}{9}$ (Watson); this makes the critical height

$$x=2(ek^2)^{\frac{1}{3}}=(\tfrac{1}{2}ed^2)^{\frac{1}{3}}$$

for a circular rod of diameter d.

For steel, we may take $e=250$ million cm, one quarter of a quadrant Q of the Earth, $\sqrt[3]{\tfrac{1}{2}e}=500$.

With a steel wire held in the vice vertical, one millimetre in diameter, $d=0{\cdot}1$ cm, the critical height $x=500\,d^{\frac{2}{3}}=107{\cdot}7$ cm, a little over one metre. As the height is increased through this length, the vibration becomes sluggish more and more, and finally ceases, and the wire droops.

The drooping of a candle on a hot day will give an illustration; also a field of corn when it is ripe, where, to obtain a complete solution, the weight of the head would require the introduction of the Fourier function of the second kind, or a Bessel-Neumann-Weber function (Gray, p. 14; Watson, p. 308); so too for the addition of a weight at the end of the vibrating chain.

Here the flexural elasticity keeps the rod, mast, or cornstalk vertical; a flexible chain cannot be made to stand upright; the sign of x would be changed in the relation, and the Fourier function has no negative root.

But a quasi-rigidity can be imparted, as in the reported rope trick of the Indian juggler magician, if our chain carries a gyroscopic flywheel in rapid rotation inside each link, like a pile of spinning tops, and then, as shown in *Phil. Mag.*, Nov. 1919, p. 506, the differential equation of the former result changes to the form

$$(a-x)\frac{d^2y}{dx^2}-\frac{dy}{dx}+\frac{y}{l}=0,$$

with x measured downward from the free end at the top; the solution is

$$y=b\mathrm{F}\left(\frac{a-x}{l}\right),$$

and the first value of $y=0$ is given by $(a-x)/l=1{\cdot}44$. Thus a length x of the gyroscopic chain can be made to stand upright, given by $x=a-1{\cdot}44\,l$.

The whip and whirl of a revolving shaft has become a question of practical importance in the swift-running machinery of a turbine, internal-combustion flying-machine motor, and gyro-compass.

Here it is obvious that the shaft will depart from the straight form when the revolutions are equal to the lateral vibrations of the shaft at rest, held between the same bearings, the disturbing and restoring force being the same in the two cases.

The more general form of the differential equation, required when the cross-section and density varies as some power of x, will be

$$\frac{d}{dx}\left(x^q\frac{dy}{dx}\right)+kx^my=0,$$

and hence a change to the independent variable

$$z=\frac{kx^{m-q+2}}{(m-q+2)^2}$$

will lead to Fourier's equation of order

$$n=\frac{q-1}{m-q+2}.$$

The general solution of Riccati's equation is thus expressed by the Fourier function; and the condition that Riccati should have a solution in finite terms requires n to be half an odd integer.

Beginning with $n=-\frac{1}{2}$,

$$\mathrm{F}_{-\frac{1}{2}}(x)=\Sigma\frac{(-x)^k}{\Pi(k-\frac{1}{2})\Pi k},$$

$$\mathrm{F}_{-\frac{1}{2}}(x)=\frac{1}{\sqrt{\pi}}\Sigma\frac{(-2\sqrt{x})^{2k}}{\Pi 2k}=\frac{\cos 2\sqrt{x}}{\sqrt{\pi}};$$

and a phase angle ϵ may be added to the variable $2\sqrt{x}$ to include both forms of the function.

Then the other Fourier functions of order half an odd integer are derived by an integration or differentiation with respect to x:

$$\sqrt{\pi}\mathrm{F}_{\frac{1}{2}}(x)=-\frac{d}{dx}\sqrt{\pi}\mathrm{F}_{-\frac{1}{2}}(x)=\frac{\sin 2\sqrt{x}}{\sqrt{x}},$$

$$\sqrt{\pi}\mathrm{F}_{\frac{3}{2}}(x)=-\frac{\cos 2\sqrt{x}}{x}+\frac{\sin 2\sqrt{x}}{2x^{\frac{3}{2}}}=x^{-\frac{3}{2}}\sqrt{\pi}\mathrm{F}_{-\frac{3}{2}}(x),$$

and so on.

The same simplicity of derivation is not so obvious in the table (Gray, p. 17) for $J_{n+\frac{1}{2}}(z)$, although the sines and cosines are replaced by sin, cos $(z+\epsilon)$.

Functions of this fractional order are of frequent occurrence in mathematical physics, as in the vibration of a sphere (Love's "Elasticity," Lamb's "Hydrodynamics") for the functions ψ_n and Ψ_n, solution of $(\nabla^2+m^2)\phi=0$, in the propagation of spherical waves or the conduction of heat; also for the function F_n of Bromwich and $\gamma\rho$ of Macdonald in electromagnetic waves; simplicity would be obtained if all these functions were referred to the Fourier form and classed there (*Phil. Mag.*, Nov. 1919, pp. 508, 526).

The Fourier function comes in useful for the discussion of a long flat tidal wave in an estuary or channel of vertical cross-section K, and surface breadth b, treated as slowly variable, on the assumption of K and b varying as x^q and x^m, simple powers of x.

The Fourier function is suitable, too, in the discussion of diffraction (Gray, Chapter XIV.), provided the area of a circular fringe is taken in the formula instead of the circumference or diameter.

The derivation, by differentiation and integration, of the Fourier function of different order marks it out as more appropriate than Bessel for the passage, in Lord Rayleigh's manner, of the tesseral harmonic $P_n^k(\mu)$ direct into a Fourier function $F_p(x=\frac{1}{4}m^2r^2)$ as the order

n is increased indefinitely (*Phil. Mag.*, Nov. 1919, p. 526).

In Gray's treatise the physical applications are kept in view throughout the book up to the end. The requirements are considered of the mixed mathematician. Not to start with general theory, but to give definite technical examples, to show how the problem may be reduced to the differential equation considered, he will consult the appropriate part of the book as the need arises, and will take for granted the discussion of details of pure analysis, on the validity of an expansion, definite integral expressions, asymptotic expansions, and all the niceties appealing to the pure mathematician of a logical metaphysical intellect.

These can be skipped by the physical student engrossed in a physical problem, and only anxious to dig out the facts and apply the formula to a concrete numerical application, for which the tables at the end of the book will give the requisite material.

The treatise of Watson has a different scope. A first short historical chapter cites name and date of the pioneers up to 1826 encountering the function in dynamical, astronomical, and heat problems, namely, Bernoulli, Euler, Fourier, Bessel.

After this introduction, all definite mention of the physical application is dismissed by Watson in the subsequent 800 pages, and the reader is not encouraged to lift his eye from the page and look up at any materialisation of the analysis, or to study a geometrical picture.

The book proceeds in what is now the conventional manner of a modern analytical treatise, stopping in a leisurely manner to emphasise and scrutinise every possible objection that may arise on the part of rigour. Those who like this work become uncommonly fond of it, and lose interest in a realisation of the ideas.

"Making possible the necessary degree of abstraction is one of the most important merits of mathematical logic."

The Bessel function has few attractive analytical qualities, and does not deserve elaborate treatment to the exclusion of more valuable interest, say of the elliptic function.

The students must be few to afford the time demanded for this subject, not to speak of the expense—for Watson's book, 70*s.*; and Gray's of 327 pages, at 36*s.*

We see the tax laid on knowledge by the price of all mathematical work; the expense of publication has risen far beyond anything contemplated in the old days of debate in the Mutual Improvement Society on the need of a free press and cheap diffusion of knowledge.

It is the fashion to-day to discard a redundant *i* in the name Bernoulli, as in the Bernoullianum Mathematical Museum in Basel, Basle, Bâle in Switzerland. But Maclaurin in his "Account of Newton's Philosophical Discoveries," 1750, spells the name Bernovilli, and here we see the etymological derivation and a reason for the restoration of the banished *i*.

G. GREENHILL.

A Yearbook of the Learned World.

Index Generalis: Annuaire général des Universités, Grandes Écoles, Académies, Archives, Bibliothèques, Instituts scientifiques, Jardins botaniques et zoologiques, Musées, Observatoires, Sociétés savantes. Published under the direction of Dr. R. de Montessus de Ballore. Pp. 2111. (Paris: Gauthier-Villars et Cie, 1923.) 35*s.*

WE welcome the appearance of the third (1922–23) issue of a work which, pending the issue of "Minerva" in its old form, is the only comprehensive directory of the learned world. Its scope is shown by the following analysis of its 2111 pages: (1) Directories of universities, colleges, and professional schools grouped by countries, 913 pages; (2) astronomical observatories, 86 pages; (3) libraries and archives, 325 pages; (4) museums and scientific institutes, 100 pages; (5) learned societies and academies, 194 pages; (6) list of *savants* who desire to exchange original dissertations with their fellow-workers, 7 pages; (7) index of names (more than 40,000), 428 pages; (8) other indexes and vocabularies, 53 pages. In part (1), in addition to the names of professors, lecturers, and other teachers and their subjects, are mentioned the principal administrative officers and, in many cases, the date of foundation, the total number of students, and the total annual expenditure: in part (2), publications, principal instruments, and programme of work; in part (3), days and hours of admission and annual holidays, date of foundation, special features, number of volumes, MSS., etc., annual budget, catalogues, rules for borrowers, name of librarian; in part (4), similar particulars with general description of exhibits or plant and mention of publications; in part (5), objects and aims, number of members, date of foundation, names of president and secretary, subscription, particulars of meetings, lists of fellows and of foreign members of some of the more important societies, and details of publications.

The editing of such an enormous mass of data is a formidable task and Prof. R. de Montessus de Ballore, the distinguished scholar who has had the courage to undertake it and the energy and perseverance to complete it, has thereby earned the gratitude of *savants* of all countries. The editor, who states that his object has been to achieve "the utmost clearness for reference," is to be congratulated on his judicious selection of type and on the ingenious device whereby he refers in the index of names not only to the page but to the particular section of the page in which the name sought is to be found.

The most generally useful part of the book, on the merits of which it will be judged, is part (1), and we have therefore examined some of the entries in this part, selected at random, in order to test its general accuracy. In such a work absolute accuracy is unattainable, but the editor, aiming at a high standard, "thought it better not to publish any information except such as has been directly communicated by administrative chief officials. . . . He has further had the proof of each entry corrected by its contributor." He has branded with an asterisk the rather numerous institutions which have failed to reply to his questionnaires in time and has reproduced the notices of them which appeared in the 1920–21 issue: thirty-one institutions which have not replied since 1919 have been excluded altogether. This procedure unfortunately has not prevented what we cannot but regard as an excessive percentage of error in the entries tested.

We venture to offer a suggestion regarding the entries in part (1) relating to institutions in the British Empire—about one-third of the total number. It is that the editor might use as the basis of such entries the Yearbook issued by the Universities Bureau of the British Empire. Had he done so he would not have omitted such important institutions as the Osmania University of Hyderabad, Deccan, the University of Rangoon, the University of Patna (except for casual references), and University College, Swansea, his entries would have been more rather than less up-to-date, he would have saved himself a great deal of labour and expense, and would have been saved from such "howlers" as *His Grace* Eamon de Valera (Chancellor of the N.U.I.) and showing (and indexing) Petro Drilling as the name of a teacher instead of showing it as a subject (petroleum well-boring).

There is, moreover, another and a very important side to the question. If our university administrative officials, after having supplied returns to their own Universities Bureau and to Government Departments, are to be plied with requests for the self-same information in different forms for international Indexes and the League of Nations (which now proposes itself to compile something of the kind), it will not be surprising if some of the answers are short or if the pages of the Index become even more abundantly starred than at present. If the universities of each country would combine to produce a national yearbook, these would make the best possible material for (if not constituent parts of) an Index Generalis. For the British Empire the work is already done. Italy has her "Annuario degli Istituti Scientifici"—not yet appearing annually, however. The American Council on Education is, in its recently formed Division of College and University Personnel, acquiring much of the requisite material for such a yearbook, and Switzerland and the Netherlands have similar inter-university organisations.

The Cactus Family.

The Cactaceae: Descriptions and Illustrations of Plants of the Cactus family. By N. L. Britton and J. N. Rose. Vol. 3, pp. vii + 255, with 24 plates. (Washington: Carnegie Institution, 1922.)

ALL who grow Cacti will be glad to learn that the third volume of this fine work has been issued. It will probably appeal to a larger number of Cactus fanciers than the two preceding volumes, because it treats chiefly of the smaller kinds, which are more generally cultivated than the columnar or climbing species. This volume is of the same high standard of excellence as the two others, and as an account was given in NATURE of July 7, 1921 (vol. 107, p. 580) of the general character, scope, and details of the work, it will be unnecessary to repeat them here.

The subtribes dealt with in this volume are the Echinocereanæ, consisting of 6 genera (3 of them new) and 115 species, the largest genera being Echinocereus, 60 species, and Echinopsis, 28 species. The Echinocactanæ consist of 28 genera (18 of them new) and 166 species, the largest genera being Ferocactus, 30 species, Malacocarpus, 29 species, Gymnocalycium, 23 species, and Echinofossulocactus, 22 species. The Cactanæ consist of the two genera Discocactus, 7 species, and Cactus (better known as Melocactus), 18 species. Altogether 36 genera (of which 17 are monotypic and 21 are new) and 306 species are described, and well illustrated by 250 figures in the text, and 24 plates, most of them coloured.

Most of the Echinocactanæ are known to cultivators as belonging to the genus Echinocactus, and they will perhaps find it difficult to understand why, in this volume, only 9 species are placed under that genus, and all the others relegated to other genera. The reason is that while the vegetative characters of a large number of species is similar in type, the structural details of their flowers differ, and these floral differences have, in this work, been utilised for generic distinction in a manner not practised before. All this is made manifest in the keys, which are concise and clear, so that with the aid of the very numerous illustrations few should find difficulty in referring an unnamed species of the group to its proper genus.

It is much to be deplored that such a cumbersome sentence-like name as "Echinofossulocactus" should have been brought into use, but unfortunately there seems no valid reason for its rejection, for although it has been overlooked, it was proposed and characterised 81 years ago. It would, however, be of benefit to horticulturists and botanists alike, if, at the next Botanical Congress, a law could be made to prohibit the formation of such atrocious names in future.

The charming coloured plates give a good idea of the beauty of the flowers of these prickly plants, and the views showing some of them as they grow wild will convey to the mind of the cultivator the appearance they should have when well cultivated. Of the plants figured, *Ferocactus rectispinus* is one of the most striking on account of the formidable aspect it presents by its stout straight spines about 4 inches long. Of all the flowers figured the most remarkable is that of *Denmosa rhodacantha* (better known as *Echinopsis rhodacantha*), which is curved in a sigmoid manner, and has the petals closed tightly around the exserted stamens and style, quite unlike that of any other genus.

The well-known spineless *Echinocactus Williamsii* is rightly removed from that genus and now forms a monotypic genus under the name of *Lophophora Williamsii*. This plant has remarkable narcotic properties and has long been used by certain tribes of North American Indians in some of their ceremonies. One peculiarity of this plant is that its stamens are irritable, and when touched at the basal part they rapidly close in around the style, dusting their pollen upon the insect or other thing that touched them; an evident means of securing cross-fertilisation. A very full index completes the volume. There remain to complete the work the subtribes to which the genera Mammillaria and Rhipsalis belong.

N. E. BROWN.

Our Bookshelf.

Kinematograph Studio Technique. (Technical Primers.) By L. C. Macbean. Pp. xii + 111. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 2*s.* 6*d.* net.

ACCORDING to the subtitle of this little book, it is "a practical outline of the artistic and technical work in the production of film plays for producers, cameramen, artistes, and others engaged in or desirous of entering the kinematograph industry." There are chapters on production, the camera and its lenses, studio lighting and outdoor work, dark-room procedure, and so on. No previous knowledge of the subject is assumed, and many will be interested to learn of the artifices by which some of the more striking film scenes are produced, while they may also be surprised at the amount of painstaking labour and attention to detail which goes to the making of a successful film.

The Chemistry of Dental Materials. By Prof. C. S. Gibson. Pp. 176. (London: Benn Bros., Ltd., 1922.) 12*s.* 6*d.* net.

A CAREFULLY selected area in chemistry, largely metallurgy, is dealt with in this treatise, but what is done appears thorough. The treatment is not narrow and utilitarian, but as scientific as is possible. The second half of the book deals with miscellaneous materials used in dentistry, such as porcelain, cements, abrasive materials and antiseptics, and in this, of course, much information is given which cannot be found in the ordinary text-books of chemistry. The Brunner-Mond process for zinc, described on p. 100, is said to be now obsolete, and the same applies to the third form of tin (p. 105). Some mention of modern processes for lead extraction might have been given. Davy's name is incorrectly given on p. 146.

(1) *Installations électriques industrielles: Installation—Entretien—Contrôle.* Par R. Cabaud. (Bibliothèque Professionnelle.) Pp. 333. (Paris: J. B. Baillière et fils, 1922.) 10 francs net.

(2) *Alternating Current Electrical Engineering.* By P. Kemp. Second edition. Pp. xi + 515. (London: Macmillan and Co., Ltd., 1922.) 17*s.* net.

(1) THE first part of M. Cabaud's book deals in a general way with electric installations for light and power. The numerical examples given will be helpful to the practical engineer. The maintenance of an installation is discussed in the second part, and in the third part methods of control are described. Various methods of penalising consumers who take their supply at a low-power factor are given.

(2) The principal changes in the new edition of Mr. Kemp's book are a new chapter on the protection of alternating current systems, and a number of alterations in the chapters on instruments.

The Radio Amateur's Hand Book. By A. F. Collins. Pp. xix + 329 + 8 plates. (London, Calcutta, and Sydney: G. G. Harrap and Co., Ltd., 1922.) 7*s.* 6*d.* net.

A POPULAR description of radio communication which will be helpful to amateurs is given in this book. The author uses the proper technical terms, so any one who has read this book will be in a position to benefit by more advanced treatises on the subject. In the glossary, however, the attempt to define highly technical terms in the simplest language is of doubtful utility. Capacity is defined as "any object that will retain a charge of electricity." The book concludes with a long list of radio "don'ts," which will prove instructive to the beginner.

The Pupils' Class-book of Geography: the Americas. By Ed. J. S. Lay. Pp. 176. (London: Macmillan and Co., Ltd., 1922.) 1*s.* 3*d.*

IT is not easy to write an elementary text-book on geography which has any interest for the pupils who use it and at the same time is truly geographical, but Mr. Lay appears to have succeeded. His book is accurate, readable, and well illustrated by excellent black and white maps, and presents the essential features of the geography of the Americas.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Nature of the Liquid State.

IN his recent lecture to the Chemical Society on "The Significance of Crystal Structure," Sir William Bragg has described and discussed the extremely important results obtained in his laboratory by the X-ray analysis of various carbon compounds, notably those belonging to the aromatic series. The special feature brought to light by the investigations is that the ultimate unit of crystal structure or elementary parallelepiped is not the chemical molecule, but, generally speaking, is a complex formed by the union of two, three, or four molecules. Further, the symmetry of the crystal tends to increase with the number of molecules in the unit, and also with the symmetry of the molecule itself. In fact, there are simple quantitative rules, first stated by Shearer, connecting these quantities.

The question naturally arises whether when a crystal is melted and passes into the liquid state, the units in the latter condition are the same as in the crystal, or whether these break up further into the individual molecules. A method of investigating this very fundamental point is furnished by studies on the molecular scattering of light. If the units in the liquid state are the chemical molecules, that is, the same as in the condition of vapour, there should be a simple quantitative relation between the amount of *unpolarised light* (due to optical anisotropy) scattered by equal volumes of liquid and vapour and the densities in the two states of aggregation. This relation was indicated in my letter in NATURE of July 1, 1922, but the method of calculation there given has to be amended to make allowance for the fact that the electric polarisation within a fluid is, according to the Lorentz-Mosotti formula, greater than in free space. When this correction is made, it is found that the amount of *unpolarised* light actually scattered is considerably smaller than that indicated by the calculation. The conclusion thus appears to be forced upon us that the ultimate unit in the liquid state is not the same as in the state of vapour. On the other hand, if we adopt the view that the ultimate unit is the same in the liquid state as in the crystalline state, a way is opened for a satisfactory explanation of the observed result. For, according to Shearer's rule, the symmetry of the unit is always greater than that of the molecule, and hence the amount of unpolarised light scattered by it should be diminished, as is actually observed.

A further consideration which suggests that the ultimate unit in the liquid state is the same as in the crystalline solid is the existence of those remarkable substances, known as liquid crystals, studied by Lehmann and others. If a liquid be conceived of as a collection of elementary crystal parallelepipeds which are ordinarily prevented from thermal agitation from forming regular arrays, it is easier to understand how in favourable circumstances, such arrays come into existence temporarily and as quickly disappear. This conception appears to fit in very well with the mathematical framework of the kinetic theory of liquid crystals recently developed by Oseen (Stockholm Academy, Handlingar, 1921).

The same conception also appears to furnish a satisfactory explanation of the tendency shown by many liquids to refuse crystallisation and to pass into a highly viscous or glassy condition when supercooled. We have only to suppose that the units gradually join up, but in an irregular way, and form an optically heterogeneous structure. This conception of the constitution of vitreous solids is supported by the results of an extensive series of observations on the scattering of light in optical glasses and in supercooled organic liquids carried out under the writer's direction.

Finally, it may be remarked that the conception suggested does not, so far as the writer can see, appear to be inconsistent with any other known facts regarding the physical properties of liquids.

C. V. RAMAN.

210 Bowbazaar Street,
Calcutta, India,
February 22.

PROF. RAMAN'S very interesting explanation of his observations on the scattering of light by liquids is not affected if a slight change is made in his suggestion as to the appearance of the crystal unit in the liquid phase.

The crystal unit is a parallelepiped of minimum volume, the corners of which are occupied by molecules alike in all respects, including orientation. The definition allows the unit to be delimited in an indefinite number of ways. It is improbable that any one of these occurs as the only kind of unit in the liquid. For Prof. Raman's purpose it is sufficient, I think, to suppose that association, when it occurs, is ordered, the molecules joining up as if they were beginning to build a crystal. Let us suppose, for example, that the crystal belongs to the monoclinic prismatic class, in which there are four types of molecular arrangement. Any molecule of one type possesses with any molecule of the other three types, a plane, a digonal axis, or a centre of symmetry, respectively.

Groups of mutually arranged molecules may well be expected to form under suitable conditions, but it is not likely that the group will always consist of four, or be put together the same way. The group could always, however, be incorporated into a complete crystal: possibly some redressing of the boundary might be required.

An ordered association or incipient crystallisation has been suggested by Astbury (Proc. Roy. Soc., 102, p. 527) as the cause of the variability of the optical activity of tartaric acid with the strength of solution. The Debye-Scherrer photographs of colloidal gold show that each particle is essentially an association of gold atoms in crystalline array. It is possible that on the surface there is disorder which affects the further growth of the particle.

The point is that whenever association takes place, it tends to do so in the ordered fashion of the appropriate crystal. W. H. BRAGG.

The Wegener Hypothesis and the Great Pyramid.

IN the discussions on the Wegener hypothesis I have not yet seen an allusion to the direct evidence given by Flinders Petrie ("Pyramids and Temples of Gizeh," second edition, 1885, pp. 11 and 41) of a change in azimuth at Gizeh amounting to four or five minutes since the erection of the Great Pyramid.

Petrie's account of the high accuracy used in the construction of the pyramid seems to render quite impossible an error of 4′ in the laying down of a meridian line 700 feet long, from which other baselines were set off during 30 or 40 years. As my brother, Lt.-Col. M. M. Bidder, pointed out to me, every annual class in the local school of engineers would, in its turn, verify the meridian line under the supervision of their instructors; yet the second pyramid has the same orientation ($5\frac{1}{2}'$ west of north) as the core-plane of the first pyramid.

There are five meridians deduced by Petrie (p. 41) from his measurements. Of these the lowest and highest values occur in the Great Pyramid, being $-3' 43'' \pm 6''$ for the casing sides and $-5' 49'' \pm 7''$ for the passage. The four of them representing the Great Pyramid core and passage, and the Second Pyramid casing and passage, are all covered by the value $-5' 33'' \pm 17''$. Petrie's conclusion (p. 11) is "that the original base was probably more accurate than 0·05 inch in length and 12″ in angle."

GEORGE P. BIDDER.

Cambridge, February 26.

THE undoubted trend of the pyramids at 4600 B.C. was about 5′ west of the present pole. Each of the data was probably set out afresh from polar observation, as that would be easier than transfer by measurement. The accuracy of work there to 12″ of angle is in keeping with the accuracy of later work, as of granite planes 20 square feet in area with only inch/160 error at 3300 B.C., or of weights in eighth century A.D. with variations all within grain/200. The cause of a change of axis of about 5″ per century might be due to ocean currents or to earth deformation.

W. M. F. PETRIE.

Science and Armaments.

DR. FRENCH'S reply (NATURE, February 10) to my letter in the issue of January 20 does not touch upon the essential idea which I desired to express. I did not raise the question of the dispensability or indispensability of armaments at the present moment: a question on which a great deal might be said, but one which, I think, is somewhat outside the province of NATURE. The very columns of this journal are, however, a witness to a very real international brotherhood between men of all lands who find a common interest in the study of natural science and in its ceaseless warfare for the knowledge and control of material things for the common good of humanity.

Taking the wider view, how can it be a *consolation* that, under the urge of apparent national expediency, men should be spending their time in devising new methods of warfare by the application of that knowledge and training which should be a blessing to mankind instead of a curse? The new weapon used against A by B is to-morrow directed by A against B. Moreover, these methods, the scientific cleverness and interest of which often provide a poor mask for their brutality, are directed, not against barbarism, but largely against those for whom we now profess friendship. Such a condition may be difficult to avoid, but the great danger is that we should treat it as natural and inevitable, and grow insensible to the shame of these things. Have we forgotten the folly of

"All valiant dust that builds on dust"?

In the time of Davy it seems clear that science was respected as a thing apart from war, and we are led to inquire the reason for the change. Has it not been the willingness of inventors to exploit their knowledge, and to allow themselves to be exploited by men who cared less than nothing for science and all that it really stands for? There was small patriotism in many transactions that might be recalled, for things were sold to the highest bidder.

My first letter was, in brief, a plea that we should treat our science as something rare and precious, belonging not to ourselves only but also to all nations. Whatever burdensome and unpleasant tasks it may fall to our national lot to perform, we shall not face them the less effectively because we keep some of our most cherished possessions free from the dust of conflict. Hence my comment on the proposed action at the Science Museum. L. C. MARTIN.

Royal College of Science,
South Kensington, S.W.7.

Hafnium and Titanium.

REFERRING to Sir Edward Thorpe's interesting letter on this subject in NATURE of February 24, I would point out that the Cornish village of "Manaccan" is in the parish of Manaccan, which adjoins the parish of St. Keverne. There is an error also in the spelling. "Menaccan" should be M*a*naccan, and so with the stream at "Lenarth," it should be *L*anarth. Presumably, therefore, the Cornish mineral should have been called M*a*naccanite and not M*e*naccanite, and the "new element" from it should have been termed "manachin" and not "menachin."

WILSON L. FOX.

Falmouth, February 26.

The Cause of Anticyclones.

IN a letter to NATURE of December 23 (vol. 110, p. 845) Mr. W. H. Dines has raised certain questions connected with the cause of anticyclones. The chief observational facts to be explained are the features peculiar to *most* high pressures, namely, the warm troposphere, the high and cold stratosphere. But not all anticyclones are warm even from a height of 3 km. up to 8 km. Some are cold to considerable heights. The gradual rise of the coefficient of correlation between pressure and temperature at the same level as one proceeds from 0 to 4 km., and the comparative uniformity of the coefficient from 4 to 8 km., is in itself strong evidence that in our latitudes these first 4 km. are the theatre of changes of air more and more frequent as the surface is approached, and that in the regions above 4 km. the air is nearly always of one sort as regards its origin. Again, with regard to persistence, Hanslik pointed out that only the "warm" anticyclones are steady and slow moving; the "cold" ones move quickly. Further facts to be taken into account are, that the conception of an anticyclone as a region of great vertical stability and of fine bright weather appears to be correct as a rule only for the "warm" anticyclone. In the other type anything short of violent weather conditions may be experienced.

I have recently (Q. J. Roy. Met. Soc., January 1923) put forward some evidence in support of the view that the explanation of the temperature peculiarities of the high- and low-pressure systems of our latitudes is, to a large extent, contained in the Bjerknes theory of their origin. In particular, when a pocket is made in the polar front by the southward rush of a great patch of polar air and when the pocket is afterwards closed behind this patch by the equatorial current from the south-west, the result is the formation of an anticyclone with closed isobars. From an examination of a more or less continuous series of upper-air observations I endeavoured to show that in such cases the change in barometric pressure at a given spot in the British Isles was indeed brought about by the fact that a thickness $h + \delta h$ of polar air had replaced a thickness h of the equatorial current, and that the upper layers of the equatorial current appeared to have been raised unchanged through the height δh. Provided that the polar air was not more than 2 or 3 km. in depth, anticyclones formed in this way would be "warm" anticyclones, and would possess the features associated with such. But there are almost certainly cases where the encroaching polar air extends right up to the base of the stratosphere, and these appear to have all the characteristics of the cold, rapidly-moving anticyclone. This cold air, passing as it does into latitudes warmer than those where it acquired the main features of its existing temperature distribution, is heated from the bottom upwards, and becomes sufficiently unstable to provide within itself moderate rain and much cloud, but probably not persistent heavy rain. (It seems likely also that anticyclones do reach us in which there is either no polar surface air or only a negligible amount. Their formation was probably a much more gradual though similar process, and took place in more southerly latitudes.)

Mr. Dines has referred to the difficulty of maintaining the polar air *in situ*. The patch of polar air with which we are dealing may be described as a roughly circular one of 1000 or more km. in diameter; in the case of a "warm" anticyclone we may limit its depth at the deepest part to 2 or 3 km.; in the case of a "cold" anticyclone the depth in the centre may include the whole thickness of the troposphere. It appears to be maintained *in situ, so far as it is maintained*, by the currents which produced it. But actually the motion of most "cold" anticyclones—*i.e.* those of the deep polar air—does strongly resemble that of the flat drop of mercury on the laboratory table.

This problem was dealt with hydrodynamically by Exner in 1918 (*Sitzungsber. Akad. Wiss.*, Wien IIa, 127, 1918, pp. 795-847). He assumed as the initial conditions the existence of a mass of cold dense air (at rest or in motion) covering a small portion of the earth's surface and surrounded on all sides and above by warmer, less dense air. Particular points made by him include—(1) that the rotation of the earth renders possible the maintenance (at a slight inclination to the horizon) of a definite fixed bounding surface between the cold and the warm air; (2) that if a long ridge of cold air divides into two ridges flowing apart like cold waves, then the square of the velocity of separation of these waves is proportional to the depth of the cold air and to the difference of density between the cold and the warm; (3) also that in such a case friction with the earth's surface results in a shallow cold film being left over the whole area traversed by the waves and in the consequent gradual reduction in the height of the waves.

There is another consideration which supports the view that an anticyclone is of complex structure, and that is the frequency with which the air above an "inversion" of temperature can be shown to be of different origin from that below. It has usually been said that the surface layers were being cooled by radiation, also that there was outflow of air in these layers, and that the upper air, descending and settling, was being warmed adiabatically. When, however, an attempt is made to apply numerical data, cases arise where the change of temperature at a given point in space appears to have taken place much more rapidly than can be provided for by the most favourable time scale of the assumed operating causes. But in particular it is difficult to see why these causes should lead rapidly to the formation of comparatively sharp discontinuities of temperature of the order of 10° F., and also how they can lead to other than a very unstable vertical distribution of temperature. It seems much simpler, being provided with air of about the appropriate temperatures to northward and southward respectively, to explain the formation of anticyclones and their temperature distribution by means of the horizontal motion and interaction of these "polar" and "equatorial" currents.

The Phantom Island of Mentone.

On a fine dark night, looking towards the point of Mentone from the sea-front about the middle of the West Bay, the appearance is presented of a dark island rising out of the sea in the gap which separates the lights of Mentone from those of Bordighera, some ten miles distant. This "phantom island" appears to be about 200 feet high, and from its darkness one would imagine it to be thickly covered with vegetation, its sides rising steeply out of the water. It is directly opposite, and quite near the sea-front of Mentone, from which it is separated by a very narrow channel of water. It appears, in fact, to be quite close to Mentone.

The explanation of this curious optical illusion is comparatively simple. The lights of Mentone and those of Bordighera present the appearance of being ranged round a curved bay, and they throw their reflections on the water, but they are separated by the East Bay, which is not seen, and by a dark, unilluminated portion of the coast. The corresponding part of the sea is devoid of reflections, and the impression is produced of a dark obstacle breaking the continuity of the line of lights and of their reflections in the water. This effect has been seen by independent observers on several occasions.

Ball Hardness and Scleroscope Hardness.

In the ball hardness test Meyer found that $L = ad^n$. By combining this relation with Brinell's formula $H = L/A$, it can be shown that the hardness number when the ball is immersed up to its diameter is $\frac{2a}{\pi}D^{n-2}$. This value has been called the "ultimate hardness" (H_u), and is independent of the initial condition of the metal with regard to cold work.

Several attempts have been made to obtain a relation between standard Brinell and scleroscope numbers. The results have been more or less unsatisfactory. If, however, values of H_u be plotted against the scleroscope numbers of metals in the annealed condition, the points lie on a smooth curve which is independent of the ball diameter. The following results have been obtained by the writer using balls of 1 mm. and 10 mm. diameter:

Sample.	a.	n.	H_u.	Scleroscope No.	Ball diam.
Tin	5·53	2·185	5·4	3·5	10 mm.
Zinc	24	2·21	25	11	
Steel A	74	2·288	91	27	
„ W	185	2·292	231	51	
„ 4	262	2·292	327	64	
„ 3	342	2·293	428	73	
Armco	94	2·164	60	21	1 mm.
Steel 2N	112	2·185	71	23	
„ A	150	2·247	96	27	
„ S90	264	2·298	168	41	
Manganese Steel	453	2·303	288	50	

These results are plotted in the diagram below (Fig. 1).

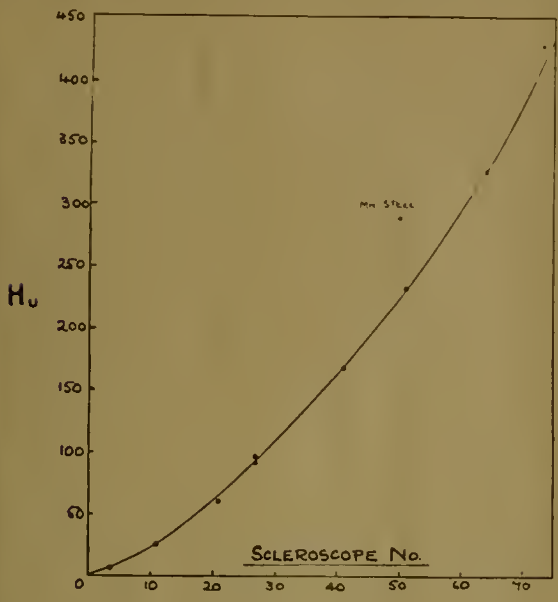

Fig. 1.

The relation between H_u and scleroscope number is quite good. The equation for the curve is:

$$H_u = 0{\cdot}79S^{1{\cdot}44}.$$

It is of interest that the ultimate hardness of manganese steel is higher than the scleroscope figure indicates.

If, as is believed, the value of H_u is independent of the ball diameter (D), then

$$kH_u = a_1 . D_1^{n_1-2} = a_2 . D_2^{n_2-2}.$$

k varies for different metals. Also, since with the 10 mm. ball

$$H_u = \frac{2a}{\pi} \times 10^{n-2},$$

then

$$0{\cdot}79S^{1{\cdot}44} = \frac{2a}{\pi} \times 10^{n-2},$$

$$S^{1{\cdot}44} = 0{\cdot}806a \times 10^{n-2}.$$

Metallic Crystals and Polarised Light.

During a research, not yet completed, on the optical properties of crystals, certain observations made in the case of metals appear to justify publication, from their importance in metallurgy.

If an etched metal specimen is examined under the microscope with the usual mode of illumination, but with plane-polarised light, and the reflected light is viewed through a "crossed" analyser, the different crystals in the field of view are sharply distinguished by differences of brightness. Rotation of the stage causes the brightest to grow dark and the darkest to light up, each crystal passing through four maxima and four minima in a complete revolution. The portions thus marked off often form parts of a crystal which appears of uniform structure under ordinary illumination; some structural difference which is indistinguishable, or with difficulty distinguishable without polarised light, produces marked differences with the crossed Nicol arrangement, which thus promises to be an effective new weapon in the metallurgist's armoury.

Curiously enough, these phenomena were observed quite independently by Miss Olwen Jones, who is engaged on the above-mentioned research in this laboratory, and by my colleague, Mr. C. Handford, of the Department of Metallurgy, who was working on a quite different problem. It was only on consulting him on the metallurgical aspects of the matter that I learned that he had noticed the effects a few days before. Her work suggests to Miss Jones that the cause may very possibly be a fine striated or laminated structure of the crystals, producing a sort of serration of their surfaces, the direction of the striation differing from crystal to crystal. When the vertical plane containing the serrations is parallel or perpendicular to the plane of polarisation in the incident beam the reflected light is plane-polarised, and is therefore extinguished by the analyser; when the angle between those planes is 45° or 135° the ellipticity, and therefore the brightness, is maximum.

Further investigations are being made both to test this theory and to develop the metallographic technique of the method. J. H. Shaxby.

Easy Method of observing the Stark Effect.

In the course of our investigations on the pole effect of the iron arc, we used a special device to keep the arc steady in the vertical position, and photographed the spectrum by means of a large quartz prism on a Littrow mounting. The lines originating in the electrode, extending from the visible part of the spectrum down to the ultra-violet, showed distinct separation, which was identical with the Stark effect observed with vacuum tubes. The separated lines show polarisations parallel and perpendicular to the field, which at the maximum amounts to about 20,000 volts per cm., and is confined to a very thin layer at the electrode, indicating a steep gradient. We found it convenient to work with a 500 volts arc, although the same phenomenon can be observed with a 100 volts arc. The effect is observed at the lower electrode, whether this be anode or cathode. Other metals can be used instead of iron.

The observation of the Stark effect is thus rendered extremely easy, as the only process involved is the production of a steady arc and the use of a spectroscope sufficiently powerful to resolve the lines into components.

Volcanic Dust and Climatic Change.

On page 20 of his very interesting book, "The Evolution of Climate," Mr. C. E. P. Brooks says that I have "attributed glaciation to the presence of great quantities of volcanic dust in the atmosphere." This is too generous. I only insist that volcanic dust is one of the factors that control climate, and that at times it may (not must) have been an important factor, especially when mountains were high and continents extensive.

The Character and Cause of Earthquakes.[1]

By R. D. OLDHAM, F.R.S.

THE character of earthquakes, that is, of the disturbance which can be felt and causes damage, has long been established as a form of elastic wave motion, originated by some sudden disturbance in the substance of the earth. In some cases, such as the Japanese earthquake of 1891 or the Californian of 1906, the earthquake was accompanied by visible fractures and displacements of the solid rock, and where these have been observed it has also been noticed that the violence of the disturbance reached its maximum close by, and became less as the distance from the fracture increased. From this it is evident that, in such cases at least, the earthquake originated from the jar caused by sudden rupture of the rocks, and the fault, or fracture, may be regarded as the cause of the disturbance to which the earthquake was due. In many other cases, where no actual faulting or fracture is visible at the surface, and especially in earthquakes of moderate intensity and extent, a study of the observations makes it very probable that the immediate cause of the disturbance was a fresh movement along an old fault, or the formation of a new one, and so may be found in many text-books the statement, put forward and elaborated, that faults are the cause of those earthquakes classed as tectonic. Thus it might seem that the cause of earthquakes had been explained, but this is only the beginning of the story, for we need to know what causes the fracture which gives rise to the earthquake.

In pursuing this object, reference may be made to an earthquake which occurred more than a hundred years ago, at a time when the observation of earthquakes was in its infancy, and when little information of present value could be expected, had it not been for certain peculiarities in the country affected, and in the effect of the earthquake. Just beyond the north-western angle of the Indian Peninsula lies one of the most extraordinary regions of the world, known as the Runn of Cutch; more than 200 miles in length, and some 30 in width, it is a level barren plain, so flat and so near the sea-level that when the waters of the sea are heaped up, by the south-west monsoon, and the streams from the surrounding country come down in floods, the greater part of the surface is covered with a sheet of water, varying from a few inches to five or six feet in depth.

The whole of this region, however, has not always been so barren as at present, for, up to the seventeen hundreds, a large river, fed by the waters of the Punjab, and by overflow from the Indus, flowed down through Eastern Sind, across the Runn to the Kori creek, and on the banks of this river were fertile and populated tracts; also on this river was situated a frontier fort of the Government of Cutch, where customs duties were collected. Then, in the eighteenth century, through changes in the river courses far inland, the supply of water in this river began to fail, and a series of bunds, or what we would now call barrages, was built to hold up the water and divert it for irrigation. Towards the end of the century, the whole of the water supply was intercepted, and the region below relapsed into a state of desolation; but the fort of Sindri was still maintained, with a small garrison and a few officials to collect the dues, and so things continued until June 16, 1819, when the classic earthquake of Cutch occurred.

The fort of Sindri was not only ruined, but the ground on which it lay was also lowered in level, water flowed in from the sea, and the small garrison of Sindri saved themselves from drowning by taking refuge in the main tower, whence they were rescued by boat the next day. Nor was this subsidence the only change noticed, for, about four miles to the north, where before had been only a dead level plain, the survivors observed a long low mound, stretching east and west with a height of about 20 feet, along the northern edge of the flooded area. This mound, so like an artificial embankment, was immediately named the "Allah Bund" or "God's Barrage," on the same principle which named the bunds or barrages higher up the stream after the names of their makers.

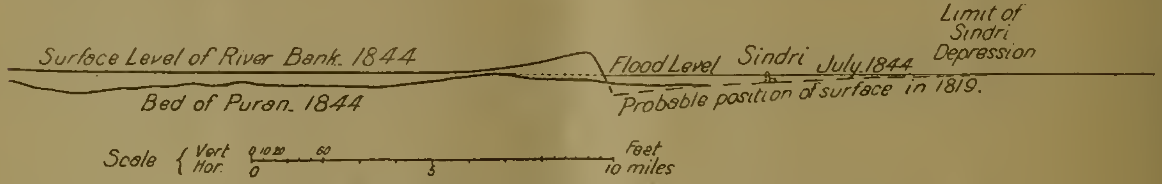

FIG. 1.—Section across the Allah Bund and Sindri depression of June 16, 1819.

Ten years later, the ruins of the fort were seen still standing out of a waste of waters, and twenty-five years later, in 1844, a careful survey was made and levels taken, and this survey revealed a remarkable condition of things (Fig. 1). From the north the surface of the delta sloped southwards, at about eight to ten inches in the mile, to within six miles from the crest of the Allah Bund, when a reverse slope was met, and the surface gradually rose to nearly 20 feet above the level of the continuation of the southerly slope, or the level at which it presumably stood before the earthquake. Thence there was a steep slope downwards, to the water of the Sindri lake. On the south the original reports mention a depth of twelve feet of water close to the shore, immediately after the earthquake, and, as the original surface level must have been a few feet above that of the sea, we have a depression of some fifteen feet, which gradually died out in a distance of some six miles to the southward. From these facts it is clear that there was no appreciable change of level at a distance of about six miles on either side

[1] Condensation of a course of two lectures delivered at the Royal Institution on January 30, February 6.

of the line of the Allah Bund, but that along that line the ground on the north was upraised by some twenty feet and on the south depressed by some fifteen at the time of the earthquake.

The next earthquake to be considered is one which has been investigated with great care and in great detail; it is the Californian earthquake of April 18, 1906. In this there was a visible fracture, following what is known as the San Andreas fault, along which the shock attained its maximum intensity. This fracture was crossed at various points by roads and fences, and after the earthquake it was noticed that, where these crossed the line of fracture, they were no longer continuous, but the ends were shifted laterally by distances which varied at different places, but frequently amounted to twenty feet. This was not all, for the displacement was of a very curious nature, revealed by surveys of the displaced fences, and by a repetition of the original trigonometrical survey of the region. These showed that for a distance of some miles back from the fault line the stations had been displaced, those nearest to the line by the greatest amount, which lessened as the distance increased and, at about five miles or so to the east, became very small. Moreover, it was found that the movement on the eastern side of the fault had been to the southwards, and on the western towards the north.

Here we have a result very like that in Cutch; in both cases there was a well-defined line along which permanent change of position of the ground took place, simultaneously, in opposite directions on either side of the line of separation, and in both cases the displacement decreased in amount with increasing distance, till it ceased to be measurable at a distance of about half-a-dozen miles. The only difference was that in California the displacements were horizontal, with little or no change of level, while in Cutch they were vertical, whether accompanied or not by horizontal shifting cannot be known.

Paradoxical though it may seem, this movement on opposite sides of the fracture in opposite directions is quite in accord with known physical principles. If any block of material is compressed or stretched in one way, while free to expand or contract in a transverse direction, or if it is twisted by two opposite sides being forced in opposite directions, a complicated system of strain is set up, and if the strain is more than the material will bear, disruption will take place, on opposite sides of which the material will move in opposite directions.

Models to illustrate this principle have been constructed by others and myself, and from these considerations there has arisen what is known as the elastic rebound theory of earthquake origin, and as generally expressed this takes the form of a very slow growth of strain and a sudden release by fracture. The former, however, is by no means necessary, and the same result, as regards displacements of the ground, would be attained if the strain was rapidly, even suddenly, produced. There are, in fact, reasons for supposing that the growth of strain is not slow but rapid, yet the fracture and elastic rebound theory might be accepted as sufficient, if earthquakes could always be attributed to a single fracture, or to a close-set group of fractures; but in the case of great earthquakes, and sometimes of minor earthquakes also, the interpretation is put out of court by a study of the distribution of the intensity of the disturbance.

In illustration I may take first the great Indian earthquake of June 12, 1897, in which the central region of greatest intensity covered an area of about 140 miles long by 40 miles broad, over which there was a complicated series of faults, fractures, and distortion, which was certainly widely different from the comparatively simple origin generally assumed for earthquakes. This seemed at the time sufficient to account for all the facts, though there were some recorded as difficult to explain, and later examination seems to have established the conclusion that the origin of the earthquake cannot be limited even to this extensive area. In this earthquake only two of the isoseists could be plotted in detail, those of eight degrees and of two, or the extreme limit at which the shock could be felt; both exhibit considerable irregularities of outline, the most conspicuous of which is a pronounced projection to the westwards, and on the continuation of this line is a detached area, where the shock was again felt, after a gap where it was not felt. Col. Harböe has suggested, from a study of the recorded times, that there was an extension of the origin along this line, and though his plotting of the origin cannot be accepted in detail, I am convinced that, in the main, his conclusions are correct, for they very materially help to explain some peculiarities of the recorded observations, which remained inexplicable on the older and more generally used interpretation.

From this it appears that in earthquakes covering a large area we are not dealing with a simple disturbance, starting from an origin of restricted dimensions and propagated outwards, but with one of complex origin; and that in the outer regions of the seismic area the disturbance may be compounded of wave motion propagated from a more or less distant origin, where the initial severity was great, and of that coming from a nearer origin, of a lesser degree of severity, so that, instead of a fracture of at most a few tens of miles in length, we have to deal with a cobweb-like system of fractures, or something analogous, which may run to hundreds of miles.

The general drift of the argument I wish to set forth is probably best illustrated by the California earthquake of 1906. In this the greatest degree of violence was found along the line of the San Andreas fault, but the plotting of the isoseists shows that there was not only an independent centre in the San Joaquin valley, some forty miles to the eastwards, but also several independent centres of great intensity at lesser distances from the San Andreas fault. Moreover, the displacements recorded by trigonometrical survey make it probable that other similar independent centres would be found to the west, if the waters of the ocean had not made observation impossible. The records, therefore, indicate a set of separate centres of disturbance, scattered over a region of about three hundred miles in length by very possibly one hundred miles in width, and these separate centres, though independent as regards the surface shock, were all evidently connected with some common cause. Had they been the result of breakage under a slowly growing strain it is difficult to understand how so complicated, scattered, and extensive a series of fractures could have originated simultaneously, but it is, to say the least, much less difficult to understand if the development of strain over the whole of the central area had been sudden, or at any rate rapid.

Then there is another point to be noticed, that in the central region the successive isoseists lie close together, while in the outer fringe they lie far apart; thus the distance separating the isoseists of ten and seven degrees, covering a range of three degrees of intensity, varies from 6 to 20 miles on either side of the San Andreas fault, while in the outer regions a similar range of three degrees covers from 120 to 250 miles. The close-set isoseists of the central region indicate a shallow origin, and such is proved by the San Andreas rifts, where the origin reached the surface of the ground; the widely set outer isoseists similarly indicate a deep-lying origin: and so we reach the conclusion that the earthquake origin was of a twofold nature, the great violence in the central region being due to fractures and displacements close to, or at a comparatively shallow depth below, the surface, and that these fractures were the secondary result of a more deep-seated disturbance or bathyseism.

Having reached this conclusion there remain two questions of importance, what is the depth, and what is the nature of this bathyseism? As to the depth, the study of a remarkable, though only feeble, earthquake which affected northern Italy on August 7, 1895, has led me to conclude that the ultimate origin lay at 100 to 150 miles below the surface; but the best indications are to be had from the long-distance records of disturbances, which need not necessarily have been great earthquakes, in the ordinary sense of the words.

From these Dr. L. Pilgrim, in 1913, deduced the conclusion that the origin of the disturbance, in the case of the Californian earthquake, lay at a depth of about 100 miles, and, more recently, a similar method has been developed in this country by Prof. H. H. Turner, who has shown that the long-distance records indicate depths of origin ranging from fifty to three hundred miles below the surface of the earth. Now it seems fairly well established that earthquakes of quite shallow origin do not give rise to distant records, even when very violent in the place where they are felt, and it is probable that the disturbance recorded by these distant seismographs is not the superficial destructive earthquake, but the bathyseism.

Next comes the question of the nature of the bathyseism. That it must be in some way accompanied by a change in bulk of the material underlying the central area of the earthquake, seems clear, in some cases at least. Fracture such as is sufficient to explain most of the features of the surface shock seems out of the question, for the depths place it in the region of what it is nowadays the fashion to call the asthenosphere, that is, a part of the earth which is weak and plastic against stresses of long duration; but as regards change of bulk, recent researches have indicated one very likely mode in which it might be brought about. It is known that the foundation rocks of the outer crust are everywhere composed of an aggregate of crystalline minerals, the detailed study of which shows that the material must once have been in a condition analogous to that of fusion, from which it has solidified by cooling to its present condition. Further, it has been shown that the same original magma may crystallise out as quite different mineral aggregates, differing in density, and therefore in volume, by anything up to 20 per cent. The exact conditions which determine the passage from one form of chemical grouping to another are not known in detail, but it is probable that in each case there is some critical limit of temperature and pressure which determines it. If there were, in the interior of the earth, a mass of material near this critical limit, a small change of pressure or temperature might bring about a change of chemical combination, and with it a greater or lesser change of bulk, which, transmitted to the upper layers of the earth's crust, would give rise to displacements and distortion. Such changes might be unaccompanied by earthquakes, if they were slow and gradual, or, if rapid or sudden, might give rise to fractures in the surface rocks, of greater or lesser magnitude, and covering a larger or smaller area, according to the bulk of the deep-seated material undergoing a change of volume.

Without insisting on this as the nature of the bathyseism, and it is possible that other causes as yet unsuspected may also be at work, it is evident that we have an explanation which would suffice in the case of the larger, and of many of the smaller earthquakes. Yet there are some causes, perhaps no inconsiderable fraction of the total, in which the whole process leading up to the earthquake seems to lie quite close to the surface. To these, always small in extent, though sometimes of considerable severity, the consideration which I have outlined cannot at present be applied; in part they must be due to quite different causes, the consideration of which is not without interest, but this interest only arises after more extended and technical study than could be presented, even in outline.

Hydrogen Ion Concentration.

By Prof. A. V. HILL, F.R.S.

CERTAIN solutions are capable of conducting electricity, although their separate pure components are themselves incapable, or capable only to a slight degree, of so doing. This conductivity is attributed to the "ionisation" of the dissolved body, that is, to the splitting up of its molecule into two or more parts, some carrying a positive and others a negative charge, the resulting "ions" being capable of migration under an imposed electric field, and so giving to the solution the power of carrying a current. The electrically neutral molecule breaks up into (*a*) a negatively charged part, containing an excess of electrons which lend it its negative charge, and (*b*) a positive portion with a deficit of electrons, this deficit resulting in an equal positive charge. These positive and negative ions attract one another, as do all positive and negative charges, and are separable only if their mutual attraction be small enough to be overcome by the inter- and intra-molecular dynamic forces (not yet properly understood) tending to their separation.

The attraction between two charges is far greater if they be separated by some media than by others, to a degree inversely proportional to the so-called specific inductive capacity of the medium. Water has one of the highest specific inductive capacities of all known substances, so that in it the attraction between two ions is relatively small: hence in water the ions may separate more effectively than in other solutions, and watery solutions are found to show the phenomena of electrolytic dissociation to an exceptional degree. Now water is a solvent of unique importance, partly because of its common occurrence, partly because it dissolves so many other bodies, and especially because, without exception, all biological phenomena occur in media which are essentially solutions or suspensions in water. Hence the study of the electrolytic dissociation of bodies dissolved in water is of quite peculiar interest, especially in physiology.

Now water itself is capable of electrolytic dissociation, though only to a small degree. In pure water at 22° C., eighteen parts in ten thousand million, that is, one ten-millionth part of one gram molecule per litre, is broken up into hydrogen ($H^{\cdot}$) and hydroxyl (OH') ions, the $^{\cdot}$ denoting the positive and the $'$ the negative charge. Such a very small degree of dissociation is of little importance in pure water: its insignificance is presumably due to the smallness of what we have called—to cover our ignorance—the dynamic forces tending to separate H_2O into $H^{\cdot}$ and OH'. In solutions, however, especially in solutions of acids and alkalies (that is, of bodies capable, by their own dissociation, of yielding one of the ions of water, $H^{\cdot}$ or OH'), even this small dissociation of water into its ions may become of preponderant importance.

It is obvious that the ions of the solvent itself, if present in appreciable amount, might be expected to play a special rôle in the behaviour of a solution: there is, however, a very real interest in the study of the hydrogen ion, in view of modern theories of the electrical constitution of matter. Atoms are supposed to possess a positive nucleus, with a charge equal to some multiple of the elementary negative charge on an electron, with layers of electrons circulating round the nucleus in stable orbits. The simplest atom of all is hydrogen, with a positive nucleus of unit elementary charge and a single negative electron revolving round it: remove this negative electron from a dissolved hydrogen atom, and we are left with a singly charged positive nucleus—next to the electron the simplest of all known natural bodies. In mobility, in combining power, in general dynamic effectiveness, this dissolved elementary unit might be expected to be, and actually proves to be, an agent of quite peculiar importance.

Expressing concentrations, in gram molecules (or ions) per litre, by means of brackets, it is found that at 22° C. in pure water,

$$[H^{\cdot}][OH'] = 10^{-14}.$$

This is the law of chemical mass action, which, in such a dilute solution as water is of its own ions, is accurately obeyed. Now in pure water there is no other agent capable of carrying electricity, and since the water itself cannot carry an appreciable resultant charge the positive and negative charges must balance one another, and therefore

$$[H^{\cdot}] = [OH'] = 10^{-7}.$$

If, however, we dissolve in the water another substance supplying one of the ions of water, for example, hydrochloric acid (HCl), which we may regard as being almost totally dissociated into its ions $H^{\cdot}$ and Cl', to a concentration (say) of one gram molecule per litre, then the equation above is entirely upset: the hydrogen ion concentration $[H^{\cdot}]$, or $c.H$ as we shall often call it, has now become unity instead of 10^{-7}, so that the hydroxyl ion concentration $[OH']$ is now only 10^{-14}. Even this, expressed in actual molecules, is an astonishingly large number: there are about 6×10^{23} molecules in a gram molecule, so that even in normal hydrochloric acid there are six million hydroxyl ions per cubic centimetre. Clearly, even a strong solution of acid contains an appreciable number of hydroxyl ions.

If, conversely, we dissolve caustic soda to make a "normal" solution, instead of hydrochloric acid, then $[OH']$ becomes unity and $[H^{\cdot}]$ becomes 10^{-14}. We may make up different strengths of acids or alkalies in which the hydrogen and hydroxyl ion concentrations

Acid.	$[H^{\cdot}]$.	$[OH']$.	Alkali.	$[H^{\cdot}]$.	$[OH']$.
N	1	10^{-14}	N	10^{-14}	1
N/10	10^{-1}	10^{-13}	N/10	10^{-13}	10^{-1}
N/100	10^{-2}	10^{-12}	N/100	10^{-12}	10^{-2}
N/1000	10^{-3}	10^{-11}	N/1000	10^{-11}	10^{-3}
N/10000	10^{-4}	10^{-10}	N/10000	10^{-10}	10^{-4}

may be calculated as in the accompanying table. It is usual to consider only the hydrogen ion concentration: the hydroxyl ion concentration may always be calculated from it, by dividing the quantity k in the equation $[H^{\cdot}][OH'] = k$ by $[H^{\cdot}]$. At 22° C., $k = 10^{-14}$, but it varies slightly with temperature. Now $[H^{\cdot}]$, or $c.H$, may change enormously from one solution to another, say from 10^{-14} to 1, that is, one hundred million million times: hence it is impossible to represent the full possible range of variation of $c.H$ in a single diagram, and since it is often necessary in physical chemistry to show the relations of $c.H$ graphically, it has become customary to express the hydrogen ion concentration in terms of logarithms. The logarithm of 10^{-14} is -14, and of 1 is 0, so that log $c.H$ can be represented, over almost the entire possible range, by numbers lying between 0 and -14. To avoid, further, the use of negative numbers the negative sign is understood, and the symbol $p.H$ (or its variants P_H, P_h, etc.) is defined by the expression $p.H = -\log c.H$. In this way, at 22° C., if $p.H = 7$ the solution is neutral, if $p.H$ be less than 7 the solution is acid, if $p.H$ be greater than 7 the solution is alkaline; and a decrease of $p.H$ means an increase in hydrogen ion concentration.

This system of nomenclature has certain obvious advantages if used with discretion: not seldom, however, it lends itself to obscuring the fact that the real agent at work is the actual hydrogen ion concentration $c.H$; it is difficult enough even for the expert to picture a quantity in terms of its negative logarithm, and it leads to confusion and suspicion on the part of the inexpert and beginner. For most of the phenomena of biology, moreover, which occur within a narrow range of $c.H$, it is quite unnecessary: for example, in physiology, apart from a few cases of secretion, the important range of $c.H$ in the body is from 10^{-7} to 10^{-8}, and it is better when possible to deal with the hydrogen ion concentration in multiples (or decimals) of 10^{-7}, and to use the $p.H$ notation only when the total range considered is outside the limits of any reasonable diagram: occasions, in physiology, where this occurs will be comparatively rare.

The hydrogen ion concentration of a solution can be measured in a variety of ways: (*a*) by calculation from the laws of mass action, with a knowledge of the components of the solution and the proper constants; (*b*) by the use of a so-called hydrogen electrode: if a platinum wire, coated with platinum black and saturated with hydrogen gas, be dipped into a solution, it acts like a metallic electrode of pure hydrogen, and its electrode potential can be measured and made to give the *c*.H of the solution; (*c*) by the use of so-called "indicators," that is, dyes which change colour as the hydrogen ion concentration is altered, owing presumably to changes in their degree of electrolytic dissociation: the colour is used to measure the value of *c*.H. The study and measurement of the hydrogen ion concentration is becoming to-day almost a complete science in itself, and progress in physiology, and in some branches of colloid chemistry, still waits on further improvements in the accuracy and adaptability of its technique.

The importance of the hydrogen ion concentration in biology is bound up with the phenomena attending the dissociation of weak acids and of the so-called amphoteric electrolytes, and with the theory of "buffers." A weak acid, for example, carbonic acid H_2CO_3, is one which is only slightly dissociated into its ions: the reaction $H_2CO_3 \rightleftarrows H^{\cdot} + HCO'_3$ goes almost entirely $\leftarrow$: similarly with a weak base. The salt of a weak acid is a very effective regulator of the hydrogen ion concentration; it acts as a "buffer" to resist the effect of adding a strong acid. Let the salt of the weak acid be XY, dissociated into its ions $X^{\cdot}$ and Y'. Let us add to this a strong acid HZ, dissociated into $H^{\cdot}$ and Z': we might expect the *c*.H to be largely increased. In our solution now are all the ions $X^{\cdot}$, Y', $H^{\cdot}$, and Z': $H^{\cdot}$ and Y', however, cannot exist side by side in solution in appreciable amount, since (by hypothesis) the acid HY is a weak one, that is, the reaction $H^{\cdot} + Y' \rightleftarrows HY$ goes almost entirely $\rightarrow$. Hence the hydrogen ions are eliminated to form the undissociated weak acid HY, and we are left (i.) with the ions $X^{\cdot}$ and Z' of the salt XZ of the strong acid, and (ii.) with the undissociated weak acid HY.

The expected increases in *c*.H can, in this way, be reduced almost to an insignificant amount, and in physiology (where an exact constancy of *c*.H appears to be necessary for the maintenance of the normal physico-chemical structure and behaviour of the living cell) the presence of very effective "buffers" in every organ, tissue, and cell has been shown in recent years to be of ultimate importance. Phosphates, carbonates, and the salts of proteins, such as hæmoglobin, are the chemical agents by which this regulation is effected. In addition to these we have what we may call "living buffers," the cells of the respiratory centre and the kidney for example, which by their activity maintain, in an amazingly accurate manner, the constant *c*.H required in the "internal environment" of all the other cells of the body; that is, in the blood and tissue fluids which bathe them. In the body, the important buffers are those absorbing the effects of added acid, especially carbonic and lactic acids, which are produced with great rapidity and amount during muscular exercise. The salts of weak bases, however, are equally effective buffers, from the physico-chemical point of view, in their capacity of neutralising the effect of strong alkalies. Some bodies, moreover, the so-called "amphoteric electrolytes," of which amino acids and proteins are the most notable, are capable of functioning both as weak acids and as weak bases: hence their salts (for example, sodium "hæmoglobinate," or hæmoglobin chloride) may act, under suitable conditions, as buffers of either type.

The importance of the hydrogen ion concentration in physiology is almost certainly concerned—at least in part—with the electrical properties of the proteins which constitute the formed constituents of living cells. It may also be concerned with the processes of oxidation and reduction occurring in metabolism, but with these we will not deal further now. Proteins are complex compounds of amino acids, and each amino acid possesses the latent possibility of acting either as a weak base (in virtue of its $-NH_2$ group) or as a weak acid (by reason of its $-COOH$ group). Hence proteins are capable, at a suitable *c*.H, of forming salts at many and varied points in their enormous molecules. These salts are largely dissociated into their ions, so that the protein of the living cell may be regarded as a large electrified molecule, surrounded by a shell of attendant positive (or negative) ions.

The electrical phenomena accompanying any form of activity in a living tissue demonstrate the importance of this electrification of the fundamental chemical basis of protoplasm, and it is well known that the existence and properties of colloidal solutions are intimately dependent upon the electrical charges on the surfaces of the colloidal particles. Now the degree of dissociation of a weak acid HZ, into its ions $H^{\cdot}$ and Z', depends upon the hydrogen ion concentration: according to the laws of chemical mass action the ratio of the dissociated to the undissociated part is inversely proportional to *c*.H. Hence, if the protein be acting as a weak acid, the degree of electrification of the protein molecule will be decreased by an increase of *c*.H, and if the behaviour of a living cell depend upon the electrical characters of its protein constituents we should expect it to be largely modified by an appreciable change in *c*.H.

This actually occurs: the most violent and extensive physiological response is produced, both in single cells and in larger complex animals, by quite small changes in *c*.H, and all animals possess the power of reacting, in a sudden and vigorous manner, to any alteration in the *c*.H of the fluid immediately in contact with their cells, in such a sense that the change is diminished, or neutralised, and the physico-chemical characters of the protein molecules of their protoplasm are maintained in their normal state. We know, at present, very little about the molecular structure of living protoplasm: we cannot, however, be far wrong in supposing that the ionic and electrical phenomena displayed by the protein molecules which constitute it are among its most fundamental properties, and that these are modified, to a high degree, in accordance with purely physico-chemical laws, by the hydrogen ion concentration of the fluid in which it is suspended or dissolved.

Obituary.

Dr. J. G. Leathem.

THE death of Dr. John Gaston Leathem on March 19, at the age of nearly fifty-two years, removes a scholar who was prominent in the world of Cambridge mathematics. Coming from Queen's College, Belfast, in 1891, he made his mark in the triposes of 1894 and 1895. He held the Isaac Newton studentship for astronomy and physical optics during the period 1896–99, soon gaining also a fellowship at St. John's College. His interests were then mainly in electrodynamic theory; and the work of his studentship produced a memoir (Phil. Trans., 1897, pp. 89-127), which ought to be classical, in which the theory of the magneto-optic rotation of light and the cognate reflection effect were finally systematised and coordinated, under the test of laborious comparisons with the numerical experimental data.

In due course Dr. Leathem became mathematical lecturer at St. John's College, and afterwards university lecturer: and for a series of years he exerted a wide influence on the teaching. For the mathematical tripos he was an examiner on as many as six occasions, two of them (1912, 1913) after he had been withdrawn from all teaching except an annual advanced course on electrodynamics. For he had become senior bursar of his college in 1908, and henceforth he threw himself into its external affairs and general administration with assiduity and practical success.

In 1905 Dr. Leathem took up the editorship, in conjunction with Prof. E. T. Whittaker, of a series of Mathematical Tracts projected by a Cambridge group of lecturers, which, in numerous volumes, has become under their care an important survey, almost an encyclopædia, of domains of recent higher mathematics. To this undertaking he contributed the earliest volume of the series, and one on optical systems. His own later special investigations, exhibiting the geometrical trend that is associated with the Irish school, thus including applications of conformal transformations to physical problems, were published mainly by the London Mathematical Society and the Royal Irish Academy. A note in Roy. Soc. Proc. established an unexpected mode of interaction between a magnet, supposed to consist of revolving electron-systems, and a varying electric field, too small, however, to permit of experimental scrutiny.

During the War Dr. Leathem felt bound to volunteer for work in the Research Department at Woolwich Arsenal, then in need of mathematical help, handing over as much of his bursarial work as was possible to senior colleagues. About two years ago he had to submit to a sudden and very drastic surgical operation: in time he recovered, and though never strong again, he resumed his activities with all the previous zeal and judgment. But the mischief could only be delayed, not removed: and his loss will now be deeply felt not only in his own college but also throughout the university.

J. L.

Dr. E. A. Merck.

THE death took place at Darmstadt on February 25 of Privy Councillor Dr. E. A. Merck, senior partner of the chemical works of E. Merck. Dr. Merck was born at Darmstadt on July 30, 1855; he studied pharmacology and chemistry, and took his degree in Freiburg i. B. under Ad. Claus. He then took over the Engel-apotheke, which had been in the possession of the family of Merck since 1668, and became one of the managers of the chemical works of E. Merck.

The works, which were then on only a modest scale, were greatly enlarged through the energy and initiative of Dr. Merck and his cousin, Louis Merck, who was his partner, and developed into one of the greatest manufactories of preparations for medical purposes. To the production of drugs was added that of alkaloids, the preparation of synthetic remedies (for example, "veronal"), and various sera. In response to the demand of chemists for pure reagents, the production of chemically pure preparations and solutions for volumetric analysis was taken in hand, and the firm's products became famous throughout the world. The connexion between the industry of chemical preparations on one hand and the pharmaceutical chemists and physicians on the other was steadily maintained by the literary publications: "Mercks Jahresbericht," "Mercks Index," and "Mercks Reagenzienverzeichnis."

Dr. Merck took an important part in all these developments. At the same time he worked continually for the improvement of the training of pharmaceutical chemists and the social position of the whole chemical profession. For six successive years he was president of the Verein Deutscher Chemiker, and he represented German chemistry at many international gatherings. His strong historical interest led him to give particular attention to the work of Liebig, and he was one of the founders of the Liebig Museum at Giessen.

WE regret to announce the following deaths:

Prof. A. S. Dogiel, professor of histology in the University of Petrograd, whose investigations on the histology of the peripheral nervous system are well known.

Prof. A. S. Flint, emeritus astronomer of the Washburn Observatory, University of Wisconsin, on February 22, aged sixty-nine.

Prof. W. S. Haines, professor of chemistry, materia medica, and toxicology at Rush Medical College, and professor of toxicology in the University of Chicago, on January 27, aged seventy-two.

Sir Joseph M'Grath, a vice-president of the Royal Dublin Society, and registrar of the National University of Ireland since 1908, on March 15, aged sixty-four.

Mr. W. Pearson, for nearly fifty-eight years prosector to the Museum of the Royal College of Surgeons of England, on March 15, aged eighty-two.

Sir Thomas Roddick, formerly professor of surgery, McGill University, and the first Colonial president of the British Medical Association, at its Montreal meeting in 1897, on February 20, aged seventy-six.

Sir William Thorburn, emeritus professor of clinical surgery in the University of Manchester, on March 18, aged sixty-one.

Prof. J. Trowbridge, emeritus professor of physics at Harvard University, on February 18, aged seventy-nine.

Mr. E. W. Vredenburg, of the Geological Survey of India, on March 12.

Prof. N. E. Wedensky, professor of physiology in the University of Petrograd.

Current Topics and Events.

The Conjoint Board of Scientific Societies was dissolved by a resolution passed at a meeting of the Board held at the Royal Society on March 22. The Royal Society took the initiative in the formation of the Board in 1916; and when a few months ago the council decided that the society no longer desired to remain in this federation, whether under the original constitution, or the new one proposed, there was little hope for the continued vitality of a body so sharply truncated. The chief scientific and technical societies—about sixty in all—in the British Isles were represented on the Board, and the special committees appointed from time to time have produced a number of notable reports. Among such committees may be mentioned those on the water power of the British Empire, glue and other adhesives, national instruction in technical optics, timber for aeroplane construction, and the application of science to agriculture. A couple of years ago the Board appointed a committee to arrange for the publication of a world-list of scientific serials, with indications of libraries in the chief centres of Great Britain where such periodicals could be consulted. It is gratifying to know that the interests of the Board in the list, towards the publication of which the Carnegie United Kingdom Trust made a grant of 1000*l.*, have been vested in three trustees, so that notwithstanding the dissolution of the Board the issue of the list is assured. For this provision thanks are due largely to Dr. P. Chalmers Mitchell. In its early years the Board owed much to Sir Joseph Thomson, who, as president of the Royal Society, was president also of it. Sir Arthur Schuster and Sir Herbert Jackson were associated with the Board throughout its existence, and did invaluable work for it, while the devoted service rendered by the Secretary, Prof. W. W. Watts, created a sense of indebtedness which can never be adequately expressed. It is impossible not to regret that a federation of such early promise should have had so short a life.

Sir Frederick Mott, pathologist to the mental hospitals of the London County Council for twenty-seven years, and director of the Council's pathological laboratory, is retiring from the service at the end of this month. By his own researches and by stimulating and encouraging the spirit of investigation in others, he has brilliantly discharged the difficult task of establishing the tradition that it is the business of the authority having control over asylums for the insane, not only to see to the security and comfort of the inmates, but also to secure that progressive work on the nature and causes of mental diseases shall be directed towards their prevention and cure. His demonstration that general paralysis of the insane is in fact a late manifestation of syphilis in the nervous system is perhaps the most conspicuous piece of his personal work among patients and in the laboratory, and it has entirely altered our conception of the disease. The *Archives of Neurology* and other journals show the quantity of good work which came from the laboratory at Claybury—the more remarkable when we remember that Sir Frederick was also a busy general physician attached to Charing Cross Hospital. Two of the plans in which he was much interested have now matured in the moving of the central laboratory to a more accessible site in London, and in the establishment of the Maudsley Hospital at Denmark Hill for the study of the early stages of mental derangement. The solid foundation which he has laid should do much to secure success for the new arrangements.

Among the important centenaries of scientific interest this year is that of the birth of Sir William Siemens, who was born in Lenthe, Hanover, on April 4, 1823, and died in this country on November 19, 1883. Siemens took up his residence in England in 1844, and from 1859 was a naturalised Englishman. It would be difficult to measure the value of his services to our industries, for he was one of the foremost electrical engineers of his day, while as a metallurgist his name is connected with the introduction of the regenerative furnace and the manufacture of open-hearth steel. His scientific knowledge was no less noteworthy than his inventive ingenuity, while above all he was a man of affairs. The first president of the Society of Telegraph Engineers, he also served as president of the Mechanical Engineers and of the Iron and Steel Institute. It was in his address to the latter body that he threw out the pregnant suggestion of utilising some of the power of the Niagara Falls and transmitting it long distances by electric conductors. In much of his work he was associated with his brothers Werner, Carl, and Friedrich. In the issue of Nature for November 29, 1883, Lord Kelvin gave an account of Siemens's scientific career and work as a contribution to our series of Scientific Worthies.

On April 7 occurs the centenary of the death of the French physicist Jacques Alexandré Cesar Charles, the pioneer of scientific ballooning. Born in 1746, Charles began life as a clerk in the Ministry of Finance. He devoted his leisure to scientific pursuits and he became known as a lecturer and experimenter. In 1783, a few months after the brothers Montgolfier had made their first experiments with the hot-air balloon, Charles conceived the idea of filling a balloon with hydrogen. His first important demonstration was made in December 1, 1783, when Charles and his companion, Francis Robert, rose from the gardens of the Tuileries to a height of 9000 feet. Charles made his hydrogen by the action of iron on sulphuric acid. To him is due the invention of the valve, the car, the use of ballast, and the employment of rubber for rendering the silken envelope gas-tight. He was also the first to use the barometer in a balloon. Very great interest was excited by the work of Montgolfier and Charles, and Lavoisier was instructed by the Paris Academy of Sciences to draw up a report as to the value of the discovery. Charles was admitted to the Academy in 1785, received a pension from Louis XVI., and, after the Revolution, occupied a post at the Conservatoire des Arts et Métiers. He is buried in the Père-Lachaise cemetery.

Thanks to the generosity of the Spanish Government the Science Museum, South Kensington, now possesses a model of the flagship of Columbus, the *Santa Maria*, in which, accompanied by the *Pinta* and *Nina*, he made his famous voyage of discovery in 1492. The model is a copy of one in the Naval Museum, Madrid, and has been made under the supervision of the director, Capt. Don Antonio de la Reyna y Pidal. From time to time many inquiries have been made regarding the details of the *Santa Maria*, and for the Chicago Exhibition of 1893 a replica was constructed and sailed across the Atlantic by a Spanish crew under Capt. Concas, the course followed being that travelled by Columbus. The *Pinta* and *Nina* were small vessels of about 40 or 50 tons, but the *Santa Maria* had a displacement of 233 tons. She was 95 feet long over all, carried a complement of 52 men, and mounted eight guns for firing stone shot. Another of the existing models of the *Santa Maria* is that made by Capt. Terry, who searched Southern Europe for information; this model is illustrated in Chatterton's well-known "Sailing Ships and their Story."

Mr. Stanley Baldwin, Chancellor of the Exchequer, announced in the House of Commons on March 22 that he had decided to withdraw the proposal to charge fees for admission to the British Museum, Bloomsbury, and the Natural History Museum. The announcement followed a statement by Major Boyd-Carpenter, Parliamentary Secretary to the Ministry of Labour, that the cost of equipping the British Museum and the Natural History Museum with turnstiles for the collection of admission fees had been estimated at £500, and that possibly one extra attendant would be required.

A conventional distinction is often drawn between science and art, but in their finest developments they have much in common. In an address before the Circle of Scientific, Technical, and Trade Journalists on March 20, Prof. Beresford Pite defined the artist as one who found his pleasure in his work—a definition that surely applies equally well to the researcher in pure science. He also pointed out that the full development of architecture requires the stimulus of contact with other countries. The Elizabethan period was one of poverty in architectural effort, though literature flourished, a condition attributed to the isolation of this country from the Continent, owing to religious differences. This again applies to science, for the crippling effect of lack of intercourse with men of science in other countries is well recognised. Perhaps a third point of similarity might be found in his claim that the architect, like the man of science, does much work without prospect of reward. He is not paid for what he "rubs out," neither is the experimenter proportionately rewarded for the many fruitless experiments that usually precede a genuine discovery. In the course of the discussion the Press, the influence of which in directing public attention to the claims of science has already been invited at previous meetings, was given an opportunity of hearing a masterly lecture on the ideals of architecture.

The annual meeting of the National Institute of Industrial Psychology was held on March 20 at the rooms of the Royal Society. Mr. H. J. Welch, chairman of the Institute, presided. Lord Balfour was the principal speaker, and he pointed out how mistaken is the idea that science has nothing to do with practical life. As a nation we are too apt to think that science exists for men of science, and that it can have no interest for practical men. He wished to bring together men of science, capitalists, leaders of labour—all the forces of society—in order to further the work of uniting science and practice. By the application of physiology and psychology Lord Balfour expressed the hope that the labours of the wage-earners may be made easier and smoother, so that work, instead of being a kind of torture, may become a pleasure. He quoted Francis Bacon to the effect that the object of science is the relief of man's estate. The next speaker, Sir Charles Sherrington, president of the Royal Society, described the changes which have taken place during his lifetime in the position of psychology. The early pioneers in experimental psychology occupied themselves with problems which seemed quite remote from any practical application; now, many of these early researches are recognised as of far-reaching practical importance. Sir Charles made a special plea for adequate support for, and sympathy with, that part of the work of the Institute which is known as vocational selection. Most boys have no chance whatever of getting into an occupation that suits them best; unguided, they drift into any trade. Both Sir Lynden Macassey and Mr. A. Pugh showed from different points of view that there is more waste in industry owing to indifferent management than to indifferent workmanship. Industrial managers are more equipped, as a rule, for controlling machines than for controlling men. Dr. C. Myers, director of the Institute, gave some details of the actual work of the Institute.

The Central Mining-Rand Mines premium of 25*l.* has been awarded by the South African Institution of Engineers to Mr. W. J. Horne, organiser of technical education, Transvaal, for his paper on "Technical Education for Trades," read at Johannesburg.

At the ordinary scientific meeting of the Chemical Society held on March 1, Prof. Bohuslav Brauner, Prof. Ernst Cohen, Prof. Gilbert N. Lewis, Prof. Charles Moureu, Prof. Amé Pictet, and Prof. Theodor Svedberg were elected honorary fellows.

The King and Queen have consented to lay the foundation-stones of the new buildings for medical research at University College Hospital, London. These buildings, it will be remembered, have been made possible by a munificent gift of 1,250,000*l.* from the Rockefeller Foundation, announced some three years ago. It is probable that the ceremony will take place towards the end of May.

THE annual general meeting of the Society of Chemical Industry will be held at Cambridge on June 21–23. Dr. E. F. Armstrong will deliver his presidential address on the first day of the meeting. On June 22, the Society's medal will be presented to Dr. C. C Carpenter, and later in the same day Dr. F. W. Aston will deliver an address on "Isotopes." During the early part of the same week, it will be remembered, the International Union of Pure and Applied Chemistry is also meeting at Cambridge.

AT the annual general meeting of the Chemical Society, held on March 22, Sir James Walker, the retiring president, delivered his presidential address entitled "Symbols and Formulæ." The following elections were afterwards declared: Prof. W. P. Wynne as president; Prof. J. F. Thorpe as treasurer; new vice-presidents, Dr. J. T. Hewitt, Prof. G. T. Morgan, Sir William J. Pope, Prof. J. M. Thomson, and Sir James Walker; new members of council, Dr. E. F. Armstrong, Prof. W. N. Haworth, Dr. C. K. Ingold, Dr. H. McCombie, Dr. G. W. Monier-Williams, and Dr. J. Reilly.

IN Great Britain the period of Summer Time will begin this year at 2 A.M., G.M.T., on Sunday, April 22, and will continue until 2 A.M., G.M.T., on Sunday, September 16. In Belgium, Summer Time begins after midnight on March 31. The Paris correspondent of the *Times* states that, in order to meet the opposition to Summer Time from representatives of agriculture in the Chamber of Deputies, the French Government has decided to substitute for it the time of Strasbourg, which is about thirty-five minutes in advance of Greenwich time.

WITH reference to the letter published in NATURE of February 17, p. 222, describing a remarkable mirage observed at Cape Wrath on December 5, 1922, a letter has been received from Mr. Albert Tarn of Thornton Heath, who describes a somewhat similar occurrence at Oban in August 1885. Mr. Tarn states that he was sleeping in a bedroom at the back of a house adjoining the Waverley Hotel, so that the room faced inland. During the course of the night he awoke, and on looking out of the window saw what appeared to be a view of Oban Bay with the moon shining on the water. The date is not given, and no observations are available to decide whether the circumstances resembled those at Cape Wrath.

THE report of the National Museum of Wales for 1921–22 announces the completion of the western section of the new building and of the western portion of the entrance-hall. A fumigating chamber has been installed to rid specimens of insects and other pests. Among the many interesting accessions we note a beaker of early Bronze Age type from Glamorganshire, which contained the remains of a child's skull showing symptoms of rickets, the earliest recorded instance of this disease in Great Britain or perhaps in the world. Several thousand specimens of fossil plants most carefully collected from the successive beds in the Coal Measures of Gilfach Coch and Clydach Vale by Mr. David Davies, and the basis of his recent paper before the Geological Society, have been presented by him and will be preserved in cabinets given for the purpose by local bodies interested in the coal industry.

THE Australian National Research Council has commenced the publication at Sydney of a quarterly journal under the editorship of Dr. A. B. Walkom, which is to give short abstracts of papers written by Australian scientific workers—even when they appear in periodicals not published in Australia. The price of the journal is 4s. per annum. The first four numbers of the journal have already appeared, and extend to 32 pages. The abstracts are arranged in sections according to the branches of science represented on the Research Council, and the 245 which constitute the first year's total are distributed among the sections as follows: agriculture 70, botany 31, chemistry 14, engineering 1, geography 1, geology 18, mathematics 1, mining and metallurgy 0, pathology 13, physics 1, physiology 4, veterinary science 3, zoology 88. Cross references are given so that an abstract of interest in a section other than that in which it appears can readily be found. The distribution of the abstracts among the sections is interesting as evidence of the extent to which science is being brought to bear on the special problems which a developing colony presents to its Government.

MR. J. REID MOIR is publishing through Mr. W. E. Harrison, the Ancient House, Ipswich, under the title of "The Great Flint Implements of Cromer, Norfolk," an account of his discoveries in 1921 of a large and remarkable series of flint implements and flakes, to which attention has already been directed in the columns of NATURE. The forthcoming volume will contain a number of illustrations by E. T. Lingwood.

WE have received from Messrs. Watson and Sons Parker Street, Kingsway, Bulletin 50.S., containing descriptions of some new X-ray accessories. A new mercury interrupter with a rotary rectifier designed for continuous work under heavy loads is illustrated, also an automatic time-switch for exposures ranging from one-sixteenth of a second to thirty seconds. The extensive use of X-rays for therapeutic purposes has led to great improvements in the design of suitable stands which serve the double purpose of holding the X-ray tube and allowing it to be manipulated at any angle. The new stand illustrated here has some good constructional features, and the tube itself is almost completely enclosed by protective material which has an absorption equivalent of 3 mm. of lead. This protective shield is provided with an arrangement which permits of forced air cooling during the working of the tube.

THE 1922 Year-Book of the Franklin Institute, Philadelphia, contains some interesting facts from the history of the Institute. It was organised in 1824 for "the discovery of physical and natural laws and their application to increase the well-being and comfort of mankind," and duly installed in its own house two years later. It is noteworthy that in 1831 a joint committee of the Institute and the American Philosophical Society began systematic meteorological observations in aid of agricultural and other interests, and eight years later the Pennsylvania legislature made a grant of 4000 dollars for the purchase of instruments at the discretion of the Institute; this is stated to be the earliest instance on record of the appropriation, in any country, of public funds for the collection of facts relating to the weather. The Institute awards medals, of which the best known is the Franklin medal, for distinguished work in advancing physical science or its applications; it was founded in 1914, and among its recipients have been Sir James Dewar and Sir J. J. Thomson. Other awards made are: the Elliott Cresson medal, for research and invention; the Howard N. Potts medal, for distinguished work in science or the arts and for papers presented to the Institute; the Edward Longstreth medal, for meritorious work in science or the arts; and the Boyden premium of 1000 dollars, to any resident of N. America who shall determine by experiment whether all rays of light and other physical rays are or are not transmitted with the same velocity; an award was made in 1907 for a solution dealing with the visible and ultra-violet parts of the spectrum.

Our Astronomical Column.

Meteors in April.—Meteors are seldom abundant in April, but there are a number of interesting showers visible, including the Lyrids, which are connected with the first comet of 1861. This display usually attains a maximum on April 21, and the conditions will be rather favourable this year, as the moon will be visible only as a crescent in the evening sky. The Lyrids exhibit a radiant which moves eastwards about 1 degree per day, and we require more evidence on this point. The shower, however, is of very short duration in its active stage, and meteors belonging to it are rarely seen two or three days before or after the date of maximum.

In April there are a large number of feeble showers which it is desirable to investigate further. These include positions near α Persei, β Ursæ Majoris, α Cygni, α Cephei, etc. In Hercules, Corona, Boötes, and Ophiuchus there are a few well-pronounced displays which apparently recur annually.

The Eclipse of September 1922 in Queensland.—Mr. J. C. Russell, of Brisbane, sends some notes on his observations of this eclipse made at Stanthorpe, a favourite summer resort, nearly 3000 feet above sea-level. The N.S.W. Branch of the B.A.A. were also stationed here. There was an extensive view over the plain to the west, and the moon's shadow was seen approaching, a little in front of the horizon line, and therefore about 10 miles distant, looking like a local rain squall. Shadow bands were observed at the same time. The central dark bands were 12 or 15 inches apart, about 4 inches wide, fringed with an equal width of half-tone on each side, and a bright strip between them. They passed at the rate of 10 per second. Their least distance from his eye was 8 feet. They were followed to a distance of 30 or 50 feet, where they appeared fainter but 3 or 5 times wider than when nearest. He ascribes them to compressional waves in the air caused by the cooling effect of the shadow cone, which was passing at a rate exceeding that of sound. Mr. Russell also makes the plausible suggestion that the shapes of the bands as seen are largely modified by the phenomenon of persistence of vision. He thinks the apparent enlargement at a distance was a (partly mental) effect due to this cause.

During totality the shadow covered most of the sky, but near the horizon to north and south there was a red glow, due to distant regions of the atmosphere beyond the shadow. (This effect was also seen in Norway in 1896.) The shadow was 120 miles wide, and the observer 9 miles north of the centre.

The corona was seen with direct vision to a distance of $\frac{3}{4}$ diameter from the limb, being very bright: with averted vision two faint extensions were seen, one to N.W., the other in the upper part, each 5 minutes wide and reaching to $1\frac{1}{2}$ diameters from the limb; they gave the corona the appearance of a wind-vane, a simile used on former occasions. Mr. Russell's description of the corona mentions three immense "spearheads" of white light, one to the zenith, the other two on the lower side, the left-hand one being the larger; these formed "as it were a great forked beard." A ruby spot, doubtless a prominence, was seen on the low left hand.

A few stars were seen during totality, but they were not specified. An account in B.A.A. Journ. (Jan.) by Dr. A. F. Turner states that six were seen, of which Venus, Mercury, Jupiter, and Spica were identified; two that were seen far to the south may have been α and β Centauri.

Problems of the Nebulæ.—The Rev. H. Macpherson contributes an article on the nebulæ to *Discovery* (March). The numerous and rapid changes of view that have taken place with regard to them illustrate the difficulty of knowing where to place them in schemes of stellar cosmogony. The "island universe" theory of the spirals was received back into general favour ten years ago, but Mr. van Maanen's detection of perceptible rotatory movements in several of them, in combination with the spectroscopic determination of radial velocities, enables hypothetical parallaxes to be estimated. These correspond to distances of a few thousand light years, so that they appear to be within the limits of our own universe. Dr. Jeans regards the luminous knots on the rims of these spirals as giant stars in process of formation at the rate of one every few centuries.

There is another difficulty not felt at the time when stellar types O, B, A were supposed to be the earliest in the spectral sequence, which the "Giant and Dwarf" theory renders puzzling: this is the frequent association of these types with planetary nebulæ in the case of O, and with bright diffused nebulæ in the cases of B, A (Orion and the Pleiades). It would seem that these nebulæ can scarcely be regarded as the parents of the stars that they surround, since, if such were the case, they would be much more in evidence round giant stars of type M. The conclusion appears to be that the natural condition of nebulosity is dark, but that it may become bright either by simple reflection, as appears to be the case with the nebulæ in the Pleiades, or by selective excitation, which causes some of its gases to glow. Prof. Russell compares this to the excitation that occurs in a comet when near perihelion.

Research Items.

Archæological Exploration at Zimbabwe.—A noteworthy contribution to the discussion of the origin and date of the Zimbabwe ruins appears in the recently issued vol. xx. of the Proceedings of the Rhodesian Scientific Association in the form of a communication from Mr. H. R. Douslin, lately Director of Public Works, on "Recent Explorations at Zimbabwe." Mr. Douslin has excavated the ruins on two occasions. In 1909 the trench made by Dr. Randall-MacIver in 1905 was carried down to solid rock by a pit under the wall of the Temple. The base of the foundations was reached at about 2 ft. and the rock at about 10 ft. below surface level. Only broken pottery, of a type common to all the ruins and similar to that made by natives to-day, was found. In 1915 excavations were carried out inside the wall of the Acropolis, which it is assumed was built before the Temple, and a large part of the red-earth filling was removed. The original entrance was discovered—a passage many feet below what is considered to be the original foundation of the wall on the western side. It ended against a dead wall of the internal red-earth filling. This filling, on which many of the internal walls are built, would therefore appear to be of more recent origin than the main outer wall. Solid rock was reached at about ten feet below present surface level, where the old dwellings were found. Their workmanship is superior to that of present-day natives and of a character unknown to them. The finds included two finely ornamented copper bands, an iron shackle, assegais, fragments of a soapstone bowl, and the usual Kaffir beads and pottery. No gold was found, and the author points out that the gold ornaments, etc., for which the greatest antiquity has been claimed, were found on or near the surface ten feet above the original occupation level.

Social Significance of U.S. Army Intelligence Tests.—Prof. P. E. Davidson discusses in the *Scientific Monthly* (February 1923) some of the generalisations which have been drawn from the now well-known American Army intelligence tests. These tests, originally applied in order to differentiate men for army posts, disclosed the unwelcome fact that large numbers of the population ranked very low in innate intelligence. Some writers have concluded from this that the traditional democratic ideal must be renounced, as only a gifted few are capable of ruling. The writer of the article believes, however, that three assumptions have to be made if such conclusions are sound: (i.) that the army draft was truly representative of the American population in general; (ii.) that the tests were really tests of native ability and not of educational advantages; (iii.) that the native intellect in question is so general as to condition social success of any significant kind. He gives reasons for disputing each of these assumptions, and shows that large numbers of the more intelligent members of the community were unrepresented, that the tests made heavy demands on language knowledge, and that many factors other than native ability help to determine a man's social position. While agreeing that the gifted minority should have every possible advantage, he disputes the belief that these alone should be trained, while large numbers are to be denied training because of an arbitrarily imputed stupidity. The article gives a salutary and timely check to the ardent enthusiasts who would impute to tests more than they can legitimately bear. It is frequently the social applications of scientific research that are unscientific.

Efficiency in Fine Linen Weaving.—A report on fine linen weaving has been prepared by Mr. H. C. Weston on behalf of the Industrial Fatigue Research Board (Report No. 20, "A Study of Efficiency in Fine Linen Weaving," Textile Series No. 5, H.M.S.O., 1922, 1*s*. 6*d*. net). The investigation was undertaken for the purpose of enabling a comparison to be made between the conditions of work and efficiency in linen-weaving sheds and in cotton-weaving sheds, the latter having previously been investigated. The output from each of forty looms was recorded, hourly readings of the wet- and dry-bulb temperatures were taken, and the amount of time noted during which artificial light was used. A detailed description of the nature of the weaving process is given and the general conditions of the sheds. Tables showing the hourly, diurnal, daily and weekly variations of efficiency and temperature are appended. The writer concludes that there is evidence to show that the economic limit of temperature for fine linen weaving is reached when the wet-bulb temperature exceeds 73° F. Up to this limit increase of temperature results in increase of productive efficiency, but beyond it efficiency falls owing to the discomfort and fatigue of the workers. He also shows that the use of artificial light reduces efficiency approximately by 11 per cent. of its normal daylight value. A similar result was reported in a previous investigation made by the Industrial Fatigue Research Board into silk-weaving. These results are not unworthy of consideration in discussions of daylight saving.

The Distribution of Megalithic Monuments in England and Wales.—In the Proceedings of the Manchester Literary and Philosophical Society (vol. lxv. No. 13) Mr. W. J. Perry supplies some further arguments in support of his theory that megalithic monuments were the work of a race of miners engaged in the search for precious metals and other valuables. This he holds to be established in the cases of Cornwall, Devonshire, Wales, Derbyshire, Northumberland, and Cumberland. The difficulty remains regarding those in Dorset, Wilts, and Oxford, including Stonehenge and Avebury. The explanation is that this latter series is situated on the Upper Chalk flint-bearing formation. "Flint implements," he remarks, "are found in all parts of the country, even in places far away from the source of the material. Sir John Evans mentions particularly Devon and Cornwall as regions where there is an abundance of flint implements and flakes, and these counties have no flint-bearing formations, though in some places there are some on the surfaces. These would not be nearly so good for the purpose as those from the chalk regions of Wilts and Dorset. We have thus the remarkable fact that flint implements are found all over the country, and that the builders of megaliths, including long barrows, have chosen out those very portions of the chalk country which produce flints."

Distribution of Organisms in Culture Media.—As a rule the accuracy of biometrical determinations must be ascertained empirically from a statistical study of the observations; in certain cases, as has been shown in the theory of hæmocytometer counts, the law of variation may be calculated, and the accuracy known with precision, provided the technique of the counting process is effectively perfect. A study of the extensive bacterial count data accumulated at Rothamsted by Cutler and Thornton, using Thornton's agar medium, indicated that the same law of variation, the Poisson series, was obeyed by the number of colonies counted on parallel plates. Statistical tests were devised which proved that, save for a small proportion of definite exceptions, the necessary perfection of technique was effectively realised (R. A. Fisher, H. G. Thornton, W. A. Mackenzie, *Annals of Applied Biology*, vol. ix. p. 325, 1923). In studying the exceptional cases it appeared that these fall into two classes, (1) an abnormally high variation which, when investigated experimentally, has been traced to certain bottom-spreading organisms isolated from soil from Leeds and from Rothamsted, and (2) an abnormally low variation ascribable to defective procedure in the preparation of the medium. Application of the same tests to other extensive series of bacterial counts showed that a similar approach to theoretical accuracy, though rare, had been obtained by Breed and Stocking in counts of *B. coli* in milk. It should be emphasised that all cases of departure from the theoretical law of distribution, which have been investigated, are associated with large systematic errors in the means; for this reason simple tests are presented by which such deviations from the theoretical accuracy of the method can be detected.

Primulas of Central Asia.—Mr. F. Kingdon Ward, who was referred to in Nature of February 17, p. 231, as returning to England after extensive travels in Central Asia, has been contributing some account of his previous (seventh) expedition in Asia in the *Gardeners' Chronicle* since May 1922. These articles not only describe very vividly the first discoveries of many new plants, to be of interest afterwards to the British growers of novelties, but also frequently raise interesting general questions from the point of view of a keen observer of plants; as, for example, the discussion in the issue of February 10 (p. 80), as to the association of meal—a granular waxy deposit developed on the cuticle—and fragrance in the Primulas, and the observation that the Primulas found growing on boggy habitats are generally without meal.

The Cuticle of Cotton.—A paper by R. G. Fargher and M. E. Probert, in the Journal of the Textile Institute, vol. 14, pp. T49-T65, February 1923, seems to represent a notable advance in our knowledge of the chemical composition of the plant cuticle. Material extracted from American cotton by benzol, heating with superheated steam, was available from some very large scale experiments. This method opens up the possibility of hydrolysis during extraction, but the large bulk of material made available by the scale of operations has provided very precise information as to certain constituents of the cotton wax, although doubt may remain as to the exact form in which they are present in the cuticle. A new alcohol, gossypyl alcohol, $C_{30}H_{62}O$, is identified and described, montanyl alcohol, $C_{28}H_{58}O$, present in smaller amount, is also described for the first time; small amounts of ceryl and carnaübyl alcohol were also found, and a mixture of phytosterols; little if any glycerol was present. Palmitic, stearic, and oleic acids were found in the free state, the sodium salts of montanic, cerotic, palmitic, and stearic acid were identified, as well as the salt of an acid, $C_{34}H_{68}O_2$, oleic acid and a lower isomeride of oleic acid were present as esters, but the proportion of unsaturated acids, either free or combined, was small. While this work, on one hand, will throw much light on the problem of scouring cotton, on the other, it gives much needed information as to the chemical constituents of the plant cuticle.

The Isoetaceæ.—Norma E. Pfeiffer has published a most valuable systematic study of this family in the Annals of the Missouri Botanical Garden (vol. 9, No. 2, April 1922). After a brief account of the morphology and ecology of the genus, which is incomplete as a bibliographical account of European work upon Isoetes, the species are grouped into sections, and keys are provided for the identification of species within the sections. Breaking away from former systematic studies, where habitat characters have largely been used for the establishment of main subdivisions, the present sections are based upon the megaspore surface, whether tuberculate, spiny, crested, or reticulate. Within the sections great use is made of the lobing of the corms and the amount of development of the velum; megaspore characters are again frequently used, and eight plates are provided with photographic illustration of megaspores of different species. The family is a remarkable one to the student of plant distribution. Of the 64 species described, most are very restricted in range, the only exceptions being *Isoetes Braunii*, Dur., in North America, and *I. lacustris* and *I. echinospora* in Europe. Some of the Mediterranean forms appear to the author to show close affinities, as though originating from a common stock; but, on the whole, present knowledge of the species and their distribution is too puzzling, and probably too incomplete, to encourage premature speculation as to centres of distribution and evolutionary tendencies. It is interesting to find one submerged species—*I. echinospora*—always without stomata while *I. Braunii* always possesses some.

Physiography of Porto Rico.—A detailed study of the physical geography of the West Indian island of Porto Rico by Mr. A. K. Lobeck is published by the New York Academy of Sciences (vol. i. pt. 4). It is the last section of a complete survey of the island undertaken by the Academy. The present part, which includes a large-scale map, is the outcome of field work in 1916–17. The physiographical history of Porto Rico appears to have begun with a complex mass of igneous rocks which were eventually reduced to a peneplain, except for two well-defined monadnock groups, now known as the Luquillo mountains and the Cordillera Central. No direct evidence on the horst nature of this ancient land mass was available. Uplift of the peneplain led to a new cycle of erosion, but only along the northern side of the island was a second peneplain produced. On the south the island was worn down less effectively, probably because of inadequate rainfall. Partial submergence then allowed the formation of coastal plains on both north and south sides which, after uplift, were considerably dissected. Mr. Lobeck traces these events and discusses also recent changes now in progress, illustrating his lucid paper by photographs and block diagrams. Some notes are added on the islands of Desecheo, Mona, Vieques, Culebra, and Muertos.

Pliocene Vertebrates from the Tertiaries of Arizona.—On the initiative of the United States Geological Survey and with the co-operation of the United States National Museum, Mr. J. W. Gidley went early in 1921 to collect fossil vertebrates in the San Pedro Valley, Arizona, with the view of establishing the age of the deposits there, which until then had been termed Pleistocene. A preliminary report has now been issued as Professional Paper 131-E of the United States Geological Survey. Unfortunately the material collected represents for the most part new species which cannot therefore be correlated with known faunas of other localities where the age of the beds has been established. With two or three species of true horse (Equus) are associated the remains of Hipparion, Pliohippus, some Proboscidia, Camelidæ, Cervidæ (including Merycodus), Carnivora, numerous Rodentia, and Glyptotherium, as well as reptilian and bird remains. The author, therefore, refers these beds to the Pliocene, and points out that the presence of a true llama, a glyptodont, and a rodent belonging to a genus now living only in South America, bears out the theory of the derivation of the South American fauna by migration from North America, and that such migration may have taken place about this epoch. Detailed descriptions, with figures, of the Rodentia and Leporidæ, all of which represent new species and total some twenty in number, form the major portion of the paper. The reptiles and birds are to be dealt with later by other writers.

THE HIMALAYAN MOUNTAIN SYSTEM IN SOUTH-EAST ASIA.—One of the objects of Prof. J. W. Gregory's recent journey to Yunnan was to study the geographical relationships of the Alps of Chinese Tibet. A sketch of his conclusions appears in the *Geographical Journal* for March. He contends that the structure of western Yunnan is best explained on the view that the line of Himalayan folding is not wholly bent in Assam into the Burmese arc which follows the Arakan mountains, the Andamans, and the Nicobars into Sumatra, Flores, and Timor. Two routes have been suggested as the eastern prolongation of the Himalayas, the Great Khingan mountains, and the Tsinling mountains. The former view is untenable owing to the essential difference in structure; the latter is a doubtful thesis since there are indications that the Taliang Shan of southern Szechwan, which would appear to be a link in this chain, are east and west folds of Hercynian age. The evidence is more in favour of the Himalayan line being continued in the Nan Shan mountains, which separate the Yangtze Kiang from the Si River, although information as to their geological structure is still meagre. According to Prof. Gregory's interpretation, the Burmese-Malay arcs of folding form a loop on this eastern prolongation of the Himalayan axis comparable with the Persian loop in western Asia and the Apennine loop in Europe. The eastern end of the Malay arc is generally represented as a reversed bend round the Banda Sea. Prof. Gregory agrees with Suess that this is not so, and holds that the Malay arc continues into the mountains of south-eastern New Guinea. On the north of the Banda Sea these folds are also obvious and are continued in the northern mountain axis of New Guinea. But the eastern end of this line of folding is now cut across by the Pacific, into which it must at one time have extended. The paper also contains important evidence on the river system of Chinese Tibet.

PERIODICITY OF EARTHQUAKES.—Messrs. D. Mukiyama and M. Mukai, in a paper too brief to be quite clear (*Japanese Journ. of Astr. and Geoph.* vol. 1, 1922, pp. 49-54), indicate a general similarity in the deviation of the atmospheric pressure-gradient at the time of an earthquake from the mean pressure-gradient in each of four selected districts in Japan. The question of the influence of rainfall on earthquake-frequency is considered, as regards the Philippines, by the Rev. M. Saderra Masó (Bull. of the Weather Bureau for February 1921). He shows that in the western districts of both Luzon and Mindanao earthquakes are most frequent during the rainy season, but in the eastern districts of both islands during the dry season. Thus, though rainfall may have some influence, it cannot be the main determining factor in the frequency of earthquakes. The late Mr. Marshall Hall, in his study of the earthquakes of Jamaica from 1688 to 1919, suggested the existence of nearly forty earthquake-periods varying in length from about 10 to about 30 days in the different epicentres, especially one of about 21 days in the epicentre of the earthquake of 1907. These periods have been examined by Prof. Turner (Mon. Not. R.A.S., Geoph. Sup., vol. 1, 1923, pp. 31-50), who arrives at the interesting results that they are multiples of 21·00 minutes, and that the intervals between the means of these periods are also multiples of the same unit, or 0·0145843 day.

STRUCTURE OF BENZENE.—In the February number of the Journal of the American Chemical Society, Dr. M. L. Huggins discusses the structure of graphite, benzene, and other organic compounds from the point of view of X-ray measurements by Hull and by Debye and Scherrer. He concludes that graphite consists of layers of close-packed benzene complexes of the type proposed, from the point of view of organic chemistry, by Körner in 1874. This is built up of six tetrahedra, three on each side of a plane, with edges adjacent, and with the vertices alternately above and below the plane. On the assumption that similar close-packed layers are present in benzene and many of its derivatives, the dimensions of the benzene hexagon are computed from crystallographic data. The half length of this is 2·47 Å., the half-width 2·14 Å., and its area 15·84 $Å.^2$. The corresponding figures from Debye and Scherrer are 2·52 Å., 2·18 Å., and 16·47 $Å.^2$ The probable error in each case is about 1 per cent.

SPACE GROUPS AND CRYSTAL STRUCTURE.—With the development of such methods of studying the arrangement of the atoms in crystals as are furnished by the use of X-rays, the geometrical theory of space groups has become of the utmost importance. Until recently the work published upon this theory has been primarily directed towards the preparation of a statement of all the different kinds of symmetry which are crystallographically possible. Such a statement, when complete, must give all the possible ways of arranging points in space which, by their arrangement, express crystallographic symmetry. In his "Krystallsysteme und Krystallstructur" (Leipzig, 1891) Schoenflies gave an analytical expression for the results of this theory in its most general form, but, before it is applicable to the study of the structures of crystals, modifications of this original representation are necessary. First, there must be selected such a portion of the grouping that, in its calculated effects upon X-rays, it can be taken as typical of the entire arrangement. Secondly, the X-ray experiments which have already been carried out show that the number of particles (atoms) contained in the unit cell is commonly smaller than the number of most generally placed equivalent points of the space group having the symmetry of the crystal. The special arrangements of the equivalent points (upon axes, planes, and other elements of symmetry), whereby the number of most generally placed equivalent positions is reduced, are thus of great importance, and it becomes essential to be able to state all of them in any particular case. In his "Geometrische Krystallographie des Discontinuums" (Leipzig, 1919), Niggli has given the simpler of these special cases. The complete set of them, enumerated by R. W. G. Wyckoff, is now presented in "The Analytical Expression of the Results of the Theory of Space-Groups," in Publication 318 of the Carnegie Institution of Washington, 1922; price 3.25 dollars.

The Dyestuffs Industry in Relation to Research and Higher Education.[1]

By Dr. Herbert Levinstein.

Within one generation we have seen the small mechanics' institute in a provincial city develop into an institution of university standing, constituting a technological faculty giving degrees, with some of its professors sitting on the university senate. In one way or another London, Birmingham, Bristol, all the large cities, show the same change. It means that within this period an enormous change has taken place in the character and requirements of our industries, and consequently in the demand for highly trained young men. The industrial world has changed. The present characteristic of industry is the tendency towards large units, using as one of their weapons an intelligence department (a research department), equipped with every resource of science. This is in itself nearly as far removed from the Victorian system of industry as that was from its predecessor, and it is causing nearly as great a social change as the industrial revolution that followed on the introduction of machinery.

The scientific educational establishments in this country are fundamental to the whole structure. By the vitality and originality, by the number and the quality of our teachers, the world can judge of the capacity of Great Britain in the long-neglected scientific industries, of which dyestuffs and fine chemicals are pre-eminent.

The dyestuffs industry is what is loosely termed a key industry. Mr. Runciman, speaking in the House of Commons on November 27, 1914, said: "The combined capital of such operations of textile and other industries which require aniline dyes comes to no less than 200,000,000*l.*, and about 1,000,000 of our employees are either directly or indirectly interested in the adequate supplies of dyestuffs for their main industries." There were few people who questioned at that time the urgency and importance of producing within our own shores the commodities required to support so many staple industries. We were at war with Germany, on whom we had been dependent in peace time for 80 per cent. of our requirements, and at that moment it was necessary, both from an economic and military point of view, to replace at once those vanished supplies from home sources.

What happened after the War? In 1913 the dyestuffs industry in England supplied about 10 per cent. of the British consumption, which amounted in round figures to rather more than 20,000 tons. The factories were comparatively small, and the number of chemists proportionately few. By Armistice Day the two principal companies, already loosely united, employed some 7000 persons, nearly 300 of whom were academically trained chemists—an unheard-of number in this country. During the two years following the Armistice more than 25,000 tons of dyestuffs manufactured by this British company alone went into consumption in Great Britain.

The extraordinary prosperity in the textile trades at that period had its aftermath in the slump. In 1919, however, the employment provided by these trades, and the money brought into this country as payment for exports, were factors without which this country would not have readily recovered from the paralysis of war. The total value of the exports of printed and cotton dyed piece goods alone during 1919–20 amounted to 270 million pounds sterling. In October 1920 the British Dyestuffs Corporation alone employed some 8000 people, with a yearly wage roll of 1,600,000*l.* This company used 4000 tons of coal per week, 1000 tons of pyrites, and corresponding quantities of heavy chemicals and raw materials. These figures may be considered large in this country, where we are not so familiar with very large plants, but they are small compared with the aggregate of the German I.G.

Suddenly in October 1920 the slump fell upon the country. The position was made much worse by four factors. German production revived, considerable quantities of German dyes were imported as reparations, the Sankey judgment temporarily removed all protection from the home producer, and the rapid external depreciation of the mark temporarily made it difficult to compete with Germany in neutral markets. Stocks fell in value, large sums of money were lost, and the production of British companies fell almost to pre-war figures.

The dyestuff and fine chemical industries in this country, are by no means assured of a prosperous development. If the factories are allowed to decay, the staffs to be gradually diminished, the capital invested rendered unremunerative, our position will become less strong. At the moment, should the occasion arise, the factories and organisations created during the war years are a source of strength.

The developments of higher scientific education in this country, on which our scientific industry is based, tend to strengthen the national life in a way which may not be immediately obvious but yet quietly and unobtrusively may be of fundamental importance to the State. There is another reason of great importance in favour of a flourishing and progressive dye industry. The dye industry is a key industry to invention. Its importance as a factor in producing new inventions is well summarised by Mr. J. A. Choate, the author of an official American publication issued by the Alien Property Custodian of the United States Chemical Section:

"The Technical skill and equipment provided by a successful Dye Industry, furnishes the means, and almost the sole means, to which every nation must look for advances in the application of chemical science to practical undertakings. No other industry offers a livelihood to any such large numbers of highly trained scientific chemists nor any such incentive to continuous and extended research."

Any firm wishing to become a serious factor in the world's markets for fine chemicals and dyes must employ a number of research chemists. Existing products tend towards obsolescence, competition from other makers tends to lower their price, and new demands constantly arise and are satisfied or created by new products for which high prices can be obtained owing to their novelty and, at first, the absence of competition. In the long run that nation will predominate in this industry which brings out the best and the largest number of new products.

These research organisations are expensive. Why then did the Germans start in this race for new products? They found this kind of research to be extremely profitable to their shareholders. Consequently, it was developed, and they were able to bring out annually quite a number of new products which, pushed by enterprising salesmen in all markets, home and foreign, gradually became established branches of manufacture in Germany.

Research for new products costing no more than the old, but for which the public will pay a higher price, is intimately wrapped up with the question of patents. Without the prospect of a monopoly for a term of years, and the lure of high profits, this kind of

[1] From a paper read before the Association of Technical Institutions on March 3.

work would not be undertaken on a comprehensive scale. Unfortunately, the monopolies granted in our country in the past for this kind of work were granted to German industries, and not to our own, and large profits were made out of British patents by the German dyestuff works. A similar research system, if sufficiently supported on the commercial and technological side and directed with sufficient knowledge of the requirements of the industry, and with some imagination, can be made to pay in England just as in Germany, where this combination existed. It is important to remember that firms employing this modern commercial weapon were large, for the amount of money that can be spent on research is a function of the turnover.

It is further true that to build laboratories, to engage for them a number of chemists, are not alone sufficient for our success.

If the stream of chemical invention can be induced to flow in this country in the future not less sluggishly than in Germany, we shall gradually build up new industries as the Germans built up theirs.

In this country we rely too much on our staple industries and look too little for new inventions to find food and employment for our people. In the Report of the Department of Scientific and Industrial Research, 1921–22:

". . . It is well recognised that for four-fifths of their food and for a great part of the necessary raw and semi-manufactured materials for industry the people of these islands are dependent on supplies from overseas. These supplies can only be obtained if this country is able to carry on its exporting industries in future with greater efficiency than the rest of the world."

The Department spent in this year more than half a million pounds with this purpose in view, and provision is made for expenditure on a similar scale for the current year. Under its auspices no less than 24 Industrial Research Associations have been formed, of which 22 are licensed by the Department, and received more than 86,000*l.* in grants during the year in question. Broadly speaking, the work of the Department and of the Research Associations with which it collaborates is to ensure the best utilisation of our natural resources and of the raw materials which we buy from abroad for our staple industries, with the view of increasing the efficiency of those industries and enlarging the demand for their products in customer countries.

This work does not replace that of private firms, but is complementary to and ought to stimulate it. There is a radical difference between industrial research carried out by a company and that by a Research Association, or by a Department of State. Patents taken out by chemists who receive part of their emoluments from the Department, belong apparently to the Government. Patents which may be taken out by a Research Association would presumably be available for all subscribers and could not easily become a profitable monopoly for any one member. For this reason it appears likely that in the future, as in the past, the dyestuffs industries and the allied fine chemical industries will be the main source from which chemical discoveries will be transferred from the laboratory to the factory.

Running through all this is one common factor which must be realised if the expectations of the State are to be satisfied. The industry must be big. There must be large factories containing plant capable of producing great quantities of organic chemicals, staffed by an adequate number of experienced and well-trained chemists. Moreover, the factories must be growing. It is an industry which cannot succeed if it be static. It must be ever increasing its plant and the number of its chemists and ever spreading its tentacles wider and deeper into the markets of the world.

It follows that if the industry is successful there will be a continual flow of students from the universities and technical schools to the industry. Two distinct classes of chemical students are required: (*a*) for factory and research, and (*b*) for the dyehouse and technical sales. It is customary in aniline dyestuff factories to recruit the chemists for plant supervision from their own research department. The young chemist engaged on leaving the university is first placed in the research department for at least a year before a permanent engagement is made. The training required of a dyestuff works chemist is usually identical, whether he intends to devote himself afterwards purely to research, or, as in the majority of cases, to become actually employed in the factory. It is of the first importance that chemists should have a good general secondary education. After taking his degree the student should cary out, under direction, original work for one or, preferably, two years. What branch of organic chemistry he studies is comparatively immaterial. A special knowledge of dyestuffs chemistry is not very important.

Undoubtedly a knowledge of chemical engineering is useful, but subjects added, however useful, will be at the expense of chemistry. The recent formation of the Institution of Chemical Engineers is welcome. Good chemical engineers are invaluable in any chemical industry, but, above all, good organic chemists are wanted in the dyestuff industry.

There is also a considerable demand for another type of chemist. All aniline dye works have a dyehouse which fulfils a treble function—the control of the production, the valuation of new specimens sent in from the research department, and the supply to the sales organisation of technical information and assistance in the application of dyestuffs. The technical salesman is a person of great importance in the industry. He should preferably take a pure or technological science degree, followed by a course in dyeing, printing, paper-making, etc., at a technical college. There is a constant demand for such men in a flourishing dyestuffs industry, the more so as the experience obtained in the experimental dyehouse is so varied, that such men are afterwards sought for as managers or as assistant managers in print-works, dyehouses, paper-works, and the like.

The foundation stones of our scientific industries were laid by those responsible for the creation of our great technical institutions and University Colleges. If that is so, we should expect to see during the years which have elapsed since 1914 a corresponding development in the chemical schools of this country. The progress in the study, teaching, and research in pure chemistry has been at least as striking as the progress of those sections of chemical industry such as fine chemicals and dyestuffs in which we were not particularly strong before the War. Twenty or thirty years ago the German organic schools were as pre-eminent in research and in teaching as the German dyestuff and fine chemical industry. To-day one may fairly say that there are several organic chemical schools in this country equal to that of any organic chemical school in Germany. Brilliant original work is being done here. Students are attracted to schools where good research is being done, and so round each head is formed a coterie of young men deriving inspiration from their chief, to strengthen the ranks of industry. Probably there has never been such a concentration of chemical talent as that which gathered round A. von Baeyer in Munich thirty or forty years ago, but something of the kind is happening in Great Britain to-day, and not in one centre alone.

Thirty years ago, institutions comparable, for example, with the Federal Polytechnic at Zurich or the Technical High School of Charlottenburg did not exist in Great Britain. The scale on whch they were designed, their large staffs of distinguished teachers, the number of full-time students, students who had remarkably good secondary school training and had passed a rigorous entrance examination, astonished all English visitors. The English organic chemist with industrial experience was equally astonished at, for example, the Leverkusen or the Badische factories. These factories differed from the corresponding English factories in scale, in the size of the buildings, their staffs, their financial results, just as the British schools differed from the corresponding German institutions.

The number of students taking a degree in pure science at 17 English and Welsh Universities in 1913–1914 was 1867. In 1921–22 the number was 4575, *i.e.* about two and a half times the 1913–14 number. At the University of Cambridge the figures were as follows:

	1913–14.	1921–22.
Number of chemical students working	498	804
Research workers	10 (about)	29
Staff, including professors . .	25	43

The growth of the dyestuffs industry within this period is well known, and there has been a similar growth in the fine chemical industry. In 1913 some 100 fine chemicals were made in England, whereas 4000 are now being made; for every ton of fine chemicals made here in 1913 exactly 2½ tons are made to-day. This ratio is identical with that of the increase in science students taking a degree course.

Is it possible that this parallel growth in our teaching institutions and newer industries is accidental? The figures are symptomatic, but they indicate that the strength of our higher teaching bodies is a measure of our strength in the industries depending on invention.

It may be said that there has been in Germany, too, and no doubt in other countries, a great increase in the number of students at their High Schools. In part this is one of the social changes brought about by the new industrial revolution.

The increase in the number of chemical students is partly due to the publicity given in 1914 to the renascent dyestuffs industry, and to the support given by public opinion and by the Press for the first time in our history to those engaged in these industries. These industries open out to a young man who has a love of research the opportunity of earning a livelihood in a most interesting way, with the added possibility, if his inventions prove commercially successful, of earning considerable profits. Before the War it was difficult to live by research.

It is probable that the grants made by the Department of Scientific and Industrial Research have tended to increase the number of chemists undertaking training, "for the underlying object of the Scheme of Grants is the output of an increased number of trained scientific investigators." At the same time, the Department has done much to increase the possibility of finding employment for chemists. The Department, including its headquarters staff, boards and committees, Fuel Research Station and the Research Associations, already employs 78 chemists, none of whom were employed in 1913, at salaries ranging from about 250*l*. to 2000*l*., the majority between 350*l*. and 700*l*. In other Government Departments, too, there has been a great increase in the number of chemists employed. In 1913–14 the staff of the Government Chemist consisted of 48, with a salary range of 120*l*. rising to 1500*l*. The majority of the posts ranged from 120*l*. to 500*l*. In 1921–22 there were 75 posts, ranging in salary from 300*l*. to 700*l*. At the War Office in 1913–14 there were 22 posts and 2 teaching posts at the Ordnance College. The salary range was about 150*l*. to 550*l*. In 1921–22 there were 93 posts, with salaries ranging from 300*l*. up to 1200*l*., but with the majority falling within a range of 300*l*. to 700*l*. At the Admiralty in 1913–14 there was one inspector of cordite, in addition to the teaching staff at the Royal Naval College at Greenwich and the schools at Dartmouth and Osborne. In 1921–22, in addition to these teaching staffs, there were 20 posts with salaries of from about 150*l*. to 600*l*. The total number of chemists who can to-day find employment in the service of the above Government Department is thus 193 more than in 1913.

In the 1921 report of the Department it is stated that of the 132 students receiving grants 24 found employment under the State or under State-aided research institutions, 22 went into the teaching profession, and none went into industry, no doubt owing to the slump in trade.

If our fine chemical industries begin to increase their staffs regularly, as in prosperous years they will, the situation will be improved, but it is to the general trade of the country and not to the specifically chemical industries that we must look to give employment to all those who have taken a chemical degree.

Large Telescopes and their Work.

SIR FRANK DYSON'S presidential address to the Optical Society on February 8 on the subject of "Large Telescopes" dealt with the progressive advance of astronomy so far as it was brought about by the increased optical powers of telescopes. The Copernican system was established before the discovery of the telescope, but Galileo's telescope removed many difficulties and commanded its acceptance. The great telescopes of Herschel revealed the vast extent and variety of the stellar system. At the beginning of the nineteenth century, excellent achromatic telescopes of 6 inches were made by Fraunhofer and Merz, and in 1824 an object glass of 9·6 inches was made for Struve at Dorpat with which he carried out his great work on double stars.

When the Russian National Observatory at Polkovo was founded a 15-inch glass was obtained from the Munich firm, and this was the largest refractor in the middle of the nineteenth century. The large telescopes of this time were the reflectors of Lord Rosse and Lassell, and with them the heat from the moon was measured and new satellites of Uranus and Neptune discovered. A new development in reflecting telescopes came with the process of silvering on glass, and gradually these superseded speculum. In England in the early 'eighties photography of nebulæ began with Common's photograph of the Orion nebula, and was pursued by Isaac Roberts. The manufacture and mounting of reflectors was brought to a high degree of perfection by Ritchey at the Yerkes Observatory, but it was with the Crossley reflector, made by Calver and presented to the Lick Observatory by Sir Edward Crossley, and remounted by Keeler, that most systematic work was done.

Meanwhile, larger refractors were being made. In 1868 one of 26 inches aperture was made by Cooke for H. S. Newall of Newcastle. This was soon followed by large telescopes in America by Alvan Clark, by Grubb in England, and the brothers Henry in France. In 1892 a 36-inch glass was made for the Lick Observatory by Alvan Clark, and a 40-inch for the Yerkes Observatory in 1897. These large telescopes led to the discovery of new satellites, the accurate determination of the sizes of planets and satellites, but their main work—used visually—was the discovery and measurement of large numbers of double stars, leading to a very satisfactory knowledge of the masses of stars. Used with the spectroscope, they gave the velocities of stars to and from the earth, and enabled the velocity of the sun among the stars to be determined as 19 kilometres per second. This result, in combination with measurements of angular motions of stars, served to give the mean distances of stars. Large photographic refractors have made possible the measurement of the actual distances of thousands of stars, leading to a much more complete view of the stellar system.

The discoveries made by the large 60-inch and 100-inch reflectors of Mt. Wilson and the 72-inch of British Columbia were also detailed, culminating with the measurement of the size of the disc of Betelgeuse and of several other stars by the interferometer as applied by Michelson.

Irish Sea Plankton.[1]

SIR WILLIAM HERDMAN, in an interesting paper recently issued, gives a summary of plankton researches in a single area extending over a period of fifteen years, and compares the results in each year in such a way that certain general facts are at once apparent.

The object of the investigations was twofold: "(1) To study the distribution of the plankton as a whole, and of its various constituents during the year; and (2) to arrive at some estimate of the representative value of the samples collected in the plankton nets."

The results show very clearly that the distribution of life in the sea is not uniform, but that the organisms appear in patches. Although this applies to a certain extent to all the plankton, it is especially the case with the copepods, which are frequently present in large swarms in one place, while possibly only a short distance away few or none occur. This naturally affects the distribution of other organisms feeding on the copepods, especially fishes, and is of fundamental importance. The diatoms were found to be more evenly distributed both vertically and horizontally during their maximum in the spring than at any other time. Comparing the records for the fifteen years (1907–21), there is always this spring maximum of phytoplankton (chiefly diatoms), which may range from March to June and reach to hundreds of millions in one haul, a dinoflagellate maximum, in much smaller numbers, coming on about a month later; and later still, a copepod maximum ranges from June to October. In late summer or autumn each group may have a second smaller maximum in the same order.

That the bulk of the plankton consists of a small number of genera, chiefly diatoms and copepods (and only a few species of copepods), is well established, and these few form the chief food of most of the marine animals. So far as fishes are concerned, copepods are by far the most important food of the young stages, and also of the plankton-eating adults; but as most copepods are predominantly diatom feeders the presence of diatoms is quite as important to the fish as to the copepod. With regard to the phytoplankton, however, Sir William Herdman apparently regards it as the direct food of many larval fishes, at any rate of the plaice in its infancy, which he has seen with its stomach full of diatoms.

The diatom maximum occurs usually just before the time when most of the fish larvæ begin to be abundant, and the copepods follow. These plankton investigations are thus of great importance relative to the food of fishes.

Dr. Johan Hjort suggests that large mortality among the fish larvæ may occur because of the lack of suitable food at the time when they begin to feed. In the present plankton investigations, together with data gathered from experiments in the plaice hatching at the Port Erin Biological Station, it is shown that diatoms are abundant usually a short time before the very young plaice are set free; but in four out of thirteen years the diatoms were late, and in these years it is possible that the young fishes may not have found enough to eat. "The evidence so far seems to show that larvæ set free as late as March 20 are fairly sure of finding suitable food: but if they are hatched as early as February they run some chance of being starved."

While discussing fully the phytoplankton in relation to fish larvæ very little is said of the zooplankton other than copepods, and one would infer from the conclusions that it is only the diatoms which are of importance as young fish food in the spring. It is, however, probable that in spite of the fact that more diatoms than anything else are present, yet the zooplankton is really of more direct value as food for the larval and post-larval fishes: for example, cirripede nauplii and mollusc larvæ besides copepods, the latter, although not at their height in the spring, yet occurring in large numbers.

Sunlight is shown to play a very important part in the growth of the plankton. In the daytime, however, the largest hauls are usually not at the surface but at about five or ten fathoms, the depth varying with the meteorological conditions. It is regarded as probable that the spring phytoplankton maximum is due chiefly to the great increase of sunlight aided by the winter increase of carbon dioxide and other food matters. The rapid disappearance of the diatoms after the spring maximum is accompanied by a greater alkalinity of the water, and it is suggested that it may be due to the injurious effect of their own metabolism. May not the explanation lie partly in the fact that the diatoms are eaten by an enormous number of pelagic animals coming on just after the diatom maximum?

As to the representative value of the samples collected in the plankton nets, it is shown that variation in the composition of similar hauls is great. These differences show clearly that the life in the sea is not spread evenly either horizontally or vertically, but everywhere occurs irregularly. Simultaneous hauls of similar nets were usually different in quality even if alike in quantity, and the same applied to successive vertical hauls in which the amount of organisms was much the same in each haul but different in kind.

In plankton investigations in which tow-nets are used, however carefully the experiments may be carried out, there is necessarily a great deal of inaccuracy, which is freely admitted and discussed. None of the numerical results can be absolutely exact, but when, by examining and recording these, certain phenomena are seen to repeat themselves year after year, we can at least feel sure that by making these careful quantitative experiments in connexion with numbers of hauls all carried out in an exactly similar way, we are approaching the solution of the general problems relative to the distribution of life in the sea.

M. V. L.

[1] "Spolia Runiana. V. Some Results of Plankton Investigations in the Irish Sea," by Sir William Herdman. Extracted from the Linnean Society's Journal—Botany, vol. xlvi., July 1922.

University and Educational Intelligence.

Bristol.—Dr. L. J. Russell, lecturer in philosophy at the University of Glasgow, has been appointed to the chair of philosophy which will be vacated by Prof. C. D. Broad at the end of the current session.

Cambridge.—The Duke of Devonshire has been elected High Steward of the University in succession to the late Earl of Plymouth. So far back as the fourteenth century a Cavendish held high office in the University, and the name of Henry Cavendish is perpetuated in the Cavendish chair of experimental physic.

Mr. G. S. Adair, scholar of King's College, Mr. P. M. S. Blackett, Bye-fellow of Magdalene College, and Mr. B. Ord, organ scholar of Corpus Christi College, have been elected fellows of King's College.

Leeds.—The Council has agreed with the University of Basle to a scheme of mutual recognition of certain courses and examinations in the case of students proceeding from either of these Universities to the other.

London.—Prof. A. V. Hill has been appointed as from August 1 next to the Jodrell chair of physiology tenable at University College. Prof. Hill was educated at Trinity College, Cambridge. He was Third Wrangler, and obtained a first class in physiology in the second part of the Natural Sciences Tripos. He was fellow of Trinity College from 1910 to 1916, and in the latter year was elected fellow of King's College. During the War he was director of the anti-aircraft experimental section of the Munitions Inventions Department and a member of the Inventions Committee. Since 1919 he has been professor of physiology in the Victoria University of Manchester. He is the author of a number of papers in the Proceedings of the Royal Society and the *Journal of Physiology*.

Mr. W. J. Perry has been appointed as from August 1 next to the University readership in cultural anthropology tenable at University College. He was educated at Selwyn College, Cambridge, and studied ethnology under the late Dr. Rivers. Since 1919 he has been reader in comparative religion in the Victoria University of Manchester, and has also delivered courses on ethnology in the department of psychology of that University. He is the author of "The Megalithic Culture of Indonesia," "The Children of the Sun," and "The Origin of Magic and Religion," and of numerous papers on ethnological and anthropological subjects.

Dr. B. Malinowski has been appointed as from August 1 next to the University readership in social anthropology tenable at the London School of Economics. From 1914 to 1918 he was engaged in anthropological field-work in Eastern New Guinea. He is the author of "The Family among the Australian Aborigines" and "Argonauts of the Western Pacific," and of a number of articles on anthropological and allied subjects.

The following doctorates have been conferred:—*D.Sc. in Agricultural Chemistry*: Mr. N. M. Comber, an external student, for a thesis entitled "The Flocculation of Soil Particles considered in relation to the Action of Lime and the Constitution of the Soil," and other papers. *D.Sc. in Physics*: Mr. E. T. Paris, an external student, for a thesis entitled "On Doubly-Resonated Hot-Wire Microphones," and other papers.

The Senate has resolved to hold a reception for the sixth triennial congress of the Société Internationale de Chirurgie, which will be held in London in July next.

Manchester.—The chairman of the council, Sir Frank Forbes Adam, has received from the Viscount Morley of Blackburn a letter asking leave, on account of the growing weight of years, to withdraw from the office of Chancellor of the University, the resignation to take effect from April 30. The council passed a resolution expressing regret at losing the Chancellor, and deep appreciation of the honour which he has conferred on the University during his tenure of office.

The council passed the following resolution: "The council have heard with deep regret of the death of Sir William Thorburn, professor-emeritus of the University. They desire to record their sense of his great services as an administrator, a teacher, and an investigator, his eminence as a surgeon, and the whole-hearted devotion with which he sacrificed himself in the service of his country. His sterling integrity inspired respect in all his colleagues and students. The council desire to convey to his relatives their profound sympathy with them in their loss."

The following appointments have been made:—Mr. F. Fairbrother, to be lecturer in chemistry; Dr. D. S. Sutherland, to be clinical lecturer in infectious diseases; and Dr. R. Marsden, to be hon. clinical lecturer in tuberculosis.

Mr. W. H. Allen, past-vice-president of the Institution of Mechanical Engineers, has presented to the Institution the sum of 1000*l*., and has desired the council to select a suitable student or graduate to receive this grant, in three annual instalments, at Trinity College, Cambridge. Applicants should preferably be between 20 and 25 years of age, and must be able to satisfy the council that they possess such educational qualifications as will ensure that they would derive the maximum possible benefit from an honours course in engineering (Mechanical Science Tripos) at Cambridge. Preference will be given to an applicant who has had some practical workshop training. Applicants must be prepared to go into residence at Cambridge in October 1923. Applications should be made on a form to be obtained from the secretary of the Institution, and must be returned not later than May 1.

The Ministry of Agriculture and Fisheries announces that a number of scholarships under the scheme approved last year for establishing scholarships and maintenance grants for the sons and daughters of agricultural workmen and others are offered for award for the session commencing in October next. The scholarships are provided out of the special fund for agricultural development voted by Parliament under the Corn Production Acts (Repeal) Act, 1921. They are of three kinds: Class I. scholarships, tenable for three years at Oxford, Cambridge, or other Universities, enabling students to attend degree courses in agriculture; Class II. scholarships, tenable for two years, at certain university departments of agriculture and agricultural colleges; and Class III. scholarships, tenable for one year at farm institutes and similar institutions. Candidates for Class I. and Class II. scholarships must be at least 17 years of age on June 30, 1923, and must satisfy the selection committee that they have reached a sufficiently high standard of education to derive educational benefit from the courses of instruction. For Class III. scholarships candidates will be required to furnish evidence of their acquaintance with practical agriculture, and they must be at least 16 years of age on June 30, 1923. Applications should be lodged with the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1, not later than May 14.

Societies and Academies.

LONDON.

Royal Society, March 22.—L. T. **Hogben** and F. R. **Winton**: The pigmentary effector system. III.—Colour response in the hypophysectomised frog. After complete removal of the pituitary gland, the melanophores remain permanently contracted, even when the frogs are exposed to conditions which are optimum for darkening of the skin; they can be made to expand by pituitary extract, but the animals regain pallor under conditions which invariably produce darkening in the normal or partially hypophysectomised (anterior lobe alone) frog. The minimum dose of pituitary extract for melanophore expansion was compared in normal and pituitaryless frogs. The experiments provide evidence that: (1) the rhythm of colour change in normal life is correlated with fluctuating amounts of pituitary secretion, and (2) direct nervous influences do not play a significant rôle in co-ordinating pigmentary responses in Amphibia.—H. R. **Hewer**: Studies on amphibian colour change. The presence of "frayed" ends to processes and isolated granules and irregular edges to the concentrated mass of granules precludes any theories postulating amœboid movement of cell processes. This is supported by (1) irregular movements of the granules; (2) slight massing of granules towards tips of processes in dispersed phase; and (3) stained sections of skin. Adult *Rana temporaria* respond, similarly to other Amphibia, to factors of normal environment. Dryness and light background cause concentration; moisture and dark background dispersion. Low temperature causes dispersion and medium temperature concentration. Higher temperatures appear to have an intermediate effect. Neither nitrogen nor hydrogen produced any effect during three hours; carbon dioxide did not affect colour before proving toxic; oxygen produced concentration in melanophores; chlorine changes melanin granules to a red colour.—J. **Walton**: On Rhexoxylon, Bancroft: a Triassic genus of plants exhibiting a liane-type of vascular organisation. The genus Rhexoxylon was instituted in 1913 for a fossil stem from South Africa. The evidence given by certain structural details was in favour of attributing it to the Palæozoic group of polystelic arborescent plants, the Medulloseæ. The study of additional specimens from South Africa shows that the organisation of the vascular system resembles very closely that of certain modern South American Lianes, especially in the anomalous methods of secondary thickening of the axis. Histologically, the secondary wood of Rhexoxylon resembles that of the group Dadoxyla, characteristic of the southern botanical province during the latter part of the Palæozoic era. Possibly Rhexoxylon, as a specialised ecological type, bore much the same relation to the gymnospermic Dadoxylon stock as the modern Liane bears to the angiospermic group at the present day, and the occurrence of an anomalous type of vascular system in the modern Liane is an example of a repetition, in a distinct phylum, of a specialised organisation evolved in Palæozoic times. The fossil stem *Antarcticoxylon priestleyi* Seward, from South Victoria Land, Antarctica, has some of these peculiarities, and its occurrence in the Beacon Sandstone Series of Antarctica points to a probably close relationship between portions of this series and the Stormberg Series of South Africa, from which came the majority of specimens of Rhexoxylon.—G. **Hewett**: The Dusuns of British North Borneo. The Dusuns themselves claim descent from the Chinese who settled in North Borneo. The general political conditions in Asia during the thirteenth century led to the invasion of North Borneo by Kublai Khan. The Bruni tribute was transferred from Majapahit to China, and the Chinese acquired the throne of Bruni. The Bruni government based its claim to the whole territory of North Borneo on the marriage of Sultan Akhmed to the Chinese daughter of Ong Shin Ping, who was in all probability the occupant of the Bruni throne at the time. The Chinese occupation and development probably lasted some four hundred years.—M. **Tribe**: The development of the hepatic venous system and the postcaval vein in the Marsupialia. The development of the hepatic veins is subject to variation. Two venous rings of vitelline origin are transformed into a spiral vessel encircling the gut. In most genera the left allantoic vein becomes the more important and in some genera it anastomoses with the spiral vessel. The mesenteric vein is probably derived, in part, from the caudal venous ring. The postcaval is derived from three sources. The postrenal section takes origin from the paired supracardinal plexus, the renal section from the subcardinal veins, the hepatic and prehepatic sections from the vitelline veins. The azygos and lumbar veins, and the suprarenal sinusoids, are derived from the supracardinal plexus. The left suprarenal vein is the persistent left subcardinal vein.—J. **Gray**: The mechanism of ciliary movement. III.—The effect of temperature. Between 0° and 33° C. the speed of the cilia on the gills of Mytilus increases with a rise in temperature, although the amplitude remains normal. Between 34° and 40° C. there is a marked falling off in the amplitude of the beat, followed by a reduction in speed. At 40° C. the cilia come to rest in the relaxed position. At 45° C. the cilia occupy the contracted position. The temperature coefficient of movement between 0° and 32·5° C. varies from 3·1-1·92. High temperatures have a destructive effect on individual cells of the epithelium. In well aerated tissue the oxygen consumption is directly proportional to the speed of the beat between 0°-30° C. At about 30° C. the initial oxygen consumption is not maintained, due to the disintegrative effect of the temperature on the epithelium. The effect of temperature on the activity of cilia is closely parallel to its effect on cardiac muscle.—E. **Ponder**: The inhibitory effect of blood serum on hæmolysis. The hæmolytic action of saponin is inhibited by the proteins of serum, and also, to a lesser extent, by the cholesterol. The action of the bile salts is inhibited by the proteins, and by the lecithin of the serum. The inhibitory power is fairly constant in man and animals, is altered by drying the serum, and is affected by bacterial action. A quantitative study of the inhibition produced by serum shows inhibition is probably due to the formation of a loose compound between the proteins of the serum and the hæmolytic agent. The inhibitory effect of hæmoglobin on hæmolysis produced by saponin and bile salts is considered. Probably the reaction which takes place between saponin or bile salts and red cells is a chemical one of the first order.

Royal Anthropological Institute, March 13.—Mr. H. J. E. Peake in the chair.—Miss M. Edith **Durham**: "Bird Men" and kindred customs in the Balkans. On the western side of the Balkan peninsula a considerable part of the population still identifies itself with birds. Thus the Albanians call themselves Shkypetars, and derive the word from Shkyp, an eagle, and regard the killing of an eagle as unlucky. In Montenegro also there is a strong bird tradition. Here it is the "soko," the falcon. Officers address their men as "my falcons," and Montenegrins hail each other as falcons. In the traditional ballads of the people the falcon appears as the messenger. Between the popular hero, Marko Kralyevitch, and the falcons there exists a very great friendship. In other ballads the hero actually refuses to kill a falcon on the ground that it is kin to him, and in yet another the Tsar's daughter is with child by a "bird man," who is a falcon by day and who dies when his wings are taken from him, killed by the jealous Vilas who, in their turn, fly about in the guise of swans. The falcon and the swans dwell on the mountains where the sun rises, and magic lights herald their coming and going. The tale is obviously the remains of some ancient beliefs about the sun and the birds and recalls the quaint bronze bird chariots of the sun, found at Glasinatz in Bosnia. Ballads also describe warriors of the Middle Ages dressing themselves up with eagle's tails and wings, and a print from a book on Turkey by Nicholas de Nicolay (1568) shows such a warrior. Plume-wearing is extinct, but in the Eagle dance of the Montenegrin he leaps high off the ground, flaps his arms, and yells.

Paris.

Academy of Sciences, February 26.—M. Albin Haller in the chair.—The president announced the death of E. Ariès, corresponding member for the section of mechanics.—André **Blondel**: The calculation of the forced oscillations of an electrogenic group (or of an analogous apparatus) turning with a constant mean velocity, but submitted to periodic variations of the motor couple at the same time as an elastic resisting force variable with the angle of deviation.—M. Louis Gentil was elected a member of the section of geography and navigation in succession to the late M. L. Favé.—Boris **Delaunay**: The geometrical interpretation of the generalisation of the algorithm of continued fractions given by Voronoï.—Maurice **Lecat**: Expression of the most general determinants of a matrix as a function of the sections.—C. E. **Traynard**: Surfaces of the fourth degree with fifteen double points and singular Abelian functions.—René **Lagrange**: Varieties with zero total torsion in Euclidian space.—Stanislas **Millot**: A criterion of the probable value of certain experiments.—J. **Grialou**: The rotational, but permanent, movement of liquids possessing viscosity, when the trajectories are plane and vertical.—C. **Flammarion**: The increase of brightness of the star β Ceti. A sudden increase in the brightness of this star was notified on February 13 by Mr. Abbott from Athens. This has been confirmed by observations at Juvisy by the author.—Emile **Belot**: The collective and discontinuous evolution of stars and nebulæ.—M. **Holweck**: The optical properties of X-rays of great wave-length. Experimental evidence has been obtained of the diffraction of X-rays of a minimum wave-length $\lambda = 47$ Å (effective wave-length $\lambda = 60$ Å approx.). Evidence of the reflection of X-rays by a polished bronze surface is also given.—G. **Laville**: The propagation of electromagnetic waves, maintained along two parallel wires. The theories of Kirchhoff and Lord Kelvin appear to explain the phenomena of propagation as exactly as the more complicated theories of Sommerfeld and M. Mie.—V. **Ylöstalo**: The measurement of high-frequency coefficients of self-induction.—H. **Copaux** and Ch. **Philips**: The heat of oxidation of glucinum. A correction of an earlier result; the new figure is 131·3 calories in place of 151·5 calories.—Paul **Riou**: The velocity of absorption of carbon dioxide by ammoniacal solutions. Curves are given showing the influence of additions of ammonium chloride, sodium bicarbonate, and sodium chloride to the solution, and of changes of temperature.—L. J. **Simon**: The action of methyl sulphate and of potassium methyl sulphate on monobasic organic acids in the absence of water. The interaction of anhydrous organic acids with these substances in certain cases may be used with advantage for the preparation of methyl esters.—A. **Roche** and V. **Thomas**: Researches on picryl sulphide. Study of the binary mixture: tolite-picryl sulphide. This explosive was extracted from German bombs: it is very stable and stands a compression of 500 kilograms per square centimetre without losing its property of detonating.—Raymond **Delaby**: The preparation of some ethers and glycidic derivatives of alkyl glycerols.—Y. **Milon**: The fauna and age of the carboniferous limestone of Saint-Segal (Finistère).—Jean **Piveteau**: The morphology of the scapular arc of the Permian reptiles of Madagascar.—Methodi **Popoff**: The respiratory system of plants. According to the generally accepted view the respiration of plants is confined to the leaves. This view leads to difficulties, and it is suggested that plants have a respiratory system presenting analogies, from the physiological point of view, with the respiratory system of animals.—Marcel **Mirande**: The proteolipoid nature of the sterinoplasts of the white lily. By the application of various microchemical tests the central body of the sterinoplasts has been proved to be of a lipoid nature, covered with a thin external layer of proteid material.—P. **Delauney**: New researches relating to the presence of loroglossin in native orchids. Loroglossin has been isolated, up to the present, from 17 species of native orchids belonging to five different genera.—Paul **Becquerel**: Observations on the necrobiosis of plant protoplasm with the aid of a new reagent. The reagent consists of methylene blue (2 parts), Bismarck brown (1 part), and neutral red (1 part) in aqueous solution ($\frac{1}{10000}$). The death of the cell is accompanied by definite colour changes in the parts stained by this reagent.—G. L. **Funke**: Biological researches on plants with creeping stems.—Marc **Fouassier**: The influence of copper on the lactic fermentation. The minute traces of copper dissolved by milk in contact with that metal have a distinctly retarding influence on the growth of the lactic organism.—A. **Desgrez** and J. **Meunier**: The mineral elements of the blood.—L. **Cuénot**, R. **Lienhart**, and M. **Mutel**: Experiments showing the non-heredity of an acquired character.—Ed. **Lesné** and M. **Vaglianos**: The utilisation by the organism of the C vitamins introduced through the parents. From experiments on rabbits the authors conclude that it does not matter whether the C vitamins are introduced by ingestion or by injection, the beneficial effect is the same in either case.—A. **Pézard**, Knud **Sand**, and F. **Caridroit**: The experimental production of bipartite gynandromorphism in birds.

March 5.—M. Albin Haller in the chair.—G. **Urbain** and A. **Dauvillier**: The coexistence of celtium (element 72) and the yttria earths. The view of Coster and Hevesy regarding the improbability of element 72 being associated with the rare trivalent earths is said to be negatived not only by the work of the authors but also by the discovery of this element by Goldschmidt and Thomassen in malakon and in alvite.—Charles **Moureu** and Charles **Dufraisse**: Auto-oxidation: attempt to explain the mechanism of anti-oxygenisers.—André **Blondel**: Elementary calculations of the couples damping alternators with a forced regime in the theory of two reactions, when the resistances of the armature are neglected.—C. de la Vallée **Poussin**: Quasi-analytical functions with real variables.—Ph. **Glangeaud**: The earthquake of October 12, 1922, in the Creuse and the Limousin, and some earthquakes in the north-west of the Central Massif. A map of the district over which the shocks were felt is given, showing also the lines of the faults in the geological strata. These earthquakes in the Central Massif are due to slipping along the old lines of the faults.—M. Gabriel Bertrand was elected a member of the section of chemistry in the place of the late H. Georges Lemoine. —Georges **Darmois**: The local integration of the equations of Einstein.—F. **Defourneaux**: A category of polynomials analogous with electrospherical polynomials.—N. **Abramesco**: The auto-generation of curves.—Henri **Milloux**: The growth of integral functions of finite order and their exceptional values in the angles.—Kyrille **Popoff**: The pendulum of variable length.—J. **Haag**: The interior problem of Schwarzschild, in the case of a heterogeneous sphere. —B. **Salomon**: The gryoscopic analogies of synchronous and asynchronous electrical machines and the transposition into mechanics of certain diagrams of electrotechnics.—MM. **Huguenard, Magnan**, and A. **Planiol**: An apparatus giving the instantaneous direction of the wind. This is a modified compensated hot-wire anemometer. By using this and the compensated hot-wire instrument for measuring wind velocity, both the instantaneous direction and velocity of the wind can be recorded on the same chart. Examples of such records are reproduced, and their bearing on problems of flight without motors indicated.—Jean **Chazy**: A correction derived from the theory of relativity to the Newtonian time of revolution of the planets.—J. Ph. **Lagrula**: Test of the rapidity realisable in equatorial measurements of small planets with a telescope provided with a photo-visual comparator and some additional accessories.—J. **Guillaume**: Observations of the sun made at the Lyons Observatory during the fourth quarter of 1922. The results of the observations taken on 61 days during this quarter are summarised in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Henri **Bêghin** and Paul **Monfraix**: A new gyrostatic compass. This instrument, composed of a system of three gyrostats, has been specially designed to neutralise the deviations produced by the motion of the ship.—F. W. **Klingstedt**: The ultra-violet absorption spectra of the cresols.—A. **Dauvillier**: The high frequency spectrum of celtium. Reply to a criticism by D. Coster and G. Hevesy.—André **Charriou**: The removal of acids from solution by precipitates of alumina. A study of the removal of chromic acid by aluminium hydroxide, and of the means of purifying the precipitate by washing with suitable reagents.—R. **Locquin** and **Sung Wouseng**: The preparation of various pinacones by the action of alkyl magnesium compounds on some α-hydroxy-methyl ketones. Details of a generally applicable method for preparing bitertiary α-glycols of the type $RR'C(OH)—C(OH)R''(CH_3)$.—Pauline **Ramart**: A molecular transposition in the pseudo-butyl-diphenylcarbinol series. A study of the compounds produced by the action of acetic anhydride and acetyl chloride upon the alcohol $(C_6H_5)_2 . C(OH) . C(CH_3)_3$.—Emile **André**: The separation of methyl oleate and methyl linoleate by fractional distillation. The separation is difficult, owing to the tendency of the linoleate to form polymers.—A. **Mailhe**: The decomposition of the aryl formamides. A new method of preparation of substituted ureas. The vapours of formanilide passed over finely divided nickel at 400°-410° C. give some aniline and diphenylurea. The formotoluides behave similarly.—Henri **Longchambon**: The study of the spectrum of the triboluminescence of some substances. Crystals of tartaric acid when broken give a band spectrum of nitrogen similar to that obtained from sugar. Crystals of cadmium sulphate, uranium nitrate, and fluor spar also show nitrogen bands. The light from the uranium salt, which has a colour differing from the other, shows the four green fluorescence bands of uranium nitrate.—E. **Schnæbelé**: The granites of the Champ du Feu (Vosges).—Léon **Bertrand** and Antonin **Lanquine**: The co-ordination and origin of the Pyrenees-Provençal structural units in the south-west of the Maritime Alps.—Pierre **Bonnet**: The tectonic relations of the gneiss and coal measures in the northern Morvan.—Henry **Joly**: The constitution of the Jurassic at Torrelapaja and Bordejo (Celtiberic chain, provinces of Saragossa and Soria, Spain).—E. **Bénévent**: The mistral on the coast of Nice. The freedom of Nice from the mistral is not due to its sheltered position, but to its situation with respect to the trajectories of the barometric minima.—Joseph **Lévine**: Triatomic hydrogen and meteorological depressions.—J. **Beauverie**: Influence of the rainfall during the "critical period" of wheat on the yield. Provided the rainfall during the "critical period" is below a certain amount, the yield of wheat is roughly proportional to the rainfall. —A. A. **Mendes-Corrêa**: The proportions of the limbs in Portuguese. The Portuguese, from the point of view of the proportions of their limbs, are of a clearly European type.—Henri **Piéron**: The propagation of luminous stimulation of the retina to the cerebral outer layers.—Marc **Romieu**: The histological study of the testicle of *Orthagoriscus mola*.—R. **Hovasse** and G. **Teissier**: Peridinians and Zooxanthelles.—C. **Levaditi** and S. **Nicolau**: The filtration of neurotropic ultravirus through collodion membranes. The virus of rabies, encephalitis, herpes, and neurovaccine can be filtered under pressure through collodion membranes. The filtrates vary in toxic power; not only from one membrane to another, but also according to the nature of the virus.

Official Publications Received.

Report of the Commissioner of Education for the Year ended June 30, 1922. Pp. iii+32. (Washington: Government Printing Office.)

Report of the Marlborough College Natural History Society (founded April 9th, 1864) for the Year ending Christmas, 1922. (No. 71.) Pp. 72+3 plates. (Marlborough.)

Forest Bulletin No. 51: An Investigation of certain Factors concerning the Resin-tapping Industry in *Pinus longifolia*. By H. G. Champion. Pp. 20. (Calcutta: Government Printing Office.) 8 annas.

Carnegie Institution of Washington. Annual Report of the Director of the Department of Terrestrial Magnetism. (Extracted from Year Book No. 21 for the Year 1922.) Pp. 266-309. (Washington.)

Diary of Societies.

WEDNESDAY, April 4.

Society of Public Analysts and other Analytical Chemists (at Chemical Society), at 8.—Dr. S. White: Physiological Standardisation.—B. S. Evans: An Investigation into the Chemistry of the Reinsch Test for Arsenic and Antimony, and its Extension to Bismuth.—Dr. G. W. Monier-Williams: The Estimation of Boric Acid in "Liquid Eggs" and other Foodstuffs.

Entomological Society of London, at 8.

FRIDAY, April 6.

Royal Society of Arts (Indian Section), at 4.—G. R. Clarke: Postal and Telegraph Work in India.

Philological Society (at University College), at 5.30.—Prof. W. A. Craigie: Dictionary Prospects.

Institute of Marine Engineers, Inc., at 6.—Annual Meeting.

SATURDAY, April 7.

Gilbert White Fellowship (Annual General Meeting) (at 6 Queen Square, W.C.1), at 2.—Sir David Prain: Presidential Address.

Problems of Tuberculosis.

IN the *Empire Review* for March Dr. Leonard Williams brings forward the perennial theme of the Spahlinger treatment of tuberculosis. This "treatment" has been the subject of extravagant and repeated press notices since 1914, and when it is shorn of its decorations, what does it amount to? Merely that M. H. Spahlinger has made, or his friends have made for him, a number of categoric statements, unsupported by proofs of the kind demanded in scientific work, that he can cure tuberculosis in man and animals. In a relatively small number of cases of consumption, clinicians have stated that the disease was arrested. Dr. Leonard Williams, an ardent supporter of M. Spahlinger, cites the communication of the latter to what he calls the "high-browed Paris Academy of Sciences." This communication (1921, t. 172, p. 494) occupies exactly one page and four lines, and is a reiteration of former statements without any evidence whatsoever that they are correct or of essential scientific value.

Dr. Leonard Williams also quotes April 28, 1914, as memorable in the history of tuberculosis, for on that day Prof. Letulle presented to the French Academy of Medicine a communication entitled "Traitement de la tubérculose par la méthode Henri Spahlinger." In the *Bull. de l'Acad. de Méd.* (1914. 3. s. t. 71, p. 610) we find that the communication occupies exactly eighteen lines, and was a preliminary note addressed to the Academy by Dr. E. Lardy of Geneva and Drs. Colbeck and Leonard Williams of London. Prof. Letulle was charged to examine the note, but up to date we have been unable to find any further reference to the matter in the Bulletin, although Dr. Leonard Williams tells us that "the text of the communication was duly published and rapidly found its way into the lay press." It would be interesting to know where the full communication may be found.

M. Spahlinger's treatment is stated to be both antigenic and antitoxic, and he claims to have produced many different tuberculous toxins by a method not published. The process is a long one, and the cost of production we are told is high, involving prolonged treatment of large numbers of cattle. The only other tuberculous problem referred to by Dr. Leonard Williams is really a panegyric on the work of Calmette. We are told that the "campaign against tuberculosis will never make any serious headway until the disease is attacked at the source. That source is the tuberculous cow." This may be Dr. Leonard Williams' opinion, but it is entirely opposed to the conclusions reached by the arduous experimental efforts of a generation of accurate workers.

W. B.

Archæological History.

(1) *Die Franken und Westgoten in der Völkerwanderungszeit.* By Nils Åberg. (Arbeten utgifna med understöd af Vilhelm Ekmans Universitetsfond, Uppsala, 28.) Pp. viii + 282 + 9 kartes. (Uppsala: A.-B. Akademiska Bokhandeln; Leipzig: Otto Harrassowitz; Paris: Libr. Honoré Champion, 1922.) 15 Kr.

(2) *The Bronze Age and the Celtic World.* By Harold Peake. Pp. 201 + 14 plates. (London: Benn Bros., Ltd., 1922.) 42*s.* net.

ARCHÆOLOGICAL method has made three principal advances hitherto. Early attempts to explain similarities and diversities of form and style in human handiwork were put on a scientific basis in Germany by Klemm (whose "Allgemeine Kulturgeschichte der Menschheit" appeared in 1843) and were re-interpreted on Darwinian lines by Pitt Rivers's "Principles of Classification" published in 1874; Kapp's "Grundlinien einer Philosophie der Technik," Semper's "Der Stil," and Hoernes' "Urgeschichte der Kunst" marking later refinements of this morphological criticism. Stratigraphical corroboration of evolutionary sequences thus indicated begins with examination of the Swiss lake-dwellings by Keller, Troyon, and others, the word *Kulturschicht* first appearing in an excavation report of 1855. The spade-work of Ramsauer at Hallstatt from 1862, of Warren and Wilson at Jerusalem from 1867, and of Schliemann at Troy from 1871, are notable early dissections of long-inhabited ground; and the developed technique of this kind of stratigraphy may be studied in Petrie's "Methods and Aims in Archæology."

The two books now under review approach archæological problems from yet another point of view. Even casual finds are at all events found *somewhere*. They can be plotted on a map; and when these plottings are sufficiently numerous, and their geographical distribution begins to be apparent, regions of occupation by this or that phase of culture may be defined, and the spread or shrinkage may be inferred of the people who practised each kind of handiwork which the finds reveal, and felt the needs which the craftsmen of each generation were there to satisfy. Thus, as Rostovtseff says of his own study of "Iranians and Greeks in South Russia" (Oxford, 1922), "we are gradually learning how to write history with the help of archæology." The method is precisely that of the staff-officer who establishes an enemy's order of battle from cap-badges and scraps of local newspaper, and estimates its artillery value from the splinters of his shells; and the value of archæological training was demonstrated on every front in the recent war.

Obviously this kind of antiquarian geography has had to wait until the finds themselves were sufficiently numerous; until they had been sufficiently announced, in museum catalogues and publications in detail; still more, until geographers (and, let us add, geologists) had accustomed their archæological colleagues to regard their proper "fossils" from the new point of view, looking not only "to the hole of the pit whence they were digged" but also "to the rock whence they were hewn."

(1) Dr. Åberg's work on the stone age culture of northern Europe, and on the first age of metal in the Iberian peninsula, is sufficient guarantee for scientific scholarship of the first order; his book on "East Prussia in the Migration Period" is an original contribution to one of the darkest phases of European history; and his present monograph on the "Franks and Visigoths in the Migration Period" is of the same fine quality. Naturally, his treatment of the material varies. Visigothic handiwork must be won by travel and research in local museums and private collections, and we are here still among the pioneers. But Frankish antiquities have been copiously published and studied, and the casual finds have been supplemented by systematic investigation of whole burial grounds, so that "sequence-dating" supplements the comparison and affiliation of types, and facilitates interpretation of regional surveys. As most of the work has been done hitherto by French archæologists, and from the point of view of the invaded regions, the principal need was now to look at the whole matter from the other side. As Rostovtseff puts it, in a parallel case, "I do not regard South Russia as one of the provinces of the Greek world . . ." but "as always an Oriental land," so Dr. Åberg might say that he does not regard the Franks as one of the peoples who intruded upon Gallo-Roman civilisation, but as always a Teutonic people. The result is an interpretation not only of the Frankish finds of the west, but also of all the congruous material east of the Rhine, north of the Alps, and so far afield as Hungary and Scandinavia, and also in Lombardy and beyond, as contributions to the narrative of a progressive Frankification (so to speak) of indigenous Teutonic culture through the instrumentality of those peoples of Teuton origin who had most completely appropriated the west-land civilisation which they mastered politically.

Thus, in a sense which will be a revelation to many, *Gallia victa victorum cepit*: or as Dr. Åberg puts it (p. 15), "the Franks in Gaul were influenced indeed, like the Goths in Italy, by Roman culture, but in contrast with them, they retained their power in spite of their loss of Teutonic quality, thanks to the maintenance of intercourse along the lines of communication with the heart of Germany. Consequently there was no gulf here between Germanic and Roman, but a gradual transition. Roman organisation pressed slowly eastward. . . . The focus of development, which in Merovingian times had been mainly Gaul, shifted over in Carolingian times on to German soil. Here came about the last amalgamation of Roman and Germanic which is the foundation of modern Europe. Only Scandinavia still stayed long outside this development, as a last remnant of ancient Germany, and a wound in the side of Europe which was hard to heal."

For the stages of this revolution in social and political structure Dr. Åberg offers us as testimony not edicts or charters, nor a *cursus honorum* such as has revealed the spirit and the structure of imperial Rome, but the mute eloquence of hundreds of brooches and buckles, of ingenious design, intricate ornamentation, and accurately plotted distribution. His inventory of type-specimens occupies 42 pages, and his nine maps of the principal phases which he has been able to distinguish are models of this kind of interpretation. His first two chapters, occupying only forty pages, trace the outlines of the whole inquiry, and summarise the course of events before the opening of the fifth century, at which his proper study begins. These and the subsequent later review of Merovingian influence east of the Rhine are what will chiefly interest the historian; the remainder of the book, with its ample and well-executed illustrations, concerns rather the student of design and of the transference of decorative motives from one repertoire to another.

The account of the Visigothic occupation of Spain and Portugal (pp. 206-240) is more tentative, because (as already noted) the material is scanty and inaccessible, and, to judge from the specimens which are figured here, less instructive as to the movements of Germanic peoples in this region. Provisionally, Dr. Åberg groups all Germanic antiquities from this area as "Gothic," reserving till a later stage the possibility of assigning some types to particular peoples.

A word should be added to congratulate the Vilhelm Ekmans Fund at Uppsala on having produced so learned, valuable, and well-appointed a volume at the rate of less than three farthings per page.

(2) Mr. Peake's book is of a different quality. Spaciously printed, and well bound—and we must add, more than adequately priced at 2½d. per page—it is little more than a reprint of a course of six University lectures, with acknowledgments of the principal sources of printed information, the bare minimum of outline diagrams, and far less than the due minimum of distribution maps. The author disarms criticism when he declares his purpose to be "not so much to record evidence as to interpret it, to restore the main features of early history than to describe archæological remains." It is, in fact, an essay rather than a formal treatise. It covers very wide ground, from a preliminary survey of the pre-Celtic continent—Nordic, Alpine, and mixed Mediterranean stocks, partially brought into economic relations by slow breach of natural barriers, especially forest and mountain, and by the pervasive wiles of the "prospectors"—to the problem of the replacement of bronze by iron for cutting-weapons, and the superposition of "P-Celts" upon "Q-Celts" and of other P's upon other Q's.

To be proficient at all points of such a programme would be a giant's task. Mr. Peake has read widely (though scarcely widely enough) and has thought independently and boldly; and his book is always readable and intelligible. Frequently his suggestions carry conviction; his mistakes are mostly of omission; and his summaries even of the most controversial matters are discreet and fair. Obsolete learning he is for the most part content to leave on one side, and where he feels obliged to review the course of inquiry, as in the chapter on the "Aryan Home," he knows how to select main turning-points, and distinguish the permanently suggestive idea from the transitory prejudices which advertised or obscured it at its inception.

The problem which Mr. Peake has set before himself is to compare the archæological evidence for reputed movements of peoples within peninsular Europe, from the end of the third thousand years B.C. to the beginning of the first, with the philological conclusions on the same subject derived from the relationships and distributions of languages. His conclusion, briefly stated, is that the distribution over Europe and its neighbourhood, of the series of types of so-called "leaf-shaped swords" of bronze, is such as to indicate successive eruptions of peoples armed with these swords, from the Hungarian plain into various adjacent regions and beyond them. Also that the disappearance of the later types of the series from Hungary itself and from surrounding districts may be so closely associated with the distribution of other swords, similar but derivative and made of iron, as to justify the inference that it was the aggression of the men of the iron swords that determined the retreat or disappearance of the users of "leaf-shaped" bronze blades. Lucky finds of typical swords in datable surroundings, and especially the discovery in Egypt of a sword of European type, about half-way down the morphological series, engraved with the name of King Seti II., who reigned only from 1209 to 1204 B.C., enable him to reckon the probable duration of the whole series of events, and to institute a very suggestive comparison of them with the movements of the two main groups of Celtic-speaking peoples, from much the same area of origin around the middle Danube, into Western Europe and Britain, and of similar waves of "P-using" and "Q-using" immigrants into peninsular Italy, and probably also into Greece; though Mr. Peake is discreetly reserved in his treatment of these last.

Much of Mr. Peake's material is, of course, familiar; it is his courageous attempt to compare disparate series, and draw historical conclusions, which justifies his book; and it will be found full of suggestive passages, even by those who will best appreciate the difficulties of his task and the defects of his equipment for it. It is eminently a book to be judged by its merits, not by its faults. It has omissions, but its main argument is clear and generally coherent; it has slips and some misapprehensions in detail, but they do not seriously detract from its cogency. Its central contribution to learning, the establishment of a morphological sequence among the "leaf-shaped swords" by comparative study, not of their blades but of their hilts, is of considerable importance. This is a kind of work of which much more remains to be done: a similar essay on the fibulæ alone would probably lead to appreciable revision of the conclusions of Montelius and his contemporaries a generation ago, and would be the only conclusive test of the validity of Mr. Peake's inferences. It must also be noted here that even what has been attempted in this essay is but the first-fruits of the great inventory of the types of prehistoric implements, so long overdue, of which only the British section of the bronze implements has been systematically attempted as yet, by Mr. Peake himself and a British Association committee. Till such an inventory has been very greatly extended, and the distributions which it alone can reveal have been plotted and compared, prehistoric archæology can scarcely be said to have entered upon a truly scientific phase. It is one of the merits of any piece of work such as this essay, that it illustrates by example, even if also in some degree by anticipation, the value of such an addition to archæological equipment as the British Association's inventory is already proving itself to be.

Gelatin and Glue.

The Chemistry and Technology of Gelatin and Glue. By Dr. R. H. Bogue. (Mellon Institute Technochemical Series.) Pp. xi+644. (New York and London: McGraw-Hill Book Co., Inc., 1922.) 30*s*.

ANYONE who, in recent years, has had occasion to deal with the question of gelatin has been confronted at the outset with the fact that no adequate summary of the existing knowledge was available. An immense amount of information was widely scattered in the various scientific and technical journals of all countries, but it was so varied in character, and very often so contradictory, that the task of making a summary which was something other than a mass of apparently disconnected facts seemed almost hopeless. The pioneering work of Procter in England, which dealt chiefly with gelatin, and of Pauli in Austria, which was concerned with proteins in general, gave the first indication of the basis on which such a summary could be made; but the more recent work of Loeb in America has perhaps helped more than anything else towards a clarification of ideas. The work of Brailsford Robertson should also be mentioned, since he has collected a large amount of experimental data, although his theoretical conclusions are accepted by few.

The clarification of ideas has been chiefly confined to the physico-chemical treatment of the subject. The more purely chemical aspect of the question has not advanced much beyond the identification of the break-down products of gelatin, and the more or less satisfactory methods of estimating the percentages of the various kinds of combined nitrogen.

During the last few years American scientific journals especially have obtained a large number of papers on gelatin, which have been published by workers other than Loeb. Among the chief of these workers has been Dr. Bogue, and it is therefore not to be wondered at that, of three books on gelatin which have been announced in the American press for some time past, his is the first to be published. Dr. Bogue is research chemist for Armour and Company of Chicago—would that English gelatin firms were as wide awake in this respect as the American ones!—and is consequently in touch with the technological as well as with the more purely theoretical side of the subject. His book has therefore been awaited with interest by those who have to deal with gelatin, and they will not be disappointed, since the author has been eminently successful in correlating and summarising the enormous amount of material at his disposal, and in giving a clear and readable account of the subject. After an introduction dealing with historical and statistical considerations, the theoretical aspects of the subject are considered. These include the constitution of the proteins, the chemistry of gelatin and its congeners, the physico-chemical properties and structure of gelatin, gelatin as a lyophile and as an amphoteric colloid.

The author seems to have contented himself with giving only such literature references as are necessary for drawing up a connected account of the subject.

This was probably a wise course to adopt, since otherwise the book would have become very unwieldy, but it has meant that a number of important papers published in German journals are not mentioned. For example, Dr. Bogue is a great advocate of the fibrillar structure of gels, but no mention is made of similar views put forward by Moeller in a number of different papers in the *Kolloid Zeitschrift*. A lucid description is given of the various physico-chemical properties of gelatins and glues and the various theories are dealt with in detail. If anything, the author has not been sufficiently critical in describing the theories of Brailsford Robertson, who assumes a peculiar kind of dissociation which appeals neither to the organic nor to the physical chemist, and against which there is a mass of evidence accumulated by Pauli, Loeb, and others. Actually, Dr. Bogue attempts to modify Robertson's theory, so as to make it more in accordance with the work of Loeb, but the modified theory is still open to most of the objections raised against the original theory.

The second part of the book deals with the technological aspects of the manufacture, testing, chemical analysis, evaluation, uses and applications of gelatin and glue. The point of view taken is that of the chemist rather than that of the plant technologist, and this makes the appeal of the book all the greater to the student and investigator. In the chapter on the uses and applications of glue there is a section on glue-room economy and technology, which may be recommended for study to all users of glue on a large scale, so that increased efficacy, based on the application of scientific principles, may be attained in their workshops.

There is also a special chapter on water-resistant glues and glues of marine origin, which should be read in conjunction with the first report of the Adhesives Research Committee. An appendix deals more especially with the electrometric and indicator methods of determining hydrion concentrations.

Generally speaking, there is little which calls for criticism, except the curious statement made on p. 221 that acetic acid is an amphoteric substance because the hydrogen of its carboxyl group may be substituted by metals and the hydroxyl by chlorine (by the use of phosphorus trichloride). A few misprints, such as "existance" and "catinary," have been noticed, and the following statement on p. 141 requires revision: "but this does not follow for a continuous membrane that was semipermeable in the sense of being able to dissolve the solvent or medium of dispersion would likewise behave as an ultra-filter." Also, why should it be necessary to write "Anfangsdekrement" instead of "initial decrement"?

T. S. P.

Flora of New Zealand.

Die Vegetation der Erde. Sammlung pflanzengeographischer Monographien. Herausgegeben von Prof. A. Engler und Prof. O. Drude. XIV. *The Vegetation of New Zealand.* By Dr. L. Cockayne. Pp. xxiii + 364 + 2 maps + 65 plates. (Leipzig: W. Engelmann; New York: G. E. Stechert and Co., 1921.)

WITH the landing of Sir Joseph Banks and Dr. Solander at Poverty Bay on October 8, 1769, our knowledge of the flora of New Zealand commenced, but unfortunately the results of the labours of these two intrepid explorers have never been published, though the plates of the new plants were prepared at Banks's expense and the descriptions were drawn up by Solander. From this time onwards various expeditions, both English and French, reached New Zealand, making small collections, the results of which were published, but Sir Joseph Hooker's first volume of his "Flora Antarctica," published in 1847, must be regarded as the first comprehensive flora of these islands. As a result of the help received from many collectors, Hooker published his "Flora Novae Zelandiae" (1853–55), which truly marked a new era in the botany of New Zealand, but still little was known of the South Island alpine flora, and it is to Travers, Haast, Hector, and Buchanan that we owe a great deal of our knowledge of the flora of this region.

Sir Joseph Hooker again contributed to our knowledge of the flora in his "Handbook of the New Zealand Flora" (1864–67), undertaken at the instance of the Government of New Zealand, and since then the task has been fittingly and very ably taken up by New Zealand botanists, among whom must especially be mentioned T. Kirk, T. F. Cheeseman, D. Petrie, and L. Cockayne, the author of the valuable work under notice. Dr. Cockayne commenced his botanical work in 1887, and has continued his explorations with great assiduity and keen insight ever since. Becoming gradually more interested in ecology, the present volume, dealing with the vegetation of New Zealand in its many aspects and in relation to the varied plant associations, could not have been entrusted to more worthy hands. Nor could the subject have been more ably treated.

In an introductory chapter the history of our knowledge of the flora is detailed and the book is then divided up into four parts. The first part, as is proper in a treatise planned on ecological lines, deals with the physical geography and climate of the three main islands and of the outlying groups, the chapter on the climate and rainfall being contributed by Mr. D. C. Bates. It is unfortunate that the maps are sadly deficient in the way of names and orographical details, both of which are essential for a proper appreciation of the work. Possibly the difficulty of publication so soon after the War, and also in Germany, may account for this blemish to a book which is remarkable in the excellence of its form and style, considering that author and publisher were at opposite sides of the world.

The second part naturally occupies the greater portion of the book, since it deals with the various formations or plant associations, and full details and excellent illustrations are given of the leading physiognomic plants and their growth forms. In the first section the sea-coast vegetation with the characteristic dune plants, salt meadow and coastal scrub, Olearia and Veronica associations, are described, and this leads to a discussion of the plant formations of the lowlands and lower hills, characterised by many peculiar endemic New Zealand plants. Among these the "Southern Beech" forests, comprised mainly of the different species of Nothofagus, are of great interest. Passing upwards through the grasslands or steppe, where the "Tussock" (Poa, Festuca, and Danthonia) associations flourish, the author naturally follows with an account of the vegetation of the high mountains. This is remarkable in that no less than 498 species of vascular plants are entirely confined to the mountains, but since many lowland plants are also found at high elevations, the alpine flora is found to number 945 species. Of these no less than 561 are endemic.

In Part III. the relationships of the New Zealand flora are fully dealt with, but it may be mentioned here that of this flora about 35 species belonging to as many genera have near relatives in subantarctic South America.

The vegetation of the outlying islands is then fully dealt with on the same lines as that of the main islands, and, in the subantarctic islands, it is shown that there are some 55 endemic, 123 New Zealand, and 32 subantarctic South American plants, nine of which are not found on the main islands of New Zealand.

The fifth section of this second part deals with the effect of "settlement" upon the plant covering of New Zealand and is by no means pleasant reading. The hand of man, his introduced animals and plants, have, in New Zealand as elsewhere, wrought irreparable destruction and modifications in the primeval and singular plant covering.

In the final part, Dr. Cockayne gives a brief but useful history of the flora from the Jurassic period to the present time, and lays stress on the subantarctic affinities both of the flora and fauna of New Zealand. Whether land connexions with an antarctic continent ever existed, or chains of islands linking the southern continents provided the bridge which enabled species to migrate to what is now S. America on one hand and Tasmania on the other, must ever remain a problem. Dr. Cockayne considers that the difficulty of transoceanic transit is too great to account for the affinities, and, no doubt rightly, inclines to the problematical bridge of land or islands in the dim past. Whatever may have been the origin of this interesting primeval flora, it is very satisfactory to note that the Government of New Zealand is taking all possible steps to preserve, so far as may be possible, its unique features.

Electrical Engineering.

Standard Handbook for Electrical Engineers. Prepared by a Staff of Specialists; Editor-in-Chief: Frank F. Fowle. Fifth edition, thoroughly revised. Pp. xviii + 2137. (New York and London: McGraw-Hill Book Co. Inc., 1922.) 30*s*.

WE think that the volume under notice justifies its title as being a "standard" handbook. The general make-up and arrangement leave little to be desired. The whole field of electrical engineering is divided into twenty-five sections each complete in itself; these are all numbered and by special depressions on the edges of the pages any particular section is found at once. The index is good, the references being made to section and paragraph. The sections have all been written by well-known American engineers and physicists and have been brought carefully up to date; for example, the section on units is written by Kennelly, magnetic circuits by Karapetoff, illumination by Millar, and electric ship propulsion by Hobart.

We were momentarily surprised to learn from Prof. Kennelly that the M.T.S. (metre-ton-second) and the Q.E.S. (quadrant-eleventh-gram-second) systems had come into extensive use. This latter system, however, is only the international electromagnetic system used in electrical engineering. We were glad to see it definitely stated that the electric and magnetic constants of the ether should not be taken as pure numerics. The section on power transmission is very thorough and data are given which would be very difficult to find elsewhere. The twenty-fourth section gives the 1921 edition of the standards of the American Institute of Electrical Engineers. In connexion with the distortion of waves, we are sorry to see that they still call a certain very variable ratio the "deviation factor" of the wave. In defining the distortion of a wave it is necessary to take into account the phase differences as well as the magnitudes of the amplitudes of its harmonics. We notice also that a resistance coil, a choking coil, and an inductive coil are now called a resistor, an inductor, and a reactor.

The final section is on general engineering economics and will be of great interest to commercial engineers. It is stated that "profits" represent a return on the capital over and above the normal rate of interest. For example, if the difference between income and expenditure was 10 per cent. then assuming that 6 per cent. is the normal rate of interest on investments, the "profit" would be 4 per cent. Apparently in America there is no agreed theory of depreciation, the straight-line or simple interest method and the sinking-fund or compound interest method are both still used.

The references given include the best American and English authorities and are useful ones. We can heartily recommend the book. A. R.

Our Bookshelf.

The Yearbook of the Universities of the Empire, 1923. Edited by W. H. Dawson. (Published for the Universities Bureau of the British Empire.) Pp. xii+692. (London: G. Bell and Sons, Ltd., 1923.) 7*s.* 6*d.* net.

The latest edition of the Yearbook, revised and amplified, should be of the greatest help not only to those officially concerned in university administration, but also to all who are interested in the developments within the British Empire of higher and professional education. It is no small feat to compress within the cover of an easily handled (and well indexed) volume the essential details of the calendars of the sixty-six universities of the Empire. Mr. Dawson, who has edited the book for the Universities Bureau, has accomplished the task very creditably, and the abbreviations and other typographical devices to which he has had recourse do not in any way militate against intelligibility, and, so far as we have tested it, the information given is both accurate and adequate.

The appendices, which now run to more than 150 pages, contain some interesting information, not easily accessible elsewhere, regarding admission to the various professions and the qualifications necessary. A section on foreign universities gives some brief but useful particulars of the principal universities on the continent and also of the universities of the United States, including a list of the institutions approved by the Association of American Universities.

Mention should also be made of the information relating to the admission to universities in the United Kingdom of persons educated abroad, to scholarships and grants for research, and to the distribution of subjects of study among British universities. Particularly interesting is a table showing the numbers of students from overseas, which suggests that the resources of this country for postgraduate and other study are now being appreciated. The total number of such students is more than 4000. At London University alone there are 81 from Egypt, 336 from South Africa, 46 from Canada, 72 from the United States, and 335 from India.

The Microscopical Examination of Foods and Drugs. By Prof. H. G. Greenish. Third edition. Pp. xx+386. (London: J. and A. Churchill, 1923.) 18*s.* net.

Prof. Greenish's volume stands alone as a modern English text-book of the subject, and it is a matter of considerable satisfaction that author and publisher combine to keep the work abreast of the times. In the new edition, the text has been carefully revised and brought up-to-date, but we are informed that the inclusion of additional matter has not been possible on account of the prevailing high costs of paper and printing. We hope that by the time a further edition is called for, a means will have been found to overcome this difficulty, if it should still exist.

The book is too well known to need detailed description, but for the benefit of new students and others we may mention that its special value lies in the fact that it furnishes detailed information regarding methods of investigation which have been developed during many years by an acknowledged expert in the subject. In work of this kind, prolonged and continuous experience is a *sine qua non* for accurate determinations, and the methods so fully and clearly set out in this handbook bear unmistakable evidence of such experience. The book is essential to all pharmacological laboratories and students, and we suggest that teachers of "pure" botany would find many hints as to methods and material which would be of assistance to them in obtaining fresh ideas for the scheme of practical work to accompany their histological lectures. If in a later edition it is decided to retain "silk" as a material for description, we suggest that space should be found for a somewhat fuller treatment of the subject, including a reference to the important results obtained by von Höhnel in his investigations of the different kinds of commercial silks.

The Analysis of Non-Ferrous Alloys. By Fred Ibbotson and Leslie Aitchison. Second edition. Pp. ix+246. (London: Longmans, Green and Co., 1922.) 12*s.* 6*d.* net.

The fact that a second edition of this text-book has been called for is evidence that it has been found useful by analysts. War experience has led to an enlargement of the field of non-ferrous alloys, and the authors have therefore added to the matter of the former edition an account of the analysis of alloys containing aluminium as their principal constituent, and also of those rich in nickel, such as cupro-nickel and nichrome. The light aluminium alloys form a particularly difficult class, and it has been found necessary to devote a special chapter to the separation of zinc and aluminium, the authors recommending the precipitation of zinc sulphide from alkaline solution or the electro-deposition of zinc. The otherwise excellent section on electrolytic analysis suggests that no cathodes other than platinum and mercury can be used successfully, but many laboratories now employ copper and nickel gauze cathodes with entire success; an important consideration when the cost of platinum is so high.

The subject of hydrogen sulphide precipitations is dealt with thoroughly, this being a matter on which it is most important to have a clear view of the conditions affecting precipitation. The newer organic reagents, such as cupferron, are not described.

The work may be thoroughly recommended to professional analysts as well as to students, the authors having a wide personal experience of the methods they describe, their views on the best methods of analysing difficult alloys being particularly valuable.

La Radiotéléphonie. Par Carlo Toché. Pp. vi+98. (Paris: Gauthier-Villars et Cie, 1922.) 10 francs.

The book under notice gives an interesting general description of the best and most modern methods of radiotelephony. It presupposes on the part of the reader an elementary knowledge of the subject and a general knowledge of science. It begins by describing the physiology of the voice, giving photographic records of voice vibrations obtained by Marage. It is interesting to note that oscillograms obtained of microphonic currents produced by speech are not so simple as those shown. The arc, alternator and valve methods of radiotelephony are next described, more stress being laid on the theory than on the history of the art. Due credit is assigned to the work done by the American Western Electric Co. A good discussion is given of the possibility of simultaneous communications in radiotelephony. The essential frequencies required for speech vary between 200 and 2000 per second, and the frequency of the carrier waves between 15,000 and three million per second. The author concludes that the maximum possible number of simultaneous communications is 1492. It has to be remembered that many of these waves have short wave-lengths and are therefore not suitable for long-distance transmission. For international and intercontinental systems the possible number would be much smaller. The number of possible radio-telegraphic systems with carrier waves is very much larger than the number of possible telephonic systems.

The Grammar of the Lamba Language. By C. M. Doke. (Published under the Joint Auspices of the University of the Witwatersrand, and the Council of Education, Witwatersrand.) Pp. ix+157. (London: Kegan Paul and Co., Ltd., 1922.) 6*s*. net.

It is a pleasure to extend a welcome to this scholarly study of the Lamba language, not least on the ground that it is published under the auspices of the Witwatersrand University and Council of Education, and bears witness to the official interest now taken in native studies.

The Lamba language is spoken throughout the Ndola district of North-Western Rhodesia and in the south of the Katanga, this area lying in the centre of Bantu Africa. It is claimed to be the most primitive dialect of Bantu now extant, a view to which the author inclines on the ground of its strict adherence to rule and the great simplicity of its phonetics. Numeration is based upon the quinary system. The use of onomatopœia is very prevalent, and not only can all verbs be reduced to a monosyllable root, but they also appear to have evolved from onomatopœic sounds, adjectives and nouns representing a further stage in evolution. Lamba contains a number of loan words from Portuguese (the earliest), Swahili, English, and Dutch, as well as from other Bantu dialects. The days of the week, it is interesting to note, are taken from Chinyanja.

A Manual of Practical Anatomy: A Guide to the Dissection of the Human Body. By Prof. Thomas Walmsley. In 3 parts. Part 3: The Head and Neck. Pp. viii+272. (London: Longmans, Green and Co., 1922.) 10*s*. 6*d*. net.

The third part of Professor Walmsley's "Manual of Practical Anatomy" is devoted to the dissection of the head and neck, for which a period of about ten weeks is suggested. The usual order of dissection is adopted, the various regions and organs being treated separately, but without that strict confinement to region which is so confusing to the student when dealing with a structure which appears in different portions of the dissection. The instructions for the guidance of the dissector are clearly given; the anatomical descriptions are complete and well illustrated by diagrams which the student is encouraged to label from his own specimen. The only defect in the book is that the index is not very complete. We are glad to observe that the nomenclature is in the British (Old) terminology. The book can be thoroughly recommended as a guide to the student in the dissecting-room.

Inorganic Chemistry: A Text-book for Schools. By E. J. Holmyard. Pp. x+560. (London: Edward Arnold and Co., 1922.) 6*s*. 6*d*.

Mr. Holmyard has written what is really an excellent text-book for schools. The style is clear and the arrangement on the whole good, although the very late appearance of the halogen elements is perhaps not quite fair to their great activity and their participation in the lives of the other simple bodies. The historical notices, as might have been expected, are excellent, and they and a number of portraits of famous chemists add considerably to the interest of the book. We wish this book the full success it deserves.

The Handbook of Palestine. Edited by Harry Charles Luke and Edward Keith-Roach. (Issued under the authority of the Government of Palestine.) Pp. xii+295. (London: Macmillan and Co., Ltd., 1922.) 12*s*. net.

This is mainly a handbook of general information, but there are short chapters on the geology and natural history and a note on the flora. Forestry receives more attention. Meteorology is scarcely noticed. The sections on races and on archæology are fairly full. A folding sketch-map shows roads, railways and archæological features, but no relief. The handbook should prove of value to every visitor to Palestine, but it might be given a wider and more permanent value if the historical and scientific sections were extended.

The Radio Year Book, 1923 (First Year). Pp. viii+148. (London: Sir Isaac Pitman and Sons, Ltd., 1923.) 1*s*. 6*d*. net.

It is intended to make this the Year Book of the new industry which is rapidly growing, owing to the great popular interest which is being taken in broadcasting. Section I. gives general information of use to radio amateurs. Section II. gives short and trustworthy articles on subjects of general interest in the working of radio apparatus, and Section III. gives information which will be useful to manufacturers and suppliers of the apparatus. The articles are by well-known experts, and the book should prove useful.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

On Urbain's Celtium Lines.

In a previous letter (NATURE, March 10, p. 322) we have shown that the optical spectrum of the new element hafnium, of atomic number 72, which was discovered a short time ago by Coster and Hevesy, does not contain any of the lines belonging to the characteristic spectrum ascribed by Urbain (*Comptes rendus*, t. 152, 1911, p. 141) to an element celtium belonging to the family of rare earths, which element was assumed by Dauvillier and Urbain (*Comptes rendus*, t. 174, 1922, pp. 1347 and 1349; NATURE, February 17, 1923, p. 218) to possess the atomic number 72.

Through an examination of the very careful measurements of the spectra of the rare earths published during the last few years by Eder, we have learned in the meantime that the greater part of Urbain's celtium lines have been observed by this author (*Wiener Ber.*, IIa, vol. 124, 1915) in the spectrum of a preparation of the rare earth element cassiopeium or lutetium. The discovery of this element (atomic number 71) was announced in 1905 by Auer von Welsbach, to whom the former name is due, while the name lutetium was proposed in 1907 by Urbain, who published at the same time the first list of lines of its optical spectrum (*Comptes rendus*, t. 145, 1907, p. 759).

In the table below we give the wave-lengths of the celtium lines from Urbain's paper, together with their relative intensities (by use of the numbers 2, 4, 6, and 8 instead of Urbain's notations: *moyenne*, *assez forte*, *forte*, *très forte*) and the corresponding wave-lengths and intensities from Eder's measurements of the cassiopeium spectrum, corrected to Rowland's scale.

Urbain's Ct Lines.		Cp Lines observed by Eder.		Urbain's Ct Lines.		Cp Lines observed by Eder.	
2459·4	2	2459·71	1	2885·1	4	2885·23	3
2469·3	2	..		2903·9	4	..	
2481·6	4	2481·79	2	2931·7	2	2931·56	1
2536·9	4	2537·09	2	2949·5	4	2949·82	3
2677·7	2	2677·35	1	3080·7	8	3080·22* 3081·59	4 8
2685·2	8	2685·24	3	3118·6	8	3118·56*	5
2729·1	6	2729·08	3	3171·4	6	3171·49*	5
2737·9	2	..		3197·9	8	3198·25*	8
2765·8	8	2765·88	3	3326·0	4	..	
2834·3	4	2834·37	1	3391·5	6	3391·73	4
2837·3	4	..		3665·6	2	..	
2845·2	6	2845·23	2				
2870·2	2	..					

It is important to notice the very close accordance in the values of the relative intensities in the two tables, which we think justifies the identification of the lines also in the few cases where the difference between the wave-lengths is slightly greater than is to be expected from the usual accuracy of Urbain's measurements of wave-lengths of rare earths. Only a few of these lines, denoted by an asterisk, were included in Urbain's original list of the lutetium lines.

In order to verify the origin of Eder's lines and to endeavour to find out why most of these lines were not included in Urbain's original list, we have examined the optical spectrum of a highly purified cassiopeium preparation kindly presented to this institute by Dr. Auer von Welsbach. At the same time Dr. Coster has photographed the X-ray spectrum of the same preparation and found it to contain no trace of an element with atomic number 72. Our exposures revealed in the spectral region investigated (2500-3500 Å) all the lines observed by Eder and brought certain new features to light, which made it possible to understand why these lines were not observed in the original investigation of the lutetium spectrum published by Urbain in 1907. In an exposure in which the salt was placed at the carbon anode of the arc, the celtium lines came out sharp and in about the same relative intensities as in Eder's investigations, but when the salt was placed at the cathode, most of the celtium lines were much more intense and very diffuse and broad, especially in the part of the arc nearest to the cathode. The only celtium lines which also under these conditions came out as sharp as the rest of Eder's cassiopeium lines were the four previously mentioned lines denoted in the table by an asterisk. On account of this behaviour of most of the celtium lines they will be very difficult to observe in less pure preparations. Some exposures taken with a less concentrated (10 per cent.) sample, formed by mixing Auer's preparation with a scandium salt, did in fact show only the usual lines, whereas most of the celtium lines could be detected only by the presence of an increase of the continuous background of the plate. Urbain's results are therefore easy to understand, if we assume that the preparations investigated by Urbain in 1907 contained a comparatively small amount of the element with atomic number 71, and that only after treating the preparations further a concentration was obtained sufficient for the production of the diffuse lines, which in 1911 were ascribed to the presence of a new rare earth element, which was called celtium.

As to the origin of the lines given by Urbain as celtium lines, and not present in Eder's cassiopeium spectrum, we have found in the spectrum of Auer's preparation a weak line with wave-length 2738·1 Å, which may be identified with a celtium line (2737·9 Å). The line 3326·0 occurs as a weak line in the mentioned mixture of scandium and cassiopeium, but could not be found in the spectrum of Auer's pure preparation. As Urbain states that scandium was present as an impurity in his preparations, and as the scandium spectrum is not very well known, we have also taken a strong exposure of this spectrum, but could not find any of the remaining lines. Probably these lines have the same origin as the other celtium lines, but as they are weaker they will need a very strong exposure, especially if they also are diffuse. For such strong exposures we had not sufficient material.

It is of interest to add that in a recent note (*Comptes rendus*, t. 176, 1923, p. 496), which first came to our notice after the above was written, dealing with the discovery by Coster and Hevesy of the element hafnium with atomic number 72, Urbain himself directs attention to the particular behaviour of the lines ascribed by him to celtium, and expresses the conjecture that these lines—the observation of which was the basis for his belief in the presence of a new element in his preparation—may actually constitute the spark spectrum of the element 71.

H. M. Hansen.
S. Werner.

Universitetets Institut for teoretisk Fysik,
Copenhagen, March 20.

On Celtium and Hafnium.

In our letter of February 9, which appeared in Nature of February 24, p. 252, we have shown that the element hafnium, of atomic number 72, detected by us in zirconium minerals, possesses physical and chemical properties quite different from those ascribed to a rare earth element celtium, the discovery of which was announced by Urbain in 1911, and which recently was believed by Dauvillier and Urbain also to possess the atomic number 72. In a communication of February 19 to the Paris Academy of Sciences (*Comptes rendus*, vol. 176, p. 496, 1923) Urbain discusses the same problem and still claims the identity of his celtium with our hafnium and by a claim of priority rejects the latter name. In the meantime, through the investigation of Hansen and Werner (see Nature of March 10, p. 322, and the above letter in this issue) on the optical spectrum of hafnium and on the spectrum ascribed by Urbain to celtium, new data have been brought to light, and we should therefore be glad to take the opportunity to complete our arguments as regards the questions discussed by Urbain.

To put the matter clearly we must go back to the time preceding the announcement of the discovery of celtium. As is well known, Marignac succeeded in 1878 in isolating from a mineral from Ytterby a substance which was considered to be a new element and called ytterbium. In 1905 Auer von Welsbach (*Wiener Anzeiger*, x., 1905; see also *Sitzungsberichte* 115, July 1906, and *Lieb. Ann.* 351, p. 464, 1907) announced the discovery that this substance was a mixture of two elements, for which he later proposed the names aldebaranium and cassiopeium. Detailed information with regard to the spectra of these elements and their atomic weights was first published by him in 1907 (*Wiener Sitzungsberichte*, 116, December 1907), shortly after a similar announcement had been made by Urbain (*Comptes rendus*, 145, p. 759, 1907), who was the first to publish lists of lines for the separate spectra of the two new elements, and proposed the names neo-ytterbium and lutetium. By continued purification of his preparations, Urbain observed in the following years a gradual change in the spectrum and magnetic properties and announced in 1911 (*Comptes rendus*, 152, p. 141) the detection of a further element, which was called celtium, for which a separate list of spectral lines was published.

Through the work of Hansen and Werner referred to above, it is clear, however, that the latter lines are due not to a new element but to the element which was called lutetium by Urbain and cassiopeium by Auer von Welsbach, in the spectrum of preparations of which the same lines were also observed by Eder in 1915. To this we may add that the same view is supported in a striking way by investigations on the magnetic properties of the various preparations. The circumstance that the paramagnetism of Urbain's preparations of 1911 was three or four times smaller than that of his former preparations need not be explained as due to the presence of a new element, but may be considered as a consequence of the gradual concentration of the element cassiopeium or lutetium in his preparations. Thus Stephan Meyer (*Wiener Sitzungsberichte*, 117, p. 955, 1908) in his investigations of the magnetic properties of the rare earths had already found in 1908 for the paramagnetism of a cassiopeium preparation a value almost as small as that measured in 1911 by Urbain for the preparation which was believed to contain the largest percentage of celtium.

In view of the conclusion drawn by Hansen and Werner as regards the optical spectrum, this circumstance may be taken as a proof that the original preparations of Urbain from 1907 (*Comptes rendus*, 145, p. 759) contained only a rather small fraction of the element cassiopeium or lutetium and presumably much less than the preparations of Auer von Welsbach of the same time. In this connexion it is of interest to mention that, according to the quantum theory of atomic structure, the element of atomic number 71 must be assumed to be diamagnetic in its trivalent chemical compounds. In fact the absence of paramagnetism of such compounds is a necessary consequence of the theoretical conclusion that in the triply charged ions of the element 71 we first meet with a completed electronic configuration of four quantum orbits. (See N. Bohr, "Theory of Spectra and Atomic Constitution," pp. 106, 114, Cambridge University Press, 1922.) It was this conclusion which led to the anticipation verified by our discovery of hafnium, that the element 72 should not have properties analogous to the rare earths, but be a homologue of zirconium.

As will appear from the above, the existence of an element with the properties ascribed to celtium cannot be maintained, and we think ourselves justified in concluding that the important problem of the nature of the element 72 may be considered as settled by the discovery of hafnium and the investigation of its properties. While thus the general conclusions of Dauvillier and Urbain must be rejected, there remains the question, of secondary importance, whether the two extremely faint X-ray lines observed by Dauvillier in Urbain's preparation, which was believed to contain celtium, can have been due to a contamination of this preparation by a trace of hafnium. In the discussion of this point it must be emphasised, in the first place, that Urbain, in the course of his purification, made all possible precautions to remove elements other than the rare earths from his preparations. In fact, in his note in *Comptes rendus*, 1911, quoted above, M. Urbain states that "des impuretés de toutes sortes, provenant soit des vases, soit des réactifs, s'accumulèrent nécessairement dans des eaux mères successives. J'ai fait différents traitements de ces eaux mères par l'hydrogéne sulfuré, l'ammoniaque et l'acide oxalique, de manière à éliminer tout ce qui dans cette substance n'appartenait pas au groupe des terres rares. J'ai examiné ensuite la terre purifiée et parfaitement blanche." Now our investigations of the chemical properties of hafnium have shown that this element, just like zirconium, can be separated easily from the rare earth elements by a treatment with oxalic acid.

Only two lines of the element 72 were claimed to have been detected by Dauvillier, and even in the case of the most intense of these lines we meet with the difficulty that it falls in the same place in the spectrum as the strongest zirconium line in the second order. As an argument against ascribing this line to zirconium, Urbain states that the optical spectrum of his preparations did not show any zirconium line. An investigation of Urbain's spectrum of the "celtium" preparation, however, does not show any line of the hafnium spectrum (see Hansen and Werner, Nature, March 10, 1923) either. If the possibility of the presence of one of these elements in Urbain's preparation can be taken seriously into consideration, it should be expected that zirconium would be present in greater amount. In fact, zirconium was likely to be more abundant in the original mineral than hafnium, and a purification of rare earth preparations from zirconium and not simultaneously from hafnium, by treating with oxalic acid or any other method mentioned by Urbain, is scarcely imaginable in view of the close similarity of the chemical properties of these elements. As mentioned in our previous letters, however, the two lines ascribed by Dauvillier to the element 72 were lying 4 X-units distant from our Hf-lines, which is distinctly more than the limit of experimental error,[1] whereas the lines of the elements 70 and 71 measured by Dauvillier (*Comptes rendus*, vol. 174, p. 1347, 1922) on the same plates closely agree with the measurements of the same elements obtained by Coster (*Phil. Mag.*, vol. 44, p. 546, 1922). As the two lines according to Dauvillier were extremely faint, they may easily be explained to be of some other origin.

It is of interest to note that, at various times, announcements have been made as to the complexity of zirconium. In 1845 Svanberg claimed that in decomposing zircons he discovered a new element "norium," with a lower atomic weight than zirconium. His and Sjögren's (1853) statements were later disproved by the work of several investigators including Marignac. In 1864 Nylander reported the existence of two earths in zirconia. Five years later, by a spectroscopic investigation of zirconium, Sorby was led to announce the discovery of "jargonium" and Church of "nigrium." Finally, in 1901 Hofmann and Prandtl thought that they had found in euxenite a new element related to zirconium. It is also interesting to note that Mendeleéff, as we learn from Sir T. E. Thorpe's letter in NATURE of February 24, p. 252 (March 17), suggested that the extraordinarily discordant values for the atomic weight of titanium, found by several chemists, might be due to the presence of a homologous element of higher atomic weight in their material. Whether these statements in some cases may be explained by the presence of hafnium in the minerals and preparations under investigation, it is not easy to decide. The intricate chemistry of zirconium, and the great chemical similarity of hafnium with this element, would in fact have made any establishment of hafnium very difficult before the development of the powerful method of X-ray analysis.

[1] Dauvillier's measurements carried out since the announcement of our discovery, on other material which possibly contained hafnium, have already led him to give new values for the same wave-lengths, which are respectively 3·4 and 2·3 X-units larger (NATURE, February 17, 1923).

Constitution of Black Maketu Sand.

THE letter of Messrs. Smithells and Goucher in NATURE of March 24, p. 397, under the above title calls for a short reply from me.

The authors do not state with what object their experiments were made, but the results of these differ so much from my own as to suggest that the sand examined by them was from another part of the deposit at Maketu, or possibly from an entirely different source, such as that on the Taranaki Coast.

Is "Prof. Bohr's conclusion that no new element is present" to be found in any paper published by him? If not, it would be interesting to know upon what authority the authors quote it.

As my original communication on this subject was made to the Chemical Society, I feel it my duty to send to the Society, in the first place, the results of my own further experiments and also those of the examination of my preparations by Drs. Coster and Hevesy. This I hope to be able to do in time for publication in the Society's Journal for April.

Tracks of α-Particles in Helium.

IN a recent issue of NATURE (January 27, p. 114), Messrs. Ryan and Harkins have published some photographs of the ionisation tracks of recoiling atoms produced by collision of α-particles with air molecules. We have been also engaged in photographing the tracks of α-particles from polonium in helium, and have obtained some interesting photographs. Besides the long range recoil helium atoms, we have obtained a few photographs in which are shown the ionisation tracks of all the constituent parts of a helium atom, namely, of the nucleus and the two bound electrons. They are shown in Fig. 1 (i and ii).

FIG. 1.

It will be noticed that both the electrons are ejected on the same side of the α-particle track. One of us (D. Bose, *Zeit. f. Phys.*, 12, 207, 1922) has previously photographed the ionisation tracks of several thousands of α-particles in hydrogen, and in no case was a photograph obtained which showed simultaneously the ionisation tracks of the two constituents of a hydrogen atom. This behaviour can well be explained on the model of the normal helium atom proposed by Lande and others, according to which the two electrons move in orbits which are inclined to one another. If an α-particle strikes the atom at the moment when both the electrons are near the point where their orbits cross, then the probability of their both being ejected in the same direction is very great.

The photograph (Fig. 1, iii, *a*) presents some special points of interest. In it is shown (1) the track of the α-particle before and after collision, (2) that of a recoiling nucleus, (3) four small tracks which radiate out from the circular patch and are due to the electrons which are ejected from the atom under collision. The circular patch, which is absent in the photographs of other recoiling atoms, resolves when seen under high magnification into a number of lines radiating from a centre. An enlarged photograph which has been slightly retouched is reproduced in (iii, *b*). It will be noticed also that the path of the recoil atom is very much curved in the beginning—a phenomenon we have not observed before in the many tracks of the recoil atoms which we have obtained in air, hydrogen, and helium. Its length is 4 cm., and is larger than any of the other recoiling atom tracks which we have obtained in helium.

Judging from the number of the electrons which have been emitted we have here evidently the collision of an α-particle with an atom more complex than either hydrogen or helium; we can suppose it to be either nitrogen or oxygen; such atoms can well be expected to be present as impurities. But it is difficult to conceive how a recoiling atom of mass 14 or 16 can produce an ionisation track of 4 cm. length in a mixture of helium and water vapour, after suffering a collision with an α-particle from polonium. The distance at which the collision took place was about 3 cm. from the source. Probably the phenomena observed can best be explained on the assumption that here we have the case of the breaking up of a nitrogen nucleus by an α-particle with the expulsion of a hydrogen nucleus, which produces the long ionisation path. The cause of the large initial curvature of the path remains to be explained. It is not due to the superposition of a number of large-angled single scatterings.

Further experiments are in progress.

Porto Santo in Pleistocene Times.

The Geological Society of America has recently published an extremely interesting review and summary of the recent work and opinions of specialists on the Pleistocene, by Dr. H. F. Osborn and Dr. C. A. Reeds. The chronology and changes of level are fully discussed, and we are invited to consider the evidence in favour of changes in sea-level depending upon the amount of water withdrawn as ice. It is improbable that the views of Depéret, in particular, will be accepted as they stand; but it must be admitted that the glacial periods produced some world-wide changes of level, and the question how great these were becomes an extremely interesting one.

The statement of these views is an invitation to geologists all over the world to search their coasts anew, and try to detect evidence of the postulated phenomena. In the course of this search I believe few places will better repay study than Porto Santo, in the Madeira group. I have on more than one occasion directed attention to the small I. de Cima, separated from the main island by a narrow and shallow channel (Boqueirao de Cima), yet possessing a very distinct species of snail in great abundance, found nowhere else. The postulated fall of the sea in glacial times would, I think, certainly unite Cima with the main island, yet the snail has not passed. That the snail has evolved in post-glacial times seems improbable. Between Cima and the main island are some rocks, and on one of these (Sircada) Miss Nancy Paterson collected for me some fossil snails, *Ochthephila obtecta* and others. I thought at first that we had evidence of a submerged island or neck of land between Porto Santo and Cima, once supporting a snail-fauna, but now washed by the waves. Further investigation, however, convinced me that the Sircada Rock was nothing more than a large piece of the adjacent high cliff of the main island, which had fallen into the sea, carrying the fossils with it. Objection may be made that in postulating long constancy of level for the islets Cima and Baixo I do not take into account denudation, which would have worn them down had they not risen (or the sea fallen). These islets are essentially flat on the top, and wear away extremely slowly above, but rapidly along the sides, so that we have what may be called *lateral denudation*. This can be seen going on at the present time.

Continuing the investigation, we naturally ask for marine pleistocene beds. These are to be found at the Campo do Baixo, west of the Villa Baleira on the main island. A wide well has been dug at this place, and it is possible to go down and explore it fully. At a depth of about 30 feet is a layer of marine pleistocene rock, full of shells firmly cemented together. This rests on dense, dark, volcanic rock, but there is no evidence of volcanic activity in the material above. Far above the marine bed, near the surface, is dense sandy rock containing snail shells, *Plebecula bowditchiana* (Fér.), *Ochthephila tectiformis* (Sby.), etc. *P. bowditchiana* is an extinct species, but it is not certain that it lived so much later than the marine beds, for it might have been carried in shifting sand, though it is a heavy shell to travel in that manner. Another species of snail, *Ochthephila coronata* (Desh.), was found in the marine layer itself. A fine slab of the marine deposit, carrying many shells, has been presented to the British Museum. I broke up a quantity of the material, and submitted a series of the shells to Mr. J. R. le B. Tomlin, who has very kindly determined them as follows: *Erato prayensis* Rochebrune, *Mitra fusca* Swainson, *Cerithium vulgatum* Brug., *Bittium latreillei* Payr. (abundant), *Alectrion incrassata* Müll., *Trivia pulex* Sol., *Rissoa costulata* Ald., *Alvania testæ* Ar. and Magg., *A. punctura* Mont.(?), *Mangilia striolata* Sc., *Natica* sp. (? *macilenta* Phil., or perhaps *sanctæ-helenæ* Smith), *Anadema cœlatum* A. Ad. (?), *Calliostoma exasperatum* Penn., *Cardium papillosum* Poli, *C. tuberculatum* L., *Ervilia castanea* Mont., *Macrocallista chione* L. To these I may add the common *Columbella rustica* L., which was not submitted to Mr. Tomlin. A peculiar Naticoid and some others were not determined.

This is a modern fauna, many of the species still abundant in the sea near by. The place is not far from the sea, a short distance behind the line of sand hills, which are planted with tamarisk. The level of the deposit is little if at all below that of the shore, and we are not obliged to postulate anything more than a deeper bay, now largely filled up with sand.

This brief discussion merely opens up the subject, and it is to be hoped that some student will pursue the matter further, combining a charming holiday with profitable research.

The Hermit-Crab and the Anemone.

In Nature of December 2 and 30, 1922, vol. 110 (pp. 735 and 877), there are two very interesting letters from Dr. J. H. Orton on the relationship between these animals and the advantages of the partnership. Many years ago (September 1901) I took the opportunity, after a short visit to Millport, to watch the habits of the species *Eupagurus prideauxii* and *Adamsia palliata*, which seem always to live together, the association presumably being needful for their mutual welfare. Possibly my observations of these may be helpful in understanding the ways of other Paguridæ.

On the occasion referred to, I brought with me to Sheffield a specimen of the hermit-crab and Adamsia living together. To ensure their being undisturbed during my experiments, they were settled by themselves in a small aquarium and regularly fed with oysters and cockles. I thus managed to keep them alive and healthy for nearly six weeks. The Adamsia, as is usual, had attached itself head downwards on the underside of the shell occupied by the hermit-crab, and the two sides of its base had grown upwards and round the shell, so as to meet in the centre above the back of the crab, forming a tube or sack for its accommodation, the crab having far outgrown the small Natica-shell, which, later, was found at the bottom of the sack.

Matters had thus been arranged between the two animals so that, as is well known, the head of Adamsia hung downwards and its tentacles, brushlike, were carried over the surface of the sand when the hermit-crab travelled from place to place. The first two pairs of the long, slender walking legs of the hermit-crab were directed backwards in a manner which suggested protection of the anemone, but this appearance was misleading, as it was soon found that their function, in addition to that of locomotion, was to steal the food collected by the anemone. This was effected most cleverly by an underneath upwards sweep of the leg, the terminal portion of which passed through the tentacles of the anemone and carried any food found therein swiftly to the mouth of the hermit-crab. It is interesting to note that these limbs seem specially adapted to this purpose. The part mentioned (the dactyl) in this species (*E. prideauxii*) is long and very slender, and its inner or concave side is beset with a row of many long fine hairs projecting inwards like the bristles of a brush, thus forming a very effective instrument for sweeping out the mouth of the Adamsia. At times, also, the claws were doubled under the hermit-crab's body and seized the food which had been secured by the anemone. At first food was supplied for the joint use of the animals. Later on I experimented and tried to *feed* the *anemone alone*, but in this I never succeeded, as although the hermit-crab could not see the food, it was so instantly detected and swiftly swept away, as described, that one wondered how the anemone ever got sufficient for its own needs. Whether some sensory hairs on the dactylopodite had anything to do with detection I cannot say.

My observations seem to show that, though both animals benefit, the advantages of the partnership in this particular case are very largely on the side of the hermit-crab, which, in addition to being supplied with food, may possibly derive some benefit from the Adamsia's power when irritated, of firing a broadside of stinging threads through the numerous portholes in its sides. So far as I can see at present, the only profit to the Adamsia is that of being carried from place to place, and thus afforded a better chance of securing food, for which, as has often been pointed out, the downward direction of the mouth and tentacles is most favourable. The anemone may, of course, derive other advantages which are less obvious, and the parallel case (to which Dr. Orton has directed attention) of the little tropical crab, *Melia tessellata*, which carries in each claw a living sea anemone and uses it as a weapon and also (like Adamsia) as a collector of food, suggests the possibility.

On the face of it, Adamsia and the little anemones first mentioned seem to be the willing slaves of the hermit-crabs, for P. H. Gosse's observation, in 1859, of how *E. prideauxii* with its claws transferred the Adamsia from its old shell to a new one ("A Year at the Shore," pp. 241-247), which was later confirmed by Col. Stuart Wortley (*Ann. and Mag. Nat. Hist.*, 1863, p. 388), seems to show that the hermit-crab is the keenly interested active agent in arranging matters so advantageously for itself. With the common hermit-crab (*E. bernhardus*) and *Sagartia parasitica*, however, matters are reversed. Here the anemone evidently takes the initiative, and except perhaps by the camouflage, etc., which is afforded by its riding on the whelk-shell occupied by the hermit-crab, the latter appears to derive no benefit. The position assumed by the anemone is unfavourable to the hermit-crab's sharing in its captures; moreover, the walking legs of the hermit-crab are not adapted to securing a portion, the concave side of the dactyl of *E. bernhardus* being smooth and practically free from hairs, whilst the limb is otherwise unsuitable for the purpose. It seems as though *S. parasitica* has taken a hint from Adamsia and improved upon it.

ARNOLD T. WATSON.

Paradoxical Rainfall Data.

PROF. MCADIE, in NATURE of March 17, p. 362, directs attention to the apparently paradoxical fact that the wettest month observed in 37 years at Blue Hill observatory fell in June, the month with the lowest rainfall average, whereas the driest month fell in March, the month with the highest average. The coincidence is a curious one, but less improbable than might at first sight appear, since the monthly rainfall is at many stations extremely variable. Some idea of its extreme variability may be gathered from the following table, showing the distribution in half-inch intervals of the rainfall at Rothamsted for 70 years from March 1853 to February 1923.

	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.
0 – ·5		4	1	5	1	3	5		1		1	2	23
·5 – 1·0	9	11	11	8	7	9	5	4	5	4	4	6	83
1·0 – 1·5	12½	19	13	12	18	10	11	13	13	7	11	9	148½
1·5 – 2·0	7½	10	16	14	12	13	7	7	11	14	4	14	129½
2·0 – 2·5	10	8	10	10	12	6½	11	8	17	5	18	7	122½
2·5 – 3·0	9	4	7	12	8	10½	5	13	7	11	11	6	103½
3·0 – 3·5	7	5	4	3	5	5	9	9	6	6	6	10	75
3·5 – 4·0	9	6	4	3	1	5	2	7	2	5	4	3	51
4·0 – 4·5	4	1	3	1	3	2	5	3	3	4	7	6	42
4·5 – 5·0	2	2	1	2	2½	3	5	2	1	3	3	1	27½
5·0 – 5·5					½		2		2	3	1	1	9½
5·5 – 6·0						1	2	1	1	4		2	11
6·0 – 6·5						2				1		2	5
6·5 – 7·0							1	3		2			6
7·0 – 7·5										1			1
7·5 – 8·0													
8·0 – 8·5									1			1	2
	70	70	70	70	70	70	70	70	70	70	70	70	840

The seasonal effect appears to be more strongly marked at Rothamsted, where the mean rainfall (per day) in October is about 54 per cent. greater than that in April, than it is at Blue Hill, where the mean rainfall (per day) in February is only about 24 per cent. more than in June. Nevertheless, even in the Rothamsted data, the variability of rainfall in the same calendar month is so great that the mean values give little or no indication as to which month should be expected to score a record for rain or drought. Indeed, both records are at present held by December, which in 1864 gave one-sixteenth of an inch of rain (0·063), and in 1914 gave 8·103 inches.

R. A. FISHER.

Rothamsted Experimental Station,
Harpenden, Herts.

Rothamsted and Agricultural Science.[1]

By Sir JOHN RUSSELL, F.R.S.

THE Rothamsted Experimental Station has just passed its eightieth year, having been founded in 1843. Its study has always been the growth of crops, with periodical excursions into problems of utilisation; the method of experiment has always been essentially statistical in that the field experiments were repeated year after year without modification, with the result that a unique mass of data has now accumulated which is proving of the greatest value for statistical investigation.

The work at Rothamsted falls into two great periods: the first, when Lawes and Gilbert were actively exploring the possibilities opened up by the knowledge of plant nutrition gained by the early nineteenth-century workers; and the more recent period, when close study of the soil has revealed certain factors of high scientific interest, and, one is constrained to believe, ultimately of great practical importance.

The great problem which Lawes and Gilbert set out to solve was to account for the fertilising value of farmyard manure. The fact was well known, but there was no satisfactory explanation. Lawes and Gilbert proceeded by a method that still—after eighty years—remains our best. It was known that farmyard manure contained three groups of components: organic matter; nitrogen compounds; and ash constituents—potassium, calcium and magnesium salts, phosphates, silicates, etc. They therefore arranged vegetation tests with these various groups. The old idea was that the fertilising value lay in the organic matter, but Liebig, in 1840, had argued brilliantly against this view, and suggested instead that the ash constituents, especially the potassium, calcium and magnesium salts, were the effective agents. Lawes and Gilbert were prepared to recognise the necessity for these mineral salts, but insisted that the nitrogen compounds were equally required. To put the matter to a test, they laid out four plots of ground, receiving respectively no manure, farmyard manure, ashes of an equal amount of farmyard manure, and these ashes plus a nitrogen compound (ammonium sulphate). The results were as follows:

PRODUCE OF WHEAT PER ACRE, BROADBALK FIELD, ROTHAMSTED, 1844.

	Grain. (bush.)	Straw. (cwts.)
No manure	16	1120
Farmyard manure (14 tons per acre)	22	1476
Ashes of 14 tons of farmyard manure . . .	16	1104
Ash constituents + nitrogen compounds and ammonium sulphate, up to . . .	26¼	1772

They concluded that farmyard manure owes its value, not to the organic matter as was for long supposed, nor to the ash constituents as Liebig had suggested, but to the ash constituents plus nitrogen compounds.

Now this discovery was of the greatest importance in plant physiology, but Lawes and Gilbert did not follow it up in that direction. Instead they applied it at once to an important agricultural problem then ripe for solution. There was then (as nearly always now) a shortage of farmyard manure on farms, and agriculturists had for generations sought for substitutes, but with little success. Lawes and Gilbert saw that the mixture of ash constituents and nitrogen compounds would form an effective substitute, and further, that it could be obtained in very large quantities, and of course independently of farmyard manure. Geologists had discovered vast deposits of calcium phosphate, which chemists had shown how to render soluble. Engineers were developing the manufacture of coal gas and producing large quantities of ammonium sulphate, while potassium compounds could be obtained without difficulty from wood ashes. Lawes and Gilbert therefore proceeded to make mixtures of these substances which they advised farmers to use.

Few experiments have proved so fruitful in stimulating scientific inquiry—it is still opening up new fields at Rothamsted—and in ministering to human needs, as this simple field trial carried out eighty years ago on the Broadbalk field at Rothamsted. At first farmers looked with some misgiving upon this new kind of manure (which was called "artificial manure" to distinguish it from farmyard manure, then known as "natural manure"); it seemed incredible that a harmless-looking powder without smell or taste could act as potently as the old-time richly odorous farmyard manure. But they soon came to recognise its value, and before long they were using many thousands of tons a year. It is safe to say that the remarkable development of British agriculture which took place between 1843, when Rothamsted began, and 1870, would have been impossible without artificial fertilisers. During that period British farmers kept pace with the growing needs of the population; indeed they did more, for they helped to change the "hungry 'forties" into the more plentiful 'seventies. The use of artificial fertilisers is now developed throughout the civilised world and the industry has attained enormous dimensions.

This was the greatest achievement of Lawes and Gilbert. They did many other things for the farmers of their day, but this alone leaves us owing them a great debt of gratitude.

As the use of artificial fertilisers spread there arose, as one might expect, many problems of great scientific interest or technical importance. Thus it soon appeared that weather conditions profoundly affected the response of crops to artificial fertilisers. The same fertiliser mixture which in one season gave results fully equal to, or even surpassing those of farmyard manure, would, on the same farm and even in the same field, prove a failure in another season. This is well shown in the fluctuations in yield on the Broadbalk wheat field at Rothamsted.

The effect of soil is also sharply marked. On our heavy soil at Rothamsted the best results are usually obtained by a fairly liberal use of phosphates, but there is less necessity for large dressings of potash. But on the much lighter soil of Woburn potash is considerably more important, while phosphates

[1] Discourse delivered at the Royal Institution on Friday, February 9.

are less needed, and, indeed, beyond a certain quantity appear to do actual harm. It is obvious, therefore, that a complete manure drawn up on the basis of the Rothamsted experiments would fail in practice to give the best results on a lighter soil. As an instance the following may be quoted, this being one of a general scheme of experiments organised from Rothamsted:

Barley: Light Sandy Soil in Suffolk, 1922.

	Bush. per acre.
Complete artificial manure	21·5
Incomplete manure: phosphate omitted	27·5
No manure	16·0

In this instance the omission of phosphates has raised the yield by 6 bushels per acre. As against this, an array of instances might be brought from clay farms where a phosphate is the one and only thing that causes crop increases. Any one who had to deal with

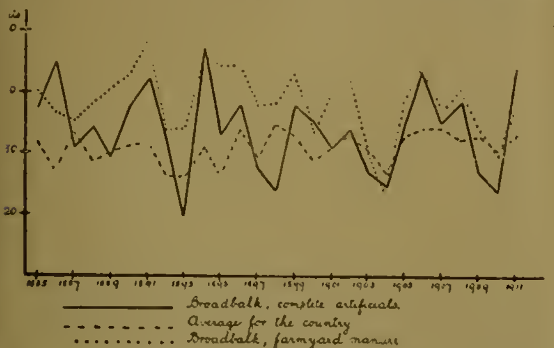

Fig. 1.—Yields of wheat from Broadbalk plots manured with complete artificial manures, and farmyard manure, respectively, compared with the average yield for the whole country.

farmers' problems could multiply apparent contradictions and inconsistencies of this kind. When one collects, as we have done at Rothamsted, the results of field trials with artificial manures made in different parts of the country they seem at first to be simply a tangled mass of unrelated facts.

Now it is the business of the man of science to sort out a tangle of this kind, to reduce it to order, to find the general principles running through it, and finally to prove the correctness of his conclusions by being able to predict with certainty what will happen in given conditions. The recognised method of procedure is to discover the various factors at work and investigate them one at a time. This is being done at Rothamsted in two ways: by field observations, and by quantitative laboratory measurements. Observations in the field show that each of the fertilising substances—phosphates, potassium compounds, nitrogen compounds, etc.—in addition to its general effect in increasing plant growth, produces certain specific effects which may be of advantage, or may be a disadvantage to the plant in the particular conditions in which it happens to be growing. Thus, phosphates have a special influence in hastening the ripening processes, which no doubt accounts for the Suffolk results just quoted. In the dry conditions of a sandy soil, ripening is already too early, and any reduction in an already short growing season cuts down the yield; in cold, wet districts, however, this property is very valuable.

In the early stages of the plant's life phosphates stimulate root development to a marked degree; this is well shown in their effect on swedes. Nitrogen compounds tend to increase leaf development and give greater vigour of growth, but beyond a certain point the advantage is counteracted by a loss of resisting power, and the plants may fall victims to attacks of disease. Crops—especially cereals—may be unable to stand up against the weather and may become "lodged." Indeed, the proper adjustment of plant nutrients affords plant pathologists one method of dealing with plant diseases.

Qualitative observations of this kind, while of high value, are not entirely sufficient: it is necessary to have quantitative measurements of as high an order of accuracy as possible. At Rothamsted this is done by means of water cultures and pot experiments; all the factors are controlled as closely as possible and the results are plotted on curves which can be studied in detail. This method was developed extensively by Hellriegel and is now in common use in agricultural laboratories.

The method naturally invites mathematical treatment, and attempts have been made, notably by Mitscherlich, to express the curve by equations. There is a seductive look about a mathematical formula which rarely fails to appeal to the biologist, but as a rule the number of experimental points obtained is much too small to justify mathematical treatment, and it is not surprising that investigators fail to agree. Ten years ago the fashion was for logarithmic curves; now it is for sigmoid curves, which are probably nearer the truth, though not yet a complete expression.

This method of studying single factors is pushed to a high degree of refinement in plant physiology laboratories, such as that of the Imperial College under Prof. Blackman, or that under his brother at Cambridge, and there can be little doubt that the effect of individual factors on the plant will ultimately be well known. All this work is giving valuable information as to causes and principles.

These curves show the relationship between yield and plant food supply at one particular temperature which remains constant, and one particular water supply which also remains constant. But a completely different set of figures would be obtained if the temperature were different or if the water supply were altered. Supposing one wished to take account of the effect of water supply as well as food, one would draw a series of curves, which would properly be expressed as a surface, and this has been done by one of the Rothamsted workers—Mr. J. A. Prescott—to show the effect of nitrate supply and spacing on the yield of maize in Egypt. The experiments had the advantage that the climatic conditions are less fickle there than here. It would be of the greatest interest to obtain such surfaces for other pairs of factors.

If an attempt were made to study factors three at a time, it would be necessary to prepare a series of surfaces and to embody them in a figure in four dimensions, which is certainly beyond the capacity of the ordinary agricultural investigator. But in agricultural field work the factors do not vary one at the time, or even two or three at the time; there may be half-a-dozen variables. This, of course, enormously complicates any attempt to apply to field conditions the results obtained by these single factor physiological experiments. It is possible that when the physiologists have completely elucidated all the single factors, some one will be able to synthesise the material and build it into some great conception or expression that will contain all, and thus account for the field results. But history shows that the genius capable of effecting a synthesis of this sort is very rare and might have to be awaited long.

We have therefore adopted another method at Rothamsted, which is being worked alongside of the single factor method. Statisticians have, during recent years, been evolving methods for dealing with cases where several factors vary simultaneously. These methods have been applied by Mr. R. A. Fisher to the Rothamsted field data, and he has been able to trace

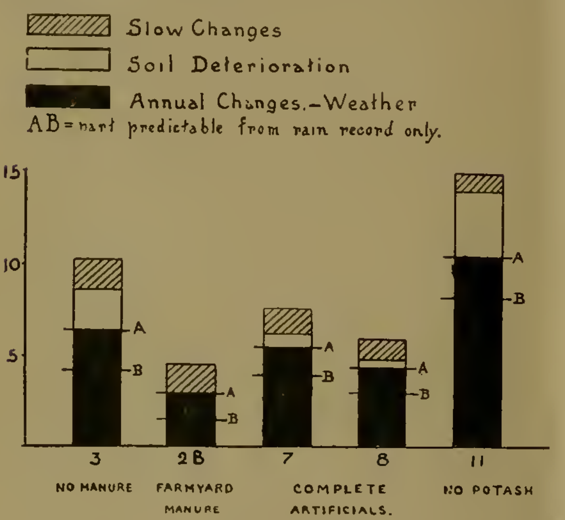

FIG. 2.—Mr. R. A. Fisher's results showing amounts of predictable variation in wheat yields, Broadbalk, Rothamsted.

certain statistical regularities which foreshadow the possibility of important developments.

Thus, the yields on the Broadbalk wheat field vary every year, apparently in a most erratic manner. But analysis of the figures showed that the factors causing variation could be disentangled and expressed quantitatively; there are slow changes in the field, such as changes in the amount of weeds, etc.; deterioration of soil; and weather changes such as rainfall, temperature, etc. (Fig. 2).

As might be expected, the effects differ according to manurial conditions; *e.g.* the influence of weather varies with the manure. Important differences appear between farmyard manure and artificials. The variation in yield is less where farmyard manure is given than where artificials are used. Further, the so-called complete manure appears not really complete at all; there is soil deterioration going on; but with farmyard manure no such deterioration is produced. The different kinds and quantities of artificial manures produce different effects on the variation in yield, the magnitude of which has been worked out.

Having disentangled the factors Mr. Fisher has proceeded to analyse the effect of rainfall, and he finds that part of the weather effect is predictable when rainfall is known. Rain above the average in autumn is somewhat beneficial; in winter and in summer it is harmful, and in spring it is less frequently harmful. As before, the effects are much more pronounced with complete artificials than with farmyard manure. The actual facts have long been known in a general way, but here is an exact quantitative measurement.

The great advantage of this statistical regularity is that it indicates the possibility of expressing in terms of chance the influence of the weather, soil, etc., on crop yields. We hope ultimately to be able to say to the farmer, given such and such conditions of soil and weather, the chances are so many to one that such and such an increase of yield will be obtained by the use of a specified fertiliser. The expression would be understood by every farmer, and he would readily decide whether to take the risk or not.

Much greater results would also follow. At present the farmer cannot cover his risks of low yields by insurance, the companies not yet having sufficient data. We hope and believe that these statistical investigations will afford the basis on which such data will be obtained. At present the position approximates to that of life insurance in the eighteenth century, when the statistical regularity of mortality was first established, after which the first life tables could be constructed. There still remains a mass of detail to work out, but the fundamental problems are now being attacked, and we see no reason to regard them as insoluble. If the expectancy of crop yields proves to be calculable the farmer will be able to insure himself against crop failure, and so meet one of the worst vicissitudes of his troubled life by merely taking out an insurance policy—perhaps even by subscribing to a particular newspaper.

We are constrained to admit that the work is still far from completion, and in the meantime agriculture has fallen on difficult days and farmers are turning to us to ask how they can obtain large crops in the most economical way. It is not general principles they want, but particular instructions.

We are not in a position to give an absolute clear-cut prescription to any farmer, but we are going a long way to meet him. Some of our field experiments of special interest or importance are being repeated at other centres where soil and climatic conditions are all different. The results are compared with ours, or with others that have been obtained, to ascertain how far or in what direction any of our conclusions would need modification in a particular district.

We now return to an important result to which I have already referred. Over a period of years the artificial manures have not proved quite as effective as farmyard manure; there has been more variation in yield and they have not so well maintained the fertility of the soil as farmyard manure has done. On some crops the effect is marked; clover responds better to farmyard manure than to artificials. It appears then that Lawes' and Gilbert's views that the fertiliser value of farmyard manure lay in its ash constituents plus nitrogen compounds is only a first approximation, and that farmyard manure does something or contains something which artificial manures do not. This difference we are now engaged in exploring.

The same method of procedure is used as in studying the effects of artificial fertilisers. A full scientific investigation into the causes is carried out, but simultaneously an attempt is made to find some working solution of the farmers' problems. The shortage of farmyard manure is still as acute as ever, and to keep more animals with the view of making more is uneconomic. At Rothamsted we have attempted to produce farmyard manure from straw artificially and without animals. This has been done by Mr. E. H. Richards and Dr. Hutchison by simulating the essentials of the natural process, namely, watering straw with a salt of ammonia (actually ammonium sulphate, but calcium carbonate is mixed with the straw), and leaving the heap so that the air can get in and the organisms can do their work. The product is not yet equal to the natural substance, but it is steadily being improved, and the very serious difficulties are gradually disappearing in Mr. Richards's competent hands. Five years ago a few ounces only of this artificial farmyard manure had been prepared; last year several thousand tons were made on various farms in different parts of the country, and the news is spreading. The serious problem of developing the work from the laboratory to the farm scale has been possible through the generous and public-spirited action of Lord Elveden. There seems here the possibility of aid to the farmer and of the development of an important new industry.

Meanwhile a full scientific investigation is being carried on to discover wherein farmyard manure differs from artificials. One important difference is already known and is being investigated by Dr. Keen. Farmyard manure opens out the soil particles leaving bigger pore spaces; it allows of the retention of more moisture and the better circulation of air. All these effects are beneficial.

There is also another difference. Farmyard manure and also plant residues (which are substantially the same thing) decompose in the soil, giving rise to many substances of different types. The plant foods are among the end products: indeed, in natural conditions, and, to a large extent, in farms and gardens also, it is in this way that plants obtain their food. In using artificial manures we supply these end products at once instead of waiting for them to be liberated gradually by the natural decomposition. Further, we do not by any means know the whole of the processes whereby plant food is made. But there are certain intermediate products, and it is quite possible that some of these may have a special effect on the growing plant. Curious stimulating effects are produced by substances formed when soil is steamed, or when oxidation is accelerated by addition of charcoal, and we have obtained the same results with small quantities of picric acid; such bodies might well be formed as intermediates in the decomposition of farmyard manure. The whole effect suggests an action like that of the vitamins of plant physiologists or the auximones of the late Prof. Bottomley. The chemical department at Rothamsted, under Mr. Page, is following out the process, and the botanical department, under Dr. Winifred Brenchley, will test any intermediate products which may be obtained.

A further important factor, which probably governs the whole situation, is that a great part of the process of decomposition and plant food production appears to be brought about by living organisms in the soil. Simultaneously, therefore, with the chemical and botanical investigations, the various biological departments are busily engaged in studying the organisms that are doing the work.

It is a wonderful story that is being revealed. The soil is shown to be the abode of a vast population of living organisms of the most varied kind. Some of them are remarkably small; among them one which brings about the last stage in the formation of nitrates—an organism which Rothamsted just missed forty years ago: another, also just missed at Rothamsted, which has the remarkable property of fixing nitrogen in the nodule of the clover plant. Others are larger and more easily picked out, but their exact place in the soil economy is not easy to determine: probably they are concerned in the preliminary stages of the decomposition.

It is impossible to peer into the soil with a microscope, so that indirect methods of exploration have to be used. At Rothamsted the organisms are counted and the work they do is estimated by some chemical process: virtually we take a census of population and production in the soil. Like other census methods, it is comparative only: a single census is not much use; it is not until several have been taken that one can find how the numbers and activities of the population are being affected by various conditions. The census is therefore repeated periodically and the results plotted on curves from which it is possible to deduce the effect of various factors on the particular organisms counted.

These curves brought out the remarkable result that partial sterilisation increased bacterial activity, and investigation showed that the normal virgin soil must contain other organisms besides bacteria—organisms, moreover, which were detrimental to bacteria and tended to keep their numbers down. A search for such organisms showed that protozoa were present: many forms have since been found in the soil, some of which are known to feed on bacteria. Mr. Cutler has discovered how to count them, and with the co-operation of willing workers has succeeded in carrying out perhaps the most remarkable census yet made of the bacterial and protozoan population of a natural field soil. Before the census began many months were spent in perfecting the methods and technique, and in making preliminary studies of the soil. The details were carefully arranged with the statistical department, and it was decided to take the census many times at short intervals. Time to a bacillus or a protozoan is a different thing from what it is to us, and instead of taking the census every ten years, or even every ten days, it was taken daily, and at the same hour every day. Many repetitions were needed so that the statistician might feel safe in drawing conclusions from the data. The census was therefore made every day for 365 consecutive days, and no less than seventeen different organisms were enumerated.

A team of five workers kept the investigation going without intermission—Sundays, Bank Holidays, and Christmas Day—for a whole year. A mass of data was obtained of high statistical value which is proving of the greatest importance in the study of the soil population. One of the most interesting results was the proof that the soil population is not steady in number as had always been assumed, but is in a violent state of flux. Every organism observed—protozoon or bacterium—showed great daily variations, which seemed to be independent of external conditions. At least one showed a two-day periodicity. The fluctuations of the amœbæ were of special interest as they were exactly the reverse of the bacterial fluctuations. Close examination of the curves leaves no doubt that the fluctuations of the amœbæ cause the fluctuations of the bacteria, high numbers of amœbæ causing low numbers of bacteria, and low numbers of amœbæ allowing bacterial numbers to rise: but why the amœbæ fluctuate remains a mystery.

In the case of bacteria it has been possible to make even closer observations. A census organised by Messrs. Thornton and Page has been taken each two hours for several days and nights; but again the same wonderful fluctuations are seen. As might be expected, the amount of work, as measured by the nitrate present, alters from hour to hour. But the curve was not quite what was expected: the increases in amount of nitrate could be understood as representing the work done by bacteria, but the decreases were more difficult to explain. There was no rain to wash it out and there were no plants to take it up; yet the nitrate tends to disappear. The results suggest that some organism is absorbing it. Algæ and fungi could both do this, and both are found in the soil: Dr. Muriel Bristol and Dr. Brierley are closely studying them.

Perhaps even more remarkable than the daily changes are the great seasonal changes. It appears that the whole soil population is depressed in winter and in summer, and is uplifted in spring and autumn. How this comes about we do not know. The phenomenon does not seem to be confined to the soil; the algæ in a pond and the plankton in the sea, like the organisms in the soil, all seem to feel the joy of spring; it is as if Virgil had got hold of some great truth in natural science, which we have not yet been able to express in cold scientific terms, when he says that in spring "Aether, the Almighty Father of Nature, descends upon the earth, and blending his mighty frame with hers, gives life to all the embryos within." ("Georgics," Bk. II. 11, 324-327).

The number of organisms in one single gram of soil—no more than a teaspoonful—often well exceeds 40 millions. This looks big, but it is difficult to form an idea of its immensity. If each unit in the whole array could be magnified up to the size of a man and the whole caused to march past in single file, they would go in a steady stream, every hour of the day and night for a year, a month and a day, before they had all passed. We must think then of the apparently lifeless soil which we tread beneath our feet as really throbbing with life, changing daily and hourly in obedience to some great laws which we have not yet discovered; pulsating with birth, death, decay, and new birth. And if the wonder were not sufficient, we know that in some way these lowly organisms are preparing the food for our crops—the crops on which we ourselves feed. It is possible—it is even probable—that our attempts to learn something of this wonderful population may lead to some degree of control which would have valuable economic results. But even if this never happened the work would still be justified because it shows to the countryman something of the abounding interest of his daily task and of the infinite wonder of the soil on which he spends his life.

The Present and Future of Marine Engineering.

THOUGH shipping and shipbuilding are passing through a period of severe depression it is generally considered that more prosperous times are in sight. The War, as is well known, occasioned tremendous losses to the shipping of the world—we ourselves lost over seven million tons—but this has been more than made up, and the latest edition of Lloyd's Register Book shows that there are afloat to-day, exclusive of sailing vessels and vessels under 100 tons, some 29,000 steam and motor ships of a total tonnage of 61,000,000 tons. This is an increase of some 14,000,000 tons on the figures for 1914, but while in that year the United Kingdom owned nearly 44½ per cent of the world's sea-going steam tonnage our present proportion is just over 33½ per cent. In spite of this, we are still the greatest users of ships and the greatest builders of ships, though to-day shipping returns are only too eloquent of ships laid up, berths empty, shops closed, and machinery idle.

While this is the case, the competition for such orders as are to be obtained has forced all designers to study more closely than ever the economics of shipbuilding and marine engineering, and a vast amount of investigation and research is being carried out. Especially noteworthy are the inquiries being made into the respective advantages of the steam engine, the steam turbine, and the oil engine. As a result of this, the shipowner is to-day offered a bewildering variety of machinery of various types, all of which have their respective merits. A quarter of a century ago marine machinery was more or less standardised. Practically every ship built then was fitted with cylindrical boilers burning coal, and triple expansion engines. Of the 61,000,000 tons of shipping referred to above, 51,000,000 tons are still driven by such engines. Remarkably successful as it has been, the reciprocating steam engine, however, has long been superseded in naval vessels and fast liners by the steam turbine, and now its very existence is threatened, on one hand by the turbine combined with mechanical, hydraulic, or electric transmission gear, and on the other hand by numerous forms of the Diesel internal combustion engine.

The present position of the marine steam turbine is scarcely less critical than that of the triple expansion engine. It is twenty-one years since the marine steam turbine was used commercially, and it is estimated that turbines of more than 50,000,000 horse-power have been fitted in ships. There are many types, such as those of Parsons, Curtis, Rateau, De Laval, Zoelly, and others, but it was the Parsons turbine which led the way. Originally the turbine was connected directly to the propeller shaft. To be economical, however, the turbine should run fast and the propeller slow. To achieve this object, Sir Charles Parsons introduced helical tooth gearing, the turbine shaft having a small pinion which geared into a large wheel in the propeller shaft. Such single reduction gearing was successfully tried in the s.s. *Vespasian* in 1909. Since then double reduction gearing, consisting of a train of four wheels, has been largely used. In this arrangement the pinion in the turbine shaft drives a wheel on an intermediate shaft, and a pinion in the second shaft drives the wheel in the propeller shaft. By this means it is possible to run the turbine at three or four thousand revolutions per minute while maintaining a suitable propeller speed. One of the finest examples of such gearing is found in the latest liner of the Canadian Pacific Railway Company, the *Empress of Canada*. Completed last summer, this vessel is the largest passenger ship running in the Pacific. Of 21,520 tons, she is driven by twin sets of Brown Curtis turbines, each set having H.P., 1st I.P., 2nd I.P., and L.P. turbines, which drive the propeller through double reduction gearing. The main gear wheel on the propeller shaft alone weighs 65 tons, while one complete set of gearing weighs about 200 tons. Additional interest attaches to this installation, due to the application of the principle of the nodal drive devised by Dr. J. H. Smith, of Belfast, in order to avoid trouble due to torsional oscillations of the various shafts.

But while mechanical gearing of this kind has been used extensively, there have unfortunately been serious failures which have given rise to more than a little doubt as to the trustworthiness of such gearing. The elucidation of the causes of the failures is among the most pressing problems facing the marine engineer. References to this were made in the recent presidential addresses of Engr. Vice-Admiral Sir George Goodwin, Dr. W. H. Maw, and of Prof. T. B. Abell to the Institute of Marine Engineers, the Institution of Civil Engineers, and the Liverpool Engineering Society respectively, and the urgent need for further research was pointed out. Failures occur from the wearing or the breaking of the teeth. In some instances where wear has taken place the trouble has not been serious, and with further use the condition of the gearing has improved. When fracture takes place the broken pieces sometimes fall clear of the wheels, and the damage is slight. If, however, the broken teeth are caught in the wheels distortion and crushing takes place immediately, and the gear wheels are rendered useless. The causes of failure have been variously assigned to inaccurate cutting of the teeth, want of alignment of the shafts, improper design, unsuitable or faulty material, and the occurrence of excessive torsional vibrations in the shafting and gearing. This latter subject has been dealt with recently in a valuable paper by Messrs. A. T. Thorne and J. Calderwood, read before the North-East Coast Institution of Engineers and Shipbuilders.

Recent improvements in steamships, whether driven by turbines or reciprocating engines, have been largely concerned with the stokehold. Though cylindrical boilers still remain the rule, water-tube boilers are being fitted in increasing numbers, and in such vessels as fast torpedo craft and cross Channel steamers the combination of the water-tube boiler with the geared turbine is likely to hold its own for a long time. The water-tube boiler leads to a reduction in weight, it can be forced at a high rate of combustion, and it is admirably adapted for use with oil fuel. Naval vessels have used water-tube boilers exclusively for many years, but it is only recently the mercantile marine have taken kindly to them. The most notable example of the use of water-tube boilers in a merchant ship is found in the White Star liner, the *Majestic*, the ex-German ship *Bismarck*, which it is anticipated will run the *Mauretania* very close for the blue ribbon of the Atlantic. The world's greatest ship, the *Majestic*, is 912 feet long, and displaces, when fully loaded, 64,000 tons. The turbines, originally designed for 66,000 S.H.P., are supplied with steam from 48 water-tube boilers of the Yarrow-Normand type. These have a total heating surface of 220,000 sq. ft., or some 40,000 sq. ft. more than the boilers of H.M.S. *Hood*. Like most of the Atlantic liners the *Majestic* is now fitted for burning oil fuel. Some 15,000,000 tons of ships burn oil instead of coal to-day, and provided supplies of oil prove sufficient, the time is not far distant when the coal-burning ship will be obsolete. When used under boilers three-quarters of a pound of oil will do the work of a pound of coal. Then, too, the use of oil-fuel leads to a great reduction in the stokehold staff, and from the shipowners' point of view it has the advantage of making it possible to reduce the time of a ship in port. The *Olympic*, for example, can fill her oil-tanks in six hours; coaling used to take 4½ days.

It is not, however, with the reciprocating engine or with the steam turbine that the future of marine engineering appears mainly to lie, but with the Diesel internal combustion engine. Diesel brought out his engine so long ago as 1893. Its success ashore has been remarkable. For driving ships it has had to serve a long probation. The Atlantic was first crossed by a Diesel-driven ship in 1910. Since then its progress has been more rapid, and practically all marine engine builders have taken up the construction of Diesel engines of one form or another. The motor ship has undoubtedly come to stay, and the placing of an order by the Union Steamship Company of New Zealand with the Fairfield Company for a motor driven vessel of 20,000 tons with a speed of 18 knots marks an important epoch in its history. This notable vessel will be 600 ft. long, and will be driven by four sets of Sulzer two-cycle Diesel engines of an aggregate power of 13,000 H.P. This is twice the power of any motor vessel running at present. Such a step is evidence of the degree of trustworthiness and success achieved by the motor ship.

The credit of building the first motor passenger liner belongs to the Elder Dempster Line, which commissioned the *Aba* for its West African trade last year, and has now placed the *Adda* on the same run. Other companies are following the lead thus given, and while in 1914 there were only 297 motor ships afloat there are now 1620, with an aggregate tonnage of more than one and a half million tons. Shipowners have the choice of a dozen types of Diesel engines, such as the Burmeister and Wain, the Werkspoor, the Sulzer, the Beardmore, the Cammellaird-Fullagar, and the Doxford, some being of the four-cycle and some of the two-cycle type. These engines differ in many respects, but all have the same characteristic in being more economical than the steam engine. Mention may also be made of the experiment being carried out with the Still engine, in which the top of the piston is acted upon by the pressure of the burning gases, while the underside is acted upon by the pressure of steam raised in a small boiler heated by the exhaust gases.

In addition to the advocates of the steam turbine and the Diesel engine there is yet another school of engineers which believes the future of marine propulsion lies with what is known as the electric drive. This system has been developed far more in America than on this side of the Atlantic, and all recent capital ships for the United States Navy have electric transmission. In these vessels oil-fired boilers supply steam to Curtis turbines driving electric generators which supply current to the motors on the propeller shafts. The general adoption of such a system, it was pointed out by Prof. Abell, may lead to remarkable alterations in the plans of ships, as the engine-rooms can be placed between decks or otherwise as thought most suitable. A turbine-electric plant involves the use of boilers, turbines, condensers, generators, and motors, but an alternative is to replace the boilers, turbines, and condensers by Diesel engines. The various proposals have been reviewed in his book on "Electric Ship Propulsion" by Commander S. M. Robinson, of the United States Navy. He there divides both naval and mercantile vessels into classes, and states which type of machinery he considers most suitable. For the cargo tramp he would have Diesel engine and electric drive, for other merchant vessels and for large war vessels steam turbines and electric drive, while for destroyers and light cruisers he would retain geared turbine.

From the foregoing it will be seen that the whole practice of marine engineering is, as it were, in the melting-pot, and what the standard form of marine propulsion will be in the future is difficult to see. Given trustworthiness, it is economy which has the deciding influence; economy in weight, economy in space, economy in upkeep, economy in fuel. What the continual striving after economy has done in the past can be judged by the fact that, fifty years ago, to convey a hundred tons of cargo a mile required 18 to 20 lbs. of coal; to-day the same result is obtained with $1\frac{1}{2}$ to 2 lbs of oil. Finality was thought by some to have been reached when the compound engine was introduced. Great advances have been made since then. But while it may not be possible to effect revolutions on the scale of the past, the time is far distant when improvements will be impossible.

Obituary.

Sir James Dewar, F.R.S.

Sir James Dewar died at the Royal Institution, in his eighty-first year, on March 27. He had been working in his laboratory until late on the night of March 20 and was taken ill in the early hours of the following morning.

Our scientific edifice is thus suddenly deprived of one of its main pillars; we shall not easily appraise the loss. The immensity and sustained originality of his genius, the service he rendered to our civilisation, can be but insufficiently appreciated outside the small circle of intimates who witnessed his work and, having penetrated through the thick mask of modesty and reticence which he habitually wore, could disregard his sometimes brusque, inconsequent manner, his volcanic, torrential outbursts of picturesque criticism—knowing these to be but the expression of an extreme intensity of conviction and purpose and an overmastering honesty. At heart he was full of human sympathy, a most gentle and lovable nature—but the presbyter was ever in him.

As an experimentalist Dewar stood alone: there has never been a greater, probably none so great. Science loses in him a worker of peculiar breadth of originality, a most fascinating character; how much the world is poorer it little knows. He was of a type—almost primitive, in this competitive age, in honesty of purpose—now fast becoming extinct, a lineal descendant of his great countryman, Joseph Black, in no way less successful than his predecessors, Young, Davy and Faraday, in adding to the reputation these pioneers created for the Royal Institution as a centre of scientific discovery and invention. He also made it a social centre of great attraction and cast over it an æsthetic spell which it had not previously known. Davy sought society but did not fashion it. Dewar could rarely be persuaded into it but became himself noted as a host, on account of his own great conversational power and the beauty of the surroundings he accumulated: his home was the salon of science and art.

As a lad Dewar met with an accident which, in after life, he regarded as fortunate. Falling through the ice, he contracted rheumatic fever and was long unable to attend school but became intimate with the village joiner. In those days, Scotland having been in close commercial relation with Italy, fiddles abounded and the lad had musical tastes. With his own hands he made several violins, from one of which we heard the sweetest of music conjured forth, by a skilled lady performer, on the occasion of the celebration of his golden wedding, less than two years ago. He always regarded the training he thus received as the most important part of his education and the foundation of the great manual dexterity which he displayed in his work and his lectures. He often complained to me of the sad lack of such ability in the modern student. His master in chemistry was Lyon Playfair. Dewar was one of the few who could appreciate Playfair's great scientific ability and were able to gauge the loss of his early deflexion into the tortuous paths of politics, which Playfair himself regretted in later life. The two men became fast friends and Playfair was long chief admirer of his pupil's brilliant ability. At one time, I believe, Playfair endeavoured to secure his entry into the dyestuff industry; had Dewar's masterful energy been operative in this field our position to-day might well have been one of unrivalled supremacy.

Dewar also came under Kekulé's influence at Ghent. Körner was then assistant in the laboratory and Dewar and he became associated in all sorts of devilry—Körner being a great practical joker and Dewar a wild young Scot. The stamp of the organic chemist was thus burnt into his soul at a critical period—the spell of Körner's marvellous preparative skill being cast over him; he often referred to the time. His mathematical and physical proclivities were thus broadened and he became a complete chemist in spirit. The Dewar benzene-formula, though an imperfect expression of modern knowledge—paper formulæ are but short-hand expressions of character—has not yet lost its vogue. His name is also written in the pyridine chapter. He and I were the first users of sulphuric chlorhydrol, SO_3HCl. He did notable work before he came south—first with Tait, in which he laid the foundation both for his later application of a vacuum in preventing heat exchanges and of charcoal as an absorbent; and with M'Kendrick, with whom he carried out an important inquiry on the physiological action of light.

In 1875 he was appointed Jacksonian professor of natural experimental philosophy in the University of Cambridge and became the colleague of Prof. Liveing. He never carried out the prime duty of his office—the discovery of a cure for the gout—though in early days he sought unsuccessfully for the qualification which might have helped in the work; unfortunately, he only spoilt his digestion and so, in later years, was perforce an extraordinarily careful liver.

Two years after his appointment at Cambridge he also became Fullerian professor of chemistry at the Royal Institution, London. He had twice lectured there previously on the work he had done with M'Kendrick. The second lecture (March 31, 1876), his trial trip, was probably the most carefully prepared, certainly the most logical, discourse he ever delivered; I well recollect how fascinated some of us were by it.

Even if it be possible for a man to serve two masters, the task becomes beyond human power when ghosts aid one of them. As an artist, Dewar had the innate belief of primitive man in ghosts and in the Royal Institution laboratory, miserable as was the accommodation it afforded, the ghosts of Davy and Faraday were ever about him. Let us hope that his successor will be gripped by thoughts of the trinity which Dewar's entry into their Valhalla has established. To have served the Institution honourably, in a way to justify mention in history on a par with them, is an achievement he, in his modesty, scarcely contemplated as possible and yet he ever aimed at it. The feeling that he had so much exceeded Faraday's period of office and not only maintained but also steadily improved the quality of his work, I have reason to think, was year by year a more and more powerful mainspring of action in the indomitable fight against circumstances which he waged during these late bitter times of strife. He was a terrible pessimist.

To return to Cambridge, he found there no tradition of practical achievement to influence him. His colleague Liveing and the Master of his College, Dr. Porter, were perhaps the only men who fathomed his outstanding ability. The crudity of youth was still upon him and the free manners of a Scottish University were not those of conventional Cambridge—his sometimes imprecatory style was not thought quite *comme il faut* by the good. No attempt was made to tame him or provide means for the development of his special gift of manipulative skill. Yet he soon began to exercise an influence which probably has had more to do with the marvellous recent advance of the Chemical School at Cambridge than is commonly supposed. The fine volume of collected researches in spectroscopy which Prof. Liveing and he published a few years ago, is a memorial not merely to their activity but of the example they set as exact observers in a field which, at that time, was in sore need of cautious workers. And the work he did in London had its reflex effect at Cambridge.

Dewar was not great as a teacher. His mind was of too original and impatient a type. He never suffered fools gladly and students are too apt to be foolish—at our old Universities, even to ape the part of superior beings. His forte lay in directing competent hands, not in forming them. He worked himself and through skilled assistants, not through pupils. He was violently impatient of failure in manipulation and his work was almost entirely manipulatory. He, therefore, never created a school. The pity of it is that circumstances were such that he never had a properly large staff. That he accomplished so much with the assistance of the few able men who have aided him is proof of his exceptional skill as a director. It is unfortunate that the Davy-Faraday laboratory was not, from the beginning, organised on lines which would have placed its resources in his hands rather than at the disposal of undirected individual workers; it is a grievous fact that he leaves no followers trained to use his incomparable methods.

Nominally a chemist, Dewar's work lay in fields of his own creation, not borderlands but regions before uncultivated. He was no mere experimentalist but an artist to his finger-tips and in nose, tongue, eye and ear—a perfect judge of *Wein*, *Weib* and *Gesang*, giving to these terms their widest significance; music came next to science in his affections.

Though deeply read and a great lover of poetry and literature, he lacked the gift of ready literary expression—except in his letters and conversation—and was often an incoherent lecturer, yet his lectures were the most masterly and fascinating displays ever witnessed. He set a standard which has made the Royal Institution table remarkable throughout the world. Faraday was celebrated for the simplicity of his style—Dewar is to be thought of on account of the daring of his displays, the wonderful refinement and appositeness of his demonstrations, all most carefully arranged and rehearsed in advance. He was a great scientific actor, playing plays with the most thrilling of plots and entirely original special scenery for each performance. His manner, his brogue, even his impatience, gave a peculiar charm to the impression he produced; but you did well to have been behind the scenes if you wished to gather the full meaning of his message. His demonstrations were unique in character; few realise the infinite loving care he devoted to their preparation. In their simplicity they were often profound. I can never forget the impression I received when I first saw him burn diamond under liquid air—the gradual accretion of the carbon dioxide snow-shower and the blueing of the fluid by ozone, also demonstrated by the iodine test. Then the rapid uprush of the mercury in a barometer-tube full of air when the tube was cooled with liquid hydrogen: it all but knocked the top off. Or again, the production of ozone at the surface of solid oxygen by the impact of ultra-violet radiations. At such moments—and there were many such—the heart beat with joy at the significance of his feats of inspiration.

To the outside world Dewar is known as the man who liquefied oxygen and other gases and as the inventor of the vacuum flask—his name will probably go down the years on this last account. It is due to his memory that this should be spoken of henceforward as *the Dewar flask*: it was his free gift to the public; had he protected and developed the invention he might have amassed a fortune and fully endowed his chair.

The real value of his work on gases, apart from the impetus it gave to the industrial use of liquefied air in particular, is to be found in the many new directions in which he developed the art of inquiry at low temperatures. Perhaps the most illuminating is the inquiry into the heat capacities of the elements at the temperature of boiling liquid hydrogen: the discovery of a periodic variation, corresponding with that in atomic volume at ordinary temperatures, is not only surprising but may well prove to be of profound significance in the future interpretation of atomic properties in terms of electronic structure.

Like his great predecessor, Dewar leaves a mass of material to be interpreted by his successors. Unfortunately, he was all too careless in placing his work on record. Like Turner, he painted for his own pleasure, to give expression to his genius—but too often did not put the picture aside for a Ruskin to glory over.

In two essays printed in the Proceedings of the Royal Institution—one on the "Charcoal Vacuum Septennate" (1909), the other on the "High Vacuum Septennate" (1917)—I have briefly summarised his later and chief work at low temperatures; in the latter I also briefly review his work generally as Fullerian professor up to 1917. These essays may serve to guide students. With him, however, we lose a vast unrecorded experience.

Of late years he had returned to a first love—the soap film: it saved his life and was his solace, keeping him from utter despair during the War. He only left it to go to his last bed of sickness. It is to be feared the record of the work is a very imperfect one. Those who were at his last lecture on "Soap Films as Detectors," on the opening of the Friday evenings this year, will not forget the occasion. He was obviously in physical distress and feeble but mentally as alert as ever; the artist was never more to the fore. His appeal was that made in Cory's beautiful *Incantation*.

My sun is stooping westward. Entrancèd Dreamer haste,
There's fruitage in my garden that I would have thee taste.

But he was the "entrancèd Dreamer"—the fruitage he gave us to taste was lovely; nothing so exquisite had before been brought in such perfect form under the public eye. He recalled Young to us; then, playing with a delicate pencil of air upon his liquid lute, he made visible, in hues of the rainbow, the multitude of its melodies, during over a third of his hour. He had never before lingered so long over a single demonstration. He knew that we were gazing upon no mere play of colour but upon a dance of the molecules such as is at the root of life—and death!

How many of us were serious listeners to the message he felt was to be his last, that he was most bent on making, to his urgent appeal on behalf of the Institution which he had served so long, so well, so nobly—was to serve even up to the moment of his death? He will have worked to no purpose if his appeal be unregarded. The fate and future of science in our country is at stake: nothing less. The Egyptians, thousands of years ago, could make worthy provision for the soul of a boy king of eighteen who had done nothing. Surely our civilisation cannot be so backward, so thoughtless, so unmindful of its present peril, that it will not properly maintain an altar and a virile priesthood to keep alive the memory of men like Davy, Faraday and Dewar in the one way they would all wish—by extending their works in the service of mankind, to its salvation.

H. E. A.

Prof. A. S. Butler.

Arthur Stanley Butler, emeritus professor of natural philosophy in the University of St. Andrews, died at his residence at Upper Redpits, Marlow, Bucks, on March 3. He was a worthy scion of a family distinguished in the church, in education, in letters, and in athletics. His grandfather, the Rev. Dr. George Butler, senior wrangler, was the distinguished headmaster of Harrow; one uncle was Dr. Henry Montague Butler, master of Trinity College, Cambridge, whose charm of manner he possessed; another uncle was the well-known Arthur G. Butler, Dean of Oriel, a not undistinguished athlete. His father, the Rev. George Butler, D.D., at one time vice-principal of Cheltenham College, was latterly Canon of Winchester; his mother, Mrs. Josephine Butler, an author, philanthropist, and active pioneer in higher education of women.

Prof. Butler was born on May 17, 1854; educated at Cheltenham and at Exeter College, Oxford (of which his father—a Hertford scholar in his day—had been fellow), where he obtained first class in Moderations (mathematics) and first-class honours in the Final School. After further study at Oxford, at Cambridge in the mechanical workshop under Prof. James Stuart, and at Liverpool, he was appointed to the chair at St. Andrews in 1880.

Prof. Butler's experience, especially at Cambridge, made him realise how desirable it is that students of natural philosophy should carry out some experimental work in addition to attending lectures and class demonstrations. But like his predecessor, Prof. Swan, he had the difficulties of want of accommodation and suitable apparatus. In the first year at St. Andrews a special grant provided him with some necessary apparatus, and in a few years he succeeded in obtaining a good practical laboratory well furnished: and then all his students were required to do some practical work.

As a lecturer Prof. Butler was highly successful. His lectures to the ordinary class were characterised by definiteness, with clear, simple, and eminently helpful expositions from fundamental principles; they were illustrated by most successful class experiments and demonstrations highly appreciated and much enjoyed, and were occasionally illuminated by quiet flashes of kindly wit: these were especially effective on the rare occasions when any student tried to make a disturbance. But probably he was at his best in his honours class, where his theoretical treatment was often very elegant and his demonstrations much to be admired.

Prof. Butler was well read, particularly in geography—he was a medallist of the Royal Geographical Society—Napoleon's Wars, and the Peninsular Campaigns. For many years he did much work as an examiner in Mathematics, Pure and Applied, and in English for the Civil Service Commissioners.

SIR WILLIAM THORBURN, K.B.E., C.B., C.M.G.

THE death of Sir William Thorburn, on March 18, at sixty-one years of age, is a loss which will be severely felt in the obscure fields of neurology and surgery which his scientific mind and clinical acumen did so much to illuminate.

William Thorburn was the eldest son of the late Dr. John Thorburn, professor of obstetrics in the Victoria University of Manchester, and obstetric physician to the Manchester Royal Infirmary. He entered the Owens College (afterwards the Victoria University) in 1876 and had a distinguished academic career. He obtained the B.Sc. London in 1880, the M.B. and B.S. in 1884, taking gold medals in medicine, obstetrics, and surgery, with a scholarship in medicine. He proceeded to the M.D. in 1885 and the F.R.C.S. in 1886. On the death of his father in 1885 he took up surgery and held junior posts until he was elected on the honorary staff of the Royal Infirmary in 1890, becoming full surgeon in 1901 and consulting surgeon in 1920.

With a particularly acute and logical mind influenced by the teachings of the late Prof. James Ross, Sir William Thorburn was early attracted to the problems presented by injuries of the nervous system, and his first contribution to medical literature was a paper on "Obstetrical Paralysis," published in the *Medical Chronicle* in 1886; this was followed by a paper on "Injuries of the Spinal Cord" published in 1887 in *Brain*. In the field of research thus early indicated he was a pioneer, and his work resulted in various publications which have made him for many years past a recognised authority all over the world on the surgery of the spinal cord.

In 1891 Sir William Thorburn obtained the Jacksonian prize of the Royal College of Surgeons and was later Hunterian professor; he was also president of the Neurological Section of the Royal Society of Medicine.

Sir William Thorburn was always interested in medical education; a first-rate teacher himself, he trained many who are now teachers in our medical schools, and was successively surgical tutor, lecturer on surgical pathology, professor and emeritus professor of clinical surgery in the University of Manchester. His wise advice and willing help were of great value to the University, not only in the organisation of surgical teaching but also in its general policy and administration. As an examiner he had great experience, particularly at the Royal College of Surgeons, where he was chairman of the Court of Examiners and at the Universities. During the War he was at first, as lieutenant-colonel, in charge of the surgical division of the Second Western General Hospital, afterwards serving with great distinction as consulting surgeon in France and the Mediterranean. He was knighted in 1919.

Of distinguished personality and strong character, with decided opinions, and a fluent and witty speaker, Sir William Thorburn will long be remembered with affection by all who came under his influence.

Current Topics and Events.

As already announced (p. 439), the Government, at the last moment, in deference to the general protest, dropped its proposal to make a charge for admission to the British Museum. It was agreed in the House of Commons on March 26 to delete the clause in the Fees (Increase) Bill which gave power to the trustees of the museum to make regulations imposing charges for admission. The old Act of Parliament remains in force, under which the British Museum is, in the words of Sir Hans Sloane, "preserved and maintained, not only for the inspection and entertainment of the learned and the curious, but for the general use and benefit of the public to all posterity." The public, which has saved its rights, should be grateful to the trustees that they did not adopt the easier course of accepting the Government proposals. Had they done so they would no doubt have placated a Treasury rightly eager to cut down the estimates. They preferred, as trustees for the nation, to take higher ground. As a consequence it seems probable that they will have to renew the fight for an adequate appropriation, if not on this budget, at all events next year. Let the public, and especially the scientific public, be quite clear on this matter. Nobody will wish to gain his freedom of admission at the cost of hampering the curatorial and scientific work of the museum. But that this would be seriously hampered by any further reduction, there is no doubt. When such items as printing, binding, glass-ware, and cases for storage and exhibition are about doubled in cost, even an amount equal to the pre-war grants is hopelessly inadequate. No cutting down can be tolerated. Let the trustees continue to maintain a firm front in the highest interests of the nation, and they will be assured of national support.

ACCORDING to an evidently inspired article in the *Children's Newspaper* for March 17, Dr. Alfred Daniell, of Edinburgh, author of a well-known "Text-book of the Principles of Physics," has elaborately reconsidered the whole theory of the Michelson-Morley experiment to his satisfaction, and has come to a revolutionary conclusion. Dr. Daniell does not care to debate whether the shift of interference bands expected by Michelson is likely to occur, or whether the smaller value elaborately worked out towards the end of his life by Prof. Righi of Bologna is more likely to be correct. For according to him it is not the shift of bands that is important, but the fact that such bands appear at all. He has convinced himself that in the Michelson experiment no interference bands ought to appear unless there is an enormous relative motion between earth and ether. Hence, from the fact that interference bands do appear in every repetition of the experiment, Dr. Daniell concludes that such relative motion, amounting to 12,000 miles a second, is proved to exist. As the interference part of the Michelson-Morley experiment is of a straightforward and elementary character, it is difficult to understand how Dr. Daniell can have persuaded himself, and can seek to persuade others, that a motion of the ether is necessary in order to account for the appearance of interference bands when a beam of light is split into two halves and afterwards reunited. The premises upon which this deduction is based are not clearly stated in the article, though several equations are given from which it is apparently deduced, but they must include an error which Dr. Daniell has overlooked.

Sir Arthur Keith, in the first of his Hunterian Lectures on "Man's Posture: its Evolution and Disorders," which appears in the *British Medical Journal* of March 17, reviewed the results of recent investigations which throw fresh light on how, when, and where man came by his erect attitude. He pointed out that extinct forms of man indicate that the upright carriage of the head was evolved later than the human form of the lower limb, of which the origin must be sought in Miocene or possibly Eocene times. He distinguished three phases of evolution. In the hylobatic phase the gibbon was differentiated from its cousins, the Old World and New World monkeys, by postural adaptations of bones and muscles in virtue of which it was orthograde and human in type as opposed to the pronograde monkeys. This differentiation probably took place towards the end of the Eocene period. The troglodytic phase was represented by the great anthropoid apes, evolved from the small anthropoids probably in pre-Miocene times. In the plantigrade phase, structural changes were confined almost entirely to the lower limbs. Seeing that man shares so many characters in common with the great anthropoid apes, Sir Arthur Keith held that man must be regarded as one of several aberrant branches of one great stem which began to break up into the various fossil and living forms at the beginning of the Miocene or the end of the Oligocene period.

Visitors to Kew during the next few weeks should make a point of seeing a special exhibit of sports requisites arranged in Museum IV., the Museum devoted to British forestry. In this exhibit are to be seen cricket bats, tennis and badminton rackets, croquet mallets and balls, hockey sticks, and other articles in various stages of manufacture. Special interest is attached to the cricket bat, for, among the many thousands of woods known to science (upwards of 5000 kinds are represented in the Kew collections), no wood has been found that makes a suitable substitute for the best English willow (*Salix cærulea*) for the blades of bats. The material for the handles cannot be grown in the British Isles; that is the product of one or more tropical palms, *Calamus* spp. (Sarawak Cane). The heads of hockey sticks, the frames of tennis and badminton rackets, cricket stumps, and the handles of croquet and polo mallets are made of the best British ash, while croquet balls are often made of beech, and polo balls of willow. Various other articles are shown, but those mentioned suffice to indicate how dependent the sport-loving public is upon the home-grown timber industry.

The Director of the U.S. Coast Geodetic Survey announces that Congress, at its recent session, made an appropriation of two thousand dollars to the State department for the support of the International Latitude Observatory at Ukiah, California, during the fiscal year 1924, or until some other provision is made for that station. In the estimates for the Coast and Geodetic Survey for the fiscal year 1924 there was included an item which, if it had been approved by Congress, would have authorised that bureau to carry on the variation of latitude observations at Ukiah as a part of its regular geodetic work. It is hoped that this authority will be granted during the next session of Congress in order that there may be no possibility of a break in the observations for variation of latitude which have been made continuously at Ukiah for the last twenty-three years.

While the specification and measurement of artificial light has been brought to a very fair state of precision, there has, until recently, been little corresponding advance in dealing with natural illumination. The chief work in this field has been in connexion with the design of windows for schools, and an exhaustive report on this subject was issued by a committee of the Illuminating Engineering Society shortly before the war. A very complete survey of natural lighting, accompanied by an account of some highly interesting methods of measurement, was presented by Messrs. P. J. and J. M. Waldram at the meeting of the Illuminating Engineering Society on March 27. These methods are based on the relation between the value of unrestricted outdoor daylight illumination, and the illumination at a specified point in a room, a factor which should be substantially independent of climatic conditions and should serve as an indication of the access of daylight. Of special interest was the account of methods of estimating the effect of obstructions to light and the predetermination of daylight-access in buildings. These have recently proved extremely valuable in ancient light cases. Mr. J. W. T. Walsh gave some account of the work on parallel lines being done at the National Physical Laboratory, and paid a high tribute to the experimental skill revealed in the paper.

It is stated in *Science* of March 16 that Mr. A. H. Fleming, of Pasadena, for many years president of the board of trustees of the California Institute of Technology, and its chief financial supporter, has recently given the Institute about 840,000*l*. as a permanent endowment fund. This gift, with Mr. Fleming's previous donations, make a total of more than a million sterling, which he has handed over to the Institute. In making this benefaction, Mr. Fleming recommends that the Institute should "specialise in research in chemistry and physics, under the direction of the most competent men obtainable, with the most liberal provision, in the way of salaries and equipment, for the prosecution of such work." He suggests that efforts should be made to seek out and assist "the superior student," and expresses his conviction that "the institute should always remain a privately endowed institution."

The Paris correspondent of the *Times* announces that at a conference presided over by M. Le Trocquer, Minister of Public Works, on March 31, it was decided to recommend that Strasbourg time as well as summer time should be abandoned, but that during the summer trains should run half an hour earlier. It is hoped that work in Government offices will begin half an hour earlier from April 28 to November 3, and that business and manufacturing firms will adopt the same course. The Brussels correspondent of the *Times* reports that the Royal order fixing the establishment of summer time in Belgium for midnight on March 31 has been revoked, pending an agreement with neighbouring countries.

The lectures at the Royal Institution after Easter begin on Tuesday, April 10, when Sir Arthur Keith will deliver the first of a course of four lectures on the machinery of human evolution. On following Tuesday afternoons there will be two lectures by Prof. A. C. Seward on the ice and flowers of Greenland and the arctic vegetation of past ages; and three by Prof. Flinders Petrie on discoveries in Egypt. On Thursday afternoons, commencing April 12, Prof. A. O. Rankine will give two lectures on the transmission of speech by light; there will be three lectures by Prof. J. T. MacGregor-Morris on modern electric lamps, two by Prof. E. G. Coker on engineering problems solved by photo-elastic methods, and one by Sir William Bayliss on the nature of enzyme action. Two Saturday afternoon lectures will be given by Dr. Leonard L. B. Williams, on the physical and physiological foundations of character, and two by Dr. Arthur Hill on the vegetation of the Andes and the New Zealand flora. The Friday evening meetings will be resumed on April 13, when the discourse will be delivered by Prof. W. H. Eccles, on studies from a wireless laboratory. Succeeding discourses will probably be given by Major W. J. S. Lockyer, Prof. C. V. Boys, Prof. F. Soddy, Prof. W. A. Bone, Mr. W. M. Mordey, and Prof. H. A. Lorentz.

The council of the Geological Society has awarded the proceeds of the Daniel Pidgeon Fund for the present year to Mr. Howel Williams, of the University of Liverpool, who proposes to investigate the stratigraphy and vulcanicity of Snowdon.

In view of the need for retrenching expenditure, the Government of India has decided to discontinue the publication of the Journal and Bulletins of Indian Industries and Labour after the issue of Vol. III. Part 1 of the Journal and of the Bulletins which are now in the press.

The Secretary for Mines has appointed a sub-committee of the Explosives in Mines Research Committee to carry out investigations on the means employed for firing explosives. The members are: Sir Frederick L. Nathan, Mr. J. D. Morgan, Mr. W. Rintoul, and Prof. R. V. Wheeler.

The following sympathetic message has been sent by the King and Queen to Lady Dewar through Lord Stamfordham: "The King and Queen have heard with much regret of the death of Sir James Dewar and desire me to express their true sympathy with you in your loss—a loss which will be shared by the whole world of science."

The Prince of Wales has, according to the *British Medical Journal*, signified his intention of being present at a dinner to be held on May 15, to celebrate the one hundred and fiftieth anniversary of the Medical Society of London. Lord Dawson of Penn, president of the Society, will preside, and a gathering widely representative of the medical profession is expected. The Medical Society of London, which was founded by Lettsom in 1773, is the oldest medical society in England; the Royal Medical Society, Edinburgh, is somewhat older, being founded in 1737.

At the annual general meeting of the Ray Society on March 16, the following officers were re-elected:—*President*, Prof. W. C. McIntosh; *Treasurer*, Sir Sidney F. Harmer; *Secretary*, Dr. W. T. Calman. Mr. Joseph Wilson was elected a vice-president, and Mr. C. H. Beston and Mr. H. Taverner were elected new members of council. In the report of the council it was announced that the final part of Prof. McIntosh's "British Marine Annelids" would be published at an early date, forming the issue to subscribers for the year 1921. On behalf of the Society, congratulations were offered to the president on the completion of this monograph, of which the first part was published just half a century ago. The fifth and final volume of the "British Desmidiaceæ," prepared by Dr. Nellie Carter, is now ready for press, and will be issued to subscribers for the year 1922.

The issues of the *New Leader* from February 9 to March 9 contain a series of articles on "The Structure of the Atom," by the Hon. Bertrand Russell. These articles provide an interesting popularisation of modern work in atomic physics. Thus the idea that the universe seems like a clock running down, with no mechanism for winding up again, is compared with the experience of a tribe of insects which live for only a single spring day, and may therefore think it strange that there should be ice in the world, since they would find it always melting and never being formed. The electron moving from one stationary state to another is compared to a flea, which crawls for a time and then hops; or to a man who, when he is insulted, listens quietly for a time, and then suddenly hits out. It is perhaps difficult for a technical reader to assess correctly the value of a popular article, but in this case a high standard appears to have been reached.

THE National Research Council of Japan has commenced the issue of journals dealing with astronomy and geophysics, chemistry, physics, geology and geography, botany, zoology, medical sciences and engineering, at intervals determined by the amount of matter available. The first six of the ten parts of the *Japanese Journal of Physics* for the year 1922 have been issued and cover 48 pages of original contributions, including one on the band spectrum of mercury by Prof. Nagaoka, and 26 pages of abstracts of 71 papers published by Japanese workers, and supplied by the authors themselves. The whole of the Journal is in English, and this fact will lead to a better knowledge and appreciation of the large amount of research work which is now being done in Japan.

THE Australian National Research Council has issued a report of its annual meeting held in Sydney in August last. The council was formed for national and international purposes in January 1921 by the Australian Association for the Advancement of Science, to which body it has to submit a full report of its work and proceedings on the occasion of each meeting of the Association. At the meeting Sir David Orme Masson was elected president of the council in succession to Sir Edgeworth David. Resolutions were passed urging the need for the State endowment of systematic research in the Pacific islands under Australian control, for research work in Australia in respect of refrigeration, and for laboratories to carry out industrial investigation and research. Offers of co-operation with the Commonwealth Institute of Science and Industry in measures for furthering these objects were made, and preliminary steps taken for the inauguration of a publicity campaign for the purpose of securing that the functions, operations, and financial needs of the Institute may be more fully appreciated by the Commonwealth Government, the Legislature, and the public generally. The council has decided to ask the Australian Association to regard it as a fully constituted body free to conduct its own affairs subject to instructions from the International Research Council. The first issue of *Australian Science Abstracts*, published by the Australian Research Council as a quarterly journal of abstracts of papers by Australian scientific workers, appeared on August 1, 1922. An invitation has been issued by the Commonwealth Government through the Research Council to the representatives of the Pan-Pacific Scientific Congress to hold the Congress in Australia in 1923.

THE Third Report of the Council of the National Institute of Agricultural Botany reveals satisfactory progress in the establishment of the work of the Institute upon a firm basis. The appeal for fellows has met with a gratifying response, and special interest attaches to the fact that the Prince of Wales and the Duke of York have consented to become honorary fellows. In the Crop Improvement Branch the conditions have now been settled on which yield trials of cereals will be carried out, and four new barleys were included in the "full trials" in 1922 at four different stations. The final year's trials will be carried out in the same districts in the spring of 1923. Varieties of oats, wheat, grasses, and clovers are all under observation, and the Institute is collaborating with the Plant Testing and Registration Station of the Board of Agriculture for Scotland, in the collection of strains of certain grasses and clovers, with the view of collecting information as a basis for a future scheme of trials and registration. Special research has been carried out by the official Seed Testing Station as to the value of "hard seeds" in clovers, and of the "broken growth" which occurs in germination tests. Increases have been made in the fees charged for seed testing in order to reduce the net cost of operating the station. At the Potato Testing Station, Ormskirk, various trials of immunity, maturity, and yield have been steadily carried on, more than 2000 entries being received for the official immunity tests. Progress has been made in the work of the Potato Synonym Committee, and less synonymous varieties are now being entered for the immunity trials.

THE second Sorby Lecture, delivered in the autumn of 1921 by Prof. C. H. Desch, has recently been published and is entitled "The Services of Henry Clifton Sorby to Metallurgy." As Prof. Desch remarks, Sorby was one of those amateur lovers of science who have played such a remarkable part in the scientific history of this country. Some have been members of noble families, such as Robert Boyle in the seventeenth and Henry Cavendish in the eighteenth centuries. Others have been men of the merchant or professional classes, possessing sufficient means to allow them to follow the bent of their minds. Such were Justice Grove, William Spottiswoode, Edward Schunck, and, greatest of all, Charles Darwin. To this group belonged Sorby. Free from the cares of a profession, he gave himself wholly to science, in the effort to advance which he worked with extraordinary diligence throughout a long life. Sorby was a pioneer in many branches of science, but left it to others to develop his new experimental methods and to fill in the details of his discoveries. His great manipulative skill and patience led him to found at least two new departments of experimental science—microscopical petrography and metallography. Prof. Desch has attempted to discover in the wide range of Sorby's scientific work, some connecting thread among the great diversity of his investigations, and he finds that a prominent motive in his work is the desire to understand the "form" of natural objects, using this word in its widest sense. The address deals, in the main, with that branch of Sorby's work which led to the foundation of metallography as a science. It is based on a careful study of his note-books and specimens, and may be commended to all those interested in this matter, as an impartial and penetrating survey of the subject.

We have received from the Eastman Kodak Company their latest catalogue, No. 9, dated January 1923, of organic chemicals. There are 1500 chemicals listed, with prices, most being products of the Eastman Kodak laboratories.

The latest catalogue (No. 8, 1923) of second-hand books issued by Mr. W. H. Robinson, 4 Nelson Street, Newcastle-on-Tyne, although dealing mainly with works in general literature, contains sections devoted to voyages and travel, folklore, and books relating to the north country. The prices asked appear to be very reasonable.

The announcement list of forthcoming books just received from Messrs. Methuen and Co., Ltd., contains particulars of many works of scientific interest, several of which are translations. Consideration of space permits reference to only a selection of titles. Among the translations are "The Origin of the Continents and Oceans," Prof. A. Wegener, translated, from the third German edition, by J. G. A. Skerl; "The Principle of Relativity," Profs. Einstein, Lorentz, Minkowski, Sommerfeld, and Weyl, translated by Drs. G. B. Jeffrey and W. Perrett; "The New Physics," Prof. A. Haas, translated by Dr. R. W. Lawson; "Atomic Structure and Spectral Lines," Prof. A. Sommerfeld, translated by H. L. Brose; "Recent Developments in Atomic Theory," Prof. L. Graetz, translated by Dr. G. Barr; "Crystals and the Fine-structure of Matter," Prof. F. Rinne, translated by W. S. Stiles; and "The Mechanism and Physiology of Sex Determination," Prof. R. Goldschmidt, translated by Prof. W. J. Dakin. Of the English science books in the list we notice the following: "Interfacial Forces and Phenomena in Physiology," Sir William Bayliss; "A Manual of Histology," Prof. V. H. Mottram; "A Text-book of Intermediate Physics," H. Moore; and "The Vault of Heaven," Sir Richard Gregory.

Our Astronomical Column.

Meteors of March 17.—Mr. W. F. Denning writes to record that several conspicuous meteors were observed on March 17. At 7 h. 9 m. a fireball was seen from near Durham, travelling from a point considerably south of the Pleiades to α Andromedæ. Its motion was slow, and it left a trail which, however, quickly disappeared. The radiant point was probably in Canis Major, near the bright star Sirius.

At 10 h. 8 m. a rather bright meteor of first magnitude was seen by Miss A. Grace Cook at Stowmarket. It passed through the eastern region of Canis Minor and was directed from near β Geminorum. It left a train. The same meteor was seen from Bristol, and it traversed a short path between α and ζ Boötis, the direction being from β Boötis. A comparison of the observations shows the radiant to have been at 309° + 76°, and that the height of the meteor was from 66 to 48 miles over the region of Epsom and Horsham. The shower in Cepheus to which the meteor belonged was seen in the third week of March, both in 1877 and 1887. At this period of the year it supplies rather bright meteors with slow motions and trains. It appears to be an annual display, and a radiant in the same position has been observed at other periods of the year, notably in August, September, and October.

The Brightening of Beta Ceti.—*L'Astronomie* for March gives a few more particulars of the observations of this star in February. Mr. William Abbott telegraphed from Athens on February 14, 10 A.M., to M. Flammarion: "Éclat subit de β Ceti, supérieur à Aldébaran." M. F. Quénisset at Juvisy glimpsed the star on February 18, but mist prevented estimation of its magnitude. But on February 23 the sky in its neighbourhood was remarkably clear, and he could observe the star from 6 P.M. till 6^h 25^m when it disappeared behind a tree near the horizon. He saw it with the naked eye in spite of the bright twilight. *It was at least of the first magnitude* (italics in original). An exact measure was impossible so near the horizon. The magnitude in "connaissance des temps" is 2·24.

On the other hand, Mr. E. O. Tancock (B.A.A. Journ. No. 5) searched for the star by day in a clear sky on February 28 and March 3 without seeing it, though he could see Mira Ceti (estimated magnitude rather fainter than 2). Beta Ceti was lower down, but he considers that he would have seen it if it had still been of magnitude 1 on those days. His observations suggest that the increase of light was short-lived.

Vesta.—Vesta, the brightest of the asteroids, is now an easy object with binoculars, in the middle of the constellation Leo. It is due south at 10 o'clock at the beginning of April. The following ephemeris, by Mr. Bawtree, is from the B.A.A. Handbook for 1923:—

Greenwich Noon.	Mag.	R.A. h. m.	N. Decl.
April 9	6·60	10 43·2	19° 20′
,, 17	6·68	10 41·2	19° 11′
,, 25	6·77	10 41·2	18 49′

The British Astronomical Association is undertaking the work of providing ephemerides of the four brightest asteroids. The B.A.A. Journ. No. 5 contains an ephemeris of Pallas, but as this will be in a much better position for observation in two months, we defer giving its place.

Old Egyptian Water-clocks.—Several ancient time-observations, such as the statement of the equality of day and night at the equinoxes, make it clear that some form of clock was employed. It is therefore interesting to note that casts of two Egyptian water-clocks have lately been presented by the Egyptian Government to the Science Museum, South Kensington. One, from Karnak, dates from the reign of Amenhotep III. (B.C. 1415–1380); the other, from Edfu, is of the Ptolemaic Epoch; in the former, time is measured by the uniform escape of the water; in the latter, by its uniform admission. In each case there are twelve different scales, corresponding to the length of the night or day in different months. Each of these scales is divided into twelve equal parts, showing that an "hour" was at first of variable length, being one-twelfth of the length of the day or night at the particular time of year.

Claudius Ptolemy collected the observed times of the phases of a number of lunar eclipses; these were used by several investigators, including Newcomb, Cowell, and Fotheringham, in studies of the moon's secular acceleration. As the times were presumably observed with some such instruments as those now exhibited, their study is of some astronomical importance.

Research Items.

Early History of the Sioux Tribe.—In the Journal of the Washington Academy of Sciences (vol. xiii. No. 3), under the title of "New Light on Early History of the Siouan Peoples," Dr. J. R. Swanton produces new evidence, largely based on phonetics, of the former distribution of this race. He summarises the results of his inquiries as follows: "The occupancy of the territory of our Middle West between the great Lakes and the Ohio by Siouan tribes seems to rest on grounds almost historical. With the strong indications now at hand there seems reason to think that a close comparative study of the Siouan dialects would enable us to reconstruct the general outlines of their ancient geographical positions with considerable accuracy. If present indications are not deceptive, when that is done we shall find that they fell into four major linguistic groups: a north-eastern, consisting of the ancestors of the later Siouan tribes of Virginia, the Hidatsa, Dakota, Biloxi, and Ofo; a south-eastern, including most of the later Siouan peoples of the two Carolinas; a south-western, composed of the five tribes of Dorsey's Dhegiha group; and a north-western, Dorsey's Teiwere."

High-altitude Mountaineering.—Basing his conclusions on his experiences in climbing Mount Everest, Mr. G. I. Finch discusses the equipment for high-altitude mountaineering in the *Geographical Journal* for March. Up to 21,000 ft. the climber's physical functions were practically unimpaired and good sleep and recuperation from fatigue were possible, but at 23,000 ft. sleep was fitful, appetite fell off, and there was a general loss of physical fitness. The conclusion is that at, say, 22,000 ft. acclimatisation to altitude ceases and above that height oxygen should be used, at first in small doses, and from 26,500 ft. in larger doses, but the dose must depend on the nature of the ground. It must also be remembered that oxygen increases the appetite, and due provision must be made for this. The stimulating effect of cigarette smoke was noted at 25,500 ft. Although greater heights than these were reached without the use of oxygen, Mr. Finch thinks this procedure unwise, and believes that above the acclimatisation level a man must become steadily weaker and unable to recover from fatigue unless he makes use of oxygen. The article contains also some hints on clothing, footgear, and apparatus.

New Plants under Cultivation.—Part II. of Vol. 148 of *Curtis's Botanical Magazine* shows that figures and descriptions under the new editor, and conditions of publication, will maintain a high level. Among the plants described by Dr. Stapf, four are due to the activities of collectors in China; two new Rhododendrons, *R. sulfureum* Franch. and *R. planetum* Balf, a delightful Labiate from Yunnan named by Forrest *Dracocephalum Isabellæ*, and a small-fruited hardy apple *Malus toringoides* Hughes. Two orchids, *Maxillaria Fletcheriana* Rolfe and *Cirrhopetalum tripudians* Parish et Reichenb., two succulents, *Euphorbia anoplia* Stapf (S. Africa) and *Echinocactus undulatus* Dietr. (Mexico), two other African plants, *Amorphophallus coffeatus* Stapf and *Lachenalia convallariodora* Stapf, are described, together with one plant from the Afghan Indian frontier, *Lonicera Griffithii* Hook. f. and Thoms., a honeysuckle that seems to offer some difficulties in cultivation, although it has been grown in an unheated conservatory successfully and with very pleasing results.

British Cytospora.—In the *Kew Bulletin*, No. 1 for 1923, W. B. Grove has provided descriptions of the British species of Cytospora which will be of great value for mycologists, particularly for phytopathologists, as these fungi do considerable damage, especially among fruit trees. Cytospora is the name given to a conidial form, producing upon the branches of the host plant pustules and ultimately roundish discs, from the centre of which conidial discharge is indicated by a black point or little tendril of conidia held together by mucilage. When the full life-cycle can be traced, it will probably be found that all the species can be shown to be stages in the life-history of some Pyrenomycete, such as Valsa, Valsella or Eutypella. The necessary cultural experiments, to connect these conidial stages with their specific ascophorous form, should be carried out during the next few years in the cases where the host plants are cultivated plants of value. The British locality for a large number of the 62 species described is given as Kew Gardens, presumably because suspicious twigs are more frequently removed for expert examination from Kew than from trees that are less closely examined. Mr. Grove's list will, however, be an incentive to a more general study of the British species of Cytospora.

The Oldest Rocks of Maryland.—Following the general trend of opinion as research progresses among pre-Cambrian rocks, Eleanora B. Knopf and Anna T. Jones ("Stratigraphy of the crystalline schists of Pennsylvania and Maryland," *Amer. Journ. Sci.*, vol. 205, p. 40, January 1923) assign a sedimentary origin to the oldest known rocks of Maryland, which are styled the Baltimore gneiss. There is no tendency to revert to the old view that gneisses were deposited from primordial hot solutions. Their layer-structure represents normal sedimentary sheets, in which a complete recrystallisation of the constituents has taken place. Some dynamic metamorphism is traced in portions of the mass; but the principal feature of alteration appears to be due to invasion by a batholitic granite magma, with consequent *lit-par-lit* injection. This fact leads the authors to write of the composite rock as an "intrusive complex of early pre-Cambrian age," an expression that surely misrepresents the general conclusion at which their work arrives. The distribution of metamorphic masses in the local Palæozoic series is anomalous, and the presence of subjacent batholitic invaders is suggested.

A Great Stratigraphical Sequence.—The enormous vertical sections provided by the Grand Cañon of the Colorado River in Arizona remind one of the old-fashioned geological diagrams, in which the succession of known strata was represented as continuous at one spot and based inevitably on a floor of granite. Yet even the 4000 feet of horizontal beds exposed by the stream-cut at Bass Trail tell us nothing of what went on between Cambrian and Devonian times, and include, as Mr. L. F. Noble's detailed study shows, several notable if lesser unconformities. In Professional Paper 131B, United States Geological Survey (1922), Mr. Noble does not confine himself to the Bass Trail section, of which he gives a drawing worthy of reproduction as a lecture-diagram. He provides photographic studies of various unconformities, which the casual visitor would find it difficult to trace, and concludes with the suggestive outlier of Lower and Upper Triassic strata, forming the flat-topped Cedar Mountain, two miles from the cañon edge. His discovery in 1920 of the frond of *Callipteris conferta* in the Hermit Shale is regarded by Mr. White as definitely fixing the Permian age of that formation, which occurs 900 feet below the top bed of the Kaibab Limestone on the cañon rim. The author, despite the possibility of an unconformity at the base of the local Permian, uses the name Carboniferous rather than Permo-Carboniferous for the whole sequence, a course that seems unwise, in view of international usage. Fossils are, on the whole, rare in these splendid sections; but Pennsylvanian and Mississippian strata are both identified, above a small representative of Upper Devonian with Bothriolepis. The whole of the Gotlandian and Ordovician systems are unrepresented, and we pass down into undisturbed Upper Cambrian beds some 900 feet above the stream.

Ranger Oilfield, Texas.—The Ranger Oilfield is situated in the north-west of Eastland County, Texas, and is one of the most important latter-day developments of the great Mid-Continent Oilfield region of the United States. Oil was first struck here in 1917, beginning with the bringing in of the McClesky well at 2000 barrels per day. In 1918 the best wells had an initial production of 6000-7000 barrels of oil, and the total output for that year amounted to more than 6,000,000 barrels. In 1919 the wells collectively made more than 73,000 barrels of oil per day. Since that time a steady production has been maintained, though a noticeable decline is apparently manifest at the present time. The geology and structure of the field have recently been dealt with by Frank Reeves in Bulletin 736-E of the United States Geological Survey. Production is from nine oil-sands occurring in the Strawn Series, Smethwick Shale, and Marble Falls Limestone, all of Pennsylvanian age. The structure is that of very slightly inclined strata, the tilt forming part of the general monoclinal feature of the region as a whole. Locally, low pitching anticlines have been formed which have an important bearing on the accumulation of oil in the rocks involved. The oil obtained from the Ranger field is of a high quality, of mixed base, and has an average specific gravity of 0·84; it yields about 30 per cent. of petrol. It is to be regretted that the bulletin, describing as it does one of the most important oilfields of the south Mid-Continent, is not so well illustrated as many which embrace far less noteworthy properties; in particular the index map is almost unreadable. The large structure maps included at the back of the publication are, however, unusually clear and are of great educational value apart from real technical utility.

Meteorology of the South Atlantic.—Mr. H. H. Clayton makes reference in the U.S. *Monthly Weather Review* for November 1922 to a communication in the monthly bulletin of the Argentine Meteorological Office on the physical condition of the South Atlantic during summer by Mr. R. C. Mossman. The communication was to aid the relief ship sent by the Argentine Government each year to and fro between Buenos Aires and the South Orkneys to carry a party of new observers and to bring back the observers of the previous year from the most southern meteorological station in the world, which has been regularly maintained for the last twenty years. The period dealt with is comprised by December, January, and February. Charts prepared are said to show the position of the controlling high and low atmospheric pressures, and wind-roses are given for each 5° square and for each of the three months. Fog frequencies are stated to be shown for each wind direction. Allusion is especially made to the difference between a fog formed by a warm wind blowing over cold water and a fog produced by a cold wind over water at a higher temperature—the fog in the latter case extending to a much greater height, but the base not always reaching the earth's surface. The British Meteorological Office has thoroughly discussed the weather of the South Atlantic, extending to the South Orkneys, in a volume of monthly charts (M.O. No. 168) published twenty years ago.

The Roar of the Mountain.—A presidential address to the Washington Academy of Sciences was given on January 9 by Prof. W. J. Humphreys of the U.S. Weather Bureau, entitled "The Murmur of the Forest and the Roar of the Mountain," which is reproduced in Vol. 13, No. 4, of the Journal. Reference is made to historical instances recognised as of weather significance through past ages, and the roaring of the mountain is taken as an indication of a general storm within six to twelve hours. The particular region dealt with is the Gap Mills valley of Monroe County, West Virginia, but the discussion has common reference to mountain meteorology. It is shown how occasionally there are strong winds simultaneously up both sides of a high mountain ridge, and it is asserted that when there is an appreciable wind from the mountain there is often a lighter surface wind in the opposite direction up portions of the mountain itself. With tempest winds the conditions are said to be much like the Helm Wind along the west side of the Pennine range. Reference is made to the familiar singing or humming of telegraph or telephone wires. The tree and forest sounds are said not to be due to the elasticity of the twigs and branches but, as in the case of the singing telegraph wires, to the instability of the vortex sheets their obstruction introduces into the air as it rushes by them. The pitch of the æolian murmur of a forest is said to be essentially that of its average twig, and though the note of the twig may be inaudible at close quarters, the forest may often be heard miles away. Cloud and humidity are dealt with, as are also rain and snow.

A Luminescent Chemical Change.—An interesting example of luminescence occasioned by chemical change in solution, which is said to be more intense than the usual experiment involving the oxidation of pyrogallol, is described by W. V. Evans and R. T. Dufford in the February number of the Journal of the American Chemical Society. A solution of *p*-bromophenyl magnesium bromide in ether is prepared by the Grignard reaction between 2·4 grams of magnesium and 23·6 grams of *p*-dibromobenzene in 130 c.c. of dry ether, with a little iodine. The solution exhibits luminescence which can be observed in daylight when shaken in a test-tube in an atmosphere of oxygen. The luminescence spectrum lies between λ5200 and λ3500.

Innocuous Metol.—It is well known that metol, which is one of the most popular of photographic developers, suffers from the grave disadvantage that if it is allowed to come into contact with the hands it may cause persistent and exceedingly irritable sores. Mr. W. F. A. Ermen, of the British Dyestuffs Corporation, finds that almost certainly this is not due to metol itself. In a paper read before the Royal Photographic Society on March 20 (*British Journal of Photography*, March 23) Mr. Ermen gave details of the five principal methods for the manufacture of metol which the Corporation tried in 1916. A method of German origin, by the interaction of methylamine and hydroquinone, gave a very good preparation with extreme ease, but caused severe outbreaks of poisoning in both the laboratories and the works. This result was traced to the presence in the metol so prepared of the very soluble and extremely poisonous symmetrical dimethyl-paraphenylene-diamine. The metol prepared by the Lapworth process proved to be quite innocuous.

American Association Meeting at Boston.

THE seventy-sixth meeting of the American Association for the Advancement of Science was held at Boston on December 26-30. Several of the addresses delivered by presidents of sections have appeared in recent issues of *Science*, and brief accounts of some of them are subjoined.

Physics and Geometry.

In his address to Section A (Mathematics) Prof. Oswald Veblen discussed some of the aspects of postulational geometry in reference to the developments of physics during the last twenty years.

In the classical branches of physics the main elements of the abstract point of view have been implicit in them for a long time. When it is stated with sufficient clearness in physical terms what is meant by undefined elements, unproved propositions, and so on, it is often found that a physicist classifies these as truisms of little importance. So far as practical results are concerned he is justified in this attitude during the earlier and cruder stages of physical theory. But experience is showing that when the results of a more refined experimental technique force a reconsideration of fundamental assumptions, the technique of the study of these assumptions must undergo a corresponding refinement. A recent illustration is afforded by Einstein's theory of gravitation, which accounts for certain observed physical phenomena by casting aside the familiar conception of space and time in favour of a new one, which is just as self-consistent and capable of logical development.

Beginning with elementary geometry, the oldest branch of physics, there is a sequence of statements arranged in a certain logical order, but void of all physical meaning. In order to apply them to Nature, the undefined terms (points, lines, etc.) are identified as names of recognisable objects. The unproved propositions (axioms) are then given a meaning, and when this meaning can be identified with a true statement the theorems which are logical consequences are also true, and the abstract geometry takes its place as a useful branch of physics.

For kinematics it is necessary to have a theory of time: the undefined terms are "instant" and "before" or "after," and the postulates one of the sets of postulates for the linear continuum. The main theorem is that there is a continuous one-to-one correspondence between the instants of time and the numbers of a real number system.

Prof. Veblen has also formulated a set of postulates for "mass" or "substance," observing that the postulates proposed may contain both omissions and redundancies. They have merely been advanced to emphasise the fact that very little work has yet been done in this direction.

Allurements in Physics.

In his address to Section B (Physics) Prof. G. W. Stewart, of the University of Iowa, president of the section, dealt with the attractive nature of some of the problems of physics at the present time.

The investigation of atomic structure becomes so exciting that we may easily forget the absence of clearness in some of our hypotheses. The static theories have the advantage that they give clear pictures of the atoms which can be used in discussion of the physical and chemical properties of the elements as they appear in periodic groups and of the compounds they form. The orbital theories, on the other hand, have been most successful in explaining the spectra of hydrogen and helium, and, by the help of a further hypothesis, the spectra of the alkali metals. In his most recent work Bohr has departed from the simplicity of his original hypotheses and has endeavoured, by assuming electron orbits which may be circular, elliptical, or highly elliptical, and penetrate each other in many ways, to construct systems which would have the properties of the elements of the periodic table. Although this method of attacking the problem is not so rigorous, Prof. Stewart thinks it will prove more fruitful than that of the statical theories.

Acoustics receives little attention from physicists of the present day, but Prof. Stewart points out its allurements, and refers with keen appreciation to the work of the late Prof. W. C. Sabine of Harvard on the acoustics of buildings, which is only just becoming known in Great Britain. The problem of the best angle for a conical horn seems nearing solution and the conception of the instrument as a collector of sound replaced by the proper conception of it as a resonator.

Gas Ionisation and Resonance Potentials.

An address on this subject was given to Section C (Chemistry) by Prof. W. A. Noyes of the University of Chicago. The ionisation potential is the fall of potential through which an electron must move to acquire speed enough to drive out of an atom of a gas on which it impinges one of its outer electrons, known as valence electrons, and the resonance potential is the fall through which an electron must move to acquire speed enough to displace an electron of an atom from an inner to an outer ring of electrons. The two potentials should, according to the Bohr theory of the atom, be connected in a simple way with the spectrum of the gas, and many measurements have recently been made to test this theoretical conclusion. The agreement is not so satisfactory as one would desire, and there is considerable difficulty in interpreting the values of the potentials found in experiment in terms of changes in the atoms. Prof. Noyes thinks, however, that it is along these lines that our knowledge of atomic structure and of the mechanism of chemical combination will develop in the future.

Geology's Debt to the Mineral Industry.

Dr. Willet G. Miller, president of the Section E (Geology and Geography), selected as the subject of his presidential address, "Geology's Debt to the Mineral Industry." He explained that, throughout the history of its development, the progress of the science of geology has been helped to a large extent by work connected with the mineral industry. Werner and his disciples did much for the science of geology in its early development by their investigations of earth-structure as revealed in mines. William Smith, the English civil engineer, whose great work as the "father of geology" is so well known, established the principles of stratigraphical geology as a by-product of his work on engineering problems. He complained that the theory of geology was in possession of one class of men, the practice with another. Logan, the great pioneer of field studies in Canada, especially in the pre-Cambrian areas, declared that for many years he was engaged in coal-mining and copper-smelting, and that his connexion with geology related largely to its economic aspects.

After Logan's time little progress was made in pre-Cambrian studies in Canada until after the discovery of ore-bodies at Sudbury, Cobalt, and Porcupine in Ontario. Meanwhile, on the United States side of the border such advance as was made was the outcome of studies connected with extensive and important developments in the mining of iron ore and copper ore in that region. Indeed, both in its inception and throughout its history the prime motive underlying the work of the United States Geological Survey has been an economic one; and that Survey furnishes an excellent example of the valuable scientific work made possible only by the great utility of the organisation by which it was carried out. Other examples could be given, and Dr. Miller mentions particularly that of South Africa, where the science of geology profited immensely as a result of the establishment of diamond-mining and gold-mining industries.

Dr. Miller had no difficulty at all in showing that geology owes a great debt to the mineral industry. His address will be read with much interest by that ever-increasing band of workers who feel, as he feels, that science and art should be mutually helpful and not distrustful of one another, and that a genuine scientific worker does not necessarily sacrifice dignity by carrying out investigations the results of which are likely to be useful.

Structure and Origin of the Plant Gall.

Prof. Melville T. Cook devoted his address, as president of Section G (Botany), to the subject of plant galls, and thus rendered a service to the workers in a field where literature is very scattered. In America, as in Europe, this study has been shared between entomologists, bacteriologists, mycologists, and other students of plants, and a general comprehensive account is difficult to find; from this address it appears that there is still much work to be done, progress probably having been delayed by the specialist angle from which each investigator has approached the problem.

The old idea that the gall arose as the result of a special fluid excreted by the insect as it punctured the plant has long been discredited; but although it is known that the gall tissue develops *pari passu* with the growth of the larva from the deposited egg, there is very little information as to how the larva reacts upon the plant tissue and whether the effect is produced by mechanical or chemical agencies. The reaction evidently depends in part upon the plant tissue affected, and Prof. Cook lays great stress upon the fact that it is usually only meristematic tissue which is stimulated to abnormal growth; but bearing in mind the conditions under which cork meristem arises in the plant as the result of a wound, it seems probable that in a living tissue the capacity for meristematic activity will usually be found in the proximity of the potential gall-former.

Küster, in 1911, divided gall tissues into abnormal growths, consisting only of parenchyma, the kataplasmas, and growths undergoing further differentiation of tissue, the prosoplasmas. Prof. Cook, and also Wells, have developed this original classification indicating that the more highly developed prosoplasm is a more specialised form of growth which has had its "kataplasmic" stage; the most complex types, such as the Cynipid galls, actually showing differentiation into four zones arranged concentrically around the larval irritant. Galls of fungoid or bacterial origin are also discussed in the light of this description of types of insect galls, and it will interest British botanists to find that Prof. Cook has evidently an open mind as to the analogy drawn by Dr. Erwin F. Smith between the crown gall caused by *Bacterium tumefaciens* and the malignant growths found in the animal. He is evidently inclined to regard Dr. Smith's "embryomas," arising at a distance from the original infection, as due to the disturbance of normal functional activity in the host, just as in the case of the formation of aerial tubers upon the potato as the result of the attack of *Rhizoctonia Solani*.

The Mining Industry of Canada.

Dr. J. B. Tyrrell selected the history of Canadian mining for the subject of his presidential address to Section M (Engineering). In such an address the details of so wide a subject cannot of course be dealt with, but Dr. Tyrrell gave a very clear outline of the general course of progress of the Canadian mining industry. Necessarily, in so doing he has included much interesting information on the development of Canadian metallurgy, for it is impossible to separate these two arts when tracing the history of either in any particular new country, any more than they can be divorced when considering the early history of human civilisation as a whole.

The records of Canadian mining commence as early as 1576 with Frobisher's attempt to find gold on the shores of the bay that now bears his name. Better success attended later efforts to work the commoner minerals, and the history of true mining in Canada may be said to date from the discovery of coal near Sydney, Cape Breton, in 1672, which laid the foundation of the important coal-mining industry and perhaps even more important iron and steel manufacture of the Maritime Provinces. Dr. Tyrrell chronicles the discovery of bog iron ore in the province of Quebec about the middle of the 17th century, and the erection of a blast furnace to smelt this ore in 1737. So far as iron is concerned, the history stops with the erection of charcoal furnaces in Ontario in 1810, followed by another in 1813 in Norfolk County, which remained in blast until 1847. It is to be regretted that Dr. Tyrrell did not carry this particular industry somewhat further. An interesting chapter would be furnished, for example, by the attempts to utilise the iron sands along the north shore of the St. Lawrence: these were discovered in 1767, when a Mr. Molson of Montreal built forges of the Catalan type to smelt them; but his enterprise was commercially unsuccessful though he made good iron, and it closed down after a life of nine years. The same fate attended attempts made afterwards by others, among whom was Dr. Sterry Hunt. A charcoal blast furnace was erected early in the 19th century at Londonderry, Nova Scotia, where a brand of pig-iron, which at one time had a great reputation under the name of Acadian pig-iron, was smelted from ores consisting chiefly of brown hæmatite and ankerite. At this place the first coke blast furnace in Canada was built about 1876 by the Steel Company of Canada, Ltd. Afterwards attempts were made to utilise the interesting fossil ore of Nictaux in the Annapolis Valley, Nova Scotia, but now the important iron industry of this province relies upon the magnificent Wabana ore brought across from Newfoundland.

Dr. Tyrrell describes well and clearly the modern developments in Canadian mining, which he dates from the construction of the Canadian Pacific Railway in 1885, and shows good grounds for his conclusion that in mining "our country offers a field for extensive and intensive research second to none in the world," though he justly emphasises the need for a thorough scientific training for those who are to take the lead in future developments.

Experimental Production of Green and Colourless Hydra.

W. GOETSCH, of Munich, has carried out a series of experiments on Hydra, and has published the results in some half-dozen short papers, two of which form the subject of this notice (*Die Naturwissenschaften*, pp. 202-205, 867-871, 1922). Specimens of Hydra are either green, brown, or grey, and these are regarded by most authors as belonging to distinct species or even genera, though in certain cases the brown and grey are difficult to distinguish. Goetsch points out that the brown and green may also be difficult to distinguish, for some of the former can take green algæ into their endoderm cells and form a symbiotic union similar to that long known in green Hydra.

Goetsch obtained from a warmed tank in the Botanic Garden in Nymphenburg some brown Hydra which showed pathological features, and when he fed these with algæ they developed a green colour first around the mouth, then in the foot region, and finally in the intervening portion, so that in about a fortnight the entire animal had an intense green colour. The spread of the algæ was accompanied by a progressive diminution in the size of the Hydras so that they had difficulty in capturing their prey, the reserve material of the interstitial cells degenerated, and budding ceased. These green examples disappeared from the aquarium, but a few which remained in culture vessels were fed with freshly killed Daphnia and were thus carried through their abnormal condition. The reciprocal toleration between the Hydra and the alga soon becomes an intimate association. Afterwards these Hydra produced buds containing the green algæ, and some of them showed ovaries or testes—apparently two were males and two were females.

It is impossible to determine whether the specimens are *H. attenuata* or *H. vulgaris*. The alga in these green specimens is (as in the true green Chlorohydra) a Chlorella, but differs from that in Chlorohydra in being twice as large, and in being situated in the distal end of the endoderm cells, whereas in Chlorohydra the algæ are near the base of the endoderm cells. These green examples differ further from Chlorohydra in that the symbiosis is easily lost; if the green specimens are kept in the dark or cold the green colour disappears with the exception of a small amount around the base of the tentacles, but on transferring the specimens to better conditions the algæ begin to multiply again. Specimens kept four weeks in darkness lost every trace of their algæ; the only way to make these green again was to introduce into them fresh algæ contained in crushed pieces of green specimens enclosed in the carapace of a Daphnia.

Goetsch suggests that this brown Hydra is a new mutant, and that with the origin of this mutant capable of receiving the algæ in the warm house in the Botanic Garden the conditions were for the first time favourable for the institution of the symbiosis. This union cannot be maintained through the cold of winter, and is not transmitted through the egg. In Nature the Hydras would probably not have come through the first attack by the algæ, for those in the cultures owed their survival to artificial help. If a brown and a green specimen of the same species be cut into two and a brown piece and a green piece be joined together by means of a hair, there is a gradual extension of the algæ into the previously uninfected part.

The problem of the production of colourless specimens from the green Chlorohydra has also been attacked by Goetsch. Colourless examples were obtained by Whitney by placing Chlorohydra in weak glycerine, which caused the endoderm cells to expel their algæ. Hadzi kept Chlorohydra in the dark and they produced eggs without algæ, and he thus obtained alga-free examples one of which was reared. Goetsch kept Chlorohydra under unfavourable conditions—cold, darkness, and lack of calcium—to suppress the growth of the algæ, and then liberally fed the Hydra so that their cells multiplied so quickly that the algæ could not keep pace. After a few weeks of such treatment the buds produced were of a paler colour, especially in the middle region of the body. As this is the region where asexual reproduction takes place, offspring were eventually obtained free from algæ. These whitish specimens are more feeble than green examples, and require careful treatment. A spontaneous return of colour in these white specimens has not occurred, although some of them have lived for four months in the light.

Deep green and colourless pieces were joined together and the spread of the green algæ was studied. Algæ thrust out of the endoderm cells of the green part are taken up with other food by the endoderm cells of the other part, so that after a few days the whitish part begins to exhibit a green colour, even at places distant from the junction. If a bud is formed at the junction of the two pieces it may be half green and half white. Such a bud affords strong evidence against the purely ectodermal origin of buds.

University and Educational Intelligence.

Aberdeen.—At the spring graduation held on March 28, Sir George Adam Smith, the vice-chancellor, presiding, the degree of LL.D., *honoris causa*, was conferred on Sir William H. Beveridge, director of the London School of Economics; Dr. E. W. Hobson, Sadleirian professor of pure mathematics, University of Cambridge; Dr. W. Mackie, of Elgin, distinguished by his researches on the geology of the north-east of Scotland; Sir George H. Makin, consulting surgeon to St. Thomas's Hospital; and Prof. C. Niven, emeritus-professor of natural philosophy, University of Aberdeen.

The degree of Doctor of Science (D.Sc.) has been conferred on Dr. J. L. Rosedale for a thesis—"On the Hydrolysis of the Proteins of Flesh."

The Senatus Academicus has appointed Prof. Matthew Hay to represent the University at the Pasteur centenary celebrations to be held in Paris and Strasbourg in May.

Prof. Kruyt, Utrecht University, will deliver a university lecture in the faculty of science on May 11.

Durham.—Prof. H. Louis, at present professor of mining and surveying, and William Cochrane lecturer in metallurgy at Armstrong College, will vacate his appointments on September 30, 1923, on reaching the retiring age. Prof. G. Poole, of the University of Leeds, has been appointed as professor of mining. This appointment was made by the council on the recommendation of a joint committee of the College and the Durham and Northumberland Coal Trades Association. Dr. J. A. Smythe, at present senior lecturer in chemistry, will take over the William Cochrane lectureship in metallurgy; other arrangements are being made in connexion with the surveying teaching, formerly under the supervision of Prof. Louis.

Prof. R. F. A. Hoernlé, professor of philosophy, has now left England to take up his appointment as professor of philosophy in the University of Johannesburg. The council of Armstrong College will proceed to the appointment of a successor to take up office in October.

Prof. G. H. Thomson, professor of education, and joint author with Dr. William Brown of the "Essentials of Mental Measurement," has been invited by the Teachers' College, Columbia University, New York, to spend next academic year there, delivering advanced courses on psychology. The council of Armstrong College has granted him a year's leave for this purpose.

LONDON.—Presentation Day will be held in the Royal Albert Hall, on Thursday, May 3.

The degree of D.Sc. in biochemistry has been conferred on Miss K. H. Coward, an internal student, of University College, for a thesis entitled "The Formation of Vitamin A in Plant Tissues."

Applications are invited for the Astor chair of pure mathematics tenable at University College, in succession to Prof. M. J. M. Hill, retired. The latest date for the receipt of applications, by the Academic Registrar, University of London, South Kensington, S.W.7 (12 from each candidate) is May 24.

MANCHESTER.—The trustees of the Dickinson scholarships, open to medical students and graduates of the University, have announced the conditions and regulations. The scholarships are as follows: (i.) research travelling scholarship in medicine, of the value of 300*l*. for one year, awarded annually; the scholar is required to spend at least ten months abroad and undertake there original investigation; (ii.) anatomy scholarship (25*l*. for one year), to be awarded to the most distinguished first-year anatomy student; (iii.) surgery scholarship (75*l*. for one year, offered in alternate years to a scholarship in pathology), open to medical graduates of the University; the scholar must devote himself to original investigation; and (iv.) pathology scholarship (75*l*. for one year), on the same lines as the surgery scholarship. Full particulars are to be obtained from Mr. Frank G. Hazell, Secretary to the Dickinson Trustees, The Royal Infirmary, Manchester.

OXFORD.—A fund amounting to nearly 2000*l*. has been raised to provide a memorial of the late Sir William Osler, Regius professor of medicine. It has been decided to place a memorial bronze plaque in the University Museum, and to award a medal every five years to a graduate of the University who has made some distinguished contribution to medical science. It is also desired to provide a fund to assist teachers in the University to travel for purposes connected with medical knowledge and research. For this latter object further contributions are required; these should be sent to Mr. A. P. Dodds-Parker, 2 Holywell, Oxford.

The professor of pathology, Dr. G. Dreyer, has been appointed to represent the University at the forthcoming celebration at Paris and Strasbourg of the centenary of the birth of Pasteur.

Mr. M. E. Shaw, of New College, has been elected Radcliffe travelling fellow. The Radcliffe prize has been awarded to Dr. A. D. Gardner, University College, sometime Radcliffe travelling fellow.

The Matteucci gold medal, conferred as a posthumous honour by the International Research Council at Brussels in 1919 on the late Mr. H. G. Moseley, of Trinity College, has been received at Oxford and delivered to his mother, Mrs. Sollas.

The governing body of Exeter College will hold an election in the summer term to a research fellowship of 200*l*. a year, free of income tax, tenable for 5 years. Candidates, who must be members of the University of Oxford of at least B.A. standing, must send in applications by May 15 to the rector, who will supply further details.

Societies and Academies.

LONDON.

Geological Society, February 16.—Prof. A. C. Seward, president, in the chair.—A. C. **Seward**: The earlier records of plant-life (presidential address). Reference was made to the views of Dr. Church on the origin of life in the waters of a primeval world-ocean, and on the origin of terrestrial vegetation from highly-organised Algæ transferred by emergence of portions of the earth's crust above the surface of the water. The vegetation of the land may have received additions from upraised portions of the crust at more than one epoch in the history of the earth. The course of evolution is probably more correctly illustrated by the conception of separate lines of development, than by that of a branching tree implying the common origin of the main groups of plants. The unfolding of plant-life must be considered in relation to the changing geological background. Diffusion-phenomena, as illustrated by the so-called Liesegang figures, possibly explain the origin of some of the structures which are usually attributed to organic agency. We have no knowledge of any Pre-Cambrian land-flora. The phyla of Lycopods and Ferns are regarded as independently-evolved groups. The wide geographical range of Archæopteris was emphasised, and reference was made to the difficult problems raised by the occurrence of Upper Devonian floras well within the Arctic circle, at least equal (in the variety of the plants and in the vigorous development of the vegetation) to the more southern floras of Ireland, Belgium, and other regions.

March 14.—Prof. A. C. Seward, president, in the chair.—E. M. **Anderson**: The geology of the schists of the Schichallion district of Perthshire. Between Carn Mairg and Schichallion the succession is:—graphite-schist: pebbly quartzite: mica-schist: non-pebbly quartzite: schichallion boulder-bed. Following the boulder-bed, and thus on the same side of the quartzite, are a white limestone, a banded series of siliceous and micaceous rocks, a grey carbonaceous limestone, and a slightly carbonaceous mica-schist, which may be named the grey schist. On approach to the white limestone the boulder-bed becomes highly calcareous. This conglomerate is probably a tillite, and has been partly formed from the material of the limestone. There may thus be a chronological sequence, of which the oldest visible member is the grey schist, extending upwards to the Ben Ledi grits in an adjoining part of Perthshire. In the northern part of the Schichallion district the Dalradian series is bordered by the Struan flags. The junction is probably not an unconformity, but either a normal fault which has been affected by strong horizontal movement, or else a folded thrust.—H. H. **Read**: The petrology of the Arnage district in Aberdeenshire: a study of assimilation. The modification of magmas by the incorporation of material of sedimentary origin is here termed contamination. In the Arnage mass in Aberdeenshire the sediments concerned in contamination are: (*a*) andalusite-schists and pebbly grits of the Fyvie series; and (*b*) biotite-schists and subordinate hornblende-schists of the Ellon series. The contaminated rocks occur as a roof-zone, some hundreds of feet thick, overlying a sheet of norite rich in magnesia, and are of four types. Assuming that the initial magma was normal gabbro, the contamination-process depends on reciprocal reaction between initial magma and xenoliths, whereby the magma loses magnesia and lime and becomes richer in alumina and alkalies, the final results of the reciprocal reaction being the granitic Ardlethen type of contaminated rock and certain xenoliths extremely rich in magnesia and lime. The modified xenoliths sink in the acidified magma of the contaminated zone; they pass into the underlying sheet of initial gabbro, which becomes enriched in magnesia and lime, with the formation of the norite now seen beneath the contaminated zone. The chemical variation in the contamination-process is exactly the same as that in igneous rocks as a whole. Reciprocal reaction may play a part in magmatic differentiation, especially in the great gabbro-sheets.

Mineralogical Society, March 13.—Dr. A. Hutchinson, president, in the chair.—A. **Hutchinson**: A graphical method of correcting specific gravity determinations. A diagram is given by which the correction for air displacement and reduction to 4° C. can be read off directly.—A. **Brammall** and H. F. **Harwood**: The Dartmoor granite (Widecombe area). Field evidence and analyses support the conclusion that the granite is a composite laccolite and that four successive stages of intrusion are recorded by (1) dark and relatively basic granites scantily exposed and by certain cognate xenoliths resembling basic segregations; (2) a more acid granite which caps many tors and yields mineral evidence of having assimilated country rock; (3) a still more acid granite intrusive into the latter; (4) minor acid intrusions. Felspars, garnet, cordierite, etc. are described, and evidence for differentiation is given.—C. E. **Tilley**: Genesis of rhombic pyroxene in thermal metamorphism; mineral associations and the phase rule. Free-silica hypersthene-bearing hornfelses of sedimentary origin can be divided into a calcic and non-calcic group, and considered as derived from a normal shale hornfels by increments either of CaO, (MgO + FeO), or less commonly K_2O. Silica-poor hypersthene hornfelses can be derived from the free-silica types, and the hypersthene is then frequently accompanied by spinel. The derivation of all these hornfelses can be graphically expressed in systems of three or four components. The hypersthene is derived from the chlorite in the original sedimentary rocks subjected to metamorphism. Hypersthene arises when enstatite, augite, or amphibole-bearing igneous rocks enter contact aureoles. Rhombic pyroxene is produced by contamination of gabbroic rocks.—C. S. **Garnett**: (1) On a peculiar chlorite-rock at Ible, Derbyshire. A band in the dolerite sill at Ible is completely altered to a foliated mass of chlorite, with associated veins of fibrous chlorite (resembling chrysotile in appearance). The analyses and characters of this material are compared with those of "epichlorite." (2) The dissociation of dolomite. Dissociation is inappreciable up to 625°, and at 898° it is complete. The temperature-dissociation curve is continuous.—J. G. C. **Leech**: Occurrences of rutile, brookite, and anatase in the St. Austell granite. These minerals occur in the red pneumatolysed granites of the area, the mode of occurrence being essentially the same as that recorded for Dartmoor occurrences of these minerals.

Linnean Society, March 15.—Dr. A. Smith Woodward, president, in the chair.—J. **Parkin**: The strobilus theory of Angiospermous descent. The idea that the flower has evolved by reduction from a bisexual cone of a special type is elaborated. This Anthostrobilus is characterised by having the microsporophylls borne on the axis invariably below the megasporophylls; it is peculiar to the Angiosperms, Bennettitales, and Gnetales. From the Pteridosperms, strobilate plants arose either (1) by the segregation of the two kinds of sporophylls into unisexual cones, or (2) by their aggregation into one and the same cone. The Anthostrobilus may have been called into being through the substitution of insect-pollination for wind-pollination. The Angiosperms are regarded as a monophyletic group and the Monocotyledons as of monophyletic origin from the Dicotyledons and of Ranalian extraction. The 8-nucleate sac is taken as primitive for Angiosperms. A return to the Ranales as the starting-point for the evolutionary study of the flower is advocated.

Aristotelian Society, March 19.—Prof. A. N. Whitehead, president, in the chair.—Miss H. D. **Oakeley**: Prof. Wildon Carr's Theory of Monads. The importance as well as the difficulties of this theory lie in its attempt to combine into a unity the points of view of idealism and of creative evolution. The means by which the two viewpoints are brought into unity is the concept of reality as activity. The theory raises complex and many-sided problems in regard to a monad's knowledge, the nature of the material world, inter-monadic intercourse and the ultimate reality within or beyond experience. The problem of knowledge is conceived by Prof. Carr from the point of view of relativity and the doctrine of perspectives. The material universe results from the dichotomy of experience essential to activity, for activity can be conceived only as an opposition of antithetical forces. "Activity" is the core of the metaphysical theory. It is the reality of the monad, and its first expression is the æsthetic creative production of images. The doctrine of the monadic nature of reality is based on intuition, but Prof. Carr claims that modern science confirms his view, arguing that science must postulate that monads constitute the real, in order to make its results fully intelligible. Knowledge according to the theory must be perspective in form, and this also is supported by arguments from modern scientific relativity.

Royal Microscopical Society, March 21.—Prof. F. J. Cheshire, president, in the chair.—M. T. **Denne**: An improved apparatus for the production of photomicrographs. The apparatus consists of a bed made up of two heavy rectangular metal bars, upon which slides a carriage, one end of which is shaped to act as support for the microscope lens system, a separate microscope not being used. The carriage also bears one end of the camera bellows, and an optical bench for the below-stage apparatus. The head of the camera with dark slide fitting is fixed at one extremity of the bed itself. The eyepiece of the microscope is brought through the orifice of the plate-holder fitting, when adjustments may be made, the camera bellows being collapsed over the body of the microscope. For metallurgical work the usual vertical illuminator is employed with a right-angle prism arranged above the main optical axis. The apparatus is compact, although giving 800 mm. camera extension, and, since it is not necessary to swing the microscope out of the axis for preliminary adjustments, difficulties due to decentralisation are eliminated.—A. C. **Thaysen** and H. J. **Bunker**: The destruction of cellulose fibres and fabrics by micro-organisms and the importance of the microscope in the study of this destruction. Destruction of fibres such as cotton and flax involves vast sums of money; the United States Department of Agriculture place the annual damage to American cotton, on this account, at seventy million dollars. Different types of cotton are differently affected. All true Indian cottons appear to deteriorate quickly, at a rate which is constant. American cottons are far more resistant, but they also show a constancy in their rate of deterioration. The greater resistance of American cottons appears to be due to at least two factors: the absence of food, and some more positive factor. This latter appears to be affected by climatic conditions, since American cottons grown in India show, on the addition of food material, an accelerated rate of deterioration. Selective breeding might possibly assist in the isolation of strains of cotton resistant to bacterial attack.—E. **Hatschek**: The standard methods of ultra-microscopy. The methods of making visible those particles small compared with the wave-length of light (100 $\mu\mu$ and less) fall into two classes: (1) illumination at right angles to the axis of the microscope (Zsigmondy-Siedentopff ultra-microscope and Jentzsch ultra-condenser), and (2) axial illumination so arranged that direct light is totally reflected at the cover glass (dark ground condensers, *e.g.* paraboloid, cardioid, concentric, etc.). The performance of the slit ultra-microscope was discussed.

Royal Meteorological Society, March 21.—Dr. C. Chree, president, in the chair.—G. M. B. **Dobson**: Characteristics of the atmosphere up to 200 km., as obtained from observations of meteors. The rate of heating and evaporation of a meteor depends on the air density. Nearly all the kinetic energy of the meteor is finally radiated as visible light, and thus observations of a meteor's total brightness and velocity give its mass. Hence from the observed characteristics of meteors it is possible to calculate the density of the air at the height of their appearance and disappearance. The rate of change of density with height will indicate the air temperature. From eye observations of meteors the temperature of the air is about 220° a. (−63° F.) up to 50 km., thus agreeing with the results of *ballon sondes*. Above 60 km. the temperature is about 300° a. (81° F.), and the density at 100 km. is about 100 times greater than that usually calculated on the assumption of a uniform temperature of 220° a. The high temperature is presumably due to the absorption of solar radiation by the air in addition to terrestrial and atmospheric radiation, due possibly to the presence of ozone formed at great heights by the sun's ultra-violet light. There is indirect evidence of an annual variation of air temperature.

Dublin.

Royal Dublin Society, February 27.—Prof. J. A. Scott in the chair.—P. A. **Murphy**: On the cause of rolling in potato foliage; and on some further insect carriers of the leaf-roll disease. The mechanism of rolling of potato foliage as caused by leaf-roll, and incidentally by some other diseases and injuries, is discussed. The cause of rolling in the cases investigated is the distension of the spongy parenchyma following the accumulation of carbohydrate in the leaves. The activities of a capsid (*Calocoris bipunctatus*), a jassid (*Typhlocyba ulmi*), and an aphis (*Myzus Persicæ*) which develops on the sprouts of unplanted tubers, in carrying leaf-roll are discussed. —John J. **Dowling**: The recording ultramicrometer: its theory and applications. The theoretical principles of the device, together with a description of some experimental investigations into the conditions of operation, are discussed. The degree of sensitivity attained under ordinary laboratory conditions is 10^{-7} cm.; this being strictly reproducible and the apparatus quite easy to operate. The operation of the apparatus at still higher sensitivities requires special precautions, such as screening and the like.

March 27.—Prof. J. A. Scott in the chair.—R. L. **Praeger**: Catalogue of scientific and technical periodicals in Dublin libraries. A card-index catalogue showing all the scientific periodicals available in Dublin has been prepared by a special committee. In each case the extent of the sets in each library is shown, together with any breaks which occur. Thus it is possible to ascertain if any number of any periodical, whether current or extinct, is available in Dublin, and where it is to be found. It is proposed to endeavour to improve the supply of such literature by suggesting the discontinuance of some periodicals which are unnecessarily reduplicated and their replacement by others at present unavailable.—W. R. G. **Atkins**: The hydrogen ion concentration of the soil in relation to the flower colour of *Hydrangea hortensis* W., and the availability of iron. The hydrangea produces blue flowers when grown in acid soil, since iron salts are absorbed in larger amounts and react with the pink flower pigment. Iron is absorbed by plants mainly in the ferrous condition, for at ordinary soil P_H values ferric iron is completely precipitated. Ferrous salts are not completely precipitated at $P_H 7$. The lessened solubility in alkaline soils is considered in relation to chlorosis. Iron pan formation is connected with the oxidation of the ferrous hydroxide precipitated when acid soil solution percolates to a region of higher P_H value.—H. G. **Becker** and E. F. **Pearson**: Irregularities in the rate of solution of oxygen by water. A form of apparatus is described which permits the process of absorption to be observed continuously by means of a sensitive water manometer, the temperature being maintained constant to 0·1° C. The results obtained show that during the early stages, absorption follows a logarithmic curve very closely, but after the gas-content has risen to about 70 per cent. of saturation the absorption tends to become irregular. This indicates that the force producing the slow mixing during the early stages tends to become very small, and therefore uncertain in its action towards saturation.

Paris.

Academy of Sciences, March 12.—M. Albin Haller in the chair.—Luigi **Bianchi**: A kinematic property of W surfaces.—M. Jules Bordet was elected a foreign associate in succession to the late M. Ciamician, and M. J. Cornet corresponding member of the section of mineralogy in succession to M. W. C. Brögger, elected foreign associate.—**Mordoukhay-Boltovskoy**: The logarithm of an algebraic number.—M. **Hadamard**: Remarks on the preceding communication.—M. **Mandelbrojt**: Taylor's series with gaps.—M. **Malaval**: Hardening (of metals). Metals can be hardened not only by longitudinal extension (Seigle) but also by compression, and the latter method was applied in 1912 to a gun, with good results.—Georges **Darmois**: The local integration of Einstein's equations (interior problem).—M. **Cisotti**: Plane movements of liquids endowed with viscosity.—D. **Eginitis**: The reform of the calendar in Greece. A discussion of the political and ecclesiastical difficulties attending the reform of the calendar in Greece.—M. **de Broglie** and E. **Friedel**: The diffraction of the X-rays by smectic bodies. The smectic state is defined as one in which the molecules, having a common direction, are distributed along parallel equidistant surfaces. Such substances should act on X-rays like the system of parallel reticular planes of a crystal. In confirmation of these views experiments on the diffraction of X-rays by solutions of sodium oleate are described. Combined with the experimental figures of P. V. Wells, these results form the first direct measurement of the wave length of the X-rays starting with optical wave lengths, and without making use of either Avogadro's constant or Planck's constant.—J. **Cabrera**: The limits of K absorption of some elements. Results are given for a group of sixteen elements, mainly from the rare earths.—M. **Volmar**:

The photolysis of tartaric acid and the acid alcohols. Solutions of tartaric acid exposed to ultraviolet light give off gas containing carbon dioxide (66 per cent.), carbon monoxide (10 per cent.), hydrogen (21 per cent.), and hydrocarbons. The solution contains an aldehyde and small quantities of a substance resembling the hexoses.—Pierre **Steiner**: The ultraviolet absorption spectrum of veratrol and vanillin. The absorption curve of veratrol resembles that of pyrocatechol: the introduction of two methyl groups into the pyrocatechol molecule has only a slight influence on the spectrum.—Victor **Henri** and E. **Walter**: The law of the distribution of the bands in the ultraviolet absorption spectrum of the vapour of toluene.—Armand **Castille** and F. W. **Klingstedt**: The ultraviolet absorption spectra of benzoic acid and of the three oxybenzoic acids. The ortho- and meta-oxybenzoic acids give nearly the same spectrum, but the para acid shows marked differences in the number and appearance of the absorption bands.—M. **Bourguel**: The preparation of true acetylenic hydrocarbons. Sodium amide removes hydrobromic acid from many brominated hydrocarbons. The reaction can be followed by titrating the ammonia evolved; the yields are good, and there is no tendency to polymerisation of the acetylene derivative.—M. **Lespieau**: The dinitrile of β-oxyglutaric acid, $CN . CH_2 . CH(OH) . CH_2 . CN$.—P. **Diénert**: Subterranean circulation of water in fissured ground.—M. **Solignac**: The tectonic of the country of the Mogods, the plateau of Hédil and of northern Bejaoua (Northern Tunis).—E. **Bauer** and A. **Danjon**: Atmospheric absorption on Mont Blanc.—Jean **Dybowski**: A new industrial force: the utilisation of the heat furnished by thermal springs. A suggestion that the hot water from thermal springs might be utilised for forcing fruit and plants under glass.—P. **Bugnon**: The number of cotyledons of Ficaria. *Ficaria ranunculoides* has been regarded by different authors as containing two, one, or no cotyledons, and the true number has an important bearing on the theory of the origin of the monocotyledons. Ficaria possesses two leaf organs having the same anatomical connexions with the root as the two cotyledons of the dicotyledonous species of the same family: the most plausible hypothesis is that Ficaria is heterocotyledonous.—Marcel **Mirande**: The nature of the secretion of the sterinoplasts of the white lily. The central body of the sterinoplasts is a lipoid solution of phytosterol.—M. **Trabut**: Carpoxeny and bud mutation in cultivated Citrus.—J. **Feytaud**: A plan of campaign against the Doryphore of the potato.—A. **Demolon** and P. **Boischot**: Researches on the assimilability of phosphatic manures. A saturated solution of carbon dioxide was used to dissolve the soluble phosphate, and special attention was given to the effect of the presence of calcium carbonate on the amounts of phosphorus extracted from various types of phosphatic manure.—H. **Hérissey**: The reversibility of the ferment action of α-*d*-mannosidase.—Marcel **Baudouin**: Radiography applied to the study of the lesions of prehistoric human bones. Human remains of the polished stone age have been submitted to radiographic examination with interesting results. Fractures in bones have been detected, certain congenital lesions identified, also a case of chronic osteoarthritis, and two traumatisms due to foreign bodies, one of which is undoubtedly a sharpened flint.—André **Broca** and Jean **Comandon**: The representation of movement in pictures.—Jacques **Pellegrin**: New contribution to the ichthyological fauna of the fresh waters of Morocco.—H. **Bordier**: The influence of diathermic d'Arsonvalisation on the endocrinic glands. Application to the treatment of Basedow's disease. This method of treatment, of which the technique is described, has been applied with success to several cases of exophthalmic goitre.

Diary of Societies.

SATURDAY, April 7.

Gilbert White Fellowship (Annual General Meeting) (at 6 Queen Square, W.C.1), at 2.—Sir David Prain: Presidential Address.

MONDAY, April 9.

Victoria Institute (at Central Buildings, Westminster), at 4.30.—A. Hiorth: Irrigation of Palestine.
Royal Institution of Great Britain, at 5.—General Meeting.
Society of Engineers, Inc. (at Geological Society), at 5.30.—T. Exley-Fisher: The Work of the Labour Corps in France during the War, with Particular Reference to the 178 Labour Company.
Royal Institute of British Architects, at 8.—H. M. Fletcher: The Architecture of Provincial France.
Aristotelian Society (at University of London Club), at 8.—Prof. C. D. Broad: The Natural Meaning of the Unconscious.
Royal Society of Arts, at 8.—E. Kilburn Scott: The Fixation of Nitrogen (1) (Cantor Lectures).
Society of Chemical Industry (London Section) (at Engineers' Club, 39 Coventry Street), at 8.—S. S. Zilva and J. C. Drummond: The Cod Liver Oil Industry of Newfoundland.—E. W. Blair, T. S. Wheeler, and J. Reilly: A Study of the Separation of the Gases formed in the N-butyl-alcohol-acetone Fermentation Process.
Royal Geographical Society (at Æolian Hall), at 8.30.—P. Bigelow: Geographical Influences bearing upon Japan and her Neighbours.
Institution of Rubber Industry (at Engineers' Club, Coventry Street).—Dr. D. F. Twiss: Rubber Pigments.

TUESDAY, April 10.

Royal Institution of Great Britain, at 3.—Sir Arthur Keith: The Machinery of Human Evolution (1). Nature of the Machinery.
Society for the Study of Inebriety (at Medical Society of London), at 4.—Dr. W. M. Feldman and others: Discussion on Racial Aspects of Alcoholism.
Institution of Petroleum Technologists (at Royal Society of Arts), at 5.30.—A. E. Chambers: Potrero No. 4. A History of One of Mexico's Earliest and Largest Wells.
Zoological Society of London, at 5.30.—Dr. G. M. Vevers: Notes on a Recent Visit to Zoological Gardens in Holland and Belgium.—Prof. K. Kostanecki: A Remnant of the Omphalo-mesenteric Arteries in the Manatee.—Dr. C. F. Sonntag: The Anatomy, Physiology, and Pathology of the Chimpanzee.
Institution of Civil Engineers, at 6.—A. Binns: The King George V. Dock, London.
Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—H. M. Cartwright: Study of Bichromated Gelatine with reference to Photogravure.—W. Clark: The Reduction Centres of a Silver Bromide Emulsion.
Röntgen Society (at Institution of Electrical Engineers), at 8.15.—M. A. Codd: A New Method of Operating Induction Coils.

WEDNESDAY, April 11.

Royal Society of Arts, at 4.30.—E. Parnell: The Resources and Trade of Sarawak.
Institution of Electrical Engineers (Wireless Section), at 6.—Dr. N. W. McLachlan: The Application of a Revolving Magnetic Drum to Electric Relays, Siphon Recorders, and Radio Transmitting Keys.
Institution of Automobile Engineers, at 7.30.—C. W. J. Taffs: Railless Trolley Traction.

THURSDAY, April 12.

Royal Institution of Great Britain, at 3.—Prof. A. O. Rankine: The Transmission of Speech by Light (1).
Institution of Electrical Engineers, at 6.—A. G. Warren: The X-ray Examination of Materials.
Optical Society (at Imperial College of Science and Technology), at 7.30.—F. Twyman: The Hilger Microscope Interferometer.—A. Whitwell: The Form of the Wave Surface of Refraction.—J. H. Barton: A New Research Microscope of Original Design.
Institute of Metals (London Local Section) (Annual General Meeting) (at Institute of Marine Engineers, Inc.), at 8.—Dr. S. W. Smith: The Surface Tension of Metals.
Camera Club, at 8.15.—E. A. Robins: The Edible Crab.

FRIDAY, April 13.

Royal Astronomical Society, at 5.
Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Madder-stained Specimens illustrating the Process of Bone-growth.
Malacological Society of London (at Linnean Society), at 6.
Junior Institution of Engineers, at 7.30.—C. B. Clapham: Instrument Equipment of Aeroplanes.
Royal Photographic Society of Great Britain, at 8.—J. R. H. Weaver: Cathedrals of Northern Spain.
Royal Institution of Great Britain, at 9.—Prof. W. H. Eccles: Studies from a Wireless Laboratory.

PUBLIC LECTURE.

TUESDAY, April 10.

Gresham College (Basinghall Street), at 6.—W. H. Wagstaff: Geometry. (Succeeding lectures on April 11, 12, and 13.)

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

*"To the solid ground
Of Nature trusts the mind which builds for aye."*—WORDSWORTH.

No. 2789, Vol. 111] SATURDAY, APRIL 14, 1923 [Price One Shilling

Registered as a Newspaper at the General Post Office.]

ROYAL INSTITUTION OF GREAT BRITAIN,

21 ALBEMARLE STREET, W.1.

GENERAL COURSES OF LECTURES AFTER EASTER, 1923.

At Three o'clock.

Sir Arthur Keith, F.R.S., "The Machinery of Human Evolution." Tuesdays, April 10, 17, 24, May 1.

Professor A. C. Seward, F.R.S., "The Ice and Flowers of Greenland," and "Arctic Vegetation of Past Ages." Tuesdays, May 8, 15.

Professor W. M. Flinders Petrie, F.R.S., "Discoveries in Egypt." Tuesdays, May 22, 29, June 5.

Professor A. O. Rankine, "The Transmission of Speech by Light." Thursdays, April 12, 19.

Professor J. T. MacGregor-Morris, "Modern Electric Lamps." Thursdays, April 26, May 3, 10.

Professor E. G. Coker, F.R.S., "Engineering Problems solved by Photoelastic Methods." Thursdays, May 17, 24.

Sir William M. Bayliss, F.R.S., "The Nature of Enzyme Action." Thursdays, May 31, June 7.

Sir Owen Seaman, "Sonnets and Ballads of Dante Rossetti." Saturdays, April 14, 21.

Dr. Leonard L. M. Williams, "The Physical and Physiological Foundations of Character." Saturdays, April 28, May 5.

Mr. John B. McEwen, "Dance Music," "Harmonic Evolution," "Musical Education." Saturdays, May 12, 19, 26.

Dr. Arthur W. Hill, F.R.S., "The Vegetation of the Andes," "The New Zealand Flora." Saturdays, June 2, 9.

Subscription (non-Members) to all Courses of Lectures (excepting the Friday Evening Discourses and the Juvenile Lectures), Four Guineas. Subscription to a Single Course, Two Guineas or One Guinea.

The Friday meetings will begin on April 13 at 9 P.M., when Dr. W. H. Eccles will give a Discourse on "Studies from a Wireless Laboratory." Succeeding Discourses will probably be given by Mr. W. J. S. Lockyer, Mr. C. V. Boys, Professor F. Soddy, Professor W. A. Bone, Mr. W. M. Mordey, Sir Aston Webb, Professor H. A. Lorentz, and Miss Joan Evans.

Information as to Membership and other matters connected with the Institution can be had at the Secretarial Office, 21 Albemarle Street, W.1.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

DEPARTMENT OF OPTICAL ENGINEERING AND APPLIED OPTICS.

A Special Course of Six Weekly Lectures on "The Polarisation of Light and Some of its Technical Applications," by Professor F. J. CHESHIRE, C.B.E., F.Inst.P., P.R.M.S., commencing on Monday, April 30, at 6.30 P.M.

The Petrological Microscope will receive special attention in these Lectures.

For admission tickets application should be made to the Registrar at the above address, or the fee may be paid at the first lecture. Fee, 10s.

UNIVERSITY OF ABERDEEN.

BLACKWELL PRIZE ESSAY.

THE BLACKWELL PRIZE of THIRTY POUNDS, open to Unrestricted Competition, will be awarded in 1924 for the Best Essay, provided the Trustees are of opinion it is of a sufficiently high standard, on "The History of the Fishing Industry of the Port of Aberdeen since 1800."

Essays must be lodged with the Secretary of the University on or before January 1, 1924.

Each Essay must bear a motto, and be accompanied by a sealed envelope bearing the same motto, and enclosing the name and address of the writer.

H. J. BUTCHART, Secretary.

BEDFORD COLLEGE FOR WOMEN

(UNIVERSITY OF LONDON).

POST-GRADUATE SCHOLARSHIP.

The Council of Bedford College for Women invite applications for a POST-GRADUATE SCHOLARSHIP in SCIENCE to be awarded in June 1923. Open to graduates of Bedford College only. Value £125 a year for two years.

For further information apply to the Secretary, Bedford College, Regent's Park, N.W.1.

UNIVERSITY OF LONDON.

DIXON FUND.

Applications for grants from the DIXON FUND for assisting scientific investigations, accompanied by the names and addresses of two references, must be made to the Academic Registrar, University of London, South Kensington, S.W.7 (from whom further particulars may be obtained) before May 15, 1923.

CHELSEA POLYTECHNIC,

CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.**
Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.**
Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.**
Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

Easter Term begins on April 17.

SIDNEY SKINNER, M.A., Principal.

Telephone: Kensington 809.

BATTERSEA POLYTECHNIC.

LONDON, S.W.11.

Principal—Robert H. Pickard, D.Sc., F.R.S.

COURSES FOR WOMEN.

Full-time day courses for women preparing to be teachers of Domestic Subjects.

Preparation for posts as Institutional Matrons and Housekeepers and for colonial and home life.

Full-time day courses of training for Women Health Visitors and Infant Welfare Workers.

Evening courses of training for Sanitary Inspectors, Health Visitors, Meat and Food Inspectors, Smoke Inspectors, etc.

Day and Evening courses in Art, Music, and Domestic Science.

Hostels for Women Students. Large Athletic Ground and numerous clubs and societies.

NATIONAL UNION OF SCIENTIFIC WORKERS.

The Aim of the NATIONAL UNION of SCIENTIFIC WORKERS is to bring together into one professional organisation all qualified scientific workers, viz.:

Those engaged (*a*) In Higher Educational and Research Institutions.
(*b*) In Industry and Consultative Practice.
(*c*) In State and Municipal Scientific Departments.

Applications for membership are invited from all scientific workers with university degree or equivalent professional qualification. Further particulars may be obtained from

THE GENERAL SECRETARY, N.U.S.W.,
25 Victoria Street, S.W.1.

TO SCIENTISTS AND RESEARCH STUDENTS.

THE INTERNATIONAL BIBLIOGRAPHICAL SERVICE BUREAU,

employed by British Government Departments, University Professors, etc., supplies complete Continental and American bibliographies on any scientific, literary, or medical subject. Chemical work a speciality. Extracts made.

Headquarters: Vienna. English representative: "Alexandrian," 1A Longridge Road, Earl's Court, S.W.5.

UNIVERSITY OF LEEDS.

DEPARTMENT OF MATHEMATICS.

The Council will shortly proceed to the appointment of an ASSISTANT LECTURER in the DEPARTMENT OF MATHEMATICS. Duties to begin October 1. Salary £350 to £400 a year, in accordance with qualifications and experience. It is desirable, but not essential, that the selected candidate shall possess a competent knowledge of the higher portions of some branch of Applied Mathematics. Applications, stating academic career and subjects of special study, together with testimonials (one copy) and references, should reach the Registrar, The University, Leeds, on or before April 27, 1923.

Research in Animal Nutrition.

THE recent munificent gift of 100,000*l.* made by Sir Alfred Yarrow to the Royal Society is a tribute to the service of science to industry from a great manufacturer. It is somewhat astonishing, however, how little money has been gifted for research work into agricultural problems, in view of the fact that animal husbandry, with the occupations that depend directly upon it, is the most important industry in this country, and that, in spite of the large home production of animal foods, it is still necessary to import to a value of more than 200,000,000*l.* per annum without even then meeting fully the demands for some of those animal products.

We are probably correct in stating that in no other industry has so little been done in Great Britain to develop the scientific side, to find out the most economical methods of feeding, to reduce the relatively enormous mortality among many kinds of stock, to investigate the true nutritive value of the raw materials of feeding stuffs and the processes by which they are converted into the commercial finished product. It is true that Rothamsted is a monument to a brilliant pioneer in agricultural research, but for long this institute stood practically alone. It was not until the establishment of the Development Commission in 1911, which was appointed with the object of developing rural industries, that any real effort was made to improve this disastrous state of things. The Commissioners came to the very rational conclusion that one of the most essential things was a national scheme of research in agriculture.

As the result of full inquiry the Commissioners determined to establish two centres for the study of animal nutrition, one at the School of Agriculture at Cambridge under Prof. T. B. Wood, and the other at Aberdeen in connexion with the North of Scotland College of Agriculture and the University of Aberdeen. At Cambridge advantage was taken of an already existing and excellent research organisation, which was assisted financially and developed. At Aberdeen, however, a new institution had to be established. The amount of the capital outlay was estimated at 40,000*l.* to 50,000*l.*, and of this sum 20,000*l.* was obtained from the Development Commission.

In spite of this splendid grant, if it had not been for the very public-spirited action of Dr. John Quiller Rowett, who promised an initial subscription of 10,000*l.* and a further contribution if necessary, it is probable that the establishment of the institute might have been delayed for years for lack of funds. It is fitting that the name of this generous donor, who was willing to support this experimental institute before its capacity to undertake research was proved, should be for all time associated with it. All who are interested not only directly in agriculture, but also indirectly in food production generally, are under a deep debt of gratitude to Dr. Rowett. It is pleasant to record that the example of Dr. Rowett has already stimulated an Aberdeen donor, Mr. Walter A. Reid, to give 5000*l.* towards the development of the library and the statistical department of the Rowett Institute.

The food troubles of the War ought to have brought it home to all that British agriculture was in a parlous state. Great Britain may be able to raise the finest horses and cattle in the world, but nevertheless our agriculture in general is in a backward condition. Sir Thomas Middleton before the war drew a most interesting series of comparisons showing the effect of the application of science between agriculture in Great Britain and in Germany, where the soil is inferior to ours. From each 100 acres of land the German farmer obtained 33 tons of corn to the British 15, 55 tons of potatoes to the British 11, 28 tons of milk to the British 17½, and even 4½ tons of meat to the British 4.

Research in Great Britain in other branches of science would have been in a poor state if it had had to rely in the past on support from public funds. We owe much of our outstanding position in various sciences to gifts from far-sighted private benefactors. Surely agriculture, which becomes the hobby of so many of our successful business men, ought to attract the necessary funds to assist in the investigation of problems of really national importance. There is abundant opening both at the Rowett Institute and at Cambridge for generous donors to assist, for example, by the institution of experimental farms on a large scale at these institutes. Such practical workshops as experimental farms are essential to demonstrate to the so-called "practical" agriculturist that there are ways better than his own of doing things, that will convince him, for example, that there is such a thing as the hygiene of the cowhouse and byre. Men talking and lecturing about the possibilities of doing things properly will not suffice; there must be actual demonstration of the value of the suggested change. The soil breeds an individual slow to convince, but facts tell. As Dr. Orr, the director of the Rowett Institute, has shown, even in the short time the work has been running at Aberdeen, such farms can be made to pay their way. The pig farm he established last year already shows a positive financial balance.

It must not be forgotten, too, that indirectly from these experiments on farm animals there will eventually emerge a great body of knowledge of direct use in the solution of human nutritional problems. Dr. Rowett, when conveying his donation to the Aberdeen Institute, definitely recognised this fact, and even stipulated that so far as possible the nutrition of man as well as that of animals should be kept in view.

As there is no institute or laboratory devoted to the investigation of the nutrition of man in Great Britain, these animal stations will have to be depended upon for a great deal of the information we now lack on mineral metabolism, to take a single outstanding example of a neglected field of study. We trust, therefore, that generous provision will be made for the maintenance and extension of the valuable research work on problems of nutrition being carried on at Aberdeen and Cambridge.

The King's English.

Notes on the Composition of Scientific Papers. By the Rt. Hon. Sir T. Clifford Allbutt. Third edition. Pp. xii+192. (London: Macmillan and Co., Ltd., 1923.) 6*s.* net.

SIR CLIFFORD ALLBUTT, the author of this little book, informs us in the preface that he has occasion in his capacity as a member of the Medical Faculty of the University of Cambridge to read, in the course of each academic year, some seventy or eighty theses which are presented for the degree of M.B. and about thirty which are offered for that of M.D. Of the value of such theses, as indicative of the prospective graduates' attainments or ability, there is a difference of opinion. Considering the usual age and opportunities of the candidates, and their limited professional experience, the theses are necessarily, for the most part, mere compilations culled from text-books, or from the records of cases in the medical journals. But, however limited their value, we are disposed to agree with Sir Clifford Allbutt that they serve a useful purpose. The search through the literature is of itself a salutary and desirable regimen. It serves to concentrate the student's attention on a single subject, and ends by making him a better informed man on that particular subject than he otherwise would be. Of course, much depends upon the choice of the subject. Sir Clifford's experience is that, on the whole, the candidates choose wisely. He tells us that the matter of these theses is good, often excellent. What he complains of is the manner of their presentation. In composition some are fair, and a few are good, but the greater number are written badly, some very ill indeed. "The prevailing defect of their composition is not mere inelegance: were it so, it were unworthy of educated men; it is such as to perplex, and even to travesty or to hide the author's meaning."

The purpose of Sir Clifford Allbutt's book is to direct attention to these faults of "style" and of literary composition, in the hope that candidates for medical degrees may avoid the many solecisms which their theses too frequently display. It is easy to see how they arise. The art of literary composition is seldom a part of the school training of a youth. If it is taught at all it is too frequently dealt with by a master who has no real aptitude for literary craftsmanship, whose knowledge of our literature is limited, and whose critical faculty is not very acute. To bring out the best that is in a boy, to "enthuse" him with the subject, requires a teacher of rare gifts, of wide reading, knowledge, and experience. It is far easier to teach mathematics, or the elements of physical science, or even such subjects as history or a modern language, than it is to inculcate the best method of handling such a rich and flexible language as English in written composition. The consequence is that literary composition occupies, as a rule, a very subordinate position in the curriculum of a school, and the youth enters upon his higher education or even upon his life's work with a very limited experience of the richness and beauty of his mother-tongue and with little or no knowledge how properly to deal with it.

Sir Clifford Allbutt's strictures are based mainly upon his experience of the graduation theses of medical students, but they are no less applicable to the composition of scientific papers in general. The man of science, as a rule, springs from the same class as that which furnishes the medical man, and their upbringing and scholastic training are identical. It is therefore to be expected that they should both suffer from the same disabilities. Hence the author is fully justified in the selection of the more comprehensive title which he has attached to his work. A very limited experience of the periodical literature of science affords ample proof of the relevancy of his criticisms. Scientific memoirs are too frequently mere transcripts of laboratory journals, with no proper attempt at selection, logical arrangement, economy of expression, lucidity, unity, or simplicity—the cardinal virtues which Sir Clifford Allbutt rightly insists should characterise all literature.

The book is evidently the result of much careful study of contemporary scientific literature, and it is replete with illustrations and examples of faults in literary composition to be found in scientific communications. The author's criticism is in the main constructive. If he points out a solecism, as a rule he shows how it should be avoided. At times, although he would doubtless deprecate the implication, he appears to be a little hypercritical and over-fastidious, and some exception might justly be taken to his ruling. The fact is the English language is not standardised, and it is contrary to its genius and to its progressive nature that it should be. Its character is largely determined by use and wont, and by the example and influence of the acknowledged masters of literary craftsmanship. There is no established standard of style. "The style is the man." The styles of Johnson and Addison, of Ruskin and Carlyle are as wide apart as the poles: they are individualistic and characteristic of the men. It is this variety which serves to make our language the noble instrument that it is.

He who constitutes himself a literary censor, and takes up an *ex cathedra* attitude in the matter of literary composition, especially in the case of a language such as English, needs to be very sure of his ground and to walk warily. Years ago a certain Dean of Canterbury was constrained to publish a little book on the "Queen's English." That book was somewhat pitilessly handled by Mr. Washington Moon in a rejoinder entitled the "Dean's English." This episode should be a warning to those who would rush in where angels may well fear to tread. Sir Clifford Allbutt has certainly the courage of his opinions and is not slow to tell us of his likes and dislikes, but even he, like the great Homer himself, sometimes nods, and lays himself open to rebutting criticism. At the same time, his book is well worthy of the attention and careful study of all who seek to write correctly, and with a pious regard to the splendid inheritance they possess in their mother-tongue.

Eastern Tibet.

Travels of a Consular Officer in Eastern Tibet: together with a History of the Relations between China, Tibet, and India. By Eric Teichmann. Pp. xxiv + 248 + 64 plates + 8 maps. (Cambridge: At the University Press, 1922.) 25*s.* net.

EASTERN Tibet remains the least known part of Asia in spite of its exceptionally interesting problems. An important contribution to its geography has now been made as one of the indirect results of the British expedition to Lhasa in 1904. The Chinese then feared the annexation of Tibet to India, and to avert this danger immediately sent an agent to Eastern Tibet; in the following year, this "Amban" and his escort were massacred, and several French missionaries were murdered at their stations along the Tibetan frontier. To suppress the revolt Chao-erh-feng invaded the country, and Chinese authority was established and agents reinstalled in Lhasa.

Chao-erh-feng was a man of remarkable capacity, and he secured the personal trust of the Tibetans by a policy which protected them from the tyranny of the lamas, and by the severity with which he punished any ill-conduct by his own soldiers. During his rule the Chinese position in Tibet was secure. When the Manchu Dynasty was tottering he was recalled eastward and made Viceroy of Szechuan. He was executed in Cheng-fu, the capital of that province, by the revolutionists in 1911, after a heroic effort to maintain the old government. The author fully recognises the genius of Chao-erh-feng, whom he describes as "one of China's greatest Empire builders," and says that "with him passed away Chinese ascendancy over Tibet." He adds that Chao-erh-feng's justice and fair dealing are still remembered. This tribute to the great Chinese administrator is the more weighty as the author's sympathies are rather pro-Tibetan.

After Chao-erh-feng's death Chinese rule in Tibet promptly collapsed. The Tibetans in 1912–13 recovered most of the lost country, and after a five years' truce resumed their eastward advance in 1918. There was then no Chinese force available for the defence of Western China, but there can be little doubt that if the Tibetans had seized some of the territory they coveted, the Chinese would reconquer it as soon as the internal difficulties in China are smoothed down. To avoid a prolonged war between Tibet and China, the British Government used its influence to secure a peaceful settlement. Mr. Eric Teichmann, then the British Consul at Ta-tsien-lu, acted as the local mediator, and in this volume he tells the story of the Tibeto-Chinese war and negotiations, and describes the journeys he made during his efforts to arrange peace. By great tact and patience he persuaded both sides to accept a temporary arrangement which may be ultimately adopted without loss of prestige to either side. He induced them to revert to the frontier which had been recognised from 1727–1905. During these negotiations Mr. Teichmann had exceptional opportunities for travel in unknown parts of Eastern Tibet. He is an enthusiastic and capable geographer, and made the best of his chances. The volume in which he records his experiences and observations will remain one of the standard works on the geography of East Central Asia.

The district including most of his routes lies north of the Ta-shueh-shan or Great Snow Mountains, which rise on the northern side of the famous road from China to Lhasa. From the foot of these mountains extends a vast tract of down country about 13,000 ft. above sea level; it is dissected by valleys from 2000 to 3000 ft. deep, and rises into high snow-covered ranges of which the heights and relations are unknown. Mr. Coales, the author's predecessor at Ta-tsien-lu, has shown that the country is largely composed of red sandstone and limestone. This view is confirmed by Mr. Teichmann; but there is no evidence as to which of four possible series this limestone belongs, and without further information as to the geological structure and trend of the snow-capped mountains, the fundamental structure of the country remains uncertain. Mr. Teichmann's careful observations are the more useful owing to the excellent index. There are numerous photographs, a series of seven sketch maps, and a large map of Eastern Tibet reprinted from the *Geographical Journal*.

J. W. G.

Hereditary Diseases of the Eye.

University of London: Francis Galton Laboratory for National Eugenics. Eugenics Laboratory Memoirs, 21. *The Treasury of Human Inheritance.* Vol. II.: Anomalies and Diseases of the Eye. Nettleship Memorial Volume. Part I.: Retinitis pigmentosa and allied diseases; Congenital stationary night-blindness; Glioma retinæ. By Julia Bell. With a Memoir of Edward Nettleship by Dr. J. B. Lawford. Pp. xv+123+26 plates. (Cambridge: At the University Press, 1922.) 45*s*. net.

All students of genetics will welcome the resumption of publication of "The Treasury of Human Inheritance," interrupted, like so many other scientific researches, by the War. Prof. Karl Pearson has now been able to issue Part I. of the Nettleship Memorial Volume, devoted to retinitis pigmentosa and allied diseases, congenital stationary night-blindness, and glioma retinæ. The report on and pedigrees of these diseases is preceded by a memoir of Edward Nettleship, written by his old colleague, Dr. J. B. Lawford. Nettleship was a fine example of the combination of clinician and researcher, which, to the honour of British medicine, has been frequent in this country and perhaps especially frequent in the department of ophthalmology. Dr. Lawford has well brought out Edward Nettleship's sterling qualities, which added lustre to a family distinguished in the fields of pure scholarship and philosophy. Nettleship possessed, to a very eminent degree, the patience, powers of observation, and natural sagacity which are essential to success in the investigation of problems of inheritance. His career adds one more to the numerous proofs that arduous medical practice is no barrier to distinguished success in pure science.

The composition of the work was entrusted to Dr. Julia Bell, who has acquitted herself admirably. The discussion of the genealogical material is preceded in each case by an historical and anatomical account of the anomaly in question which, while scientifically adequate and strictly impartial, is intelligible to the educated layman. The pedigree plates maintain the very high standard of achievement set by former publications of the Galton Laboratory. With the exception of glioma retinæ—a rare and malignant disease—few of the conditions here dealt with threaten life, while nearly all of them so greatly interfere with the comfort of existence—in some cases making it impossible for the victim to follow his profession—that their recognition is frequent. It would therefore be expected that a large amount of genealogical material should be available. Such is the case, but the absolute frequency of the diseases is small, and in many instances, such as that of the classical Nougaret family, victims are by no means anxious to reveal their disability to strangers.

It is particularly appropriate that the volume should be dedicated to the memory of Nettleship, for a large share of the material relating to retinitis pigmentosa and the lion's share of the data of congenital stationary night-blindness are the product of his own researches.

"The Treasury" is planned to be a storehouse of facts, so that no complete analysis of the data is attempted; but certain interesting points are made. Attention is specially directed to two: (1) the presence of other defects in the family histories, (2) the etiological importance of consanguinity. As to (1), it would seem that each of these defects tends to occur largely as a single defect, but that if retinitis pigmentosa is associated with deafness in the stock the link is a close one. With respect to (2), consanguineous marriages are far more common in the diseased stocks than in the general population, save in the case of that form of congenital stationary night-blindness which is limited to males. In only one case, however, does the proportion of affected offspring of consanguineous marriages seem to exceed materially that found among the offspring of non-consanguineous marriages, a result differing from what has been observed in the records of deaf-mutism and albinism.

The very rare and usually fatal anomaly, glioma retinæ, scarcely lends itself to statistical treatment. However, in view of its absolute rarity—it is estimated not to furnish more than 0·03 per cent. of all patients suffering from diseases of the eye—the fact that it has been possible to compile thirty-six histories showing more than one case in a stock is strong evidence that this, too, is an hereditary defect.

In a prefatory note, Prof. Karl Pearson thanks the Medical Research Council for a grant in aid of the work, and expresses a "hope that the work as completed will be considered to have justified their support." The scientific public will have no doubt on that score; there could be few objects more worthy of national support than the preparation of scholarly and impartial records of the facts of human inheritance. Dr. Bell has, in our opinion, produced a thoroughly satisfactory monograph, which will at once take rank as a standard work while being—a quality by no means to be predicated of all standard works—adequate from both the literary and the artistic points of view.

Chemical and Physical Tables.

Tables annuelles de constantes et données numériques de chimie, de physique et de technologie. Vol. IV.: Années 1913–1914–1915–1916. Première partie. Pp. xxxii + 626. Deuxième partie. Pp. xxxv + 627–1377. (Paris: Gauthier-Villars et Cie.; London: Cambridge University Press; Chicago: University of Chicago Press, 1921–1922.) 2 parts, 7*l.*

FOR reasons which are not very clear, the earlier volumes of the "Tables annuelles" have not been fully used in this country; but a cursory inspection of Volume IV. will give the physico-chemical doubter cause to think, while an hour's serious use of it will convert him completely. Which of us can lay his hand on his heart and say that he has missed nothing essential to his subjects of research? Let him open these volumes and—unless he has already consulted them — he will be humbled. Landolt-Börnstein carries us up to the end of 1911; from that time onwards, no indexes or abstracts, however complete of their kind, afford a sufficient guide to the seeker after data, who must nowadays add to his scientific equipment the faculties of a British Museum historian and the time in which to exercise them.

There are here recorded the classified, clearly indexed data amassed during four years from 340 periodicals and other sources by 32 abstractors in 19 countries, collated by 27 well-known compilers who are specialists, and edited by Dr. Charles Marie (to whose devotion and enthusiasm the "Tables annuelles" so largely owes its existence and its success). The general control is vested in an executive of eight eminent physical chemists from a powerful international committee representing 23 nations.

It is obvious that to neglect the output of such an organisation as this would be sheer waste. In the writer's opinion (formed in spite of a hitherto somewhat inert attitude towards the earlier volumes) there is no library of physics and chemistry, pure or applied, which can now afford to be without this publication. The price seems high at first sight; but it is an investment which will repay itself many times, even before the next volume appears.

In the plan of the work much has, naturally, been gained from Landolt-Börnstein, but the scope is considerably wider and at the same time more detailed.

A series of practical tests in various sections shows that it is easy to trace at once the information sought; and to this end a system has been adopted in which rigidity has been tempered very wisely. There are chapters in Part II. which one might have expected to be placed near others in Part I.; for example, thermochemistry is separated from thermodynamics in this way, and cryoscopy from vapour pressures; but some change in the sequence of sections may doubtless be made hereafter, and in the meanwhile there is no obstacle to utility. The printing is clear; and with the tabulated data the compilers give sufficient indication of the experimental method used, mention any general formulæ found applicable by the author, and state the conditions quite unambiguously. The use of graphs instead of tables in dealing with subjects such, for example, as absorption-spectra, equilibrium mixtures of metals, or the ignition of gaseous mixtures, is well carried out. In chapters treating of organic compounds Richter's classification is used; and it is clear that the vexed question as to the organic or inorganic nature of calcium carbide would present no difficulty to the editor, for he provides the useful category of "Corps mixtes." This name, however, although no doubt correct in French, should certainly not be rendered in English as "mixtures." The misspellings of English authors' names are probably not more frequent than can be matched in English references to foreign literature.

Dr. Marie prints his regrets that this volume, covering 1913–1916, is only now issued; but, as in the case of Dr. Johnson's dog, the marvel is, not that it is done so well, but that it is done at all; for the difficulties during and just after the War must have been very great. That these difficulties have been passed, so that we have Volume IV., are informed of an accelerated issue of Volume V. (1917–1921), and may look for a regular progression thereafter, is a real achievement in advancing research. I. M.

Our Bookshelf.

Modern Tunneling. By David W. Brunton and John A. Davis. (New Chapters on Railroad Tunneling, by J. Vipond Davies.) Second edition, revised and enlarged. Pp. x+612. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 33*s*. net.

The first edition of this work was published in 1914, and its contents were limited to mine and water-supply tunnels. The present edition has been revised and enlarged by Mr. John Vipond Davies, and contains new matter dealing with large-sized tunnels. The early part of the volume contains a very good discussion on the plant required in the construction of tunnels, and includes such subjects as the factors influencing the choice of prime movers, types of air compressors, surface plant generally, and methods of ventilation. This is followed by critical descriptions of the various underground appliances, such as rock-drilling machines, the methods of blasting, haulage, etc. The great development of tunnels during the last fifty years has been due to the application of high explosives and rock-drills, and this part of the subject receives adequate treatment. Details of the cost of a large number of tunnels are included, together with the speeds attained in driving them. There are two comprehensive bibliographies, and these may be regarded as an essential feature in a book on this subject and of moderate dimensions. The matter is presented in a very readable manner, and the volume will be of service not only to the engineer engaged in practice but also to the student of civil engineering.

La Force motrice électrique dans l'Industrie. Par Eugène Marec. Pp. viii+613. (Paris: Gauthier-Villars et Cie., 1922.) 55 francs.

M. Marec's book is written for those who, having a sound theoretical knowledge, are more concerned with the choosing and installing of electrical machines than with the manufacture of them. The operation of the finished machine is discussed mainly by describing its characteristic curves. The engineer is thus enabled to judge which type of machine will prove the most useful for the particular purpose he has in view. The various methods of installing electrical machinery in a workshop are fully described. The book will be of use to the English engineer, as it will show him the best modern French practice, and it will be helpful for him to compare it with his own. The various French methods of charging for alternating-current power will interest him. One method is to charge the consumer for the watt-hours he has consumed. In addition a further charge is made for the magnetising hours, this further charge only being zero when the consumer uses apparatus the power factor of which is unity. The latest French rules for standardising apparatus and methods in electrical engineering are given. The comparison of them with the American and English rules is instructive.

Orographical, Regional, Economic Atlas. Edited by T. Franklin. Part 4: Africa. Pp. 32. (Edinburgh: W. and A. K. Johnston, Ltd.; London: Macmillan and Co., Ltd., n.d.) 1*s*. 6*d*. net.

This collection of forty-seven diagrams and maps of Africa and parts of Africa is wonderfully good value. It includes a coloured orographical map of the whole of Africa and sectional maps of the same on enlarged scales. A uniform scale for these sectional maps would have been an advantage. The maps appear to be accurate and revised to date. The allocation of the Cameroons to the League of Nations on one map is apparently a slip. The atlas deserves a wide use.

The All-Electric Age. By A. G. Whyte. Pp. xiii+242. (London: Constable and Co., Ltd., 1922.) 7*s*. 6*d*.

Mr. Whyte gives an interesting and accurate account of the latest electrical developments. He has refrained from speculating about the future, but we think that if he had pointed out the directions in which advances will probably be made he would have added to the interest of the book.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Cause of Anticyclones.

In reply to Major Goldie's letter in Nature of March 31, p. 429, the following figures may be of interest.

Defining an anticyclone as a region where the barometric pressure exceeds 30·20 inches (1022·7 mb.), there are 52 cases of anticyclones in the British Isles during the years 1909 to 1922 inclusive in which the results of registering balloon observations are available.

Expressed as a departure from the mean for the height and date, these 52 cases give $+1·6°$ F. at 1 km., $+4·5°$ F. at 2 km., and $+5·6°$ F. at 3 km. for the mean departure in an anticyclone. At 1 km. there are 18 negative values, at 2 km. there are 16, and at 3 km. there are 13. Ten instances, or only about one in five, show negative departures at each height.

For cyclones with a barometer reading below 29·40 inches (995·6 mb.) the corresponding mean figures are $-6·1°$ F., $-8·3°$ F., and $-9·7°$ F., with 3, 2, and 1 positive signs respectively, out of 27 cases.

The above figures, the results of observations published by the Meteorological Office, do not seem to me to point to the conclusion that in England anticyclones are formed by pockets of cold polar air, but another test is available.

As I understand the theory of the Polar Front, polar air should be cold and have a low relative humidity; cold because it comes from a colder latitude, and dry because it is gradually warming up without a fresh supply of water and hence has a decreasing humidity. Conversely, equatorial air should be warm and nearly saturated. Where, then, polar air lies under equatorial air and forms a discontinuity, the inversion of temperature should be associated with an increase of relative humidity in the upper layer. Actually, just the reverse is the case.

I have examined the published figures for the continent, where records of the humidity are available for the years 1910 and 1911 separately; both years are consistent, and the combined result of nearly 300 observations is as follows:—

Percentage value to the nearest digit of observations in which an increase of relative humidity accompanies a temperature inversion, 0 per cent. Cases of inversion with no appreciable change of humidity, 4 per cent. Cases with distinct decrease, 36 per cent. Cases with very distinct decrease, 22 per cent. In these results both surface inversions and those over 3 km. are excluded.

Since the figures are not published on a homogeneous plan, classification is difficult, but "No appreciable change" means 5 per cent. or under, and 'Distinct decrease" means a fall of 20 per cent. or more.

One solitary instance of an increase of humidity exceeding 5 per cent. (it was 6 per cent.) was found; it occurred at Vienna on December 6, 1911.

The continental figures are fully supported by many hundreds of kite ascents in England, and they prove that cases of warm damp air overlying colder and drier air are practically non-existent.

Thus it appears from the abundant observational material available that the lower layers of the atmosphere are almost always cold in a cyclone, and are usually (three cases out of four) warm in an anticyclone; also that when an inversion of temperature occurs it is nearly always associated (58 cases out of 62) with dry rather than damp air above.

Hypotheses of Continental Drift.

In many recent discussions of Wegener's theory and of other geological hypotheses, the assumption has been freely made that any force, however small, can deform the earth to any assignable extent if only it acts long enough. To declare that this assumption is incorrect is scarcely possible, in the absence of much more accurate knowledge of the physical conditions within the earth than we at present possess; but there is substantial evidence against it.

We believe that mountains have stood for millions of years, indicating that the rocks at their feet can endure for that time stress-differences equal to the pressure at sea-level in the middle of a mountain. The strength of rocks at depths of 200 to 400 km. is almost certainly less, but no geodetic observations indicate that the strength is insufficient to support an uncompensated hill 200 metres in height; inequalities greater than this appear on the whole to be compensated, but the unexplained gravity anomalies remain almost the same whether we suppose that inequalities less than 200 metres in height are compensated or not. Other data, however, indicate that isostasy is not always perfect: Dr. Morley Davies has pointed out one, and I have shown that several otherwise uncoordinated data can be coordinated on the hypothesis that the rocks in the asthenosphere, though weaker than those near the surface, have a finite permanent strength. Accordingly, the hypothesis that the asthenosphere can be deformed to an unlimited extent by any small force acting for a long time is one to be regarded with great suspicion, and not to be accepted until it has been proved that it will account for more than appears to be explicable on the contrary hypothesis.

In conjunction with this hypothesis another is often utilised, which can be definitely stated to be inconsistent with physical knowledge: namely, that such a small force can overcome a much larger force acting for the same time in the opposite direction. In Wegener's theory, for example, not only is a small force supposed to have moved America across the Atlantic, but also the resistance of the ocean bottom to deformation is supposed to have caused the elevation of the Rocky Mountains. Now, given a sufficiently weak asthenosphere and enough time, it would be possible to twist the outside of the earth over the inside to any extent. So long as the layers of equal density remained symmetrical about the polar axis, no elevation or depression of rocks taking place, deformation could proceed undisturbed, America going steadily on its way without mountain-building or any other phenomenon observable by geologists. In order that mountain-building may take place, however, energy must be supplied to raise and lower the rocks affected against gravity; and to keep them in position, in spite of the tendency of gravity to restore the symmetrical form, the force required must be enough to overcome gravity and the strength of the surface rocks. The minimum stress needed to account for mountain-building is therefore greater than the pressure due to the weight of the mountain. Tidal friction and differences between the values of gravity at the tops and bottoms of continents are capable of producing stresses of the order of 10^{-5} dynes per sq. cm., whereas to elevate the Rockies something like 10^9 dynes per sq. cm. would be required.

A hypothesis that may be of use in accounting for continental drift, if the latter is considered to be indicated by the geological evidence, is based on Jeans's proof (Proc. Roy. Soc. 93, 1917, 413-417) that the earth is stable with regard to first harmonic deformations. The fact that most of the land is in one hemisphere indicates that a first harmonic deformation exists, and must therefore be tending to die down; the only possible means of destroying the asymmetry being for the continents to break up and spread out so as to get as far apart as possible. If, then, we are prepared to admit that the continents were once all united into one mass, it is probable that they would have broken up and separated widely, since the stresses in them must have been comparable with the pressure at sea-level due to the weight of a continent, which is at any rate a moderate fraction of the strength of rocks. Wegener's suggestion that India has moved towards the main mass is, of course, inconsistent with this hypothesis.

The possibility that the continents were formerly united has been regarded by Mr. Crook (Nature, February 24, p. 255) as in harmony with Osmond Fisher's theory of the origin of the Pacific. The latter theory, however, is open to a serious objection. The birth of the moon on the resonance theory would require a violent distortion of the earth, sufficient to shatter into fragments any crust that might have already been formed, and these would distribute themselves symmetrically over the liquid interior at once instead of waiting a thousand million years to do it.

Prof. Sollas's suggestion, mentioned by Dr. Evans in Nature of March 24, p. 393, that there are traces in the earth of the incipient formation of a second satellite, is not in quantitative accordance with the resonance theory of the origin of the moon. It is practically certain that the earth-moon system, when combined into one body, did not rotate sufficiently fast for instability, but it is just possible that it could have rotated fast enough for resonance to magnify the solar semidiurnal tide to such an extent as to rupture the mass into two parts. If the moon was formed in this way, however, it must have taken away with it so much angular momentum that the earth could never again have approached conditions suitable for either resonance or instability.

The Life-Cycle of the Eel in Relation to Wegener's Hypothesis.

The argument in Dr. Wemyss Fulton's very interesting letter in Nature of March 17, p. 359, must be divided into two parts. First, it is pointed out that the gradual recession of the east and west coast-lines of the North Atlantic Ocean from one another would explain in a very satisfactory manner the evolution of the amazing migrations of the larval eel. Secondly, it is assumed that Wegener's continental drift is the only method of effecting that gradual recession. It is possible to concur heartily with the first thesis, without admitting the second.

Suess explained the North Atlantic Ocean as having been formed, during the later ages of the Cainozoic era, by successive foundering of portions of a pre-existing land surface. Except that the recession of the two coasts would then have been spasmodic instead of continuous, the general result from the point of view of the inhabitants of the sea would be just the same as if the two continents were drifting apart. While acknowledging our indebtedness to Dr. Fulton for pointing out how the life-history of the eel fits in with the other evidences of a gradually widening Atlantic, we need not admit that these wonderful migrations prove continental drift any more than the migration of birds across the Mediterranean proves that Africa has drifted away from Europe.

The Combination between Oxygen and Hæmoglobin, and the Criteria of Adsorption.

Hæmoglobin combines with oxygen approximately in the ratio of 16,670 to 32, by weight, as was shown by Peters (*Journ. of Physiol.*, vol. 44, p. 131). It is clear, then, that in solution the particle of hæmoglobin is very much larger than the particle of oxygen which combines with it. If one might assume that the densities and shapes of the particles were similar, then their surfaces would be in the ratio 64 to 1; in any case, and whatever the degree of aggregation of the particles, probably only a very small part of the surface of the hæmoglobin particles can be actually covered by oxygen when combination ceases at the stage of oxy-hæmoglobin.

This shows that the attraction of hæmoglobin for oxygen is a highly localised property of the hæmoglobin particles. For if this attraction were more or less evenly distributed over the surface, it would be satisfied only to a small extent, when a small part of the surface was covered, and at higher concentrations of oxygen than those which are found experimentally to give saturation with oxygen, more oxygen would be taken up.

Taking the thermal motions of the particles into account does not affect this argument, since the movements of the particles according to the laws of the kinetic theory do not affect their surface areas.

Now, if the attraction of hæmoglobin for oxygen is of such a character that it is satisfied when only a small portion of the surface is covered, it seems impossible to regard this combination as a case of adsorption.

The criteria of adsorption are perhaps not yet so well defined as could be wished, if differences of opinion as to whether a given process should be classified as adsorption or not are to be avoided. I am inclined to think that a process is rightly classified as adsorption, *if the substance taken up by the surface continues to be taken up until the whole surface is uniformly covered*, but not otherwise. Covering the surface uniformly is of course meant in the sense in which a gas or homogeneous solid is said to fill space uniformly; that is, uniformly to a being armed with a microscope to which individual atoms are small.

This definition is both definite theoretically, and in accordance with common conceptions of adsorption. It is difficult, indeed, to see what other definition is possible in the present state of knowledge. It is perhaps, however, desirable to state the definition clearly; although, as I feel it must have been present, whether formulated or accepted as self-evident, to the minds of many workers on adsorption, no sort of novelty is claimed for it here.

A definition of adsorption based on the nature or quality of the forces attracting the adsorbed substance, is now impossible, since it appears proved by Langmuir's work that there is no difficulty in accounting both qualitatively and quantitatively for many cases of adsorption, by means of the already very familiar forces which cause combination between metals and oxygen to form oxides, or the forces which bring about solution.

Obviously adsorption cannot be defined as "that which occurs at the surface of a colloid"; since colloids themselves are not yet a well-defined class of substances, and indeed the best studied cases of adsorption are at plane interfaces, not at the surfaces of colloids.

With the definition of adsorption proposed, a process would be excluded if, as with hæmoglobin and oxygen, combination occurs only at some defined locality on the surface. Similarly, the ordinary reactions of organic chemistry will be excluded, as they should be, since the substances taken up go to definite atomic groupings in the molecule. The combination of oxygen with hæmoglobin is seen to belong to the same class as most organic reactions.

It remains to examine whether the definition is practically applicable to known cases of adsorption, as well as theoretically justified; and whether, in the case of oxygen and hæmoglobin, the arguments originally put forward in support of the adsorption process are cogent enough to override the definition.

All cases of adsorption, from a gaseous phase, or from solution, on plane, or nearly plane, interfaces, are obviously compatible with the definition, since the common method of calculating the amount of adsorption assumes uniformity of distribution on the surface, and the results are generally expressed per sq. cm. of interface.

In the cases of adsorption on colloidal surfaces, when the extent of surface is usually not known, and the adsorption is expressed per gram of adsorbent, the definition is probably also applicable. Mecklenburg (*Zeitsch. f. physikal. Chemie*, vol. 83, p. 622) described experiments showing in several cases that the adsorption on different specimens of the same adsorbent, prepared, however, under different conditions, varied in a precisely similar way with concentration for each adsorbent, but the total amount adsorbed per gram was proportional to a factor in each case, this factor being presumably proportional to the area of the adsorbent.

In proposing the theory that the oxygen in oxyhæmoglobin is held by adsorption, Wo. Ostwald (*Koll. Zeitsch.*, vol. 2, pp. 264, 294) based the argument on two supposed facts: first, that no definite saturation point of oxygen with hæmoglobin could be found, a fact now shown to be incorrect; and, second, that the amount of oxygen taken up at different pressures could be fairly accurately represented, under certain conditions, by the so-called "adsorption isotherm," $y = kc^n$ (y = amount taken up, c = concentration of oxygen).

The mere fact that the variation of the amount taken up fits the "adsorption isotherm" does not seem now to be a sufficient ground for classing a process as adsorption. The "isotherm" has, until quite recently, been an empirical fact without theoretical explanation; and not only does it contain two independent arbitrary constants, which makes the fitting of a set of experimental data easier than would be the case otherwise; but also it is, at the best, usually only accurate at low concentrations, divergences being found at higher concentrations.

A more accurate equation relating amount adsorbed to concentration has been deduced recently (Henry, *Phil. Mag.*, vol. 44, p. 689, 1922) on the assumptions of a small range of molecular attraction and a monomolecular adsorbed layer, using well-established equations of the kinetic theory; and the author also gives a derivation of the "adsorption isotherm" on theoretical grounds. It would seem undesirable, however, to use the form of the relation between amount adsorbed and concentration as a criterion of adsorption, for this relation can never be a very simple conception, depending as it does on so many factors; but nothing could be simpler than to conceive of a surface as possessing either localised or diffuse attraction for a substance it takes up. It may be that in some instances it is not yet possible to form any estimate of the fraction of the surface covered; yet as accurate knowledge of the dimensions of molecules and of their orientation on surfaces accumulates, the applicability of the criterion here suggested will increase. I have tried to show, however, that it is already more generally applicable than any other.

The University, Sheffield, March 6.

Labour and Science in Industry.

The article by "F. S. M." under this heading in Nature of March 24, p. 385, emboldens me to inquire whether the time has not come for a really searching scientific re-examination of the natural fundamental basis of the economic system under which we perish. That it is necessary to ask such a question as that in this article, whether, after a century's unparalleled progress in the domination of the forces of Nature and the fertile labours of inventors and producers, the average lot of the people is really better than it was in consequence, suggests a certain lack of scientific imagination. The question which many thoughtful people are now asking themselves, and which a few scientific men at least should have asked before the War, is not whether the material lot of the people is up to what it was before the use of science, but why is it not vastly improved. What kind of a civilisation ought to be the result, if science were directed in accordance with natural laws to the constructive purposes of life, rather than only so for the purposes of mutual destruction? Civilisation can scarcely revert in peace-time to economic law, in which the tokens of wealth usurp the place of reality, without raising the very general aspiration that the advantages of war and peace might be combined by proceeding according to natural laws in peace-time.

The first economists, the French Physiocrats, did make an effort to base their system on the laws of Nature, and in their doctrine, that the origin of wealth was the land, and in the later doctrine of Marx, that it was in human labour, certain obvious elements of natural truth were embodied. But in the present system there is no natural truth obvious at all. It is an offence against common sense. The production of wealth to-day is a relatively finished science, in which probably little that is fundamental remains unknown; whereas a century ago it was an empirical art as different from the present science as astronomy is from astrology or chemistry from alchemy. But the science of distributing the product—that is, the science of token wealth—is so little understood that the most incredible consequences are accepted as natural and inevitable.

In a natural community, if people were short of the necessities of existence, and knew how, they would produce and consume them. In ours, with the return to conditions of peace and victory, they are idle by the million and deteriorate mentally, morally, and physically, dumbly acquiescent in the requirements of a system no one pretends to understand. If one asks why, it is because of certain conventions with regard to bits of metal and paper to which we have all been born and brought up, but to which probably not one in a hundred, even among scientific men, has given two minutes' original thought.

The great clarification of ideas which distinguishes modern science, and especially physical science, ought not to stop short of this most vital and fundamental problem which so menaces the well-being of the community. It is, indeed, a most fascinating problem for its own sake. The mathematician would enlarge his knowledge of the consequences of a mistake in sign in a field where such mistakes are of fearful import to whole nations, and the physicist, of a perpetual-motion machine fallacy underlying and destroying the hopes, not of a half-crazy would-be mechanic, but of a half-crazy would-be mechanical civilisation. In his well-known book, "Instincts of the Herd," Mr. Trotter has put one obvious point inimitably. "It is this survival, so to say, of the waggoner upon the foot-plate of an express engine, which has made the modern history of nations a series of such breathless adventures and hairbreadth escapes." I venture to suggest that the survival of the herd-instincts of the waggoner in an express age applies as much to those who have built the express as to those who try to drive it.

The British Association naturally suggests itself as providing the proper platform for this proposed re-examination of the physical basis of our economic system, since it has an Economics Section which, no doubt, would welcome as eagerly as the public the introduction of an element of science into its proceedings. One needs to be only a casual observer of the trend of events to know that the public, thoroughly alarmed by the consequences of peace, and fearfully awaiting asphyxiation in the next war, would take an interest in this question that would rival that of the palmy days of Huxley and the Bishops.

Frederick Soddy.

We shall all sympathise with Prof. Soddy's desire that our industrial system should give a state of society in which the material lot of the people should be "vastly improved" by the application of science. We should differ from him in various degrees as to the extent to which this has been already secured, and the means which should be taken to accelerate the process. I gave in the article quoted some reasons for believing that considerable improvement had taken place: it seems, in fact, untrue to say that "we are perishing" under our present economic system. The only country which can be said to have come near to "perishing" is Russia, which attempted entirely to discard the system and is now, after a desperate experience, painfully and slowly retracing her steps. The next most seriously distressed country in the world is China, which has never attained to our modern industrial system.

By all means enlist the Economics Section of the British Association in a discussion of the problem—or rather the host of problems—involved. But do not antagonise the Section at starting by suggesting that it would be a good thing to introduce "an element of science into its proceedings." The Section has been proceeding on that assumption for a good many years now.

F. S. M.

Tactile Vision of Insects and Arachnida.

With reference to Commander Hilton Young's suggestion noted on p. 409 of Nature for March 24, it may possibly be of interest to record the conclusion at which I and my colleagues arrived, when engaged, two years ago, in research on the so-called eyes in insects and arachnida. In all the species studied, including the house-fly and red ants among the former, the house spider (*Tegenaria domestica*) and many of the Epeiræ among the latter, we were forced to the conclusion that the organs generally known as eyes do not act as organs of vision. What their main purpose is, was never *certainly* determined by us; but the many phenomena which were studied as evidence of sight could all be reduced to *touch* sensations. For example, to take perhaps the simplest illustration, if the hand be slowly advanced towards a fly on a window-pane, the insect, if it be a vigorous specimen, will evade the caress. But if the hand be advanced towards the fly when the insect is on the opposite side of the glass to the hand, it may often be necessary to tap severely in order to disturb its wanderings.

Apart from air currents due to the motion of the hand, and possibly some convection currents due to the heat of the same, it is difficult to afford any other satisfactory explanation of this simple phenomenon, which any one can examine for himself with the greatest of ease.

The Resonance Theory of Hearing.

The difficulty expressed by Sir James Barrett in Nature of March 24, p. 396, is probably more apparent than real. If attention is focussed on the relative dimensions of the various parts of the cochlea rather than their actual sizes, I think that the range of analysis can be explained.

In the short compass of a letter I cannot deal with a full consideration of the analytical mechanism of the cochlea. A variation in pressure applied to the *fenestra ovalis*, if it is to cause a movement of the basilar membrane, must cause movement of the liquids in the cochlea. The impedance due to the inertia of the liquid is considered by Mr. Wilkinson as a "load" on the vibrating strings. In all considerations of the action of the cochlea the influence of the viscosity of the liquid has been overlooked (see *Philosophical Magazine*, 1922, vol. 43, p. 349). The friction of the liquid against the walls of the cochlea impedes the movement of the liquid so that if the diameter of the cochlea were uniform the resistance would be proportional to the distance from the *fenestra ovalis*. As the cochlea becomes narrower this is a safe assumption. If the highest audible note acts on the basilar membrane 5 μ from the commencement of the cochlea, the ratio of the impedance due to viscosity of this highest note to the lowest note might be 35,000 to 5. This is approximately the ratio given by Mr. Wilkinson without the assumption of any difference in tension in the fibres of the basilar membrane. I do not wish to imply that there is no difference in tension, but the greater bulk of the spiral ligament may be merely to resist a greater strain, and is not necessarily an indication of a greater initial tension.

If one wishes to look at this subject from the point of view of resonance, the effect of viscosity can be illustrated by narrowing the orifice of an air resonator. This lowers the note, just as the viscosity makes the note lower for the distal end of the cochlea, but the viscosity of a liquid will be much more important than the viscosity of a gas. Viscosity, however, is only one of the factors concerned in sound analysis.

The Sun-Cult in Ancient Egypt.

By Aylward M. Blackman, D.Litt.

I.

THE recent discovery of Tut'enkhamūn's tomb has naturally aroused a great deal of interest in the attempt made by that king's father-in-law, Ōkhnatōn, to establish a monotheistic form of sun-worship as the State religion of Egypt, and indeed of the whole Egyptian empire. Properly to appreciate this very striking phase of Egyptian religious thought, it is necessary to have some knowledge of the old "orthodox" sun-cult, the State religion of Egypt, since at any rate the sixth, and possibly the third dynasty—a cult which can be traced back to the very dawn of Egyptian history.

The centre of this ancient sun-cult was On, the Heliopolis of the Greek writers, a city which lay close to Memphis and the site of modern Cairo. Heliopolis was almost certainly the political centre of a united Egypt in the predynastic period, though at a time not necessarily long anterior to the beginning of the first dynasty and the founding of Memphis by Menes. The predynastic king of Heliopolis was high-priest of his city-god, the sun-god Rēʿ-Atum, and was also regarded as his embodiment. Immense influence was exercised by Heliopolis upon Egyptian theology and ideas in general, and even when Heliopolis ceased to be the actual capital of Egypt, the Egyptian king was still regarded as the embodiment of the sun-god and his high-priest, and Rēʿ-Atum still maintained his place as the State-god. Owing to the religious and political ascendancy of Heliopolis, a number of the local provincial gods were identified with the sun-god by their priests in order to enhance their prestige. Of course, this identification was particularly likely to take place when what was once a provincial town became the centre of government, as did Heracleopolis at the beginning of the ninth, and Thebes at the beginning of the eleventh dynasty.

As a result of their being identified with the Heliopolitan sun-god, and owing to the great prestige, and, no doubt in early times, superior culture, of Heliopolis, the temples erected for the worship of the solarised local gods were copies of the Heliopolitan sun-temple; moreover the liturgy celebrated therein in honour of these divinities was that celebrated in honour of their Heliopolitan prototype. In course of time the Heliopolitan form of temple was universally adopted in Egypt, and also, by a natural process, the Heliopolitan liturgy came to be celebrated in honour of every important god and goddess throughout the length and breadth of the land. This remarkable uniformity in temple architecture and in worship seems to have prevailed so far back as the old kingdom, about 2900 to 2475 B.C.

The king of Egypt, as we have seen, was the high-priest of the sun-god. He was also high-priest of all the local divinities of Egypt, and in this capacity he celebrated, or rather was supposed to celebrate, the liturgy in every Egyptian temple. His relations with the solarised divinities were of course practically the same as his relations with the Heliopolitan sun-god himself, a circumstance which naturally must have influenced his relations with other divinities and must have helped forward greatly the solarisation of all Egyptian temple-worship.

What, it may be asked, were the ideas of these ancient sun-worshippers as to the nature and character of their god? The most outstanding of all the qualities attributed to the sun-god by the Heliopolitan priests is his righteousness. The sun-god is not only represented as loving righteousness and truth and hating iniquity, but also it was said that he it was who "fashioned righteousness." Righteousness is so much a part of the god's being that he is said to live (*i.e.* feed) on it, just as Hapi the Nile-god is said to live on fish! This righteous god demanded righteousness in his worshippers also, and before the Osirianisation of the Egyptian conceptions of the life after death, a process which they underwent in the period between the end of the Old and the beginning of the Middle Kingdom (about 2475 to 2160 B.C.), the sun-god was regarded as the judge of the dead, in which capacity certain texts represent him as weighing righteousness in a balance, *i.e.* testing the righteousness of the dead.

Now the king of Egypt (in the first instance the king of Heliopolis) was thought to be, as we have seen, the embodiment of the sun-god. Accordingly, like his divine prototype he was supposed to be the upholder of righteousness, truth, and justice. But the close association of the king with the god not only associated the god's righteousness with the king: it also associated the kingship with the god. Thus the sun-god, who is represented in the myths as the first king of Egypt, came to be regarded as the prototype of all Egyptian sovereigns, the ideally righteous king, the pattern of all would-be righteous Pharaohs. In a literary composition of the Feudal Age, describing the miserable plight of Egypt under the rule of a weak Pharaoh, a sage contrasts the prevailing unhappy conditions with the state of affairs in that far-off golden age when the sun-god, the ideal king, ruled over Egypt. He speaks of the sun-god as "the shepherd (lit. herdsman) of all men, with no evil in his heart." "Where is he to-day?" he asks. "Does he sleep perchance? Behold his might is not seen!"

Purity, and particularly physical purity, was another attribute of the sun-god. Everything connected with him must, it was maintained, be pure, and only those who were pure could approach him. Consequently lustral washing was a marked feature of the sun-cult, no priest being able to enter the sun-temple (eventually any temple) to officiate until he had undergone purification. Even the sun-god himself is represented as washing or being washed every morning in some mythological lake or pool before appearing above the eastern horizon.

Now according to one conception, the sun-god was reborn every morning, having been born in the first instance, be it noted, out of the waters of the celestial ocean. Naturally enough, therefore, his daily rebirth came to be associated with his daily lustration, and he was supposed to be reborn every day at dawn as the result of washing or being washed in the waters of this or that sacred pool. In accordance with this conception, an early and important episode in the liturgy, which was celebrated every day at dawn in all Egyptian temples (in the first instance, of course, the Heliopolitan sun-temple), was the washing or sprinkling of the divinity's (originally the sun-god's) cultus-image with water, in imitation of the sun-god's supposed daily matutinal lustration.

The Heliopolitan king, the sun-god's embodiment, was, as already stated, his high-priest, and in this capacity he entered, or was supposed to enter, the sun-temple every day at dawn to celebrate the liturgy. Before he entered the god's presence he had, like every other priest, to undergo purification, but in his capacity of embodiment of the sun-god he was conceived of as reborn as the result of his ceremonial washing, just as was his divine prototype. As we shall see, the king was also regarded as the son of the sun-god, and was thus thought of as rebegotten as well as reborn through the agency of the lustral water, this being identified with the sun-god's own efflux, the very efflux with which he had brought into being his two children, Shu and Tefēnet. The king's lustral washing took place in an adjunct of the sun-temple, called the House of the Morning, so named on account of the very early hour at which this ceremony took place. The king not only underwent lustration in this chamber, but he was also robed, anointed, and crowned there, invested with the royal insignia, and apparently also presented with a light repast, after which proceedings he was ready to enter the temple to officiate.

The consort assigned to the Heliopolitan sun-god by his priests was Ḥathor, a goddess who was especially associated with music and dancing. The queen, as wife of the high-priest of the sun-god, was, in accordance with Egyptian custom, that god's high-priestess; moreover as wife of the embodiment of the sun-god she was considered to be the god's earthly wife, and so was identified with Ḥathor. Like her divine prototype she was associated with music, and it was her function to sing and rattle her sistrum while her husband, the high-priest, celebrated the liturgy.

A notable feature of the worship of Ḥathor was the performances of her musician priestesses, who were attached to her temple in large numbers. These performances consisted in dancing to the accompaniment of the rattling of sistra and the beating of single-membrane drums. Since Ḥathor was assigned to the sun-god as his wife, musician-priestesses were attached to his temple, and their dancing, singing, and playing thus became a feature of the sun-cult—eventually of all the solarised cults of Egypt. Over these musician-priestesses in the provincial temples presided the high-priestess, the wife of the high-priest, who, as inscriptions occurring in several temples explicitly state, was regarded as the wife of the god, and was as such identified with Ḥathor—the god himself being identified with the sun-god. The musician-priestesses attached to the great solar or solarised temple at the capital were, of course, presided over by the queen, the earthly counterpart of Ḥathor *par excellence*. These musician-priestesses of Ḥathor consciously impersonated Ḥathor in their performances, and are actually spoken of as Ḥathors. Thus not only the high-priestess was identified with Ḥathor, but the musician-priestesses over whom she presided were designated Ḥathors also.

Since the chief musician-priestess—at the capital the queen, or in the provinces the local high-priest's wife—was regarded as the god's earthly consort, the ordinary musician-priestesses were reckoned to be his concubines, in which connexion it is interesting to note that the Temple of Luxor, which was dedicated to the solarised Theban Amūn, was known as the Southern Ḥarīm of Amūn; so it was possibly the headquarters of that god's concubines.

Owing to the queen holding the position of wife of the sun-god, her son, the future king, naturally came to be regarded as the actual physical son of that divinity, the explanation of this wondrous happening being that the god had intercourse with the queen by incorporating himself in the reigning Pharaoh.

A brief description must now be given of an ordinary Egyptian temple, and some account of the ideas which the Egyptians entertained with regard to it, all of which will show effectually how preponderating was the influence of Heliopolis in all matters religious, and how complete was the process of solarisation which Egyptian temple-worship and all its accessories had undergone, certainly before the end of the Old Kingdom, possibly at a much earlier date.

A great ornamental gateway flanked by two towers, commonly called a pylon, admitted to an open court surrounded by a colonnade. Behind this court was the hypostyle or pillared hall, and behind it again, buried in profoundest darkness, lay the sanctuary, containing the cultus-image of the divinity to whom the temple was dedicated. In adjoining rooms were enshrined the images of the co-templar divinities. Yet other rooms served as store-chambers for the sacred utensils and vestments, or for the performance of special ceremonies.

Owing to the prevailing solar influence, Egyptian temples, certainly in early times and often later, were orientated east and west, so that the rising sun at the equinoxes might light up their dark interiors. Indeed, according to the current Egyptian conception, it was the sun-god before all others who dwelt in every temple, which was regarded as a small replica of heaven itself. Thus a favourite description of a temple is that it is "like heaven in its interior, while Rēʿ (the sun-god) rises within it."

Against the eastern face of either of the above-mentioned pylon-towers were erected two or four, sometimes even five, tall masts—four to ten in all—from the tops of which fluttered white, green, blue, and red flags. These towers themselves were equated with the two sisters Isis and Nephthys, who were regarded as a pair of midwives lifting up the newly-born sun into the sky every morning.

In front of the pylon there generally stood two obelisks, one on either side of the gateway. The obelisk, or rather the pyramidion on top, was closely connected with the sun-cult, being a replica of the sacred *benben*-stone in the temple at Heliopolis. This stone was the emblem of the sun-god, one of the forms under which he was worshipped, and on it he was said to have sat when he begat of himself the god Shu and the goddess Tefēnet.

Colossal statues of the royal founder or benefactor of the temple were often erected in front of the pylon beside the obelisks. Other statues of the king, representing him either in the guise of a worshipper or offerer, or as just standing or seated, were set up in various parts of the temple. Through the medium of these statues, which to the Egyptian mind were very closely connected with the person they represented (that person being regarded as immanent in them), the king could, according to the character of the statue, function perpetually either as worshipper or offerer, or else as the recipient of worship and offerings.

In the main sanctuary, and in the sanctuary of each of the co-templar divinities, was a shrine containing the cultus-image, which was as a rule quite small—sixteen inches to four feet in height—and made of wood. Sometimes the shrine was a monolithic naos set up against the back wall of the sanctuary, with a bronze frame inserted in front fitted with double doors. More often the shrine was in the form of a boat, which rested upon an altar-like stone pedestal, the place where it stood being designated "the great place." In the centre of the boat, covered with a veil, was a cabin containing the image. Poles were attached to these boats so that they might be carried in procession, the number of priests who supported them varying from eight to twenty-four, or even twenty-six. In the sanctuary of the Heliopolitan sun-temple there were two such boat-shrines, representing the morning- and evening-barque of the sun-god. The boat-shrine is undoubtedly of solar origin, for it was the sun-god in particular who was conceived of as sailing across the sky in a boat.

The sanctuary, or else the actual naos containing the image, is often designated "Heaven" or the "Horizon" in inscriptions, and one of the titles borne by the high-priest of the solarised Theban Amūn was "Opener of the Doors of Heaven in Elect-of-Places (Luxor)," it being the duty of the chief officiating priest to open the doors of the shrine or sanctuary at an early stage of the temple liturgy.

Every temple possessed its sacred pool containing the water used for purificatory purposes, and it is to be noted that this pool, for reasons that have been fully set forth above, seems always to have been associated with the sun-god.

Again, every temple down to the latest times possessed its vestry or House of the Morning, an adjunct, as has already been pointed out, of the ancient Heliopolitan sun-temple.

One of the clearest proofs of the complete solarisation of institutional religion in Egypt is to be found in the organisation of the priesthood, which at every temple was divided into four "watches," or, as the classical writers designated them, phylæ. These "watches" bear the names of the four quarters of a ship—the bow-, stern-, starboard-, and larboard-watch, names which mythological texts assign to the four watches into which the crew of the sun-god's ship was divided. It was evidently the Heliopolitan priests who were first divided into four watches bearing these names, for, as already stated, the sun-god was supposed to traverse the heavens in a ship and his priests may well have been regarded as his crew.

The liturgy itself consisted largely of a series of toilet-episodes, and thus closely resembled the ceremonial toilet of the Pharaoh in the House of the Morning, a resemblance due to the fact that both imitated the same performance, the supposed daily matutinal ablutions of the sun-god, the cultus-image of the divinity (originally the sun-god) being washed or sprinkled with water every day at dawn, as the god himself was believed to be. That the other toilet episodes in the temple liturgy—robing, anointing, crowning, etc.—were like those performed for the king, was due to the fact that the sun-god, for whom the rite was instituted, was himself regarded as a king—the divine prototype of all Heliopolitan kings. The chief officiant at the liturgy was supposed to be the Pharaoh, but it was of course impossible for the supreme head of the highly organised Egyptian state of historic times to function daily as high-priest, even in the temple at the capital, let alone in the countless temples scattered over the length and breadth of the land. His place was therefore taken by a deputy, the local high-priest, or some other member of the higher grade of the priesthood. In addition to the chief officiant a number of assistant priests took part in all the ceremonies, as certain representations clearly show.

The liturgy falls into three main divisions: (1) A series of pre-toilet episodes, among which were included the unbolting and opening of the sanctuary or naos doors, the sweeping of the sanctuary floor with a cloth or besom, preliminary fumigations with incense, the prostration of the celebrant, the chanting of the praises of the god, and the removal of the image from the shrine. (2) The lustral washing of the image, followed by a long series of other toilet performances. (3) The liturgy terminated with the presentation of a meal to the god, a lengthy and highly ceremonious proceeding. When the food- and drink-offerings had all been laid in order before the image—the heaped-up food offerings surmounted with bouquets of flowers and the wine-jars wreathed with garlands—the officiant extended his right arm and, bending his hand upwards in the prescribed manner, pronounced a formula beginning with the words "An offering which the king gives." The recitation of this formula was preceded by the burning of incense and the pouring out of a libation. The priest having next recited the formula of "Summoning the divinity to his repast," performed the act of consecration, by which each item of food and drink was finally made over to the divine banqueter. This act consisted in the king, or his deputy the priest, standing before what was to be offered, and four times stretching out over it or towards it a ceremonial baton called the *kherp*-baton, which he grasped in his right hand.

The last act of the officiant before he left the sanctuary was to remove all traces of his own and his assistants' footprints. This he did by sweeping the floor once more with a cloth or besom. The sanctuary door was then closed and bolted and a clay seal affixed to the bolts.

Before bringing this preliminary article to an end, it should be pointed out that music, vocal and instrumental, was a great feature of Egyptian worship—a much greater feature than may have appeared from what has already been said in connexion with the musician-priestesses. These priestesses, it would seem, headed by the god's earthly wife, the high-priestess, rattled their sistra, beat single-membrane drums, and chanted hymns in the divinity's praise, all the time that the chief officiant and his assistant priests were executing the various ritual acts, while male musicians also bore their part in the proceedings, singing, and playing on flutes and stringed instruments.

The following and concluding article will deal with the monotheistic Aton-religion instituted by Ōkhnatōn, and so enthusiastically practised and propagated by him at his capital, El-Amarna, in Middle Egypt.

The Photosynthesis of Plant Products.[1]

By Prof. I. M. HEILBRON.

DESPITE the enormous strides that have been made by chemists during the last decades in the elucidation of many classes of plant products and the actual synthesis of individual members, the methods hitherto employed in the laboratory are so essentially different from those carried out by the plant that the synthetic processes of the living organism have come almost to be regarded as something fundamentally apart from those of the laboratory. The investigations on photosynthesis now being carried out in Liverpool by Prof. Baly and myself, although as yet of a quite preliminary nature, have, in my opinion, already shown that such a conclusion is entirely unwarranted and that the key to the problem of plant syntheses is to be found in the study of the energy transformations involved in the primary reaction wherein the plant brings about the fixation of atmospheric carbon dioxide. Apart from the purely academic interest of the subject, the problem of photosynthesis demands the attention of the community as a whole, for, with the elucidation of the reactions involved, the economic aspect of the question must inevitably become more prominent, and practical results of the greatest value to mankind may conceivably accrue.

The work of the earlier investigators on the subject has led to the formulation of certain definite conclusions. Thus, it has been proved beyond question that photosynthesis takes place in the green leaf of the plant and that, under natural conditions, assimilation apparently consists in the absorption of carbon dioxide by means of the chlorophyll contained in the chloroplasts and its deoxidation and condensation therein, in the presence of water and sunlight, to sugars. It is obvious that, in order to obtain any satisfactory explanation of the rôle played by the chlorophyll, its constitution, and above all its reactions, must be known. The first advance in this direction is due to von Baeyer,[2] who suggested that the initial product of assimilation was formaldehyde, which then further condensed to form carbohydrates. This hypothesis was rapidly put to the test in two directions. Innumerable attempts have been made to prove the presence of formaldehyde in the green leaf itself, but in every case where this appeared to be established its formation could as readily be explained as being derived from sources other than assimilation. As regards the production of formaldehyde from carbon dioxide *in vitro*, this has actually been carried out in numerous ways,[3] none of which, however, are directly comparable with the conditions existing in the plant itself. The most detailed work in this connexion is that of Moore and Webster,[4] who showed that, under the action of light, formaldehyde was readily produced in solutions of carbonic acid containing colloidal uranium hydroxide or ferric hydroxide. As a result of these experiments, Moore concluded that, although chlorophyll had come to be universally regarded as the fundamental agent for photosynthesis, the evidence was purely inferential, and it was more probable that the synthesis of formaldehyde in the presence of sunlight was actually due to the inorganic iron present in the colourless portion of the chloroplast.

Recent research shows this hypothesis to be incorrect. Iron is undoubtedly essential to plant life, just as it is to animal life, and its function seems to be closely associated with chlorophyll formation. Leaves starved of iron suffer from chlorosis but, in these, photosynthesis does not take place, and there can be little doubt that the real catalyst for the assimilation reaction is chlorophyll. Our knowledge of the constitution of this interesting and highly complex pigment is mainly due to the work of Willstätter and his collaborators,[5] who have established the fact that the following four pigments are invariably present in the green leaves of all land plants: Chlorophyll A, $C_{55}H_{72}O_5N_4Mg$, chlorophyll B, $C_{55}H_{70}O_6N_4Mg$, carotin, $C_{40}H_{56}$, and xanthophyll, $C_{40}H_{56}O_2$. From an exhaustive study of the assimilation of carbon dioxide by the green leaf, Willstätter[6] has been able to arrive at certain very important generalisations. He has found that in all cases the oxygen evolved is absolutely equivalent to the carbon dioxide absorbed, which definitely proves that formaldehyde must be the first product, since the primary formation of such other substances as have from time to time been suggested would necessitate a volume ratio greater than 1 : 1. Further, from the results of experiments carried out both in the leaf and *in vitro*, he has been able to show that, although chlorophyll is inactive to dry carbon dioxide, it is nevertheless capable of combining with carbonic acid to form a labile addition compound. He concludes that this latter, by the absorption of light energy, is rearranged into a formaldehyde peroxide complex from which, by means of enzyme action, formaldehyde is liberated, oxygen evolved, and chlorophyll regenerated.

[6] Willstätter und Stoll, "Untersuchungen über die Assimilation der Kohlensäure," Berlin, 1919.

This work still leaves much unexplained and in no way helps to disentangle the paradox that whereas, on one hand, formaldehyde must actually be produced, it nevertheless does not exist in the leaf. Nor does it afford an explanation of the rapid synthesis of either the disaccharides, such as cane-sugar, or of storage starch. Again, it is curious that, if the reactions are actually those specified by Willstätter, Nature should, apparently by caprice, invariably ensure the presence of the two chlorophyll components and also the carotinoid pigments, when one chlorophyll individual would by itself be sufficient. It would seem more probable that the four pigments are present because each has an absolutely definite rôle to play in the mechanism of assimilation. This suggestion is strongly supported by a consideration of the striking oxygen values existing between the two pigment classes, these being in strict agreement with the amount of oxygen liberated in the photosynthetic operation.

Returning now to the consideration of the primary synthesis wherein carbonic acid is deoxidised to formaldehyde, this reaction is a highly endothermic one, impossible to realise under the conditions commonly employed in the laboratory. On the other hand, carbonic acid is able to absorb light of very short wavelength ($\lambda = 200\ \mu\mu$), and, if exposed to light of this frequency, the formation of formaldehyde, without the agency of any catalyst, can readily be demonstrated under these purely photochemical conditions. Moreover, in the presence of a suitable basic coloured substance, such as malachite green, with which the carbonic acid can combine loosely, the formation of formaldehyde can be demonstrated in visible light, the malachite green acting as a photocatalyst for the reaction.[7]

Carbohydrate Production.

The formation of sugars on exposure of aqueous solutions of formaldehyde to ultra-violet light was demonstrated by Moore and Webster.[8] These observations have been fully confirmed, and it has been found that the wave-length of light which brings about this reaction ($\lambda = 290\ \mu\mu$) is photochemically distinct from that required for the synthesis of formaldehyde itself. In our earlier experiments in Liverpool, it was considered that the photosynthetic formation of carbohydrates had to take place in two distinct stages, but, as will be explained below, later experiments have shown that this interpretation was incorrect, the actual process being simpler. The formaldehyde molecule, when first produced by photosynthesis from carbon dioxide, exists in a highly reactive phase, identical with that obtained when ordinary formaldehyde is photochemically activated. This type of formaldehyde we have designated "activated formaldehyde," and it is this which must be photocatalytically produced through the agency of the chlorophyll, and immediately condenses to sugars, for, as is well known, ordinary formaldehyde has no such property. It follows from this that the formaldehyde detected in the carbonic acid experiments cannot have been a direct product of photosynthesis, but must have resulted from a subsequent decomposition of photosynthesised sugar. That carbohydrates readily yield formaldehyde under the influence of short wave-length light has been proved experimentally, and thus the detection of formaldehyde in any photochemical operation may be regarded as sure evidence of photosynthesis.

The investigation into the nature of the sugars formed by the photochemical activation of formaldehyde is still being carried out, but we have been able to prove conclusively that the condensation leads to the production of hexose sugars alone. This fact affords a ready explanation of the formation of disaccharides and starches, for the freshly photosynthesised hexose molecule must exist in a highly reactive phase, and consequently further condensations will inevitably take place.

Nitrogen Assimilation.

The problem as to the origin of the many classes of nitrogen compounds occurring in the vegetable kingdom is one fully equal in importance to that of the formation of carbohydrates, but although many have speculated on their possible synthesis, little definite evidence has hitherto been adduced to account for their production. The questions which have to be considered in this connexion are, first, under what conditions and in what state does the nitrogen enter the plant, and secondly, is the fixation process a photosynthetic reaction? With regard to the manner in which nitrogen is supplied, the general method would appear to be that it passes into the roots in the form of nitrates, or possibly ammonium salts, present in the soil. In addition to the introduction of nitrogen in this manner, Moore[9] has found that in the case of unicellular algæ, providing abundant carbon dioxide is present, elemental nitrogen from the atmosphere can be absorbed and directly utilised. This discovery, which is of quite exceptional interest and fully corroborates Jamieson's[10] earlier investigations, is still further supported by the recent observation of Lipman and Taylor,[11] who claim to have proved that ordinary wheat is able to assimilate up to 20 per cent. of its total nitrogen content in the form of free nitrogen.

It was noted by Schimper that nitrites are invariably present in the green leaf when kept in the dark, but that they rapidly disappear on exposure to light, and the deduction may thus be drawn that these are the active substances employed in the nitrogen fixation. The direct assimilation of atmospheric nitrogen in no way invalidates this conclusion, for there can be little doubt that the free nitrogen will readily react with the nascent oxygen formed during the photolysis of the carbon dioxide to yield oxides of nitrogen.

With these facts in mind, exhaustive experiments are now being carried out in Liverpool on the interaction of nitrates with activated formaldehyde. It has been found that under all conditions the primary reaction product is formhydroxamic acid,[12] $\begin{matrix} H \\ HO \end{matrix}\!\!>\!C{=}NOH$, a substance which had previously been obtained by Baudisch[13] in his pioneer work in this field. The formation of formhydroxamic acid takes place only in the presence of activated formaldehyde, no trace of it being found

when solutions of ordinary formaldehyde and potassium nitrate are allowed to remain in the dark. Now, as this acid is also produced on passing carbon dioxide through aqueous solutions of either potassium nitrate or potassium nitrite exposed to ultra-violet light, the requisite proof is furnished of the statement that the freshly synthesised formaldehyde must be beyond doubt activated formaldehyde. These experiments have led us to the conclusion that formhydroxamic acid marks the initial stage in the phytosynthesis of nitrogen compounds. This view is further substantiated by the fact that, on exposure to ultra-violet light, formhydroxamic acid rapidly reacts with activated formaldehyde to form various other products, many of a complex nature, whereas in the absence of light no such change occurs.

In the course of these experiments, other facts of great importance have been noted. It has been found that by employing excess of nitrite no reducing sugars whatsoever are formed, but that if the activated formaldehyde is in excess of that utilised by the nitrite, the presence of reducing sugars can be readily detected. These experiments prove that the synthesis of nitrogen compounds by the interaction of nitrites with activated formaldehyde takes precedence over the condensation of the latter to carbohydrates. In the plant, however, as the amount of nitrogen actually fixed is small in comparison with the total carbon assimilated, both carbohydrate and protein formation take place simultaneously.

As regards the type of substances which have been classified up to the present, conclusive proof of the formation of α-amino acids has been obtained, and thus a definite intermediate stage in protein production has been reached. At least four distinct types of α-amino acids have so far been isolated in the form of their copper salts, and it is certain that at least one of these is a complex acid, possibly analogous to histidine.

In addition to the synthesis of amino acids, nitrogen bases, such as methylamine, pyridine and piperidine, have been isolated. Substances of alkaloidal character are also formed in the reaction, but as yet we have been unable to separate any one alkaloid in sufficient quantity for detailed investigation.

Another line of attack, at present in active progress, is the study of the action of ammonia on photochemically activated formaldehyde. Here again it has been ascertained that, whether one starts from carbon dioxide and ammonia or from ordinary formaldehyde and ammonia, identical products are obtained. Moreover, although under normal conditions interaction only occurs under the influence of light of very short wavelength, by employing ammoniacal copper solutions the reaction can be photocatalysed to take place in visible light. In all cases the presence of methylamine, pyridine or piperidine, can again be recognised after comparatively short exposure to light, and by extending the period of illumination to several days the presence of alkaloids can also be experimentally confirmed.

In this case it has been possible to isolate an individual alkaloid in sufficient quantity to enable numerous qualitative and physiological tests to be carried out. Despite the difficulties of identification of these substances, the experimental evidence obtained would seem definitely to indicate that this photosynthetic alkaloid is coniine.[14]

In conclusion, I would direct attention to some general deductions naturally arising from the work in hand. According to the views now put forward, it necessarily follows that, both in the case of the photosynthesis of carbohydrates and also in that of the phytosynthesis of nitrogen products, the whole centre of activity must be contained in the green leaf itself. As to the manner in which translocation from this point to other portions of the plant is brought about, it may be suggested that, as the synthesis of active hexoses takes place concurrently with the production of nitrogen compounds, the conditions are especially favourable for glucoside formation. In this way a method would be found for the easy removal of insoluble materials from the leaf.

Finally, I would emphasise the point that in regard to the work being carried out by Prof. Baly and myself, our only claim is that we consider it by no means impossible to reproduce in the laboratory processes strictly analogous and directly comparable with those taking place in the plant. The chemistry of photosynthesis is new and strange, and as such will undoubtedly be viewed with a certain degree of scepticism, for the inherent conservative spirit among even scientific investigators tends to react against any new order of things. Photosynthesis is in the main the chemistry of one single substance—formaldehyde. The whole process is dependent on energy supplied from the sun and made available through the wonderful activity of the pigment chlorophyll.

Obituary.

Lord Carnarvon.

We much regret to record that Lord Carnarvon died at Cairo on April 5, from the effects of pneumonia, supervening on erysipelas and blood-poisoning, the result of a bite on the cheek by an insect, presumably a mosquito.

Lord Carnarvon was born on June 26, 1866, and was the son of the fourth Earl, whom he succeeded in 1890. He was educated at Eton and Trinity, Cambridge. He travelled extensively, won a reputation as a big-game shot, and was interested in the Turf. He was a great connoisseur and collector of illuminated books, manuscripts, and medals, as well as of antiquities of fine workmanship and small size. Of the last-named he had a remarkable and, in some respects, a unique collection. It is, however, in connexion with the study of the history and antiquities of Egypt that Lord Carnarvon's name will be handed down to posterity. In 1906 he, in association with Mr. Howard Carter, formerly inspector under the Egyptian Antiquities Department, began excavations, chiefly on the north side of the Assassif Valley near Der el Bahari, which resulted in the discovery, among other finds, of the tomb of the "King's Son" of Dynasty XVIII. in 1908 and, in 1910, of a rich tomb of Dynasty XII. The results of these early excavations were embodied in Lord Carnarvon's "Five Years' Excavations in Thebes," which appeared in 1912.

After the War, Lord Carnarvon began excavations in the Valley of the Kings, a site which had rewarded the excavations of Mr. Theodore M. Davies with some remarkable finds. No striking results were obtained until November 5 last, when Mr. Carter discovered the tomb of King Tutankhamen—a discovery unique in the annals of archæology. The interest of the objects taken from the tomb, remarkable both in their number and character, grew from day to day, and culminated on February 17, when the opening of the inner chamber revealed the shrines in which it is expected that the body of the king will be found. Work was then closed for the season.

It adds a note of tragedy to Lord Carnarvon's death that he will not be present when the opening of the innermost shrine crowns his labours, but his name will always be honoured as one who added a vast store to our knowledge of the civilisation of Ancient Egypt.

Dr. C. I. Forsyth Major, F.R.S.

Dr. Charles Immanuel Forsyth Major, who died at Munich on March 25, aged seventy-nine, was born in Glasgow, of Scottish parents, but removed when an infant to Constantinople, and lived for most of his life abroad. He was educated in Switzerland, Germany, and Italy. Graduated Doctor of Medicine in Basle in 1868, and began his career as a medical practitioner in Florence.

Dr. Major was, however, always interested in natural history, and his association with Rütimeyer in Basle led him to become an enthusiastic student of fossil mammals. While occupied with his professional duties in Florence, he took every opportunity of collecting and examining the mammalian remains found in the superficial deposits in the valley of the Arno, and from 1872 onwards he published in Italy a series of small papers on these remains, describing and discussing them in a more exhaustive manner than had previously been attempted. He summarised his results in the Quarterly Journal of the Geological Society of London in 1884, pointing out that the later Pliocene mammals were all distinguishable from those of the early Pleistocene when fossils were studied in detail. At the same time he published valuable memoirs on the dentition of rodents from the Bohnerz of Switzerland and South Germany (*Palæontographica*, xxii., 1873), and on the dentition of the early true horses (*Abhandl. Schweiz. Paläont. Ges.*, 1877–80).

About 1886 Dr. Major abandoned his medical practice, and began to devote himself entirely to scientific research. With the help and encouragement of his Swiss friend, M. W. Barbey, he made a thorough exploration of the Pliocene accumulation of mammalian bones in the island of Samos, and brought back a great collection, of which part was presented by M. Barbey to the Collège Gaillard at Lausanne, and the other part was purchased by the British Museum. In 1889 Dr. Major made another important collection of mammalian remains from a Pliocene torrent-deposit at Olivola in the Carrara mountains in Italy, and this was also purchased by the British Museum. Dr. Major followed his collections to the British Museum, and was temporarily employed there in cataloguing the fossil mammals until 1909. While thus occupied he published a valuable series of papers in London. He also arranged to prepare a Catalogue of Fossil Rodentia for the British Museum, and a large monograph of the Samos Mammalia, which unfortunately were never produced.

In 1893 Dr. Major contributed his important memoir on the skull of a giant lemur, Megaladapis, from a cavern in Madagascar, to the Philosophical Transactions of the Royal Society, and the novelty of this discovery led him to plan an exploration of the caverns and marshes of Madagascar. With the aid of a government grant from the Royal Society, he visited Madagascar in 1894–95, and brought back an important collection of fossil mammals and birds, which is also now in the British Museum. On these fossils he wrote several descriptive papers.

In his later years, however, Dr. Major found increasing difficulty and diffidence in preparing his results for publication, although his researches were pursued with accustomed diligence. Much of his valuable work on rodents and on the relationship between the fossil Samotherium, which he discovered in Samos, and the existing okapi of the Congo Forest, is thus unfortunately lost to science. Dr. Major was elected a fellow of the Royal Society in 1908, and about the same time was awarded a small Civil List pension. He then returned to the Mediterranean region which had interested him for so many years, and spent most of the remainder of his life in Corsica. He still continued to collect and study mammalian remains, chiefly from the caverns and rock-fissures of Corsica, but he now ceased to do more than make manuscript notes.

A. S. W.

Mr. E. W. Vredenburg.

Geology has lost a cultured worker by the death of Ernest Watson Vredenburg, who passed away on March 12, at the age of fifty-three. His death was probably hastened by the constant and now painfully verified foreboding that he might never be able to finish the great task which he had undertaken of revising the Tertiary palæontology of the Indian region. We have had occasion at times to notice some of the numerous instalments which he has published during the past few years in the Records of the Geological Survey of India; they and other papers now in the press were intended to prepare the way for a comprehensive monograph which he hoped would justify his reason for differing from his colleagues on some questions of stratigraphical correlation; but the burden was too great for that hyper-sensitive, artistic, and retiring nature which tended to keep him apart from his colleagues, who nevertheless appreciated his deep learning, unrelenting industry, and tenacious adherence to independent views.

Mr. Vredenburg, who was half French in race and wholly so in upbringing, graduated at Paris in Science and Letters before entering the Royal College of Science and School of Mines, where he took a double associateship, in geology and mining, before joining the Geological Survey of India in 1895. He spent the first part of his official work on the relatively uninteresting unfossiliferous rocks of Central India, and did not get an opportunity of discovering his main bent till his transfer to Baluchistan, the geological features of which he revised and summarised in 1910. There and in the adjoining regions of Sind he became deeply interested in the stratigraphy and palæontology of the

Lower Tertiary system, extending his work afterwards to the younger beds in the Burma oil-fields.

South Kensington students will remember him as a brilliant pianist who would have had a distinguished position in the musical world if he had not concentrated on the palæontology of India. During his early days in India he showed a tendency to become engrossed in archæological interests until palæontology claimed him first as a devotee and finally as a victim.

Count Fernand de Montessus de Ballore.

The small band of seismologists has suffered a serious loss through the death of M. de Montessus de Ballore. Born in 1851, he was trained at the École Polytechnique, where he was a fellow-student of Marshal Foch. In 1881 he was sent as chief of a military mission to San Salvador. There he became interested in the frequent earthquakes of the Central American republics, and he continued his seismological studies on his return to Paris as Directeur des Études at the École Polytechnique. In 1907 he was appointed director of the earthquake-service in Chile, a service which, through his efforts, became one of the first rank.

De Montessus will be chiefly remembered and valued for his studies on the distribution of earthquakes. His great work on "Géographie Séismologique," which occupied his leisure for twenty-four years, was published in 1906. Few men could be so well qualified as he for an undertaking so vast, for he had a good knowledge of six foreign languages. Having collected records of nearly 160,000 earthquakes, he showed that seismic regions follow the principal lines of relief, that, in a group of unstable regions, the most unstable are those of the greatest relief, and that more than 90 per cent. of the earthquakes occurred along two narrow zones occupying great circles of the earth, which he called the Mediterranean circle and the circum-Pacific circle. In 1907 his second work, "La Science Séismologique," appeared and at once took its place as an authoritative treatise.

Besides these two volumes and a small popular book published in 1911, de Montessus was the author of many memoirs. One of the latest was a bibliography of seismology containing the titles of more than 9000 books and papers. In the preparation of these works, he had collected a library, perhaps the most extensive of the kind in existence. This was bought a few years ago by the late President J. C. Branner, and was presented by him to the University of California. C. D.

Prof. M. Abraham.

The issue of the *Physikalische Zeitschrift* for February 1 contains an obituary notice of Prof. Max Abraham by Profs. M. Born and M. v. Laue. He was born at Danzig in 1875 and studied under Planck at Berlin. After graduating he became Planck's assistant, and in 1900 privatdozent at Göttingen. For a short time in 1905 he acted as professor at the University of Illinois, and, after his return to Göttingen, was in 1909 appointed professor of theoretical physics at Milan. The War ended this, and he held temporary posts till last year, when he was appointed professor of theoretical mechanics at Aix-la-Chapelle. Illness prevented him commencing duties there, and he died of tumour on the brain on November 16, 1922. He was well known in this country for his book "Theorie der Elektrizität," for his articles on vectors and on electromagnetic waves in the "Mathematische Encyklopädie," and for his papers on the dynamics of electrons, all giving evidence of a clear and logical mind.

We regret to learn from Australia of the death, at the end of January, of Dr. J. L. Glasson, at the age of thirty-four years. Dr. Glasson was a student of the University of Adelaide, where he worked under Sir William Bragg, and from that University he received his doctor's degree. He succeeded in winning a travelling research scholarship of the Exhibition of 1851, and with it came to this country. He entered Gonville and Caius College, Cambridge, in 1909 as an advanced student, and, going to the Cavendish Laboratory, did valuable research work under Sir J. J. Thomson. In 1912 he was appointed lecturer in physics in the University of Tasmania, Hobart, and while there he did valuable work for the Electrolytic Zinc Co. and for the Tasmanian Carbide Co. This post he resigned in 1919, returning to Cambridge for research for a couple of years, after which he accepted an appointment as lecturer in physics in the University of Melbourne, which he held at the time of his death.

The sudden death from angina pectoris on March 15 of Mr. G. E. Bullen, Curator of the Herts County Museum at St. Albans, is announced. Among the smaller museums in the country there can be few which have been raised to such a pitch of excellence, and this has been due entirely to the whole-hearted devotion and enthusiasm of Mr. Bullen during the past twenty years. A considerable extension and rearrangement of the collections has recently been completed, and, especially on the archæological side, the museum is now a model of what a local museum should be, the clear demonstrative labelling of the exhibits being a special feature. Mr. Bullen's work had been for some time carried on in defiance of indifferent health, and his death at the early age of forty is a great loss.

The *Chemiker Zeitung* of March 17 announces the death in the beginning of March of Prof. Robert Scheibe, formerly professor in the Academy of Mines, Berlin, and later active in South-west Africa and Bolivia. In the issue of March 15 the death on March 10 of Prof. Ernst Salkowski, since 1880 director of the chemical side of the Berlin Pathological Institute, is announced. Prof. Salkowski was born on October 11, 1844, in Königsberg, and at first worked with Virchow. His researches covered a wide field in physiological chemistry.

We regret to announce the following deaths:

Dr. H. H. Stock, professor of mining engineering in the University of Illinois since 1909, on March 1, aged fifty-seven.

Dr. John Venn, F.R.S., president of Gonville and Caius College, Cambridge, and for many years lecturer in logic and moral philosophy in the University, on April 4, aged eighty-eight.

Mr. S. H. Wells, director-general of the Egyptian Department of Technical, Industrial, and Commercial Education since 1907, on March 28, aged fifty-seven.

Current Topics and Events.

With this issue appears the first of a series of supplements which it is proposed to publish from time to time dealing descriptively with subjects of wide scientific interest. The present supplement is devoted to a discourse delivered at the Royal Institution on March 2 by Dr. G. C. Simpson, director of the Meteorological Office, and it provides in a convenient form a synopsis of existing knowledge of common meteorological phenomena. The method of dealing with the subject is characteristic of the present-day physicist, and it is essentially interesting. Saturation and relative humidities are somewhat fully described, and this is followed by a discussion of condensation at temperatures above the freezing point. It is of interest to note that the number of nuclei present in the air varies from a minimum of about 100 per c.c. to 100,000 or 150,000 per c.c. at times in cities such as London and Paris. Condensation nuclei are formed in various ways, one being the household fires and factory chimneys which produce large quantities of nucleus-forming material, chiefly sulphurous oxide. In England something like 5000 tons of sulphur are burnt each day in coal fires, giving enough sulphur products to pollute the atmosphere of the whole of Great Britain. Haze and mist, though so much alike in appearance, appear to be fundamentally different, haze owing its origin to foreign matter and a small amount of water, while mist is due to an actual precipitation of water from vapour to liquid. On the other hand, there appears to be no fundamental difference between mist and fog, fog is generally only a dense mist. Above the fog temperature inversion prevents all upward motion of the air and the smoke made by large towns is kept fairly stationary and within a few hundred feet of the ground. Clouds, rain, thunderstorms, hail, snow, and other aspects of weather are so often topics of conversation that Dr. Simpson's authoritative discourse upon them will be welcomed by all scientific readers.

The nomination of Sir David Bruce as president of the British Association for the meeting in Toronto next year is a well-deserved honour which will be gratifying to the many friends and admirers of this distinguished scientific investigator. Sir David belongs to the Royal Army Medical Corps, and early in his career made a name for himself by cultivating the *Micrococcus melitensis* and establishing its causative relationship to Malta fever by reproducing the disease in monkeys. Later, in 1904, he was the leader of the Royal Society's Malta Fever Commission, which made the important discovery that fifty per cent. of the goats in Malta were infected and ten per cent. of them excreted the micrococcus in their milk. Within a year of prophylactic measures based on this fact being put in force, the cases at Malta fell to one-tenth of the former numbers, and since that time the Navy has been practically rid of one of the main causes of sickness in its personnel. Of still greater interest and importance are Sir David's patient and well-thought-out researches on the greatest obstacle to the civilisation of tropical Africa, tsetse-fly disease of animals and man. His demonstration of the *Trypanosoma Brucei* as the cause of the fatal tsetse-fly disease of cattle and horses in 1894 paved the way for his demonstration in 1903 that "sleeping sickness is, in short, a human tsetse-fly disease," by a wonderfully well conceived and worked-out experiment carried out as leader of a series of Royal Society Commissions working in Africa over a number of years. The etiology of two of the most important tropical fevers was thus elucidated by his investigations, with widespread results. Sir David is characterised by the thoroughness of his work and the intuition he has always brought to bear on every problem he has tackled. He is very fortunate in his helpmeet, Lady Bruce, who has shared in both the hardships and the scientific work of his many African expeditions.

Fifty years ago, on April 18, 1873, Justus von Liebig died at Munich at seventy years of age. In 1824, at the early age of twenty-one, he began his career as professor of chemistry at Giessen and he devoted the first twenty years of his academic work to researches in the field of organic chemistry and in developing and perfecting practical laboratory instruction. The results of these labours quickly met with general recognition, and on his first visit to England Liebig was referred to by Faraday, at the meeting of the British Association at Liverpool in 1837, as one of the greatest of living chemists. Great difficulties had to be overcome by Liebig when he began to extend his theoretical and practical work to biological problems. In 1840 he published "Organic Chemistry as applied to Agriculture and Physiology," and in 1842 "Animal Chemistry, or Organic Chemistry as applied to Physiology and Pathology." The doctrines of the nutrition of plants and animals contained in these epoch-making works were at first rejected by chemists, physiologists, and agriculturists, but most of them were established in the course of the following years. Liebig's view that plants build up their organic parts exclusively from the carbon dioxide of the air and the water contained in the atmosphere and the soil, and that in intensive agriculture the mineral substances, especially potash, phosphoric acid salts, and nitrogen compounds, must be supplied to the soil in the form of artificial fertilisers, in addition to natural manure, was first accepted in England. After Liebig had modified his original opinion that the artificial fertilisers must be fairly insoluble in order not to be washed away by the rain, having recognised the extent to which the soil is capable of absorbing these substances, his doctrine of artificial fertilisation was generally accepted and forms the foundation of modern agriculture. In 1864 and 1865 Liebig wrote, at the request of the Lord Mayor of London, important papers on the utilisation of the sewage of London. Other widely-known publications are those on meat extracts, baking methods, soup for infants, silver mirrors, etc. Liebig gave a popular exposition of his views in his "Familiar Letters on Chemistry," a work from which many students of science have derived interest and inspiration.

The season's excavations at Ur of the joint expedition of the British Museum and the University of Pennsylvania closed early in March. The chief results were described by Mr. C. Leonard Woolley in a lecture, reported in the *Times* of April 2, which he delivered at Bagdad before leaving for England. The excavations were made in a walled enclosure, resembling a citadel, within the walls of the city, in which the most prominent building was a *ziggurat* of four stories, the tower of the Temple of Nanna, the Moon god, completed about 2250 B.C., and coated with blue glazed bricks by Nabonidus about 550 B.C. One of the most interesting finds was a headless diorite statue of Eannatum, King of Lagash about 2900 B.C., which may have been a trophy of war. From its earliest beginnings, possibly in 3600 B.C., until it was altered by Nebuchadnezzar in about 600 B.C., the plan of the Temple remained unchanged. The find of a golden statue in a small temple at the foot of the tower indicates that this monarch introduced a change in ritual, to which reference is made in the book of Daniel, and brought the god from the seclusion of the sanctuary out into the open to be an object of public worship and veneration.

A question agitating workers in several branches of science at the present day rather more intensely than usual is the furnishing of an adequate guide to the growing volume of published work. The lapse of the International Catalogue and the great increase in the costs of production have made the situation acute. It has long been recognised that there is a vast amount of overlap and of wasted effort, and that, if only the various societies and publishing bodies would combine, they could provide a better service at less cost. This was the line followed by Dr. J. R. Schramm, of the National Research Council, Washington, in a recent lecture on the indexing of biological literature (*Science*, November 3, 1922). He held up *Chemical Abstracts* as the example to be followed, and considered that the Federation of American Biological Societies, to which we have previously referred, could produce a similar *Biological Abstracts*, equally complete, at an annual expenditure per member of 6 to 8 dollars. Dr. Schramm, it will be seen, believes that abstracts are what the workers want. Prof. Cockerell, in his comments on Dr. Schramm's proposals (*Science*, January 5, 1923), seems to prefer an analytical index, such as is furnished by the "Zoological Record." We agree with Prof. Cockerell; but, apart from that, the question is: Will a sufficient number of individuals be prepared to pay? The experience of the "Zoological Record" suggests that they certainly will not. This, however, may in part be due to the existence of the many competing, though less complete, abstracts and indexes, and in part to the ignorance and inertia of the workers. If, not only the American societies, but also the biological societies of the whole world, would federate for this purpose, so that the proposed *Record* or *Abstracts* were virtually the only one in existence, and were thus inevitably brought before each individual worker, then success would be assured. But that "if" implies the suppression of vested interests and of the nationalism which hampered the International Catalogue.

The theory of the tides is a very strong source of attraction for a certain group of unscientific speculators. One of the latest of these to put his ideas into print is Mr. Evan McLennan, of Oregon, from whom we have received a pamphlet entitled "Nature Notes, Critical and Constructive." After betraying a complete misunderstanding of the theory of the tide-generating force on the principle of gravitation, he remarks, "It would, quite probably, be regarded as a far greater violation of the principles of science to question the theory of gravitation than to swallow the inconsistency," and "Of the forty federal institutions established by our own Government alone for the purpose of scientific research and the increase and diffusion of knowledge, and of the more than 1500 investigators paid from the public treasury to do this work, there is in all probability not one who could be induced by an outsider to give the slightest attention to any vital criticism of the Newtonian theory of gravitation." We can assure Mr. McLennan that in his own country alone there is a large number of scientific men who would enthusiastically give their attention to any real inconsistency in the accepted theory of gravitation.

The Corn Sales Act came into force on January 1, so that it is no longer possible for buyer and seller of corn in Great Britain to misunderstand each other as to the particular kind of stone in which a transaction had been conducted. All such transactions must now be in cwts. of 112 lb. The Union of South Africa has, according to the March issue of the *Decimal Educator*, adopted the cwt. of 100 lb., so that the same kind of difficulty is likely to be felt in dealings between South Africa and this country as we have just avoided here with regard to corn. In both cases the Decimal Association advises the use of the 50-kilogram standard, which is approximately 110 lb. In the same way, to overcome the difficulty of the American gallon being only about five-sixths of the British gallon, the Association and the Metric Association of America recommend the introduction of the litre for all trade in liquids. With regard to our coinage, the Decimal Association is concentrating its efforts on the introduction of a high-value penny, of which 10 would go to a shilling, and the withdrawal of the threepenny-piece. In place of the latter a double-penny nickel coin would be issued. It is not proposed that new penny coins should be issued.

The annual meeting of the Iron and Steel Institute will be held at the Institution of Civil Engineers, Westminster, on Thursday and Friday, May 10 and 11. The Bessemer medal will be presented to Dr. W. H. Maw, and the award of the Andrew Carnegie research scholarship for 1923 will be announced.

Twenty-four papers will be presented during the meeting, and their subjects will be announced in the Diary of Societies in Nature.

The May lecture of the Institute of Metals for the present year will be delivered by Dr. W. Rosenhain at 8 o'clock on Wednesday, May 2, at the Institution of Mechanical Engineers. The subject will be "The Inner Structure of Alloys."

The Hansen prize for distinguished microbiological work has been awarded this year by the committee of Danish trustees to Dr. E. J. Allen, director of the Marine Biological Association's laboratory at Plymouth, for his experimental researches in marine microbiology. It will be remembered that this award, to which we referred in our issue of February 3, p. 156, consists of a gold medal and a sum of 2000 kroner. Dr. Allen has been invited to visit Copenhagen to receive the medal and to deliver a lecture on his work on May 1.

A well-preserved rib of the gigantic dinosaur, *Cetiosaurus leedsi*, obtained by the late Mr. Alfred N. Leeds from the Oxford Clay near Peterborough, has just been added to the other remains of the skeleton exhibited in the geological department of the British Museum (Natural History). The rib measures six feet in length, and is remarkable for its slenderness.

The three lectures of the series on physics in industry arranged by the Institute of Physics last year will be published shortly in the series "Oxford Technical Publications." The fourth lecture of the series, entitled "The Application of Physics to the Ceramic Industry," will be delivered by Dr. J. W. Mellor on Wednesday, May 9, at 5.30 p.m., at the Institution of Electrical Engineers. Other lectures will be delivered later by Prof. C. H. Desch on "The Physicist in Metallurgy," and by Dr. A. E. Oxley on "The Physicist in the Textile Industries."

As no Bill providing for a period of Summer Time was passed by the French Chamber of Deputies before adjourning for the holidays, the French Government has decided not to define such a period this year, but merely to take particular measures in regard to holiday and health resorts.

The seventy-sixth annual meeting of the Palæontographical Society was held on March 31 in the Geological Society's rooms, Burlington House, Mr. E. T. Newton, president, in the chair. The annual report of the council referred to the reduction in the size of the society's annual volume owing to increased costs and smaller membership, but announced the early beginning of new monographs of Malacostracous Crustacea, by Mr. Henry Woods, and of Gault Ammonites, by Dr. L. F. Spath. Contributions had been received towards the cost of plates from the University of Bristol and from Mr. F. W. Harmer. Messrs. A. J. Bull, E. Heron-Allen, H. B. Milner, and A. Wrigley were elected new members of council. Mr. E. T. Newton was re-elected president, and Mr. Robert S. Herries and Dr. A. Smith Woodward were re-elected treasurer and secretary respectively.

A note on cleaner air for London appears in the *Meteorological Magazine* for March. The Public Control Committee of the London County Council is considering how far fog in London is the result of atmospheric pollution due to preventable causes, and how far the atmosphere may be improved by the larger use of electricity for power and other purposes. It is also being considered whether further powers are required to deal with the emission of smoke. Detailed reports have been prepared, and these appear to be under discussion by the Council.

A new type of pocket magnifier is now included in the optical products of Messrs. Cooke, Troughton and Simms, Ltd., Buckingham Works, York. We have had an opportunity of examining one of these. The lens consists of an achromatic doublet giving a magnification of five with a focal length of 2 in., an aperture of 0·85 in., and a field of view of about 2 in. in diameter. The field is flat and free from distortion and colour, and the definition is good over the whole of it. The lens is fitted in a duralumin mount which can be folded when the magnifier is not in use. Magnifiers of this type are now being supplied with powers of 2½, 5, and 10 respectively.

Beginners in bee-keeping will find some useful information in Leaflet 128, recently revised by the Ministry of Agriculture and Fisheries. Bee-keeping is an occupation eminently suitable for small-holders, cottagers, and others with only a limited space available. The insects are, moreover, active pollinators of fruit blossoms, and consequently have other uses besides the production of honey. Having mastered the contents of this leaflet, we advise the beginner to procure the collected leaflets on bee-keeping (seven in number), which can be obtained from the Ministry, at 10 Whitehall Palce, S.W.1, at the low price of 6*d*., post free.

The Gifford Emonds prize, value 100*l*., which is awarded every two years for an essay on a subject dealing with ophthalmology and involving original work, and open to any British subject holding a medical qualification, is now open to competition. The subject chosen is "Iridocyclitis." Preference will be given to original work based on any branch of the subject, rather than to compilations of the writings of previous observers. Full particulars of the prize can be obtained from the Secretary Superintendent, Royal London Ophthalmic Hospital, E.C.1. Essays must be sent in not later than December 31, 1924.

Messrs. H. Sotheran and Co. (43 Piccadilly, W.1) have recently purchased and are offering for sale as a whole the library of books on British ornithology formed by Major W. H. Mullens. It contains about 3000 volumes, and ranges from the "Avium praecipuarum" of William Turner, 1544, to Beebe's recently completed "Monograph on the Pheasants."

The catalogues issued by the firm of Bernard Quaritch, Ltd., 11 Grafton Street, W.1, are always of interest. The latest one (No. 376) contains upwards of 1700 titles (with, in many cases, comments) of books in the following subjects: botany, agriculture, early medicine and surgery, forestry, fruit-culture, gardens and gardening, herbals, and tobacco. As usual, many choice and rare volumes are included.

No. XI. of the "Publications de la Société de Chimie Physique" is a short monograph of 15 pages on isotopes, by M. Maurice de Broglie, which was delivered as a lecture in November 1920. The previous publication was a lecture on Bohr's theory of the constitution of the atom. The monograph is published by Hermann et Cie at the price of 2 francs. Two series of somewhat similar monographs are being issued by the Libraire Scientifique Albert Blanchard. One of these, of which seven parts are announced, consists of groups of two or three lectures on physical subjects. In addition to these a series of foreign scientific monographs is being issued. The third of these, which has recently come to hand, is by Prof. Kossel, and bears the title "Les Forces de Valence et les Spectres de Röntgen." The monograph covers 70 pages, and is issued at a price of 4·50 francs.

The Society of Glass Technology, which has its headquarters at the University of Sheffield, has issued a useful handbook, a "Directory for the British Glass Industry," price 7*s.* 6*d.* to non-members of the Society. The volume is divided into sections providing lists both alphabetical and classified of glass manufacturers and craftsmen, with particulars in most cases of the class of work produced, and lists of firms supplying material and machinery required in glass making and working. The concluding short sections give useful information concerning industrial associations, trades unions, City Companies, educational institutions, and research associations, and publications dealing with glass technology. It is difficult to understand on what principle the selection of a group of publications, mentioned in the last section, which are referred to as "Periodicals in which articles on glass and ceramics occasionally appear," has been made.

Our Astronomical Column.

A Supposed Meteorite at Quetta.—The *Pioneer Mail* for February 23 reports the fall of a supposed meteorite at Quetta on January 25, which, if confirmed, will for the first time establish the power of a meteorite to cause a conflagration. The fragments of the meteorite collected are said to weigh 6 tons, with a volume of 500 cubic feet! Hence the material must be abnormally light for a meteorite. It struck a large stack of closely packed straw 30 feet high, and penetrated it nearly to the ground. The "meteorite" is said to consist of materials like slate-grey igneous rock, volcanic glass, and coke. Possibly the stack was struck by lightning and the fused residue of the straw has been mistaken for a meteorite. The Geological Survey of India will doubtless settle the nature of this phenomenon.

Solar Eclipse Investigations.—At the meetings of the Australasian Association for the Advancement of Science held at Wellington, N.Z., two papers dealing with observations of the total solar eclipse at Wallal were communicated by Prof. A. D. Ross, who was a member of the Crocker Eclipse Expedition of the Lick Observatory. Shadow bands were observed for two minutes before and for one minute after totality. They altered in appearance, but the most persistent type was indistinct dusky bands about 6 inches wide, at 17-inch intervals, moving in a direction 30° S. of E. at 6 or 7 miles per hour. The bands at times came in groups and developed from a general shimmering effect. Their appearance was inconsistent with a diffraction theory, but suggested irregular refraction due to atmospheric temperature inequalities. The wind was from N.N.W. to N.W. at about 4 miles per hour, and there was a temperature drop of about 8° due to the eclipse. By comparison of six photographic plates exposed to a region surrounding the south celestial pole about mid totality and during twilight the same evening, it was found that the eclipse illumination corresponded to twilight with the sun 7½° below the horizon. Wellington Anti-screen plates were used. The humidity was about 45 per cent. at the time of totality and about 50 per cent. at twilight, so that it is unlikely that the estimate of brightness was much affected by variation in the transparency of the atmosphere. Determination of the brightness of the corona was attempted with a specially designed integrating photometer, but the measurements of the plates had not been completed.

Planetary Radiation.—No. 460 of the Scientific Papers of the Bureau of Standards, Washington, contains an account of researches made at Flagstaff by W. W. Coblentz on the thermal radiation from planets and stars. A cell of water 1 cm. thick is used to separate the long heat-waves from planets (due either to inherent heat or to warming of the surface by the sun) from the reflected solar radiation. A vacuum thermocouple made of bismuth wire was used to measure the radiations, the instrument being mounted on the 40-inch reflector. Observations on the moon are stated to confirm Very's results, but are not described in detail.

The observations lead to the conclusion that the planetary (long wavelength) radiations, expressed as percentages of the total radiation received from them, are Jupiter (0), Venus (5), Saturn (15), Mars (30), the moon (80). The high figures for the moon and for Mars indicate that rarity of atmosphere increases the warming of the surface; further, the northern hemisphere of Mars, which was in autumn, and more cloudy than the southern hemisphere, indicated a lower planetary radiation. It is hoped to compare the radiation from the orange and dusky regions of Mars, which might give a clue as to the conjectured interpretation of the latter as regions of vegetation.

The zero figure for Jupiter is concluded to be due to the enormously thick atmosphere, which acts as an opaque screen to the radiations from the (supposed) heated interior. The instrument is restricted to wavelengths 7 to 12 μ. Hence nothing can be stated about radiation between 4 and 7 μ, or from 12 to 15 μ.

The star temperatures are given as 3000° for type M, 5900° for Capella and sun (type G), and 12,000° for type B, in close accord with previous results.

Research Items.

Migrations of the Waxwing.—The waxwing, *Ampelis garrulus*, is not a rare visitor to our shores. Seldom a winter passes but one or more is observed in eastern parts of Britain, and occasionally its numbers indicate a very considerable immigration. The largest ever witnessed in Scotland occurred in the late autumn of 1921, and is discussed by Dr. J. Ritchie in the *Scottish Naturalist*, September 1922–February 1923. The immediate cause of Scotland's share in this immigration is due in the first place to the lack of food-supply in Norway. The summer of 1921 in that country has been notorious for the lack of wild berries upon which the waxwings feed. Large flocks of the birds congregated in the southern part of Norway, but, finding insufficient food, took advantage of easterly winds accompanied by a rapidly rising barometer to reach our shores. The meteorological phenomena associated with the migration are complex, and Dr. Ritchie promises to deal with them in a future paper.

Botanical Survey and Ecology in Yorkshire.—Under this title a most valuable and comprehensive account of the development of our knowledge of the Yorkshire flora is given by Dr. T. W. Woodhead in the *Naturalist* for March 1923. The first flora of Yorkshire was published at Halifax in 1840 by Henry Baines, and since then the three Ridings have been more intensively dealt with in the three well-known floras, Baker's "North Yorkshire," Arnold Lee's "Flora of West Yorkshire," and Fraser Robinson's "Flora of the East Riding of Yorkshire." Many other valuable systematic works dealing with the Yorkshire flora are described by Dr. Woodhead, who then proceeds to narrate the development of botanical survey and the mapping of plant associations, under the inspiration of the brothers Robert and William G. Smith. Around these men an active band of workers gathered, and in December 1904 the Central Committee for the Survey and Study of British Vegetation was formed at a meeting held at the house of Dr. W. G. Smith in Leeds; in 1913 this Committee was replaced by the British Ecological Society with its wider membership. Two vegetation formations that have been extensively studied in Yorkshire are the woodlands and the moorlands, and Dr. Woodhead briefly traces the development of our knowledge of these characteristic vegetation features, their distribution, development and occasional retrogression. There is an interesting discussion of the significance of the vegetation found in the peat of the Southern Pennines, and the bearing that the studies have upon persistence of the flora from pre-glacial times. Dr. Woodhead's work upon the relation of vegetation survey to the many other activities and interests of a district was well illustrated by the extraordinarily interesting series of maps of the Huddersfield area that were on view in Hull during the British Association meeting, in the exhibition room of the Yorkshire Naturalists' Union. It is therefore natural to find that the presidential address to the Yorkshire Naturalists' Union closes with the expression of a hope that such ecological studies may extend to man, and that the local museum may enshrine the results of an intensive local survey of plant and animal, including human communities.

A New Process for making Stereoscopic Maps.—A paper read at a recent meeting of the Paris Academy of Sciences (*Comptes rendus*, January 22) described a new method, due to M. G. Poivilliers, for obtaining stereoscopic maps. The various methods proposed hitherto have been based on the use of two conical perspectives, the production of which involves practical difficulties; in M. Poivilliers's method two cylindrical projections are used, one vertical and the other oblique. Referring to the accompanying illustration (Fig. 1), the projection A is an ordinary contour map; the projection B is obtained from A by shifting the contour lines in the direction east-west by an amount proportional to their altitude above an arbitrarily chosen datum line. The resulting stereoscopic view shows theoretically a slight curvature effect which, however, does not alter the relative relief. In examining with a stereoscope even the above reproductions, the result obtained is very striking. The "falsified" map B was in this case drawn by hand with the aid of a tracing of A, but it is easy to imagine a simple apparatus by means of which this can be done semi-automatically. The contour interval is in this case 20 metres, and corresponds to a horizontal shift of 0·5 mm. It is anticipated that M. Poivilliers's method, on account of its simplicity, will tend to generalise the use of stereoscopic maps, especially for purposes of instruction in topographical surveying. It has also been suggested that the process could be usefully applied to geological maps, by making it possible, for example, to visualise the superposition of successive layers inside the earth.

A—Ordinary contour map. Fig. 1. B—Complementary map, with contour lines displaced.

Atmospheric Humidity in the United States.—Prof. R. de C. Ward, of Harvard University, is the author of a communication on the above subject in the U.S. *Monthly Weather Review* for November 1922. The communication is admirably illustrated with diagrams; two are given for January, at 8 a.m. and 8 p.m., and two for the corresponding hours in July, showing the relative humidity by lines of equal value over the whole of the United States. The element is a real and definite factor in climate, and especially affects our bodily comfort. The values give the ratio between the amount of moisture in the atmosphere and the amount which could be present without condensation. On the Pacific, Atlantic, and Gulf coasts the lines show a distinct tendency to be parallel to the sea-coast. The distribution is chiefly controlled by temperature, direction of prevailing winds, distance, and direction of the chief source of moisture supply, and general topography. Charts given with the communication are taken from the 'Atlas of American Agriculture." A belt of uniformly high relative humidity along the coasts averages about 75-80 per cent., and at times exceeds 90 per cent. on the Pacific coast. Inland, in parts, the minima relative humidity during the hot summers fall to 30 per cent., and even 20 per cent. over the districts of most extreme aridity. Absolute humidity, which shows the actual amount of water vapour in the air expressed in decimals of inches, and known as vapour pressure, is also dealt with; two charts are given showing the equal pressure lines over the United States in the months of January and July. Temperature is essentially the chief control of absolute humidity; in mid-summer the amount of moisture in the atmosphere is generally from two to four times as great as in mid-winter.

Geology and the Ice-cap in Northern Greenland.—The interest of Dr. Lauge Koch's geological mapping in Northern Greenland (Nature, vol. 110, p. 91) is now increased by his preliminary account of Peary Land. His new map (*Am. Journ. Sci.*, vol. 206, p. 190, 1923) shows the continuation of the Caledonian folding through the north of the region, where moraine-matter from the glaciers descending from the south obscures much of a country in any case difficult for research. The ice-cap extended a good deal farther north at the maximum of the Pleistocene ice-age, but did not cover all the coastland. It may be remarked that in this area we have once more evidence of the potency of snow-domes in promoting widely spread glaciation. It seems unnecessary, if unfashionable, to shift the pole to account for every local centre of ice-radiation. The main result of Lauge Koch's recent work is the discovery of a richly fossiliferous Ordovician series far greater in extent and thickness (870 m.) than he could anticipate when he began his arduous explorations in 1917.

Production of Lead in Britain.—In the numbers of *Chemistry and Industry* for March 16 and 23, Prof. H. Louis contributes a most interesting and valuable account of the production of lead in Britain. He begins with a clear account of lead in ancient times. The first definite mention of the production of lead in Britain occurs in Pliny (A.D. 77); a pig of lead has been found in the Mendip Hills bearing the name of the Emperor Claudius (A.D. 49), and in A.D. 64 smelting in Flintshire began. Some pigs of Roman lead are stamped *ex arg.*, *i.e.* desilvered—probably by cupellation. The progress made in the Middle Ages is described in detail by Prof. Louis, whose articles have a wide interest.

Substitution in the Benzene Nucleus.—In the *Chemical News* of March 16, Messrs. R. Fraser and J. E. Humphries discuss the problem of substitution in the benzene nucleus in the light of the Lewis-Langmuir theory of co-valence. They start from three simple postulates related to the octet stability of an atom or group, and discuss in an interesting manner many known results in organic chemistry. In the chaotic mass of unco-ordinated facts which lies heavy on organic chemistry a ferment is evidently moving; in time the material will no doubt be brought into order, and discussions of the type of that mentioned cannot fail to be of service in this direction.

Early History of the Gas Process.—The early history of the manufacture and distribution of towns' gas was briefly outlined by Mr. D. Brownlie in a paper read before the Newcomen Society on March 20. Van Helmont, in 1600, observed that "coal did belch forth a wild spirit or breath." Other early pioneers include Thomas Shirley (1667), Robert Boyle (1691), Stephen Hales (1726), J. Clayton (1739), Bishop Watson (1781), the Earl of Dundonald (1781), and Minckelers (1784). William Murdoch lighted his house at Redruth with coal gas in 1792. At first the gas was burned at the open end of an iron pipe, but the accidental use of an old thimble led to the introduction of a burner in which the gas was lit at a number of jets issuing from a perforated thimble. Messrs. Boulton and Watt's works at Soho, Birmingham, were illuminated by gas in 1802. The plant erected by Murdoch for this purpose differed in little but scale from the horizontal settings and gasometers of to-day. Lebon, in France, worked along much the same lines as Murdoch, and illumined his house with coal gas in 1801. Winsor illumined part of Pall Mall with gas in 1807. Samuel Clegg introduced lime purification in 1806, and invented the first gas-meter in 1815. In the early days gas was distributed through lead or wood pipes. Cast-iron pipes were introduced in 1810, and wrought-iron pipes in 1825. John Grafton, in 1820, introduced the use of fireclay instead of iron for retorts. This permitted the temperature of carbonisation being raised from 1400° F. to 2000° F. Clegg patented retorts for continuous carbonisation in 1815. The first vertical gas retort was patented in 1828 by John Brunton.

Photometry.—In his annual address before the Philosophical Society of Washington, the retiring president, Mr. E. C. Crittenden, presented an interesting survey of problems involved in the measurement of light. The address has appeared in the Journal of the Washington Academy of Sciences (vol. 13, No. 5, March 4, 1923). In the introduction Mr. Crittenden recalls several notable advances in photometry, such as the adoption of the international unit of candle-power by all leading countries except the Germanic nations. In view of the uncertainties attending the use of flame standards, this unit is now usually preserved by the aid of calibrated electric incandescent lamps; the process is analogous to that adopted for the international ohm, derived from a mercury standard but maintained by means of wire resistances. However, there is this important distinction, that we have as yet no adequate, accurate, and reproducible primary standard of light. One of the most hopeful lines of investigation is that pursued at the U.S. Bureau of Standards, where experiments on a black body maintained at a definite temperature have been made; the black body takes the form of a carbon-tube electric furnace matched in colour by comparison with certain standard incandescent lamps. But further information on the accuracy with which temperature can be maintained is needed. The address also directs attention to the fundamental distinction between conceptions of light as radiation, and as a physiological impression—a distinction that becomes specially important when we have to deal with sources yielding light of different colour. The physiological phenomena affecting such comparisons are discussed, and some remarks are made on the results of "equality of brightness" and "flicker photometer" measurements. The visibility curve, throughout the spectrum, of the normal eye has now been ascertained with fair precision. A knowledge of this should enable us to evaluate the luminous power of any variety of radiant energy; and if, in addition, the primary standard based on the black body at specified temperature should prove satisfactory, considerable progress towards the scientific measurement of light will have been made.

Biometry and Genetics.

PROF. RAYMOND PEARL and his students continue to make important contributions to the biology of man and other organisms on a statistical basis. In a recent paper (Pearl and Bacon, Johns Hopkins Hospital Reports, vol. xxi. Fasc. iii.) an analysis is made of the relation of the relative size of heart, liver, spleen, and kidneys to tuberculosis. The data were derived from 1341 autopsies in which there were tubercular lesions. Six indices for the relative weights of the above organs were used as the basis of statistical investigation in relation to age, sex, race, and cause of death. It is shown that the relative weights of liver and heart, and heart and spleen change progressively during life; also that in cases of fatal tuberculosis the absolute weight of the heart is less and of the spleen greater than normal, probably because these changes are brought about by the disease. Curves of age show that when tuberculosis alone is fatal it kills at comparatively early ages. Many other interesting facts are brought out in this statistical study.

In "dry" America, experiments with alcohol have a particular interest. Stockard has shown with guinea-pigs and Pearl with fowls that individuals which throughout life received daily doses of alcohol by inhalation are much longer-lived than their untreated sibs. In a recent note (*Amer. Journ. Hygiene*, vol. ii. No. 4) Prof. Pearl points out that the actuarial data of insurance companies, which are generally supposed to show that the consumption of alcohol in man in any quantity shortens life, are practically worthless. From 1569 family history records carefully collected in the vicinity of Baltimore, he concludes that while heavy or steady drinking lowers the expectation of life, the moderate or occasional consumption of alcohol has no such effect on either sex.

In experimental studies on the duration of life in Drosophila (Pearl and Parker, *Amer. Naturalist*, vols. 55, 56) the authors compare the percentage of survivals at successive ages with the corresponding curve for man. A day in the life of a fruit-fly corresponds roughly with a year in the life of a man. Large numbers of flies of different stocks were bred under carefully standardised conditions. The length of the imaginal life was noted and the results compared with the statistics for man, beginning at the age of fifteen years. Fundamentally similar curves are obtained in the two cases. In Drosophila it is shown that long-winged flies have two or three times as great an expectation of life at any age as short-winged flies, and that other hereditary differences in duration of life also occur. The death-rates generally increase steadily with advancing age. The mortality curve for Drosophila is then compared with that for modern man and for the population of the Roman provinces in Africa about the beginning of the Christian era (from data of MacDonnell, *Biometrika*, 1913). The Drosophila curve generally runs intermediate between these two. The modern curve of human mortality is diverted from the normal by the prolongation of life of many of the less rugged by measures of public health and sanitation.

By selection and inbreeding from Drosophila stocks it was possible to isolate strains showing large differences both in mean duration of life and in the form of the mortality distributions, while in inbred lines the genetic differences remained constant for ten to twenty-five generations. It was shown that occasional etherisation of the flies has no appreciable effect in lessening their duration of life. There is some evidence that in crosses, duration of life may segregate like a Mendelian character. A pedigree indicating something of the same kind in man is presented by Pearl (*Amer. Journ. Hygiene*, vol. ii. No. 3). In the father's family only 10 per cent. survived to the age of fifty years, in the mother's family 75 per cent. reached that age, and in the offspring 87·5 per cent.

Using 100 births/deaths as a "vital index," Pearl and Burger (Proc. Nat. Acad. Sci. vol. 8, No. 4) plot the curve for this index for England and Wales in the years 1838–1920, from statistics in the Annual Reports of the Registrar-General. This ratio shows a slow but extremely steady increase until 1914, with only two slight fluctuations caused by influenza epidemics in 1847 and 1890. The birth-rate in the meantime showed a slow increase until about 1878, then a more rapid decrease until 1914, and a marked recovery since the war. Thus while in the year 1838–39 the number of births for each death was 1·4, in 1920 it was more than 2. The whole curve for the vital index shows a remarkably steady increment in the rate of population growth, with a high degree of regulation of death-rates to variations in the birth-rate. Measured by the criterion of the vital index, it is concluded that the population of England and Wales is "biologically more vigorous" than in 1838. But this merely means that its net rate of increase is greater, and takes no account of the differential character of the birth-rate. In another note in the same issue, Pearl considers the seasonal fluctuations in the vital index of the population, based on the same data, and finds that in each year it has its lowest value in the winter quarter (ending March 31), and its highest value in the summer quarter. In other words, in the winter months the birth incidence is relatively low and the death incidence relatively high, as might be expected.

That density of population influences fecundity was formerly shown for fowls, and similar results have now been obtained for Drosophila (Pearl and Parker, Proc. Nat. Acad. Sci. vol. 8, No. 7). The rate of reproduction of this fly is shown experimentally to vary inversely with the density of population. This is the converse of Farr's law that the death-rate varies directly with density of population. It is suggested that the world-wide increase in density of population may account for the general decline in birth-rates which has taken place in the last forty years. The subject is one which deserves further investigation.

A hexadactylous Norwegian family in which the postaxial digits (little fingers and toes) are double, is described by Aslaug Sverdrup (*Journ. Genetics*, vol. xii. No. 3). The condition is traced through six generations, and two types of polydactylism are recognised. In type A one finger, usually the fifth, is duplicated, while in type B the sixth finger is represented by a small attached appendage. Both these types are already well known. The condition behaves in general as a dominant character, but in one line of the family, showing chiefly the A-type, there is an excess, and in another, showing only the B-type, a deficiency of polydactyls. Moreover, an A-type individual may have either A- or B-type offspring, whereas B-types cannot produce A-types. It is concluded that the B-type is probably determined by a single Mendelian factor with sometimes a failure of dominance, while the A-type is probably due to cumulative factors. The A-type of polydactyly is sometimes accompanied in this family by a form of brachydactyly due to shortening of certain metacarpal bones, but also in some cases to short phalanges. Such papers on the inheritance of human abnormalities are important in their recognition of the necessity for accurate and detailed observations.

In a study of the inheritance of patching in the flower of the sweet pea Prof. Punnett (*Journ. Genetics*, vol. 12, No. 3) introduces facts which cannot be explained on the ordinary Mendelian basis. The sweet pea Duke of Westminster sometimes has on the wings a larger or smaller patch of purplish pink. Such patched plants give normal, red, and patched offspring in varying proportions. Certain branches of "patched" plants are sometimes normal. The seeds from such normal branches show no constant genetic difference from the rest of the plant, nor was any evidence obtained that the normal, patched, and red flowers on a patched plant differed from one another genetically. There is no indication of genetic differentiation in the germplasm of different parts of the plant. Nevertheless, patched plants are not apparently all alike. As in striped Mirabilis, the pair of colour characters may behave either as a segregating Mendelian pair or form a mosaic. There is no sufficient explanation of this mosaic condition at the present time, but it represents a condition differing distinctly from ordinary Mendelian behaviour.

In a second paper on the inheritance of characters in some of the many rice varieties, Mr. F. R. Parnell, with the assistance of Messrs. G. N. R. Ayyanger, K. Ramiah and C. R. S. Ayyangar (Mem. Dept. Agr. India, Botany, vol. xi. No. 8), deals with the colours of glumes and grain, also with dwarfing and with shape of grain. The dwarf variety differs very markedly from the type, but behaves as a simple recessive. A result of economic importance is that the weight of the grain varies with the shape. The hereditary behaviour of a number of colour factors is analysed. Another genetic paper of economic value is a study of certain forms of cotton by Mr. Ram Prasad (Agric. Inst. Pusa. Bull. No. 137). Long fibre is considered to be a dominant character in cotton. Some evidence is obtained that long fibre is correlated with long stigma, plants with short lint having shorter styles. If this is the case it would enable roguing of undesirable plants producing short lint to take place much earlier than would otherwise be possible.

Norway and Iceland: An Interesting Contrast.

NORWAY has many interesting features to a visitor with scientific and technical tastes. The ubiquity of electricity generated from water-power has often been the subject of comment. The peculiar formation of the high tablelands, with lakes at heights of 1000-3000 feet, constantly renewed by water from the snows above, is favourable to hydro-electric supply. The potential value of the water-power of Norway has been assessed at 15,000,000 h.p., of which about one million is at present in use.

The mountainous nature of the country has other interesting consequences. One curious result is that communication between valleys is often less easy in summer than in winter, when roads and passes become covered with deep snow and can be traversed by ski and sleigh. The nature of the country has developed isolated scattered communities with pastoral tastes and special local industries, such as the hand-woven fabrics for which Norway is famous.

The climate has much in common with that of England. Bergen is notorious for its rainfall, and the humid atmosphere is doubtless responsible for the luxuriant growth of trees, springing in masses out of the bare rock lining the fiords in a manner that seems to invite study by experts in forestry. The use of timber in Norway is universal. Buildings are almost invariably of wood, and the humbler cottages are roofed with turf, which seems to thrive in the moist atmosphere. In mountainous Norway grass is scarce. Hence the custom of sending cattle up to the mountain "sæters" in the summer, so that the grass at the level of the fiord can be stored in summer-time. This cut grass is hung up to dry on horizontal lengths of wire. Possibly British farmers could take a hint from this practice, as crops in this country are often spoiled by rain.

Geologically the great tablelands of Norway, with their stretches of perpetual snow at relatively low level, and their vast glaciers (the largest in Europe with the exception of those in Iceland) are of great interest. It is a strange sight to find these great glaciers descending right down to the level of the fiord, as happens, for example, at Fjaerland.

Iceland furnishes some interesting contrasts to Norway. The climate is more stable and less like that of Britain. Whereas in Norway trees are everywhere, in Iceland there are practically none. Hence we find a new material for buildings of the better class—corrugated iron! Grass is also scarce, and Iceland is one of the few countries where rabbits will not thrive. The scenery, though almost destitute of verdure, is not monotonous and has a charm of its own. It consists mainly of alternations of rock, lava, and sand, with, on the lower slopes of mountains, stretches of moss. All vary remarkably in colour. Rocks are black, brown, purple, and occasionally bright red. Sand may have any tint from yellow to black. Amazing changes in colour, difficult to explain and offering an interesting study to the physicist, occur as the sun sets. A curious feature is the astonishing brilliancy of the setting sun, exceeding by far that usual in England. The pools of molten lava also afford a field for study. Their position is indicated by a sulphur-yellow crust, but the upper liquid contents are often bright blue, changing to scarlet at a lower level. Hecla, by the way, although the mountain best known to English readers, is by no means the best example of volcanic action, and is a comparatively inconspicuous mountain.

Ice and snow, usually not far distant in Norway, are universal on the higher mountains of Iceland, and the blanket of ice and snow creeping over the edges of precipices forms an important element in the general scheme of coloration.

In one respect Iceland and Norway seem to be much alike—in the hospitality accorded to the English visitor. In Norway, especially when one leaves the beaten track, one is conscious of an atmosphere very different from that in many hotels in Europe. In Iceland, once he leaves the capital, the traveller finds practically no hotels, but he can rely on the generous hospitality of the districts visited. Ponies are the usual mode of conveyance. It is stated that the import of horses is forbidden, as the Icelandic Government desires to keep the strain of ponies pure.

In Norway the present writer was impressed by the high general level of education. One could converse on equal terms with persons of all degrees, and learn facts of interest about the country. English is a compulsory language in the schools, and is often spoken with considerable facility. Even in Iceland, it appears, English is spoken more frequently than might be expected. Here again there is a high level of education, but owing to the remoteness of the island some strange conceptions of England prevail.

In Iceland, as in Norway, a variant of Danish is spoken. But whereas in Norway the entrance of foreign words is not resented, in Iceland they invariably undergo translation before acceptance. The writer was given to understand that the language is written and spoken in almost exactly the same manner as it was a thousand years ago, and that the ancient sagas can be read with the same ease as the modern newspaper. Probably there is no other country in Europe where this strange perpetuation of ancient forms of speech prevails.

The Survey of India.

THE report by Col. Ryder, the present Surveyor-General of India, referred to below,[1] shows that in the year 1919–20 the Indian Survey Department had fully recovered from the dislocation due to the War.

During this period there were no less than 19 survey parties in the field, of which 12 were topographical. On the normal scale of one inch per mile (much of which was revision) and smaller geographical scales, about 2800 square miles was turned out, while on the larger scales, ranging from 1½ inches to 24 inches and even 64 inches (city and town surveys), the output, detailed partly in miles and partly in acres, was reckoned to be satisfactory. Every class of country was included in the field of work, from the sands of Rajputana to the dense forest-covered hill tracts of Burma, and we read of the time-old difficulties, heavy and continuous rain, malaria, and even of the clearance of villages by man-eating tigers. It is interesting to observe that the sources of the Irawadi (so long a geographical problem) were finally mapped.

Although the costs of the different classes and scales of survey are set out in considerable detail, it is difficult to frame any conclusion as to whether those costs have risen since the War. The normal one-inch scale of original survey apparently varied between 20 Rs. per square mile in Bengal and 70 Rs. in Lower Burma. This does not indicate any great increase on pre-war costs, but in itself scarcely justifies any general estimate.

In the geodesic and scientific branch of the department there is a curtailment of activity. No first-class triangulation was carried out, and both the pendulum and latitude observations were suspended, but the registrations of tidal curves by means of self-registering tide-gauges were continued at Aden and at the principal ports of India. Levelling operations were also continued, and a new geodesic level net of India has been inaugurated on which levelling of high precision on the "fore and back" system will be the method employed. Like the exact determination of the height of the principal peaks of the Himalaya, it might be open to question whether the practical results of extreme precision are worth the expense of determination. The magnetic survey was also carried on during this season. The report closes with the usual returns of the computing- and drawing-offices.

The chief point of interest in the volume is found in Appendix II.—the report on the expedition to Kamet by Major Morshead, who afterwards took such an active part in the Everest expedition. Kamet (25,445 feet high) is the culminating peak of the Zaskar range, and afforded Major Morshead and that distinguished mountaineer, Dr. Kellas, an excellent opportunity for scientific observation on the effect of high altitudes on the human body. Appendix III. is also interesting, recording a note on the topography of the Nun Kun massif in Ladakh by Major Kenneth Mason. He has a good deal to say in criticism of Mrs. Bullock Workman's claim to have established the height and position of certain peaks of that group, in which she disagrees with Indian Survey results. It is always dangerous for the amateur to claim greater accuracy than that maintained by the Trigonometrical Survey of India. Mrs. Bullock Workman, in publishing her account of her extraordinary feats of climbing, pits herself against the G.T.S. and suffers accordingly.

T. H. H.

Polish Celebrations of the 450th Anniversary of the Birth of Copernicus.

NICOLAUS COPERNICUS was born on February 19, 1473, in Toruń (Thorn), a town situated on the Vistula, in the north-west of Poland; the 450th anniversary of the birthday of the great astronomer occurred thus on Monday, February 19, and was celebrated in many parts of Poland with much solemnity. Impressive ceremonies were held in Warsaw, Wilno, Poznań, Lódź, Wloclawek, and Kieke; in the Jagellonian University of Cracow (where for four years, 1491–1495, Copernicus was an undergraduate) the celebrations in commemoration of the anniversary will be held at a later date, probably in May.

In connexion with the Cracow proceedings a work, "Stromata Copernicana," will be published under the auspices of the Polish Academy of Sciences and Letters in Cracow; its author is Prof. L. Birkenmajer, the well-known biographer of Copernicus. We have not the space to enter into an account of Prof. Birkenmajer's investigations, but the following interesting fact may be mentioned: On the October page for the year 1505 of the book "Calendarium Magistri Joannis de Monte Regio," preserved in the Uppsala University Library (sign. "Incunab." 840), Prof. Birkenmajer discovered, in Copernicus's well-known handwriting, the Polish inscription (twice repeated) "Bok pomagay" (Our Lord, help us). Writing on this interesting detail, Prof. Jan Loś, the well-known philologist (and professor of the history of Polish language in the Jagellonian University of Cracow), says: "In the year 1505 every Pole would have written the words given above exactly in the form in which Copernicus has written them" (*Jezyk Polski*, vol. viii., No. 1). Prof. Birkenmajer adds that in 1505, or perhaps in 1506, Copernicus had already in his mind the ideas which eventually took form in the well-known revolutionary "Commentariolus."

The Copernicus commemoration at Toruń extended over the two days—February 18 and 19; delegates from all the universities, high schools, scientific societies, etc., of Poland, and other guests were cordially received by the municipality and citizens of Toruń. The proceedings included the inauguration of the first general meeting of the Polish Astronomical Society. This meeting resolved unanimously to ask the Polish nation to establish a National Astronomical Institute in Poland; an attempt with this object in view was made by Prof. Banachiewicz, of the Jagellonian University of Cracow, and exists in the form of an astronomical station in the Carpathian Mountains. A memorial tablet on the house where Copernicus was born was also unveiled.

Pathology of Market Produce.

DURING recent years great efforts have been made by the biologist to gain such a knowledge of the diseases of cultivated crops as will permit methods of control to be placed at the disposal of the grower.

A reference to the pages of the *Annals of Applied Biology*, the official organ of the Association of Economic Biologists, together with the number of other papers published each year dealing with the life history of disease-producing organisms infecting plants, will show that considerable progress has been made in this still comparatively new field. But some brief papers published in *Phytopathology*, the official organ of the American Phytopathological Society, will show that in the United States a new field of scientific investigation has been opened between the crop and the consumer. Much of the produce, especially of market garden and greenhouse, is extremely perishable, and the cost of fruit or vegetables to the consumer is largely contributed to by the heavy loss that occurs during transit and marketing.

In 1917 in the States a Food Products Inspection Service of the Bureau of Markets was established and was soon working in close collaboration with the trained investigators of the Bureau of Plant Industry.

As is pointed out by G. K. K. Link and M. W. Gardner in a brief review of the first year's work that resulted from the joint attack upon the pathology of market crops (*Phytopathology*, 9, pp. 497–520), the first result was a revelation of the enormous economic importance of the problem, to which the long distances of transit in the United States naturally contributed. In water-melons alone, from four States during 1918, the market inspection services record a loss of 1¼ million dollars, while hundreds of car loads of grapes from California were almost a total loss, due to decay induced by Botrytis, Penicillium, and Aspergillus. Furthermore it was found that these losses, stoically borne by the trade as "part of the game" and passed on to the consumer, very largely arose from preventable causes, with the result that pathologists are being pressed to extend their survey from the growing crop to the study of the crop during harvesting, storing, shipping, and marketing.

Another line of biological inquiry has also been indicated: the task of salvage when prevention of loss is no longer possible. Most of these diseases are fermentation processes, and a controlled fermentation may yield a by-product of value. At the outset the market pathologist has found himself forced to recognise almost a new type of disease organism. Under field conditions this type has limited importance, but under market conditions the plant tissues are less resistant and these organisms show much greater virulence while attacking a wide range of plant species; among such organisms are found the bacterial soft rots and Botrytis.

The American pathologist has already reached the stage at which his first survey enables him to indicate to grower and salesman the most harmful types of disease, the characters by which they may be recognised by the non-expert eye, the conditions leading to the spread of these diseases and the most practicable methods for their control during transport and storage. It may be argued that in Great Britain, the small distance involved in transit renders the question of less importance. But short distances do not always mean rapid transit, and in any case, the most casual inspection of a fruit and vegetable market would show that American experience in this question may be of real value.

Of general application also are such results of the preliminary American work as their experience with strawberries, where N. E. Stevens finds (*Phytopathology*, 9, pp. 171–177) that strawberries picked early in the day, even if wet, keep better than those berries picked after the sun has been on them for some hours. Pomologists also will be quick to admit that we have still to learn the reasons for the different keeping qualities of the same variety of apple if gathered under different conditions. Under the stimulus of war conditions very great progress was made in Great Britain in the investigation of food storage conditions, and as a consequence some attention has been paid in recent scientific communications to the organism found causing damage among stored produce. American experience, however, would seem to raise the more general question whether the phytopathological experience of the investigator should not be reorientated so as to embrace the whole history of the vegetable, from field to table.

The Eruption of Sakura-jima in 1914.

PROF. OMORI has recently (*Bull. Imp. Earthq. Inves. Com.*, vol. 8, pp. 467-525) published his sixth, and apparently last, memoir on the eruption of Sakura-jima of January 12, 1914, and following days—the greatest of all known eruptions in Japan, if greatness be measured by the amount of lava outflow and ash precipitation. The six memoirs fill a volume of 525 pages and are illustrated by 107 plates. They constitute, according to the author, "a modest geometrical and seismological report on the great Sakura-jima eruption of 1914, and the course of the after-events followed for the next 8 years." Prof. Omori's readers will, I imagine, take a somewhat different view. They are more likely to regard the volume as the finest monograph, from a physical point of view, that has ever yet been written on a volcanic eruption.

Summaries of previous memoirs have from time to time appeared in these columns.[1] The first (September 1914) contains a general account of the eruption and its accompanying phenomena. The second memoir (April 1916) deals with the sound and ash-precipitation areas of the eruption, the accompanying changes of level and the earlier outbursts of the volcano. The third (December 1916) summarises the subsequent course of activity. After a pause of more than three years, the fourth memoir (March 1920) appeared containing the results of the levelling surveys and the soundings in Kagoshima Bay made after the eruption. The fifth part (March 1920) is devoted to the seismographical observations of the fore-shocks and after-shocks, while the sixth (November 1922) deals chiefly with the destructive earthquake of January 12, 1914.

The interest of this earthquake lies in its occurrence during the eruption about 8½ hours after it began. It was clearly a tectonic, and not a volcanic, earthquake. Instead of being a sharp brief shock of small disturbed area, the movement at Kagoshima was of considerable strength and duration; it was felt for about 220 miles to the N.E. and S.S.W., and was strongly registered by European seismographs.[2] The epicentre was situated in the Kagoshima channel, about 4 km. south-east of the observatory in that

[1] Vol. 94, p. 289; vol. 98, pp. 57-58; vol. 100, p. 35; vol. 106, pp. 165-166.

[2] NATURE, vol. 92, 1914, p. 717.

city. Judging from the duration (1·9 seconds) of the preliminary tremor, Prof. Omori infers that the focus was distant 14 km. from the observatory and therefore at a depth of 13 km. Numerous stone-lanterns and tombstones were overthrown in Kagoshima, the average direction of their fall being N. 68° W., which agrees roughly with the direction of the first movement registered in the same place. The trigonometrical re-survey of the district revealed horizontal movements since the eruption began of 2·62 to 4·52 metres to the north-east and north in the north and north-west parts of the island, while new soundings made in the north part of Kagoshima Bay showed that the floor of the bay had sunk from one-half to four fathoms, except in two spots in which a rise of from one to three fathoms had occurred. An hour or a little more after the earthquake, small sea-waves or *tsunami* swept over the shore at Kagoshima. At about the same time or later, the cable from Kagoshima to Sakura-jima, which crosses one of the elevated spots, was fractured on the flat bottom of the channel about one-third of its width from the coast of the island. Prof. Omori points out that it was not a single clear fracture, such as might have been formed if the application of the tension had been instantaneous, but that numerous breakages occurred over a length of 420 feet, the average distance between successive breaks being 1·7 feet. He infers that the horizontal and vertical movements of the sea-bed took place gradually.

The occurrence of a great tectonic earthquake in a volcanic district and during the progress of an eruption is somewhat rare. Prof. Omori gives some other examples from Japan in this memoir. Their connexion with the corresponding eruptions can scarcely be doubted. It seems equally clear that they do not owe their origin to the volcanic outburst itself, but that eruption and earthquake are both effects of the same deeply-seated cause.

C. Davison.

Fishery Research in Lancashire.

THE report on the scientific fishery investigations carried out under the auspices of the Lancashire and Western Sea Fisheries District Committee during the year 1921, which is edited by Prof. James Johnstone, the honorary director of the scientific work, is characterised by the extremely cautious way in which it has been drawn up. While the absence of very definite conclusions must to some extent be a matter for regret, it has to be admitted that the amount of evidence collected, though very extensive when considered in the aggregate, is still insufficient to make any other course possible for a highly-trained and critical mind. Like so much of the valuable fishery work which has been accomplished during the last twenty or thirty years, these investigations have tended to show how exceedingly complex the problems may become, and how difficult it is to get together data sufficiently varied in character and in sufficient quantities to provide material for their solution. The investigations do, however, afford clear indications of the lines upon which future research should proceed and make it certain that many of the questions discussed may be answered in the future, if the necessary facilities can be provided on an adequate scale.

The two most important articles in the report deal with the plaice and the herring. The plaice investigations were commenced in 1908 and were specially extended in 1919–21. They are now summarised for the whole period in a series of tables which include all the data. These tables will have a permanent value as a record of the condition of the plaice population, and will be invaluable for comparison with the results obtained in future years. The discussion of the data is limited to broad general features, and is directed throughout to show the bearing of the work on the actual practical problems with which the Sea Fisheries Committee is called upon to deal.

The herring work is of a more technical statistical character, and it is difficult to avoid a feeling of regret that so much work in mathematical analysis has been carried out upon samples containing for the most part only 50 fish. The work, it is true, is preliminary, and it will probably be found more profitable in the future to examine fewer samples and fewer characters but with very much larger numbers of fish.

Mention must be made of Mr. R. J. Daniel's work on the chemical composition of mussels, especially on the substance which has been called "glycogen" in these shell-fish. It is most important that these biochemical studies should be continued, for they promise results of much interest.

The report of the Marine Biological Station at Port Erin for 1922 has also been published recently. The most important paper in this report is by the late Prof. Benjamin Moore, in co-operation with Messrs. E. Whitley and T. A. Webster, on the subject of photo-synthesis in marine algæ. The authors show that green, brown, and red algæ are arranged on the shore so that each kind is in that intensity of illumination which is the optimum for the colour scheme of chromophylls it possesses. In strong illumination, green algæ synthesise far more rapidly than red, but in weak illumination the red algæ synthesise more rapidly than green. The brown algæ are intermediate in their action.

The two reports reflect credit both on those responsible for the organisation of the investigations and on those who have carried them out.

University and Educational Intelligence.

Aberdeen.—By the bequest of the late Miss Anne Hamilton Cruickshank in 1911, a sum of money was set aside for the foundation of a chair in astronomy. The special trustees have now reported to the University Court that the accumulated sum available exceeds 15,000*l.*, and have recommended the foundation of a chair, or lectureship, in astronomy, including navigation and meteorology. The recommendation is under consideration by a committee of the Court. Miss Cruickshank was the daughter of John Cruickshank, professor of mathematics in Marischal College and University from 1817 to the union of the Universities in 1860. Miss Cruickshank also founded the Botanic Gardens and the Cruickshank Law prize, while the Science Library of the University is associated with her name.

Notice is given that the Blackwell Prize Essay, value 30*l.*, and open to all, will be awarded in 1924 for the best essay on "The History of the Fishing Industry of the Port of Aberdeen since 1800," provided any essay sent in is of sufficient merit. Each essay (which must bear a motto and be accompanied by a sealed envelope bearing the same motto and enclosing the name and address of the sender) must be sent to reach the Secretary of the University not later than January 1, 1924.

Cambridge.—A Bill has been presented to the House of Lords appointing Statutory Commissioners for the Universities of Oxford and Cambridge to make statutes and regulations in general accordance with the recommendations contained in the recent Report of the Royal Commission. The Cambridge Commissioners named in the Bill are Viscount Ullswater (chairman), Bishop Ryle, Sir Thomas Heath, Sir Richard Glazebrook, Sir Henry Wilson, Sir Hugh Anderson, Dr. Peter Giles, Mr. William Rendell, and Dr. Hugh Dalton. It is perhaps significant of the difference between the two Universities that the only Fellow of the Royal Society among the Oxford Commissioners is Sir Archibald Garrod, Regius professor of medicine. A few only of the provisions in the Bill can be selected for mention here. In making statutes the Commissioners are to have regard to the main design of the founder of any institution or emolument affected by the statute. In the case of a statute affecting a college they are to have regard to the maintenance of the college in the interests of education, religion, learning, or research. In particular, in prescribing the scale or basis of assessment of contributions made by the colleges to University purposes, regard is to be had in the first place to the needs of the several colleges in themselves for educational and other collegiate purposes. It is not desired in reforming Oxford and Cambridge to reform away the peculiar characteristics which have built up their present strong position in the world of education, religion, learning, and research.

Dr. G. S. Graham Smith, Pembroke College, has been appointed reader in preventive medicine; Dr. J. T. MacCurdy, Corpus Christi College (also of Toronto and Johns Hopkins Universities), has been appointed University lecturer in psychopathology; J. Mills, research student, Gonville and Caius College, has been elected to the Nita King research scholarship in the etiology, pathology, and prevention of fevers.

London.—The latest date for the receipt of applications for grants from the Dixon Fund for the assistance of scientific investigations is May 14 next. Applications, accompanied by the names and addresses of two references, must be sent to the Academic Registrar, University of London, South Kensington, S.W.7.

Dr. Ethel N. Miles Thomas, fellow of University College, London, has been appointed lecturer in botany and zoology at University College, Leicester.

The *Times* announces that Sir Walter Buchanan, a pioneer of the frozen-meat export industry, has given 10,000*l*. for the establishment of a chair of agriculture at Victoria College, Wellington (N.Z.).

The University of Budapest announces that summer courses will be held this year from August 1 to September 15 under its auspices. Lectures will be given by members of the faculties of theology, law, medicine, arts, and economics. Full prospectuses are in preparation.

The Government of Western Australia has allocated a special grant this year for the commencement of the permanent buildings of the University of Western Australia, Perth. As recommended by the professorial board, the science departments will be the first to be removed to new premises, and the present grant for the period ending June 30, 1923, is for the provision of a joint building for the biology and geology departments. The next buildings to be erected will be those for chemistry and for physics. The new site for the University is at Crawley, and covers an area of about 160 acres. The science buildings will be placed on high ground adjoining the national reserve of King's Park, and their southern frontages will command a splendid view of the broad sheet of Melville Water on the Swan River.

We notice that numerous appeals have been issued by professors in Germany for money for institutions for higher education and research, such as the Emperor William Institute for Physics, the English Seminary in Berlin University—by Prof. Alois Brandt, who advocates the compulsory teaching of English in all the higher public schools of Germany—the Cancer Research Institute, the Seminary for Christian Archæology, the Egyptian Seminary, and the High School of Jewish Studies. It is stated that a good deal of political recrimination has found its way into the appeals. Whatever may be thought of the policies of the German Government since the War in other respects, it cannot fairly be charged with failure to appreciate the vital importance of education. We have excellent authority for believing that throughout its financial difficulties Germany has had no disposition to economise in its educational expenditure. The universities, as was pointed out in these columns some months ago, were never depleted of students during the War to anything like the same extent as ours, while since the War they have been filled to overflowing; but the appeals would seem to indicate that the Government has been less generous to institutions for higher education and research than to the elementary and secondary schools and the new "People's High Schools." The depreciation of the mark has of course led to difficulties in the way of obtaining English books and periodicals, and these have been to some extent met by a system of exchange with British universities established last year by the Universities Bureau.

The twenty-first annual meeting of the Carnegie Trust for the Universities of Scotland was held on February 14, Lord Sands presiding. The original endowment fund of 2,000,000*l*. has been increased by 547,000*l*., in addition to which there are reserve funds amounting to nearly 183,000*l*. Expenditure for the year ended September 30, 1922, amounted to 125,292*l*., including: assistance in payment of class-fees, 61,217*l*.; grants to universities and colleges for buildings, lectureships, libraries, etc., 44,925*l*.; encouragement of post-graduate study and research, 17,063*l*.; annual grant to women students' union, 250*l*.; management expenses, 5193*l*. Post-graduate study and research were encouraged by fellowships, scholarships, and prizes (6958*l*.), grants towards salaries of part-time research assistants (3600*l*.), grants to the Laboratory of the R.C.P., Edinburgh (2740*l*.), to St. Andrews Institute for Clinical Research (1000*l*.), and other grants (2765*l*.). Arrangements were made with the Department of Scientific and Industrial Research for the simultaneous consideration of applications. During the year sums amounting to 1387*l*. were voluntarily repaid by or on behalf of 39 beneficiaries, making a total of 12,583*l*. repaid since 1901. The repayments by women exceeded those by men for the first time both in number and total amount. In the annual report of the Carnegie Corporation of New York, issued a few days earlier than the Scottish report, stress is laid on the dangers and difficulties incidental to the administration of all such charitable foundations and the necessity for the exercise of careful discrimination and constant watchfulness for the harmful as well as the beneficial results of giving. Among the former it mentions the overcrowding of the colleges with students, many of whom would find their greatest happiness in other vocations than those to be sought through college training.

Societies and Academies.

London.

Zoological Society, March 20.—Prof. E. W. MacBride, vice-president, in the chair.—S. Ch. **Sarkar**: A comparative study of the buccal glands and teeth of opisthoglyph snakes, and a discussion on the evolution of the order from Aglypha.—Oldfield **Thomas** and M. A. C. **Hinton**: On the mammals obtained in Darfur by the Lynes-Lowe expedition.—R. I. **Pocock**: (1) On the external characters of Elaphus, Hydropotes, Pudu, and other Cervidæ. (2) The classification of the Sciuridæ.

The Optical Society, March 22.—Instr.-Commander T. Y. Baker in the chair.—Dr. L. C. **Martin**: Surveying and navigational instruments from a historical standpoint. Before A.D. 150 accurate knowledge of the Mediterranean basin was obtained by Ptolemy. One of the best known of the early instruments was the astrolabe, and this instrument was developed considerably by the Arabs and others. Specialised forms were used for navigation. In the seventeenth century a simplified form of the astrolabe, capable of being suspended or mounted horizontally on a stand, was employed as a theodolite. This was subsequent to the description of Digges's *theodolitus*, in which independent horizontal and vertical axes were employed. The use of the telescopic sight was not applied to surveying instruments till the beginning of the eighteenth century. The history of the level, from the "open sight and gravity controlled" forms to the telescopic levels of Picard and the bubbles of Thévenot, was also discussed. Improvements by various artists in the methods of graduation of circles and the development of dividing engines from Hindley to Ramsden and Troughton were matters of the greatest moment in the development of modern instruments. Later developments were shown in the instruments by Troughton and by Cary, which brought the level of construction (from the purely scientific point of view) almost up to that of our own time.

Cambridge.

Philosophical Society, March 5.—Mr. C. T. Heycock, president, in the chair.—Sir Ernest **Rutherford**: The capture and loss of electrons by α-particles. In a recent paper (Proc. Roy. Soc. A, 102, p. 497, 1922) G. H. Henderson showed that swift α-particles can capture electrons and are thus converted into singly charged and neutral helium atoms. The magnetic deflexion of a pencil of α-rays in a high vacuum showed by the photographic method after passing through mica the presence of two bands—one, the main band, due to He + +, and the other, the midway band, due to He + particles. The relative number of the latter increased rapidly with reduction of velocity of the α-rays. These conclusions have been confirmed by the scintillation method. By deflecting the midway band by a combined electric and magnetic field, it has been proved that it is due to He + particles. For any velocity there is a temporary equilibrium between the number of He + + and He + particles, such that the number of captures is equal to the number of losses. The ratio of the numbers of singly and doubly charged particles between the velocities $7 \cdot 7 \times 10^8$ and 18×10^8 cm. per second, varies approximately as the inverse fifth power of the velocity. The disappearance of the midway band when gas at low pressure is introduced in the path of the rays gives a method of determining the mean free path of the He + particles in air and other gases before conversion into He + +. The mean free path varies roughly as the velocity of the α-rays, and is 4 to 5 times longer in hydrogen and helium than in air. The mean free path for capture varies roughly as the inverse sixth power of the velocity. The mean free path in air for a velocity $1 \cdot 5 \times 10^9$ cm. per sec. is about 0·56 mm. at N.T.P. for capture and 0·008 mm. for loss. The average α-particle captures and loses an electron many hundred times before it is absorbed.—P. **Kapitza**: Some observations on α-particle tracks in a magnetic field.—H. **Lamb**: The magnetic field of a helix.—W. **Burnside**: (1) The theory of errors of observation; (2) The solution of a certain partial difference equation.—P. M. S. **Blackett**: A note on the natural curvature of α-ray tracks. An apparent relation exists between the plane and direction of the curvature of the parts of a forked track and the plane and type of the fork itself. The natural curvature possibly involves the effect on the ionisation of the probable assymmetric structure of singly charged α-particles.

Sheffield.

Society of Glass Technology (Birmingham meeting), March 21.—Prof. W. E. S. Turner in the chair.—H. S. **Blackmore**, Violet **Dimbleby**, and W. E. S. **Turner**: A rapid method of testing the durability of glassware. When a very dilute solution of 1 part in 1000 of the alkaloid, narcotine hydrochloride, is heated to boiling-point inside a glass vessel, the alkaloid is thrown out of solution, and can be seen as a fine precipitate if the glass is of poor quality. Good glasses should show no sign of deposit when heated at the boiling-point for an hour.—D. **Turner** and W. E. S. **Turner**: The corrosion of fireclay refractory material by glass and glass-making materials.—Edith M. **Firth**, F. W. **Hodkin**, and W. E. S. **Turner**: The effect of saltcake in corroding fireclay materials. Both papers were presented by Prof. Turner. Experimental evidence was detailed, showing that in glass-melting the corrosion of the pots or the tank blocks is most severe during the early stages of the melting of the batch; sodium nitrate, potassium nitrate, and borax are particularly corrosive. As the proportion of saltcake used in the batch increased, so did the extensiveness of the corrosion. Resistance to corrosion can be improved by firing the pots and blocks at 1400° C. before the charge of batch was inserted

Paris.

Academy of Sciences, March 19.—M. Albin Haller in the chair.—The president announced the death of M. Van der Waals, foreign associate.—Emile **Borel**: The approximation of rational or incommensurable numbers belonging to given enumerable ensembles.—L. **Lecornu**: The time of revolution of the planets. A discussion of a question raised in a recent note by M. Jean Chazy.—Charles **Moureu** and Charles **Dufraisse**: Auto-oxidation and anti-oxygenic action. The catalytic properties of iodine and its compounds. The case of acrolein. According to the theory of the mechanism of anti-oxygenising action developed by the authors, iodine and its compounds should exert catalytic properties in phenomena of auto-oxidation, and should, under certain conditions, possess the anti-oxygenising property. Iodides of various metals and organic bases (33 in all) were shown to inhibit the oxidation of acrolein at a concentration of 1 in 1000.—L. **Maquenne**: The hydrolysis of maltose by malt extract.—G. **Gouy**: The improvement of the microscope by the use of X-rays.—C. **Guichard**: Triply indeterminate systems of spheres, circles, and double points.—Jules **Andrade**: An arrangement of four regulating springs producing a constant friction and a quadratic friction.—J. B. **Senderens**: The catalytic dehydration of alcohols by dilute sulphuric acid. Both the ether and substituted ethylene can be prepared by the action of sulphuric acid on the corresponding alcohol, and the ratio of ether (alkyl oxide) to ethylene can be varied by the addition of water to the acid.—Ph. **Glangeaud**: A trial boring for petroleum at Crouelle, near Clermont-Ferrand (Puy-de-Dôme). The boring was taken down to 856 metres, and full details of the strata met with are given. At 596 metres there was a strong evolution of inflammable gas and about a ton of a heavy oil was collected (density 0·963, sulphur 9·3 per cent.). More oil, in smaller quantities, was obtained at greater depths. The tube was broken by an accident at 787 metres.—M. Emanuele **Paterno** was elected foreign associate, in succession to the late Prince of Monaco.—Georges **Bouligand**: Some points in functional analysis.—W. **Margoulis**: The general theory of the representation of equations by means of mobile elements.—J. **Haag**: The problem of n bodies in relativity.—Henry **Hubert**: A method, considered as new, for the stereoscopic representation of topographical surfaces.—R. **Dufour**: High frequency induction furnaces.—A. **Leduc**: A new improvement of the equation of state of gases.—Léon and Eugène **Bloch**: Spark spectra of higher order. A study of the spectrum of mercury obtained by the oscillating discharge in a silica tube without electrodes. The appearance and number of lines change as the voltage increases.—C. E. **Guye**: The kinetic interpretation of the rule of van't Hoff.—Réne **Audubert**: The action of gelatin upon concentration cells. A study of the effect of the progressive addition of gelatin on the E.M.F. of the concentration cells $AgI—AgNO_3$; $AgCl—AgNO_3$; $Ag_2S—AgNO_3$. The results appear to show that the Ag ion is adsorbed by the gelatin.—L. **Bert**: A new synthesis of cumene and p-cymene. Isopropyl sulphate reacts with C_6H_5MgBr giving cumene: the magnesium derivative of p-bromotoluene with isopropyl sulphate reacts similarly, giving p-cymene.—Emile **André**: The acid-alcohols contained in the oil from grape stones.—Henry **Joly**: Some peculiarities of the Bajocian in the neighbourhood of Montmédy (Meuse).—Ch. **Maurain**: Magnetic measurements in Brittany. The results of observations made at forty-one stations in August and September 1922, and the magnetic elements (declination, inclination, and horizontal component) reduced to January 1, 1922.—Filippo **Eredia**: The temperature of the air in the province of Tripoli.—L. **Blaringhem**: New facts relating to the hybrids of wheat and Ægilops.—H. **Colin** and Mlle. Y. **Trouard-Riolle**: Dissociation of the hybrid: smooth-bearded black barley and Albert barley.—Lucien **Daniel**: Regeneration of the potato by grafting. An account of attempts to increase the resistance to disease of the potato by grafting on tomato. The experiments have given promising results.—A. **Polack**: The accommodative compensation of the chromatism of the eye. Insufficiency of d'Alembert's theory.—L. **Garrelon** and D. **Santenoise**: Relations between the resistance of the organism to poisons and the rapid modification of the oculo-cardiac reflex. Contribution to anti-anaphylaxy.—Marc **Romieu**: Contribution to the comparative histology of striated muscle.—Mme. J. Samuel **Lattès**: The physical conditions which accompany the phenomenon of necrosis produced by radium radiation.

Official Publications Received.

Diary of Societies.

MONDAY, April 16.

Royal Geographical Society (at Lowther Lodge, Kensington Gore), at 5.—W. Irwin: The Salts of the Dead Sea and River Jordan.

Royal College of Surgeons of England, at 5.—Prof. Shattock: Demonstration of Specimens Illustrating Repairs of Fractures.

British Psychological Society (Industrial Section) (at University College), at 6.—Dr. G. H. Miles: Rest Pauses.

Royal Society of Arts, at 8.—E. Kilburn Scott: The Fixation of Nitrogen (2). (Cantor Lecture.)

Chemical Industry Club (at 2 Whitehall Court), at 8.

TUESDAY, April 17.

Royal Institution of Great Britain, at 3.—Sir Arthur Keith: The Machinery of Human Evolution (2). How Old Structures are Lost.

Royal Society of Medicine, at 5.—General Meeting.

Royal Statistical Society, at 5.15.—Dr. E. C. Snow: Trade Forecasting and Prices.

Royal Society of Medicine (Orthopædics Section), at 5.30.

Institution of Civil Engineers, at 6.—Special General Meeting.

Institute of Marine Engineers, Inc., at 6.30.—R. Clark: The Operation of Water-tube Boilers for Cargo-Passenger Ships.

Royal Photographic Society of Great Britain, at 7.—J. C. Dollman: Difficulties in Painting and Photography.

Royal Anthropological Institute, at 8.15.—Miss Tyra de Kleen: The Ceremonial Dances and Magic Rites of the Island of Bali, Dutch East India.

WEDNESDAY, April 18.

Royal Meteorological Society, at 5.—W. H. Dines and L. H. G. Dines: An Examination of British Upper Air Data in the Light of the Norwegian Theory of the Structure of the Cyclone.—Tatuo Kobayasi: The Mechanism of Cyclones and Anti-cyclones.—Capt. E. C. Shankland: Notes on the Fluctuations of Mean-sea-level in Relation to Change of Atmospheric Pressure, from Observations at Liverpool, August and September 1920.

Geological Society of London, at 5.30.—J. F. N. Green: The Structure of the Bowmore-Portaskaig District of Islay.

Royal Microscopical Society, at 8.—D. W. Cutler: The Protozoa of the Soil.—Prof. A. C. Seward: The Use of the Microscope in Palæobotanical Research.

THURSDAY, April 19.

Royal Institution of Great Britain, at 3.—Prof. A. O. Rankine: The Transmission of Speech by Light (2).

Linnean Society of London, at 5.—E. Heron-Allen and A. Earland: The Foraminifera of Lord Howe Island, South Pacific.—The General Secretary: The History of Botanic Illustration in Colour during Four Centuries.

Institution of Mining and Metallurgy (at Geological Society of London), at 5.30.

Society for Constructive Birth Control and Racial Progress (at Essex Hall, Strand), at 8.—C. E. Pell: Is the Fall in the Birth-rate a Natural Law?

Chemical Society, at 8.—R. Ibbotson and J. Kenner: The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part VII. Reactions of 2:5- and 4:5-dinitro-m-xylene.—S. F. Birch, G. A. R. Kon, and W. S. G. P. Norris: The Chemistry of the Three Carbon System. Part I. The Influence of the *Cyclo*hexane Ring on the $\alpha\beta$-$\beta\gamma$ Change.—S. Medsforth: The Promotion of Catalytic Reactions. Part I.

FRIDAY, April 20.

Royal Society of Arts (Dominions and Colonies and Indian Sections), at 4.30.—Sir Richard A. S. Redmayne: The Base Metal Resources of the British Empire.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: The Shape and Relationships of the Stomach.

Institution of Mechanical Engineers, at 6.

Junior Institution of Engineers, at 7.30.—H. H. Munro: The Business of Engineering.

Institution of Engineering Inspection (at Royal Society of Arts), at 7.30.—C. H. Richardson: The Inspection of Ball Bearings.

Royal Photographic Society of Great Britain, at 8.—J. Sewell: The Commercial Aspects of Pictorial Photography.

Royal Society of Medicine (Anæsthetics Section) (Annual General Meeting and an Ordinary Meeting), at 8.30.—Dr. J. H. Chaldecott and others: Discussion on Coroners' Inquests: the Classification of Anæsthetic Deaths as violent or unnatural.

Royal Society of Medicine (Electro-Therapeutics Section), at 8.30.—Dr. R. W. A. Salmond: A case illustrating the value of Pneumoperi-cardium.

Royal Institution of Great Britain, at 9.—Dr. W. J. S. Lockyer: The Growth of the Telescope.

Science and Government Administration.

SENSE, experience, humility, and imagination may teach one the need of advice: but some understanding of the subject is required to know whom to ask for advice and how to ask him; and still more to select advice, apply it, and act on it. In scientific matters this receptiveness of the recipient is an essential condition, otherwise the adviser is merely pouring water upon a flat plate; it bounces off, yet the plate shines and glories in its wetness.

In view of the supremely scientific character of modern war, can we say that the Army Council, Board of Admiralty, and Air Force Council possess the *sine qua non* for asking, selecting, applying, and acting on scientific advice in relation to the myriad problems of their occupation? These administrative bodies are called upon to foresee the wants of war and to make purchases and initiate researches for their fulfilment. They should, therefore, not only know what is wanted, but also understand what can be obtained. In the restricted sense of this use of the word "want" Julius Cæsar did not *want* electric light. He would have had to be even more remarkable than he was to want it, and then he could not have described the want effectively to any listener.

It is quite common for the lay public to be too unacquainted with what it can get to form a clear idea of its requirements—the man who tries to install central heating, or drains, without architect or builder will understand what is here meant. Luckily most people have sufficient knowledge of the subject and feeling of humility to determine them to go to the architect—that is because central heating and drains are everyday things. The lay public did not want railways—it did not know how to want them; it did not want automobiles until some years of education had been applied, and, coming nearer to our subject, the Army and Navy did not want aeroplanes until long after they were shown them. We are not making an accusation, but merely giving examples to show that the human faculty of wanting is a function of knowing what can be evolved, that is, education; and of imagining to what uses that provision can be extended, that is, vision.

There is the reciprocal of this also in "*not*-wanting." Ask any young officer at random if he wants the Finance Member of the Army Council; facetiously, but not without disclosing a true feeling, he will reply that "he has no use for him." With fairly precise analogy, if it were to be suggested to any member of the three councils named that a man of distinguished scientific attainments is wanted on these councils, he would with equal conviction, equal error, and possibly with equal facetiousness say, they "have no use for him" . . . "they have their advisers."

Suppose that there rises to the top at rare intervals a scientific admiral, "M.G.O.," or "Member for Supply and Research," it still remains the fact that in the absence of provision for securing by the law of the land that there *shall* be a man of wide scientific attainments on those councils, we cannot depend that, when a problem arises in council, its possible relation to science will be automatically and early considered. In many cases science will not be thought to touch the matter at all—and no attempt be made to get such advice. Unless there be some one, with full rights of membership, to probe into what can "per impossibile" be got from science, it is no comfort to know that there exist outside the Council advisers of great skill—since they would not be consulted—nay, they could not be consulted owing to the difficulty for the inexpert to pose the question even if he suspects the want.

A strong case can be made out for a scientific member of council—present at the fountain-head of war policy—at the place where the large problems arise, just as there is, at present, a finance member of council. The analogy of the finance member is apt because the public mind is far more financially sensitive and sane than scientifically acute and trained. Indeed, these councils themselves are almost certainly more awake to finance than they are to science. Is there not a House of Commons and a Press with money sense and taxation sensitiveness? But there is no similar power behind the scientific aspects of the case. It is not worth while to pose the false dilemma: which won the war, money or science? But it may be said that it is no use thinking the nation can safeguard its money if it does not safeguard its science. The awareness in money matters of the public due to its daily preoccupations, its annual state accountancy, etc., has ensured for money a representative at headquarters, but science has nothing of the kind.

No doubt the appeal of science would be better appreciated if it were expressed on terms of money. As an illustration of this the following episode is worth relating. The war council of a certain State was in session. A grave question had to be settled: advisers were outside the sacred chamber whence a member of council emerged, and, taking aside a man of science of European reputation who was in attendance and in the employ of that Army, propounded a question. As happens in such cases the inquiry sounded like: "How far is it from Somaliland to Good Friday?" so that the reply (and who has not gone through this ordeal!) began by hypothecating the alternative possible meanings and an inquiry as to which was intended. "I am not here to be interrogated but to be answered," was the reply inspired by a very proper fear of disclosing a clue to the secret policy in contemplation. The representative of science then gave an elementary lecture in which he reserved with dramatic instinct the essence of his reply for the climax. Before that was reached, however, the august member had excused himself and returned to his colleagues—fortified as a schoolboy would be for the reading of Plato by a knowledge of his subject limited to the alphabet. In the sequel some millions (not of marks) were expended on the scheme, which, however, was unfruitful.

Events and actions of this kind can be avoided only if the following principles are borne in mind:

(1) It is difficult even to ask for scientific advice so as to get it—unless the inquirer has scientific training.

(2) After asking for advice it cannot be taken without scientific training.

(3) When advice is taken it cannot be made effective without scientific training.

(4) However scientifically competent a man may be, he cannot advise on a case without knowing *à fond* how the problem arose and when, what qualifies it, and what alternatives might be employed to bye-pass the difficulty while still arriving at the goal.

It must be accepted that a genuine and thorough scientific training is not compatible with the multifarious changes of duty, changes of locality, changes of personnel, etc., essential to naval, military, and air force training. The development of a versatile, more or less uniformly trained force requires a *rota* of occupations by which officers and men, at stated periods of two or three years, are moved on to the various forms or classes which constitute the war school we call the Army, Navy, and Air Force. It is an accepted principle that no fighting man must become an indispensable expert; his loss would be too severe a discomfiture—his *ipse dixit* too formidable a threat to authority—his specialised training, and the unexpected bye-paths into which the laws of Nature would lead him, too incompatible with the whole principle of a versatile force of obedient and capable units united by a sedulously cultivated esprit de corps.

This is sound policy, and its acceptance leads to the conclusion that the scientific member of council cannot, any more than the finance member, be one of the routine organisation as we know it. We need scarcely plead here, after the War, that there is not, in a man of distinguished scientific attainments, any inherent unworthiness to be entrusted with State secrets. There is nothing peculiar about a suitably selected major-general that makes him a more acceptable recipient of such secrets than an equally well-chosen man of science. Nor yet is administrative ability incompatible with the widest range of scientific attainments.

The present-day divorce between the science which must infuse the war machine and the men who administer it is *not* of all time. Of old, as now, transport, communications, weapons, archery, etc., involved a knowledge of man's endurance, food consumption, horses, shoe leather, the elastic qualities of yew, the flight path of arrows, and the like, but then, unlike to-day, every member of the governing staff was easily an adept in these matters, competent to select and profit by any expert specialisation—when for a spell generals commanded the fleet they were soon discovered not to be adept and the sea was entrusted to those who were. In both cases it was unnecessary to provide a seat on the council for the astrologer, alchemist, or magician of the time. To-day, however, all this is changed.

It is not to be expected that even a carefully chosen and widely informed scientific member of council can know ballistics, meteorology, chemistry, metallurgy, the thermodynamics of the petrol engine, the intricacies of sound detection, or of wireless procedures, the stability of ships, the phugoids of aeroplanes, the rotary derivatives of their equations of motion, etc.; but given a really sound scientific representative none of these subjects is to him what most of them are to the Army Council, Admiralty, and Air Force Council—at the best, jargon: at the worst, stupidity. Such a man would and could seek advice, because he knows enough of the problem and of the outlook of science to see that it was wanted. He could take advice because he would know enough to sift it, test it, select it, and present it for consideration to a council with the real purpose and personalities of which he would be acquainted.

How can we make such a need be felt by the war machine, which is certainly not asking our advice about it? Only by public opinion; and clearly this is difficult. Scientific opinion deserves better regard and esteem than it gets, and it suffers this loss because of the quite unreasonable contempt with which it views the operations of politicians. The world of science abstains from making its voice heard in the only way it can be heard, through the megaphone of the politician, by reason of the pressure of its organisation. It has itself no organisation. Some of the wiser men, who lifted their heads from the absorbing interest of their own grindstones, did in fact form a Conjoint Board of Scientific Societies, which died a month ago. This body comprised the leading Institutions and Societies in the British Isles concerned with pure and applied science. It might have leavened the lump, and reminded the technical world that it is an organic part of modern social organisation. Let us hope, as taxpayers, if from no higher motive, that science and technology may yet form a federation to promote recognition of their significance in the affairs of the State.

Mervyn O'Gorman.

The Structure of the Atom.

The Theory of Spectra and Atomic Constitution: Three Essays. By Prof. Niels Bohr. Pp. x+126. (Cambridge: At the University Press, 1922.) 7*s.* 6*d.* net.

The beautiful conception which inspires and co-ordinates practically the whole of modern atomic physics is the atomic model of Rutherford and Bohr. Its essential feature—the nucleus—was first put forward by Rutherford in 1911 on the basis of experiments on the scattering of α-particles. So convincing is this model that after only twelve years it is known no longer as "the atomic model of Rutherford and Bohr," but is simply taken for granted as "the atom." In this development, moreover, the ideas of Bohr have played such a dominating part that it is of the greatest importance that the three essays of this volume should be accessible in English, as well as in the original Danish and German, to the widest circle of readers. We welcome most heartily their opportune appearance.

When a theory such as the present is expounded semi-historically by its principal creator, a critical account of the theory itself is scarcely the function of a review. Such a critical discussion could be nothing less than an exhaustive survey of the whole tendencies of modern physics. It is perhaps a less impossible—certainly a more relevant—task to attempt to bring to notice the various stages of the theory represented by the three essays in this book, in the hope that some faint reflections of their beauty and convincingness may be conveyed to those whose studies are directed elsewhere.

Some preliminary remarks of a general nature may not be out of place. Though the theory itself finds a place for much advanced mathematical analysis and demands the development of new and more powerful weapons than those yet available, in the hands of Bohr it is never an abstraction divorced from contact with physical realities. Rather he succeeds in bringing it ever into closer contact, and expounds it in these essays in a simple non-mathematical way which should be capable of being followed by any one who is prepared to accept the mathematical theorems on which the work is necessarily based. The mathematician will desire to look further into the foundations and will be rewarded. But those who are not mathematicians need not for that reason fall short of full conviction. It is unavoidable to speak of the theory, in description or exposition, as "explaining" certain facts of experience. But the theory is non-mechanical—in fact, is nowadays identical with the quantum theory—and "explanation" by the theory cannot mean explanation in the classical sense. Explanation of a fact can mean no more than its correlation with and co-ordination among an existing body of other facts which can all be similarly related to the same general principles; this, however, is enough. Beyond this we can ask for nothing less than a re-formulation of the whole principles of physics, which shall present both classical mechanics and electro-mechanics and the quantum theory as parts of a homogeneous whole. So far the divergencies between the two theories have become, if anything, rather more than less fundamental and mysterious, but the points of contact between the two theories, embodied mainly in Bohr's correspondence principle, have become ever more numerous and more sure. They are linked in a way which compels regard for them as two aspects of the same reality. It is the range and power of the correspondence principle, emphasising all these resemblances, which gives the theory its overwhelming appeal.

It is unnecessary to dwell on the first essay—"On the Spectrum of Hydrogen" (December 1913)—which presents, in a way now generally familiar, the suggestive but *ad hoc* arguments by which Bohr started the theory with such a combination of the ideas of Planck and Rutherford as to explain the spectra of the atoms of hydrogen and ionised helium and to promise an interpretation of the general laws of spectra. We pass to the second, "On the Series Spectra of the Elements" (April 1920), which breaks fresher ground. During 1913–1920 the theory had developed rapidly in its applications to subsidiary features of the hydrogen spectrum, which, besides Bohr and others, Sommerfeld, Schwartzschild, Epstein, and Debye took part in working out. It was extended to account with complete success for the fine structure of the hydrogen lines, and the effect thereon of external electric or magnetic fields. These advances can be summarised by saying that the way had been discovered for applying the quantum theory to a certain class of atomic systems of any number of degrees of freedom. This class is technically known as the class of quasi-periodic systems which permit of separation of the variables. Meanwhile Bohr put forward his correspondence principle, of which the germ is already present in the first essay, and the principle of mechanical transformability which he derived from Ehrenfest; principles which knit the foregoing results into a co-ordinated whole.

Briefly, the correspondence principle is this. If we expand the motion of a system in a series of sines and cosines of the time, a multiple Fourier series, in the complete radiation of the system demanded by classical theory a component of definite frequency, a definite "combination tone," will correspond to each term in the expansion. The correspondence principle asserts that there is a fundamental connexion between each "combination tone" and the possible switches from orbit to orbit, or changes of quantum number, which, on the quantum theory, give rise to radiation. In the limiting case of large quantum numbers there must be full agreement not only in frequencies but also in polarisations and intensities. This presents a rational means for extending the correspondence to all quantum numbers; every switch "corresponds" to a definite harmonic constituent in the mechanical motion of the atom. If any particular constituent is absent not only from the motion in the initial and final states but also from the whole family of mechanically possible motions, which are not themselves permitted orbits or stationary states but form a continuous transition between the initial and final states, then the corresponding switch will never occur. The complete success of this principle in accounting for details of the hydrogen spectrum is well known. A successful beginning has even been made by Kramers in the study by its means of relative intensities.

This, however, is only part of the ground covered by the second essay, which also applies these ideas to other spectra, in particular those of helium and the alkali metals. These sections must be read with Parts II. and III. of the third essay, which make important corrections. First, the assumptions of stationary states and the fundamental relation $E=h\nu$ between energy and frequency (first essay) explain naturally the combination principle of Ritz, for Ritz's "terms," the combinations of which are spectral lines, have now a physical meaning as the energies of the atom in its various stationary states. Consider a concrete example—sodium—with nuclear charge 11 and 11 planetary electrons. The inert properties of neon (10) indicate that we must suppose that the first ten electrons form together a very stable structure into which no further electron can be taken up on the same footing.

To a first approximation then, from the point of view of the eleventh electron, the effect of the first ten will simply be to modify the field in which it moves, so that, while its central symmetry is approximately preserved, the effective nuclear charge is a function of the distance from the nucleus, which is 11 at short distances and 1 at large. The same arguments hold for other alkali metals. If the exact law of variation of effective nuclear charge were known (numerically), the energies of all possible stationary states of the single external electron could be computed. We must, in any case, find that the set of stationary states forms no longer (as with hydrogen) a single series of terms depending on an integer n, but a double series depending on two integers n and k. We find that with absolute confidence we can identify the sharp terms with those for which $k=1$, principal terms $k=2$, diffuse terms $k=3$, and Bergmann (fundamental) terms $k=4$. Moreover, on the correspondence principle, only those combinations of terms will normally give rise to lines for which k changes by ± 1. This is precisely what is found to occur, and the puzzling incompleteness of Ritz's combination principle is entirely accounted for. There is, moreover, no real element of arbitrariness in this explanation, for the variation of the effective nuclear charge is of course due to the already bound electrons. These must lie in permitted orbits of definite quantum numbers which fit in with those of the spectral terms for an approximately central field of force, not very greatly modified from that which acts on the last electron. The numerical requirements of the theory can be satisfactorily met, and there remains no doubt that the atom must be regarded as fitting together in some such way. Perhaps this paragraph somewhat overstates the completeness of the theory as here expounded by Bohr, but it does not, I think, misrepresent it.

Besides its main contribution, the second essay also touches on and exhibits in their proper perspective other spectral facts—the spectra of ionised atoms, in particular those of the alkaline earths, with their Rydberg constant $4N$, which results naturally from the double residual charge with which the ionised atom controls its last electron; doublet and triplet separations, which arise from the deviation of the atomic field from central symmetry leading to the introduction of a third quantum number; finally, the unique nature of the helium spectrum with its absence of inter-combinations, of which an explanation in terms of a further generalisation of the correspondence principle may at least be said to be in sight.

These are mainly facts of which the explanation is still under development, but three further complete successes of the theory must also be recorded. The idea of stationary states accounts completely for the differences between emission and normal absorption spectra. An atom in its normal state can absorb only those lines for which the normal state is the initial stationary state of the absorption switch. For an alkali metal this means the principal series of doublets only—for an alkaline earth the principal series of singlets. In other cases, such as the aluminium subgroup, the theory leads us to expect that the normal state will correspond to the first principal term and that the absorption spectrum will be the sharp and diffuse series—an expectation recently confirmed by direct experiment. Secondly, the phenomena of resonance spectra are fully accounted for. Thirdly, the theory assigns definite energies to the various atomic states, and this assignment can be tested directly by the study of electronic impacts. This is by itself a complete branch of modern physics directly inspired by the theory, which it as directly and completely confirms.

The third essay, "The Structure of the Atom and the Physical and Chemical Properties of the Elements" (October 1921), is the most novel and important of the three. It differs from the others in being slightly revised in translation to bring it up-to-date (May 1922). This essay brings the whole of the available evidence—X-ray, chemical, optical—to bear on the specific question of the structure of the atom; that is, the way in which the planetary electrons are arranged. We have already seen that this is implicitly discussed, and a definite view reached, in connexion with the theory of series spectra. Other evidence merely confirms and crystallises this view. The goal to be attained is the theoretical deduction, from the principles of the quantum theory properly formulated, of the periodic table of the chemical elements, and all other atomic properties. Bohr shows that the fundamental process which must be considered is the successive binding of electrons one after another by a nucleus originally naked, and that, if we could say what would be the final orbit of the nth electron bound by a nucleus of charge Z, we could deduce the general features of the periodic table and other atomic properties in the desired manner. He shows that already we know, partly theoretically, partly empirically, a very great deal about these binding processes. The arguments cannot usefully be summarised. The result is that we can specify with considerable certainty the two principal quantum numbers, n and k, of the orbits in most atoms. The orbits thus fall into a number of groups, and we know the number of equivalent orbits in each group. The groups of orbits are arranged with various types of spatial symmetry; they must on no account be thought of, as in earlier models, as forming coplanar rings of electrons. The systematic study of X-ray levels begun by Kossel in the field opened up by Moseley has played a leading part in this development.

There are two crucial points to be emphasised in the present position of the theory, which can best be stated as questions. *Can we deduce from the quantum theory the particular points at which a group of electronic orbits fills and a new group starts?* In particular, can we prove that the third electron in the lithium atom must remain in a new type of orbit ($n=2$, $k=1$) and not fall into an orbit equivalent to those of the first two electrons ($n=1$, $k=1$)? Secondly, *can we deduce from the theory the regular sequences of physical and chemical properties, together with their occasional interruption for groups of homologous elements such as the iron group or the rare earths?* It can scarcely be said, and Bohr, I think, does not claim that an unqualified "yes" is yet the answer to the first question; but putting the question is itself a great advance, and the lines on which an answer will be forthcoming are already clear. It seems certain that the impossibility of the third electron getting into a 1-quantum orbit is of the same nature as the impossibility of intercombinations in the helium spectrum or of the two coplanar electrons of the orthohelium spectrum getting both into coplanar 1-quantum orbits. These impossibilities seem to be connected with the absence of any coherent class of mechanically possible orbits which continuously connect together the initial with the desired final state, but the absence of such classes is scarcely yet established.

Granted the answer "yes" to the first question, the answer "yes" in general terms can now be given fairly to the second, though of course only a fraction of the interesting points of detail have yet been worked out. It can already be stated definitely that, for example, the iron group accompanies the establishment of orbits of type ($n=3$, $k=3$) in the normal atom which (it is almost a direct deduction) appear for the first time at scandium. They occur in the fourth period and differentiate it from the second and third because there for the first time is it arithmetically possible for successive atoms to differ by an extra electron in an inner orbit instead of in an external one. In the same way the rare earth group is associated with the development of orbits of the type ($n=4$, $k=4$), the outer orbits consisting of both 5-quantum and 6-quantum orbits, the same in number and much the same in form from atom to atom.

It is a great theory and a great work. Its most fruitful stages are yet to come.

R. H. Fowler.

Religion and Evolution.

The Religion of Science. By Prof. William Hamilton Wood. Pp. xi+176. (London: Macmillan and Co., Ltd., n.d.) 6*s*. net.

At the present time it is especially interesting to compare the way in which, in different parts of the world, thoughtful men regard the relation between religion and science. We should expect to find a general uniformity in the different attitudes of representative thinkers in Great Britain and America. We are largely of the same stock. We speak substantially the same language, so that books in large numbers pass in both directions across the Atlantic. But it is a curious fact that the popular religious dislike of evolution, which even enters into politics in the Middle Western States, affects leaders of American thought. No theologian of eminence in England would now challenge a scientific conclusion, for which experts combine to demand our assent. Yet, in the book before us, the professor of biblical history and literature in a college at Hanover, N.H., makes a vigorous attack on "the religion of science," and argues that man cannot be fitted into the scheme of biological evolution. *No fossil or organic half-man*, says the professor in impressive italics, *has ever been discovered, and never will be.* (Grammatically the final clause means the opposite of what the professor intends; but we will let that pass.)

Most readers of Nature will be tempted to say at this stage, "The man's a crank. No need to read further." But the judgment would be unjust. Prof. Wood, though his literary style is at times painful, has clearly given close thought to the problems which he discusses. As against certain views expressed by American writers, in works with which we are unfamiliar, he argues acutely. He shrewdly exposes the illegitimate metaphysical assumptions of the "science-theology," which we should agree with him in condemning. But he has not apprehended the larger synthesis generally accepted by English theologians. Because his outlook is too limited, the theory of evolution seems to him to eliminate "God as a real existence and personality." So to preserve religion he rejects evolution.

This apparent necessity could not arise were there not a latent dualism in his thought. Christian theology in the third century took over from Neoplatonism a belief in the unity and solidarity of the universe. This belief, of course, is in fundamental harmony with the teaching of Christ. Failure to preserve it intact in all its implications is the source of most of the difficulties which have troubled Christian divines in their warfare with "science-theology." Prof. Wood is really following a degenerate tradition when he opposes the "natural" to the "supernatural" instead of pleading that in all Nature spiritual activity is manifest. His dualism causes him to speak of, "on one side, the non-moral development of the universe which is continuous, while within this, or related to it, is the moral evolution terminating in man." He can also say, "The main point is not whether mankind came originally from a single pair or was spawned like larvæ, nor is it our simian ancestry. It is that man is a derived and, therefore, secondary product." We need not comment on the biological character of the first sentence; but we would ask, Why should the derived product of the harmonious working of a universe, informed by Spirit, be secondary? Surely we should expect the creative activity of Spirit to work towards something of which it is the archetype; or, in more familiar language, that God has, by the slow process of evolution, created man for communion with Himself.

Prof. Wood does not see that, if Christian thinkers can justify their belief that the whole world arose and took its pattern because of the creative activity of Spirit, they need not quarrel with evolution. On the contrary, the biological doctrine then becomes a description of the way in which Spirit has worked; and, by interpreting it, we get an understanding of the nature of spiritual reality. By tacitly opposing Nature and Spirit the professor finds it difficult to resist the conclusion that "the original and primal is the real." But if we are convinced that the process "from nebula to man" reveals Spirit working in time, we shall see, in Nature, degrees of reality which have successively emerged, the last being the consciousness of civilised man.

How can we meet the contention that there is no such reality as Spirit? We answer that the fundamental objection to the naturalism, which Prof. Wood terms science-theology, is that it is inconsistent with itself. It makes spiritual judgments while denying spiritual reality. Science, within its proper sphere, is quantitative. In it the mind abstracts those aspects of Nature which can be measured. But then the mind forms scientific concepts "in which the phenomena given in perception attain to a higher degree of coherence and of truth." We prize these concepts because of their truth-value. But value-judgments belong to the world of spirit, to a kind of existence to which merely numerical categories do not apply. To the same spiritual world such qualities as justice and virtue belong. Strictly speaking, they lie outside the realm of natural science. Men of science are always, often unconsciously, interpreting their results by means of value-judgments. Such a phrase as "the survival of the fittest" is a well-known example of this process. For the explanation of a thing or an event we have to use what is above it in the scales of existence or value. Yet, in spite of this, men of science who are constantly studying properties of matter, living or dead, jump to the metaphysical conclusion that matter is ultimate reality. The legitimate conclusion is rather that ultimate reality is spiritual, and that goodness and beauty, like truth, reveal its nature.

The relation of matter to spirit continues to perplex us. But the tendency of modern physics is increasingly to reduce matter to a mere metaphysical abstraction, like the ether, which is the subject of energy. Some physicists appear to regard matter as nothing but a form of energy. But neither view will allow us to regard the universe as a self-acting machine, for in such a conception mind can have no place. Moreover, as soon as natural science ceases to be merely descriptive, the idea of causation enters in. We cannot explain cause unless we admit creative action working towards a definite end, so that the laws of Nature express the uniform mode of action of a Supreme Will. The doctrine of evolution indicates the purpose of that Will, for it asserts that earth's life-process has led to man, whose conscience tells him that he must be loyal to absolute values external to himself. God, in short, reveals His own nature in the highest faculties of humanity.

It cannot, we think, be fairly argued that belief in evolution destroys the Christian hope of eternal life. That hope rests ultimately upon belief in "the conservation of values," upon a conviction that the attributes of God are eternal with Him. We now know enough of the universe to be sure that within a measurable period life upon this earth will come to an end. All humanity's spiritual achievements will then perish unless there is a Kingdom of Heaven where they are eternally preserved. Among such achievements the perfecting of personality ranks highest. It is difficult to conceive either of timeless existence or of a perfect human soul; but the reasonableness of our hope of eternal life is not thereby destroyed. Significantly Christianity connects belief in human immortality with its doctrine of the Incarnation, its affirmation that, in a perfect Man, God has actually been revealed.

We can do no more than hint at our reasons for disagreeing with Prof. Wood's point of view. But, because we have criticised his views, we would commend his honesty, his freedom from bigotry, and the high seriousness of his aim. The problems which have engaged his attention are as difficult as they are vital. It is probable that humanity will never solve them completely; it is certain that now we can but see "as in a glass darkly."

E. W. BARNES.

A Peruvian Desert.

Geology of the Tertiary and Quaternary Periods in the North-west Part of Peru. By Dr. T. O. Bosworth. With an Account of the Palæontology by H. Woods, Dr. T. W. Vaughan, Dr. J. A. Cushman, and others. Pp. xxii+434. (London: Macmillan and Co., Ltd., 1922.) *2l.* *5s.* net.

THERE are few contributions to geological science, published in recent years, of greater value than this description of some three thousand square miles of the littoral of northern Peru.

Dr. Bosworth, who was formerly in the British Geological Survey, was still a young man when he left it to take up economic work, but he had already made himself a name for sound and original geological research. The present publication is not the result of a rapid traverse of the area with which it deals, but is the fruit of several years of exploration, reinforced by detailed surveys in many places and numerous borings for oil, in which the characters of the strata traversed were carefully observed. Dr. Bosworth has had one great advantage; the desert conditions that prevail expose clearly to view much more of the characters and structures of the rocks than meets the eye in more fertile regions. At the same time, he has spared no pains to make his work as complete as possible. In order that the fossils collected should be properly described he has enlisted the services of a number of the leading palæontologists in this country and America, and their descriptions, figures, and conclusions are given in full.

The district described rarely exceeds a thousand feet in height above sea-level. It lies between the Pacific and a background of the Western Andes, which consist of pre-Tertiary rocks folded under the stresses of the zone of compression that encircles the greatest in the immediate neighbourhood of the shore, raised above its previous level. It was at the same time broken up into numerous blocks separated by minor faults, often of considerable throw, constituting a kind of fault breccia on a gigantic scale.

In this aggregate of dislocated sediments the action of the sea, assisted by subaerial agencies, excavated a broad, nearly horizontal shelf, which reached to the foot of the mountains, and became submerged sufficiently to allow of a new series of deposits being laid down upon it, which must be referred to the Quaternary Period, as they contain remains of forms identical with those living in the adjoining sea. Then a period of elevation supervened, and the former sea-floor was exposed to view as a nearly level plateau—a *tablazo*,

Fig. 1.—Ridge-and-furrow topography, produced where the strike of the beds is in the same direction as the prevalent wind. From "Geology of the Tertiary and Quaternary Periods in the North-west Part of Peru."

of our oceans. The latest strata involved in the folds are of Cretaceous age, and it must have been after their deposition that these mountains were raised up and exposed to the destructive activities of sun, wind, and running water, and in all probability frost and ice as well. From the debris a great succession of sedimentary strata of Tertiary age were accumulated to a thickness of some 20,000 feet on the slowly subsiding ocean floor, not without important breaks in the succession, for only the Eocene and Miocene are represented.

The denudation of the mountains and the accumulation of the sediments over a broad tract on the margin of the Pacific appear to have destroyed the isostatic balance that had previously existed and created a state of strain which finally resulted in a great fracture off the coast, the western side being thrown down deep below the surface of the sea, and the eastern, which included such of the Tertiary deposits as were as it is called locally—and it still remains in many places almost in the same condition as it was when the sea left it. Its western margin was now attacked by the waves and a second shelf was carved out, which was covered by another series of deposits, and afterwards raised to form a second *tablazo*. Still another *tablazo*, possibly more, would seem to have come into existence in the same manner. The last tracts to be raised from the sea were the *salina* or salt plains, which are scarcely above the reach of the spring tide. Indeed, some parts are occasionally submerged. Remains attributed to the Incas are found upon them, and some of the land a few hundred yards from the high-water line has been irrigated, apparently by them. It would seem therefore that there can have been no appreciable change of level since the coming of the Spaniards. The author infers that not a ten-thousandth part of the Quaternary history can have elapsed in the last five hundred years. This would give Quaternary time a duration of at least five million years, which seems an over-estimate. In all probability the rise of the land has not been continuous, but rapid movements of elevation have alternated with long ages of quiescence, while the occasional periods of submergence may be explained by a slow continuous rise of the ocean level, such as is believed by Daly to have taken place in the Pacific. It is worthy of note that there appears to be no evidence of any renewal of compression since that to which the mountains owed their formation in late Cretaceous or early Eocene times. This suggests a doubt as to whether the westward movement of South America, postulated by Wegener, can have continued far into Tertiary times.

There is not space to follow the author in his description of the climatic conditions in the desert; of the effects of the rare torrential rains and the slow desiccation that succeeds; of the deeply cut valleys, the breccia fans, and the valley and marine terraces; of the work of sun and wind, and of the scanty animal and vegetable life; except to say that the book should take its place beside the writings of Walther and Cloos in the libraries of all students of the desert.

The concluding chapters contain a useful account of the petroleum deposits of the area, in which oil-wells have been sunk to a depth of 4000 feet. Valuable information is afforded as to the stratigraphical range of the oil, and the history of its exploitation is described; but it is unfortunate that in deference to the wishes of the International Petroleum Company no detailed account of the main oil-field is given. "With the exception of a few general comments, sanctioned by the Company, the development and conclusions of the past eight years are excluded from this description." Considering how much the great industrial organisations owe to science, one would expect from them a little generosity, even a little sacrifice of material advantage, if such be required, that they may repay their debt to research by adding their quota to the general fund of human knowledge.

Fig. 2.—"*Rabo de Leon*" growing among blocks of quartzite in the Amotape Mountains. (The height of these plants here is about 3 feet.) From "Geology of the Tertiary and Quaternary Periods in the North-west Part of Peru."

It only remains to state that the book is excellently illustrated by numerous sketches and reproductions of photographs (two of which are given here) and by clearly-drawn maps, plans, and sections.

John W. Evans.

Our Bookshelf.

Aspects of Science. By J. W. N. Sullivan. Pp. 191. (London: R. Cobden-Sanderson, 1923.) 6*s.* net.

Most works on that department of thought which lies on the frontier between philosophy and science should be included by pharmacologists among the class of narcotic drugs. As narcotics they are very effective, for they induce oblivion rapidly and profoundly, and they have the great advantage of being without any of the undesirable—or other—after-effects that are common with such drugs. Notably, they have not the great drawback of most narcotics of inducing a craving for the constant repetition of the dose. Perhaps this character is partly determined by the circumstances in which these works are mostly used. Observation will confirm the general impression that such books are largely resorted to by elderly men of science, after working-hours, in the fastnesses of club libraries or by the domestic fireside. Mr. Sullivan's book is, however, useless for such purposes, for he defies slumber!

We do not remember to have read in English anything on the philosophical implications of science comparable to this little book for its wit. Easy writing is said to make hard reading, and, if the converse is true, an immense amount of labour must have been thrown into this series of very short chapters. Short though they are, many of them leave a feeling of remarkable completeness, and some of them, such as those on "Assumptions in Science" and "The Sceptic and the Spirits," are really little masterpieces in which we feel Mr. Sullivan has said the last word in the present state of knowledge.

There are many books on the nature of science and on its philosophical and ethical relationships, but there are very few that will appeal to younger people. Mr. Sullivan has, however, produced such a work. It can be safely placed in the hands of any student; most of it can be understood by any intelligent boy or girl of the age of sixteen; it is always challenging without ever being dogmatic, and witty without ever being cruel or "cheap." Any scientific man with the slightest philosophical bent must find this work stimulating and refreshing, and it is obviously written by one with a remarkably wide working knowledge of science.

C. S.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr. Emil Abderhalden. Abt. IX: Methoden zur Erforschung der Leistungen der tierischen Organismus. Teil 4, Heft 1: Methoden der Erforschung bestimmter Funktionen bei einzelnen Tierarten. Lieferung 76. Pp. 122. (Berlin und Wien: Urban und Schwarzenberg, 1922.) Grundzahl: 4·8 marks.

THE new section of Abderhalden's invaluable "Handbuch der biologischen Arbeitsmethoden" contains a very useful résumé of methods for the study of digestive secretions in the lower forms, an account of the technique of gonadectomy and transplantation of germinal tissue in insects, together with a rather longer review of experimental procedure in the study of pigmentary responses. This section, by Dürken, suffers, like the author's recent "Einführung in die Experimentalzoologie" (1919), from a complete disregard of the large volume of experimental work on amphibian metamorphosis and the illuminating observations on colour response which have emerged from it during the past eight years; consequently it deals exclusively with methods for studying factors which induce pigmentary responses rather than the mechanism which co-ordinates them. Perhaps it is inevitable that such omissions should occur owing to the economic handicaps under which scientific workers are pursuing their labours in Central Europe at the present time. Still, it is difficult to believe that the author of the "Methoden zum Studium des Pigmentwechsels" had no opportunities of consulting the extremely important work of Spaeth, Redfield, Smith, Allen, Laurens, and Swingle, none of whom is mentioned in his survey, though there have been since 1918 few numbers of the *Journal of Experimental Zoology* which do not contain some contribution to the physiology of pigment response in amphibia, reptiles, or fishes.

Infant Mortality. By Dr. Hugh T. Ashby. Second edition. (Cambridge Public Health Series.) Pp. xii+224. (Cambridge: At the University Press, 1922.) 15*s*. net.

BY "infant mortality" is meant the ratio which the number of infants who die in any one year bears to the number of births in that year. The rate for the country generally remained more or less stationary until 1905, since when, however, it has steadily decreased, so that during the last two or three years it has been only about half that which obtained in the late nineties of last century. Infant mortality is of enormous national importance, for with the present low death-rate, which it will be difficult in the future materially to reduce, and a falling birth-rate, now only about two-thirds what it was at the end of last century, the maintenance of our population will largely depend upon the survival of as large a proportion as possible of the infants born.

The appearance of a second edition of Ashby's "Infant Mortality" is therefore opportune. The practical side of the question has been kept in view throughout, and purely medical technicalities have been omitted. The condition is a very complex one, but an attempt is made to ascertain its main causes; one of these, summer diarrhœa, has been practically suppressed. The number of still-births and the mortality during the first week of life are still far too high, and their causes merit further investigation. Maternal mortality shows an actual increase of late, and needs to be taken seriously in hand.

The author has skilfully marshalled his facts, and the chapter on the means by which infant mortality may be further reduced gives an excellent summary of the subject.

Pests of the Garden and Orchard. By Ray Palmer and W. Percival Westell. Pp. 413+47 plates. (London: Henry J. Drane, Farringdon Street, n.d.) 25*s*. net.

IN the work under notice the authors have aimed at meeting the needs of practical agriculturists and horticulturists by collecting into one book all the available information on plant pests and diseases necessary for their guidance. Insects and other animals, fungus diseases and weeds, are all dealt with categorically under their separate headings, a short description and the methods of treatment being given in each case. Many of the numerous illustrations are very clear, but others are scarcely sharp enough to prove efficient aids to identification.

Among other useful features special attention may be directed to the detailed formulæ for sprays, with antidotes to the various poisons used in their composition, and also to the identification and spraying tables for insect pests and plant diseases. For identification these are classified under the heading of the plant attacked, and the chief features of each are indicated with reference to the further descriptions in the text, whereas the spraying tables summarise the applicable methods of treatment with instructions as to the time they should be carried out. Altogether the practical man, and others, will find this a most useful handbook for obtaining much of the necessary information that is otherwise very scattered.

Business Geography. By Ellsworth Huntington and Prof. F. E. Williams. With the co-operation of Prof. R. M. Brown and Lenox E. Chase. Pp. x + 482. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 13*s.* 6*d.* net.

The authors intend this volume to be used after a course on commercial and industrial geography. It deals with the principles of geography, the effect of specific geographical factors, types of human communities, and the trade and commerce of the continents, with more detailed consideration of the United States. The book is a welcome addition to the volumes already available on the geography of production and commerce, and in its width of outlook and wealth of ideas should prove very stimulating, and occasionally provocative, to all readers. In one essential respect it differs from most books on the subject: the human factor in business relations receives ample consideration. The world is treated not merely as so many places, each producing so many products: the varying physical and mental qualities of races are recognised and given their due weight in the explanation of the development of the world. Stress is also laid on the relation of man to different climates in respect of wealth and efficiency. The book is admirably illustrated, and there are a number of ingenious exercises attached to each chapter. It is a book that should find wide acceptance in spite of its unattractive title.

Practical Colour Photography. By E. J. Wall. Pp. vii + 248. (Boston, Mass.: American Photographic Publishing Co.; London: H. Greenwood and Co., Ltd., 1922.) 13*s.* 3*d.*

The representation of colour, in addition to form and light and shade, by photographic means is a subject that has been allowed to get very far behindhand so far as text-books of photography are concerned. Mr. Wall's volume is therefore very welcome as doing a great deal towards filling this gap in photographic literature, which has been automatically increasing for many years. It does not quite fill the gap, for photo-mechanical methods are not treated of, historical and theoretical data have been, so far as possible, omitted, and the scope of the work has been restricted by the fact that all methods and formulæ given have been personally tested in practice. But within the limits indicated it is surprising how many methods there are of representing colour. Of three-colour processes there are the carbon and gum bichromate processes, the imbibition of dyes, mordanting processes, the bleach-out process, and the use of screen plates (autochrome, Paget). Of what may be called direct processes there are the interference heliochromy of Lippmann, the use of "silver subchlorides," and the diffraction and prismatic dispersion processes. Finally there are two-colour processes, and those adapted specially for cinematography. The book forms an excellent practical introduction to the subject.

Le Négatif en photographie. Par A. Seyewetz. Deuxième édition, revue, corrigée et augmentée. (Encyclopédie scientifique: Bibliothèque de Photographie.) Pp. viii + 308. (Paris: Gaston Doin, 1923.) 15·40 francs.

M. Seyewetz is chiefly known to us by the researches that he has carried out, often in conjunction with M. M. Lumière. One naturally expects an author to treat more fully of those subjects that he has personally studied. In the present case this is a distinct recommendation, for the author's investigations have been so largely connected with the processes involved in negative making. The summaries of the characters, use, and effects of the various developing agents are especially valuable. It is of interest to notice that M. Seyewetz is not one of those who believe that development is a mechanical process which cannot be varied except to the detriment of the negative. The paper and the quality of the illustrations of this volume show that our neighbours have not recovered so far as we have in this country from the detrimental effects of the War, but these matters do not detract from the sterling character of the volume.

Practical Handbook on the Diseases of Children: For the Use of Practitioners and Senior Students. By Dr. Bernard Myers. (Lewis's Practical Series.) Pp. xvi + 548. (London: H. K. Lewis and Co., Ltd., 1922.) 21*s.* net.

The important subject of diseases of children is one which is too often neglected in the curriculum of the medical student. Dr. Bernard Myers has produced a handbook in which he has treated the subject mainly from the practical side. He has adopted the usual arrangement of considering anatomy and physiology first, then clinical investigations and the diseases of the various systems. Articles have been contributed by experts in their special branches, *e.g.* biochemistry, serum therapy, physiology of digestion, and syphilis. Some confusion may arise from the separation of nutritional disturbances from affections of the stomach and intestine, and also from the classification of nutritional disturbances as "failure to gain," "dyspepsia," "decomposition," and "intoxication."

The moderate size of the book, its concise descriptions and practical aspect, combine to make it a useful addition to the student's text-books and the practitioner's library.

Religion and Biology. By Ernest E. Unwin. (Christian Revolution Series, No. 15, Pp. 185.) (London: The Swarthmore Press, Ltd.; New York: George H. Doran Co., 1922.) 6*s.* net.

This work, written from the point of view of a member of the Society of Friends, is an attempt to outline the biological approach to questions of religious thought, and should be of use to school teachers. The author believes he has a message for biologist and schoolmasters. His gentle and spiritual point of view never raises opposition, and the book will be found of value for the purpose for which it is designed.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Crystal Structure of Basic Beryllium Acetate.

PROF. G. T. MORGAN recently sent me some well-formed crystals of basic beryllium acetate $Be_4O(C_2H_3O_2)_6$, suggesting that their analysis by X-ray methods would, in all probability, be of considerable interest. The results show, I think, that the anticipation was well founded.

The molecule is a perfect tetrahedron. The crystal structure is that of diamond, a molecule replacing each atom of carbon. The carbon atom is itself tetrahedral, but is very nearly a sphere. The slight departure from sphericity is shown by the presence of a very small second order in the reflection by the tetrahedral plane of diamond. In the acetate this effect is large, because the tetrahedral character is so much more pronounced than in the carbon atom.

The oxygen atom must be at the centre of the tetrahedron. The beryllium atoms lie on the lines from the centre to the corners; and each $(C_2H_3O_2)$ group must be associated in a very symmetrical manner with one of the tetrahedron edges.

Prof. Morgan and I hope to give, at a later date, a fuller description of the analysis, and to discuss the inferences that may be drawn from it.

W. H. BRAGG.

A Theory of the Viscosity of Liquids.

As is well known, the viscosity of gases and its variation with temperature has received a satisfactory explanation on the basis of molecular theory. Little progress has, however, been made towards explaining the phenomena of the viscosity of *condensed* media—that is, of liquids and solids from a molecular point of view. What is evidently required is a working hypothesis which will indicate why, when a substance passes from the state of vapour to that of liquid, its absolute viscosity is greatly increased but *diminishes* with rising temperature, while that of the vapour *increases* in the same circumstances. I propose in this note to put forward briefly the outline of a theory which appears to have claims to serious consideration, as it indicates a quantitative relation between the viscosity of a liquid and of the corresponding vapour which is supported by the experimental data.

The manner in which transverse stress is propagated through a material medium is known in the cases in which the substance is in the state of vapour and in that of a crystalline solid. In the former case, momentum is transferred through the diffusion of the molecules between parts of the medium in relative motion, and this is a relatively slow process. In the crystal, on the other hand, the stress is transmitted in the form of transverse elastic waves, and the latter process, at least for ordinary displacements, is extremely rapid. We may conceive that in a liquid, momentum is transported partly by the first process and partly by the second, and that the effective viscosity depends on their relative importance. The ratio in which the two modes of propagation are operative may be determined from thermodynamical considerations, combined with certain simple suppositions regarding the constitution of a liquid.

We shall assume that the state of aggregation of the molecules in a liquid is of a composite character: some of the molecules are quite free to move, and may be termed "vapour" molecules; the others are attached to each other somewhat as in a crystal, and may be termed "crystalline" molecules. In determining the proportion of the two types, we shall consider only binary encounters between molecules. Let E_1 be the work required to separate a pair of molecules of the first type, and E_2 those of the second type. Then applying Boltzmann's distribution law, we may, as a first approximation, take the relative proportion of the two types of aggregation in the dissociation equilibrium to be as $e^{E_1/RT}$ to $e^{E_2/RT}$, where R is the gas-constant and T the absolute temperature. The next step is to determine the rate of transport of momentum through the medium. In the "vapour" part of the aggregation, the transport occurs by bodily movements. In the "crystalline" part, the rate of transport may be considered to be practically infinite. The effective rate of transport in the liquid is therefore greater than in the vapour at the same temperature and pressure in the ratio $e^{E_2/RT}/e^{E_1/RT}$. The viscosity of the liquid is therefore given by the formula $\eta_{\text{liquid}} = \eta_{\text{vapour}}\, e^{(E_2 - E_1)/RT}$. Since $E_2 > E_1$ it follows that the viscosity of the liquid will *diminish* with rising temperature.

The next step is to determine the absolute magnitudes of the energy constants E_1 and E_2. As was first pointed out by Sutherland, in the cases of gases and vapours the attractive forces between the molecules tend to *increase* the frequency of collisions and thus *diminish* the viscosity. The matter has been further examined by Chapman, who has shown that Sutherland's constant is one-sixth of the mutual potential energy of the molecules when in contact. It is convenient to use an amended form of Sutherland's formula and write

$$\eta_{\text{vapour}} \propto T^{\frac{1}{2}}\, e^{-E_3/RT},$$

where E_3 is another energy-constant. From Chapman's work it would appear that $E_2 = 6E_3$, and we may also take $E_1 = E_3$. Hence, finally, we have

$$\eta_{\text{liquid}} = \eta_{\text{vapour}}\, e^{5E_3/RT}.$$

E_3 may be found from the data for the viscosity of vapour at different temperatures, and the formula thus enables the viscosity of the liquid to be calculated *a priori*.

To illustrate the matter, it will suffice to take the case of benzene as an example. The table shows the viscosity of liquid benzene at different temperatures as determined by Thorpe and Rodgers, and also as calculated from an empirical equation of the type $\eta = Ae^{B/T}$.

VISCOSITY OF BENZENE LIQUID.

A = 0·0000951. B = 1237.

Temperature.	Calculated Viscosity.	Observed Viscosity.	Difference.
7·67°	0·00781	0·00789	+8
13·46	0·00714	0·00717	+3
19·39	0·00654	0·00654	0
25·96	0·00595	0·00595	0
32·07	0·00549	0·00547	−2
38·47	0·00504	0·00502	−2
45·35	0·00464	0·00461	−3
51·66	0·00429	0·00429	0
57·37	0·00403	0·00402	−1
63·29	0·00377	0·00377	0
69·41	0·00353	0·00354	+1
73·36	0·00332	0·00333	+1

Viscosity of benzene vapour at 100° C. = 0·0000930.
$5E_3$ calculated from the value at 212·5° C. is 1300.

It will be seen that the formula represents the viscosity of the liquid within an average error of 2 parts in a thousand; and that the constants A and B are in fair agreement with the values calculated from the data for the viscosity of the vapour. An empirical formula of the type $Ae^{B/T}$ is found to represent closely the variation of the viscosity of many liquids, especially at the higher temperatures. As we have assumed that the "vapour" molecules are identical with those actually found in the gaseous state, we cannot expect the experimental constants A and B to agree exactly with those indicated by the theory outlined in this note in all cases. Considerable deviations actually occur in the case of "associated" liquids, in which presumably the effect of the molecular fields of force cannot be handled so simply.

The further discussion of this question and of the extension of the theory to the case of dense vapours on one hand, and to supercooled liquids and amorphous solids on the other hand, offers a most interesting field of research. The treatment suggested can obviously be improved in several directions, especially in the discussion of the dissociation equilibrium between the two types of molecules, and the effect of high pressures on the viscosity of liquids could probably be explained by a more exact investigation.

Colour Temperature and Brightness of Moonlight.

OUR more complete knowledge of full or black-body radiation embodied in Planck's law makes it possible to speak of the temperature of radiation as well as the temperature of radiating bodies. Thus, the temperature of any visible radiation is the temperature to which a black body must be raised to emit light as nearly as possible of the same integral colour or quality as that of the radiation in question.

The necessary "colour matches" involved in comparisons of a given radiation with that of a black body at a known temperature may be easily and quite accurately made with a contrast photometer. Radiation temperatures thus determined are called "colour temperatures." The colour temperature of the zenith sun as seen from the earth, according to Abbot's bolometric data, which extend into the infra-red spectrum, is 5600° abs. If correction is made for the absorption of the earth's atmosphere, we get a value of 6500° abs. for the colour temperature of sunlight above atmospheric limits. When a contrast photometer is used for making "colour matches" to determine colour temperature, a black-body source at a corresponding temperature is necessary for comparison. To avoid the necessity of a comparison black body at very high temperatures, advantage can be taken of Planck's formula for black-body radiation for computing a distribution of intensities in the visible spectrum which will give the integral colour of the source under examination, as measured by an optical pyrometer with monochromatic screens.

This procedure was followed in some observations made to determine the colour temperature of moonlight. The disappearing filament pyrometer with blue and red glass screens was focused on one of the brighter portions near the centre of the full September moon, 1916, when near the meridian. These readings were repeated under nearly the same conditions a year later. The colour temperature found for moonlight on the two evenings in question agreed to within 50°.

With the same pyrometer data we can also determine the brightness temperature of the moon for a given wave-length; that is, determine the temperature of a black body which has the same brightness or intensity for the same small wave-length interval chosen for comparison. Thus, with a red glass screen transmitting an average or effective wave-length of 0·665 μ, we may determine the brightness temperature of the moon for this wave-length. It is also possible, from the data thus obtained and the brightness of a black body, to calculate the brightness of the moon in candles per square centimetre. Thus, knowing the illumination due to the sun, the reflecting power of the moon for sunlight may be calculated.

The data determined from these various observations and calculations are shown in the following table:

Colour temperature of moonlight .	4125° abs.
Brightness temperature ($\lambda = 0{\cdot}665\,\mu$)	1575° abs.
Brightness for total light . .	0·25 candles/cm.^{2}
Reflecting power for total light .	0·07

The difference in colour temperature between the sun and sunlight reflected from the moon, 5600° and 4125° respectively, indicates that the observed area of the moon reflects selectively, the coefficient being about twice as large at the red end of the spectrum as at the blue. The greater difference in brightness temperature of these two is due to the low albedo or average reflecting power of the moon's surface.

Botanical Aspects of Wegener's Hypothesis.

IN the account which appeared in NATURE of January 27, p. 131, of the discussion on the distribution of life in the southern hemisphere, which took place before the Royal Society of South Africa, I am said to regard the botanical evidence as completely opposed to Wegener's theory. The remainder of the article generally followed the official report issued by the society.

My point was that the ancient phyla, with excellent means and ample time for dispersal, are generally valueless as indicating former land connexions. On the other hand, the distribution of the modern groups, especially the Angiosperms, in the South Temperate sub-continents took place in the main after the disruption envisaged by the Wegener theory. Thus neither ancient nor recent groups give us any material assistance in criticising this suggestive hypothesis, so far as concerns the relationships between the South American, South African, and Australasian floras. The botanical evidence for the southern hemisphere is certainly not "completely opposed" to Wegener's theory: it simply does not provide any critical test of that theory, so far as I can see at present.

R. H. COMPTON.

National Botanic Gardens,
Kirstenbosch, Newlands,
Cape Town,
February 26.

I ACCEPT Prof. Compton's correction of the phrase "completely opposed"; it is perhaps too strong a term to have used. Prof. Compton's letter, however, at least admits that the evidence from the botanical side is valueless as a critical test for or against

Wegener's hypothesis, and emphasises the fact that supporters of that hypothesis must look elsewhere than to the facts of animal and plant distribution for positive evidence in its support. Zoologists and botanists are dependent on the geologist and geophysicist for the correct interpretation of the palæogeographical changes which have taken place in the earth, and must be guided by them in selecting the basis on which the known geographical distribution of living forms can be explained.

THE WRITER OF THE ARTICLE.

Use of the Triode Valve in Spectrometry.

THE three-electrode valve offers a very simple and trustworthy method of amplifying the small currents produced in the thermopile of an infra-red spectrometer. Bright lines are more readily picked up and the limits of absorption bands determined with greater certainty with a valve and telephone than with a galvanometer. Moreover, the valve is instantaneous in action, while a sensitive galvanometer takes an appreciable time to give a trustworthy indication—so much so that the fainter lines are apt to be missed when using a long-period galvanometer. In the thermopile circuit an interrupter is necessary: this may take the form of a steel wire maintained in vibration electrically to which is attached a small wire dipper making contacts through a cup containing mercury. The interrupted thermopile current is passed through the primary of a small step-up transformer the secondary of which is connected to the grid of the valve.

For quantitative work the thermopile current is balanced by a potentiometer, a minimum of sound in the telephones indicating the point of balance.

The valve has a further advantage over the galvanometer in that it is unaffected by vibration or stray magnetic fields. The use of a valve for such work would seem to have many other applications, and to this end further experiments are being carried out.

The Release of Electrons by X-rays.

IN his interesting article, "Recent Advances in Photographic Theory," in NATURE of March 24, Dr. Mees touches upon the nature of X-rays and the mechanism of their production, and quotes Sir William Bragg's analogy of the plank of wood dropped into the sea.

I believe that Sir William Bragg put forward this analogy in a Robert Boyle Lecture, rather with a view towards successfully visualising the electron-X-ray process than of proving an individual relationship between them. One is tempted to say that an analogy never proves anything, although it may be thoroughly illuminating.

It is an extraordinary fact that a beam of X-rays will release electrons from an object which they hit, with just the velocity of the stream that originates the rays; it appears probable from energy considerations that this relation cannot hold down to the individual electron, so it might not be unprofitable if experiments were directed towards finding the limiting strength of the stream of electrons for the production of X-rays.

The Magnetic Disturbance of March 24–25.

A CONSIDERABLE magnetic disturbance occurred on March 24–25, as recorded by the Stonyhurst magnetographs. There was no marked sudden commencement of the disturbance, but the declination magnet began to move steadily towards the W., accompanied by a decrease in horizontal force, between the hours 8 and 9 G.M.T. The declination magnet attained the extreme limit of its westerly movement at 13 h. 14 m., when it began to move gradually towards the E. At 17 h. 12 m. a period of rapid oscillations commenced on the declination magnet. On the horizontal force magnet the decrease in force was succeeded, at 12 h. 24 m., by an increase. A very rapid oscillation of increase and decrease occurred between 17 h. 2 m. and 17 h. 18 m., the range being 88 γ (1 $\gamma \equiv 10^{-5}$ C.G.S. unit).

A quieter period ensued on the declination magnet between 18 h. 24 m. and 21 h. 12 m., while the horizontal force magnet, after the rapid oscillation at 17 h. 2 m., showed a gradual decrease in force, which reached its limit at 18 h. 48 m. A remarkable rapid oscillation, to E. and return to W., occurred on the declination magnet, between 21 h. 12 m. and 21 h. 26 m., the range of the oscillation being 38′. This was accompanied on the horizontal force magnet by an even more noteworthy rapid oscillation of increase and decrease of force, of range 189 γ, between 21 h. 24 m. and 21 h. 50 m.

The only other notable feature of the disturbance was a bay in both elements, between March 25, 2 h. 12 m., and 3 h. 0 m., the range in declination being 16′, and in horizontal force 97 γ. The more violent phases of the storm had ceased by March 25, 8 h. The extreme ranges were, in declination 1° 6′, and in horizontal force 238 γ. The vertical force magnet showed a general movement, with oscillations, of increase and decrease of force between the hours March 24, 17 h. 12 m., and March 25, 4 h. 24 m. This would indicate the period of the greatest activity of the disturbance. The sensibility of the magnet is uncertain, but the extreme range was about 80 γ.

A disturbed period in magnetic activity occurred on February 25–28, so that this storm follows after an interval of 27 days, the synodical rotation period of the sun. But the solar surface has been unusually quiet during the past two months, at least so far as spots, which have been very few and of small area, and faculæ, which have been very faint, are concerned. The connexion of these disturbances with solar phenomena will require further elucidation. Father Dechevrens, *S.J.*, recorded strong earth-currents at his observatory, St. Louis, Jersey, during the February disturbance. It will be interesting to hear of any observations of aurora borealis.

Pressure of Fluidity of Metals.

MR. HUGH O'NEILL, in his letter in NATURE of March 31, p. 430, gives what he calls H_u, the "ultimate hardness" of tin, zinc, and steel. On referring to my letter at p. 17 of NATURE of January 6, it will be seen that H is there used for H_u, and that the pressure of fluidity = *twice* the ultimate hardness. The units of H_u given at p. 430 are evidently kilograms per sq. mm. Expressing these in kilos per sq. cm. and multiplying by 2 we obtain the following values of the pressures of fluidity as calculated by Mr. O'Neill by means of his equation given at p. 773 of Nature of December 9, 1922.

Metal.	Pressure of Fluidity.
	Kilos per sq. cm.
Tin	1,080
Zinc . . .	5,000
Steel A	19,200
Steel S90 . .	33,600

I have recently (with the generous aid of Mr. R. H. H. Stanger of the Broadway Testing Laboratories, and the following firms who prepared and presented the necessary three specimens of each metal) determined the pressures of fluidity of several metals by direct experiment, so it will be interesting to compare the results, remembering of course that the specimens were *not* made from the same piece of metal as those used by Mr. O'Neill. In the case of my tests the three specimens of each metal were made from the same piece.

The British Aluminium Co. Ltd. supplied the specimens of aluminium.

Messrs. David Colville and Co. Ltd. supplied the specimens of mild steel.

Messrs. Dewrance and Co. supplied the specimens of tin, lead, and zinc.

The Elliott's Metal Co. Ltd. supplied the specimens of copper.

The Muntz's Metal Co. Ltd. supplied the specimens of Muntz's metal.

The experiments were made not merely to determine the pressures of fluidity, but also to test an hypothesis to account for the phenomenon of pressure of fluidity. This hypothesis is far too long to reproduce here, but it will be found in the Transactions of the Society of Engineers for the quarter January-March 1923. It connects the pressure of fluidity with the ultimate shearing and tensile strength of the metal, and was devised in connexion with experiments with clay, and then found to apply to plastic metals as well.

If p be the pressure of fluidity in kilos per sq. cm.,
f be the shearing stress in kilos per sq. cm.,
c be the ultimate tensile strength in kilos per sq. cm.,

then the hypothesis shows rationally on the assumptions made that

$$p = 3{\cdot}68c + 5{\cdot}21f. \quad . \quad . \quad . \quad (1)$$

The pressures of fluidity were determined by means of cylindrical specimens 70 mm. in diameter and 70 mm. high, using a flat-nosed punch 10 mm. in diameter at the end and reduced in the shank to 9 mm. so as to clear the sides of the hole.

Metal.	Tensile Strength c.	Shearing Strength f.	Pressure of Fluidity p.	p' the calculated Value of p.	$\frac{p'-p}{p'} \times 100$.
Lead . . .	114·5	125	777	1,072	+27·5
Lead-tin alloy	244·0	156	1,233	1,706	+27·7
Tin . . .	223	232	1,367	2,025	+32·5
Aluminium .	827	577	4,015	6,045	+33·6
Copper . .	2192	1445	10,860	15,590	+30·1
Muntz's metal	3686	2004	(16,800)*	23,966	
Mild steel .	4380	2990	(22,140)*	31,625	Mean +30·3
Zinc . . .	214	755	[7,760]	4,707	..

All stresses are in kilograms per sq. cm.

* These are *not* experimental values, but merely predictions.

The relation given by equation (1) thus on the average gives results which need reducing by 30 per cent. to arrive at the actual values, and the maximum departure from this mean is 3·3 (aluminium).

Zinc is a rank outsider as regards this hypothesis! But zinc has no plasticity. It did not elongate or show any contraction of area under a tensile force. In shear even it failed by tension, and when the pressure of fluidity experiment was made, the specimen gradually burst by yielding in tension on several vertical planes.

With regard to the variation of the figures in the last column, it must be remembered that these depend on the experimental values of f and c, which themselves vary. For example, in the case of the shearing tests, two experiments were made with each metal, the planes of shear being about one inch apart on the same specimen. For all this the values of f differed by 4·3 per cent. and 5·5 per cent. in the cases of tin and aluminium respectively.

Use of the Millibar in Aerodynamics.

The millibar, introduced by Sir Napier Shaw into British meteorology, brings the same drastic simplification into the numerical relations between pressure and velocity in aeronautics.

The accompanying diagram (Fig. 1) shows the

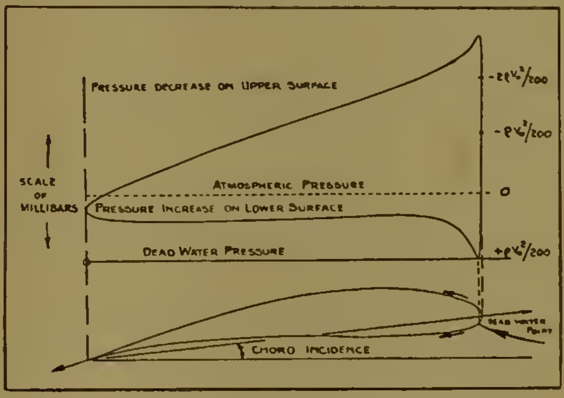

Fig. 1.

pressure distribution round a wing profile, calculated in accordance with Joukowsky's theory.

In C.G.S. units $p - p_0 = \frac{1}{2}\rho\,.\,(v_0^2 - v^2)$ dynes/cm.^{2} or microbars, where p, v are the variable pressure and velocity at points on the profile, p_0, v_0 the values at a distance, and ρ the density of the air.

Expressing ρ and v in M., Kg., S. units, which are more convenient for aeronautical measurements,

$$\begin{aligned} \text{pressure} &= \tfrac{1}{2}\rho\,.\,(v_0^2 - v^2) \text{ m.kg.s.}^{-2}\text{m.}^{-2} \\ &= \tfrac{1}{2}\rho\,.\,(v_0^2\,.\,10^{-2} - v^2\,.\,10^{-2})\text{mb.} \\ &= \tfrac{1}{2}\rho\,.\,10\,.\,(v_0^2\,.\,10^{-2} - v^2\,.\,10^{-2}) \text{ megadynes/m.}^2. \end{aligned}$$

The last two forms lend themselves to computation, since flying speeds usually lie between 10 m./s. and 100 m./s. The absence of all extraneous factors save integral powers of ten is sufficient proof of the practicality of Sir Napier Shaw's action.

In the minority of cases where the forces considered are produced by the action of gravity on known masses, they are easily transformed, for the megadyne is $10/9{\cdot}81 = 1{\cdot}02$ kgm. weight, and the millibar is $1000/981 = 1{\cdot}02$ cm. head of water with an accuracy amply sufficient for aeronautical measurements.

London, March 22.

The Sun-Cult in Ancient Egypt.[1]

By Aylward M. Blackman, D.Litt.

II.

It has often been maintained that the Aton-cult instituted by Ōkhnatōn (Amenōphis IV.) displays non-Egyptian features and is in a large measure the product of foreign influences. I hope, however, clearly to show here that in the main it is the outcome of certain tendencies of the old solar religion discussed in the previous article — tendencies which had begun to manifest themselves so far back as the Old Kingdom, which came increasingly into evidence during the Middle Kingdom and the eighteenth dynasty, and finally found in the teaching of King Ōkhnatōn a somewhat particularised expression.

It was pointed out in the first article that the sun-god, owing to the political and religious importance of Heliopolis, became at a very early date the State-god of Egypt, and that the priests of a number of the local gods, in order to enhance their prestige, identified them with the sun-god, the goddesses who were associated with these gods being identified with Ḥatḥor, the sun-god's consort. There was also, it must be noted, a distinct tendency to identify the various divinities with one another, thus considerably reducing their number as separate entities in the Pantheon. All this, combined with the prevailing uniformity in the structure and equipment of the temples, the temple liturgy, and the organisation of the priesthood—a uniformity due to the predominant influence of Heliopolis—fostered the growth of monotheistic or, anyhow, henotheistic ideas.

During the Middle Kingdom, when a Theban line of kings ruled over a united Egypt, Amūn, the local god of Thebes, was identified with the sun-god, being henceforth known as Amunrēʿ. As a result of the imperial expansion of Egypt under the Theban emperors of the eighteenth dynasty, the sun-god, originally the national god of Egypt and the prototype of the Egyptian Pharaoh, became in the person of Amunrēʿ a world-god and a world-ruler. Thus the victorious Tethmōsis III. says of Amunrēʿ that "he seeth the *whole world* hourly." A hymn in praise of the sun-god, written in the reign of Amenōphis III., the father of Ōkhnatōn, speaks of the sun-god as "the sole lord taking captive all lands every day, as one beholding them that walk therein." The once merely national god has thus become a deity who exercises universal sway and possesses universal vision.

But the god of this hymn is not only the all-powerful, all-seeing ruler: he is also the beneficent protector and sustainer of mankind—"the valiant herdsman who drives his cattle, their refuge and the giver of their sustenance." It will be remembered, of course, that the sun-god appeared already in the literature of the seventh to eighth dynasties in the guise of "the shepherd (or herdsman) of all men." This same hymn further emphasises the sun-god's beneficent nature in calling him "a mother, profitable to gods and men." As is so frequently maintained in the religious literature of the Imperial Age, this hymn also asserts that the sun-god is the source of all, including his own, being. "Thou art the craftsman shaping thine own limbs; fashioner without being fashioned."

From this and other compositions it can be seen that the religious thought of the period just preceding the reign of Ōkhnatōn was distinctly monotheistic in its tendency. It was only necessary to advance this tendency a step or two further to arrive at actual monotheism. This is what Ōkhnatōn did when he asserted definitely once and for all that the sun-god was not only the supreme and universal god, but also the only God—an assertion that had never been definitely enunciated by the theologians who had preceded him, but had only been sporadically and somewhat vaguely hinted at by them.

The universality of Ōkhnatōn's god is clearly set forth in the famous hymn, which so closely resembles the 104th Psalm, and of which the king claims, probably with right, to be the author. The sun-god is represented as the All-Father, the source of all life. He it is who has created the different nations and assigned them their divers complexions and languages. He has also provided for their sustenance, making the Nile to well up out of the nether world to water the land of Egypt, but setting a Nile in the sky for other peoples, whence it comes down as rain. "Thou didst make the distant sky in order to rise therein, in order to behold all that thou hast made. . . . All men see thee before them, for thou art Aton of the day aloft."

There has been a certain amount of controversy as to whether Ōkhnatōn was actually himself responsible for the establishment of this monotheistic sun-cult. As has been stated at the beginning of this paper, some scholars incline to the view that the Aton-cult is distinctly of foreign origin and that its being established as the State-religion was due to the influence of Tyi, herself a foreigner, by whom her son Ōkhnatōn was completely dominated. Others, again, have maintained that the establishment of this cult was due to the successful intrigues of the Heliopolitan priests, who, attaining the ascendancy over a weak king, temporarily regained the religious hegemony of Egypt.

Those who take the view that the religious revolution was the work of Tyi and foreign influences, or of an intriguing priesthood, find the main support for their respective theories in the fact that the body, supposed to be that of Ōkhnatōn, is that of a man who could not have been more than 25 to 26 years old when he died, while the skull shows distinct signs of hydrocephaly, indicating that the person in question was weak intellectually. As Ōkhnatōn is known to have reigned for more than sixteen full years, he can, if this is his body, have been only ten or eleven years old when he came to the throne and the religious revolution began, and only sixteen or seventeen when he definitely broke with the priests of Amūn, changed his name from Amenḥotpe to Ōkhnatōn, and deserted Thebes and founded his new capital at El-Amarna. Yet before this change in name and residence two of his daughters, as a relief distinctly shows, were old enough to accompany him when he officiated at the temple liturgy, and, moreover, before the aforesaid change

[1] Continued from p. 502.

took place, *i.e.* before the sixth year of his reign, we happen to know that Ōkhnatōn celebrated the so-called *sed*-festival, a festival marking the 30th anniversary of the Pharaoh having been designated heir to the throne. Had it not been for the age-limit imposed by Okhnatōn's supposed body, we should naturally have imagined, in view of this last piece of evidence, that when he succeeded his father, Amenōphis III., he must have been at least 24 or 25 years old.

As a matter of fact, however, though the coffin in which the body was found was beyond question made for Ōkhnatōn, yet the body itself is almost certainly not his, the date of the objects found thereon, as Prof. Sethe has recently shown, precluding that possibility.

There can be little doubt, therefore, that Ōkhnatōn was a full-grown man when he came to the throne, while at the time of his break with the priests of Amūn and his shifting of the capital to Middle Egypt he was more than 30 years old, and accordingly at the height of his intellectual and physical vigour. The fact that Ōkhnatōn's supposed body is not his at all also disposes of the theory that he was weak mentally. There is, therefore, no necessity whatever to suppose that the new faith, which contemporary records so closely associate with the person of the king and which he was certainly quite old enough to have formulated, was the product of foreign influences during a regency of Tyi, nor yet of the Heliopolitan priesthood struggling for a religious and political supremacy. That Ōkhnatōn really was a man of exceptional mental gifts and high ideals—Breasted calls him "the first individual in history"—is evident from that remarkable portrait of him found at El-Amarna in 1912 and now in the Berlin Museum. All who see it are impressed by the beauty of the features and expression, the thoughtfulness pervading the whole countenance.

We need not, however, go to the other extreme, as some writers have done, and regard the love of righteousness and the beneficence attributed to Ōkhnatōn's god as primarily the expression of the king's own ideas and feelings. On the contrary, as has been pointed out in the preliminary article, these are the very qualities assigned to the old Heliopolitan sun-god. How far, indeed, the old solar religion had advanced in these particular directions, even before the Middle Kingdom, is especially evident in a literary composition of the ninth to tenth dynasties, to which by an oversight no reference was made in the above-mentioned article. In one portion of the work in question the ancient writer speaks of men as "the flocks of God (*i.e.* the sun-god)." God, he goes on to say, "made heaven and earth at their (*i.e.* men's) desire. He checked the greed of the waters, and made the air to give life to their nostrils. They (men) are His own images proceeding from His flesh. He arises in heaven at their desire. He sails by (*i.e.* in the celestial solar barque) in order to see them. . . . When they weep He heareth. . . . How hath He slain the froward of heart? Even as a man smiteth his son for his brother's sake. For God knows every name."[2] In the preceding section of the same work we read that "more acceptable (to the sun-god) is one righteous of heart than the ox of him who doeth iniquity."

[2] A. H. Gardiner, "New Literary Works from Ancient Egypt," in *Journal of Egyptian Archæology*, vol. i. p. 34.

That Ōkhnatōn's sun-cult is nothing more than a special development of the older sun-cult becomes only more evident the further one pursues one's researches. In the earliest stage of the cult the god appears simply in the guise of the Heliopolitan sun-god, Rēʿ-Horus of the Two Horizons (Rēʿ-Harakhte), with whom indeed, as we shall see, he was actually identified. As such he is depicted as a human figure with a hawk's head surmounted by the uræus-encircled sun's disk. Later on, however, but before the migration of the court to El-Amarna, the mode of representing the god was entirely changed. He was depicted as a solar disk, from which descend rays terminating each in a human hand—these hands being the only trace left of the old anthropomorphism, if they are not, as is quite likely, simply an expression of poetic fancy. The uræus was also retained, sometimes hanging from the disk, generally, however, rising up from the bottom edge towards the centre, though it was of no religious significance, but merely the emblem of kingship—Ōkhnatōn's deity being not only the world-god but the world-king.

The name of the new god in ordinary everyday parlance was *pa Aton*, "the Aton," aton (*itn*) being the word used then and earlier to denote the visible, physical solar body, though, as Sethe points out, the word seems occasionally to have been employed, even before Ōkhnatōn's time, to designate the sun-god himself. Generally, however, it just denotes the sun as a natural phenomenon or cosmic body, as distinguished from the god dwelling in it, a sense in which the word Rēʿ is never used.

According to the old theological teaching the physical sun was simply the embodiment of the god. Thus we read of "Atum (the sun-god) who is in his *aton*," "Rēʿ whose body is the *aton*," and him "who lightens the Two Lands (Egypt) with his *aton*." In fact, it was exactly on account of the very definite meaning of the word *aton*, Sethe maintains, that Ōkhnatōn chose it as the designation of his god; for the new religion was entirely materialistic in its conception of the Supreme Deity, in marked contrast to the—it must be confessed—much more spiritual conception of the old religion. Indeed it is just here that Breasted has gone astray when he asserts that "it is evident that the king was deifying the force by which the sun made itself felt on earth,"[3] an assertion that is based on a mistranslation of the Aton's official nomenclature (see below). On the contrary, it was the actual cosmic body, the physical sun itself, not a mysterious power incorporated in it or working through it, which Ōkhnatōn made his subjects worship.

In addition to the ordinary name, the Aton, the god also bore an official or formal designation, the words composing it constituting a short profession of faith—a compressed creed. This designation, which, on account of the god's world-wide kingship, was, like the two names borne by every Pharaoh, enclosed in two cartouches, appears in two forms, an earlier and a later. The earlier, which dates from the very commencement of the reform, and continued in use until after the seat of government had been moved from Thebes to El-Amarna, is as follows:—"Liveth Rēʿ-

[3] Breasted, "Development of Religion and Thought in Ancient Egypt," p. 321.

Horus of the Two Horizons, rejoicing in the horizon, in his name Shu who is Aton." The new god is thus identified with the two forms under which the sun-god was known both before and after the reign of Ōkhnatōn—Harakhte (= Horus of the Two Horizons) and Shu. The epithet "rejoicing in the horizon" is not, Sethe points out, an invention of Ōkhnatōn's, but appears earlier in the eighteenth dynasty as a description of the sun-god. Shu, originally personified space, was, as Sethe also points out, a common appellation of the sun-god from the Hyksos period onwards, and never (certainly not as written in this cartouche with the sun-determinative) can be used in the sense of "heat" or "splendour," as Breasted and Erman respectively have supposed. Sethe rightly maintains that the prominent feature in this official nomenclature is the element Rēʿ-Harakhte, the name of the Heliopolitan sun-god, all the rest, even the name Aton, being purely subsidiary.

The later official designation, which came into force apparently soon after the eighth year of the king's reign, is marked by certain significant changes. It runs as follows:—"Liveth Rēʿ, the ruler of the Two Horizons, who rejoices in the horizon, in his name Father of Rēʿ, who has come as Aton."

It will be seen that Horus and Shu, names which Ōkhnatōn perhaps thought were too definitely associated with the old religion, have been struck out and replaced by two epithets, "Ruler of the Two Horizons" and "Father of Rēʿ." The name Rēʿ, which has not been interfered with, had been, as Sethe points out, a regular element in the Pharaoh's first cartouche ever since the fifth dynasty, and as such was of no theological significance. Also the king evidently had no objection to this old name of the sun-god. For example, he still retained the royal title Son of Rēʿ; Rēʿ appears as an element in his own first name and in the names of his two daughters; two temples or shrines associated with his mother Tyi and his daughter Meritaton bore the name "Shade of Rēʿ"; and the king himself, like other Pharaohs, is officially spoken of as Rēʿ.

The element "Father of Rēʿ" in the god's official designation is interesting, taking as it does the place of Shu. Shu, according to the old Heliopolitan theology, was the son of Rēʿ, and as such he actually was assigned that title. It would, Sethe suggests, have been scarcely tolerable to the founder of the new religion that Aton, the creator and author of all being, should be regarded as the son of Rēʿ, the sun-god of the old religion. Ōkhnatōn therefore asserts that his god is the father of Rēʿ, *i.e.* he makes him cosmically older. The fact that the god is called Rēʿ, and, at the same time, the Father of Rēʿ, reminds one of the old epithet of Amūn, Bull of his Mother, which simply means that he is self-created, that is, that he was not begotten by another. Sethe rightly maintains that though this epithet has a polytheistic touch about it, Ōkhnatōn would have been as little conscious of this as were the Christian Fathers when they formulated the doctrine of the Blessed Trinity.

Sethe directs attention to another very interesting point in this later designation of the god. "To come," he says, "has obviously here, as so often, the meaning of 'to come again.' The Father of Rēʿ in question is thought to have come again after he had obviously disappeared or had been mistaken for another through man's ignorance, and indeed he has come again in the form of the apparently new but in reality primæval god of Amenōphis IV."

Let us now consider briefly the temples of the Aton erected at El-Amarna and the liturgy celebrated therein. The main difference between the temples of the Aton and those of the old Solarised religion lies in the fact that the former seem to have been roofless. There were thus no columned halls and dark, mysterious sanctuaries with their surrounding chambers, the place of these being taken by a series of main and subsidiary courts lying behind the forecourt and leading one out of another. The reason for this architectural change was that Ōkhnatōn permitted no cultus-image of his god to be made, not because he was an iconoclast or afraid of idolatry, but because his conception of God was so intensely materialistic. The Aton, as already pointed out, was the actual physical sun, the cosmic body itself, not a divinity dwelling in that body and manifesting himself through it, and therefore ready similarly to manifest himself through a cultus-image, which was "the body" of the divinity it represented, according to the ideas of the ancient theologians—as we should express it, the divinity's embodiment. Offerings had, therefore, to be made direct to the god in the sky, a procedure which necessitated a roofless temple, for no roof must intervene between the god and the offerings held up to him and laid on the altar.

Despite this complete break with the old conception of the indwelling presence of the god in the temple-sanctuary,—a conception which brought the god so near to his priests and worshippers—it is remarkable how closely in many respects the general plan and equipment of the traditional Egyptian temple were adhered to, a clear indication that there were no direct foreign influences at work in the new religion; indeed, the architecture down to the very last detail is purely Egyptian. We still find the pylon with its two beflagged towers and the great forecourt with its large stone altar in the midst[4]—the forecourt being colonnaded in the case of the temple bearing the name of "Shade of Rēʿ of the Queen Mother, the Great Royal Wife, Tyi." Evidently, too, the rearmost court of all in the Aton-temples, which occupied the place of the sanctuary in the ordinary Egyptian temple, was regarded as particularly sacred. Again statues of the king and also of the queen were set up as heretofore in different parts of the temples, the king and queen being thus enabled, so it was thought, to function perpetually as worshippers and offerers, or conversely as the recipients of worship and offerings. Yet again, before the entrance to what N. de G. Davies calls "the inner temple" of the Aton stood eight tanks of water for the purification of those who entered it. Such tanks or pools of water were, as pointed out in the preliminary article, a characteristic feature of the old Heliopolitan sun-cult. Finally, the "inner temple" was called the House of the Benben, the *benben* being, as we have seen, the sacred pyramidion in the great sun-temple at Heliopolis. Curiously enough, in the representations we possess of Ōkhnatōn's Aton-temples,

[4] By an oversight no reference was made in the account of an ordinary Egyptian temple, given in the preliminary article, to the stone altar that always stood in the colonnaded forecourt.

no obelisks (which were so closely associated with the old sun-cult) are depicted as standing before the main entrance or elsewhere in the sacred precincts. However, we know that Ōkhnatōn erected an obelisk in honour of Harakhte-Aton at Karnak, probably in connexion with his *sed*-festival celebrations.[5]

The Aton-temple liturgy itself is clearly the old temple liturgy adapted to the new ideas and new requirements. As there was no cultus-image, there was no place in the new worship for the toilet, or indeed many of the pre-toilet, episodes of the old liturgy. The worship of the Aton seems to have consisted mainly in the presentation to the god of food- and drink-offerings, perfumes, and flowers, and in the chanting of hymns and in musical performances in general. But the ceremonies connected with the presentation of offerings were those of the old religion, the officiant consecrating the offerings in the time-honoured fashion, *i.e.* by extending over them the so-called *kherp*-baton. As in the old liturgy, this ritual act was preceded by the burning of incense and the pouring out of a libation of water; indeed, the burning of incense and the pouring out of a libation were, as in times past, the regular accompaniments of every act of offering. The liturgy was celebrated, as of old, to the accompaniment of the rattling of sistra, and also of other musical performances, vocal and instrumental. Lastly, it should be pointed out, the ceremony of sweeping the floor—the removal of the foot-prints—before and after the celebration of the liturgy seems almost certainly to have been retained.

This article cannot be satisfactorily concluded without a brief discussion of two important questions that have already been touched upon in the preceding paragraphs, namely, Ōkhnatōn's quarrel with the priests of Amūn, and the theory advanced by some scholars that in the establishment of the Aton-cult we are to recognise a temporary restoration of the political and religious supremacy of the Heliopolitan priesthood.

Long before the time of Ōkhnatōn the Theban god Amūn had been completely identified with the Heliopolitan sun-god. What, then, was the cause of the king's rupture with the priests of Amūn and his breaking away from all Theban influences?

It must be borne in mind that the monotheistic tendencies of the preceding period had in no way affected the customary performances of the old institutional religion. Whatever may have been the speculations and ideas of the learned and enlightened few, the worship of the gods was conducted in exactly the same way as it had been for centuries, without a single hint at a change in the traditional ceremonial. Ōkhnatōn's religious revolution, on the other hand, not only entailed a great change in the conduct of the temple services and far-reaching structural alterations in the temple buildings, but also, since the king would brook no rival to his god, the suppression of all the festivals and other performances connected with the provincial cults and with the various cults established at the capital. All this was a completely new attitude in Egyptian religious experience; indeed we are encountering the "jealous God" for the first time in human history, several centuries before His appearance among the Hebrews. The feelings both of the priests and of the masses of the people must have been deeply stirred by this attack on their religious observances, particularly in so far as it affected the festivals celebrated in honour of the local divinities, festivals which no doubt played as great a part in the lives of the people as do those celebrated in honour of the local Egyptian saints at the present day.[6] In fact, there can be no question that Ōkhnatōn's reform meant far too sharp a break with the past for his intensely conservative-minded subjects.

It should here be pointed out that so early as the reign of Tethmōsis III. all the priesthoods of Egypt had been combined in one great organisation, with the high-priest of Amūn at their head. To the high-priest of Amūn, therefore, and to the priesthood of Amūn as a whole, all the local priesthoods would have looked to champion their threatened rights, while in Ōkhnatōn's eyes this very high-priest and priesthood would have appeared as the embodiment of all the forces of reaction against which he was struggling. Herein lay quite sufficient cause for his breaking away entirely from Thebes and the Theban god. We must also remember that Ōkhnatōn's materialistic conception of the Aton was entirely opposed to the—as already pointed out—much more spiritual conception of the sun-god formulated by the theologians of the old religion. It was impossible to regard the actual corporeal and localised divinity, such as Ōkhnatōn maintained his sun-god to be, as capable of identification with a being (or beings) who could manifest himself (or themselves) in all manner of forms and in many places. Did the cause of the final rupture reside in this difference of conception as to the nature of the Godhead? If so, we have here a foretaste of those great theological controversies which troubled the Christian Church of the first five centuries, and of the seventeenth-century wars of religion.

Let us now briefly consider the theory that in the institution of the Aton-cult we are to recognise the restoration of the political and religious supremacy of Heliopolis. In view of all that has been set forth in the preceding paragraphs, the Heliopolitan sun-cult is clearly to be regarded as the basis of the new religion, or rather as supplying all the material out of which the new edifice was constructed. On the other hand, the particular shape that that edifice assumed must be regarded as the work of Ōkhnatōn. If the sun-cult had been officially promulgated by the organised priesthood of Heliopolis or, as Borchardt[7] suggests, of Hermonthis (Heliopolis of Upper Egypt [*Iwnw šmʿ*]), Ōkhnatōn, instead of founding an entirely new capital at El-Amarna, would have been obliged to install the seat of government in or very near the actual official centre of the religion he had adopted. But he was able to act as he did, because the religion he professed was regarded as a completely new religion, a special revelation to himself, as he distinctly asserts. It was therefore not associated with any particular locality, so he was free to make his capital in any place that seemed to him to be most free from the old traditions and best adapted to his requirements.

Lastly, just a few words on the frequently-made assertion that foreign influences are discernible in the

[5] Schäfer in *Amtliche Berichte aus den preuszisch. Kunstsammlungen*, xl. 10, col. 227.

Aton-cult. That there are no traces whatever of such influences, but that the Aton-cult is in every respect essentially Egyptian, the facts set forth in this article must have made perfectly clear. However, it is possible that Ōkhnatōn had foreign blood in his veins, for Prof. Elliot Smith maintains that his maternal grandfather, Iuyu, is distinctly non-Egyptian in type. To this dash of foreign blood, therefore, may well be due the originality clearly displayed by Ōkhnatōn in the particular expression which he gave to a certain trend of religious thought prevailing among his contemporaries.

Scientific Investigation of the Whaling Problem.

By Sir Sidney F. Harmer, K.B.E., F.R.S.

The Colonial Office has recently announced that the *Discovery* has been purchased by the Crown Agents for the Colonies, on behalf of the Falkland Islands, for employment in researches, principally on whaling, off South Georgia and the South Shetlands. The *Discovery* was built for Capt. R. F. Scott's first Antarctic Expedition (1901–1904). She is a strong wooden vessel of about 700 tons register, and she has been chosen with special reference to her suitability for ice-work.

Subantarctic whaling commenced at the end of 1904, at a time when the industry was regarded as almost obsolete, owing to the exhaustion of the old whaling fields. It increased with so much rapidity that more than 10,000 whales were caught during the season 1911–12. At first concerned almost exclusively with the humpback, the operations are at present supported almost entirely at the expense of the much larger fin whale and blue whale. Humpbacks showed an alarming decline in numbers after the 1911–12 season, though they have made some recovery during the last two whaling seasons.

It should be realised that modern whaling is carried on by comparatively small steam vessels fitted with appliances for the capture of the whales, the products of which are worked up by factories on shore or by larger steamers, the floating factories. In either case, suitable harbours are required as bases, and the most favourable localities at present known are South Georgia, which lies to the east of the Falkland Islands, and the South Shetlands, which are farther to the south-west. These islands are dependencies of the Falkland Islands, and are accordingly under British jurisdiction.

As the result of several memoranda which were prepared in 1917 by Mr. E. R. Darnley, of the Colonial Office, an Interdepartmental Committee on research and development in the dependencies of the Falkland Islands was appointed by the Secretary of State for the Colonies in 1918; and its report (Cmd. 657) was published in 1920. The report contained a number of recommendations with regard to the investigations which were required; and the purchase of the *Discovery* is the first practical result of these suggestions. It should be mentioned that an earlier Anglo-Swedish scheme for the investigation of the same problems was abandoned on the outbreak of war in 1914.

The object of the projected voyages is to obtain scientific evidence bearing on the whaling problem generally, with the view of ascertaining to what extent protective measures are required. It has to be determined, in the first instance, what are the species of whales which are being hunted. Although known to the whalers as humpback, fin whale, and blue whale, it is uncertain whether these are identical with the northern whales known by the same names. Whales are migratory animals, and there can be no reasonable doubt that they visit the Antarctic Ocean in order to profit by the rich food-supply of its waters, and that they afterwards depart, fatter than when they arrived, to warmer waters, which are probably visited for breeding purposes. More definite information is required with regard to these migrations, and it is hoped that it may be possible to obtain direct evidence by a system of marking individual whales.

The period of gestation, the seasons when pairing and birth take place, and the rate of growth after birth all need further study. The plankton requires investigation, in view of the dependence of the whales on it for food; while the temperature of the water, with other hydrographical questions, has to be studied, in order to ascertain how far these factors influence the movements of whales. There is already some reason to suppose that the position of the northern edge of the Antarctic ice is a factor which is correlated with the success or failure of a season's working. If the summer is relatively warm the ice will be too far to the south and the whales will probably be too distant from the base. If the summer is cold the whales will be too much to the north. It may be anticipated that there is an optimum position for the ice which brings the main stream of whales to the neighbourhood of the whaling stations.

Although whalebone whales all feed on plankton, individual species are known to have a preference for one kind of plankton rather than another. In most localities the humpback consumes a considerable amount of fish, while the blue whale is said to feed exclusively on Crustacea. The distribution and the seasonal occurrence of various kinds of plankton, and the examination of the stomach-contents of whales, are matters with which the expedition will certainly have to deal; and the results may prove to have a distinct bearing on the question why each species of whale differs from the others in its seasonal occurrence. The abundance of whale-food is dependent on conditions favourable for the growth of diatoms and other chlorophyll-containing organisms; and in this connexion may be mentioned Mr. A. G. Bennett's interesting observation that the skin of certain whales is covered by a film composed of innumerable diatoms. The evidence is in favour of the view that this skin-film is not present on thin individuals which have recently come down from the north, but that it develops during the stay of the whales in Antarctic waters. The study of the film and perhaps of whale-parasites may prove to be capable of giving important information with regard to migrations.

For many years the Norwegians have taken the leading place in the whaling industry, and they have large interests in Antarctic whaling. It is thus natural that they should feel anxiety with regard to the possible results of a protective policy, and this is shown by an article recently published in the *Anglo-Norwegian Trade Journal* (Vol. 9, No. 98, February). The comments in question were a rejoinder to criticisms of the whaling industry which had appeared in the *Morning Post*, based on a lecture given by myself, as reported in NATURE (Vol. 110, December 16, 1922, p. 827). I had pointed out, on the incontrovertible evidence of history, that the operations of whalers in the past have been invariably followed by a depletion of the whaling fields. The Atlantic right whale no longer frequents the Bay of Biscay in numbers sufficient to maintain a whaling industry, nor is the Greenland whale still common in the bays of Spitsbergen, in Davis Straits, or even in the North Pacific. The grey whale disappeared long ago from the lagoons of California, and there is no longer occupation for the hundreds of vessels which left European and American ports annually, in the eighteenth and part of the nineteenth centuries, in pursuit of the Greenland and other right whales and the sperm whale. With these facts in view the least that is required is the adoption of a cautious policy, lest the mistakes of the past should be repeated.

The whaling companies are admittedly interested in the avoidance of extermination, which would mean the closing of their operations, but their advocates have maintained that, in view of the enormous extent of the oceans which are frequented by whales, the activity of hunters in a small area is not likely to produce much effect in reducing their number. It will be seen, however, by consulting a map, that South Georgia and the South Shetlands lie in the region where the Antarctic Ocean is narrowest, and that they are admirably situated to intercept the stream of whales in their circumpolar movements. It would not be surprising if operations at these stations alone were found capable of depleting very seriously the entire stock of Antarctic whales, even if no new stations were to be founded in other localities, as seems likely to happen in Ross Sea, for example. The danger is all the greater, taking into consideration the highly efficient methods of modern whaling.

The acquisition of a sound body of scientific evidence is the object of the expeditions which are being planned by the Colonial Office. Although I do not conceal my personal conviction, as at present informed, that whaling is being conducted on too large a scale, I do not deny that a study of the subject by competent investigators on the spot may lead to a different conclusion. The Trustees of the British Museum have acted in an advisory capacity to the Colonial Office since they first became interested in Antarctic whaling, not long after its inception. I am authorised to state that they do not desire to take up an extreme position in the matter, but that their efforts are directed to the restriction of whaling to an extent which is not inconsistent with the permanent preservation of whales. This is a moderate view, with which it may be hoped that the representatives of the whaling industry will agree in principle. The article to which I have referred virtually admits as much, and the willing co-operation of the whaling companies will be of the greatest value to the expedition. It may be hoped that it will be possible to find a *modus vivendi* satisfactory to both parties, who are equally interested in preventing the extermination of whales.

Einstein and the Recent Eclipse.

THE results of the expeditions from Canada and the Lick Observatory to Wallal, Western Australia, for the solar eclipse of last September have now come to hand; and both report in favour of the Einstein shift of starlight. In each case the number of stars measured was very large—exceeding eighty—the magnitudes being between the seventh and the tenth. From this it is evident that the exposures were comparatively long, and consequently there would be considerable extension of the corona on the plates, which would obliterate the stars nearest the sun. The measures, however, were sufficiently exact to give a decisive result using the more distant stars. Profs. Campbell and Trumpler measured all their plates in duplicate; the values for the shift at the limb of the sun deduced from the individual plates ranged from $1{\cdot}59''$ to $1{\cdot}86''$, the mean of all being $1{\cdot}74''$, which is only $0{\cdot}01''$ less than Einstein's predicted value.

As Prof. Campbell is well known to have been in no sense predisposed in favour of Einstein's theory, this result, combined with that of Prof. Chant and the mean of the Principe and Sobral results in the 1919 eclipse, will probably be regarded as setting the question at rest. Prof. Campbell says in his telegram that he considers further work of this kind unnecessary, so that he will attack other problems in the Californian eclipse of next September. There are still the plates taken by the Australian expeditions to be measured. This is to be done at Greenwich; their scale is smaller than that of the Lick Observatory plates, so that probably less weight will attach to them.

The evidence as regards the presence of the shift in the solar spectral lines is now fairly evenly balanced "For" and "Against"; but in any case this test is a less decisive one than the other two, since there are so many known causes of shift of spectral lines, which it is not easy to eliminate completely.

A. C. D. C.

Current Topics and Events.

THE agricultural Tribunal of Investigation appointed by the Government to inquire into the present position of the farming industry and to suggest methods for its improvement has issued an interim report. Its recommendations are being actively discussed in the daily press, mainly from the political aspect. At present the majority of farmers are undoubtedly in an unsound economic condition, and especial interest therefore centres in these sections of the report dealing with agricultural organisation and education. The Tribunal is impressed by the extent of co-operative measures both in Europe and in America, and in urging that British farmers should form similar organisations, suggests that the study of the economic organisation of the industry should have fuller recognition in the farm institutes and agricultural colleges. The Tribunal pays a tribute to the work carried out by the research staffs of these institutions and considers that the departments dealing with the economic problem should be further developed. New systems of farm management, in particular the maintenance of livestock on arable land,—the soiling system,—are suggested as urgent problems to be investigated from this point of view. It is pointed out that in the United States 50 per cent. of the research grants are devoted to farm economics as against 10 per cent. in this country. In this connexion, however, it should be remembered that the term "farm economics" has a much wider interpretation in America than would be admitted here, due in part to the absence, until recently, of the settled rural population that marks the older countries. Making due allowance, however, for this and for the characteristic American tendency towards over-organisation, the comment of the Tribunal still remains true in substance. It is to be hoped that this essential bridge between the research workers and the farmers will be strengthened as a result of the Tribunal's recommendations.

THE Secretary of State for the Colonies has appointed an executive committee to control the researches recommended by the Inter-Departmental Committee on Research and Development in the Dependencies of the Falkland Islands, and in particular the investigation of the question of the preservation of whales and of the whaling industry, which has been subject to Government regulation since its inception nearly twenty years ago. The members of the committee are as follows:—Mr. Rowland Darnley (chairman), Colonial Office; Sir Sidney Harmer (vice-chairman), British Museum (Natural History); Mr. H. T. Allen, Colonial Office; Mr. J. O. Borley, Ministry of Agriculture and Fisheries; Capt. R. W. Glennie, R.N., Admiralty; Mr. J. M. Wordie, Royal Geographical Society: and Sir Fortescue Flannery, of Messrs. Flannery, Baggallay and Johnson, consulting naval architects to the Crown Agents for the Colonies, who has consented to serve as a member of the committee until the *Discovery*, which has been purchased for the purposes of the research expedition, has been reconditioned. In another part of this issue, Sir Sidney Harmer gives some account of the scientific results to be expected from the cruises which it is anticipated the *Discovery* will undertake.

THE report of the nineteenth year's work of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington has lately been issued in the Year Book of the Institution for 1922. The non-magnetic ship *Carnegie*, after twelve years' voyages which have been of great import to the science, is now out of commission for a time, while the observing staff is largely occupied with re-observations in land areas where further information, chiefly to determine the secular variation, was needed. An analysis of the vast body of data acquired by the Department is now in progress. Two magnetic observatories have been set up, in Western Australia and in Peru, regions of the globe where such institutions are much needed, and help has been given in carrying on the former German observatory at Apia, in Samoa. The Department has now turned its energies to the much-neglected study of earth-currents, and is devising new methods of registration. Dr. S. J. Barnett, chief of the section of experimental work in pure magnetism, is vigorously prosecuting his researches on magnetism by rotation, and the converse effect. The investigation of atmospheric electricity is also being extended. A conference of American men of science was held at the Department during the year, in order to consider what modifications, if any, of the original programme of the Department should now be made, and the conclusions and recommendations of the conference are being taken as a guide in the further development of the activities of the Department.

IN the "Shirley Institute Memoirs," vol. 1, 1922, recently received, are collected the ten papers published during the year by the British Cotton Industry Research Association. A perusal of this volume affords an encouraging picture of the future of textile research in this country if the high standard indicated is maintained. The work described falls naturally into three well-defined sections—chemical and physical, biological, and technological. Four papers are résumés of the literature of some chemical, physical, and botanical aspects of cotton, and should be of much value to workers in this field, in which the literature is scattered and much of it almost inaccessible: more than 380 references are given. The biological papers have been dealt with previously in these columns and need no further mention. The three most striking papers are the technological contributions dealing with some properties of yarns, such as regularity in relation to tensile strength and twist. They materially increase our somewhat scanty knowledge of the nature of yarns, and the original methods of investigation described are of wide application. Until the present publication little of permanent value has been done on yarn structure since the pioneer work of

Oliver in 1905–7 (Proc. Roy. Soc. Edin.). A large field of work of extreme difficulty and fascination is here awaiting attack by the physicist and the mathematician, and not the least important of the functions of textile research associations lies in removing such problems from the almost complete obscurity and isolation they have hitherto "enjoyed." It is almost unknown outside the industry that many of the most fundamental problems in textile technology are problems for the mathematician and the mathematical physicist, and there is little doubt that in a few years' time a real and considerable demand will exist in the textile industries for such workers: this should not be without interest for those engaged in the training of students in our universities.

The Ministry of Agriculture and Fisheries has re-issued Leaflet No. 71, dealing with the Colorado beetle. The discovery of this destructive insect in the neighbourhood of Bordeaux last year renders it necessary to take any precautions possible in order to guard against its entry into this country. On several occasions it has been carried by shipping to Europe, and has even become temporarily established on a small scale. During 1901–02 it occurred in potato plots in the neighbourhood of Tilbury docks, but was successfully eradicated by prompt measures. The present infestation in France is of a most serious nature, and it is known to have spread over about 100 square miles. In all probability its area of occupation is even larger, as it is difficult to investigate so large a district with equal thoroughness. The reappearance of the insect during the coming season will be watched with some anxiety, and, unless the most drastic measures are taken on a very large scale, there is every chance that it will remain, and ultimately establish itself as a continental pest. In the latter event it can be scarcely more than a matter of time before it reaches England, since it is obviously impossible to prevent stray insects coming over unobserved in vessels from Bordeaux. The potato in this country is singularly free from insect pests, and it is to be hoped that the Colorado beetle will be unable to establish a footing. It is, however, gratifying to know that the Ministry of Agriculture has given the matter the fullest consideration; but it is incumbent upon all growers to inform the Ministry of the first sign of the appearance of the insect in the field, in order that it can be dealt with immediately by experts. There is no doubt that it can be eradicated if measures are taken sufficiently early; but it is evident that in France it has spread and multiplied to an extent which renders effective control a matter of great difficulty.

In the issue for March 9 of *Chemistry and Industry* appears a review of the position of the nitrogen industry in France. The French Chamber of Deputies has recently approved the agreement made in November, 1919, with the Badische Anilin und Soda Fabrik, whereby the French were to pay 5,000,000 francs for the right to work the Haber process, together with all information necessary to carry on the process as worked at Oppau and Merseburg. Part of this sum would be paid on the ratification of the agreement, and the remainder when the factory has produced a minimum of 20 tons of fixed nitrogen per day for fifteen consecutive days. A royalty would also be paid when production reached a certain figure. The agreement has given rise to much discussion of the merits of the Haber and other processes. An inquiry instituted by the French Government in 1921 led apparently to the conclusion that under existing conditions the Haber and Claude processes offered practically equal advantages, and the matter can be settled only on the basis of experience gained in working the various processes on a large scale over a considerable period. (Cf. Nature, vol. 107, page 765; vol. 111, page 101.)

Several new flying records were established during February, according to the *Meteorological Magazine* for March. A record climb of 20,000 feet in 12 min. 24 sec. by Flight-Lieutenant Haig at Martlesham Heath is noted as announced in the *Times* of February 6. The speed at ground level was 189 miles per hour. At Marseilles, on February 15, M. Sadi Lecointe is said to have broken the world's record for speed over a four-kilometre course: his average speed was 234⅝ miles per hour, breaking the previous record by more than 10 miles per hour. Another French airman, M. Maneyrol, on February 26 established a record, making a motorless flight of 10 kilometres (horizontal distance) near Cherbourg during a strong south-westerly wind. Three notable flights are said to take place this year: an expedition of five French aeroplanes was to start on March 15 on a world tour, probably lasting two years. An American crew will fly from Berlin to Chicago, towards the end of the year, in the Zeppelin air-cruiser now being constructed for the American Government. A flight across the North Pole is to be attempted at the end of June in connexion with Amundsen's expedition; the distance to be covered is 2250 miles, and it is expected to fly this distance from Point Barrow to Spitsbergen in 26 hours.

We are asked to announce that the Museum of Practical Geology, 28 Jermyn Street, S.W.1, is closed for repairs until further notice. The offices and library of the Geological Survey remain open.

The Brussels correspondent of the *Times* states that it has been decided to begin Summer Time in Belgium on April 21.

On Thursday next, April 26, at 3 o'clock, Prof. J. T. MacGregor-Morris will begin a course of three lectures at the Royal Institution on "Modern Electric Lamps," and on Saturday, April 28, Dr. Leonard Williams will deliver the first of two lectures on the "Physical and Physiological Foundations of Character." The Friday evening discourse on April 27 will be delivered by Prof. C. V. Boys on "Measurement of the Heating Value of Gas," and on May 4 by Prof. Soddy on the "Origins of the Conception of Isotopes."

At a quarterly meeting of the council of the Royal College of Surgeons of England, held on April 12, the

Jacksonian Prize for the year 1922 on "The effects produced by radium upon living tissues, with special reference to its use in the treatment of malignant diseases," was awarded to Mr. H. Sidney Forsdike, of the Soho Hospital for Women. Sir Arthur Keith was elected Vicary lecturer for the ensuing year.

Dr. H. H. Dale, head of the department of biochemistry and pharmacology of the Medical Research Council, the Rev. G. Milligan, Regius professor of divinity and Biblical criticism in the University of Glasgow, and the Very Rev. Dr. W. F. Norris, Dean of York, have been elected members of the Athenæum Club under the provisions of the rule of the club which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

The Institute of Physics admits physicists to a grade of associate membership, and it is believed that there must be a large number of young physicists at present outside the Institute who are eligible for this grade. All students and others who have conducted a year's work of satisfactory research are eligible if they have a degree of approved honours standing, or if they pass the equivalent examination of the Institute. Ultimately, it is probable that the associate group will be much larger than that of fellowship, and that new fellows will be selected mainly from it. The Institute has now an appointments register, and many applications for young physicists have been received from manufacturing firms and research laboratories. Regulations for admission to the Institute can be obtained from the secretary, Mr. F. S. Spiers, 10 Essex Street, Strand, London, W.C.2.

At the meeting of the Royal Geographical Society held on April 9 the president announced that H.M. the King had been pleased to approve the award of the Royal Medals as follows: The Founder's Medal to Mr. Knud Rasmussen for his exploration and research in the Arctic regions during the last twenty-five years; the Patron's Medal to the Hon. Miles Staniforth Cater Smith for his explorations in the unknown interior of Papua. The council has awarded the Murchison Grant to Capt. A. G. Stigand for his map of Ngamiland; the Back Grant to Mr. B. Glanvill Corney for his studies in the historical geography of the Pacific; the Cuthbert Peek Grant to Messrs. R. A. Frazer and N. E. Odell to assist them in continuing their explorations of Spitsbergen; and the Gill Memorial to Capt. Augiéras for his journey in 1920–1921 from Algiers to Mauritania.

Preliminary notice has been issued of the arrangements for the Hull congress of the Royal Sanitary Institute to be held on July 30–August 4. An inaugural address will be delivered by the Right Hon. F. R. Ferens on the first day of the meeting; on July 31, Sir Alexander Houston will lecture on "A Pure Water Supply," and a popular lecture on "Industry and National Welfare" will be given by Mr. B. Seebohm Rowntree on August 2. The congress will meet in four sections dealing with sanitary science, engineering and architecture, maternity and child welfare including school hygiene, and personal and domestic hygiene, respectively, and there will be numerous conferences of sanitary inspectors, health visitors, medical officers of health, veterinary inspectors and representatives of sanitary authorities. During the congress, a Health Exhibition will be held in the Wenlock Barracks.

The annual report of the director of the Field Museum of Natural History, Chicago, for 1921, is written by D. C. Davies, who succeeded the late F. J. V. Skiff on December 19 of that year. The chief event chronicled is the re-opening of the museum in its new building (which is, we believe, in Grant Park) on May 2, 1921. The opportunity has been taken to place on exhibition for the first time a skull of the northern mammoth, found in gold-mining at a depth of 100 feet at Woodchopper Creek, Alaska. The specimen is represented on a Plate. Among accessions is to be noted the collection of Lower Palæozoic fossils made, chiefly from Ohio localities, by the late C. B. Dyer. The bird collection has been enriched by a large number of albinos and specimens of abnormal coloration. The removal of the museum has led to a large increase in the number of visits, especially by school children.

At the Boston meeting of the American Association for the Advancement of Science in December last, the centenary of the birth of Gregor Mendel and Sir Francis Galton was celebrated by a series of addresses which are published in the March number of the *Scientific Monthly*. Prof. E. M. East dealt with "Mendel and his Contemporaries." Prof. T. H. Morgan, in a paper on "The Bearing of Mendelism on the Origin of Species," points out that small mutations are really the material on which Darwin chiefly relied to furnish a basis for evolution. He also discusses the question of species sterility, and points out difficulties of evolutionary interpretation which may arise from the occurrence of parallel mutations. Dr. J. Arthur Harris compares the influence of Mendel and Galton on the history of biology, and concludes that the latter has had a more varied and far-reaching effect on the history of science. Finally Prof. G. H. Shull asks for donations to a "Galton and Mendel Memorial Fund," the money to be applied to the publication of expensive illustrations in the journal *Genetics*.

We have received from Messrs. Ridsdale and Co., of Middlesbrough, a report on the second period of three years in the preparation and use of a series of chemical standards prepared by this firm, with the voluntary co-operation of a number of analytical chemists throughout the country. The report was submitted to a meeting of the co-operators held recently at York. Very thin turnings of steel are now being used to facilitate the determination of carbon by combustion. The series of standards now available includes the whole range of carbon steels, together with four alloy steels, two cast irons, and a basic slag. Certain resolutions were passed at the meeting, urging the desirability of extending the use of chemical standards for analysis, and the establishment of a more formal organisation on a firmer financial basis. These standards are now widely used, and the movement seems likely to become self-supporting, some 15 or 20 co-operators taking part in each standardisation, and the number of users, both at home and abroad, being large.

Under the title *Capita Zoologica*, a new quarto Dutch zoological periodical has recently appeared. It is issued under the editorship of Prof. Dr. E. D. van Oort, director of the State Museum of Natural History at Leyden, and is composed of transactions on systematic zoology, each part forming a complete work which is sold separately. A number of transactions will form a volume of about 500 pages, with plates and engravings. The contributions are published in English, French, and German. The part before us of this well-executed publication is Deel 1, Aflevering 4 (1922, price 24 guilders), and is devoted to a description of flies of the group Dolichopodinæ of the Indo-Australasian region by Th. Becker. It is evidently an important contribution by this recognised authority, and extends to nearly 250 pages, 222 illustrations occupying 19 plates. The previous three parts of this journal deal respectively with Nematodes, by Dr. J. G. de Man; Rhizostomes, by Dr. G. Stiasny; and Oligochætes, by Prof. W. Michaelsen.

We have received from Messrs. Pastorelli and Rapkin, Ltd., of 46 Hatton Garden, E.C.1, a new catalogue of chemical thermometers. All the instruments listed are stated to be of British make, and as a guarantee of this the thermometers bear the name "Britgla," the registered trade mark of the British Lampblown Scientific Glassware Manufacturers Association, Ltd. The list in question is very comprehensive and covers a variety of ranges from −30° C. to 600° C. Thermometers with corresponding ranges on the Fahrenheit scale are listed in most cases. The ranges are varied in such a manner that it should be possible to select a reasonably open scale thermometer for any temperature. Quotations are given for two main classes of thermometers, namely, low-priced chemical thermometers and best quality standard laboratory thermometers. We are pleased to note that in both classes there is a considerable reduction in the prices which have been prevailing of late years. For convenience, the cost of supplying National Physical Laboratory certificates with the latter class of instruments is shown separately. A special section is also devoted to high range thermometers constructed of borosilicate glass and nitrogen-filled. These can be supplied in metal sheaths for industrial use.

Part 3 of volume 1 of the Abstract Bulletin of the Research Laboratory of the Lamp Works of the General Electric Co., Cleveland, Ohio, deals with 36 researches recently published, and extends to nearly 220 pages. It has been found advisable to expand the pure and applied sections of the laboratory into two separate laboratories for pure and applied science under the directions of Dr. E. F. Nichols and Mr. M. Luckiesh respectively. Both laboratories contribute to the researches abstracted in the present part. As an illustration of the thorough way in which industry in America is going into the scientific and technical questions which underlie manufacturing processes, we would direct attention to a paper of 32 pages by Mr. Luckiesh on the physical basis of colour technology, in which the methods used to investigate, by the help of the spectro-photometer, the properties of the dry pigments used in the paint industries, of the dyes, their mixtures and solutions, and of the various substances used in producing coloured glasses, are described. With data of the kind described available, many of the difficulties and obscurities of the colour industries are removed, and progress becomes rapid, while without them much groping in the dark is inevitable.

Part F of the "Guide-book of the Western United States" has just been issued as Bulletin 707 of the U.S. Geological Survey. Its author, Marius R. Campbell, writes for the tourist who looks with an intelligent interest from the windows of his parlour-car on the "Denver and Rio Grande Western Route"; but side-excursions are duly encouraged and described, and the maps show, in brown stippling, some ten miles depth of country on either side of the adventurous line. Numerous illustrations are given of the scenery along the route, which starts from Denver and ends at Salt Lake City. West of Canon City (not "Cañon" or "Canyon," be it observed) the railroad enters the Royal Gorge of the Arkansas River, which is cut 1000 ft. sheer in pre-Cambrian granite, overlain by stratified rocks of Upper Cretacous age. We are shown the fantastic arid weathering of the rose-red Permocarboniferous sandstone in the famous Garden of the Gods, and Pike's Peak appears as a portion of a snowy range. The ancient local glaciation of Colorado is not neglected, and the time-honoured error as to the origin of the term *roches moutonnées* is once more repeated on Plate 55. The protected fauna is illustrated, and the fauna that tried in vain to protect itself at the opening of Cainozoic times is finely represented by restorations of Stegosaurus and Triceratops. Stegosaurus, by the bye, means "roofed lizard," not "plated lizard." This and the other guide-books of the series must not be overlooked by those who travel in America, and they contain much geographical and geological information which is rendered accessible in European libraries, through the generosity of the Survey, for those who may never cross the Atlantic.

Bulletin No. 133 of the Engineering Experiment Station of the University of Illinois is entitled "A Study of Explosions of Gaseous Mixtures," by Prof. A. P. Kratz and Mr. C. Z. Rosencrans. The report contains a valuable bibliography of the subject, beginning with Dalton and Humphry (not "Humphrey" as in the report) Davy, and after passing in review such classical researches as those of Dixon, Berthelot, Petavel, Bone, Jouguet (not "Jouget," as in the report), Thornton, and others, the literature references are carried up to 1921. A brief summary of this work, and some new experiments by the authors are given. The report will prove useful to all who are interested in this very important subject.

Messrs. Dulau and Co., Ltd., 34 Margaret Street, W.1, have just issued a valuable catalogue (No. 100) of upwards of 2600 second-hand science books and serials which they have for disposal. The list is conveniently arranged under the headings—ornithology, entomology, conchology, the lower invertebrates, general zoology, botany, horticulture, agriculture, geology, mineralogy, astronomy, mathematics, engineering, and early medical works. It should interest many readers of Nature.

Among the books shortly to be published by the Oxford University Press is "The Glass Palace Chronicle of the Kings of Burma," which has been translated for the Burma Research Society by Pe Maung Tin and G. A. Luce. The chronicle is the work of the committee of "learned monks, learned brahmans, and learned ministers" appointed in 1829 for the purpose by King Bagyidaw of Burma. The title is taken from the Palace of Glass, in a chamber of which the compilation was made.

Our Astronomical Column.

Greece adopts the Gregorian Calendar.—The Gregorian Calendar was adopted for civil purposes in Greece from the beginning of March. As Russia has apparently taken the same step, the old or Julian style becomes practically obsolete. M. D. Eginitis, director of the Athens Observatory, contributes a paper to the *Comptes rendus* of the Paris Academy of Sciences, March 12, in which he notes that the finding of the decree of Nicæa, A.D. 325, shows that, far from prohibiting such a change, it in reality rather demands it. The decree simply directed that Easter should everywhere be kept on the same day; by implication this day was the first Sunday after the 14th day of the first lunation after the spring equinox, which was assumed to occur on March 21. When it was found that the Julian Calendar did not maintain the equinox at this date, the reform at once became appropriate. The causes that for so long retarded its acceptance in eastern Europe were largely removed by the War, and M. Eginitis addressed a memorandum to the Greek Government in December 1918, which has now been followed.

The Greek Church is not at present adopting the reform, the reason being the expectation of the speedy adoption of other calendar changes in the west, for which it prefers to wait.

Some of these reforms are being discussed by the International Congress of Chambers of Commerce now meeting in Rome; but experience shows the extreme difficulty of persuading the world to adopt changes in their fixed habits, however desirable in themselves, so that we can scarcely share the sanguine view of M. Eginitis, who shares the expectations just mentioned.

The Eighth Satellite of Jupiter.—Prof. E. W. Brown contributes an article on this satellite to *Astronom. Journ.* No. 817. He makes use of Delaunay's algebraical expressions for the various terms, which are theoretically available for any satellite; however, in cases of such large eccentricity and inclination as those of J. VIII the terms do not converge rapidly enough to be used straight away. Prof. Brown, whose great experience gained in his new lunar theory comes useful, shows how estimates may be made of the remainders, and in particular finds a solution for the mean motion of the perijove. The general rule both with planets and satellites is that the apse moves in the same direction as the body, but in the case of J. VIII the higher terms of the series reverse the earlier ones, and produce motion in the opposite direction. Prof. Brown refers in his work to G. W. Hill's paper on the motion of the lunar perigee; it is interesting to recall that it was this work of Hill's that gave Brown the idea that he afterwards followed so successfully in his lunar theory.

The period of revolution of the perijove of J. VIII is about 800 years, an unusually long period for a satellite. It is welcome news that Prof. Brown proposes to continue his work till he has arrived at expressions which will enable the place of the satellite to be predicted without the tedious method of mechanical quadratures. Mr. J. Jackson has also been at work on the satellite, using a combination of observed and calculated positions, and gives an ephemeris for the present apparition in the *Observatory* for March. The chief importance of observing this satellite and the still fainter J. IX is that they will ultimately give a better value of Jupiter's mass than any other method.

Astronomy in the United States.—The section of Year Book, No. 21, of the Carnegie Institution of Washington, dealing with astronomical work carried out in departments of the Institution includes several items of general interest. The so-called K-term in radial velocities, that is, an average motion of recession shown by all spectral types, but especially by type B, where it amounts to 4 km./sec., is discussed. More than half of this is removed by adopting newly determined wave-lengths for the lines of oxygen, nitrogen, silicon and helium that were used; it is further pointed out that certain lines formerly used were double, and therefore unsuitable. A small residual recession may be due to the Einstein effect. Work on the proper motions of the red stars has shown that these are generally small in the case of types M and N; M stars have large radial velocities, they are therefore mainly giants, and very distant. The radial velocities of type N stars are small, indicating that their average mass is high. Both types give much the same direction for solar motion as that generally adopted.

Studies have also been made on the progressive differences of spectra from type B0 to B8. In B8 the oxygen and nitrogen lines disappear, while a number of enhanced metallic lines appear; it is anticipated that discussion of these facts may advance the theory of ionisation, and our knowledge of the constitution of matter.

The meridian observers seem to be worked very hard; they are on duty for a week at a time, and observe time-stars at intervals not exceeding 6 hours, besides circumpolars at both culminations. What would the advocates of an 8-hour day say to this? The object is to eliminate personality, but it is found that when an observer is fatigued he observes differently than he does when fresh. One of the objects of this series of observations is to determine the laws of differential refraction both in Right Ascension and Declination, and if possible to connect it with the meteorological conditions. There is little doubt that differential refraction is the cause of the perplexing variations in time-determinations from different observatories, and that its determination would mean a marked increase of accuracy in meridian work.

Research Items.

Bone Harpoons discovered in Yorkshire.—In 1922 Mr. A. Leslie Armstrong described in *Man* two bone harpoons said to have been found at Hornsea, West Yorkshire. At the Hull meeting of the British Association the harpoons were again exhibited, and Mr. Sheppard, curator of the Hull Museum, questioned their authenticity on various grounds. The matter having been brought to the notice of the Council of the Royal Anthropological Institute, a committee, consisting of Sir C. H. Read, Dr. A. Smith Woodward, and Prof. Percy F. Kendall, was appointed to investigate the matter. The report of the committee is published in the April issue of *Man*. The members report that there is no evidence in the objects themselves that is conclusively against their genuineness: that the similarity of the barbs in the two examples, though found 4 miles apart, points to the conclusion that they are the work of the same individual. "It is worthy of remark that at the time the earlier find was made there was no available example of a Maglemose harpoon." "Mr. Sheppard appears to have had strong grounds for doubting the authenticity of the harpoons, but the evidence on which his judgment is based is no longer verifiable."

Baby Clinic Statistics.—No. X. of the "Studies in National Deterioration" (Cambridge University Press, 15*s*.), forming a subsection of the series of Drapers' Company Research Memoirs, is a thorough analysis of data provided by a baby-clinic in a large manufacturing town, carried out by Miss M. N. Karn and Prof. Karl Pearson. The authors have made very full use of the method of correlation and reach various conclusions of interest and practical importance. Two of these may be noted. The first is that there is a considerable if not very large (0·37–0·43) correlation between the health of an infant at birth and at the end of the first year, a result compatible with general biological considerations, incompatible with the catch word "all babies are born healthy." The second is that although the use of a baby "comforter" is associated with ill health over the full period of observation, the correlation is almost doubled when the health of babies under 14 days old is correlated with use of a comforter. The most plausible interpretation is that the delicate babies are preferentially supplied with comforters rather than that the comforter itself is an important cause of ill health. Those readers who are not versed in the correlational calculus will find the numerous diagrams helpful.

Botany in India.—The report for 1921–22 of Lieut.-Col. A. T. Gage, the director of the Botanical Survey of India, directs special attention to the appearance of Parts I. and II. of the "Botany of Bihar and Orissa," by Mr. H. H. Haines. These two parts contain the description of 70 families, from the Ranunculaceæ to Cornaceæ. Part IV. of the "Flora of the Presidency of Madras," by Mr. J. S. Gamble, has also appeared, containing the families Rubiaceæ to Ebenaceæ. The most interesting economic development in progress appears to be the promotion of cinchona planting in Southern Burma under the superintendence of Mr. P. T. Russell. Cinchona seedlings were planted out in May 1921, on a site near the Heinze river at an elevation of 1700 feet. Unfortunately this situation proved to be apparently "the point of impact of the very arrow head of the monsoon"; during June, July and August more than 240 inches of rain fell and more than half the seedlings succumbed. The survivors have since been growing very well, but it is proposed to recommence operations farther south in the Tenasserim Division of Burma, where the rainfall is both less in amount and more evenly distributed over the year. The cultivation of Ipecacuanha has apparently commenced very successfully on an experimental scale in Southern Burma, the temperature being more equable in this climate than in the Eastern Himalayas where this plant is grown.

Genetics and the History of Wheat.—The Maine Agricultural Experiment Station continues to be prolific in genetic results, the chief contribution being from Drs. Karl Sax and John W. Gowen. In an important paper on sterility in wheat hybrids (*Genetics*, vol. 7, p. 513), Dr. Sax continues his work, in which it is shown that the three groups of wheat species, namely, the Einkorn, Emmer, and Vulgare groups, have respectively 7, 14, and 21 chromosomes as their haploid numbers. He has now investigated the chromosome behaviour in various hybrids between these different groups and finds conditions very similar to those obtained by Rosenberg, Gates, and others in similar hybrids. In crosses between members of the first two groups there are, for example, 7 bivalent and 7 single chromosomes, the latter separating at random when the former split. The origin of the tetraploid and hexaploid conditions in wheat is also discussed. Prof. Percival has shown that all three of the groups of wheat can be traced back to prehistoric times, Einkorn being grown in Central Europe in Neolithic times, Emmer and Vulgare also being prehistoric in Europe, and the former dating back to 5400 B.C. in Egypt. All the groups are therefore of sufficient age for a considerable evolution to have taken place within them. The higher numbers of chromosomes appear to have arisen by duplication of the original set of 7 pairs. This would mean also duplicating the hereditary factors present. Now in wheat, 14 different characters are known to be dependent on one factor, 4 depend on two factors, while only the red grain colour is represented by three independent factors. Hence it would appear that in the polyploid wheats most of these factors had arisen as mutations after the origin of the tetraploid and hexaploid conditions. Prof. Percival considers that the Vulgare (hexaploid) group arose as a hybrid between *Triticum aegilops* and a member of the Emmer (tetraploid) group. The study of the chromosomes is clearly of the greatest importance in tracing the history of our cultivated crops. The species of Avena (oats) show a similar series of chromosome numbers. Polyploid wheat hybrids produce small or wrinkled seeds. The endosperm in a cross between tetraploid and hexaploid forms may contain $14 \times 2 + 21 (= 49)$ chromosomes or $21 \times 2 + 14 (= 56)$ chromosomes according to which is the male parent, as the female parent contributes two nuclei. These unbalanced conditions result in abnormal development of endosperm.

Infection and Cytological Studies of Plasmopara.—In the Journal of the College of Agriculture, Hokkaido University, Sapporo, Japan, Vol. XI., Part 3, Makoto Nishimura gives a description of the methods of infection and of fertilisation of *Plasmopara Halstedii* Farlow, parasitic upon *Helianthus annuus* and other Composites in America. Although published in Japan this work was carried out at Columbia University under the guidance of Prof. R. A. Harper. The most striking feature of the infection experiments is the demonstration of zoospore infection through the roots, the zoospores apparently penetrating the middle lamellæ in the absorptive region of the root.

Oospores were freely formed by the fungus, especially in the roots of the host, but also in stem and leaf, and fertilisation was studied in properly fixed and microtomed material. An interesting description is given of a large "receptive pupilla" of the oosphere which protrudes into the antheridial cell at first, in a manner that recalls Murphy's description of fertilisation in *Pythium erythroseptica*. Afterwards this protrusion is withdrawn and apparently its retraction conducts the fertilisation tube from the antheridium into the centre of the oosphere. One nucleus is discharged through this tube into the oosphere from the antheridium.

United States Geodetic Survey.—The annual report of the United States Coast and Geodetic Survey for 1922 contains a long record of work accomplished during the year. Hydrographic surveys were carried out principally in the approaches to Chesapeake Bay, off northern California, in the waters of south-east Alaska, and the Philippine Islands. New charts, to the number of 27, were published to cover all areas for which adequate data were available. In some areas, principally Alaskan waters, the production of new charts is delayed until the primary triangulation is completed. The aerial survey of the Mississippi delta was finished and promises such favourable results that an extension of this means of coastal survey is projected. Outstanding features of the geodetic work of the Survey were the completion of the 1600-mile arc from Huntsville in Alabama to Williams in Arizona by way of Memphis and Albuquerque. This arc furnishes accurate positions in seven states and crosses an area badly in need of horizontal control. Work was continued on several other arcs, including one from Dixon Entrance to White Pass, Alaska, which is part of a long arc from Puget Sound, in which the Canadian Geodetic Survey is co-operating. Good progress was made in precise triangulation in Alaska. The Survey is co-operating with a committee of scientific workers in making an intensive study of earthquake phenomena. Magnetic work and tidal observations were extended during the year. The director points out the need for investigations on the Atlantic coast and particularly for the exploration of the Gulf Stream. He urges also that oceanographical work should be undertaken in the Atlantic outside the 100-fathom line and in the Pacific beyond the 1000-fathom contour. Lastly, he emphasises the amount of wire-drag work that must be done along the coasts in the interests of navigation.

The Crumpling and Rifting of Earth-Blocks.—Otto Baschin, of Berlin, in *Die Naturwissenschaften* for February 9, directs attention to what he believes to be a hitherto unnoticed factor in the tectonics of the earth's crust. He starts by the admission of considerable vertical movements of elevation and subsidence in the crust, and these are probably of an order that Wegener's hypothesis rejects. Baschin urges that a rising earth-block, as it comes into a region with greater rotational velocity than that in which it previously lay, becomes a retarding influence in its new surroundings, and in consequence exerts a pressure towards the west. Similarly, a sinking block is an accelerating factor and exerts a pressure to the east. If a continental block sinks on the east side of a line running north and south, and rises on the west, rifting may occur along the line; if it rises on the east and sinks on the west, compression and axial folding are set up. Other cases are of course considered, and the drifting of blocks towards the equator (*Polflucht*) is discussed.

The Laramie Problem of the Rocky Mountain.—The coal-bearing beds of the Rocky Mountain region have now been the subject of a considerable literature, and in Professional Paper 130 of the U.S. Geological Survey (Washington 1922), F. H. Knowlton presents a useful review of the progress of what is known as the "Laramie problem." In 1875 this problem led Cope to the conclusion that there was no alternative but to assume the possibility "that a Tertiary flora was contemporaneous with a Cretaceous fauna, establishing an uninterrupted succession of life across what is generally regarded as one of the greatest breaks in geologic time." The term Laramie itself arose out of the need for a non-committal term for beds regarded by Clarence King, then at work upon the exploration of the fortieth Parallel, and by F. V. Hayden, busy with the survey of Northern Colorado, as certainly conformable, although it was regarded by King as Tertiary and by Hayden as Cretaceous. Knowlton, having shown that the work of Lee and himself makes clear the existence of an unconformity in the midst of the coal-bearing so-called Laramie rocks of Colorado and New Mexico, points out that when their flora is studied in detail the strata below the unconformity are Cretaceous, and those above Eocene. This work, based upon a long study of all the main collections of plants from these strata, has been in progress since 1889, its publication being delayed until its author was clear that the long-standing problem was definitely in process of settlement. The flora so carefully studied is not in itself extensive, and the preservation of the plant impressions in the soft friable sandstone is far from perfect. The specimens are very fully described, and are figured in 28 plates, some pen drawings, and photographs.

Osage Oilfield, Wyoming.—The Osage Oilfield, Weston County, Wyoming, was developed as the result of the chance striking of oil on land adjacent to the Chicago, Burlington, and Quincy Railroad in 1919, and there sprang into existence, within a year after this discovery, a town having a population of more than 1500 persons, possessing well-built roads and buildings in addition to the usual field equipment in connexion with the production of petroleum and its products. During the same period more than 200 wells were drilled, pipe-lines were laid, and a refinery with a capacity of 500 barrels of oil per day was established. According to investigations by A. J. Collier, published as a bulletin of the United States Geological Survey (No. 736-D), in 1921 the Osage field had an average daily output of 550 barrels of oil; several gas wells were giving collectively 500,000-1,000,000 cubic feet of gas per day, and some eight or nine *flowing* wells yielded a good supply of water (a characteristic feature of this part of the State). Production of oil was maintained during that year from about 100 good wells. Stratigraphically the rocks belong essentially to the Cretaceous system and are of typical Rocky Mountain region facies. The Colorado group, containing the Newcastle sandstone, is the important series of deposits from the point of view of petroleum production. Structurally the field is related to the Black Hills uplift lying to the N.E., and the general dip of the rocks is to the S.W., at about 5° where normal. Minor corrugations in what is otherwise a simple monoclinal structure determine the presence of local anticlines and of the oil. The oil-pools are formed by moderately porous sandstones (about 19 per cent. average porosity) occurring as lenses within the shale formations, and the oil itself is of a light olive-green colour, low specific gravity, and high petrol content.

Climatic Continentality and Oceanity.

By L. C. W. Bonacina.

Not much less important among the geographical factors which determine climate than latitude and altitude, is the relative distribution of land and sea, or, in short, continentality *versus* oceanity, and in view of the somewhat large class of students who encounter this aspect of climatology it seems desirable to direct attention to a couple of German maps which have recently appeared indicating the distribution of continentality over the globe as a whole and over Europe in detail (*Petermanns Mitteilungen*, June 1922, R. Spitaler after G. Swobodna).

It is possible to represent the mean or normal temperature of a particular latitude at any time of the year in an equation involving, also, the intensity of insolation and the relative distribution of land and water in the neighbourhood; and therefore it comes about that there is a means of seeing how the temperature of a given point in summer, winter, or the year as a whole, compares, on one hand, with full "continentality" such as would uniformly prevail over a hemisphere covered entirely with land, or, on the other hand, with full "oceanity" such as would characterise an entire water hemisphere. The maps in question are based upon the annual range of air temperature between January and July, but are not quite the same thing as simple maps of equal annual range would be, because the annual range is to some extent affected by differences of latitude which are allowed for in the relationship just referred to. Taking full "continentality" as 100, and full "oceanity" as 0 (zero "continentality"), lines of equal percentage value are drawn across the entire map of the world except the inter-tropical belt, uncertainty for which attaches to the fact that the significance of the seasons is not the same as it is in extra-tropical latitudes.

There is a large area in the interior of North America with 90 per cent. continentality, the Sahara region and much of Western Asia with 100, and a considerable portion of Eastern Asia suffering from a super-continentality amounting to as much as 130. This is explained by the abnormal winter cold of Central Asia, due to a certain type of atmospheric circulation set up over this great land-mass, which results in a local degree of continentality greater than that proper to a uniform land hemisphere. A high degree of continentality also prevails over the land-locked North Polar basin where the ice-covering raises the percentage of the Arctic Ocean to near 100. At the other end of the scale we find 5 per cent. (95 per cent. oceanity) over that part of the North Atlantic between Iceland and Norway, and 0 (full oceanity) over much of the oceanic areas in the Southern Hemisphere, while local regions in the South Pacific and the Southern Ocean, under a special trend of sea and air currents, experience a slight degree of super-oceanity amounting to -5 per cent. on the continentality scale (105 oceanity). In consequence of the circulation of the atmosphere there are regions where continentality trespasses upon the sea, *e.g.* the Yellow Sea and Sea of Okhotsk with 70 per cent., and where oceanity invades the land, *e.g.* England and France with 20 to 45 per cent., values actually lower than that of the land-locked Mediterranean Sea, which averages about 45 per cent.

It is clear, therefore, that these maps show something more than the simple effect of local land and sea influences upon the annual range of temperature, and it would have been instructive to have a cartographical representation of this effect as well, uncomplicated by the effect due to the transference of continental and oceanic conditions beyond their respective domains. If one turns, for example, to the more detailed map of Europe, there is 10 per cent. continentality along the west coasts of Ireland and Scotland, and the 50 per cent. line, marking the boundary between the "continental" and "oceanic" parts of the continent, driven back by the prevailing Atlantic winds to the longitude of eastern Germany except for outliers around Spain, Switzerland and Sweden. Even the neighbourhood of London, the most continental portion of the United Kingdom, has a percentage no higher than 27, and the generally low value, about 25 per cent. for England as a whole with a position fairly well balanced as between land and sea, unmistakably reflects the dominating influence of the prevailing oceanic winds. There can be little doubt, indeed, that if the south-east of England were normally controlled by a stagnant contracyclonic system of circulation allowing more local temperature controls to gain the ascendant, the continentality would rise to near 50 per cent., and to near 75 per cent. if the prevailing winds were continental east winds instead of the actual oceanic west winds. This conclusion is strongly supported by the high degree of continentality, about 70 per cent., which prevails on the east coast of the United States in consequence of the westerly circulation from the interior of the continent.

Instructive as these German maps are, they do no more than touch the fringe of the subject inasmuch as there are other criteria by which thermal continentality may be judged, namely, diurnal range of temperature and the magnitude of irregular deviations from the normal, both of which run roughly, but not exactly, parallel with the seasonal or annual range above considered. It could be shown, for example, that in relation to the inland parts of England the east coast is somewhat more "continental" according to annual range than according to diurnal range of temperature. This is because the short-period range between day and night is more definitely influenced in the long run by local distance from the sea, whereas the seasonal range of temperature is more markedly affected by continental types of weather, transporting summer heat or winter cold, on the east coast than it is farther west.

Interesting, too, is the study of continentality from the point of view of deviations of particular seasons from the normal, and here a striking lesson is afforded by the climates of London and Paris. The French capital on the average of a long series of years is 2° F. colder than the English in January and 3° F. hotter in July, the greater difference in summer being apparently due to the more southerly latitude, which would work with the continentality difference in the warm season but against it in the cold. Yet it is during occasional periods of severe cold that the more violent continentality of Paris is so emphatically demonstrated. The month of December, 1879, was, on the continental mainland, one of unparalleled rigour, the mean temperature day and night for the entire month in Paris being so low as 18° F., or some 20° below the normal. But the coldest December ever recorded in London, that of 1890, a month of appalling gloom and as cold as any winter month that has occurred since the establishment of records, had a mean temperature not lower than 29° F., or only 10° below normal, while the same month in Paris was 12° below, or only less cold than 1879. There are many similar instances of wider departures from the normal on the other side of the Channel.

Facts of this kind constitute an obtrusive aspect of climate, but they are apt to be eclipsed in the common practice of limiting one's studies to means and averages.

Discovery of Marine Beds at the Base of the Gondwana System in Central India.

MOST of the papers recently published in the Records of the Geological Survey of India naturally take the form of shading with details the general outline previously known. Some of the results published in the last general report of the director (Records, Geological Survey of India, vol. 54, Part 1) are, however, of special interest as showing that some of the previously accepted outlines need reconsideration. We have space to notice only one of them at this stage, and that because the director's announcement may not be superseded for some time by a more detailed description.

Among the results hitherto regarded as final has been the conclusion that the Peninsula of India has never been submerged beneath the sea since early Palæozoic times, except for narrow strips extending not far from the present coast lines. Towards the end of 1921, however, the discovery by Mr. K. P. Sinor of a very thin marine bed at the base of the Lower Gondwana system, on the small coalfield at Umaria in the Rewah State of Central India, suggested a review of the previously accepted view regarding the stability of the peninsular *Horst*. Early last year, after this discovery had been reported to the director of the Geological Survey of India, a field collector was deputed to obtain further specimens, and these included, besides Productus, a species of Spiriferina related to and probably identical with *Spiriferina cristata* var. *octoplicata*.

This discovery thus unexpectedly provides evidence of the fact that the sea in Carboniferous times trespassed on to the continent of Gondwanaland farther than was previously suspected; for the Umaria coalfield is some 500 miles from the present west coast, 400 miles from the east coast, and 400 miles from the marine formations which lie away to the north of the crystalline axis of the Himalayan range. In view of the fact that portions of the western States of Central India and the northern parts of the Bombay Presidency were invaded by the sea just before the outflow of the great Deccan trap early in Cretaceous times, one is tempted naturally to regard marine trespass from the west as the most natural line of advance and subsequent retreat; but there is a possibility also that this Productus bed in Rewah records the spread southward of the Permo-Carboniferous sea which left thick masses of Productus limestone in the Punjab, Kashmir, and Tibetan plateau.

The discovery is thus one of very great interest to students of geomorphology; but though doubtless the basal (Talchir) rocks of the Gondwana system will now be searched afresh with renewed hope, the chances of finding further evidence are remote. The coal seams of peninsular India all lie above the Talchirs, and mining operations naturally are not carried below the coal beds for purely scientific objects, while it is only around the edges of the coal basins that narrow strips of the underlying Talchirs occasionally peep out. The surface is fairly flat—a soil-covered peneplain which is lapped over on its northern margin by the mantle of Gangetic alluvium of unknown thickness.

Some years ago this discovery would have had a double interest; for the problem of correlating the great freshwater Gondwana system with the standard stratigraphical scale was the occasion of some controversy due to differences of opinion which naturally follow indirect inferences from homotaxis. But twenty years ago characteristic members of the Lower Gondwana Glossopteris flora were found associated with Productus beds in Kashmir, whither presumably they were carried by one of the rivers then running from Gondwanaland into the great Eurasian ocean known to geomorphologists as Tethys. The base-line thus became definitely established and at a level in the vertical scale near that which W. T. Blanford and others had advocated from indirect evidence many years before. Blanford lived long enough to hear of the Kashmir discovery, which proved that in the Indian region the Productus marine fauna and Glossopteris land flora were contemporaneous. What polemics would have been saved, probably, if he had surveyed the Central Indian instead of the economically more important eastern coalfields, and had thus been able to start from a recognisable stratigraphical base line on the Peninsula itself.

The Calcutta School of Tropical Medicine and Hygiene.

THIS teaching and research institution was opened two years ago, and an account of its work is given in a paper by one of the staff, Major Knowles. The laboratory has four floors with 220 feet of north light and a shorter wing at right angles to the main front, while the special hospital for tropical diseases has more than 100 beds, both having been constructed and partially endowed at a cost of about 120,000*l.*, nearly two-thirds of which were raised by the founder, Sir Leonard Rogers, and by Major Knowles. The staff of whole-time professors and research workers now numbers thirty-three, special laboratories and investigators being provided for kala-azar, dysenteries, ankylostomiasis, leprosy (for which a separate institute is to be built opposite the school at a cost of another 20,000*l.*), diabetes and filariasis, all in addition to the teaching staff of the school. The departments now number seventeen, three or four sections commonly combining on one research under the director, Col. J. W. D. Megaw, thus furnishing the team work so essential to success.

The teaching is purely post-graduate, the number admitted being limited to 50 by strict selection. The course for the diploma in hygiene lasts nine months and that in tropical medicine six months, against four in the Liverpool and three in the London School of Tropical Medicine. After an hour's clinical work in the hospital, a lecture is given illustrated by numerous lantern slides, epidiascope pictures, and cinematograph films. This is followed by practical work in the class-rooms for the rest of the day illustrating the same subject, after which that lecturer is free for the rest of the week for research and preparation for his next class.

In the short time the Institution has been open, important work has been published, or is in the press, on the pathology and treatment of leprosy by Muir; on the diagnosis by a new test and the treatment of kala-azar by Napier; on the differentiation of chronic dysenteries by the reactions of the stools by Knowles and Napier; on the poisonous amines of dysentery and cholera bacilli, and also in lathyrism and epidemic dropsy by Acton, Chopra (professor of pharmacology), and S. Ghosh (chemist). Tropical skin diseases are being closely studied with the help of the full-time artist and the photographer of the school. Every case admitted is worked out clinically and microscopically by all the sections concerned, and careful records are kept. This cannot fail in due time to result in important additions to our knowledge of tropical diseases in view of the unrivalled clinical material available in the special hospital and in the 600 additional beds of the adjacent Medical College group of hospitals.

The new Institution is evidently destined to take a leading place in scientific medical research and teaching in the British Empire.

Virus Diseases of Plants.

HUMAN pathology has naturally had first claim upon the services of the investigator of disease, but a study of plant diseases is probably equally essential to human progress, and the timely review in *Science Progress* (No. 67, January 1923), by Dr. E. J. Butler, director of the Imperial Bureau of Mycology, bears eloquent witness to the great activity with which the special problems of plant pathology are now being attacked. It was only towards the close of the last century that the propagation of disease in plants was shown to be effected in some cases by a filterable virus, but since then facts and theories as to virus transmission have followed in rapid succession from various Continental and American laboratories. Very few observations have so far come from British laboratories, and it may be hoped that the very comprehensive and critical review presented by Dr. Butler will direct more attention to this fascinating field of work.

Many obscure conditions prevailing among growing plants should receive elucidation as a result of investigation into this problem, while the facilities the plant provides for experimental work may enable the whole mechanism of transmission by a virus to be submitted to a very critical analysis. For more than a century it has been known that in certain cases of variegation, if a branch bearing variegated green and white foliage be grafted upon a plant of the same species with normal green foliage, the variegated habit will slowly extend to the branches formerly bearing normal green leaves. This type of "infectious chlorosis" is still of obscure origin, and in this case, as with the curious "peach yellows," investigated in the United States, and in the "spike" disease of the sandalwood tree in India, grafting appears to be the only artificial method of transmission. All these puzzling abnormalities, varying from innocuous variegation to serious diseases such as the "spike" disease, which threaten to extinguish a profitable crop, may receive elucidation through the study of virus diseases more amenable to experimental treatment.

Among the diseases suitable for investigation, perhaps the best known are the "mosaic" diseases, so called from the patchy discoloration they usually produce upon the plant surface. Tobacco mosaic provides a remarkable case of transmission by a highly infectious virus which has been very thoroughly examined by H. A. Allard in the United States. In this case, if the hairs upon an infected plant are carefully cut with a sterile scissors, infection may follow if the hairs upon a healthy plant are then cut with the contaminated scissors. Originally considerable support was given to a theory that the infectious principle in tobacco mosaic was enzymic in nature, but Allard showed that, although ultramicroscopic, the infectious substance could be removed from the expressed plant juice by filters that left the oxidase activity of the juice practically unimpaired. However, the strongest argument in favour of an organism is furnished by dilution experiments in which the expressed juice, diluted to 1 in 10,000, still retains infectious properties. One of the most puzzling properties of the tobacco virus is its extraordinary stability to chemical reagents usually very toxic to living protoplasm and its resistance to relatively high temperatures. In the absence of any information as to the life-history of the invisible parasite it is impossible to correlate this resistance with any special growth form.

The invisibility of the organism sets an upper limit to its size in accordance with the resolving powers of the microscope; experiments with bacterial filters, in view of their tendency to clog, do not permit a lower limit of size to be assigned with confidence, while, on the other hand, the way in which a mycetozoan plasmodium will filter through a cotton-wool plug, cleaning itself from ingested food particles in the process, suggests caution in considering passage through a filter a proof that the natural diameter of the organism is smaller than that of the pore of the filter.

Although a filterable virus was first demonstrated as a cause of disease in the case of the tobacco mosaic, plant pathology is not so far advanced in its study of the organism as human pathology.

One great difficulty is that the culture of the organism outside the plant has so far proved impossible; in this respect these are as confirmed pathogens as the well-known group of rust fungi. Some of the virus diseases, as potato leaf-roll, net necrosis of the tuber, etc., seem to propagate only within a special tissue, the phlœm. This is worthy of consideration when attempts are made to cultivate the organism on artificial media, as the phlœm is relatively alkaline in reaction and both cell walls and contents are probably very distinctive in chemical composition.

Many of these virus diseases are propagated by insects, and Dr. Butler discusses critically the evidence which has been brought forward to explain the greater success of transmission when the plant cuticle is pierced by the insect rather than by needle or knife. One interesting possibility is the need for a necessary part of the life cycle of the pathogen to be completed in the insect carrier, but more work is also required upon the natural healing of punctures caused by insects and by instruments. The manner in which some aphids are also alleged to puncture always in the neighbourhood of the phlœm also provides a very interesting problem for further observation and experiment.

One interesting result of this work is the considerable significance it gives to the aphis as a carrier of plant diseases. At the International Potato Conference held under the auspices of the Royal Horticultural Society in November 1921, Mr. A. D. Cotton pointed out how the recent work of Quanjer in Holland and Schultz and Folsom in the States emphasised the importance of the relative intensity of aphides and possibly other insects in the propagation of leaf-roll. This disease, which is of very great economic importance, seems to spread from plant to plant chiefly in districts where the aphis-attack is general early in the season. As a result, the disease is transmitted very extensively in the warmer English counties, while in the Northern Scottish counties its spread may be little or nil, coincident apparently with the relative absence or late development of aphis infestation. This is very suggestive in relation to the proved value of Scotch seed-potatoes, and this important problem alone, with the new light it throws upon the principles to follow in seed-selection, would justify the extensive exploitation of this comparatively new field of scientific investigation.

University and Educational Intelligence.

Aberdeen.—Mr. W. G. Mackinnon has been appointed assistant in geology in succession to Miss Margaret Smith, resigned.

Liverpool.—On March 2 a new building comprising five chemical laboratories was opened by Lord Haldane as an extension of the University. Three floors are devoted to inorganic and two to organic chemistry, with extensive provision for research work. The building forms part of a scheme outlined before the War, which will require a further sum of 175,000*l.* for completion.

London.—The following doctorates have been awarded:—*Ph.D. in Science*: Mr. R. J. Ortlepp, of the London School of Tropical Medicine, for a thesis entitled "Studies on Helminthes Parasitic in Terrestrial Vertebrates," and Miss W. A. Leyshon, an external student, for a thesis entitled "Forced Oscillations in Self-maintained Oscillating Circuits."

A number of free public lectures and courses of lectures by distinguished men of science has been arranged for this term. At University College, Sir Thomas Holland will deliver three lectures on "Phases of Indian Geology"; Prof. G. N. Lewis, professor of chemistry in the University of California, three lectures on "The Structure and Behaviour of the Molecule"; and the following lectures by well-known Dutch scientific workers: "The Electric Charge of Colloids," by Prof. H. R. Kruyt, professor of organic chemistry in the University of Utrecht, on May 8; "The Rotation of the Earth and its Influence on Optical Phenomena," by Prof. H. A. Lorentz, professor of physics in the University of Haarlem, on May 17, in addition to a course of three lectures, commencing June 4, on "Problems in Relativity." Other lectures at University College include three by Mr. W. Macnab on "Some Scientific Principles of Chemical Industry," three by Prof. G. Dawes Hicks on "Kant's Theory of Beauty and Sublimity," one by Prof. C. Spearman on May 25 on "Psychology as a Career," and one by Prof. W. M. Flinders Petrie on May 17 on "Recent Discoveries in Egypt."

At King's College, there is a course of three lectures, on "Ethics and the Philosophy of History," prepared by the late Prof. E. Troeltsch, professor of philosophy in the University of Berlin; and four lectures on the tercentenary of the birth of Blaise Pascal by Prof. H. Wildon Carr.

Other lectures arranged under the auspices of the University are: three lectures by Dr. P. Giles at the School of Oriental Studies on "The Aryans," and a lecture, on May 7, at the Imperial College of Science, by Prof. W. de Sitter, professor of astronomy in the University of Leyden, on "Problems of Fundamental Astronomy."

Notice of the lectures will be given from week to week under the heading "Public Lectures" in Nature.

It is stated in the *British Medical Journal* that Dr. J. S. Anderson has been appointed to the chair of medicine at the University of Hong Kong. Dr. Anderson had a distinguished career at the University of Glasgow, and afterwards joined the staff of the Helminthological Department of the London School of Tropical Medicine.

A preliminary announcement has been issued regarding the University of Geneva Summer School to be held on July 16–September 1. In addition to the usual courses in modern French language and literature and lectures on current international problems (including the projects and achievements of the League of Nations, the International Labour Office, the Red Cross, etc.), there will be, for advanced students only, laboratory and field work in botany under the direction of Prof. Chodat at La Linnea (altitude 5600 feet) in the Mont Blanc district, and field geology and mountain climbing under the direction of Prof. Collet in the Mont Blanc, Jungfrau, and Matterhorn regions. Among the lecturers at the Summer School last year were professors of the Universities of Geneva, Paris, Bonn, Vienna, Christiania, Turin, and Washington, and of Dartmouth College (U.S.A.). Detailed information can be obtained from the Swiss Legation.

Prof. E. W. Scripture, formerly of Yale University and latterly engaged in carrying out investigations in London, has been appointed honorary professor of experimental phonetics in the University of Vienna. The appointment is significant alike of the growing importance of the subject, of the revival of this University after the devastation caused by the War, and of the movement discernible in the universities of the world as a whole towards such an interpenetration in disregard of international boundaries as was characteristic of the universities of the middle ages. Prof. Scripture was one of the pupils of the Abbé Rousselot, who was a pioneer in a field of knowledge the scientific exploration of which had scarcely been attempted when the Abbé began his researches thirty years ago. Recently it has yielded results of such immediately practical importance that it is receiving greatly increased attention. Prof. Scripture himself claims to have discovered that phonetics provides an efficient means of diagnosing earlier than would otherwise be possible, and thereby giving opportunities for the application of curative treatment to, general paralysis and disseminated sclerosis; also that the study of speech records of epileptics points to a revision of the hitherto accepted theory of the essential nature of this disease.

We have received from the Universities Bureau of the British Empire a list of students from the King's Dominions Overseas and from foreign countries enrolled for the current session in universities and university colleges of the United Kingdom. It affords material for some interesting statistical comparisons. The total number, 4131, shows a decrease of 8 per cent. compared with the total for the previous session (1921–22). In the following analysis showing the numbers of students from the several continents and countries, the corresponding figures for 1921–22 are given in brackets wherever markedly different: Africa 1171, America 764, Asia 1401 (1576), Europe 542 (645), Australia and New Zealand 250 (280); Egypt 298, including 67 at Birmingham and 81 at London; South Africa and Rhodesia 303, including 82 at Oxford, 43 at Cambridge, 336 at London, 142 (178) at Edinburgh, and 76 (95) at Dublin; Canada and Newfoundland 157 (200), including 60 (87) at Oxford; South America 73; U.S.A. 402, including 224 at Oxford; West Indies and Bermuda 120; China 119 (143); India, Burma, and Ceylon, 1094 (1240), including 175 at Cambridge, 335 (446) at London, 150 (170) at Oxford, 137 (173) at Edinburgh, 101 (65) at Glasgow; Japan 51 (73), France 52, Russia 91, Switzerland 43 (61), other countries of Europe 356 (431). In Nature, March 3, p. 308, we gave similar statistics regarding students in the United States and in Switzerland.

Societies and Academies.

London.

British Mycological Society, March 17.—A. S. **Horne** and H. S. **Williamson**: The morphological and physiological characteristics of two new species of Eidamia were described and compared with those of *E. acremonioides*, the only species previously included in the genus. One species obtained from oak wood is strongly acidophile and causes coloration of the wood; the other, isolated from decaying apples, is capable of causing rot in Bramley's seedling apple when kept under ordinary storage conditions or at a constant temperature of 1° C.—M. H. **Carré** and A. S. **Horne**: Various fungi were grown in soluble pectin of a high degree of purity extracted from apples. Certain fungi utilise the pectin with production of acidity (Botrytis, *Diplodia cacaoicola*), others break it down completely with the production of sugar (Eidamia from apple), while some are apparently incapable of growth in pectin.—A. S. **Horne** and H. M. **Judd**: The Eidamia from apple grown in sugar solutions exhibits different reactions according to the sugar used, as evidenced by the odour (of coconut oil), liquid coloration, and rate of growth (on plates). The reactions appear to show a definite relation to the configuration of the sugars concerned.—H. S. **Williamson**: The species of Eidamia from oak caused the production of a yellow colour in seasoned wood. This colour was reproduced when normal oak was inoculated with conidia of the fungus, and was found to be partly due to the colour of the conidia and partly to a yellow refractive substance produced in the metabolism of the fungus and accumulated in some of the cells of the wood.—J. S. **Bayliss Elliott** and O. P. **Stansfield**: The life history of *Polythrincium Trifolii*. The Hyphomycete stage is followed by a pycnidial stage. After the pycnidial stage reaches maturity the clover leaves wither. It was found possible to obtain further development by placing the leaves between glass cover-slips placed between ivy leaves buried in soil in plant pots in the open. The perfect form is not a species of Phyllachora as has usually been supposed, but Dothidella.—J. **Ramsbottom**: The correspondence between M. J. Berkeley and C. E. Broome preserved in the National Herbarium covers a period of more than forty years, and gives a clear idea of the way in which the collaboration between the two was carried on. It contains a mass of biographical detail, particularly of Berkeley, and gives a much better picture of the "Father of British Mycology" than do the meagre and misleading biographies which have so far been published. —P. J. **Alexander**: The dates of appearance and habitats of the Mycetozoa of Surrey. No month is without a representative, and three-quarters of the British species have been recorded for the county.

Association of Economic Biologists, March 23.—Prof. E. B. Poulton, president, in the chair.—J. H. **Priestley**: The causal anatomy of the potato tuber. The potato haulm is angular with three leafy expansions rising from the angles; a primary endodermis in the underground stem disappears in the region where the leafy angles appear. The circular, unwinged stem formation is a result of growth in darkness. The formation of the tuber at the end of the stolon coincides with the disappearance of the endodermis and the appearance of cork in the epidermal or subepidermal layer. The increase of tissue in the tuber is due to the meristematic activity both in the cortex and in the periphery of the pith. Earthing up potatoes may increase the stem area from which tuberiferous stolons may arise, and adequate moisture in spring with consequent vigorous root pressure may favour the formation of stolons; tubers may be expected to arise upon the stolons when the evaporation of water from the leaves exceeds water supply from the roots.—E. R. **Speyer** and O. **Owen**: The action of simple aromatic compounds on the cucumber woodlouse (*Armadillidium speyeri*, Jackson). Observations were made on the effects due to contact, vapour, and mixing with the soil at a concentration on M./100 in 250 gm. of soil; *p*-cresol and *p*-nitrophenol are less active than the corresponding ortho compounds, and both nitrophenols are less active than phenol. One part phenol in 750 parts soil is sufficient to kill all woodlice introduced during a period of 20 days, and this time corresponds with the disappearance of retardation in germination of tomato seeds sown in the same soil. Phenol and the cresols were the most active compounds tested; naphthalene disappears within 4 days of mixing with soil; thymol, camphor, hydroquinone, and α-naphthol act slowly.

Royal Microscopical Society (Industrial Applications Section), March 28.—Mr. J. Leonard Spicer in the chair.—S. R. **Wycherley**: Microscopy in the examination of manufactured paper. Paper is composed of disintegrated vegetable fibres, their length, strength, and breadth giving colour and durability. Linen fibres give the strongest and toughest of papers, and in their natural condition are tapered at the ends. The fibres have nodes which often burst, and then the fibres curl over and the hooks entangle one with the other, knitting together. Tested with Herzberg solution the result is brown coloration; with zinc chloride solution, claret coloration. Cotton fibres, the main constituent of high-class writing papers, are even and round with a number of twists along the whole length. Wood fibres are merely fibres of wood crushed or reduced to pulp: chemical wood-pulp fibres are always longer and cleaner than those of mechanical wood pulp. The fibres are distinguished by their bordered pits; they give a low-grade paper. Esparto fibres are long, thin, and smooth with a narrow canal, and there is always a residue of seed hairs. A microscope will often show whether the fibres have been too severely treated by the beaters, and also whether a heavy proportion of re-pulped paper has been used.—J. **Strachan**: The manufacture of papers for wrapping and containing food-stuffs. Legislation is required specifying the proper wrapping for particular foods. Papers for this purpose are classified as follows: Food-holders, such as the paper wrapper and the paper container; food-carriers, such as the box, the carton, and the fibre-board packing-case. The paper bag is used both as holder and carrier. The most important class of paper is that used in direct contact with the food-stuff. The basic paper for this should be a pure bleached cellulose, sterilised during the process of manufacture. Chemical and physical treatment of this base gives a variety of papers for specific purposes, such as the exclusion of colloids, moisture, and gases, or the retention of oily matter and flavours.—H. B. **Wrighton**: Objectives for metallurgy. The mounts should be of a metal which will resist the strongly acid atmosphere present in laboratories where analytical work on metals is carried out, and the front lenses should be protected against damage by accidental contact with metallic specimens. Glasses and cements used must be of a permanent character, as considerable heat is developed by the intense light used in the photomicrography of metal specimens. The most suitable balance among the various optical corrections differs somewhat from the one generally accepted for the other branches of microscopy; in particular, flare should be reduced to the absolute minimum. The requirements of metallurgical microscopy are sufficiently distinct to justify the production of objectives computed and designed specially for this work.

Paris.

Academy of Sciences, March 26.—M. G. Bigourdan in the chair.—R. de **Forcrand**: Thallium hydroxide. The usual method of preparing thallium hydroxide by precipitation of the sulphate with baryta is very tedious, and liable to give an impure product. A better method is to treat thallium ethylate, $C_2H_5 . OTl$, with water and starting with TlOH and Tl_2O prepared in this way, the thermochemical constants have been redetermined.—M. **Soula**: Taylor's series having an infinity of zero coefficients.—P. **Noaillon**: A harmonic function the gradient of which vanishes at infinity.—Henri **Chrétien**: Recording time, in figures, to the thousandth of a second, with an electrically maintained pendulum. A description, with illustrations, of a new recording chronograph of simple construction.—G. E. **Beggs**: The exact solution of problems indeterminate statically by means of paper models.—M. **Lafay**: The possible use of the microphone to facilitate problems of flight.—J. **Trousset**: Can the observation of the planets furnish arguments for or against relativity? The author gives reasons for answering this question in the negative.—Paul **Mondain-Monval**: The variation of heats of solution with temperature. Details of experiments on heats of solution of potassium, sodium, and ammonium nitrates, potassium sulphate, and ammonium and potassium chlorides at 0° and 18° C.—Th. **Tommasina**: Contribution to the dynamo-kinetic theory of the electron and the atom.—Georges **Déjardin**: The critical velocities of the electrons in krypton and the production of the spectra of this gas. An account of work done with a three electrode tube of an improved type. The ionisation potentials of argon and krypton were found to be $15 \cdot 2 \pm 0 \cdot 2$ volts and $12 \cdot 7 \pm 0 \cdot 2$ volts respectively: the double ionisation potentials were 34·0 volts and 28·25 volts. Krypton, like argon, gives two spectra, details of which are given.—Albert **Portevin**: The variations of capacity accompanying the thermal treatment of hollow steel bodies. Study of the influence of the tempering temperature, rate of cooling, and hardness of steel on the changes of capacity of steel shells.—L. J. **Simon** and M. **Fréjacques**: The methylating and sulphonating action of methyl sulphate on phenols in the absence of water. This reaction is very complicated. With phenol at least eight substances are present: methyl ether, anisol, phenol and anisol sulphonic acids and their methyl esters, and methylsulphuric acid. The methods of separation are given.—A. **Mailhe**: A new preparation of the tetrasubstituted ureas. The formamide of methylaniline, $C_6H_5 . N(CH_3)(COH)$, passed as vapour over finely divided nickel at 380°-400° C. gives symmetrical dimethyl-diphenylurea, $CO(N(CH_3)(C_6H_5))_2$. That the method is of general application is proved by other examples.—F. **Bordas** and T. **Touplain**: The denaturation of ethyl alcohol. The use of alcohol as a constituent of a motor fuel requires a cheaper denaturant, and one easily detected. The use of methyl or ethyl borate is suggested.—P. **Gaubert**: The liquid crystals of anisal-*p*-amidoazotoluene. A reply to some criticisms of G. Friedel.—M. **Solignac**: The tectonic of the plain of Mateur and its approaches (Tunis).—F. **Baldet**: Contribution to the study of atmospherics. A method of searching for and partially eliminating low frequency parasitic currents of atmospheric or telluric origin.—Pierre **Dangeard**: The vacuome in the pollen grains of Gymnosperms. Application of the vital coloration method (neutral red) to the study of the pollen grains of *Taxus baccata*, *Cephalotaxus Fortunei*, *Cupressus Lawsonia*, and *Pinus Armandi*.—Mlle. France **Gueylard**: Intervention of the spleen in the phenomena of adaptation to changes in salinity. It is known that *Gasterosteus aculeatus* can be transferred from fresh to salt water, and rapidly adapts itself to the change of medium. It is shown that change in the salinity of the medium results in changes in the spleen, the higher the proportion of salt in the water, the greater the reduction in the proportional weight of the spleen.—Marcel **Duval** and P. **Portier**: The impermeability to urea of certain tissues of selacian fishes.—Jules **Amar**: The law of vivireaction in biology and pathology. This law is stated thus: any pathological or physico-chemical act which tends to reduce the phenomena of organic oxidation provokes, by a defence mechanism, a relative increase of the pulmonary ventilation.—L. M. **Betances**: The specific differentiation of the hematic cell in the Metazoa.—André **Lwoff**: The nutrition of the Infusoria. Although, under natural conditions, the nutrition of free infusoria is purely phagocytic, it is possible, in a suitable medium, to feed some species by means of dissolved substances.—Boris **Ephrussi** and André **Lwoff**: The double cyclic periodicity of the zone of division in *Colpidium colpoda*.

Washington.

National Academy of Sciences (Proc. Vol. 9, No. 1, January).—H. W. **Brinkmann**: On Riemann spaces conformal to Euclidean space. An n-dimensional Riemann space can be "imbedded" in an $(n+2)$-dimensional Euclidean space.—O. **Veblen**: Equiaffine geometry of paths. A definition of volume which generalises that used in Riemann geometry is derived.—L. P. **Eisenhart**: Affine geometries of paths possessing an invariant integral.—J. R. **Kline**: Closed connected sets which are disconnected by the removal of a finite number of points.—R. S. **Woodward**: Some extensions in the mathematics of hydromechanics. A development of some of the equations used to describe fluid motion when viscosity is taken into account.—P. D. **McMaster** and P. **Rous**: Hydrohepatosis, a condition analogous to hydronephrosis. Prolonged obstruction of the bile duct in dogs causes distention of the duct and of the gall-bladder with "white-bile," a colourless, watery fluid. A pressure obstacle causes reduction in total secretion and in the percentage output of some of the substances secreted, as in kidney obstruction, though the distention caused is less marked.—H. **Laugier** and R. **Legendre**: Novocaine and curarisation. Novocaine causes morphological changes in nerve fibre, and a solution (1 in 10,000) in physiological salt solution causes an increase in the intensity of a suddenly established current necessary to provoke visible muscular contraction, and decreases the interval before response occurs.—F. G. **Benedict** and E. G. **Ritzman**: Under-nutrition and its influence on the metabolic plane of steers. Eleven adult steers were fed for about 4½ months on one-half their original maintenance ration. Changes in body tissue were measured by the carbon dioxide output, using a respiration chamber. At first there was rapid reduction in live-weight, due to changes in intestinal ballast or fill; afterwards there was slow steady loss, due to drafts on body material; and during the last few weeks the weights were practically constant. The animals remained active, but the pulse dropped from 44 to about 28. Maintenance level of metabolism in control beasts was 2150 calories per 24 hours per square metre of body surface; for the underfed animals it was 1475. On refeeding, the animals rapidly regained weight and were readily fattened. The energy value of the fæces remained practically constant at 4·778 calories per gm. of water-free substance under all feeding conditions.—C. G. **Darwin**: A quantum theory of optical dispersion (see Nature, December 23, 1922, p. 841).—W. H. **Cole**: Circus movements of Limulus. The animals were subjected to diffuse and non-directive illumination, and only one lateral eye was allowed to function. In accordance with Loeb's tropism theory, the diameter of the circles traced out was inversely proportional to the intensity of the light.

(Proc. Vol. 9, No. 2, February).—R. W. G. **Wyckoff**: On the hypothesis of constant atomic radii. Starting from cæsium dichloro-iodide, values have been calculated for the "spheres of influence" or atomic radii of several atoms. These values are compared with the corresponding observed interatomic distances. Many discrepancies occur, showing that it is not in accord with experiment to assign a definite size to each atom. In some groups of isomorphous compounds composed of two kinds of atoms a law of constant atomic radii appears to hold. In compounds of different crystal structure, in which the manner of arrangement of the atoms of one kind about those of another (atomic environment) is different, the interatomic distances are unlike.—A. Van **Maanen**: Photographic determination of parallaxes with the 100-inch reflector (Mount Wilson). Four fields have been measured, including the helical nebula (N.G.C. 7293). Using the parallax derived, +0·058, the object appears to have a diameter 375 times that of the solar system.—H. **Shapley**: Light and colour variations of Nova Aquilæ 1918.4. The nova was a star (10-11 mag.) at least 30 years before its discovery. Rise in brightness began on June 7, 1918, reached a maximum, at visual magnitude −1·2, in two days, when it was brighter than any star in the sky except Sirius, and decreased four magnitudes by June 25. Semi-periodic fluctuations occurred until October, with decreasing brightness, and since then it has continued to decrease until it is now about magnitude 10.—E. H. **Hall**: A theory of the Hall effect and the related effect for several metals. When a magnetic field acts at right angles to a current flowing along a thin strip of metal, the equipotential lines are no longer at right angles to the line of flow (Hall effect) and a transverse temperature gradient is set up (Ettingshausen effect). Analogous effects are obtained if heat is flowing along the strip. The explanation offered assumes that conduction implies the existence of two streams, one of free electrons and the other of associated electrons, which oppose each other.—F. B. **Sumner**: Studies of sub-specific hybrids in Peromyscus. Three different crosses between geographic races of deermice were studied in respect of 17 quantitative characters. The mean values for any character in the hybrid is usually between the parental values. Means for the two hybrid generations (F_1 and F_2) generally agree. There appears to be a tendency towards increase of variability which is not due to environmental factors. Most of the elements of the total sub-specific complex seem independent of each other in inheritance, and no single character behaves in obvious Mendelian fashion.—G. A. **Miller**: Sets of conjugate cycles of a substitution group.—A. **Carrel**: Leucocytic secretions. Evidence was obtained of the production of substances promoting growth of homologous fibroblasts and destroying foreign erythrocytes, both *in vitro* and *in vivo*. This supports Renaut's view that the function of the white corpuscles of the blood is to bring nutritive substances to the fixed cells of the tissues, and it also appears that they can bring regenerative substances to injured adult tissue. A foreign protein added to leucocytic cultures increases the production of growth-activating substances; *in vivo* this may precede the production of anti-bodies.—W. M. **Davis**: Drowned coral reefs south of Japan. Some of the Riu Kiu and Bonin Islands are on the margin of the coral seas of to-day; they have no regular sea-level reefs, though their shore-lines resemble those of the embayed islands of the coral seas. The islands may have been protected by reefs while suffering erosion during a period of greater emergence followed by relatively slow submergence. Continued upward growth of the protecting reefs has possibly been inhibited by decrease of ocean surface temperature. A temperature high enough for the growth of the suggested coral reefs may have been caused by the deflexion of the North Equatorial current of the Pacific when the ocean surface was lowered during the Glacial epochs.

Calcutta.

Asiatic Society of Bengal, March 7.—Lily **Strickland-Anderson**: Music and the Hindu Pantheon. An attempt to apply the principle that Hindu mythology represents a kinetic or fluidic and not a static or concrete mode of thinking, to the Hindu Pantheon, specially relating to music.—K. G. **Sinha**: On some Maithili dramas of the seventeenth and eighteenth centuries. An attempt is made to explain the nature and importance of the dramas as throwing light on the development of Mithilā art and culture.—C. V. **Raman**: (1) A theory of the viscosity of liquids. An attempt is made to calculate the viscosity of liquids theoretically on the basis of the molecular hypothesis. (2) The molecular ælotropy of liquids. The optical anisotropy of the molecules evidenced by experiments on the scattering of light is discussed, and an attempt is made to find how the molecules influence each other's position and orientation.—N. **Annandale**: Bivalve molluscs injuring brickwork in the Calcutta docks. A note on injury done to brickwork by the boring mollusc *Martesia fluminalis* and on other molluscs associated with it.—P. **Brühl** and K. **Biswas**: On a new species of Cylindrospermum from Bengal. Description of a new species, *Cylindrospermum doryphorum, sp. nova*, Brühl et Biswas. Comparison with known species.—L. Dudley **Stamp** and L. **Lord**: A preliminary note on the ecology of part of the riverine tract of Burma. The area dealt with embraces a zone of country on either bank of the Irrawaddy river between Prome and Yenangyaung, which covers more than 4000 square miles. The inter-relationships existing between the geological formations, soils, climate, and the distribution of the vegetation are traced in detail. The plant formations are classified into 13 groups and the investigation revealed that climate, especially rainfall, is really the main determining factor in the development of any particular type of vegetation within this region.—S. L. **Hora**: Zoological results of a tour in the Far East. (Fish, Part I.) The first part of a report on a collection of fish from a maritime lagoon connected with the Gulf of Siam which contains water of very variable salinity. Forty-eight species of the Selachii and of seven teleostean orders are discussed. A new species of pipe-fish, and one of Mastacembelus, are described and also a new colour form of *M. armatus*.—B. Prashad: Revision of Kobelt's nomenclature of the Indian Ampullariidæ.

Diary of Societies.

MONDAY, APRIL 23.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Dr. D. Anderson-Berry: Occultism: at the Bar of Philosophy and Religion.

ROYAL SOCIETY OF MEDICINE (General Meeting), at 5.—Sir Archibald Garrod, Dr. F. J. Poynton, Dr. M. Cassidy, and Dr. A. F. Hurst: Discussion on The Ætiology and Treatment of Osteo-arthritis and Rheumatoid Arthritis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. Shattock: Syphilis.

INSTITUTION OF MECHANICAL ENGINEERS (London Graduates' Section), at 7.—S. H. G. Warne: Recent Steam-Wagon Progress, and a Suggested Design.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—E. H. Shaughnessy and others: Discussion on Practical Broadcasting.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—W. G. Newton: The Literature of Architecture.

ROYAL SOCIETY OF ARTS, at 8.—E. Kilburn Scott: Nitrates from Air (3). (Cantor Lectures.)

FARADAY SOCIETY (at Chemical Society), at 8.—J. H. Shaxby and J. C. Evans: The Properties of Powders—The Variation of Pressure with Depth in Columns of Powders.—E. E. Walker: The Properties of Powders. Part VI. The Compressibility of Powders. Part VII. The Distribution of Densities in Columns of Compressed Powder.—E. K. Rideal: The Rate of Hydrogenation of Cinnamic and Phenylpropiolic Acids.—A. Taffel: The Temperature of Maximum Density of Aqueous Solutions.—L. Anderson: Note on the Coagulation of Milk by Acid.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—Dr. C. F. Sonntag: Some Points in the Comparative Anatomy of the Mouth and Tongue.—G. J. Harborow: A Case of Unerupted Incisors and Canines in a Male aged 59.—E. Sprawson: The Vascular Supply of the Enamel Organ of *Felis domesticas*.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—L. M. D. Buxton: Inner Mongolia.

TUESDAY, APRIL 24.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Arthur Keith: The Machinery of Human Evolution (3). How New Features are Gained.

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5.30.—Dr. C. Gouldesbrough: Osteo-arthritis of the Spine.—Dr. H. L. Tidy: Glandular Fever and Infective Mononucleosis.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—R. B. Murray: Exhibition of a Giant Centipede from Trinidad, and Mounted Skins of Oil-birds.—Lt.-Col. S. Monckton Copeman and Major E. E. Austen: Exhibition (with photographs) of a unique British Dipteron, taken on Primrose Hill.—Baron F. Nopcsa: The Origin of Flight in Birds.—E. C. Stuart Baker: Cuckoos' Eggs and Evolution.

INSTITUTION OF CIVIL ENGINEERS, at 6.—Annual General Meeting.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—Capt. J. W. Bampfylde: Photomicrography as applied to the Iron-Carbon.

WEDNESDAY, APRIL 25.

ROYAL SOCIETY OF ARTS, at 4.30.—Conference on the Milk Question.—Papers: Prof. R. S. Williams: The Arguments for maintaining an Open Market for Fresh Milk.—Prof. J. C. Drummond: Changes in the Digestibility and Nutritive Value of Milk induced by Heating.—Dr. S. S. Zilva: The Effect of Heat on some Physiological Principles in Milk.—Capt. J. Golding and Mrs. A. T. R. Mattick: A Demonstration of some of the Chemical Changes in Milk on Heating to various Temperatures.

ROYAL MICROSCOPICAL SOCIETY (Industrial Applications Section), at 7.—C. Baker: Junior Engineer Metallurgical Microscope and the Greenough Binocular Microscope.—R. and J. Beck, Ltd.: New Research Outfit for Metallurgical Work, including Microscope, Camera, Optical Bench, etc.—Edison Swan Electric Co., Ltd.: Projector and Fullolite Lamps.—M. P. Swift: Use of Dichroiscopes for the Identification of certain Gem Stones.—W. Watson and Sons, Ltd.: Petrological Microscopes.—At 8.—J. E. Barnard: The Manipulation of the Microscope in Industrial Laboratories. Part I. Illuminants and Illumination.—Dr. M. C. Stopes: The Microscopical Examination of Coal in relation to Fuel Economy and Efficiency.

BRITISH PSYCHOLOGICAL SOCIETY (Medical and Education Sections) (at London Day Training College), at 8.—Drs. East, Burt, Shrubsall, and Stoddart: Symposium on Delinquency and Mental Defect, to be followed by a discussion.

THURSDAY, APRIL 26.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. J. T. MacGregor-Morris: Modern Electric Lamps (1). Glowing Solids *in vacuo* (Tungsten Lamps).

ROYAL SOCIETY, at 4.30.—Prof. T. R. Merton and R. C. Johnson: Spectra associated with Carbon.—R. A. Watson Watt and Dr. E. V. Appleton: The Nature of Atmospherics.—Prof. W. A. Bone, D. M. Newitt, and D. T. A. Townend: Gaseous Combustion at High Pressures. Part III. The Energy-absorbing Function and Activation of Nitrogen in the Combustion of Carbon Monoxide.—Dr. I. Masson and L. G. F. Dolley: The Pressures of Gaseous Mixtures.—W. R. Bousfield and C. Elspeth Bousfield: Vapour Pressure and Density of Sodium Chloride Solutions.—Prof. F. A. Lindemann and G. M. B. Dobson: A Note on the Temperature of the Air at Great Heights.—Prof. G. H. Hardy and J. E. Littlewood: Lindelöf's Hypothesis concerning the Riemann Zeta-function.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—Grace Chisholm Young: The Solution of a Pair of Diophantine Equations connected with the Nuptial Number of Plato.—H. W. Richmond: (1) The Electrostatic Field of a Plane Grating with Thick Rounded Bars; (2) Notes on the use of the Schwarz-Christoffel Transformation in Electrostatics.—E. G. C. Poole: The Discontinuous Motion produced in an Infinite Stream by Two Plane Obstacles.—A. E. Ingham: Two Mean Value Theorems concerning Riemann's Zeta-function.—A. E. Jolliffe: The Inflexions of the Non-singular Plane Quartic.—R. Vaidyanathaswami: Transversal Problems in Hyperspace.—T. Stuart: Certain Diophantine Equations.—M. Riesz: Sur l'équivalence des certaines méthodes de sommation.—K. Basu: The Perturbations of the Orbit of the Valency-electron in the Generalised Hydrogen-unlike Atom.—Pandit Oudh Upadhyaya: Cyclotomic Heptasection.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 5.30.—Annual General Meeting.—At 6.—Dr. W. G. Sleight: Children's Taste in Pictures.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—L. Breach and H. Midgley: The Drive of Power Station Auxiliaries.

SOCIETY OF DYERS AND COLOURISTS (London Section) (at Dyers' Hall, Dowgate Hill), at 7.—L. G. Lawrie: Fur Dyeing.

ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30—Clinical and Pathological Evening.

FRIDAY, APRIL 27.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Theatre, Imperial College of Science and Technology), at 2.30.—Dr. C. M. Wenyon: Some Recent Observations on Pathogenic Protozoa of Plants and Animals.—(To be followed by a discussion.)

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children Section), at 5.—(Epidemiology and State Medicine Section), at 8.—Dr. T. F. Dewar: The Incidence of Venereal Disease in Scotland.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—The Research Staff, General Electric Co., Ltd.: The Analysis of Bubbles in Glass.—Dr. H. P. Waran: A Simple Regenerative Vacuum Device, and some of its Applications.—Capt. H. Shaw and E. Lancaster Jones: Application of the Eötvös Torsion Balance to the Investigation of Local Gravitational Fields.—L. F. Richardson: Demonstration of an Electromagnetic Inductor.—Dr. F. Ll. Hopwood: Demonstration of Experiment Illustrating Time-Lag in Vision.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Surgical Anatomy of the Foot.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—Adjourned Discussion on paper by A. E. L. Chorlton: The Use of Light Alloys in place of Iron and Steel.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—J. Feard: Stock Control.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—A. Watkins: Early British Trackways.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. C. V. Boys: Measurement of the Heating Value of Gas.

SATURDAY, APRIL 28.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. L. L. B. Williams: The Physical and Physiological Foundations of Character (1).

PUBLIC LECTURE.

WEDNESDAY, APRIL 25.

KING'S COLLEGE, at 5.30.—The late Prof. E. Troeltsch (by Dr. E. Barker): Ethics and the Philosophy of History. (Succeeding lectures on May 2 and 9.)

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

" To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

Education and Science in the Civil Service Estimates.

THE provision for Education, Science, and Art for the year ending March 31, 1924, in the Civil Service Estimates continues to show reductions upon previous years. Excluding Ireland, the expenditure under these heads was 61,675,301*l.* in 1921–22 and 54,150,207*l.* in 1922–23. For 1923–24 the estimate is 49,902,435*l.*—a sum which is less than the actual expenditure of 1921–22 by 11,772,866*l.* This is an enormous reduction, and however serious the economic situation—and one must grant that the financial stringency is still great—such a reduction cannot be viewed with unconcern by those who have the real interest of the country at heart.

It should be noted, however, that the estimates under review include expenditure other than that upon school education. They include the cost of national museums and art galleries, as well as grants to scientific and industrial research, and to universities and institutions of university rank. The Board of Education estimate is 41,934,047*l.*, a decrease of 3,340,953*l.*; while the estimate of the Scottish Education Department is 5,922,995*l.*, a decrease of 869,379*l.* These two reductions together make up the major portion of the proposed reduction of 4,247,772*l.* for the current financial year.

It will be instructive to examine in more detail some of the proposed expenditure. In the Board of Education estimates the grant for elementary education is put down at 33,069,100*l.*, a reduction on last year of 1,999,693*l.* and on 1921–22 of 3,929,613*l.* One is moved to remark that if a reduction in this grant of almost four millions in two years can be made without detriment to the future efficiency of the nation, there must have been something radically unsound in the distribution of these grants in the past. If, however, the future efficiency is seriously threatened by such a reduction, then an apparent economy may well turn out to be a real extravagance. Again, the estimate for the grant for higher education is 7,315,520*l.*, which means a reduction of 707,055*l.* on last year's grant, or of 1,462,910*l.* on that for 1921–22. It is clear that the reductions in the grants for higher education are proportionately much greater than for elementary education and may well have serious consequences. In particular, it would be difficult to justify the reduction of 4000*l.* for technical colleges—and this in addition to a reduction of 10,000*l.* in the previous year—and that of 123,725*l.* for the training of teachers. On the other hand, it was to be expected that the grant for the higher education of ex-Service officers and men should automatically decrease. Accordingly, 310,000*l.* is estimated as compared with 1,015,000*l.* last year, with a corresponding reduction of 7283*l.* in cost of administration of this grant.

So far as the administrative staff of the Board of Education is concerned, there seems to be little reduction in numbers. Apparently the reduction in the cost of this service will depend mainly upon the fall in the index figure of the cost of living, since the bonuses on salaries are made with reference to it. One would think that in view of the extensive reductions in the grants to elementary and higher education, the estimate of 356,982*l.* for inspection and examination, notwithstanding a reduction of 26,061*l.*, is higher than necessary, and could be further reduced without serious detriment. With one important exception, reductions have been the rule rather than the exception; the estimate for pensions to teachers is 2,400,000*l.*, as against 1,860,000*l.* last year. This increase of 540,000*l.* was expected, and no doubt will be exceeded next year. With regard to this, of course, one must take into consideration the contribution of 5 per cent. of the teachers' salaries.

Under the head of Aid to Students, further reductions are noticeable. Last year there was a reduction of 4500*l.* in the sum allowed for scholarships, studentships, and exhibitions tenable at universities; this year there is a further reduction of 2000*l.* Similarly for students at training colleges the total estimate for this year is 119,170*l.*, as compared with 137,095*l.* last year. The total reduction in the grant in aid of students is 19,982*l.*, and this comes as a further reduction upon a drop of 10,213*l.* last year. One cannot but feel uneasy at the withdrawal of 30,195*l.* in two years from a class of students, presumably deserving, but unable to afford the cost of a higher education.

The estimates contain some interesting "Notes" as to the further measures proposed for keeping down the cost of education. The Board of Education defines its attitude regarding the expenditure of local education authorities which will be recognised for purposes of grant. In 1922–23 this expenditure was not to exceed 62,450,000*l.* A later revision fixed the sum at 60,595,000*l.* This year the amount is limited to 58,902,000*l.*, and of this total not more than 300,000*l.* may be spent on the provision of meals. Higher education fares no better. The total expenditure by the local education authorities to be recognised by the Board of Education for 1923–24 must not exceed 12,160,000*l.*, as compared with 13,000,000*l.* in 1922–23. This year, too, a clause is inserted in the Notes to the effect that the number of students recognised for grant under the Regulations for the Training of Teachers during the financial year 1923–24 is expected to be 12,066, as compared with 12,640 in 1922–23. This reduction, it may be stated, is not due to a lack of candidates coming forward, but to the policy adopted by the Board of reducing the number of those in training.

Turning now to the votes under the Treasury, we find that there are still further reductions. After the reduction of 19,157*l.* last year in the grant for scientific investigation, it is a little disquieting to find a further decrease of 1303*l.* this year. Similarly, the drastic reduction of 118,486*l.* last year in the vote for scientific and industrial research has been followed this year by the proposal of a further net reduction of 20,574*l.* It will be unfortunate if this reduction should hinder the progress of scientific research at a time when such research is most urgently needed. The grant in aid of universities and colleges is estimated at 1,169,000*l.*, which is the same as last year. It will be remembered that in 1921–22 the grant from the Exchequer for the university institutions of the United Kingdom was 1,500,000*l.* Although the present estimate is only for university institutions in Great Britain, the reduction for these bodies this year will be little short of 250,000*l.* At the same time it should be noted that other institutions (in particular, Oxford and Cambridge) and certain clinical units of the London Medical Schools have been since added to the list, and are now receiving substantial grants under this vote. It would seem that universities and colleges as a whole have been badly hit by the economies of the last two years. One can readily understand why those who believe in education, and particularly in higher education, are viewing with grave concern the present position. It would be little short of a national calamity if the opportunities for research or the development of university education in this country were to be restricted at the very time when they should be fostered and encouraged.

Weights and Measures, with some Geophysics.

A Dictionary of Applied Physics. Edited by Sir Richard Glazebrook. In 5 volumes. Vol. 3: Meteorology, Metrology, and Measuring Apparatus. Pp. vii + 839. (London: Macmillan and Co., Ltd., 1923.) 63*s.* net.

IT would be difficult to over-estimate the value of the contents of this book, and our debt of gratitude to Sir Richard Glazebrook for having collected and edited the articles is very great indeed. A certain amount of the information contained is new, and practically the whole of the remainder is inaccessible to the ordinary student.

It is not easy to specify in a few words the subjects treated, and the sub-title—meteorology, metrology, and measuring apparatus—is not very helpful; in fact, it is difficult to understand why this title was chosen, except for its attractive alliteration, for it certainly would not lead us to expect articles on earthquakes, oceanography, radiation, and many other subjects which are not meteorology, or metrology, or measuring apparatus.

As a matter of fact, most of the subjects treated appear to fall into some such classification as the following:

Measurement.—Theory and practice of measurements of length, mass, time, and their derivatives; alcoholometry; saccharometry; drawing instruments; calculating instruments; combination of observations; and allied subjects.

Geophysics.—Form and mass of the earth; meteorology, including atmospheric electricity; oceanography; seismology and tides.

On the other hand, terrestrial magnetism, electrical and magnetic measurements, and thermometry are not treated in this volume.

One of the chief values of the articles lies in the fact that they are not compilations from text-books and scientific journals, but each is written by a man whose life is engaged on the work he describes. This is clearly seen from the following list of the institutions which have provided writers from their staffs, past or present. There are 43 main articles in the volume, of which 12 are provided by the National Physical Laboratory, 7 by the Meteorological Office, 2 each by the Royal Geographical Society and the Survey of India, 1 each by the Bureau of Standards, U.S.A., and the Ordnance Survey. The writers of the 18 remaining articles include such well-known names as Profs. Boys, Knott, Sampson, Skinner, and Turner; Sir Horace Darwin, and Mr. C. T. R. Wilson.

Before dealing with the articles themselves, it may be worth while to remark on a few points connected with the general arrangement of the book which have struck us very forcibly while reading the 800 or so pages of which it consists. The arrangement is obviously a compromise, and a compromise can never give entire satisfaction. It would appear that the first idea of the work was that of a dictionary with probably the alphabetic arrangement throughout, as in the "Encyclopædia Britannica." But that idea has been modified, and a series of volumes each dealing with more or less allied subjects has been adopted. We cannot be too grateful for this decision; for in these hard times a single volume may be within the means of many who could not afford the whole set. We cannot help regretting, however, that the whole dictionary idea was not abandoned at the same time. Whatever the intention may have been, the volume before us is practically a collection of 43 articles and an index to them; but instead of the latter being placed at the end, it is embodied by the dictionary method throughout the whole book, and the articles are strung on to it like large beads on a necklace. This method has two great drawbacks: in the first place, the long breaks in the sequence of the words, due to the interpolation of the long articles, make it difficult to turn up a word quickly. Then technical difficulties of printing have made it impossible to give references to pages, and the reader is referred to sections and paragraphs of the main articles, the title of the article being set out in full in each case. This entails a great deal of unnecessary printing, and it is not easy to find a specified paragraph, as the sections in some cases extend over several pages. A simple index with references to pages would have served the same purpose, and would not only have been easier to use but also probably have reduced the size of the volume by many pages, with great convenience to the reader and a reduction in the cost of printing.

While we are discussing the convenience of the reader, it may be as well to direct attention to the want of system with regard to references to literature. Some of the articles have very full references while others have practically none, but the method of making the references varies from article to article. In some the references are given in the text, in others in footnotes, while in a few they are collected together in a bibliography at the end of the article, the numbered items of which are indicated in the text by the use of numbers in brackets. In fact, this book reflects the chaos in general scientific literature in this matter. Nothing is more disturbing when reading a difficult article than to have the attention constantly distracted by frequent references to footnotes, some of which may be of importance to the argument, and therefore must be read, while others are only references to literature. For this reason it is surely desirable that there should be some distinction between the two kinds of references. The method which seems the most reasonable is to use figures in brackets in the text to connect with references to literature collected together at the end of the article—or chapter in the case of a text-book—while notes necessary to the argument should be given, if they cannot be avoided, at the foot of the page, and attention directed to them by an asterisk or other conventional sign used to indicate a footnote. In this way a reader would almost unconsciously pass over the literature references and yet never miss a footnote. The advantages of this method are so obvious when many references are given that it is surprising it is so little used.

There is still one more point of arrangement which affects the convenience of the reader. The articles in these volumes owe their outstanding value to the high authority of the authors, and it is unlikely that any one will consult an article without wishing to know who wrote it. He will look first at the beginning of the article, and not finding the name there he will probably turn to the end, where he will find the initials of the author. But it is very seldom that the initials of the best-known writers are familiar, so the reader has not yet got the information he requires. He may then recollect having seen a "List of Contributors" at the beginning of the book, and here he will finally find the name belonging to the initials. Why should not the name of the writer have been put at the commencement of each article, where the reader naturally turns to find it?

Returning now to the articles themselves, they are so numerous, and deal with so many subjects, that it is quite impossible to notice them all, so we must content ourselves with a few words on one or two of the most important.

In the group of articles dealing with measurement, the discussion of metrology by Mr. J. E. Sears, the Deputy Warden of the Standards, is of outstanding merit. Without going into a great deal of detail a clear account is given of the history of the British and metric standards of length, mass, and volume, followed by the theory of the methods used in comparing these standards with practical measuring apparatus. It will come as a surprise to most people to read in this article that two kilogram masses can be compared with a greater accuracy than two metre standards, the accuracy being one part in 10^8 and in 10^7 respectively. Mr. Sears's discussion of the relative advantages of the British and metric systems is very valuable, and clearly indicates that the advantages are not all on one side. He is strongly opposed to attempts to hurry a change in Great Britain, and concludes: "The only practical policy, and that which has actually been followed, is to give legal sanction to the *alternative* use of the metric system, and to trust to the processes of time to effect a gradual change. The efforts of those who desire to see the metric system in universal use would be more usefully employed in endeavouring to encourage and facilitate its voluntary adoption in this way, than in seeking to secure legal compulsion in advance of public desire."

This article on metrology is supplemented by separate articles dealing with the practical side of making measurements and comparing standards. These are nearly all written by members of the staff of the National Physical Laboratory, hence we have in them extremely valuable information of the actual methods used in this country. It is true that when reading the articles one misses information on some point or other which would have been useful, but everything cannot be included in a book of finite dimensions, and on the whole the choice of subjects is good. The only criticism one has to make in this respect, and it applies to the book in general, is that the articles are very uneven in the amount of detail given. There can be no doubt that "gauges" are an important accessory in all accurate measurements of length, but are they so important as to justify the longest article in the volume and more than fifty per cent. more space than is given to the article on metrology itself? One cannot help feeling that in this article we are taken outside applied physics into engineering practice.

The chief article on the measurement of time is one by Prof. Sampson on clocks and time-keeping. It is a delightful article to read, for while it is short and not overburdened with detail, there is no difficulty in grasping the principles employed in the different forms of clocks described. After reading these thirty pages, one has the feeling (it may not be justified) that one knows all there is to know about clocks and their ways from the Glastonbury Abbey clock of 1325 to the latest Riefler.

In the geophysical section we cannot help regretting that more space has not been allotted to the writers, even, if necessary, at the expense of the articles dealing with measurements, which in some cases, as already mentioned, are overburdened with detail. Some of the articles are so abbreviated as to lose a great deal of their usefulness; this is particularly the case with the article on meteorological optics, which consists of only sixteen pages, while the descriptions of thirty-two different map projections are compressed into five pages.

The articles by Sir Napier Shaw and Capt. Brunt indicate very clearly the great changes which have taken place during the present generation in the outlook of meteorologists. Meteorology has changed from being an observational study of weather and its changes to a study, largely deductive and mainly mathematical, of the atmosphere as a whole. It is not surprising, therefore, that one hears occasional complaints that the modern meteorologist is too fond of theory and long names. On the other hand, the recording of weather had gone on for many, many years without much progress in our knowledge of the "way of the air"; but in recent years the physicist and mathematician have looked our way and the progress has been startling. In this advance two names stand out pre-eminent in this country, Dines and Shaw, and both have written articles for this volume. Sir Napier Shaw's article on "The Thermodynamics of the Atmosphere" is characteristic, and therefore full of new ideas and new views of old ideas. He treats the atmosphere as a whole as a "heat engine" of the classical type. An indicator diagram of a novel type, in that the co-ordinates are temperature and entropy, is constructed, and we are taken through a "cycle of operations" which involves a return ticket from Java to "the cold slopes of the mountainous Arctic and Antarctic lands," and during the course of which we realise our entropy like a normal traveller cashes his circular notes, and occasionally we receive fresh funds from the water vapour which we have smuggled in our luggage. Sir Napier also introduces us to the "resilience of the atmosphere," from which "arises the capacity of a layer of air to act as a 'deck' or ceiling, preventing any vertical motion, and therefore limiting the motion of the atmosphere to horizontal layers." The whole article is stimulating and its value cannot be overrated.

Those of us who are interested in atmospheric electricity are feeling more and more the need for a good account in English of this branch of meteorological physics. There is more than enough material for a good-sized book, but the few workers in atmospheric electricity in this country have other interests, and there appears to be no immediate prospect of the need being satisfied. We have all the more reason, therefore, to be grateful to Mr. C. T. R. Wilson—one of the qualified workers who has other interests—for his article. There are so many unsolved problems in atmospheric electricity that any account of the work done and of the theories propounded to explain the observations must of necessity exhibit the personal opinion of the writer. This article is no exception, and Mr. Wilson's point of view is clearly discernible. His account is, however, perfectly fair, and as unbiassed as it could be in the circumstances.

Most writers have recently acknowledged themselves defeated in their attempts to explain the maintenance of the earth's normal electrical field, but Mr. Wilson makes it quite clear that in his opinion thunderstorms offer a way of escape from this impasse. The small amount of evidence which he adduces is not very impressive, but until more work has been carried out along the lines indicated by Mr. Wilson it will not be possible to say that his solution is incorrect.

We began this review with expressing gratitude to Sir Richard Glazebrook, and we cannot do better than end on the same note. The criticisms we have made are of secondary importance and are very much in the nature of looking a gift horse in the mouth. But there is no objection in examining the mouth if it helps one to understand the gift and to make the best use of it.

G. C. Simpson.

Climatic Changes.

(1) *The Evolution of Climate.* By C. E. P. Brooks. Pp. 173. (London: Benn Bros., Ltd., 1922.) 8*s.* 6*d.* net.

(2) *Climatic Changes: their Nature and Causes.* By Ellsworth Huntington and S. S. Visher. Pp. xvi+329. (New Haven: Yale University Press; London: Oxford University Press, 1922.) 17*s.* 6*d.* net.

"A HUNDRED million or a thousand million years ago the temperature of the earth's surface was very much the same as now," say Profs. Huntington and Visher in the first chapter of their "Climatic Changes" (p. 15). This uniformity of climate throughout geological time, in contrast with the inconstancy of the weather from day to day and from year to year, is the great paradox of geological meteorology. The climatic conservatism of the earth as a whole is qualified by great local changes which have produced glaciations at about ten different geological dates and acclimatised in high latitudes plants allied to those now confined to warmer regions. The study of climatic changes has the especial attraction that it is a tempting explanation of the fall of civilisations and States, since man is obviously dependent on the weather.

(1) The perennial controversy as to whether climatic change is due to terrestrial or to celestial causes is continued in the two new works by Brooks and by Huntington and Visher. While Mr. Brooks maintains that the climatic changes proved by geology can be explained by alteration in the distribution of land and water, the American authors attribute them to occasional changes in the condition of the sun. Mr. Brooks in expounding, his conclusion, rejects the atmospheric theories based on variations in the amounts of carbon dioxide and of volcanic dust, and his verdict on this question is given added weight by Dr. G. C. Simpson's testimony, in an introductory note, to his authority on meteorology. Mr. Brooks explains the last main geological change of climate as due to great uplifts of land in high latitudes having enlarged both polar glaciers and tropical deserts. He "shows how enormously effective the land and sea distribution really is," by calculating what the temperatures on one zone on the earth would be if it were composed solely of land or were occupied entirely by sea. In a useful appendix he provides data by which the effects on temperature of variations in land and sea can be calculated.

Unfortunately, the meteorological sections of Mr. Brooks's work are relatively short, and most of it is devoted to accounts of geological and historical variations of climate on which the author's opinions are less authoritative. He adopts the views of Prof. Ellsworth Huntington that some great political changes in classical times were due to a climatic change in the southern part of the North Temperate zone. These views were discussed and rejected in a paper in the *Geographical Journal* (vol. 43, 1914, pp. 148–172, 293–318), and as Huntington and Visher, who quote that paper, say (p. 92) that in the main its "conclusions seem to be well grounded," the former author has apparently abandoned some of the views which Mr. Brooks still quotes on his authority. That section of Mr. Brooks's work is out of date, as is also the argument based upon the occurrence of Galaxias in South America and New Zealand, since the discovery that this fish breeds in the sea. The main value of Mr. Brooks's book depends on its meteorological chapters and its weighty support to the conclusion that glaciations can be explained by geographical changes. He omits reference to the impressive testimony on behalf of that theory by Lord Kelvin.

(2) The interesting and suggestive volume by Messrs. Ellsworth Huntington and Visher shows an exceptional knowledge of the literature and contains an illuminating discussion of important problems on the borderland of meteorology, astronomy, and geology. They discuss Brooks's paper in support of the geographical explanation of glaciations, but dismiss it, since the distribution of ocean and continent at the time of the Pleistocene glaciation was much the same as it is now; the differences they claim were insufficient to have produced so great a climatic change. They admit that changes in the positions of land and sea may be an important secondary agency. Differences of opinion as to past climates are not surprising in face of the authors' divergencies of statement as to existing geography: "To-day the loftiest range in the world, the Himalayas, is almost unglaciated" (Huntington and Visher, p. 144); "The Himalayas, owing to their heavy snowfall derived from the south-west monsoon, bear numerous great glaciers . . ." (Brooks, p. 77).

The authors adopt the view that climatic changes are due to variations in solar activity. They have been convinced, in spite of a prepossession to the contrary, that the periodicity and seasonal variation in earthquake action and concurrent climatic changes are due to a planetary influence which also controls the appearance of sun-spots. They discuss the nature of this influence and conclude that it is not tidal but electrical. The effect on the earth of increased sun-spots is not by direct variation in temperature, since increased glaciation does not involve any general change in the earth's temperature, which the authors insist has been practically uniform throughout geological time. Increased solar activity affects the earth by producing special storminess, with increased snow-fall in areas of high pressure and diminished rainfall and loess formation elsewhere. If the planets have such an important though indirect effect upon the earth's climate, the approach to the solar system of some of the greater stars must from time to time have a still more powerful influence on solar activity. The authors claim that great stars may approach the solar system sufficiently to stimulate intense activity in the sun, and thus produce glaciations on the earth at intervals of time consistent with the requirements of the geological history of climate.

The views on geological climates put forward by Messrs. Huntington and Visher appear to be generally well substantiated, as in their belief in the existence of climatic zones throughout geological time (p. 171) and that (p. 169) "as far back as we can go in the study of plants, there are evidences of seasons and of relatively cool climates in high latitudes"; but their conclusions as to historic variations in climate are less well supported. They attribute the English famines of 1315–16 and 1321 to a special climatic stress due to a "considerable swing towards the conditions" that produce glaciations. In support of this view they quote Petterson (Quart. Jour. Meteor. Soc., vol. 38, 1912), that the 14th century was a period of extreme climatic variation, but they have overlooked Hildebrandsson's reply to Petterson's paper (Nov. Act. R. Soc. Sci., Uppsala (4), IV., 1915).

Famines are so often due to an untoward concatenation of many unfavourable circumstances that they are not a sure foundation for hypotheses of climatic change. Standard authorities on the historical distribution of famine do not support the view that the English famines in the early part of the 14th century were abnormal in origin. It is even doubtful whether that period was especially famine-stricken. Dr. Farr, in his classical paper on the variation of wheat prices (Journ. Statist. Soc., London, IX., 1846, pp. 158-174), shows that famines were evenly distributed throughout the 11th to 16th centuries. "In the 11th and 12th centuries a famine is recorded every 14 years on an average, and the people suffered 20 years of famine in 200 years. In the 13th century my list exhibits the same proportion of famine, and nearly the same number of years of famine. . . . Upon the whole, the scarcities decrease during the three following centuries; but the average from 1201 to 1600 is the same—namely, 7 famines, and 10 years of famine to a century. This is the law regulating scarcities in England." Walford's table of famines (Insurance Cyclopædia, 1874, vol. 3, pp. 165–170) shows that the rise in the price of wheat during the famine of 1315–16 was exceeded in that of 1437–38, when the rise of price from 4*s*. or 4*s*. 6d. a quarter to 26*s*. 8*d*. was higher than the quintuple increase upon which Huntington and Visher lay stress for 1315.

The English scarcity from 1581–1603 was equally far-reaching, as famine at the same time caused cannibalism in Ireland and devastated Persia. The famine in England from 1694–99, attributed also to "rains, frosts, snows—all bad weather," might have produced as disastrous consequences as that in the 14th century, but for the improvement in internal transport. An instructive table in Brooks's volume (p. 155) discredits the hypothesis that the English famine of 1315–16 was due to a period of abnormally severe weather, as it represents severe winters as fairly evenly distributed throughout the half centuries from 1075 to 1425. The discussion of the causes of these famines by Thorold Rogers ("Agric. and Prices in England," vol. i., 1259–1400, 1866, pp. 28–30), whom Huntington and Visher quote for facts about the 1315–16 famine, gives no support to the view that they were due to any progressive change in climate or to climatic severity of a special order.

J. W. Gregory.

The Copper Age in Spain and Portugal.

La Civilisation énéolithique dans la Péninsule Ibérique. (Arbeten utgifna med understöd af Vilhelm Ekmans Universitetsfond, Uppsala, 25). By Nils Åberg. Pp. xiv + 204 + 25 plates. (Uppsala: A.-B. Akad. Bokhandeln; Leipzig: Otto Harrassowitz; Paris: Libr. Honoré Champion, 1921.) 15 Kr.

IT is a pleasure to peruse the work of an author like Dr. Nils Åberg, whose studies are so comprehensive. Too many prehistorians work and publish in their own small area without much reference to cultures outside, or occupy themselves with the necessary, though in the long run barren, task of extracting the more important essentials from the ever-growing mass of literature in order to present a concise scheme that can be used by others as a basis of study. Dr. Åberg's objective is far wider in scope, for although his main interest is naturally in Scandinavia, the whole of Europe is really included for the purposes of his work. The volume in front of us is only the latest of a number of memoirs, the object of which is to trace, from a study of the typology of various objects, the directions from which came the influences that were at work in Europe from Neolithic to Bronze Age times.

Any prehistorian who has worked on the Continent will derive pleasure from the very first page, for the book is dedicated to Émile Cartailhac. To those who have worked with and drawn inspiration from Cartailhac such a dedication seems natural. But here it is not only a tribute to that wonderful old man, who died in harness only a short while ago, for his book, "Les Ages préhistoriques de l'Espagne et du Portugal," published so far back as 1886, still remains a standard work on early times in the Iberian Peninsula, and again and again the reader will notice the use that Dr. Åberg has made of it.

A great deal of work has been done by Dr. Åberg, and a number of collections, both private and in museums (not to speak of the considerable literature on the subject), has been utilised in the compilation of this work. The book opens with a short preface in which the author exposes his reasons for studying the area and his general views. There follows an introduction in which the current views and the literature of the subject are shortly discussed. Next, after giving an account of the background to the period under discussion, the development of the megalithic tombs in the Peninsula, and the principal objects and types of tool found during the Iberian copper age, are described and illustrated by numerous and excellent figures and plates. The whole forms an exceedingly useful study which can only be gathered elsewhere by a process of foraging in much larger works. There follows an account of a number of sites in Portugal and Spain; finally a brief comparative study of similar cultures elsewhere, in France, Italy, and England. Much local work has still to be published by Bonsor and others, and many details still await solution, but in the meantime, the volume before us gives a clear and rapid account of what has been done, and its important bearing on the contemporary cultures farther north. The Spanish Peninsula has been favoured in having large deposits of metal ores, and so a brilliant copper age developed, the influence of which was felt farther north in regions where stone tools still had to be used owing to lack of metal ores, at a time when little commerce was possible.

The book is lacking in one particular respect, and that is in the absence of an account of the Spanish "Third Group" rock-shelter paintings. This art clearly belongs in date to our author's period, for many of the conventionalisations figured on pottery appear on the walls of the rock-shelters. Thus on pages 133 and 145, decorations engraved on pottery from Los Millares and Las Carolinas are illustrated, which can be matched exactly by paintings on the rock-shelter walls (for example, at Jimena, at Las Figuras, and a score of other sites). This art was not purely decorative; it had some (as yet imperfectly known) object, and so is important in tracing out the civilisation of the period. It is true that there has not been as yet any complete or satisfactory study published on this subject, so that its importance has not been always properly realised.

Sufficient has been done, however, in this respect to make its omission from Dr. Åberg's book a serious blemish. This can easily be rectified in a later edition by the addition of a further chapter.

Dr. Åberg is to be congratulated on his excellent work, which indeed well repays a careful perusal.

M. C. Burkitt.

A Railway Manual.

Manuel des chemins de fer. Par J. Bourde. (Bibliothèque Professionnelle.) Pp. 444. (Paris: J.-B. Baillière et fils, 1922.) 12 francs.

M. BOURDE'S book is intended for workers who are desirous of extending their knowledge over larger fields than is covered by their actual every-day work, and for whom the big special volumes are inaccessible or unintelligible. The author is of opinion that the workman is too often condemned to be a mere wheel in a mechanism, and that he is not allowed sufficient initiative. The series of volumes to which our author's book belongs is intended to furnish opportunities for the workman, and each of the 150 volumes has been written by an author who has special knowledge of the subject on which he writes. The reason for the lack of works of this type in this country is probably connected with the difference between the French and English people in their mental characteristics and in their education. The English are of course intensely practical, and not at all bookish. It is not implied that the French are not practical, but they have been brought up more on the bookish side than English engineers. The present writer knows one railway engineer who is—or was—anxious to write a book on railways, and he had accumulated a great mass of material. His lack of literary skill and the immense volume of his own knowledge will, however, in all probability prevent the completion of the book.

The volume under review, dealing with railways from the engineering point of view, covers the ground very thoroughly; it is written in plain language and gives the essentials to such an extent that a person having already a practical acquaintance with any one branch of railway work would, by the aid of the book, readily fit himself to deal with problems outside his own special domain.

With regard to the details of the book, a beginning is made with surveying and levelling, the drawing of plans and representation of heights by contour lines and other methods. With this preliminary the author is in a position to tackle the general design of the railway line, including questions of traffic, gauge of rails, curves, and gradients, all from the most general point of view, and so as to decide on the best route. Other chapters discuss, from the same point of view, transition curves, cuttings and embankments, the calculation of earthwork, the latter subject being treated in considerable detail; also the problem of the economical arrangement of excavation and embankment, considered especially with respect to length of haul.

Assuming now that the actual route is decided upon, the author treats of the detail design and carrying out of the work, this portion of the book taking up more than one half of the whole 444 pages. There are six chapters treating in succession of the design and execution of cuttings and embankments, bridges, viaducts, culverts, and tunnels; then follow two chapters on masonry works with a general discussion of the materials to be used: stone, metal, wood, etc.

With all the earthwork finished, bridges and heavy masonry work completed, the next subject is the permanent way of the line, and the author gives a very clear and concise account of the several component parts, especially dealing with the rail, its different sections and methods of support, with a clear treatment of the gradual introduction of curvature on rails by means of transition curves. The planning of stations, with the various problems involved in the junctions and crossings of the tracks, is given fairly thoroughly, and a chapter is devoted to station buildings, including the buildings required for the rolling stock.

The book is of a type which would be welcome in Great Britain, although of course a translation would be of little use.

Our Bookshelf.

Carl Rümkers Hamburger Sternverzeichnis 1845·0, enthaltend 17724 Sternörter, abgeleitet aus den Beobachtungen am Meridiankreis der Hamburger Sternwarte in den Jahren 1836 bis 1856. Herausgegeben von Dr. Richard Schorr. Pp. xiv+488. (Bergedorf: Verlag der Sternwarte, 1922.) n.p.

Dr. Richard Schorr has rendered a great service to exact astronomy in making and publishing this re-reduction of the great Hamburg catalogue of Carl Rümker, containing 17,724 stars, mostly faint, observed with the Repsold Transit Circle (of 4 inches aperture) between 1836 and 1856. It is of interest to learn from the short biographical sketch of Rümker that he held a commission in the British Mediterranean fleet from 1812 to 1817, holding the post of instructor in navigation. He then went to Paramatta Observatory, N.S.W., as director; while there he made useful observations of Encke's Comet at its first predicted return in 1822. He returned to Hamburg as director of the Observatory in 1833, remaining there till his health failed in 1857. The Transit Circle was quite a good one, and the early date of the stellar observations renders them of value for the determination of proper motion.

The reduction has been repeated *ab initio*, the data being entered from the original observing books. The clock and azimuth errors and equator-points were derived by the use of Auwers's positions of fundamental stars. Pulkovo refractions were used. The probable error of a re-reduced catalogue place (depending on 1·8 observations, the average number) is 0·083^s secant decl. in R.A., and 1·0″ in decl. The difference of magnitude equation for 3·5 mag. and 8 mag. is about 0·08^s. This has not been applied. The star places were compared individually with those of the Astronomische Gesellschaft Catalogues and the differences are given beside the star places, though the interval in years is not given.

Many errata in Rümker's reductions were detected and corrected in the course of this comparison. These are mentioned in footnotes. There were some stars for which Rümker did not read the full number of microscopes, but in all cases there is ample material to determine the necessary correction. Finally a list is given of the proper motions that have been published for Rümker stars, some 6000 in number. It should now be possible to increase this list with the aid of the newly published positions.

To save expense the catalogue was not set up in type, but written by hand and multiplied by a mechanical process. It is, however, quite clear and legible.

A. C. D. C.

Mathematik und Physik: Eine erkenntnistheoretische Untersuchung. Von E. Study. (Sammlung Vieweg, Heft 65.) Pp. 31. (Braunschweig: F. Vieweg und Sohn. 1923.) 675 marks.

In this tract Prof. Study's chief aim is to discuss the question: What is to be regarded as mathematical and what as specifically physical in theoretical physics? How comes it that parts of mathematics and of physics can be combined so as to form a higher unity? For the purposes of his discussion he defines mathematics as the limit towards which present-day mathematics seems to him to be tending, in which it will include calculation by means of natural numbers (positive integers) with all that is based thereon, and nothing besides. When, for example, projective geometry is "arithmetised" by identifying a point, or a straight line, with the set of homogeneous co-ordinates representing it, the word point, or straight line, as the case may be, becomes merely a symbol bearing no logical relation either to the material world or to our concept of space.

Thus all branches of geometry, Euclidean or other, are logically independent of experience. Similarly "arithmetical physics," arising from the arithmetisation of the mathematical portions of physics, is based logically on calculation by means of numbers alone, developed in one particular direction, chosen from many possible alternatives on the basis of a judgment of value, not of cause, in so far as it is desired to make only investigations closely related to experience. Thus the relation of theoretical physics to the content of experience appears to be not logical, but only psychological and historical. The content of theoretical physics is threefold: (1) a purely mathematical part, characterised by the method of deduction; (2) an experimental part, characterised by the method of (incomplete) induction; and (3) an intermediate part, characterised by an independent method, that of "idealisation." By idealisation Prof. Study means the process whereby we substitute the simple abstract reality of mathematics for the infinitely complex and barely comprehensible reality of physics.

This tract can be recommended as a very stimulating introduction to the philosophical aspects of mathematics and physics by a writer who is eminently fitted for the task by the wide range of his knowledge as well as the importance of his own contributions to science.

Musical Acoustics based on the Pure Third System. By Thorvald Kornerup. Translated by Phyllis A. Petersen. Pp. 56. (Copenhagen and Leipzig: Wilhelm Hansen, 1922.) 2*s.* 6*d.*

In this little book the author discusses very fully the relations of the pitches of the notes in the various scales in just intonation and in a variety of temperaments. Instead of Ellis's logarithmic cents, the millioctave is here used, which (as its name implies) is one-thousandth of an octave instead of Ellis's one-twelve-hundredth of the octave. It is pointed out early in the work that for a pure intonation of the minor triad, D F A, the D must be only a small tone above C and a large tone below the just E. The fact that the major chord, G B D, equally needs a D which is a small tone below the just E and a large tone above C, does not seem to receive equal emphasis.

The book contains very many diagrams and tables. One of the most striking diagrams is the author's tonal circle in which the circumference contains a single octave, equal *angles* corresponding to equal *differences* of frequencies. Thus, putting one C at the starting-point on the circumference, the other notes occur at the following angles, the D being what is called in England grave D and denoted by D′. The ordinary D would be at 45°.

Angles .	0°	40°	90°	120°	180°	240°	315°	360°
Notes .	C	D′	E	F	G	A	B	C′

Quite a number of scales and temperaments are treated at length, special attention being directed to the nineteen steps to the octave, which is considered to be the consequence of the third system and the practical ideal. Other temperaments considered are as follows, and illustrate the fulness of the treatment:

No. of Tones.		Steps in Tone.		No. of Semi-tones.		Steps in Semi-tone.		Steps in Octave.	Author.	Date.
5	×	2	+	2	×	1	=	12	Aristoxenos.	c. 350 B.C.
5	×	3	+	2	×	2	=	19	Elsasz.	c. A.D. 1590.
5	×	5	+	2	×	3	=	31	Vicentino.	c. 1546.
2; 3	×	6; 7	+	2	×	4	=	41	Paul v. Janko.	1882–1901.
2; 3	×	8; 9	+	2	×	5	=	53	Nicholas Mercator.	c. 1675.

The work is in some respects rather fanciful but will repay careful study.

E. H. B.

Production économique de la vapeur. Par Dr. O. Manville. Pp. vii + 407. (Paris: Gaston Doin, 1923.) 25 francs.

M. Manville's work is timely. While French industries in pre-War days consumed 64 million tons of coal, the addition of Alsace-Lorraine has increased the potential demand to 80 million tons. To meet this there exists but 25 to 30 million tons from the French mines (compared with 40 millions in the days when the mines had not suffered from war), leaving a possible gap of 55 millions in the balancing of the account. The author, who is obviously alarmed by these figures, estimates the supplies from Belgium, England, the Saar, and Lorraine as but 29 millions and speculates doubtfully on the prospect of getting regularly the required balance from Germany. He points out that in any case the cost of the imports must be in the neighbourhood of 6 milliards of francs, unless the present wasteful methods of coal utilisation are changed. To the elimination of these wasteful methods the author accordingly addresses himself, suggesting that in the matter of steam production alone two of the six milliards can be saved.

The book contains a full and satisfactory account of modern steam plant and its various accessories, besides giving much space to calculations. The author remarks, "La plus grande partie de nos usines ont une origine modeste. Ce sont de petites installations, qui se sont développées, au cours d'affaires plus ou moins heureuses." Those in charge of the modest organisations of which he speaks may find the book rather difficult, but their remedy is simple since the author is a consulting engineer and his personal assistance will doubtless be available on demand.

The Sea Gypsies of Malaya: An Account of the Nomadic Mawken People of the Mergui Archipelago. By W. G. White. Pp. 318. (London: Seeley, Service and Co., Ltd., 1922.) 21*s.* net.

The Mawken of the Mergui Archipelago, more generally known as the Selung, whose customs, beliefs, and modes of life are described in this volume, are literally nomads of the sea, as the greater part of their life is passed in their peculiarly constructed boats. The reason they themselves give for this mode of existence is, that after they had migrated from the mainland, whence they had been driven by the incursions of Burmese peoples, they had to abandon their settlements on the islands owing to the raids of Malayan pirates. It is a moot question whether they are to be regarded on linguistic grounds as the northernmost branch of the sea-going Malays or as a derivation from Further India. Their own traditions, as already mentioned, favour the latter origin. As the author was in charge of the census of these people in 1911, he was able to obtain a considerable insight into their system of relationship, of which a remarkable feature is the stress laid upon the distinction between elder and younger in most, but not all, the degrees of relationship. It is a pity that Mr. White's work has called him to another part of the world and that he will not be able to carry out further investigations among this interesting and little known people.

The Meaning of Meaning: a Study of the Influence of Language upon Thought and of the Science of Symbolism. By C. K. Ogden and I. A. Richards. (International Library of Psychology, Philosophy, and Scientific Method.) Pp. xxxii + 544. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co. Inc., 1923.) 12*s.* 6*d.* net.

This rather pretentious volume is at least twice the size it need have been in consequence of the choice by the editors of uncomfortably large type and extravagant spacing. Its title is apparently adopted from the subject of a symposium at the Oxford philosophical congress of 1921, and the book is a medley of already published papers and editorial paragraphs. The collaborating authors of the main essay apologise in the preface for its lack of systematisation, and make the excuse that their lives are too busy for them to spare the time necessary to re-write it. They have included in their book an introduction by a third author and supplementary essays by a fourth and fifth. The aim of the whole is to provide materials for a science of meaning. The book contains a good deal of amusing matter and some valuable criticisms, but it is formless and unequal.

Chile: To-day and To-morrow. By L. E. Elliott. Pp. x + 340 + plates. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1922.) 24*s.* net.

Among recent books on Chile this stands out as one of the most important and fullest for purposes of reference, although its value in this respect is somewhat impaired by the lack of an index. The sections on Chilean history and on mining and agriculture are particularly full and useful. The book would be enhanced by more attention to the physical features and climate of the country, which are both treated very briefly. Like most books on South America this volume is mainly eulogistic, but the critical note is not absent, and the author clearly has a wide experience of the country. There is an interesting chapter on Easter Island, the distant possession of Chile in the Pacific.

Elementary Determinants for Electrical Engineers. By H. P. Few. Pp. vi + 98. (London: S. Rentell and Co., Ltd.; New York: D. Van Nostrand Co., 1922.) 4*s.* net.

In many of the everyday calculations of electrical engineering, determinants are useful, and Prof. Fleming showed many years ago how the resistances of networks can be computed by their means. The very complicated formulæ which telephone engineers use in order to balance the capacity effects in multiple twin cable are easily proved by determinants. This book can be very easily understood, and will be appreciated by those for whom it is written. The examples are numerous and well chosen.

Optical Methods in Control and Research Laboratories. By Dr. J. N. Goldsmith, Dr. S. Judd Lewis, and F. Twyman. Vol. 1: Spectrum Analysis, Absorption Spectra, Refractometry, Polarimetry. Second edition. Pp. iv + 56 + 3 plates. (London: Adam Hilger, Ltd., 75A Camden Road, 1923.) 1*s.* 6*d.*

This pamphlet forms a valuable introduction to the use of spectroscopes, spectrophotometers, refractometers, and polarimeters, and, while avoiding detailed descriptions of the instruments, gives ample references to such descriptions. Sufficient information is given in the pamphlet to enable a works physicist to select the proper instrument for the work to be done and to know where to look for further information on the subject.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Crossed-orbit Model of Helium, its Ionisation Potential, and Lyman Series.

TAKING for granted the dynamical legitimacy of the crossed-orbit model as originally proposed by Bohr (*Zeits. für Physik*, ix., 1922, p. 1) for normal helium, I find for its negatived total energy, with the usual Coulomb law of force, and treating the two orbits as "*circular*" *in the literal sense of the word*,

$$-E = 7N_\infty ch\left[1 - \frac{1}{4\pi}F\left(\sin\frac{i}{2}\right)\right], \quad . \quad . \quad (1)$$

where F is the complete elliptic integral of the first kind, i the inclination of the planes of the two one-quantic orbits, in Bohr's case 120°, and the remaining letters are the usual symbols of the universal constants. In accordance with symmetry, the electrons are assumed simultaneously to pass the nodes, that is, the opposite ends of the common diameter. (Details of deduction of (1) are given in a paper to be published shortly.) If one of the electrons be removed to "infinity," the energy of the remaining ionised atom He^+ is $-4Nch$, where $N = N_\infty : (1 + m/M)$. The small difference $N_\infty - N$ being irrelevant for our purpose, the ionisation work thus becomes, by (1), $W = Nch(3 - 7F/4\pi)$, or, the equivalent wave-number (of the flash emitted at the return of the removed electron),

$$\nu = N\left[3 - \frac{7}{4\pi}F\left(\sin\frac{i}{2}\right)\right]. \quad . \quad . \quad . \quad (2)$$

For Bohr's model $i = 120°$ and, to four decimals, $F = 2{\cdot}1565$. Thus $\nu = 1{\cdot}7987N$, and since N is equivalent to 13·54 volts, the corresponding *ionisation potential*,

$$V = 24{\cdot}35 \text{ volts}, \quad . \quad . \quad . \quad . \quad (3)$$

which is remarkably close to 24·5, the latest value observed and corrected by Lyman. The wave-length corresponding to (3), or the limit of Lyman's new series, would amount to $\lambda_\infty = 506{\cdot}8$ Å.

Thus far Bohr's (idealised) model, corresponding to $-\cos i = \frac{1}{2}$, a value supported in Bohr's paper (*l.c.*, p. 32) only by a terse reference to the quantum condition for atomic angular momentum.

Now, suppose for the moment that there are dynamically possible states of the system also for some inclinations differing from 120°. Then the wave-number emitted at the passage from He^+ to such an i-model will be given by (2), with $N = 1{\cdot}097_3 . 10^5$ as a sufficiently correct compromise value. It has seemed especially interesting to apply (2) to *simple rational values* of $-\cos i$ other than $\frac{1}{2}$, with a particular view of covering, perhaps, some of the observed members of Lyman's series, which are four,

$$\lambda_1 = 584{\cdot}4, \ \lambda_2 = 537{\cdot}1, \ \lambda_3 = 522{\cdot}3, \ \lambda_4 = 515{\cdot}7,$$

with the conjectured λ_∞ corresponding to 24·5 volts or, very nearly, to (3) as limit. The results thus obtained were as follows:

The "normal" value $-\frac{1}{2}$ being already treated, the next simple rational value $\cos i = -\frac{2}{3}$, to which corresponds $F = 2{\cdot}3404$, gave, by (2),

$$\lambda = 537{\cdot}2,$$

encouragingly close to the observed λ_2. The very next, however, $\cos i = -\frac{3}{4}$, yielding $\lambda = 561{\cdot}9$, was, for the present, without interest. Further, $\cos i = -\frac{4}{5}$, with the semi-inclination 71·585° and $F = 2{\cdot}5892$, gave

$$\lambda = 585{\cdot}0,$$

close enough to the observed λ_1, and $\cos i = -\frac{3}{5}$, $i/2 = 63{\cdot}435°$, $F = 2{\cdot}2571$, yielded

$$\lambda = 522{\cdot}9,$$

equally close to λ_3. But one observed member of the series, 515·7, remained uncovered. Working back from this, by (2), the required semi-inclination is found to be 61·97°, whence $-\cos i = 0{\cdot}558$, while the nearest simple fraction $\frac{5}{9}$ is 0·555. . . . But whether 5 and 9 are still "small" integers must be left to every one's own judgment. In fine, the formula (2), *regardless of its significance or deduction*, gives the correct ionisation potential for $-\cos i = \frac{1}{2}$, and at the same time, for

$$-\cos i = \frac{5}{9}, \ \frac{3}{5}, \ \frac{2}{3}, \ \frac{4}{5},$$

the observed Lyman lines λ_4, λ_3, λ_2, λ_1, respectively, the initial state being always that of He^+, and the final energy level being each time given by (1) with the corresponding inclination. Notice that for $i = 0$, $F = \pi/2$, and (1) gives $49{\cdot}8\,Nch$, the familiar energy level of Bohr's older (untenable) ring model.

Whether the model of normal helium ($i = 120°$), with almost circular orbits, is dynamically legitimate, seems doubtful. Finally, a decision with regard to the dynamical possibility of the remaining four configurations, leading to remarkable coincidences, would require a thorough and complicated analysis, which the writer is not in the position to offer. Unless some new lines are discovered beyond 500 Å., the domain worthy of investigation in this respect, on either the accepted or modified dynamical and quantic principles, would extend only from $i = 120°$ to less than 177·63°, the latter being the inclination for which the right-hand member of (2) vanishes, when the system is ready to break up of its own accord.

L. SILBERSTEIN.

Rochester, N.Y., March 1.

The Nature of Light-Quanta.

IN a letter to NATURE of April 21, 1921 (vol. 107, p. 233), Sir Arthur Schuster pointed out that a quantum radiation could not, on account of the finiteness of its energy, $\epsilon = h\nu$, be regarded as homogeneous light of frequency ν, for homogeneity implies, strictly, the existence of an infinite train of waves of constant amplitude.

Since all attempts to find a type of nearly homogeneous light with total energy $h\nu$ have been comparatively unsuccessful, it seems worth while to consider the hypothesis that an approximately homogeneous type of light is the result of the *interference* of two or more quantum radiations of an elementary character.

Let us assume that an elementary quantum radiation, in the form of a plane wave travelling in the direction of the axis of x, is specified by an electromagnetic field in which the electric vector E is transverse to the direction of propagation and represented by a vector of type $f(x - ct)$F, where F depends only on z and y and represents in magnitude and direction the electric force in a two-dimensional electrostatic field, of finite energy W, arising from positive and negative charges situated within a small finite area A in the yz-plane.

If $f(x) = \frac{\sin px}{x}$, the total energy in this electromagnetic field is πpW and is thus finite in spite of the fact that there are electric charges travelling in the direction of the waves with the velocity of light. These charges lie within a cylinder meeting the plane of yz on the boundary of A. The magnetic vector is perpendicular to the electric vector and equal to it in magnitude both inside and outside the electric charges. The Maxwell-Lorentz equations are satisfied everywhere, and the fact that we are able to specify a type of radiation the total energy of which is proportional to the maximum frequency $pc=\nu$ indicates that quantum theory may be quite compatible with these equations. That all frequencies up to pc occur is seen at once from the equation $\frac{\sin px}{x}=\int_0^p \cos qx\,.\,dq$. We are justified in regarding this type of field as elementary because, as Levi-Civita pointed out many years ago (*Comptes rendus*, t. 145, 1907), the electromagnetic force on the moving electricity vanishes everywhere and so the electricity moves freely under no forces and no forces are needed to keep it intact. In this connection it may be mentioned that the force of type $2\psi\nabla(\rho\sqrt{1-v^2/c^2})$, which has been used to balance the electric force in a suggested model of a stationary electron (*Physical Review*, September 1922), is also zero in the present case because $\psi=0$ and $v^2=c^2$.

Superposing two quantum fields with

$$f=\frac{\sin(p+dp)(x-ct)}{x-ct} \text{ and } f=-\frac{\sin p(x-ct)}{x-ct}, \text{ respectively,}$$

and with coincident cylinders (or light-darts, to use Silberstein's term), we obtain a wave of nearly homogeneous radiation of total energy $\pi W dp$. When the light-darts in the two fields are separate entities but close together, the total field still represents an approximately homogeneous type of radiation, but it also possesses some of the properties of a quantum radiation because the light-darts can be regarded as independent and one of them can be captured by an atom and its energy $h\nu$ absorbed while the other one escapes.

The composite field will behave like radiation of frequencies lying between ν and $\nu+d\nu$ when reflected and refracted if the elementary quantum-radiation behaves like light of frequency $\nu=cp$.

To test this point we have considered the reflection of our elementary quantum radiation at the surface of the moving mirror $x=ut$. The reflected wave proves to be one of the same type as the first, the electric vector being $-f(x+ct)\mathrm{F}$, where $f(x)=\frac{\sin p'x}{x}$ and $p'=p\frac{c-u}{c+u}$.

Thus Doppler's principle holds just as if pc were the frequency of homogeneous light instead of the maximum frequency contained in the quantum radiation. The energy relation $\epsilon'=h\nu'$ still holds and it looks as if W could be regarded as a universal constant hc/π.

It should be remarked that the elementary radiant field considered here is simply a particular case of a more general type of simple radiant field in which the rays and light-darts issue from a moving point. An ordinary type of electromagnetic field can be built up by superposing two or more simple radiant fields of this type and proceeding to the limit. If, then, ordinary electromagnetic fields are to be regarded as composite, there is nothing strange in regarding an approximately homogeneous type of radiation as composite.

Spermatogenesis of the Lepidoptera.

I SHOULD be glad of the hospitality of the columns of NATURE to reply to two observers whose papers in the December number of the *Quarterly Journal of Microscopical Science* have only recently come under my attention. Dr. Robert H. Bowen, of Columbia University, has investigated the spermatogenesis of the Lepidoptera, a subject which formed the first part of my series of papers on the "Cytoplasmic Inclusions of the Germ Cells." His account differs from previous ones chiefly in two respects—he states that the mitochondrial part of the spermatid is not a skein or spireme but a plate-work, and what is a much more interesting objection, he denies the previous descriptions of the metamorphosis of this skein into a tail-sheath, and instead describes it as degenerating, and the tail region being formed of a new central substance.

In the same Journal, Mr. Graham Cannon has redescribed the louse mitosome, and supports Dr. Bowen's conclusion that this body is not a skein but a plate-work. Dr. Bowen agrees with me so far as the general appearance of the material is concerned, but in a long discussion brings up a number of reasons for supposing that the body in question is a plate-work something roughly like the head of a fancy chrysanthemum. Mr. Graham Cannon has also given a similar and short account of his reasons for supposing that this body is actually a plate-work formed by a system of vacuoles.

Some years ago when Prof. Doncaster was writing his latest book, he came to see the material illustrating my view that the acrosome is always formed in association with the Golgi apparatus. He was shown my preparations of Smerinthus testes, and objected then to my description of the mitosome or nebenkern as a spireme. Dr. Bowen and Mr. Cannon will be glad to know this. However, I never found any reason to alter my views, even with such distinguished opposition, because it seemed to me that whether the "spireme" was formed of a flat ribbon, or a round string, it was actually pulled out as the spermatid lengthened, much like a ball of string. The figure formed by the mitochondria of the spermatid is not a matter of importance so far as concerns the larger questions surrounding the study of the cytoplasmic inclusions.

When, however, we turn to the second objection brought forward by Dr. Bowen, we find a matter of considerable importance. Dr. Bowen's "central substance" was believed to be the partly unravelled or pulled-out mitochondrial skein; it is figured by me in Plate 25, fig. 47, of my paper. His account of this new substance being something apart from the nebenkern or mitosome, and of the latter not taking direct part in the formation of the tail, is worthy of reinvestigation.

Except for Dr. Bowen's new interpretation of the formation of the sperm tail, he adds nothing new to our knowledge of the spermatogenesis of the Lepidoptera. His account is valuable, however, because of the fact that it confirms my drawings of the appearances of the material already described by me. Some of his spermatid cells are effete and drawn from bundles which are in the process of formation of atypic sperms. The whole question will be dealt with by me in a full account elsewhere. I merely take this early opportunity of stating my position.

Mr. Graham Cannon's statements will also be examined at length elsewhere.

A Static or Dynamic Atom?

Some writers still contrast the static atom of Lewis and Langmuir with the dynamic atom of Bohr, as if the two alternatives were mutually exclusive. It does not seem to be realised generally that any inconsistency there may have been between them has vanished completely with the publication of Bohr's later views on atomic orbits; speculations about chemical constitution based on the static atom can be translated directly into the language and conceptions of the dynamic atom.

The fundamental idea of Lewis is that non-polar combination consists in the sharing of electrons between atoms in such a way as to complete stable electronic configurations. If the sharing of an electron means the sharing of an orbit, and if the stable electronic configurations are those in which the groups of highest quantum number are completed, as they are in the rare gases: then the Lewis-Langmuir theory, expressed in terms of Bohr's conceptions, states that such compounds are formed when some of the electronic orbits, instead of surrounding one nucleus only, surround both, and therefore help to complete the quantum groups of both atoms. With this principle as a guide, it is merely a matter of linguistic alteration to interpret on the basis of a dynamic atom the conclusions which have been reached on the basis of the static atom.

Of course the question remains whether the theory can be true and whether such shared orbits are possible. This is a matter for quantum theory to decide. My last letter to Nature on this subject (November 25, 1920, vol. 106, p. 408) succeeded in eliciting from Prof. Bohr the first statement of the later and most exciting developments of his theory; perhaps this one will be equally fortunate!

Until the question is settled, it would be waste of time to make the necessary translation, even in a few examples. But it may be well to point out that, if this interpretation of the "sharing of electrons" can be accepted, the task of explaining chemistry according to the Lewis theory will probably be facilitated. For it seems likely that some limitations at present imposed upon the forms of sharing and upon the stable configurations could be removed. So far as I can see, Lewis's principle that only pairs of electrons are shared, and Langmuir's principle (in the original statement) that the stable configuration is always an octet, are based not so much on definite facts as on the need of some guiding principle if speculation is to be limited. The limitations suggested by the identification of stable configurations with the completion, or partial completion, of quantum groups are not exactly those which are usually adopted at present; but once more, while the whole basis of the theory is so uncertain, the attempt to decide the constitution of particular compounds is premature.

Norman R. Campbell.

The Zwartebergen and the Wegener Hypothesis.

Critics of the Wegener hypothesis have made a good deal of capital out of the northward deflexion of the folds of the Zwartebergen on approaching the west coast of Africa, but their failure to point out the cause of this deflexion seems to me to lay them open to the charge of advocacy which they so freely lay at Wegener's feet.

The deflexion is produced by the incidence of the chain on a massif of older rocks of the Swaziland System with a core of granite trending north-west. On nearing this resistant axis, the folds bend north-west and then north forming the Cederbergen. Finally, they flatten and die out northwards. It is clear that the existence of the granitic axis has interfered with the direct westerly continuation of the folds. The interference, however, is only local, for the Cederbergen do not continue for any distance to the north.

An exactly analogous deflexion occurs in the case of the Armorican folds in Ireland where they impinge on the highly resistant north-easterly trending Wicklow chain with its massive granitic axis. The folds turn north-east in Tipperary as they approach the granite and then north in Kilkenny and Queen's County, where they flatten out and finally disappear. The analogy is very perfect in that the final deflexion from the general trend of the folds is greater than would be brought about by a mere falling into line with the Wicklow chain.

Now, as every one is aware, the interruption along the line of the Wicklow granite does not stop the Armorican folds. They are renewed on the other side of St. George's Channel in southern Wales, where they once more assume their normal direction. If, therefore, we imagine the supposed Atlantic rift valley to have opened up along St. George's Channel, so as to leave Ireland attached to Newfoundland, we may profitably consider what would have happened when one of those irrepressible Germans had come along and announced that it once formed part of the British Isles, basing his argument on the fact that the Irish and Welsh folds, as well as other geological structures, fitted one another when the countries were placed in juxtaposition. The critics would at once have objected that the Armorican folds in Ireland on the west side of the Atlantic turned up northwards before they reached the coast, and therefore could not be regarded as a continuation of those of Wales. It is clear that the objection would have no force in this instance, so one may well ask whether it has any in the actual case of Africa and South America.

Egyptian Water-Clocks.

Permit a brief correction to the paragraph in Nature of April 7, p. 479, on the casts presented to the Science Museum. The variable divisions of the water-clocks are not for different lengths of day, but compensations for the changes of viscosity of water, over 9° and 12° F. respectively. This is proved by the extremes being nearer to the equinoxes than to the solstices, to harmonise with the slow passage of heat through massive temples. Further, the conical form of the clepsydra of 1400 B.C. was to compensate for the greater flow under fuller pressure, the form being a near approach to a portion of a parabola. Thus the variation of pressure was as 1 : 3·7, and the water varied as 1 : 2·9 to meet this.

W. M. Flinders Petrie.

A Permanent Image on Clear Glass.

After silvering an ordinary clock glass (about 5 in. diameter) on the convex side, I noticed on removing the wax, with which the concave side had been protected, that a perfectly distinct image of a small child's head had been rendered visible. The image is a photographic "positive."

It occurred to me that the clock glass had possibly been a photographic plate at some earlier time. Presumably it was a plane surface then. In giving the glass the curvature requisite to a clock glass it would be expected that any silver which may have been deposited while the plate was flat would have been disturbed when the glass had been moulded in a molten condition to its present shape. The image, however, is not distorted in the slightest degree.

I should be glad if any readers of Nature would supply an explanation of the production of this image.

Eric Robinson.

Bedford School, Bedford,
March 24.

I must thank the Editor for the opportunity he has given me of examining the very interesting silvered reflector specimen submitted by Mr. Robinson.

The image of the child's head has evidently a photographic origin, as Mr. Robinson suggests, but that the glass was at some earlier time a photographic plate that had later been heated and allowed to settle down in a suitable mould seems to be improbable, for the following reasons:

The image occupies only a small part, about an inch square, near the edge of the plate, the remainder of which shows no photographic details. There is, as Mr. Robinson remarks, no evidence of distortion at the curved portions, and a close examination of the surface shows none of those minute fractures that are usually visible when an old photographic plate is stripped and silvered.

When the image is examined closely, it is seen that there is a sharp line of demarcation especially at the right-hand side and the bottom, which suggests that at some time the head has been cut from a photograph and pasted inside the clock face. As the result of contact, or possibly under the action of the light, the image has then been impressed upon the glass. At some later date the photograph has been removed but the image on the glass has persisted and been rendered visible by silvering.

There are many examples of images being formed in the manner described on glass surfaces. A "To Let" notice pasted inside a window often becomes imprinted on the glass, and the image may persist thereafter for a very long time. Recently I observed on a tramcar window the wording of an advertisement that had been pasted on the glass and later removed. Silvering would of course make the images much more conspicuous.

In the hope of being able to reproduce Mr. Robinson's specimen, two photographs were attached with water inside a similar clock face and exposed to the light of an arc lamp for four hours. After the photographs had been removed the surface was thoroughly cleaned and silvered. Notwithstanding the briefness of the exposure, the images were then quite recognisable.

As there was reason to think that the appearance might be wholly or partly attributable to contact rather than exposure to light, a glass surface was cleaned with caustic potash and upon it there was roughly sketched a face by means of a quill moistened with stannous chloride. The liquid was allowed to remain for two minutes on the surface of the glass, which was then recleaned by means of a cotton-wool pad and weak caustic potash solution. After silvering, the details of the sketch could be observed, although previously no traces were apparent.

Another plate was similarly treated but not silvered. When this plate is breathed upon, the face can be distinctly seen.

The subject is one that deserves fuller investigation.

So materialistic an explanation as the above is not, I fear, so attractive as a psychic one.

James W. French.

Anniesland, Glasgow, April 9.

Tactile Vision of Insects and Arachnida.

It would be interesting to know more details of the research carried out by Mr. J. P. O'Hea on the "so-called eyes in insects and arachnida" (Nature, April 14, p. 498, in connexion with Commander Hilton Young's suggestion), from which he arrives at the surprising conclusion that "the organs generally known as eyes do not act as organs of vision." The species Mr. O'Hea mentions are the house-fly, red ants, *Tegenaria domestica*, and "many of the Epeiræ." We have here an assortment of which the power, and even manner, of vision are scarcely comparable.

Taking first the spiders, sight plays practically no part in the life of the common Epeirides; the eyes, so far as one can see, simply serve to distinguish light from darkness, and form no clear image. This is not quite true of Tegenaria (the other spider mentioned). A sudden movement of the hand, when the spider comes out to take a fly, I have known to send it back (this is also true of *Agelena labyrinthica* and others). In this case, however, it is a large moving object which frightens the spider, and it will hesitate in its attack if the insect cease to struggle, so that it does not find it by sight.

As for the red ants (the species is not stated), we have the mass of Lord Avebury's work, as well as that of Forel and many others, in determining the part vision plays. One of the simplest cases is that quoted by Forel ("Senses of Insects," pp. 124-128), in which he found that specimens of *Formica pratensis* experienced considerable difficulty in finding the nest when their eyes were varnished (the antennary sense, however, playing the most important part).

It is in the case of the house-fly that Mr. O'Hea's conclusions are most surprising. He maintains that if one gradually brings the hand up to a fly on a window-pane, "if it be a vigorous specimen, [it] will evade the caress," whereas if one approaches it from the other side of the pane the fly takes little notice. His conclusion is that the fly recognises the approach of the hand, not by vision but by currents of air due to the motion of the hand or by convection currents due to heat of the same.

I have lately had occasion to catch a number of flies (*Musca domestica* and *Calliphora vomitoria*), and have found that one of the best ways was to bring a glass tube slowly and continuously up to the fly (any sudden movement almost always causes the fly to escape). If the movement is quite steady, the fly does not realise the situation until covered by the tube; it cannot apparently appreciate a slow movement.

When the fly is on the other side of the glass we have several factors to consider. For example, if the fly is *outside*, its field of vision *below itself* will be limited owing to bright reflections all round (its eye being close to the glass); hence movements from inside, even if the fly could see below itself, would have to be sudden and on a larger scale to disturb it.

The most obvious test to apply is as follows: Approach the under side of the fly (1) through glass, when, as stated, it often takes no notice; (2) through trellis (such as a meat-safe is made of), when, in my experience, the same thing occurs. This seems to dispose of the idea that the fly is affected by convection currents. The explanation of the facts I should suggest to be somewhat as follows: The surface of the compound eye available to the fly for looking downwards is smaller than that on the top of the head. Moreover, the lower portion is never used when the fly is resting normally on a solid opaque body and the fly has only to take into account attacks from above. An attack from below (when the fly is at rest) is outside its normal experience. One may recall also that the ocelli are situated on the top of the head and are usually considered to be useful for close vision. The experiment, to be in any way conclusive, should be repeated with the eyes of the fly varnished.

Mr. O'Hea must, however, have more facts which enable him to deny the use of an insect's eyes for vision in the face of all the work of Lord Avebury, Plateau, Forel, and many others.

As for Arachnida, an immense number of examples could be quoted as indicating power of vision. The following are obvious (and are cases where "convection currents" are definitely excluded):

A male Attid will start to dance before the female, though a glass partition separate them, and he turns his head to watch her as she moves.

I have at present two specimens of *Lycosa Narbonensis*, which, when out of their burrows, will dart back when a sudden movement is made near them, that is within about three yards. (They are always under glass, so that convection currents will explain nothing.) A slow approach, as with the fly, does not disturb them.

It seems to me that, in testing, Commander Hilton Young's hypothesis, we cannot assume the absence of insect vision on such slender evidence as that brought forward by Mr. O'Hea. We must either experiment with species which are *known* to possess *absolutely no power of sight*, or obliterate the eyes with a varnish, and *then* see how the insect behaves in the neighbourhood of a solid body.

G. H. LOCKET.

Salmon's Cross, Reigate, Surrey,

Science and Economics.

PROF. SODDY is an eminent chemist and physicist, and it is consistent with his own investigations that he should seek for the "natural fundamental basis of the economic system under which we perish" (NATURE, April 14, p. 497). If the natural basis of the system be such as to cause us to perish, the object of a re-examination is, perhaps, to alter Nature and reconstruct *de novo*. Or, does Prof. Soddy mean that there are natural economic laws of which we are, as yet, not aware, and for which we should search? We know, however, that nineteenth-century economists enunciated natural laws of economics such as *competition* (survival of the fit) and *supply and demand* (action and reaction). These laws, nevertheless, were not "natural" to economics; they were adapted from Nature, as then expounded, and applied artificially by the governments in certain countries.

Prof. Soddy now says, and with some reason, that the present economic system is an offence against common sense. It seems then that the natural obvious truths of the nineteenth century as interpreted economically are, in this century, both unscientific and senseless. Many no doubt will agree with him that the complex modern financial system which evolved through several centuries *pari passu* with science, and admirably served to stimulate, restrain, and direct the desires and ambitions of an imperfect human race, does not function as responsively as it did. Age may be the cause; it has not renewed itself by new forms of thought as has science. But, whatever the cause, one ventures to disagree with Prof. Soddy when he says that no one pretends to understand the system. This is true only as one might say "no one pretends to understand the 'atomic' theory": a few do—that is, those who conduct the operations. Certain axioms hold good until new conditions are introduced; but it is somewhat easier, one would think, to find the formulæ necessary to control operations under new conditions in a laboratory than in the world of human affairs. In the former, mathematics are at hand, but of what assistance are these scientific methods in dealing with complex and unequally developed human beings whose conflicting desires and opinions cannot be mathematically computed and resolved by formulæ?

Again, Prof. Soddy's assertion that the production of wealth is now "a relatively finished science" has a ring of finality hitherto unassociated with science. Many civilisations have shown evidences of great wealth, and its *production* is always a finished science at any time in an epoch, though relatively so to another. In our own day the need for human labour has not yet been entirely eliminated. It is even less probable that the *distribution* of wealth will ever become a finished science—at least, until "Earth's last picture is painted." Were the dispensers of credit (whether by patronage or "democratic control") to achieve a temporary perfection in adjusting the desires and deserts of the social hierarchy even in regard to material things, the mere force of individuality in human beings would upset the balance in time, and the fact of evolution makes this event inevitable, as history shows. There may be a science of the distribution of wealth, and, if so, it is probably associated with the science of government, an art in which rulers and princes of earlier times were especially trained; but one must conclude that its principles are not those of applied physics, for mankind cannot be controlled, transmuted, and led so rapidly and readily on the path of evolution as can the "elements" in the physicist's laboratory.

The ultimate basis of credit in any age is character and ability, on which have been founded the Codes of Laws and social formulæ of all great civilisations from the earliest Laws of Manu. It may be as well, therefore, for the preservation of our modern knowledge, that the system by which "tokens of wealth" are distributed should not be radically changed until character is once more clearly defined and appreciated by all classes.

Effect of Plant Extracts on Blood Sugar.

(BY CABLE.)

IN the early days of my investigations in connexion with insulin, I predicted that whenever glycogen occurred in Nature an insulin-like substance would also be found. Putting this theory to the test, I obtained positive results first with clam tissue, and later with yeast. This result was obtained during the latter part of January. In the light of this latter result, my mode of reasoning was changed. If yeast contains an insulin-like hormone, other plants may also contain it. Extracts of tissue of a variety of the higher plants were, therefore, prepared, and the effect of subcutaneous injection of these extracts upon the blood sugar of the normal rabbit was ascertained. The effect of certain plant extracts upon the blood sugar of depancreated dogs was also studied. Extracts made from onion tops, onion roots, barley roots and sprouted grain, green wheat leaves, bean tops, and lettuce were found to produce marked hyperglycæmia in normal rabbits. The day following the administration of an extract of green onion tops to a depancreated dog with a blood sugar of 0·190 per cent., a blood sugar of 0·090 per cent. was observed. The results of this investigation were communicated to the Society for Experimental Biology and Medicine at the meeting in New York City on March 21, when I suggested the name "Glucokinin" for this new plant hormone. Since that date I notice in NATURE of March 10 a letter by Messrs. Winter and Smith stating that they have obtained positive results with yeast extracts. These authors would, therefore, share coincident priority with me in this particular.

The Interferometer in Astronomy.[1]

By Prof. A. S. Eddington, F.R.S.

To the naked eye the stars and planets equally appear as points of light. A telescope magnifies the planets into discs, but no telescope is large enough to render visible the disc of a star. We can calculate that a lens or mirror of 20 ft. aperture would be needed to show us even the largest star disc; the construction of such an instrument, if not hopeless, is far distant. We have considerable knowledge as to the size of stars, but until recently it was all found by indirect calculation; no test had made out the image to be other than that of a geometrical point. At the risk of going over familiar ground I must consider briefly the mode by which a telescope forms an image—in particular how it reproduces that detail and contrast of light and darkness which betrays that we are looking at a disc or a double star and not a blur emanating from a single point. This optical performance is called resolving power. Resolving power is not primarily a matter of magnification but of aperture; provided we use an eyepiece of reasonably high power the limit of resolution is determined by the size of aperture of the object-glass.

To create a sharply defined image the telescope must not only bring light where there ought to be light, but it must also bring darkness where there ought to be darkness. The latter task is the more difficult. Light waves in the æther tend to spread in all directions, and the telescope cannot prevent individual wavelets from straying on to parts of the picture where they have no business. But it has this one remedy—for every trespassing wavelet it must send a second wavelet by a slightly longer or shorter route to interfere with the first, and so produce darkness. This is where the utility of a wide aperture arises—by affording a wider difference in route of the individual wavelets, so that those from one part of the object-glass may be retarded relatively to and interfere with those from another part. A small object-glass can furnish light; it takes a big object-glass to furnish darkness.

Recognising that the success of an object-glass in separating double stars and other feats of resolution depends on the production of darkness in the proper place by interference between the waves from different parts of the aperture, Michelson asked himself whether the ordinary circular aperture was necessarily the most efficient for giving the required interference. Any deviation from the circular shape is likely to spoil the definition of the image—to produce wings and fringes. The image will not so closely resemble the object viewed. But, on the other hand, we may be able to sharpen up the tell-tale features. It does not matter how different the image-pattern may be from the object, provided that we are able to read the significance of the pattern. If we cannot reproduce a disc, let us try to produce something which is *distinctive* of a disc.

A little reflection suggests that we ought to increase the resolving power by blocking out the middle of the object-glass and using only two extreme regions on one side and the other. For these regions the difference of light-path is greatest, and the corresponding wavelets are the first to interfere; they are the most efficient in furnishing the dark contrast needed to outline the image properly.

But if the middle of the object-glass is not going to be used, why trouble to construct it? We are led to the idea of using two widely separated apertures, each involving a comparatively small lens or mirror—after the pattern of a range-finder. That is much easier to construct than a huge lens circumscribing both apertures.

It is one thing to detect a small planetary or nebular disc; it is another thing to make a close measure of its diameter. It is one thing to detect the duplicity of a star; it is another thing to measure the separation of the components. Michelson's first experiments were directed not towards performing feats of resolution beyond what had previously been attained, but towards improving the accuracy of measurement. He applied his method first to measuring the diameters of Jupiter's satellites—discs which are easy to detect, but very difficult to measure trustworthily with an ordinary micrometer. But it is easier to understand the application of the method to measurement of double stars than

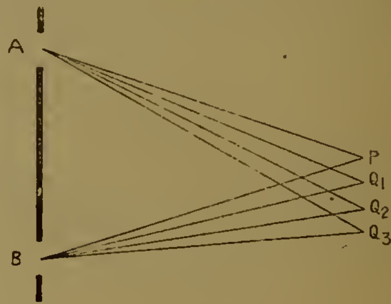

Fig. 1.

to the diameters of discs; and I shall therefore speak more particularly of the double-star problem first, although that is not the historical order.

Consider light coming from a distant point and passing through two small apertures, A and B, the rest of the object-glass being blocked out (Fig. 1). From each aperture the light disturbance diverges in all directions, and our problem is to find the nature of the luminous pattern formed in the focal plane, this pattern constituting the image which is viewed and magnified by the eyepiece. At the point P (where, according to geometrical optics, the single point-image ought to appear) we have full illumination because the waves from the two apertures have equal paths, AP and BP, and reinforce one another. A little to one side we have another point of full illumination, Q_1; the paths, AQ_1 and BQ_1, are unequal, but differ by exactly a wave-length, so that the waves again arrive in the right phase to reinforce one another. Similarly we shall have a series of points of full illumination, Q_2, Q_3, etc., where the path-difference amounts to 2, 3, etc., wave-lengths. Intermediately there will be points of darkness where the path-difference is $\frac{1}{2}$, $1\frac{1}{2}$, $2\frac{1}{2}$ wave-lengths, and the waves arrive in opposite phase and

[1] From the presidential address delivered before the Royal Astronomical Society on February 9, on presenting the gold medal of the Society to Prof. A. A. Michelson.

cancel one another. The light-pattern viewed by the eyepiece is thus a line of alternate bright and dark fringes. At first sight it might seem that the fringes would continue of equal brightness to a great distance; but actually they soon fade away, because in the more oblique directions there is interference, not merely between the two apertures, but between different parts of the same aperture. In fact the fringes appear as fine detail in the midst of the small diffraction disc which would be formed by either of the apertures singly.

Arrange that the two apertures are movable, and widen their distance apart. The points Q_1, Q_2, Q_3 now come closer together, that is to say, the fringes contract. Decrease the distance and the fringes spread out. It is a simple matter to find a formula giving the width of the fringes for any given separation of the apertures.

When the object viewed is a double star—two points of light—each point will produce its own line of fringes, and these will be superposed if the double star is a close one. It may happen that the two systems of fringes are in step, in which case the alternate bright and dark spaces will be conspicuous: but if they are at all out of step the pattern will be blurred. Remembering that we can alter at will the width of the fringes by varying the separation of the apertures, we can adjust them, so that the bright fringes for one component coincide with the dark spaces for the other component. If the two systems are of equal brightness one system will fill the gaps in the other, leaving merely a line of uniform brightness; if the two components are of unequal brightness the same adjustment will give minimum visibility of the alternation of light and shade. Varying the distance between the apertures this critical position can be fixed with considerable precision; and for close double stars of not too unequal magnitude the separation is measured in this way much more accurately than with a micrometer.

The disc of a single star or planet is likewise measured by finding a position of the apertures for which the fringes disappear. It is not now a problem of two points producing overlapping fringes, but every point of the circular disc produces a fringe-system, and the effects must be summed. When the diameter of the disc is 1·22 times the width of the fringes (*i.e.* the distance from one bright fringe to the next) the integrated effect is uniform illumination and the fringes disappear altogether. It is not much use trying to see in one's head a result which is more fittingly the subject of algebraic calculation; but we may notice in a general way that with this ratio the two outer quarters of the disc fall at places where the central half is producing dark spaces. That indicates roughly how the different portions of the disc compensate one another. The observation consists in varying the separation of the aperture until the fringes disappear; the diameter of the disc is then 1·2 times the fringe-width calculated for that separation.

The possibilities of a method of this kind had been explored to some extent before Michelson took up the problem; indeed Stéphan in 1874 had attempted unsuccessfully to detect the discs of stars by this means. We owe to Michelson the practical demonstration of its success. His first paper appeared more than thirty years ago in the *Philosophical Magazine* for July 1890. The next year he followed up the theory by measuring the diameters of the four satellites of Jupiter at the Lick Observatory. The method proved entirely successful, and his measures were afterwards closely confirmed by Hamy at the Paris Observatory in 1899 using the same device. The great value of the method seemed to be proved; it was thoroughly tested; and it forthwith lapsed into oblivion.

In 1919 Michelson again took up the matter with energy. He made observations in August with the 40-in. refractor at Yerkes which were found to be encouraging; and he went on to use first the 60-in. and then the 100-in. at Mount Wilson with the more ambitious design of surpassing the highest resolving power yet reached. At Mount Wilson he had the co-operation first of J. A. Anderson and afterwards of F. G. Pease. A great success was quickly obtained with the double star Capella. Capella is a spectroscopic binary with a period of 104 days. It was known that the distance of its components must nearly approach the limit of visual detection, but attempts to observe it visually had failed. (I may remark that that is a rather controversial statement to make—particularly at the R.A.S.—but the controversy is now ancient history.) With two narrow apertures in the beam from the 100-in. mirror the fringes were observed and then brought to minimum visibility by varying the position angle and separation of the apertures. The changing position angle and distance were traced through the revolution. Anderson's measures, afterwards continued by Merrill, have given a very accurate orbit. The separation of the two components varies from 0·04″ to 0·05″. From a comparison of this visual orbit with the spectroscopic orbit we find the parallax of Capella and also the mass. The parallax is 0·063″, and the components are respectively 4·2 and 3·3 times as massive as the sun. The parallax does not differ much from that given by trigonometrical and spectroscopic determinations; but these were very rough values, whereas the interferometer parallax is presumably of the highest order of refinement. I suppose that the mass determinations are about the best we have for any star.[2] But what is especially important is that Capella is the *only giant star* for which we know both the mass and the absolute luminosity.

I may perhaps be allowed to refer to a personal interest in this first big result of Michelson's method. Capella now supplies the chief lacking constant in the radiative theory of stellar equilibrium, for which I had waited five years. It is, I think, generally conceded that the absolute magnitude of a giant star mainly depends on its mass, and theoretical formulæ can be found expressing the law of dependence. But we need to know one pair of corresponding values in order, as it were, to anchor the formulæ. Hitherto that correspondence could only be guessed roughly from statistical knowledge of the average luminosity of giant stars and an estimate of the corresponding average mass based on our general knowledge of the masses of stars (which, unfortunately, relates chiefly to dwarf stars). Having now the exact figures for Capella, we can substitute a precise determination

[2] The masses of α Centauri, Sirius, and Procyon may have about the same accuracy, but I do not think that any others reach this standard.

instead of the provisional estimate; the change is by no means unimportant, the original estimate having been considerably in error.

Capella would have been slightly beyond the theoretical resolving power of the 100-in. if used in the ordinary way, though an elongation might have been detected. Resolving power was actually gained by blocking out the mischievous central portion of the aperture. But now came the final step—to produce fringes with a greater path-difference than any telescope yet constructed could provide. In 1920 a 20-foot interferometer, designed by Michelson and Pease, was constructed, in which the two interfering apertures could be separated to a distance of 20 ft. This was used in conjunction with the 100-in. mirror, which helped to bring the two beams together to produce their fringes. One might say that Michelson was now employing a 20-foot mirror; only, since he was only intending to use two small areas at its edges, he economically constructed those particular areas and left the rest of the mirror to imagination.

On July 10, 1920, the great 20-foot beam was placed across the telescope. On December 13 success was attained, and the diameter of Betelgeuse was measured. Its interference fringes had totally disappeared when the mirrors were at 10 ft. separation, although the other stars showed them. The deduced diameter was 0·045″—about the same size as a halfpenny fifty miles away.

Michelson's visits to Mount Wilson were limited to the summer months, and he was not present when this result was obtained. When he returned in 1921 he found his collaborators much occupied in trying to find some plan of obtaining definite measures of the visibility of the fringes instead of vague judgments. He suggested the plan of using two apertures, one fixed and the other variable; a difference in the size of the apertures reduces the visibility to a definite extent, depending on the ratio of the two apertures. Finally, a comparison apparatus was constructed with one square aperture of 4 in. and the other a square variable from 4 in. to zero, in order to afford a definite scale of visibility.

In the early trials it took days to find the fringes, but as gradual improvements were made a few hours' work on the first night of a series of observations sufficed; the subsequent settings being made in a few moments.

I need only touch very briefly on later developments. Diameters of Antares, Aldebaran, Arcturus, and β Pegasi have since been measured. But, of course, the discs of most stars are far below the limits for a 20-foot instrument. Prof. Hale is now constructing a 50-foot interferometer, and it is estimated that thirty or forty stars will be within its grasp. There is no need for a large mirror, and the use of the 100-in. in conjunction with the first interferometer was rather a luxury. The 50-foot is of different design, and will not depend on any other telescope. All the diameters of stars measured up to the present confirm very closely the theoretical values that had been predicted for them. The enormous actual size of these stars—the earth's orbit could be placed entirely inside Betelgeuse—is a picturesque feature of the results; but that was a confirmation of facts already established almost beyond doubt.

It is not unlikely that interesting bypaths may be opened up. Considerable fluctuations in the diameter of Betelgeuse have been found, which may or may not be due to varying definition. The star is an irregular variable showing also changes of line-of-sight velocity, and the correlation of varying diameter with these other fluctuations would be of great physical interest if it turns out to be genuine. Michelson has pointed out that it is theoretically possible to determine by the interferometer the distribution of light over the disc—the law of darkening at the limb. That is a conceivable development for the future.

Sunlight and Disease.[1]

By Dr. C. W. SALEEBY.

"IN the beginning, God said, Let There Be Light." In or before the eighth century B.C., Zarathustra, foremost among many sun-worshippers in many ages, taught the cult of the sun and the green leaf and thrift, in place of pillage and murder. In the beginning of medicine, Hippocrates, practising at Cos in the temples of Æsculapius—son of Phœbus Apollo, god of the sun and medicine and music—practised the sun-cure. In the beginning of our era, Galen and Celsus used the sun. In the Dark Ages, by a pitiful misconception, the cult of the sun fell into desuetude as a species of pagan Nature-worship, and ill persons were treated alike in physical and in intellectual night. Tuberculosis and other ills were treated by the Sovereign touch, reputed to cure the "king's evil."

In the second half of the nineteenth century, we find certain heralds of the dawn. In 1856, Florence Nightingale vigorously but vainly protested against the orientation of Netley Hospital, observing that no sunlight could ever enter its wards. In 1876, Sir Benjamin Ward Richardson praised sunlight in his "Hygeia, The City of Health." In 1877, Downes and Blunt showed that sunlight will kill anthrax bacilli. In many writings at this period, John Ruskin upheld sunlight and declaimed against the "plague-cloud" of smoke above our cities. In 1890, Dr. Theobald Adrian Palm (*nat.* 1848), who still practises medicine at Aylesford, in the Garden of England, showed by the geographical method that lack of sunlight is the chief factor in the causation of rickets, and added an admirable series of recommendations accordingly.[2] His paper was entirely ignored, and I found it in America, thanks to an American bibliographer. Robert Koch and others showed that sunlight kills tubercle bacilli. In 1893, Niels Finsen began to cure lupus, a form of cutaneous tuberculosis, by the local use of sunlight, and Sir James Crichton-Browne made observations to the same effect in this country. In 1900, on May 1, the London Hospital

[1] From a discourse at the Royal Institution on March 9.

[2] "The Geographical Distribution and Ætiology of Rickets," *The Practitioner*, October and November 1890.

began the cure of lupus by the local use of sunlight, thanks to the really effective Sovereign touch of Queen Alexandra, who was instrumental in bringing her young fellow-countryman's idea from Copenhagen.

In 1903, Dr. A. Rollier opened at Leysin, in the Alpes Vaudoises, the first clinic for the treatment of so-called surgical tuberculosis by sunlight; and in 1910 he applied his idea to prevention by the establishment of the "school in the sun," at Cergnat, just below Leysin.[3] In 1914, he published his book, "La Cure de Soleil," but the world catastrophe of that year caused it to be overlooked. In this country his methods have been followed recently by Sir Henry Gauvain, at the Treloar Hospital at Alton and Hayling Island, where very simple sheds and solaria serve to achieve results never approached by Netley, the pretentious and misplaced architecture of which exists in the same county to point the contrast between its century—the last of the ages of darkness—and the dawn in our own. In a very few other places, also, such as the Queen Mary's Hospital for Children at Carshalton, under Dr. Gordon Pugh—photographs of which from the air show a series of three-sided solaria strongly resembling the health temple at Cos,—at Leasowe near Liverpool, at Perrysburg near Buffalo in the United States, and, following a recent lecture of mine, at the Heritage Craft Schools, Chailey, Sussex, the sun-cure is employed. At several others, which I have visited, the sun-cure is said to be employed, but is not, the elements of the matter being unknown to the persons in charge.

The results of heliotherapy, as seen in person, or recorded in Rollier's radiographic and clinical atlas of 1914, or shown by means of illustrations, are unapproached, for certainty, safety, ease, beauty, restoration of function, and happiness during and after treatment. No explanation of them, to be called intelligible or adequate, is offered by any of its practitioners. Being myself without patients or laboratories, I have used only the geographical method, and have found, at each place studied, a tendency to believe that the various factors there present are essential for the results obtained. In the mountains, altitude is insisted upon; at the sea, the argument for "helio-Alpine" is replaced by an argument for "helio-Marine." In high latitudes, the Mediterranean is described as impossible for sun-cure; on visiting the Mediterranean, I found the sun-cure gloriously successful on the French and Italian Riviera, and there are similar reports from Spain. The fundamental bases were lacking for a superlatively successful empirical practice, conducted by various clinicians under widely varying conditions and in ignorance, for the most part, of each other's methods. No rational statement of the scope of heliotherapy could be obtained, some strongly denying, while Rollier strongly averred, that tuberculosis is amenable to the treatment when it happens to be situated in the lungs, as it is amenable when situated elsewhere. In his volume of 1914, Rollier mentioned certain other conditions besides tuberculosis, such as rickets, a non-bacterial disease, but the only explanation of the sun-cure that he offered was based on the antiseptic action of sunlight, while Gauvain explicitly regarded the sunlight as only an adjuvant in his method.

Clearly the need was for a properly co-ordinated scientific inquiry into the action of sunlight upon the body in health and disease. We were using it as we used digitalis for the heart before pharmacology (to compare a great thing with one relatively trivial); we needed a true physio-pharmacology of this incomparable medicament. My demands (*e.g.* in NATURE, December 8, 1921, p. 466; January 5, 1922, p. 11) for such an inquiry were met, after six months, by the Medical Research Council, early in 1922, and from the date of the appointment of the Special Committee, under the chairmanship of Sir William Bayliss, a new chapter in clinical and preventive medicine, I believe, will be seen to begin, its provisional opening being the new and largely rewritten translation into English of "La Cure de Soleil,"[4] on which I resolved immediately after my first visit to Leysin.

Already we have at least made it clear to all critics that the action is due to the sun's light and not to its heat. So long ago as 1779, Ingenhouss showed that the dissociation of carbon dioxide by the green leaf is due to the sun's light and not to its heat. Yet, in several instances, the sun-cure has been tried, with calamitous results, by clinicians who, making no inquiry into the matter, have exposed the unaccustomed chests of phthisical patients to the mid-day sun, perhaps for an hour or two, with natural results in fever and hæmoptysis. Already, also, the idea that the light is less valuable in killing the infective agent than in raising the bodily resistance to it—an idea to which I invited attention nearly twenty years ago, at the death of Finsen—has come into the clinical mind. Since last August in the Light Department of the London Hospital—which has done such splendid though limited work on the older hypothesis, since 1900—the general light bath has been used as well as the local treatment, and cases which resisted the latter have been completely cured by general exposure of the nude skin to the electric arc lamp, without local irradiation. We must use a combination of light and cold, which I have been commending for some time on the evidence of visits to Canada, where a magnificent childhood, free from rickets, thrives in extreme cold, thanks, as I believe, to a brilliant sun.

In various American laboratories the subject is now being advanced: notably in Columbia University, New York, under Dr. Alfred F. Hess and his fellow-workers. They attribute the major part of the action of the sun to the ultra-violet rays, by which, in experimental animals and also in infants, they are able to cure rickets with great speed, ease, and certainty, and to increase very markedly the phosphorus in the blood of infants on a constant diet. When I saw this experimental and clinical work in New York last December, the result had already been reached of demonstrating an annual curve, from month to month, of phosphorus in the blood of infants, with a maximum in June-July, and a minumum in March, corresponding with the monthly height of the sun in New York. By radiographic study of the bones of infants, it had also been shown that no new cases of rickets occur

[3] The "school in the sun," in summer and winter, was demonstrated after the discourse by means of a film.

[4] "Heliotherapy," by Dr. A. Rollier, with forewords by Sir H. J. Gauvain and Dr. C. W. Saleeby. Oxford Medical Publications, 1923.

in New York in June-July, and the maximum number occur in March. Dr. Hess now informs me that the calcium content of the blood follows the same curve as the phosphorus content. Among earlier noted seasonal effects of sunlight, quoted by Hess in his latest paper, are the presence of increased iodine in the thyroid of cattle from June to November, and the greater resistance of guinea-pigs to aceto-nitrile poisoning in summer.

Hess and his workers have also begun the study of various clothing materials in this connexion, and find that they vary in their power of permitting or obstructing the action of light. Specimens of a mercerised cotton, one white and the other black, otherwise identical, the former allowing light to act and the latter interfering with it, have been examined by me, and I find no difference, due to the black dye, in the spacing between the fibres of the material. But I understand that the Department of Applied Physiology of the Medical Research Council has found, in a series of observations as yet unpublished, that the biological action of light can be graded by temperature. I am in hope that these specimens of material may be studied by the delicate methods associated with the name of Prof. Leonard Hill, and that it may be found that the black material produces a higher temperature than the white of the subjacent skin, thus prejudicing those unknown and beneficent chemical reactions which appear to need light and cold for their development.

The belief grows upon me that the asserted futility of heliotherapy in phthisis is due to the overheating of the patients in the sun. I think that a new chapter will open in the treatment of that disease when practitioners acquaint themselves with the principles and practice of heliotherapy before exposing their patients to the sun.

The power of sunlight and of cod-liver oil in rickets has suggested to Prof. Harden that the light may cause the skin to produce vitamin A for itself—though no instance of the synthesis of a vitamin by the animal body is known. The most recent work at the Lister Institute shows that light is unable to replace vitamin A completely, but appears to make a small quantity more effective. Miss Coward's work shows that vitamin A is present in the parts of flowers which contain carotin. Sir William Bayliss has suggested to me that the production of this vitamin in green plants is a function of the carotin rather than of chlorophyll, and that probably the carotin acts as a sensitiser for ultra-violet rays. In this connexion we must remember that pigmentation of the skin is a marked feature of the sun-cure, and that patients who do not pigment well do not progress well. No one who has seen and touched the typical pigmented skin of a heliotherapeutic patient can doubt that very active chemical processes are there occurring. Perhaps we should regard the skin less as a mere integument than as an organ of internal secretion. The pigmented skin under the sunlight is surely that; and we may ask whether it contributes, as Sheridan Delépine suggested,[5] to the making of hæmoglobin. I owe also to Sir William Bayliss the information that Dr. H. H. Dale, a member of his committee, has shown that smooth muscle can be made to contract by ultra-violet rays.

Aerial and other photographs of Manchester, and the Potteries, and of Sheffield, taken at successive hours on Sunday and Monday, demonstrate the obstruction of sunlight by our urban smoke, the industrial and the domestic chimney being both responsible: but while Sheffield deprives itself of more than half its sunlight, Essen is absolutely smokeless, and Pittsburg, which I have visited for the purposes of this inquiry, has abolished 85 per cent. of its smoke. Sections of the lungs of an agricultural labourer and a typical urban inhabitant of our country, the latter being heavily infiltrated with smoke, illustrate a cognate aspect of our subject.

Yet another point is illustrated by recent work of Hess, which shows that the milk of cows fed on pasture in the sunlight maintains the growth and health of young animals, whereas the milk of cows fed in shadow and on vitamin-free fodder will not maintain life. Our children are thus disadvantaged in winter by light-starvation, and by the defect of the milk of light-starved cows.[6]

Photographic study of houses and housing on both sides of the Atlantic illustrates the problem of urban light-starvation. Finding New York smokeless in 1919, I later made investigations with the aid of Dr. Royal S. Copeland, the Health Commissioner of that city, and found that the death-rate from pulmonary tuberculosis had been reduced by one-half in the period, 1905–1919, of the operation of the sanitary regulation against smoke.[7] The restoration of sunlight to our urban lives is the next great task of public health in this country.

"There is no darkness but ignorance," as Shakespeare said. In every sense we need "more light." Then we must apply our knowledge, less for heliotherapy than heliohygiene, until we have banished what I call the diseases of darkness, and it may be said of us that "The people that walked in darkness have seen a great light, and they that dwell in the land of the shadow of death, upon them hath the light shined."

[5] *Journal of Physiology*, vol. xii., 1891, p. 27.

[6] To some extent, Antipodean sunlight, in the form of dried milk from New Zealand, comes to the rescue.

[7] The smoke prohibited in New York, or in Winnipeg, where I found similar regulations, need not, as in our futile Public Health Act, be "black." See "The Eugenic Prospect" (Part II., "Let There Be Light"), by Dr. C. W. Saleeby. (Fisher Unwin, London; and Dodd Mead and Co., New York, 1921.)

Domestic Animals in Relation to Diphtheria.

THE perennial alarm of the possible transmission of diphtheria from diseased animals to man is again occupying the attention of the British daily press. This time it arose out of the death of a little girl who was thought by her mother to have contracted diphtheria from certain chickens which were kept in the house. The mother's view was supported by a medical man, who said that birds are subject to the germs of diphtheria and die of the disease. He had no doubt also that dogs and cats could have diphtheria, and he knew of instances of pigeons which had it.

The present writer has recently made an exhaustive critical analysis of the literature on this subject, and can state definitely that this bird, cat, and dog story is a pure myth. Diphtheria bacilli have been found on three occasions in cows (cases of Dean and Todd (1902), Ashby (1906), and Henry (1920)), and by two authors (Cobbett (1900) and Minnett (1920)) in horses. No proved diphtheria bacilli have ever been found occurring spontaneously in cats, dogs, or fowls. In 1920 Simmons obtained, from two cats, bacilli resembling diphtheria bacilli in man, but differing in the fundamental respect that they fermented cane sugar, which human diphtheria bacilli do not.

The belief that cats are frequently capable of transmitting diphtheria arose in Great Britain largely out of work done by E. Klein for the Local Government Board in 1889 and 1890. He based his opinion on the existence of spontaneous diphtheria in cats on the fact that a very fatty condition was found in the kidneys, a lesion which he regarded as pathognomonic of the disease in this animal. Before Klein published this statement it was already well known (Gluge (1850), Handfield Jones (1853), and Beale (1869)) that all normal cats show this lesion—a fact confirmed by modern writers like Hansemann (1897), Fibiger (1901), and Mottram (1915–16). In an extensive inquiry in 1919–20, Savage was unable to find, nor could any one produce, a cat infected with diphtheria bacilli.

The doctrine of milk-borne diphtheria was also largely based on Klein's work (1890). He alleged that when cows are injected with cultures of diphtheria bacilli in the shoulder, these diphtheria bacilli appear in the milk and the animals suffer from an eruptive disease of the udders and teats. Dean and Todd (1902) traced a milk-borne epidemic of diphtheria to cows with scabs on the udders. They showed that the eruption was not due to diphtheria, and they regarded the diphtheria bacilli found in the udder as a superposed infection from the saliva of an infected milker. In 1920 Henry studied an epidemic of thirty-two cases. The disease was traced to milk. The dairy-maid was found to be suffering from cutaneous diphtheria, and from her the udder became affected, this in turn transferring the disease to the hands of the maid's father.

So far as is known, these are all the positive facts of the animal transmission of diphtheria to man. We may therefore assume that it is an event of exceeding rarity. With regard to birds there is no proved instance that these animals have ever transmitted the disease. So-called croup and diphtheritis in birds have nothing to do etiologically with human diphtheria. It is not necessary to assume an animal origin of an outbreak of diphtheria until all possible human sources in the immediate neighbourhood have been excluded. This can be done only by cultivations, and not by the pious opinions of mothers and medical men without experience in bacteriology.

W. B.

Obituary.

Prof. E. Majewski.

The late Prof. Erazm Majewski, the Polish naturalist, who died on November 15 last in Warsaw, was a scholar and pioneer worker of a type characteristic of the difficult and discouraging conditions in pre-War Poland—a country divided by three alien states, two of which forbade the use of the native language, even in the primary schools, excluded native teachers, and suppressed native culture.

Born in 1858, in the provincial town of Lublin, Prof. Majewski studied science at the University of Warsaw. In order to devote himself to research, to which he had felt attracted from earliest youth, he had first to gain a financial independence, for at that time there were no endowments, no academic positions, no possibilities of scientific publication for a Pole who wanted to work in his own language and for his own country. Prof. Majewski took up and developed an important branch of chemical industry and thus obtained a living at first, and afterwards what, for Polish conditions, might be considered a small fortune. With this he could not only find leisure for his own research, which soon became very strenuous and extensive, but he also was able to finance research and help a number of younger students.

Prof. Majewski's own activities were astoundingly multifarious: translations into Polish, popular expositions, manuals, monographs, scientific novels, treatises, and last, not least, solid original contributions, partly based on research in the laboratory and in the field. The subjects of his work were commensurately extensive: chemistry, botany and geology; later on, ethnography, prehistory and archæology; finally, in the last ten years of his life, economics, sociology, and history of civilisation. Perhaps the most lasting value will be retained by his archæological and prehistoric studies, through the impetus which he gave to excavation and collecting, through the foundation of an excellent periodical (*Swiatowit*), which he financed and edited himself, and through the formation of a large and valuable collection of Slavonic archæology, presented in 1921 to the Scientific Society of Warsaw.

All Prof. Majewski's work reveals a man of genius in the marvellous grasp of each problem touched upon, in the original and independent point of view, in the amazing power of study and assimilation. It shows, of course, also the defects of its qualities: such enormous output over a wide range is bound to entail a certain degree of dilettantism, many hasty generalisations, and a tendency to avoid all negative evidence. All the defects of the late Prof. Majewski's work, however, are due mainly to the unfavourable conditions under which he worked: absence of scientific organisation, of co-operation and of division of work, all of which leads to the unlimited pegging out of claims over the vast territory of science by an enterprising and independent mind, to lack of self-criticism, to an easy lapsing into over-ambitious schemes. The qualities which he possessed, on the other hand, are native and intrinsic to his own mind, and entitle us to hope that his country, which can produce such people as he under the most discouraging conditions, will, when its political and economic foundations are once more secure and its scientific work organised, be able to contribute its due share to the progress of science.

B. M.

Dr. Hartwig Franzen.

On February 14 the death occurred at Karlsruhe, Baden, of Dr. Hartwig Franzen, extraordinary professor of organic chemistry at the Technical High School.

Hartwig Franzen was born on March 21, 1878, at Nortorf, Holstein; he studied at Heidelberg, Berlin, and Copenhagen, graduating in 1901 at Heidelberg and becoming a private lecturer in chemistry at that university. His first work was published in collaboration with Th. Curtius, the discoverer of hydrazine and hydrazoic acid (azoimid), whose favourite pupil he was. In 1910 he became extraordinary professor and was called in 1912 to the Technical High School at Karlsruhe as sub-director of the organic chemistry institute. Franzen worked on gas analysis and embodied his results in his "Practicum," which was published in 1907. He also investigated the hydrazine compounds and problems in the chemistry of fermentation and the physiology of plants. Many of his publications deal with the constituents of green plants. Franzen was a well-known investigator and an efficient teacher. His early death leaves a great gap in the ranks of the younger German chemists, and his numerous friends and pupils will faithfully preserve his memory.

We regret to announce the following deaths:

Mr. F. W. Harmer, for more than fifty years a fellow of the Geological Society and well-known for his studies of Pliocene mollusca, on April 24, aged eighty-seven.

Prof. G. D. Hinrichs, formerly professor of physical science in the University of Iowa and of chemistry at the St. Louis College of Pharmacy, aged eighty-six.

Sir Albert J. Hobson, pro-chancellor of the University of Sheffield and for twenty years a member of the council of the University, on April 20, aged sixty-one.

Prof. V. Th. Homén, Pippingsköldsche professor of applied physics in the University of Helsingfors, aged seventy-five.

Dr. A. Latham, physician and lecturer in medicine at St. George's Hospital, who was known for his work on pulmonary consumption, on April 13, aged fifty-six.

Prof. E. W. Morley, professor of chemistry at Western Reserve University from 1869 until 1906 and known for his part in the Michelson-Morley experiment to detect motion of bodies through the æther, aged eighty-five.

Sir John Watney, chairman of the Council of the City and Guilds of London Institute, on March 25, aged eighty-nine.

Mr. J. Wright, well-known for his work on Irish foraminifera and carboniferous fossils, on April 7, aged eighty-nine.

Current Topics and Events.

The "Zoological Record," which for nearly sixty years has annually supplied zoologists with bibliographical references to the literature of their subject, and in particular has performed the task of recording the names of new genera and species introduced each year, is threatened with extinction. Although the responsibility for producing the Record was temporarily shared with the International Catalogue, which has ceased to exist, the credit for its publication, during recent years, has otherwise belonged exclusively to the Zoological Society, which has thus earned the gratitude of workers in all parts of the world. The decision of the council of the Society to cease publication, except on certain terms which are explained in another part of this issue, will be received with regret and consternation by a large number of investigators. It is urgently necessary that a combined effort should be made to save this invaluable serial, and those interested are invited to communicate with Sir Sidney Harmer, at the British Museum (Natural History). Suggestions will be welcomed, but it is hoped that many will be able to express their sympathy in a practical form, by undertaking to subscribe for the annual volumes or for the separate parts in which they are individually interested, or by giving assistance of an even more direct nature.

The treatment of diabetes by the use of the extract of the pancreas known as "insulin" is now made more widely possible by the fact that it has been put upon the market by the British Drug Houses in conjunction with Messrs. Allen and Hanburys, Burroughs, Wellcome and Co., and Eli Lilly and Co. On account of the limited supply as yet available, the Medical Research Council has made certain recommendations to the Ministry of Health with regard to its economical use. The Minister has appointed the following committee to advise him on the subject: Sir George Newman, Dr. R. A. Bolam, Sir Walter Fletcher, Sir Humphry Rolleston, Dr. Alfred Salter, and Dr. McCleary. This committee, which can be addressed at the Ministry of Health, Whitehall, has recommended that insulin should be supplied only to hospitals and medical practitioners who have at their disposal means of determining the sugar content of the blood. Those to whom the preparation is supplied shall undertake to make observations of the changes in the amount of sugar in the blood in correlation with the dose of insulin given. It shall not be given where the symptoms can be controlled by moderate restriction of diet. It may, however, be given in coma, as an emergency treatment, or in preparation for a surgical operation. Detailed instructions for its use and for obviating the results of too large a dose are supplied by the makers with each sample.

A member of an Indian Provincial Legislative Council was reported recently to have demanded that the budget allotment for combating hookworm disease should be cut out because, as ninety per cent. of the people suffered from this serious disability, "it was a normal state of health and there was no meaning in spending money on investigation and prevention of the disease." The demand revealed a dangerous depth of ignorance, or, what is worse, a perversion of knowledge—for the speaker was an Indian doctor—which is only equalled by that of another member asking not long ago what steps a Provincial Government proposed to take to diminish the deaths due to lightning! Unfortunately, the Retrenchment Committee has recently recommended decentralisation of medical research in India, with consequent dependence of all grants for its support being voted annually by the large Indian Council majorities. The qualifications for such serious responsibility can be gauged by the above examples, and they are combined with administration by an Indian Minister who is very unlikely to look beyond his own province and race for research workers. Moreover, the original grant of five lakhs of rupees (33,000*l.*) a year for medical research was cut down to 3½ lakhs during the War, and is now recommended to be abolished. In its place the 33 lakhs accumulated by the Indian Research Fund Association during the War, and ear-marked for a new research laboratory in Delhi, is to be capitalised to bring in about two lakhs a year for the full support of the bacteriological department, which is to be deprived of twelve of its officers—more than one-third of the total number—the whole savings from this small department being disproportionally great as compared with many far less valuable and life-saving forms of expenditure. The future of medical research in India will be dark indeed if such large reductions in finance and personnel are effected, and still more so if the remaining funds are to be placed at the mercy every year of the large Indian majorities on all the Provincial Councils, few of whom have had the slightest scientific knowledge or training.

The first congress of Polish Chemists and Physicists met in Warsaw on April 3. With a total membership of about 850, this meeting has taken a high place among recent Polish scientific congresses, and the organising committee is to be congratulated upon the brilliant success achieved. A large gathering of scientific and industrial chemists and physicists, together with representatives of the Government, the Municipality of Warsaw, and of various societies and corporations, filled the Great Hall of the Technical High School of Warsaw on April 4, when the meeting was welcomed by Dr. Mikulowski Pomorski (Minister of National Education), and short scientific addresses were delivered by Prof. Ladislas Natanson (Rector of the Jagellonian University of Cracow), and by Profs. Marchlewski, Bialobrzeski, and Moscicki. The scientific proceedings of the sections were full of interest; about 120 papers were read in various chemical sections and about 36 in the section of physics; there were many communications showing serious work and real progress. Particularly interesting, in the section of physics, were communications by Profs. Pienkowski, Zakrzewski, Wolfke, and Reczynski on experimental investigations in progress in various University laboratories in Poland. The meeting concluded on April 6 with an address delivered by Prof. Tolloczko, and the usual votes of thanks. The hearty reception accorded to scientific men coming from all parts of Poland was much commented upon by those who attended this very successful meeting.

The first conversazione of the Royal Society this year will be held at the Society's rooms, Burlington House, on Wednesday, May 16.

The *Times* announces that the Anthropological-Geographical Society of Stockholm has conferred the Anders Retzius Medal in gold upon Sir Aurel Stein for his archæological research in Central Asia.

The twenty-ninth James Forrest lecture of the Institution of Civil Engineers will be delivered on May 4 by Sir Richard Glazebrook, who will take as his subject "The Interdependence of Abstract Science and Engineering."

Dr. H. H. Dale will deliver two Oliver-Sharpey lectures at the Royal College of Physicians of London on May 1 and 3, at 5 o'clock, taking as his subject "The Activity of the Capillary Blood-vessels, and its Relation to certain Forms of Toxæmia."

The Adolph von Baeyer Memorial lecture will be delivered before the Chemical Society by Prof. W. H. Perkin, in the Lecture Hall of the Institution of Mechanical Engineers, Storey's Gate, S.W.1, on Thursday, May 10, at 8 p.m.

The Secretary for Mines has appointed the following to be additional members of the Safety in Mines Research Board: Prof. W. S. Boulton, Prof. S. M. Dixon, Dr. J. S. Haldane, Prof. C. H. Lees, and Prof. J. F. Thorpe.

The Chemical Society Research Fund Committee will meet early in June. Applications for grants should be made on forms obtainable from the Assistant Secretary, Chemical Society, Burlington House, Piccadilly, W.1, and must be lodged with the Assistant Secretary by June 1.

Applications for grants in aid of scientific investigations bearing on agriculture to be carried out in England and Wales during the academic year beginning on October 1 next should reach the Secretary, Ministry of Agriculture and Fisheries, Whitehall Place, S.W.1, by, at latest, May 15. The applications must be made upon form A. 230/1, copies of which can be obtained from the Secretary to the Ministry.

Applications are invited by the Ministry of Agriculture and Fisheries for a limited number of research scholarships in agricultural and veterinary science, tenable for three years and each of the annual value of 200*l.* The latest date for the receipt of applications, which must be made upon a prescribed form, is July 15. The form and particulars concerning the conditions of the scholarships are obtainable from the Secretary, Ministry of Agriculture and Fisheries, Whitehall Place, S.W.1.

An election of not more than six junior Beit Memorial fellows for medical research will take place in July next, and the persons elected will be required to begin work on October 1. Each fellowship is of the annual value of 350*l.*, and the usual tenure is three years. The latest date for the receipt of applications is June 1, or, in the case of candidates giving residents abroad as referees, May 15. Forms of application and all information may be obtained by letter only addressed to Sir J. K. Fowler, Honorary Secretary, Beit Memorial Fellowships for Medical Research, 35 Clarges Street, W.1.

Dr. Edward P. Hyde, who organised the Nela Research Laboratories in 1908, and for the past few years has occupied the position of director of research of the National Lamp Works of the General Electric Co., Cleveland, has tendered his resignation, to take effect on June 30. Dr. Hyde, who has been active in scientific and technical affairs for a number of years, has decided to take a prolonged rest abroad. He will temporarily discontinue many of his activities in scientific and engineering societies, but will retain the office of president of the International Commission on Illumination until its plenary meeting, to be held in the United States in 1924.

In connexion with Dr. Simpson's Royal Institution discourse on "The Water in the Atmosphere," published in Nature of April 14, Prof. A. W. Bickerton writes to suggest an alternative formation for hailstones which have the form of cones mounted on hemispherical bases. It is suggested that these may be formed by the freezing of raindrops which solidify first on the outside, then, as the core freezes, the expansive pressure bursts the spheres along the lines of minimum resistance, these being the lines of a pentagonal dodecahedron. The difficulty of this explanation is that soft hail, to which reference was made by Dr. Simpson, forms above the region where raindrops are met with. Also the "stones" of soft hail are frequently so large that the mass of twelve of them would be much greater than the mass of the largest possible raindrop—which has a diameter of less than half a centimetre.

The Gifford Lectures delivered in 1922 by Prof. C. Lloyd Morgan will shortly be published by Messrs. Williams and Norgate under the title of "Emergent Evolution." Among the chapter headings are the following:—emergence, mental and non-mental, relatedness, reference, memory, images, towards reality, vision and contact, relativity, causation and causality, and evolutionary naturalism.

Messrs. Sotheran's Catalogue of Science and Technology is always of bibliographic interest and value, being carefully classified, and containing informative annotations to many rare volumes offered for sale by the publishers of the catalogue. The latest part is No. 783, dealing with mathematics. It should be seen by all who take an interest in the subject. The catalogue is obtainable from H. Sotheran and Co., 140 Strand, W.C.2.

Our Astronomical Column.

The Planet Jupiter.—This planet will arrive at opposition to the sun on May 5, when its distance from the earth will be about 410 millions of miles. It is now visible during the whole night, and is favourably situated for telescopic examination. The Great Red Spot in the southern hemisphere remains faintly visible, and a slight increase in its rotation period has occurred in the last few years. Its present longitude is 228°, so that it precedes the zero meridian of System II. by about 3 h. 38 m. Observations of the transits of this marking will be valuable, and may be witnessed at about the following times:—

	h.	m.			h.	m.	
April 29.	8	47	G.M.T.	May 8.	11	6	G.M.T.
May 1.	10	21	,,	,, 11.	8	37	,,
,, 3.	11	59	,,	,, 13.	10	15	,,
,, 6.	9	28	,,	,, 18.	9	22	,,

The extensive dusky marking, known as the south tropical disturbance, is now in contact with the following end of the Great Red Spot, and it will be interesting to watch this object, as it passes the Red Spot in ensuing months.

From recent observations by Mr. F. Sargent of the Durham University Observatory, it appears that the rotation period of the south edge of the South Equatorial belt of Jupiter shows an abnormal period of $9^h\ 52^m\ 37^s$. This latitude on Jupiter falls between the two well-known currents, on which Systems I. and II. were based, the periods being $9^h\ 50^m\ 30^s$ and $9^h\ 55^m\ 40{\cdot}6^s$ (Nautical Almanac, 1923, p. 568-71).

The unusual time of rotation was derived from a mean of three markings, but the observations extended over too short an interval to obtain exact results. There is no doubt, however, that there is an intermediate current between that in which the Great Red Spot is situated and the equatorial markings, and it will be important to follow the objects seen by Mr. Sargent which on March 29 were in longitudes from 309·7° to 325·1° (System I.).

Spectra of Three O-type Stars.—Dr. H. H. Plaskett contributes to the Publications of the Dominion Astrophysical Observatory (vol. 1, No. 30) an important research on the spectra of three O-type stars. These stars show enhanced line spectra which can only be reproduced terrestrially under extreme conditions of excitation. Their spectra thus afford an opportunity for testing theories on the origin of spectra and for ascertaining some of the physical conditions in stellar atmospheres. The stars in question were 10 Lacertæ (Oe 5), 9 Sagittæ (Oe 5) and B.D. 35° 3930 N (Oe) and their spectra were secured with the universal spectroscope attached to the 72-inch reflector using one-, two- and three-prism dispersion. Dr. Plaskett first points out that if the Pickering lines (ζ Puppis) are due to enhanced helium, Bohr's theory predicts the existence of enhanced helium components about 2Å to the violet of the hydrogen lines. He then gives his evidence for showing that those predicted components are present in his spectra, which demonstrates that the Pickering lines and λ 4686 are due to enhanced helium.

In two of the stars Dr. Plaskett employs the mean wave-lengths of the enhanced helium lines for the determination of the value of the Rydberg constant N_2 for helium, and deduces the values of Planck's constant and the mass and charge of the electron. Those values he compares with recomputed values from Paschen's value of N_2 and with results from other methods of determination. He deduces the temperatures of the O-type stars under discussion and gives the following values: 9 Sagittæ, 18,500° K; 10 Lacertæ, 15,000° K; and B.D. 35° 3930 N, 22,000° K. He finally suggests a modification of the Harvard Classification of the O-type stars as follows:

Class Oo, Pickering lines disappeared; Class O5, (B.D. 35° 3930 N) ordinary helium disappeared; Class O7 (9 Sagittæ) Mg +, 4481 missing; Class O9, Si III +, pair 4552, 4567, on the point of appearing.

Research Items.

Excavations at Ancient Carthage.—A correspondent writing in the *Times* of April 9 describes the result of excavations on the site of ancient Carthage conducted by a party of Americans working in co-operation with French archæologists. Their work is timely, as the site of this city is in danger of becoming a modern suburb of Tunis. Within the city itself the remains of two sanctuaries and the potters' quarter have yielded some sculptured stones and numerous specimens of pottery. But the most important discovery is an underground corridor through which a supply of water passed, and some rock-cut tombs, containing statues, two on recumbent stone coffins of Greek work, and others showing that the Carthaginians were dependent for their art on Greece and Egypt. It is hoped that further exploration will throw light on the Roman buildings and North African architecture during the Christian period.

Clash of Ideals in Modern India.—The Earl of Ronaldshay, Governor of Bengal, 1917–22, delivered an interesting address before the Indian Section of the Royal Society of Arts, which is printed in the Society's Journal (vol. lxxi., No. 3, 665), on the situation in India. The motive force of the native movement is " fear lest before the triumphant assertiveness of Western civilisation all that is essentially and distinctively Indian is doomed to perish and utterly to disappear." As regards education, there is dissatisfaction with the present system, but it is not easy to discover what it is that Indians desire to see taking its place. There is an emphatic demand for vocational or practical instruction—they object to the present courses as displaying a Western bias; the demand in Bengal for medical training is clamorous and widespread, " and many Indians who are far from being hostile to the British connexion desire to see a more distinctly Indian orientation given to the education imparted to their people." The address, which deserves attention, takes, on the whole, an optimistic view of the present situation.

Psychology and Criminal Responsibility.—In *Psyche* (vol. iii., No. 2) Dr. W. Brown discusses the attitude of modern psychology to responsibility. He shows that there is a tendency for those who understand incompletely the aims of modern psychology, to believe that a general spread of its doctrines will result in a weakening of the sense of moral responsibility. He discusses the legal definition of responsibility and describes cases where a crime of violence may be committed for which the person cannot be held responsible. The psychologist, as such, is concerned with the problem of studying the causes in the history of the person which have led to the act, and the contribution of recent work is in the direction of tracing the influence of the acts and phantasies of infancy and childhood; it appears not infrequently that the people answerable for the victim's upbringing were really responsible. Modern psychology does not contest the reality of moral responsibility. While it holds the view that criminals suffering from certain forms of mental disease are less fully responsible than are normal people, it does not countenance the view that all criminals suffer from mental illness, nor that mental illness is an invariably sufficient excuse for crime.

The Alphabet used in Writing Malay.—There is no record of the Malay language having been written until the Arabs reached Indonesia, the oldest existing documents being written in the Arabic character, which is still largely used. After the Arabs came the Portuguese, Dutch, and English, and each nation adopted its own system. It has been felt for a long time that it would be a convenience if a uniform system of spelling were adopted. Hitherto the choice has lain between Arabic characters and the Dutch or English spelling, none of which are quite satisfactory. Mr. C. H. Pownall in a pamphlet entitled " The Writing of Malay " (Cambridge, W. Heffer and Sons, Ltd.) suggests that the system known as " Peetickay," advocated by Dr. W. Perrett in a book issued by the same publishers in 1920, should be adopted. It possesses the special advantage that those who suffer from writer's cramp find it a great relief, as the pen is more frequently raised from the paper than in ordinary writing. Mr. Pownall regards this system as preferable to the symbols used by the International Phonetic Association: but it does not seem probable that a conservative oriental race will be inclined to adopt a new system instead of the systems to which they are accustomed. In the end, in spite of certain difficulties, English will hold the field.

The Laws of Vision and the Technique of Art.—In his treatise on landscape painting, Birge Harrison shows that a picture is most artistic when it reproduces our retinal impressions, and his theme has been taken up and developed by Messrs. A. Ames and C. A. Proctor and Miss Blanche Ames in an interesting paper published under the auspices of the Rumford Fund in the February issue of the Proceedings of the American Academy. The retinal picture is less distinct at the edges than at the centre and is distorted in the " barrel " manner, while the retina itself is more sensitive to blue near the edge than at the centre. When a photograph of a landscape or building taken with a camera having a lens with the same properties as the eye is compared with one taken with a corrected lens, that taken with the artificial eye produces the more artistic effect. On examining a number of pictures by distinguished artists, the authors have found evidence of the use—conscious or unconscious—of the technique suggested by these laws of vision by da Vinci, Rembrandt, Israels, Millet, Turner, Whistler, De Hoogh, and others, but only by one living artist—Orpen. The authors urge that the retinal picture should be made the basis of the technique of art.

Classification of Cirrus Clouds.—In *Geografiska annaler*, 1922, 3-4, Mr H. H. Hildebrandsson has a short paper in which he discusses an international terminology for the various kinds of cirrus clouds. After full consideration of the forms of cirrus described by L. Besson, C. J. R. Cave, A. W. Clayden, C. Ley, J. Loisel, l'Abbé Maze, H. Osthoff, and J. Vincent, all the classifications of whom are summarised, Mr. Hildebrandsson proposes seven main types. Some of these are rare and none is common in its typical form, but they serve as a basis of a classification to which all cirrus can be referred. The seven types, each of which is briefly described and in many cases illustrated, are uncinus or caudatus, vertebratus, pennatus, filosus, confertus, floccosus, and nebulus. The names have the merit of being indicative of each type, and are easily remembered. The classification certainly seems to be sounder than some former ones which recognised a dozen or more main types.

Climatological Normals for Egypt and the Sudan.—The Physical Department of the Ministry of Public Works, Egypt, has issued a book of normals which comprises 63 stations, and in addition to the Egyptian and Sudanese stations, it includes seven stations in Cyprus, one in Crete, and one in Abyssinia. Many of the normals cover a period of 20 years. Normals for rainfall are given for 76 stations, for the total number of years for which trustworthy records are available. It is said not to be uncommon, especially in the Sudan, for the relative humidities to fall below 10 or even 5 per cent. Wind force given throughout is stated to be in terms of numbers on the Beaufort scale. The scale is given as 0–10, but Beaufort scale should be 0–12. The equivalents in miles per hour given for the scale 0–10 is in fair agreement with the Beaufort values 0–10 given by the British Meteorological Office. The percentage frequency of wind direction is given for most stations. Most of the Egyptian stations have single louvred screens; this seems scarcely satisfactory, especially for a hot country. Monthly maps are given for isobars and prevailing winds, for air isotherms, and for rainfall. The tables of normals are of great value to the world's meteorology. The absolutely highest temperature on a single day at many stations exceeds 120° F. and in places even touches 130° F. On the coldest day in winter frost is exceptional in the shade to the south of 20° N. Rainfall for a single day is occasionally more than the average total fall for the month; there are two instances of 11 inches and more in the 24 hours—at Alexandria in December 1888 and Tombé in the Sudan in July 1914. A rainfall map intended as a frontispiece will be issued separately.

PEAT IN THE UNITED STATES.—Though peat is still looked on with hesitation as a source of industrial fuel in the near future, every national geological survey is attracted by the numerous schemes for its exploitation. That of the United States has issued Bulletin 728, on "The occurrence and uses of Peat in the United States," by E. K. Soper and C. C. Osborn (1922). The maps record very considerable deposits in the regions of more temperate climate, as in Minnesota towards the Canadian border. It is pointed out that, contrary to popular belief, the Mississippi basin is poor in peat, owing to the high temperature, which accelerates the decay of vegetation, and the frequent floods, which deposit sheets of alluvium. Some of the plates illustrating the infilling of basins of various types introduce unusual scenes, such as the Dismal Swamp, with its decaying forest, in the Virginian coastal plain. When we come to the treatment of peatlands for raising crops, we find that the customary advice is given, to clear away the upper peat as much as possible, to drain thoroughly, and to add materials that will provide the land with something like a reasonable soil. The case is familiar to us through agriculture in the English fenlands. The Bulletin forms a good handbook for the appreciation of lowland peat-deposits by the student.

GENETICS OF PRODUCTIVITY.—In a study of productiveness in apple trees, Sax and Gowen (Bull. 305, Maine Agric. Expt. Sta.) show that this quality is closely associated with habit of growth, although soil differences in an orchard also play a part. They also show (Bull. 307) that many commercial varieties of apples are self-sterile and that insect visits are essential for the setting of fruit. They recommend the interplanting of different varieties which are inter-fertile and flower at the same time. In two other papers (Bulls. 301 and 306) on milk production in Holstein-Friesian cattle, a further study is made of the transmitting powers of sires for milk production, and of the relative merits of a 7-day or a 365-day test for the relation between milk yield and percentage of butter-fat. That the daughters of different sires inherit differences in their milk production is well known. But pedigree results show that the cattle breeder's principle that "like begets like" is not a sufficient one to follow in breeding for milk production.

MOULDS ON MEAT IN COLD STORAGE.—On behalf of the Food Investigation Board, F. T. Brooks and M. N. Kidd recently published, in Special Report No. 6 of the Board (1921), an account of the "black spot" produced upon meat in cold storage by the activity of moulds. In this report it was demonstrated that the moulds responsible for the discoloration could grow and reproduce, although the meat was kept at −6° C. F. T. Brooks and C. C. Hansford have now published the more interesting mycological results of this valuable piece of applied research in the Transactions of the British Mycological Society, vol. 8, Part III., pp. 113-142, 1923. They conclude that *Cladosporium herbarum* is the species responsible for all the cases of "black spot" on meat they have observed, and that *Hormodendron cladosporiodes* is identical with it. This Cladosporium appears to occur very generally on vegetable refuse as well as on meat, and to be very variable in habit, so that a careful control of its structure and growth on a wide range of culture media is necessary for its identification. Many of its forms appear to have been described as species. Among the other moulds growing on cold stored meat two new species, *Sporotrichum carnis* and *Torula botryoides*, have been isolated; while on one occasion a new genus turned up in a woolly patch of mould present on a consignment of skinned Australian rabbits. In view of the laboratory from which the present work is issued, it is appropriate that the authors have named the new genus Wardomyces in memory of the late Prof. Marshall Ward.

THE SPREAD OF RUSTS UPON CEREALS.—With work proceeding for the new Ph.D. degree at many British Universities, we shall probably have many theses published in which essentially British problems are materially elucidated by overseas investigators. Certainly Karm Chand Mehta, now professor of botany at Agra College, India, as a result of his work at Cambridge under the direction of Mr. F. T. Brooks, has given us a most valuable study of the methods by which cereals are attacked year after year by the various species of the rusts (now published in the Trans. Brit. Mycological Soc., vol. 8, Part III., pp. 142-176, 1923). The rusts are quite unable to grow as saprophytes, hence there is great difficulty in their continued maintenance in pure culture, and much discussion as to the method by which these fungi maintain themselves through the winter when their normal host plant is harvested in the autumn. These parasites were some of the first microscopic forms in which a well-marked life cycle was traced with essential stages in two separate host species, often plants of widely different nature, and in the case of the black rust of wheat, *Puccinia graminis* Pers., the present paper supplies further evidence for the truth of an oft-contested thesis that the wheat plants may be infected from the accidial stage upon the winter host, the wild barberry. In the case of the other rusts of wheat, brown rust, *P. triticina* Erikss., and yellow rust, *P. glumarum* Erikss. and Heun, the observations and experiments here recorded show the significance of the self-sown seedlings of the wheat left in the ground after the harvest; upon these the fungus persists and the uredospores formed upon them are the main source of infection of the new crop. This paper, as some earlier classic papers from the Cambridge laboratory, is fundamentally opposed to the point of view of the great Scandinavian mycologist Eriksson, who has assumed that the fungus must persist through the life-cycle of the host plant as an undetectable protoplasmic contamination, "mycoplasm," intermingled with its own living substance.

Artesian Water in Australia.—In the report for 1921 of the Director of Mines and Government Geologist for South Australia, there is included a useful map of the principal artesian basins of Australia, made in connexion with the interstate conference on artesian water which met at Adelaide in September 1921. The map is of special interest in showing the isopotential lines or the heights above sea-level to which the water will rise. These lines have been accurately determined in many parts of the great artesian basin, especially in New South Wales and Queensland. They are less certain in parts of South Australia, but they are sufficiently accurate to show the absence of any concealed south-westerly outlet. The basin as a whole has marginal intake beds surrounding it. Fragmental isopotential lines for the Murray river basin have been embodied in the map. The scale of the map is too small to allow detail in the case of the basins of Willochra valley, Port Pirie, Cowell, and Adelaide plains. There is a lack of information in the case of the Eucla basin, but from the variable salinity of the water it would seem to be derived from more than one source in the sandy desert.

Generalised Optical Law.—Part 1 of volume 24 of the Transactions of the Optical Society contains the generalised optical law communicated by Mr. T. Smith to the Society in December last and called by him the optical cosine law. It includes as special cases the law of refraction, the coma sine law, the axial displacement and other exact laws of optical instruments, and runs thus: If I is the angle of inclination of a ray to a chosen fixed direction in the object space and I′ the inclination of the emergent ray to a chosen fixed direction in the image space, then the rays for which $\cos I = p \cos I' + q$ where p and q are constant touch caustics S in the object and S′ in the image space, and if S be displaced a small distance s along the fixed direction in the object space to S_1 the image caustic S′ will move along the fixed direction in the image space through a distance s', where $n's' = nsp$ and n n' are the refractive indices of the object and image media. The application of this generalised law to the construction of a telescope aplanatic at all magnifications is given as an illustration.

Wind Steadiness in the Upper Air.—To the March number of the *Meteorological Magazine* Mr. H. Harries contributes some curious facts about the flights of toy balloons in "races" organised by Major MacLulich at Brighton during the summer of 1922. On August 23 two balloons were liberated together, and next morning they descended in the little village of Marcel par Vitrey, Haute Saône, having travelled in company S. 51° E., 295 miles. On September 21 two others started together in a dead calm, made a perpendicular ascent of about 2000 feet, and disappeared in a cloud. Within 12 hours both dropped in the streets of Cassel, Germany, the course and distance being N. 85° E., 365 miles, at a rate of 30 miles an hour. Numerous balloons were sent off on September 9, under well-marked anticyclonic north wind conditions. The cards of 43 of them were recovered within a small area in the north of France, nearly all having followed a course between S. 2° E. and S. 5° E. They had attained an altitude where the wind was of gale force, one of the balloons, found 2½ hours after its despatch, having covered 108 miles, at a rate exceeding 43 miles an hour. Of a different character were the flights of September 13, the balloons being liberated in front of a cyclone approaching Brighton from the midland counties. The cards of 20 were returned, and of these 15 were drawn into the cyclone and descended in various places in Kent, Essex, Suffolk, Bucks, and Berks—the greater part of the circuit of the cyclone. The other five, apparently attaining a higher altitude, were caught in a westerly, veering north-westerly, current, which carried them to north-eastern France. One dropped at St. Ouen, Paris, 226 miles distant from another despatched at the same time, which descended at Thatcham Park, Stowe, Bucks.

Active Hydrogen and Chlorine.—In the Proceedings of the Science Association, Maharajah's College, Vizianagram, published in December 1922, Mr. Y. Venkataramaiah gives an account of some further experiments he has made on active hydrogen. Hydrogen gas obtained by the action of heat, and of water, on sodium hydride, as well as hydrogen gas which had bubbled through molten sodium, reacted with sulphur in the cold, and therefore contained active hydrogen. Similar results were obtained with potassium and calcium. Other methods for the activation of hydrogen (burning oxygen in hydrogen, surface combustion of hydrogen and oxygen on platinum, high tension arc in hydrogen, high temperature arc in hydrogen, and the passage of hydrogen through heated platinum and palladium) are described in further papers. In the same journal Mr. Venkataramaiah describes the activation of chlorine, prepared by heating gold chloride and dried with phosphorus pentoxide, by the silent discharge, by electric discharges in the gas, by ultra-violet light, and by the heat of an electric arc. The gas combines with ozone to form Cl_2O, with sulphur to form S_2Cl_2, and reacts with benzene in the dark to form $C_6H_6Cl_6$.

The Herbert Pendulum Hardness Tester.—Two points to be looked for in a "hardness" tester are simplicity of operation and results independent of the mass and thickness of the specimen. These are among the desirable features of a new instrument made by Messrs. Edward G. Herbert, Ltd., of Manchester, others being portability and the immunity of the specimen from damage due to testing. Thin strip, case-carburised steels, minerals, and glazes on pottery thus come within the scope of the machine. The apparatus consists of an arched casting weighing 4 kg., surmounted by a curved spirit-level graduated from 0 to 100. It is supported on the specimen by a 1 mm. ball fixed beneath the centre of the arch. With the standard setting the instrument has its centre of gravity 0·1 mm. below the centre of the ball, and is thus free to oscillate. "Scale tests" are made by placing this rocker normally on the specimen and tilting it until the level-bubble reads 0. On releasing the instrument the graduation to which the bubble floats is the "Scale Hardness Number" (*e.g.* glass 97, mild steel 30). The recommended "Time tests" are made by causing the "pendulum" to oscillate and noting with a stop-watch the time for ten swings. Strange to say, while mild steel requires 20 seconds, the "Time Hardness Number" of glass is 100 seconds. Both tests, then, depend upon the degree of indentation of the specimen, and a time factor appears to be involved. There is good agreement between successive determinations. While the instrument detects "strain-hardness," it does not appear to indicate relative machining properties. The high ranges of the time hardness scale may be opened out by raising the centre of gravity of the "pendulum," and altogether the system presents many important possibilities.

The "Zoological Record."

With the exception of the "Archiv für Naturgeschichte," which is about nine years behindhand and consequently of very little use, the "Zoological Record" is at present the only bibliographical guide to zoological literature being published in the whole world. In the annual report which the Council of the Zoological Society will lay before the forthcoming annual general meeting it is recommended that the Society shall not undertake the printing of any further volumes after the issue of the one in hand unless it receives substantial assistance towards meeting the cost. It is estimated that the cost of preparation and printing is 1900*l.*, towards which about 800*l.* is received from sales and subscriptions, leaving a net cost of 1100*l.*

With the object of ascertaining the views of other societies interested in scientific zoology on the question, a meeting of representatives was held in the Board Room of the Natural History Museum on April 16. In the absence of Sir Sidney Harmer, the director, owing to a family bereavement, the chair was taken by Lord Rothschild, a Trustee of the Museum and himself an eminent zoologist. Among the institutions and societies represented were the following: Linnean Society, Geological Society, Marine Biological Association of the United Kingdom, Imperial Bureau of Entomology, British Ornithologists' Union, British Ornithologists' Club, Royal Society of Tropical Medicine and Hygiene, Wellcome Bureau of Scientific Research, Malacological Society, Conchological Society, Challenger Society, Entomological Society of London. Letters urging the need for the "Zoological Record" were received from representatives of the Tropical Diseases Bureau, Liverpool School of Tropical Medicine, and the Universities of Cambridge, Durham, Birmingham, and Wales. The meeting was unanimously agreed as to the imperative need for the continuance of the Record, and authorised Sir Sidney Harmer to form a committee of those interested to confer with the Zoological Society as to the arrangements for carrying on the work.

In response to a question as to the attitude of the Trustees of the British Museum, Lord Rothschild stated that they had ordered the following statement to be sent to the Zoological Society for use in support of its appeal for assistance:

"The Trustees of the British Museum recognise the great value of the services rendered to science by the Zoological Society, which has for some years produced the annual volumes of the 'Zoological Record.' The indexing, year by year, of the names of newly-described genera and species, and of alterations in the names of others, may be regarded as an absolutely essential adjunct to work in this science. Although primarily of importance to systematists, the establishment of a correct nomenclature and the recording of new names are quite as necessary to workers in other branches of zoology, who are ultimately dependent on the systematists for the discrimination of the species with which they deal. With the accumulation of an enormous body of new facts, increasing in amount each year and much of it hidden away in the pages of publications which are difficult of access, the study of zoology is peculiarly dependent on having the record kept complete and up-to-date. The work of future naturalists would become almost impossible if each investigator had to make for himself a complete survey of the literature of his subject, published during many years without being indexed. The Trustees are accordingly of opinion that the continued publication of the 'Zoological Record' is indispensable to the progress of zoology. They have heard with regret that the Council of the Zoological Society is unable to undertake the sole financial responsibility for the appearance of the annual volume, and they have no hesitation in expressing their conviction that in these circumstances a strong effort should be made to obtain contributions from scientific societies and other bodies interested, with the view of relieving the Zoological Society of a part of the burden which it is no longer willing to carry unaided."

Agricultural Progress in India.

The steady advance in the progress of scientific agriculture in India is reflected in a recent number of the *Agricultural Journal for India* (xvii., part vi.), in which a variety of experimental work is reported. D. R. Sethi describes successful attempts to reclaim large tracts of the desert area of the Kapurthala State, illustrated by striking photographs. Since 1918 about 100 acres of the worst land in the district have been levelled and provided with an ample supply of irrigation water, free from alkali salts, by means of a large tube well equipped with power-driven machinery. The loose sandy soil was rendered more tenacious by green manuring with sann-hemp, which decays in about a fortnight after ploughing in and has a most marked action in binding the sand together, further improvement being effected by the introduction of clay carted from the low-lands. Good crops of maize, cotton, wheat, sugar-cane, cow-peas and other leguminous crops are now being grown on the land, and it is hoped to be able to render such reclamation an economic proposition.

As the relative value of nitrogenous organic manures depends largely upon their nitrifiability, F. J. Plymen and D. V. Bal have tested a number of these on various typical soils of the Central Provinces and Behar, under varying conditions of climate and cultivation. The nitrogen of castor cake appears to be quickly available in most soils, the others following in decreasing order of availability. Ground nut cake is exceptional in that it decomposes slowly in most soils, but very rapidly and effectively in black cotton soil. The nitrifying power of typical rice soil, where the cultivation is of an anaerobic or semi-anaerobic nature during a great part of the year, is much less than that of soils subject to open cultivation.

The phosphatic manuring of rice soil has received attention from M. R. Ramaswami Sivan in pot and field experiments with Trichinopoly phosphatic nodule. This mineral contains too much lime, iron, and alumina to be manufactured economically into superphosphate, but it appears to be a suitable manure for paddy lands when applied with decomposing organic matter. In pot cultures with rice the phosphate alone was ineffective, but the addition of green manure brought the phosphate into action and resulted in a very considerable increase in crop. Nitrogen, as sulphate of ammonia, was a less efficient agent in rendering the phosphate available. The residual effect of this mineral phosphate seems to be considerable, but this point is still under investigation.

The hydrogen-ion concentrations of some Indian soils and plant juices have been determined by W. R. G. Atkins (Bull. 136, Agricultural Research Institute, Pusa), who suggests that the method may be useful to agriculture in various ways, as, for example, to delimit the degrees of soil acidity or alkalinity within which it is possible to grow certain crops, and to determine the lime requirements of particular soils. The acidity of some sandy Assam soils is suggested as the cause of their high content of available phosphate, which is beneficial to indigo and other crops. The reaction even of highly calcareous soils may be somewhat modified by manurial treatment, the use of such manures as sulphate of ammonia or potash rendering the soils slightly less alkaline, the reduction being about P_H 0·4. A further reduction takes place in waterlogged soil, owing to the accumulation of carbonic acid. The value of gypsum on black alkali lands is attributed to the fact that calcium sulphate will, by precipitation of calcium carbonate, reduce the alkalinity of a sodium carbonate solution from P_H 10 or less to P_H 8, the latter being a limit suitable for plant life, whereas the former is not.

Fact and Phantasy in Industrial Science.[1]

The title of the lecture is intended to add to the obvious meaning of "industrial science" the complementary idea of a discipline or school of philosophy, and an interpretation under which the antithesis conveyed in the current expression "pure and applied science" is divested of any unreality. In regard to accumulation of exact knowledge of phenomena, no distinction of method or object is evident. "Pure science," however, is ideal in a sense which seldom characterises industrial research or scientific development of production.

The cellulose industries represent a vast accumulation of exact knowledge and a formidable array of statistical evaluation of fundamental matters of accepted fact. This tends to eliminate phantasy and imagination from the investigation of the primary routine processes of these industries, whereas these faculties have full play in the secondary arts of decorative treatment, *e.g.* in weaving design, bleaching and finishing, dyeing and printing: on the other hand, science has contributed new products, *e.g.* mercerised cottons, and the artificial (cellulose) silks, and attendant progressive extensions and developments, both artistic and scientific. Systematic scientific study of cotton, as an organic structure, as a colloidal complex with specifically characteristic hydration capacity, and as a chemical individual, is opening a vista of new developments of the primary textile industries.

Moreover, industrial research in this section adopts the unit cotton hair, as the determining factor of the industry, which is a radical change of the basis of accepted fact, from the empirical to the scientific. Similarly in the papermaking industry, current research concerns itself with units of minute dimensions, and the phenomena of the unseen and subsensible order. This trend of research again involves the faculties of phantasy and its more disciplined form of imagination.

The future of creative or constructive development of the cellulose industry would appear to be bound up with the application of physical and biological method: the former in investigating the properties of cellulose as such, and its actions and reactions in relation to light, heat and electricity; the latter in investigating the conditions of origin of cellulose structures, the natural history of bacterial resolutions, and the formation of humus, peat, lignite and coal. This general sketch of the matter of the lecture was developed by specimens and demonstrations.

[1] Abstract of a discourse delivered at the Royal Institution on Friday, February 2, by Mr. C. F. Cross, F.R.S.

Depth of Earthquake Foci.

The question of the depth of earthquake foci is attracting considerable attention among seismologists, and forms the subject of several recent papers (Mon. Not. R.A.S., Geoph. Sup., vol. i., 1923, pp. 15-22, 22-31, and 50-55). In the first of these Dr. Dorothy Wrinch and Dr. H. Jeffreys consider the seismic waves from the Oppau explosion of September 21, 1921, which were registered at five observatories on the Continent at distances ranging from 110 to 365 km. from Oppau. Using the method of least squares, they find that the velocities of the P and S waves (first and second preliminary tremors) are respectively 5·4 and 3·15 km. per sec. These values, which are of course those for the superficial sedimentary layer, are much less than those determined from observations of earthquake waves (7·1 and 4·0 km. per sec.) for the upper layers.

A more important earthquake with a superficial origin is the Pamir earthquake of February 18, 1911, which, as Prince Galitzin suggested and Dr. Jeffreys has shown, was the result of the fall of a great landslip. This earthquake was recorded at seismological stations all over the world. Dr. Jeffreys compares the times of arrival of the P and S waves at various distances from the origin with those given by the standard tables. The latter represent the average of a large number of earthquakes, the foci of which were situated at various, though unknown, depths, but none of which was on the surface. Now, if the latter depths were great, as suggested by the late Dr. G. W. Walker, there should be considerable differences between the observed times for the Pamir earthquake and those given by the tables. From the absence of any such differences, Dr. Jeffreys concludes that the foci of the earthquakes on which our tables are based were not at depths greater than 120 km.

In the third paper, Prof. Turner supplements a former note (see Nature, vol. 110, p. 55). Observations on the angle of emergence of earthquake waves at Pulkova led Galitzin to discern the existence of three new "critical surfaces" at the depths of 106, 232, and 492 km. Prof. Turner remarks that the relative depths of earthquake foci also concentrate about three chief values. The absolute depths are unknown, but, if they are the same as those of Galitzin's surfaces, they result in a surface value of the P waves agreeing with that obtained from the Oppau explosion, and suggest that destructive earthquakes probably originate in the uppermost layer, at a depth of 106 km.

Prof. Omori attacks the question from a different point of view, but also depends on time-observations (*Japanese Journ. of Astr. and Geoph.*, vol. 1, 1922, abstracts p. 16). He finds that the distance (x km.) of a station from the earthquake centre and the duration (y sec.) of the first preliminary tremor at the station are connected by the relation $x = 7{\cdot}42y$. From observations made at three stations (Tokyo, Mito, and Choshi), he finds that the focal depths of ten earthquakes felt at Tokyo in 1919–1921 range between 27·5 and 46·0 km., with an average of 34 km. In a later paper (*Seismol. Notes*, vol. 1, No. 3), he assigns, by the same method, a depth of 48 km. to the focus of the semi-destructive Tokyo earthquake of April 26, 1922. C. D.

University and Educational Intelligence.

Belfast.—At the meeting of Senate of the Queen's University held on April 20, it was agreed to receive the resignation of the vice-chancellor, the Right Honourable and Rev. Thomas Hamilton. Dr. Hamilton was appointed vice-chancellor by Queen Victoria in 1889 as president of Queen's College. At that time the annual endowment was 8000*l.* and the number of students less than 400. The annual endowment is now 36,000*l.* and the number of students 1250. During his long presidency his services were invaluable. In 1901 a fund of 100,000*l.* for the better equipment of the College was received, which made possible the erection of laboratories for teaching and research. By the Universities Act of 1908 the Queen's College was dissolved and became the Queen's University, and Dr. Hamilton was named in the charter as vice-chancellor and president. The Senate appointed a special committee to make inquiries as to a person suitable for nomination to the office of president and vice-chancellor.

Leeds.—The Leeds Education Committee and the University have co-operated in setting up a new course of training for students who may expect to occupy posts of directive responsibility in the printing trades. The University has no Printing Department of its own; but in other respects is able to offer the kind of training which is needed by a man who will afterwards take a responsible position in business life. The Leeds Technical School Printing Department, on the other hand, is to provide technical training in the various processes of printing and the full course will extend over four years. The first three years will be spent in reading for the University degree, one of the subjects for which will be printing. A fourth year, leading to a diploma, will be spent wholly on printing at the Technical School. The work for the degree will comprise economics, including commercial and financial organisation and the economics of the printing and allied industries, statistics, accountancy, commercial law, mathematics, physics, mechanical engineering, and printing. The scheme will come into operation next October.

The Dewsbury County Borough Council has voted a grant of 400*l.* a year to the University and the Halifax County Borough Council has made a grant of 750*l.* for the current financial year.

Dr. R. W. Whytlaw-Gray, Fellow of University College, London, has been appointed professor of chemistry as from October 1 in succession to Prof. Arthur Smithells. From 1900 to 1902 Dr. Whytlaw-Gray worked under Sir William Ramsay on a re-determination of the atomic weight of nitrogen. This work was completed in the laboratory of Prof. R. Anschütz in the University of Bonn. On his return from Germany in 1906 Dr. Whytlaw-Gray was appointed on Sir William Ramsay's staff at University College, London, and in 1908 he became assistant professor. While there, he conducted important investigations on the physical constants of gases and was associated with Sir William Ramsay in the well-known work on radium emanation (niton). This work involved exceptional experimental difficulties, less than one-tenth of a cubic millimetre of the gas being available. With this almost infinitesimal quantity Messrs. Ramsay and Whytlaw-Gray succeeded in determining its physical properties, thus proving that the emanation belonged to the helium family of elements. In connexion with this very delicate work, Dr. Whytlaw-Gray constructed a specially designed balance which was sensitive to 1/250 thousandth of a milligram. Since 1914 Dr. Whytlaw-Gray has been science master at Eton College.

London.—A course of eight free public lectures on "Nutrition" will be given at King's College for Women (Household and Social Science Department), 61 Campden Hill Road, W.8, by Prof. V. H. Mottram, on Mondays and Wednesdays, beginning on April 30. The lecture hour is 4.30, and no tickets are required.

Oxford.—The next award of the Rolleston Memorial Prize will be made in Trinity Term, 1924. The Prize, the value of which is about 100*l.*, is given for original research in animal and vegetable morphology; physiology and pathology; or anthropology. Candidates must be graduates of Oxford or Cambridge of not more than six years' standing. For other conditions the *Oxford University Gazette* for April 11 should be consulted. Candidates wishing to compete must forward their memoirs to the Registrar of the University of Oxford before March 31, 1924.

Mr. George Grant, Appointments Secretary and Senior Warden of the University Halls of Residence for Men Students, University of Liverpool, has been appointed Registrar of University College, Southampton, as from September 1, 1923.

Dr. S. P. Smith has been appointed professor of electrical engineering at the Royal Technical College, Glasgow, in succession to Prof. Magnus Maclean, who is about to retire after occupying the chair for twenty-four years. Since 1912, Dr. Smith has been lecturer, and later assistant professor, in the Electrical Department of the City Guilds (Engineering) College, Imperial College of Science and Technology, London.

An important conference is being organised by the University of Leeds for the discussion of certain questions affecting the supply of full-time education for boys and girls beyond the age of eleven years and the choice of subjects in school examinations. The conference will be held in the Great Hall of the University on Saturday afternoon, June 9, and will be attended by representatives of schools and universities, as well as by others engaged in educational work. The main subject of discussion will be the broadening of the basis of the secondary-school curriculum. Though less than three per cent. of pupils in State-aided secondary schools proceed to universities, the courses usually followed lead to examinations of university matriculation standard and scope, and are unsuitable for pupils who will not continue their education at universities. The following motions will therefore be put before the conference for consideration, and a vote will be taken upon them:—(1) That representations be made to the Board of Education, urging the pressing need of further provision (by legislative change, if necessary) for the full-time education of boys and girls up to the age of sixteen, to include not only instruction of the type now offered by the recognised secondary schools, but such variations from it as will meet the needs of pupils who may not intend to proceed to a university. (2) That this conference welcomes the recent action of the Joint Matriculation Board of the Northern Universities in the direction of allowing greater freedom in the choice of subjects in the First Secondary School examination, but is of opinion that greater freedom in the grouping of courses for the Higher Certificate is desirable in the educational interests of the pupils in secondary schools. Correspondence on the subject of this conference may be addressed to Sir Michael Sadler or to Mr. A. E. Wheeler, The University, Leeds, who will be glad to have the names of those intending to be present at the conference.

Societies and Academies.

London.

Geological Society, March 28.—Dr. H. H. Thomas, vice-president, in the chair.—E. **Greenly**: Further researches on the succession and metamorphism in the Mona complex. Fragments from the volcanic series of Bangor show that the metamorphism of the complex is older than that series. The basic schists of the Eastern Aethwy region appear to be derived from the spilitic lavas. A singular effect of anamorphism in its earliest stages is that quartz-epiclasts have been corroded and invaded by the carbonates of a calcareous grit. Titaniferous varieties of the Bodwrog marble in the Penmynydd Zone furnish evidence as to the conditions of development, under dynamic metamorphism, of rutile and of sphene. As regards the ancient floor, more fragments of ancient crystalline schists have been found, one of them being in the Fydlyn Beds, a lower horizon than any that had hitherto yielded any such fragments. The gneissic structures are older than the deposition of the bedded succession. Banding resulted from deformation of a differentiated basic magma at an advanced stage of consolidation. Three generations of pegmatite are distinguished, the earliest of which is subsequent to the consolidation of the banded gneiss. Granitoid banding followed granitoid permeation, and also the appearance of the basic magma from which the hornblendic gneisses were developed. Thus, the micaceous gneisses must be regarded as the oldest known member of the gneissoid complex.

Aristotelian Society, April 9.—Prof. A. N. Whitehead, president, in the chair.—C. D. **Broad**: Various meanings of the term "unconscious." Six senses of the term "unconscious" are distinguished. (1) As used to differentiate one kind of substance from another, it means "inanimate." (2) As applied to the temporary condition of an animate substance, it means "not at the moment consciously aware of anything." This definition is not complete till we have defined (3), "conscious" and "unconscious," as applied to experiences. An experience is "relatively unconscious" if it is owned by some mind which is not at the time in control of a body. It is "absolutely unconscious" if, at the time of its occurrence, it is owned by no mind. These are the only senses in which we can *literally* talk of "unconscious *experiences*." (4) The traces and dispositions which have to be assumed in order to explain memory, instinctive behaviour, etc., are often called "unconscious states." There is no reason to think that these are, or are anything like, experiences. It is best to call them "mnemic continuants." (5) Experiences which were conscious when they happened, but cannot now be remembered by normal means, are often called "unconscious." It would be better to call them "inaccessible." Their traces form part of the unconscious in sense (4). They themselves are not literally unconscious experiences in sense (3). Lastly, (6) the name "unconscious" is often applied to ordinary conscious experiences (especially desires and emotions) which are not properly discriminated by their owner because the acknowledgment of their true nature and objects would be unflattering to him.

Royal Meteorological Society, April 18.—Dr. C. Chree, president, in the chair. W. H. **Dines** and L. H. G. **Dines**: An examination of British upper air data in the light of the Norwegian theory of the structure of the cyclone. A list of dates on which temperature observations were available in England S.E. was sent to the Meteorological Office, which notified all those on which evidence of the polar front might be expected. Graphs of the lapse rate from 0·5 km. to 5·0 km. were drawn for such dates, but no peculiarities not readily explained by the ordinary casual variation were found. The probability of finding an inversion appears to be almost a linear function of the surface pressure. Kite ascents made at Pyrton Hill indicate that an inversion is nearly always associated with a decrease in the humidity, whereas the Norwegian theory requires an increase. The observational evidence for England does not support the theory that the superposition of equatorial over polar air is the usual form of the structure of a cyclone.—T. **Kobayasi**: On the mechanism of cyclones and anticyclones. Mathematical expressions are obtained which represent a cyclone having definite properties. As the cyclone advances it draws into its inner region a strip of air lying near the ground in its track. Meanwhile the air outside the two edges of the strip flows round the opposite sides of the cyclone, meeting behind it. Thus if the portions of air outside the two edges of the strip were at different temperatures, then by their contact they would produce the instability which is characteristic of the squall line.—E. C. **Shankland**: Notes on the fluctuations of mean sea-level in relation to change of atmospheric pressure. The heights to which tides will rise in the world's principal harbours and estuaries are pre-determined by analysis and presented to navigation in the form of tidal predictions. Meteorological conditions interfere with these predictions. Observations show that the mean sea-level varies inversely with the height of barometer; there is a tendency to increase the factor from 13·25 (the specific gravity of mercury as compared with sea-water), to a figure approaching 20 when using the mean isobar of the locality as barometric datum. Observations extending over a period of autumnal anti-cyclonic weather of considerable geographic extent, point to the acceptance of a 1/20 factor under these meteorological conditions, the barometric pressure being above normal during the entire series.

Paris.

Academy of Sciences, April 3.—M. Guillaume Bigourdan in the chair.—Emile **Picard**: Two elementary theorems on the singularities of harmonic functions.—M. **de Sparre**: The yield of reaction turbines furnished with aspiration tubes. Modifications of the formulæ given in earlier communications produced by the addition of an aspiration tube, with and without partitions. An example is given in which the initial maximum yield was 0·816, with simple aspiration tube 0·865, and a still higher figure for certain cases of tubes with partitions.—E. **Mathias**, C. A. **Crommelin**, and H. Kamerlingh **Onnes**: The latent heat of vaporisation and the difference of the specific heats in the saturated state for neon. A table is given showing the molecular heats of vaporisation for oxygen, argon, nitrogen, neon, and hydrogen.—S. **Lefschetz**: The integrals of the second species of algebraical varieties.—G. **Valiron**: Remarks on a theorem of M. Carlemann.—Hilaire **de Barenton**: A new interpretation of the Sothaic period. A new theory of the ancient Egyptian calendar. L. **Vegard**: The spectrum of the aurora borealis and the upper layers of the atmosphere. An account of work done at the Tromsö Geophysical Institute. The greater number of the lines in the spectrum of the aurora borealis can be identified with nitrogen lines, but there are four lines not given for nitrogen, which cannot be attributed to hydrogen, oxygen, or helium. There is no evidence for the existence of hydrogen or helium in the upper atmosphere. It is possible that the four lines not identified, including the green line (5578·4), may be due to nitrogen.—L. **d'Azambuja**: New measurements of the velocity of rotation of the filaments. Evaluation of the height of these objects above the solar chromosphere. The average velocity does not sensibly vary from one filament to another: it is independent of the shape, intensity, and extent of the filaments observed. There is a clear reduction of velocity toward the pole, the angular velocity being $14 \cdot 45° - 1 \cdot 90° \sin^2 \lambda$, where λ is the heliographic latitude.—Louis **Dunoyer**: Induction spectra and spark spectra. Reclamation of priority as regards work by Léon and Eugène Bloch, and a discussion of the nomenclature of spectra.—Pierre **Lamare**: Geological observations on the Yemen. The region of the Yemen (south-west angle of Arabia) presents remarkable geological and lithological analogies with the Somali and Abyssinian regions. The properties of the six main types of basalts are summarised.—C. E. **Brazier**: Magnetic measurements in Normandy. The magnetic elements (on January 1, 1922) are given for 43 stations in the Departments of Eure and Seine-Inferieure.—Mlle. Y. **Dammann**: The Kansou earthquake: determination of the epicentre. This earthquake took place on December 16, 1920, in the north China province of Kansou, and for the determination of the epicentre the seismological records from 24 observatories were utilised.—Mme. J. Samuel **Lattès**: Some numerical values characterising the radium rays responsible for the phenomenon of necrosis.

Broadcasting and Wireless Licences.

THE wireless licence problem has for some time been engaging the attention of the Post Office authorities, and acute differences appear now to have arisen between the Postmaster-General and the British Broadcasting Company as to the conditions under which licences may be issued to amateurs who either own home-made wireless sets or desire to build up such sets. Matters have been brought to a head by the present Postmaster-General refusing to impose upon amateurs restrictions which the British Broadcasting Company claims it has a right, under its agreement with the Post Office, to insist upon. The Postmaster-General made a statement in the House of Commons on April 19 on the situation that has, in consequence, come to pass: he then informed the House that negotiations had taken place on the licence question between himself and the Company, and that the latter had suggested that the Post Office issue to the home-constructor a licence, without any clog, at 20*s.*, of which 15*s.* was to go to the Company. This proposal was promptly declined by the Postmaster-General. Then, in the course of further negotiations, the Company expressed its willingness to permit the Post Office to issue to amateurs a licence at 10*s.*, of which one-half was to go to the Company, but such licence was to be subject to the clogging provision that it should alone be issued to those home-constructors who either own, or propose to build up, listening-in sets with parts of "B.B.C." manufacture. This proposal has also proved unacceptable to the Postmaster-General.

It was perhaps inevitable, in view of the terms and conditions contained in the agreement entered into between the Post Office and the British Broadcasting Company, and of the provisions in the articles of association of the Company, that the present trouble should have arisen. Neither the Post Office authorities nor those responsible for the promotion of the British Broadcasting Company appear to have appreciated correctly certain psychological aspects of the wireless situation from the point of view of a large and important section of those interested in that field. The subject, it may be remembered, was well ventilated at the time that the provisional committee representing the promoters of the British Broadcasting Company was carrying on its preliminary negotiations in the autumn of last year. It should, therefore, have been clear to the Postmaster-General of the day, his advisers, and the promoters of the Company, that many conflicting interests were involved and that the greatest caution was needed in handling what was undoubtedly a difficult problem (see NATURE for August 19 and

October 7, 1922—vol. 110 at p. 237 and p. 469). The situation actually created by the agreement between the Post Office and the British Broadcasting Company has been such that, almost from the very beginning, two important classes—the small manufacturer and salesman of wireless apparatus and the amateur experimenter—in the wireless field have felt themselves seriously aggrieved by the policy adopted by the parties to the agreement in relation to wireless licences, owing to the deliberate attempt made to fetter their freedom of action, each in his own particular field.

As regards the small manufacturer, it is argued that he has no real cause of complaint, since by subscribing but for a single one-pound share he can at once avail himself of all the benefits secured by the British Broadcasting Company from the Post Office under its concession. However, there is a not unnatural objection and disinclination on the part of small manufacturers to join a combine in which their most powerful competitors have a preponderating influence and voice. Further, an impression prevails, rightly or wrongly, that the inquisitorial powers which the British Broadcasting Company appears to have acquired under its articles of association may be, and are being, used to the detriment of the smaller shareholding companies: for example, a suspicion exists that the organisation of the Company is being made use of by the powerful shareholding companies, to some extent, as a sort of intelligence department for the purpose of obtaining information likely to be useful in connexion with the protection of their patent rights and interests. In all the circumstances, then, it would obviously be wrong for the Post Office to take any action with the view of compelling any British manufacturer to join the Broadcasting Company: in this view the present Postmaster-General has expressed his concurrence.

One of the chief arguments used in favour of broadcasting services being provided alone by a single company, and of the present rule that only apparatus bearing the "B.B.C." mark shall be used for broadcasting purposes, is that the British market is being flooded with wireless apparatus manufactured in countries with depreciated currencies; and, therefore, without safeguards of the nature indicated here, the broadcasting industry would be destroyed. It may, of course, be of vital importance, as the British Broadcasting Company alleges to be the case, to protect from unfair foreign competition, at the present time, the industry in question. Should any protective measures be desirable, the proper method of dealing with this aspect of the situation is surely by the direct and open one of imposing on foreign telephone apparatus and parts an import duty to be collected in the ordinary way by the Customs authorities, and not by the indirect, clumsy, and, what must prove to be, ineffective method of attempting to prevent the use for a specific purpose, by means of ministerial regulations and articles of association of a trading company, of some particular material after its unrestricted importation.

As regards the other class the rights of which appear to be seriously infringed under the broadcasting agreement, that is to say, the amateurs, a misapprehension seems to exist in the minds of some of the promoters of the British Broadcasting Company as to the nature of the bargain made by them with the Post Office. Owing to the great and rapid increase in the so-called "experimental licences" issued since the advent of broadcasting—the actual increase is from about 10,000 in the summer of last year to 35,380 at the present date—the Company seems to have taken alarm at the construction placed by the Postmaster-General on the language of Section 2 (1) of the Wireless Telegraphy Act, 1904 (4 Edw. 7. c. 24), which authorises the issue on special terms of a licence to an applicant who "proves to the satisfaction of the Postmaster-General that the sole object of obtaining the licence is to enable him to conduct experiments in wireless telegraphy." Certain of the promoters of the Company appear to think that, in view of the terms and conditions of the agreement negotiated by them with the Post Office, they are to be the judges as to the meaning to be placed on the provisions of the Section of the Act referred to. They are inclined to put an exceedingly narrow construction on the language of the statute, and seem to claim that the issue of the "experimental licence"—the rights of the Postmaster-General in relation to the granting of which are in no way abrogated or restricted under the Company's broadcasting agreement—shall alone be to actual research students and those in a strictly analogous position: that is to say, they wish to see the ordinary amateur deprived of his right to an "experimental licence." Owing to the attitude taken up by the British Broadcasting Company, the issue of licences other than those in respect of the listening-in sets bearing the "B.B.C." mark has been suspended since January 1 last, and, in consequence, some 33,000 applications for "experimental licences" were waiting to be dealt with on April 19.

When addressing the House of Commons on April 19, the Postmaster-General announced that, in the opinion of the Law Officers of the Crown, if he is satisfied that the object of an applicant for a licence is to experiment in wireless telegraphy, not only may he issue an "experimental licence" to him, but also he is bound to do so. Accordingly, he has referred the outstanding applications in question to some expert members of his staff in order that they may advise him as to the cases in which the licences are being honestly sought for the purpose of conducting experiments in wireless telegraphy, and on this advice he intends forthwith to act. It would, indeed, be exceedingly mischievous if the narrow construction sought to be placed on the language of the statute as it affects "experimental licences" were to be accepted by the Postmaster-General. It is to be hoped that his expert advisers will deal with the question submitted to them in the light of the plain language of the Act of 1904 and in accordance with the well-known principles relating to the interpretation of the provisions of statutes which affect private rights. The expert advisers will, no doubt, bear in mind that in the case of any particular amateur the dominant reason prompting him to apply for a licence may well be, and often is, that he desires to conduct experiments, and, therefore, in his case as in that of the research student, the listening-in to broadcasting services is altogether a secondary consideration, although the existence of such services is possibly of some assistance to him in connexion with his experiments, and for this use he will, under the Postmaster-General's proposal, be contributing his 5*s.* a year.

The Postmaster-General made the further important announcement on April 19 that he proposed immediately to set up a committee consisting of members of Parliament, expert members of his staff, a member of the British Radio Society, and a director or other official of the British Broadcasting Company, if possible, to consider the whole future of broadcasting. The members of this committee have now been appointed and their names appear in another part of this issue. It is eminently desirable that a thorough inquiry should take place; in this way the various issues which have been raised can most satisfactorily be separated out, in order that each may be dealt with on a practical basis on its own merits. One of the most important of the questions upon which a sound decision is required is that relating to the position of the amateur worker in the wireless field: there are to-day thousands of young fellows who are induced to take up as a hobby some technical or scientific subject, owing almost entirely to the pleasure they derive in carrying out practical work with a view of obtaining a clear understanding of some of the mysteries of Nature. It is desirable that the committee which the Postmaster-General has now appointed should make a definite pronouncement on this particular point: it cannot fail fully to recognise the importance of seeing that nothing is done unreasonably to hamper the activities of this particular class of workers in the wireless field; indeed, it is likely to appreciate the value of encouraging them, both with the view of benefiting science by their work and by their inventive faculty, should they possess any, as well as of assisting the industries of the country by the trade in the sale of the materials they may require for the purposes of their experiments.

History teaches that there are certain directions in which an attempt to impose statutory restrictions prompts people alone to measures of evasion, and on so wholesale a scale as practically to paralyse the arm of the law: to mention but a single example, the legislature, with doubtful wisdom, endeavoured at the beginning of the eighteenth century to suppress the so-called "Common-law Companies," and passed the famous Bubble Act, 1718 (6 Geo. I. c. 18), with this object in view. The Act, as is well known, proved a dead letter and was, a century later, repealed; the legislature, finding that it must tolerate the joint-stock company, set accordingly to work to regulate what it could not suppress, and to-day the whole country is reaping benefit from the facilities which were created to permit the incorporation of commercial and industrial undertakings. The present situation in relation to the amateur worker in the wireless field is almost identical with that which existed a couple of centuries ago in relation to the joint-stock company. It behoves those, then, who may be called upon to deal with the wireless licence problem to bear steadily in mind the teachings of history of the kind to which this allusion refers.

Biology in Utopia.

Men Like Gods. By H. G. Wells. Pp. viii + 304. (London, New York, Toronto and Melbourne: Cassell and Co., Ltd., 1923.) 7*s.* 6*d.* net.

THE columns of NATURE are not the place to discuss the literary merits of Mr. Wells's new book—although, for the matter of that, good style or artistic capacity and appreciation are qualities as natural as any others. Suffice it to say that he has achieved a Utopian tale which is not only interesting but also extremely readable. Most readable Utopias are in reality satires, such as "Gulliver's Travels," and the no less immortal "Erewhon." Mr. Wells has attempted the genuine or idealistic Utopia, after the example of Plato, Sir Thomas More, and William Morris; and, by the ingenious idea of introducing not a solitary visitor from the present, but a whole party of visitors (including some entertaining and not-at-all-disguised portraits of various living personages) has provided a good story to vivify his reflections.

However, since Mr. Wells is giving us not only a story, but his idea of what a properly-used human faculty might make of humanity in the space of a hundred generations, his romance has become a fit subject for biological dissection in these pages.

Mr. Wells pictures a world where, in the first place, the advance of physico-chemical science and its application, to which we are already accustomed, has attained a far higher pitch of perfection. Further, machinery has become so self-regulating that it does not make man captive, as Samuel Butler prophesied, but is a real servant. Also, instead of machinery and mechanism occupying the foremost place in the life of the majority of men, as Bergson laments that they are tending to do to-day, they have apparently been rendered not only more efficient, but also more self-regulating, and are as subservient to the will of the community as a motor-car that never gets out of order is to its owner.

In the second place, life has been subjected to a similar control. This is a process which the biologist sees so obviously on its way that it should excite no surprise. As our knowledge of genetics increases, our application of it must outstrip the past achievements of empirical breeding as much as the application of scientific knowledge of principle in chemistry, say, or electricity, has outstripped the achievements of empiricism in those fields. Mr. Wells's wonderful flowers and trees are almost there already: we will not worry about them. Even his domestic-minded leopards and tigers, more "kittenish and mild" even than Mr. Belloc's, should not be lightly dismissed after recent experiments on the inheritance of tameness and wildness in rats—not to mention our knowledge of many breeds of dog.

Meanwhile, Mr. Wells also imagines a purging of the organic world. The triumphs of parasitology and the rise of ecology have set him thinking; and he believes that, given real knowledge of the life-histories and inter-relations of organisms, man could proceed successfully to wholesale elimination of a multitude of noxious bacteria, parasitic worms, insects, and carnivores. Here again we have no right to quarrel. Mr. Wells does not need to be reminded of the thistle in California or the rabbits in Australia: his Utopians proceed with exemplary precautions. All this is but an extension of what has already been begun.

In the third place, however, human as well as non-human life has been subjected to this control; and this in two ways. First, by an extension of the methods previously used. The accidents and circumstances of life have been altered—there has been a further control of external machinery. This has been, of course, chiefly in the fields of social and political institutions. A great part of such change is only intelligible as a corollary of the other supposed change. But we may here direct attention to one idea which is imagined as at the root of much of it—the idea that man is master in his own house of Earth, as opposed to the idea which, with few exceptions, has until now dominated his history—the idea that he is the slave, sport, or servant of an arbitrary personal Power or Powers.

Finally, we come to the most radical and inevitably the most provocative of our author's imaginings—that which concerns not the alteration of things in relation to a constant human nature, but the alteration of that human nature itself. Here Mr. Wells is extremely interesting. He reduces the rôle of eugenics to a minimum, exalts that of education, or, if you prefer it, environment, to a maximum. Eugenic change has been restricted to "breeding out" (Mr. Wells does not initiate us into methods) certain temperamental qualities—habitual gloominess, petty inefficiency, excess of that "sacrificial pity" Mr. Wells dislikes so much, and so forth.

The rest has been accomplished by proper education, and, above all, by a "change of heart" as regards the essential aims of life. Mr. Wells sums this up in a phrase (in which one recognises his devotion to the late headmaster of Oundle) as the substitution of the ideal of creative service for that of competition.

The realisation of this ideal is made possible in the first instance by a proper application of psychology to early life, so that painful repression and stupid suppression shall not occur, and men and women shall grow up unridden by hags of sex or fear, and yet without separation of any important fragment of their mental organism from the rest. Education *sensu restricto* then steps in, and enlarges the capacities of the unhampered growing mind, while the substitution of a form of telepathy for speech reduces the time and energy needed for communication. Meanwhile, a rational birth-control provides a world not overcrowded and overstrained.

By these means, Mr. Wells imagines, a race has been produced of great beauty and physical strength, great intellectual and artistic capacities, interested primarily in two things—the understanding of Nature for its own sake, and its control for the sake of humanity. By control Mr. Wells means not only utilitarian control, but that which, as in a garden, is to please and delight, and that highest control of material—artistic and scientific creation.

The Utopians, owing to their upbringing and social environment, come to think and act so that they need no central government, no law-courts, no police, no contracts. In this Mr. Wells is only telling us what we all knew already, that in most men it seems theoretically possible to produce a "change of heart"—*i.e.* substitute new dominant ideas for old—and that if this is effected, restrictive measures gradually become unnecessary. He is careful not to make his Utopia too ideal. It is as ideal compared with this world as would be Olympus: but as short of perfection as Olympus seems to have been. The men and women there are often discontented and restless; criticism is abundant. Mr. Wells knows that intellectual and æsthetic achievement opens the door to the highest known happiness of the present; he keeps them so, with all conditions and limitations of their being, in Utopia.

Let us go back and try to see how much of Mr. Wells's speculations fall within the bounds of possibility. All Utopias must suffer from lack of familiar associations, for it is by familiar associations, especially with things of youth and childhood, that emotional appeal is made and real assent gained. Thus, whatever stores of loved memories a Utopian may have, whatever driving force he may draw from the sight of familiar places and objects, we can only see his emotional life from outside, as an Englishman on his first visit to the United States notices the differences from England rather than the resemblances. But if we remember that they must have each their private growth of life, and that this must be in many ways like ours, we get over the first stile.

We have already dealt with Mr. Wells's applied physics and chemistry and his applied biology of lower organisms. That in a sense is commonplace—commonplace made surprising; none the less, it is good to have it so well done, to have people reminded that the rate of this sort of change not only need not slow down, but can continue, and continue to be accelerated, for a very long time. What of his applied biology of man? Minor criticisms are easy to make. The Utopians, for example, go either almost naked, or else clothed in garb of the indeterminate simplicity that seems to be fashionable in all Utopias. Mr. Wells is perhaps so revolted by the dulness of modern male attire that he underestimates the amount by which dress enlarges the human horizon, giving us a hundred extra variations of personality, raising the possibilities realised in the courtship-decorations of lower animals to an infinitude of permutations.

With the rediscovery of Mendel's laws and their recent working out, we are introduced to the theoretical possibility of an analysis of the hereditary constitution similar to the chemist's analysis of a compound; and so, presumably, in the long run to its control. There are great technical difficulties in higher organisms, and application to man presents yet further difficulties. Still, the fact remains that the theoretical possibility exists for us to-day, and did not exist twenty-five years ago. We must further remember that all discoveries concerning the history of man remind us that we must think, not in centuries as heretofore, but in ten-thousand-year periods when envisaging stages in human development.

We must further recall the lessons of evolutionary biology. These teach us that, however ignorant we may be regarding the details of the process, life is essentially plastic and has in the past been moulded into an extraordinary variety of forms. Further, that the attributes of living things have almost all been developed in relation to the environment—even their mental attributes. There is a causal relation between the absence of X-rays in the normal environment and the absence in organisms of sense-organs capable of detecting X-rays, between the habits of lions and their fierceness, of doves and their timidity. There is, thirdly, no reason whatever to suppose that the mind of man represents the highest development possible to mind, any more than there was to suppose it of the mind of monkeys when they were the highest organisms. We must squarely recognise that, in spite of proverbs to the contrary, it is probable that "human nature" could be considerably changed and improved.

Next, we have the recent rise of psychology. Much nonsense doubtless masquerades under the name of psycho-analysis or "modern" psychology. None the less, as so shrewd a critic as the late W. H. R. Rivers at once saw, and as has been put to such practical uses in therapeutic treatment, there is not only something in it, but a great deal. Repression, suppression, sublimation, and the rest are realities; and we are finding out how our minds do work, ought not to work, and might be made to work. It is clear that the average mind is as distorted and stunted as a much-below-average body; and that, by just so much as a great mind is more different from an average one than great from average bodily capacity, by so much would proper training be more efficient with mind than even with bodies. Here the extravagances of some eugenists find their corrective; Mr. Wells's imagination is pursuing to its logical end the line taken by such authorities as Mr. Carr Saunders in his "Population Problem."

Again, Mr. Wells, being a major prophet, perceives without difficulty that the substitution of some new dominant idea for the current ideas of commercialism, nationalism, and sectarianism (better not beg the question by saying *industry, patriotism,* and *religion*) is the most needed change of all. Here, again, he is in reality only adopting the method of Lyell and Darwin—uniformitarianism—and seeking the key of the future, as of the past, in the present. There is to-day a slowly growing minority of people who not only profoundly disbelieve in the current conceptions *and valuations* of the world and human life, but also, however gropingly, are trying to put scientifically-grounded ideas in their place.

Belief is the parent of action; and so long as the majority of men refuse to believe that they need not remain the slave of the transcendental, whether in the shape of an imaginary Being, of the Absolute, or Transcendental Morality, they cannot reap the fruits of reason. If the minority became the majority, society and all its institutions and codes would be radically altered.

Take but one example, and a current one—birth-control. When Mr. Wells's "Father Amerton" finds that it is the basis of Utopian civilisation he exclaims in horror: "Refusing to create souls! The *wickedness* of it! Oh, my God!"

. . . . . .

This is the great enemy of true progress—this belief that things have been already settled for us, and the consequent result of considering proposals not on their merits, but in reference to a system of principles which is for the most part a survival from primitive civilisations.

Mr. Wells may often be disagreed with in detail: he is at least right in his premises. A perusal of his novel in conjunction with a commentary would be useful. "Men Like Gods" taken *en sandviche* with, say, Punnett's "Mendelism," Trotter's "Instincts of the Herd," Thouless's "Psychology of Religion," Carr-Saunders's "Population Problem," Whetham on eugenics, and a good compendium of recent psychology, would be a very wholesome employment of the scientific imagination. J. S. H.

Linnean Correspondence.

Bref och Skrifvelser af och till Carl von Linné med understöd af Svenska Staten utgifna af Uppsala Universitet. Första Afdelningen, Del 8: Bref till och från Svenska enskilda personer Kalm-Laxman. Utgifna och med upplysande noter försedda af J. M. Hulth. Pp. v+200. 6 kroner. Andra Afdelningen, Utländska brefväxlingen; Del 1: Adanson-Brünnich. Utgifven och med upplysande noter försedd af J. M. Hulth. Pp. viii+430. 12 kroner. (Uppsala: A.-B. Akademiska Bokhandeln, 1916 and 1922.)

SINCE the death of Carl von Linné, better known in this country under his Latinised name of Linnæus, nearly a score of works have been issued containing selections of his letters, many of them restricted to his relations with a single person, as Jacquin, B. de Jussieu, or Sauvages. But these only dipped into the extensive correspondence which is available, and the Swedish Government has aided the University, of which Linnæus was so distinguished a professor, to bring out a complete issue of all the letters known to be in existence, as part of the publications commemorating the bicentenary of the birth of the great naturalist in 1907. The editor was, naturally, Emeritus Professor T. M. Fries, who, four years earlier, had produced his monumental life of Linné and was steeped in Linnean lore and knowledge of his contemporaries. Six volumes had been brought out under his editorship when his death, early in 1913, closed his industrious career, and left the series of volumes less than half finished. These six belonged to the first section, devoted to letters to and from Swedes; a seventh was partly prepared, and the first volume of the second section, devoted to foreigners, was in course of preparation when the editor's life closed. The successor to Fries was Dr. J. M. Hulth, chief librarian of the University of Uppsala, but the time available for the subject so essential was obtained with difficulty by a very busy man. Nevertheless, we have here two volumes for a brief survey—volume 8 of the first section, extending from Kalm to Laxman, and a first volume of the second section, embracing the letters from Adanson to Brünnich.

Naturally, the latter volume attracts the non-Swedish reader, nearly the whole being in Latin, and the forty-nine writers include Francis Calvert, sixth and last Lord Baltimore (the owner of Maryland), Sir Joseph Banks, John Bartram, the early North American botanist of Philadelphia, Johann Bartsch, the close friend of Linnæus, who fell a victim to the climate of Surinam, Anna Blackburne, Herman Boerhaave, the celebrated Dutch physician, whose pathetic farewell to Linnæus is one of the most touching episodes in the Swede's career, and Patrick Browne, whose volume on Jamaica plants incited Linnæus to buy his herbarium for himself. Much might be extracted from these letters, but their comparative accessibility prompts our passing on to the other volume before us.

The forty-one letters from Pehr Kalm to his former teacher extend over 118 pages, more than half the volume, and are especially interesting. Kalm had travelled in Russia, whence the first letters were sent, but having undertaken a journey to North America, he, with an assistant, reached London in February 1748, and hastened the same day to report his arrival. His letters, written in Swedish, are couched in a fresh and lively style, and convey his first impressions. He hesitated to call upon the persons to whom he had been recommended till he should have acquired a better command of English, for though many wrote and spoke Latin, it was differently pronounced, and thus difficult to understand. In this he succeeded, as he was obliged to stay six months in London, waiting for a ship to America. He remarked on the milder winter of England compared with that of Sweden, and of the many plants which could stand out of doors unharmed. Soon we find him telling about his acquaintances. Philip Miller of Chelsea Physic Garden, and a special friend Richard Warner of Woodford (1711–1775), whose splendid garden yielded many seeds for Uppsala, John Ellis, Ehret the botanical artist, Dr. John Mitchell, and others were among the earliest of his acquaintances in London. Then the scene shifts to Philadelphia, where he was often with Bartram: "he lives about five miles from Philadelphia, a thoroughly good fellow and a strong Linnean; we have botanised a good deal round the country, and he has promised to send a quantity of rare seeds to Uppsala if he can manage to do so with the next ship." Kalm then turned his steps to Canada, and returned to Pennsylvania at the end of the year, again reaching London in the spring of 1751, and Stockholm a month later, passing on to Abo; in that University he had been appointed professor of economy, and on his return he took up the duties of his chair until his death in 1779, the year after the death of his old teacher. There are but few letters here from Linnæus, the reason no doubt being that, the recipient having sewn these letters into a volume, they probably perished in the fire of 1827, which destroyed the town and University of Åbo.

Martin Kähler (1728–1773), another of the Linnean pupils, had intended to travel to the Cape, but that intention was hindered by the Dutch. He therefore travelled in France and Italy, whence he returned in 1757. Magnus Lagerström (1691–1759) was a director of the East India Company of Göteborg (Gottenburg), and in that capacity was able to supply novelties to Linnæus; thirteen letters are here printed, but the letters to Lagerström are unknown. The last writer in the volume is Erik Laxman (1737?–1796), whose name is well known for his work amongst Siberian plants.

B. D. J.

Technology of Oils and Fats.

Chemical Technology and Analysis of Oils, Fats, and Waxes. By Dr. J. Lewkowitsch. Sixth edition, entirely revised by George H. Warburton. (In 3 vols.) Vol. 3. Pp. viii+508. (London: Macmillan and Co., Ltd., 1923.) 36*s.* net.

THE third and final volume of this well-known book deals principally with the technology of manufactured oils, fats, and waxes, as, for example, the refining of edible oils, the making of soap and candles, the purification of glycerine, oil hardening, and the preparation of polymerised, boiled, and oxidised oils. In appraising the value of these sections it must be remembered that the book deals essentially with the chemical aspect of these industries, and that in the few pages which can be spared to each it is impossible to attempt more than a general outline of the processes in common practice.

In particular, it is not part of the author's scheme to indicate on the more mechanical side of the industry which type of plant or process is at the moment generally in use in an up-to-date factory. One consequence of this treatment is that the accounts of the manufactures appear antiquated when read by one acquainted with practice, and the student of chemical technology trained on this book would justly be accused in the works of being too theoretical. On the other hand, it will be said there are numerous highly specialised text-books devoted to each of these subjects, and a brief summary of them from the more purely chemical point of view is quite enough to attempt. In this connexion it may be suggested that the book is rather overburdened with statistics.

An important section is that devoted to waste oils and fats: it may be defined as an essential function of the chemist in any industry to eliminate waste and to utilise the so-called waste products. In oil-refining, for example, much depends, from the economic point of view, on obtaining both a high yield of the refined product and the retention of the foots in a form in which they can be utilised. The respective values of soap stock, or soap stock fatty acids, often make all the difference in the refiner's profit. Latterly a number of alternative processes have been tried in this connexion, and some reference to them might well have been included in this volume.

The subject of hydrogenated fats is dealt with very adequately in the well-known book of Carleton Ellis, so that the author may be excused for devoting only ten pages to it. Of some interest is a paragraph referring to the use of such fats in the edible-fat industry, particularly on the Continent, and indicating doubt as to their suitability. Actually to-day hardened fats, particularly whale oil, are the most popular materials for edible fats on the Continent, and the refiners are willing to pay a price for the raw oil which puts it beyond the reach of the soap-maker, at whose instance, it may be remembered, the hydrogenation process was invented. The refined product, which is absolutely free from nickel and of a high standard of purity, has many desirable qualities, though from the most modern point of view the absence of vitamins must be held to be a disadvantage. Very little hardened fat, however, is used in margarine made in Britain.

Probably no section of the industries based on oils and fats has developed more in this country than the manufacture of margarine, owing in the main to the abnormal conditions imposed during the War. The advance in the technology of this industry has been enormous, both in the methods of refining the crude fats, in their selection and blending, and in the actual manufacture of the margarine, including the bacteriological processes of imparting the special butter flavour. The new factories are models of their kind, and triumphs of cleanliness and organisation. Unfortunately, the difficulties of distribution are such that the consumer cannot with certainty buy his pound of margarine in perfect condition unless his retailer is certain of a quick sale; and although the same difficulty applies to butter, more tolerance is extended to the older commodity.

A problem which is engaging an increasing amount of attention in the fat industry is that of texture. A fat, that is to say, a triglyceride, may either contain three of the same acid radicles or two or more different acid radicles, in which case it is spoken of as a mixed glyceride. A mixed glyceride has properties very different in regard to melting-point, consistency, etc., from a mixture of glycerides. Again, fats which, when separate, have similar properties which are satisfactory from the technical point of view, may have altogether different and far less satisfactory properties when mixed. Such theoretical considerations have an important practical bearing in the chocolate and biscuit industries.

Sufficient has perhaps been said to indicate how diverse are the problems to be found within the industries of the fats and oils, and how wide must be the scope of a work dealing with their chemical technology. Dr. Lewkowitsch's book has played no small part in aiding many an investigator to do his share in advancing the knowledge of them, and each new edition has reflected in turn the new information acquired. The newest edition is no exception to this and is replete with information, and it is with no wish to detract from its value that it is suggested that when the time comes for it again to be revised it may be advisable largely to remodel the plan on which it is built.

Our Bookshelf.

(1) *Steam Turbines.* By Prof. W. J. Goudie. Second edition, rewritten and enlarged. Pp. xviii + 804. (London: Longmans, Green and Co., 1922.) 30*s.* net.

(2) *Modern Practice in Heat Engines.* By T. Petrie. Pp. xi + 264. (London: Longmans, Green and Co., 1922.) 15*s.* net.

(3) *Notes and Examples on the Theory of Heat and Heat Engines.* By John Case. Second edition, revised and enlarged. Pp. vi + 138. (First issued in 1913 as "A Synopsis of the Elementary Theory of Heat and Heat Engines.") (Cambridge: W. Heffer and Sons, Ltd.; London: Simpkin, Marshall and Co., Ltd., 1922.) 7*s.* 6*d.* net.

(1) Prof. Goudie's treatise was first issued in 1917, and the volume has become a standard work. Its value has been proved by teachers, students, and professional men engaged in practice. The book has been out of print for some time, owing to the author's desire to bring it up-to-date, and this has meant the formidable task of rewriting practically the whole work. To those acquainted with the first edition, the result will be found extremely serviceable, inasmuch as not only recent designs are included, but also additional matter is given bringing the theory up-to-date. The thoroughness with which the task of revision has been carried out is evidenced even in the numerical examples. The volume is now one which cannot be dispensed with by any one engaged in steam engineering.

(2) This book is divided into three sections dealing with steam boilers, steam prime movers (including steam turbines), and internal-combustion engines respectively. Some of the descriptive parts of the section on steam turbines are taken from the article written by Prof. Gerald Stoney and the author for the "Dictionary of Applied Physics" (Macmillan). The field covered is wide, and the book contains a large number of illustrations descriptive of the details of modern plants. Despite this, the author has succeeded in presenting as much of the theory as the average student requires in his college course. Students require a general treatment such as is contained in the present work, and they will also appreciate the fact that it contains no very difficult mathematics. There are a number of worked examples in the text, but it would be an improvement if some exercises were included for the purpose of enabling the student to test his knowledge.

(3) Mr. Case's volume of notes, worked examples, and exercises on the theory of heat engines will be helpful to many students. Most parts of the subject are covered, and those omitted do not present any particular difficulties.

The Pageant of Nature: British Wild Life and its Wonders. Edited by Dr. P. Chalmers Mitchell. (Complete in about 36 fortnightly parts.) Part 1. Pp. 72. Part 2. Pp. 73–144. Part 3. Pp. 145–216. (London: Cassell and Co., Ltd., 1923.) 1*s.* 3*d.* net each part.

The avowed object of this new publication is to provide the libretto to the play of Nature in Britain, and, by describing in clear and accurate language the varied phenomena which can be observed at all seasons of the year during almost any country ramble, to stimulate observation, to foster a love of Nature and, perhaps, to spur on to further independent discovery the keener and more gifted of its readers. It is essentially a book of Nature study, of observation in the field, of animals and plants in their natural surroundings. All the authors who have contributed to its pages—and there are no fewer than twenty in the three parts under notice—are well known for their admirable first-hand studies of wild Nature, in one or other of its many branches, with eye, field-glass, and camera and, may we add, with pen, and their articles are illustrated with original photographs taken either by themselves or by other equally skilled and enthusiastic Nature photographers.

It is perhaps invidious to make a selection from a number of articles all of which reach a high level of charm, accuracy, and simplicity; but special mention should be made of Dr. Francis Ward's delightful studies of otters and fishes, illustrated by a unique series of remarkable photographs of these animals taken under water, Mr. Edgar Chance's account of the egg-laying habits of the cuckoo, and Dr. Landsborough Thomson's articles on birds. The illustrations, in colour, photogravure and half-tone, are excellent on the whole. Particularly charming are four studies of the feeding of a cuckoo by its foster-parent, a meadow pipit, the work of Mr. T. M. Blackman. The reproductions of the photographs illustrating Mr. Chance's article, however, scarcely do justice to the originals.

The general editor, Dr. P. Chalmers Mitchell, in a short introduction, makes a strong appeal for the wider study of Nature in the field. This publication should go far to stimulate such study and to fulfil his hopes "to turn all our readers into watchful lovers of Nature."

Chambers's Encyclopædia: a Dictionary of Universal Knowledge. New edition, edited by Dr. David Patrick and William Geddie. Vol. 1: A to Beatty. Pp. vi+824. (London and Edinburgh: W. and R. Chambers, Ltd.; Philadelphia: J. B. Lippincott Co., 1923.) 20*s.* net.

A new edition of this work is welcome, for in spite of the many encyclopædias now available, Chambers's still holds its place. It is not exhaustive and does not claim to be a compendium of all knowledge, but at the same time it would be difficult to find any subject of general interest that finds no place in its volumes. The work has the further merit of easy reference, the subdivisions of the larger subjects being arranged in their respective places in the alphabet. The form and appearance of the pages which have been familiar to several generations are unchanged, but the matter has been revised, new articles being given where necessary and others brought up-to-date. New coloured maps, mostly by Bartholomew, have been added. That of North America needs a little revision in the north of Greenland, but for all general purposes they are excellent. The illustrations would appear to be mainly the woodcuts of earlier editions.

In one respect we might suggest an improvement in this useful work. Some geographical articles still contain descriptive matter that is unworthy of the advances in modern geography. Without any greater demands on space the descriptions of many countries could be made far more explanatory and graphic than is the case. Thus, in the article on the Balkans certain striking features, such as the central plateau, the fold ranges parallel to the sea, the two great corridors, and the gateways to the sea should be emphasised as being keys to many Balkan problems. The article as it stands is full of accurate information which might be better displayed. The same criticism is applicable to Albania and other articles. The low price of the encyclopædia is noteworthy.

Wind and Weather. By Prof. Alexander McAdie. Pp. 82. (New York: The Macmillan Company, 1922.) 1.25 dollars.

Prof. McAdie's little work is more historical than a current discussion of wind and weather. Much of the work is a dissertation on "The tower of the winds," which has been standing at Athens for the past twenty-two centuries. The allegorical figures of the winds given are reproductions copied from the frieze of the tower and the author has extemporised on them. Boreas, the north wind, is referred to as a cold and boisterous wind from the mountains of Thrace; Kaikias, the north-east wind, who carries in his shield an ample supply of hailstones, is supposed to be ready to spill them on defenceless humanity; Apheliotes, the east wind, is styled a graceful youth, with arms full of fruit and wheat; Euros, the south-east wind, is depicted as a cross old fellow, intent on the business of cloud making; Notos, the south wind, is the master of the warm rain; Lips, the mariners' wind, the south-west, said to be favourable for bringing the ships speedily into harbour; Zephyros, the west wind, is represented as a graceful youth, scantily clad, with his arms filled with flowers, while Skiron, styled lord of gusty north-west gales, carries with him a brazen fire bucket and is said to spill a generous stream of hot air on all below.

The latter part of the book is more practical and deals with the weather map and current meteorology, although in an elementary way, and this part seems to suggest that the author had American weather in mind rather than the weather in other parts of the world. C. H.

Text-Book on Wireless Telegraphy. By Dr. Rupert Stanley. Vol. 2: Valves and Valve Apparatus. Second edition. Pp. xi+394. (London: Longmans, Green and Co., 1923.) 15*s.* net.

In this edition a new chapter has been added describing high-speed signalling, recorder reception, short-wave signalling, and directional apparatus. In the author's opinion the two outstanding problems for research work are the elimination of atmospherics and the invention of a cheap system of high-speed reception able to withstand ordinary wear and tear. We agree with him that the well-established term "valves" should be used to designate the special vacuum tubes used in radio signalling.

In his preface the author points out that the development of radio signalling since 1918 has been much hampered owing to doubts about the validity of the patents of many of the methods and types of apparatus which were used in the War. The tedious delay in the establishment of broadcasting stations in Britain was largely due to disagreements between manufacturing firms on this question.

The Year-Book of Wireless Telegraphy and Telephony, 1923. (Edition for Amateurs.) Pp. xcv+824. (London: The Wireless Press, Ltd., 1923.) 6*s.* net.

The progress in the art of radio communication is so rapid that a new "Year-Book" is a necessity for all who wish to keep abreast of the times. We learn that in the United States nearly two hundred broadcasting transmitting stations are now in practically continuous operation and that the number of listeners is nearly a million. Canada comes next with fifty-three broadcasting stations, twelve of which are in Toronto alone. In France great progress has been made in perfecting high-frequency alternators. It is now possible to get a 500-Kilowatt 15000-frequency alternator which will have an over-all efficiency of 85 per cent. Latour has also shown how, by means of a 100,000-volt transformer and using two electrode valves as rectifiers, a pressure of 200,000 volts direct current can be easily and comparatively cheaply obtained. These high pressures are of great value as they open up new fields for physical research.

Letters to the Editor.

Hafnium and New Zealand Sand.

THE account which was given in NATURE of February 10 (p. 195) of the very refractory substance which I obtained from a black titaniferous iron sand from New Zealand and believed to be the oxide of the newly discovered element, hafnium, requires now to be brought up-to-date. In that account it was mentioned that I had sent to Copenhagen practically all my purified material for X-ray examination and comparison with the preparations and specimens of the discoverers. Three specimens were sent: (*a*) the sand itself, (*b*) the cream-coloured substance labelled in 1918 "New Oxide," (*c*) the cinnamon-coloured oxide which resulted from the atomic weight determinations (Chem. Soc. Jour. for February, p. 312). The total amount of (*b*) and (*c*) was between 0·3 and 0·4 gram each and was all I had. The result of the first examination by Drs. Coster and Hevesy was to the effect that they were unable by X-ray spectral analysis to detect hafnium in any of the three specimens, and this I announced at the meeting of the Chemical Society on February 15.

Drs. Coster and Hevesy very kindly undertook a much more thorough and laborious examination, both by X-ray and by optical spectral analysis, especially of (*c*), which was naturally regarded as the purest sample of the oxide. They did this in the hope of finding some evidence of the presence of some of the other elements still missing, and in particular element No. 75, but in this they were unsuccessful. Their final report is that "The chief components are undoubtedly iron and titanium" with traces of manganese, aluminium and magnesium. As soon as I received this statement on March 19 I set to work on what remained of (*b*) and (*c*) to try to unravel the mystery of the high atomic weight which had seemed to prove conclusively that the oxide was that of an element with an atomic weight at least one and a half to two times that of zirconium (90·6). As the full analytical details and the steps by which the explanation was arrived at are given in the Journal of the Chemical Society for April, p. 881, I need not do more here than give the general conclusions. My further chemical examination of the cinnamon-coloured powder (*c*) agrees entirely with that of Drs. Coster and Hevesy in proving that it consists practically of oxides of titanium and iron, the latter only to the extent of about half a per cent. It is to the presence of this iron oxide that the cinnamon colour is undoubtedly due.

The "New Oxide" (*b*), however, seems to be a new oxide so far as chemical literature is concerned, but not the oxide of a new element. Further investigation showed it to contain a large percentage of silicon and that, so far as could be ascertained with the small quantity which I had, there seems to be but little doubt that it is a form of titanium dioxide in which part of the titanium is replaced by silicon. It is due in all probability to this replacement of titanium by silicon that the "New Oxide" owes its resistance to the attack of sodium bisulphate on one hand and caustic soda on the other.

The substance extracted from a New Zealand sand (while my specimens were in Copenhagen) by Dr. C. J. Smithells and Mr. F. S. Goucher (NATURE, March 24, p. 397) in the Research Laboratories of the General Electric Company, is entirely different from my "New Oxide." This is clearly proved by their own statements; hence their experiments with it have no bearing on the composition and properties of the substance isolated by me.

I gladly avail myself of this opportunity of acknowledging and thanking Prof. Bohr and Drs. Coster and Hevesy for all their courtesy and for the very great trouble they have taken to assist me in the elucidation of what seemed to be a real mystery. It is with sincere pleasure that I have just learned that they have succeeded in the difficult task of preparing hafnium compounds in a state of purity sufficient to enable them to locate its atomic weight between 179 and 181.

A Meteorological Disturbance of an Oscillatory Character.

A DISTURBANCE possessing a pronounced oscillatory character swept across the Gulf of St. Vincent, South Australia, on the morning of February 24. It may be of interest to put upon record its chief features.

At 5.10 A.M. those who were sleeping out of doors were rudely awakened after a stifling airless night (wind N.N.E., strength 0–1) by a sharp westerly squall. A lull was succeeded by a second squall about 7 minutes after the first; a well-marked line-cloud accompanied it, but no rain fell. The wind then dropped to a gentle S. breeze for a few minutes, but the approach of another splendidly developed line-cloud arching the horizon from S.S.E. to N.N.W. heralded another squall from the west. The upper atmosphere was almost cloudless, save on the western horizon, where an alto-cumulus layer drifted slowly from a northerly point. Again the wind went round to the S. and dropped, but a third line-cloud brought a fresh squall from the west.

The writer, observing from Glenelg, faced forty miles of sea stretching out to the westward, and it was a very fine sight to watch the unbroken lines of cloud, 2000 to 3000 feet up, approaching at a very great speed and stirring up an almost calm sea into momentary activity. The three clouds passed over within the space of a quarter of an hour, and were separated by approximately equal intervals of time. The wind which accompanied them was not very violent, probably between 30 and 40 miles an hour, but strong enough to cause the anchored yachts to swing round through 90° from S. to W. in a few seconds.

Though no further line-clouds were observed, the oscillatory character of the disturbance continued, and at two further intervals of 8 and 7 minutes respectively the squalls and vagaries of the shipping were noted. Eye observations were then suspended, but the writer is indebted to Mr. Bromley, Commonwealth Meteorologist for the State of South Australia, for traces of the automatic records obtained at Adelaide, 6 miles inland and E. of Glenelg, which show that the pulsations continued for about an hour altogether. The periodicity is especially well-marked in the barograph and wind velocity curves reproduced below; at first they keep remarkably in step, each rise in the barometer coinciding with an increase in wind velocity and vice versa, but there is some confusion in the velocity graph towards the end of the disturbance. The anemo-biagraph has been under suspicion of furnishing low readings, but it is also probable that the squalls lost something in intensity in travelling inland.

From the accompanying graphs (Fig. 1), the average period appears to be about 7·5 minutes; from the times of observation of the pulsations at Glenelg and Adelaide we calculate that they were travelling inland at approximately 30 miles an hour, and that they were between $3\frac{1}{2}$ and 4 miles apart.

The wind direction graph shows that, except for the initial squall, the changes in direction were neither so regular nor so pronounced in Adelaide as they were on the coast; as would be expected, the changes generally, but not invariably, coincided with the rise of the barometer. This graph records a series of small abrupt changes in direction, leading from W.S.W. to S.S.E., each pulsation, except the third, sending the wind round some 15°. This is very different from what was observed at Glenelg, where,

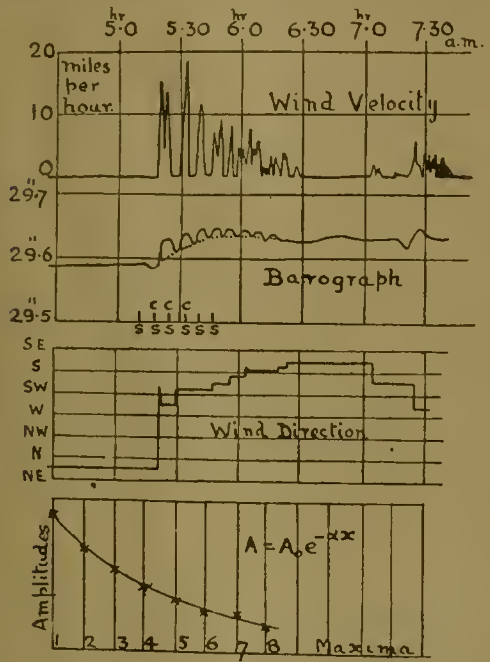

FIG. 1.—Records of an oscillatory meteorological disturbance at Glenelg on February 24. The times at which squalls and line-clouds were observed at Glenelg are marked S and C respectively. The autographic instruments were at Adelaide.

at any rate for the first 6 pulsations, the wind was S. during the lulls and W. during the squalls, rather as though there were intrusions of westerly air from above into a gentle S. current in the lower levels. It is difficult to account for these differences because the intervening country is flat, and both Glenelg and Adelaide are on the direct line of advance of the disturbance.

The barograph record shows first a slight depression and then a sudden rise of about 0·04 inch, something like half the amount observed in the case of some famous line-squalls. Later oscillations are less intense, the average of all being 0·02 inch from hollow to crest. From the original barogram I have measured the amplitudes of the successive oscillations, taking the dotted line drawn through the minima as datum line. Except for the last oscillation, which shows some irregularity, the amplitudes closely follow an exponential law. This is indicated in the final graph, where the abscissæ represent equal time intervals between successive maxima, and the ordinates the amplitudes, A. The full line represents the curve $A = A_0 e^{-\alpha x}$, where x is the time between maxima; the crosses mark the measured amplitudes on an appropriate scale. The logarithmic decay of the amplitudes suggests that viscous forces are involved in the phenomenon, though whether they act by diminishing the forces which occasion the pulsations, assuming that they are formed successively, or by diminishing the oscillations in their transmission, we have no means of ascertaining.

As regards the general meteorological conditions, the barometer had been falling for some time and the disturbance marked the beginning of a rise which continued for some hours. The Commonwealth weather-map compiled at 8.30 A.M. indicates that a shallow V-shaped depression, probably part of a monsoonal system, had recently passed across Adelaide from W. to E.; the axis then lay along a S.S.E.-N.N.W. line, which is rather curiously the direction along which the axis of the lines of cloud extended. Mr. Bromley kindly gave me access to a large number of weather charts and barograms, from which it appears that though unstable conditions are liable to arise with the passage of depressions, no evidence of regular pulsations occur except that above described and, also rather curiously, a comparatively feeble example on the previous day (11 A.M. February 23). In this case the oscillations increased in intensity as time went on. There were 5 pulsations with an average period of about 7 minutes, but the maximum amplitude was not more than 0·01 inch. Seven well-marked pulsations are shown upon the wind velocity graph, reaching 10 miles per hour.

W. G. DUFFIELD.

Dundrennan, Glenelg, South Australia,
March 3.

Phosphorescence caused by Active Nitrogen.

IN 1904, in the *Astrophysical Journal*, the present writer described the spectrum of the afterglow of active nitrogen, and showed that the vapours of mercury and other metals present in the tube participated in the afterglow. Some years later the present Lord Rayleigh showed that luminosity of the vapours of many substances is excited by active nitrogen.

Recently I have found that it also excites phosphorescence in a number of solid compounds. By opening a stopcock between the discharge tube and the pump, a jet of active nitrogen could be directed against a small quantity of the substance. In a number of cases phosphorescence was produced, which lasted for several seconds. The colour was green or bluish green, and the spectra all appeared to be continuous, except in the case of the first two substances named below, which showed characteristic bands. The results were as follows:

Strong.—Uranium nitrate, uranium-ammonium fluoride, zinc sulphide, barium chloride, strontium chloride, calcium chloride, cæsium chloride. These are arranged in the order of brightness.

Weak.—Lithium chloride, sodium chloride, potassium chloride, sodium iodide, potassium iodide, sodium carbonate, strontium bromide.

No effect.—Potassium sulphate, potassium nitrate, potassium hydroxide, mercurous bromide, calcium carbonate, calcium sulphate, calcium sulphide, lead chloride, cadmium iodide, magnesium nitrate, zinc chloride, manganese chloride, thorium oxide, chalk sugar, sulphate of quinine.

With the exception of the first three, the excited substances are little or not at all affected by light, but most of them are excited by cathode rays. It is remarkable that a specimen of calcium sulphide very sensitive to light was not at all affected. With the same exceptions, the effect was obtained only after partial drying, but appeared to be destroyed by complete calcination. Some of the substances did not always respond, even when taken from the same bottles as portions that did. None were chemically pure.

It seems possible that the phenomenon is due to chemical reactions with the active nitrogen, or it may be due to the presence of free electrons. An insulated electrode was sealed into the exhaust tube about a metre from the discharge tube and connected with an electroscope. When the latter was negatively charged little effect was produced by a stream of active nitrogen just past the stage of luminosity. When it was positively charged, it was rapidly discharged. When an uncondensed discharge was used with the same nitrogen, or the condensed discharge through inactive nitrogen, little effect was produced in either case. Recombination was apparently complete before the gas reached the electrode. As there must have been equal numbers of positive and negative ions, the loss of the positive charge must have been due to the greater mobility of the negative ions, and presumably they were free electrons. An attempt to measure the specific ionic velocities of the ions failed, on account of the electrostatic disturbances due to the disruptive discharge.

Under the conditions of these experiments, the line spectrum of nitrogen was not given by the light in the discharge tube. This indicates that molecular dissociation was small. The ions were probably for the most part molecular ions and electrons. The isolated bands in the first group which are the most characteristic feature of the spectrum of the active nitrogen afterglow must, of course, be due to molecular radiators. The afterglow depends upon the presence of a trace of oxygen (or some electronegative element) and is destroyed by the presence of more than a trace. It may be that in pure nitrogen there is no appreciable afterglow, because the great electron density favours rapid recombination. When there is an excess of oxygen, the electrons may all attach themselves to oxygen, and the final step may be the formation of nitric oxide, with the emission of Deslandres' third group of bands. If there is enough oxygen to remove most but not all of the electrons, recombination may go on slowly, the afterglow continuing while it lasts, the spectrum being due to the recombination of electrons with positive molecular ions. Of course the alternative is not excluded that active nitrogen may be monatomic and the characteristic radiation is emitted when it resumes its ordinary state.

Active Hydrogen by the Action of an Acid on a Metal.

Evidence for the formation of active hydrogen from its positive ion in an acid has been negative. The reports of the latest workers in this field, Wendt and Landauer (Jour. Amer. Chem. Soc. 42, 930: 1920) show that there are certain difficulties to be met. The main one is to eliminate the moisture that accompanies a rapid evolution of hydrogen and at the same time not to destroy the active hydrogen if any were formed. If the velocity of the gas stream were too low, the active component would decay before reaching the sulphur. Then if the velocity were too high the moisture carried over would form a protecting film on the powdered sulphur and prevent the reaction between the two to form hydrogen sulphide.

During the work on the activation of hydrogen by corona discharge it was found by Wendt and Grubb (Jour. Amer. Chem. Soc. 42, 937: 1920) that active hydrogen combines with pure nitrogen to give ammonia. This method of testing for active hydrogen can be used to good advantage where moisture is carried along with the evolved hydrogen, since the spray does not prevent the contact of active hydrogen and the nitrogen.

If hydrochloric acid or sulphuric acid is dropped upon metallic magnesium suspended in such a way that the metal is at no time immersed or partly covered with any large portion of liquid, the drop of acid can react with the metal in the shortest possible time. This gives off hydrogen very rapidly, in fact almost explosively, and with a minimum quantity of spray. If this evolved hydrogen is brought in contact with pure nitrogen it is found that ammonia is formed very readily. The active hydrogen was then passed through a plug of glass wool before coming in contact with the pure nitrogen. The activity of the hydrogen still persisted as shown by the formation of ammonia. Therefore, the activity of the hydrogen cannot be due to ions or atomic gas. But Langmuir (Jour. Amer. Chem. Soc. 34, 1324 (1912)) has shown that monatomic hydrogen does not react with nitrogen to form ammonia. In view of this fact, if we allow pure nitrogen to escape at the surface of the magnesium where the hydrogen is evolved we find a maximum quantity of ammonia formed. The amount of ammonia formed increases with an increase in the rate at which the acid is dropped upon the metal. This, of course, means that the amount of the active component varies with the velocity of the gas stream.

If the acid is dropped on the metal very slowly and the evolved hydrogen passed through glass wool before coming in contact with nitrogen, no ammonia is formed. This indicates that the active hydrogen has reverted to the ordinary form before meeting the stream of nitrogen. The life of the active gas seems to be not longer than two minutes. This checks very closely with the life of triatomic hydrogen formed by other methods.

These results seem to substantiate the theory of Wendt and Landauer (Jour. Amer. Chem. Soc. 44, 510: 1922), namely, that triatomic hydrogen ought to be produced wherever atomic hydrogen is evolved. It is reasonable then to expect that a higher percentage of active hydrogen would be found in the gas evolved from the surface of the metal, than in the molecular hydrogen subject to electronic bombardment in a discharge tube. In the former all the hydrogen evolved goes through the atomic state, while in the latter case only a very small amount of atomic gas may exist at one time. The discharge would also destroy some of the active variety.

The preliminary results to determine the percentage of activation are in harmony with this theory. Further work is in progress to determine the quantitative relations of some of the factors involved.

The Viscosity of Liquids.

I wish very briefly to supplement the remarks made in a previous communication on this subject in which I have suggested that the viscosity of liquids and its variation with temperature may be explained on the hypothesis that the liquid state of aggregation is composite in character; that is, is composed in part of molecules "rigidly" attached to each other as in a solid, and in part of molecules which are relatively mobile as in the gaseous state (NATURE, April 21, p. 532).

That the supposition made regarding the constitution of liquids is *prima facie* a reasonable one is, I think, clear from thermodynamical considerations. The liquid stands midway between the solid and the gas and has affinities to both. The volume of a liquid at temperatures slightly higher than the melting point is only moderately different from that of the solid, and hence the probability that many of the molecules are at any instant at the same distance from each other as in a solid is considerable. This probability may indeed be found from the latent heat of fusion of the substance. If W be the heat of fusion in ergs per mol, the number of molecules in the "rigid" and "mobile" states should be approximately in the ratio $e^{W/RT}$.

The mechanism of viscous flow of a liquid is perhaps clearest if we consider the case of a thin layer enclosed between two parallel plates, one of which slides over the other. When a steady state is reached, the "rigid" parts of the liquid move practically as complete wholes, and hence the effect of their existence is to diminish the thickness of the layer through which momentum has to be transported by the "mobile" molecules, and thus to increase the viscosity. As a rough approximation, this increase is in the proportion of the numbers of the two types of molecules. A more exact theory should take into account also the volumes occupied by the two types of aggregation and their changes with temperature.

The effect of pressure on viscosity of liquids would arise in two distinct ways. In the first place, we have a change of volume on fusion, and hence, by the Le Chatelier-Braun principle, the assumed dissociation from the "solid" to the "mobile" aggregation would be retarded by pressure, so that the viscosity should be increased. With substances such as ice which contract on melting, we have the opposite effect. In the second place, pressure diminishes the volume occupied by the "mobile" molecules, and therefore also the distance through which they have to transport momentum. This would increase the viscosity. At temperatures not much higher than the melting point, the first effect would preponderate. This is strikingly illustrated in the case of water, the pressure-coefficient of viscosity of which is negative up to 32° C., that is, even at temperatures much higher than that of maximum density.

Green and Colourless Hydra.

IN NATURE of April 7 a short account is given of the interesting experiments made by Goetsch on the conversion of the green Hydra into a pale Hydra. Some years ago I observed what may be called a natural experiment of the same kind. At the south end of the tunnel that conducts the water supply of Manchester from Lake Thirlmere under Dunmail Raise to the Grasmere valley there is a small settling tank, and on the walls of this tank I found a very large assembly of milk-white Hydras. An examination with a pocket lens led me to the conclusion that they were only a white variety of the common *Hydra viridis*, and were probably the offspring of parents living in the tunnel. These white Hydras were evidently enjoying the full vigour of life.

Single Crystals of Aluminium and other Metals.

WITH reference to Prof. Porter's letter in NATURE of March 17, p. 362, the accompanying photographs (Figs. 1 and 2) may be of interest. They illustrate at a magnification of 100 diameters the type of fracture obtained when a drawn tungsten wire consisting of a single crystal is broken in tension. The fracture is

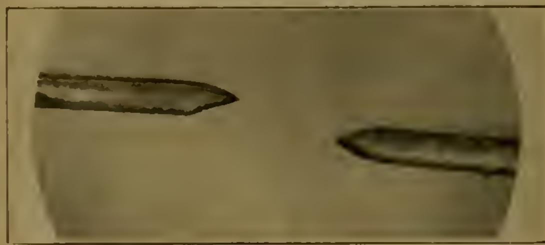

FIG. 1.—0·05 mm. single crystal tungsten wire broken in tension, showing reduction in diameter. (× 100.)

FIG. 2.—Same specimen photographed in a plane at right angles to that of Fig. 1, showing no reduction in diameter in this plane.

always of the wedge type, the wire being very greatly reduced in diameter in one plane while it suffers no appreciable reduction in the plane at right angles. The photographs show the same specimen after fracture taken from two planes at right angles. The diameter of the wire was 0·05 mm.

Stirling's Theorem.

A SMALL modification of the proof given by Mr. Strachan in NATURE of March 24, p. 397, leads to an asymptotic series for $n\,!$ rather more convergent than Stirling's. The symbol $n\,!$ standing, generally, for $\Gamma(n+1)$, we have

$$\log(n+\tfrac{1}{2})\,! - \log(n-\tfrac{1}{2})\,! = \log(n+\tfrac{1}{2}).$$

Hence, by Taylor's theorem,

$$\left(D - \frac{D^3}{2^2\,3\,!} + \frac{D^5}{2^4\,5\,!} - \ldots\right)\log n\,! = \log(n+\tfrac{1}{2}).$$

$$\therefore \log n\,! = \left(\frac{1}{D} - \frac{D}{24} + \frac{7D^3}{5760} - \ldots\right)\log(n+\tfrac{1}{2}).$$

$$\therefore n\,! = \sqrt{2\pi}\left(\frac{n+\frac{1}{2}}{e}\right)^{n+\frac{1}{2}} \times \exp.\left(-\frac{1}{24(n+\frac{1}{2})} + \frac{7}{2880(n+\frac{1}{2})^3} - \ldots\right),$$

the constant in the integration being determined as before.

Stirling's first approximation, $\sqrt{2\pi n}\;n^n e^{-n}$, makes $1\,! = 0{\cdot}922$, whilst $\sqrt{2\pi}\{(n+\frac{1}{2})/e\}^{n+\frac{1}{2}}$ makes $1\,! = 1{\cdot}028$ and so is a little closer.

Selection and Segregation.

IN view of recent discussions in the columns of NATURE, the following remarks may be of interest.

Charles Darwin did not explore for himself the vast resources of the new territory which he discovered, nor did he traverse all the passages leading to it. He "allured to brighter worlds and led the way." In doing so it is possible that he did not arrive at the point of disentangling the qualitative from the quantitative implications of selection. It will be remembered that his theory was followed by long discussions on "What is a species?"

Natural selection is mainly qualitative, while specific differences are essentially quantitative. If Darwin can be said to have missed this distinction it was because he could not anticipate all the objections that might be brought to bear upon his marvellously fruitful concept. Moreover, quality and character often appear without any obvious separation, and in all cases the mind has to be addressed to the task of discrimination.

It is the province of Mendelism or genetics to deal with the analysis of unit characters and to exploit favoured individuals. Natural selection is concerned with the combination of characters, internal as well as external, and with the preservation of favoured races. Combination of characters gives quality to a genus; segregation of characters imparts novelty to a species. Mendelism and Darwinism clearly belong to different categories; though of course they meet on the common stamping-ground of heredity.

Natural selection is the directive force which controls the motive impulse of evolution and holds it within bounds. It thus becomes to our view the guardian of mutations, the custodian of change; that is to say, it provides an automatic control over the fitful mutations of the organism. The four pillars of organic evolution—struggle, survival, mutation, and adaptation—are properly orientated by natural selection. This operates in certain directions under certain conditions of climate and contact; it is the chain of events which assigns an organism to its place in Nature. Nevertheless, the simple thesis had not been excogitated before it was expounded by Darwin. It was a permanent gain to knowledge which can never be repeated, like the discovery of the circulation of the blood by Harvey and the biogenesis of reproduction by Redi.

Darwin gave us a theory of qualitative evolution by the natural selection of spontaneous variations in the open. Survival for an hour or for an æon implies unconscious selection for the time being. On the other hand, Mendel gave us a quantitative law of alternate inheritance of contrasting characters under culture. A single example, expressive of many, may serve to bring the distinction between intrinsic qualities and gross realities into crude relief.

Leaf-mimicry is one manifestation of interrelation of plants and animals, of which floral imitation and stick and twig shapes are others. It is a quality so intangible that it may be called into question even when most obtrusive. Individual observations are therefore of little moment until confirmed. The leaf butterfly (Kallima) and the leaf insect (Phyllium) resemble a leaf in different senses—the former vertically, the latter horizontally—the recognition of the resemblance in these classic examples being old-established. Some years ago ("Spolia Zeylanica," II, 1904) it was my privilege to bring to scientific notice for the first time the behaviour of a leaf fish (Platax) in Ceylon. Similar observations on a species of Platax in the Philippines have since been recorded by Dr. Th. Mortensen of Copenhagen. (*Vidensk. Medd. fra Dansk naturhist. Foren.*, Bd. 69, 1917, p. 63.)

Admitting the existence of leaf-mimicry in diverse planes and orders, we can only begin to explain it on the basis of natural selection, the leaf shape being desirable and attainable when other contributory factors are equal.

Distribution of Megalithic Monuments.

IN NATURE of March 31, p. 442, reference is made to Mr. W. J. Perry's speculations upon the builders of megalithic monuments. Perhaps you will be good enough to find room for some criticisms. There is a real danger that the scientific study of archæology may be overwhelmed by the tide of theorising which is now flowing so strongly in this country.

Mr. Perry believes that the builders of megalithic monuments chose to settle in those regions which furnished natural supplies of what the note in NATURE terms "precious metals and other valuables." If so, then why did so many of them settle in the Cotswolds, where natural flint is almost non-existent, and where no metals occur? In this region—in the counties of Gloucestershire and Oxfordshire—there are fifty-six Long Barrows, which Mr. Perry rightly includes within the class of megalithic monuments. Why are there more than twice as many Long Barrows in Gloucestershire alone as in all the other flint-producing counties of East and South-east England?—The East Riding of Yorks, Lincolnshire (none), Norfolk (none), Cambridgeshire (none), Essex (none), Herts. (one), Bucks. (none), Beds. (two), Oxfordshire (none in Chilterns), Surrey (none), Sussex and Kent (perhaps a dozen at most between the two). If it was flint that determined their settlement-areas, there is more to be found in any single *parish* of any one of these counties than occurs naturally in the whole of Gloucestershire! Why, further, is it that there is not a single Long Barrow within forty miles of Grimes Graves, the great Neolithic flint-mining district of East Anglia, and no megalithic monuments within a hundred miles?

But the greatest difficulty is in Mr. Perry's suggestion that the builders of megaliths travelled in search of metals. There is no evidence that the builders of British megaliths knew of or made any use of metals. Not a single fragment of metal has ever been found in a megalithic burial chamber in England, Wales, or Scotland. Accordingly, the opinion of archæologists for half a century has been that all megalithic burial-chambers (including those in Long Barrows) are neolithic; and there is no evidence of any sort to suggest that this opinion is erroneous, much less to prove it wrong.

Some controlling factors in the distribution of Long Barrows over a part of England and Wales were suggested in Ordnance Survey Professional Paper No. 6. The facts upon which my conclusions were based were presented fully, both in tabular form and upon a map (O.S. quarter-inch, Sheet 8). For this region the facts—about a quarter of them new to science—are not available elsewhere. When the survey of England and Wales is complete, it will be time to draw conclusions about the country as a whole. Until then, those interested would be serving science better by assisting in the collection of facts than by indulging in premature speculation.

The Surface Movements of the Earth's Crust.[1]

By Prof. J. Joly, F.R.S.

THE land surface of the globe has been, for the most part, many times covered by the sea in the course of geological time. The mountain ranges of the earth, as now known, have only recently attained their present elevation ; other mountain ranges formerly existed which have now been all but obliterated by the remorseless effects of denudation.

It is important that we should study for a little what happens when a great mountain range is developed on the surface of the globe. There is a long period of preparation for the stately event ; a period many millions of years in duration. First, there are signs of unrest in the solid land of the continents. The sea rises on the coasts and transgresses on the wide lands within, very gradually stealing over the lower levels. This process may not be steady and continuous. There may be periods of retreat followed by periods of advance, but always the land, as a whole, goes on sinking deeper and deeper into the sea. Many millions of square miles may be covered with the shallow seas—perhaps to a depth of two or more hundred fathoms—so that a considerable portion of the land area of the globe may become sea before the downward movement ceases. This transgression is a slow process ; so slow and long-enduring that, while the submergence lasts, great depths of sediment accumulate in the transgressional seas.

Then at length there comes a resurrection. The land begins to emerge ; but not the old land which went down. Where the great accumulations of sediment had been, mountain ranges arise. In short, what arises from the ocean grave is a crushed and wrinkled world, shattered by faults and over-thrusts and exhibiting every evidence of great horizontal compression. One attendant of these events is the outbreak of volcanoes and floods of lava welling out of fissures in the earth's crust. The latter generally appear along western coasts, or to the west of the new-born mountain ranges.

These events draw to a close when the land has attained its former elevation, more or less. There is then a new era of geological history—a long era of organic progress, lasting many millions of years, during which minor oscillations of the crust and local deformation may occur. This is a period of active denudation. The last-born mountains are degraded by denudation, and their sediments collected into the great troughs or geosynclines, and the sublime but unreasoning sequence of events is repeated all over again.

Such has been in leisurely repetition the history of the earth. Certain world-revolutions are generally accepted—although geologists are not all agreed as to their number—as comprised in the period of 150 or 170 million years which the statistics of denudation and the record of thorium lead ascribe to the age of our era. Four or five world-revolutions appear to enter into that time interval. Thus 30 or more millions of years may, tentatively, be ascribed to the genesis and consummation of a world-revolution.

[1] From a public lecture delivered under the auspices of the Royal Dublin Society on March 7.

From these broad features of geological history it is evident that some source of unrest, acting upon the surface of the earth, which periodically recuperates its strength, runs a course involving an enormous expenditure of energy, and then dies down into quietude, must exist. What can this source of unrest be ?

In the science of isostasy we are confronted with the strange fact (for fact it undoubtedly is), that the lands of the earth—firm as they may appear—are yet floating like rafts or pontoons on a yielding substance far beneath. Now, the continents are built of rocks, such as granite, gneiss, sandstone, etc., and in the same way as the sea-water must be denser than the icebergs which float upon it, so the substance which buoys up the continents must be denser than granite and chemically similar materials.

We get a very sure guidance as to the nature of the sustaining substance in a direct and simple way by paying attention to the nature of the lava which is poured out in enormous volumes on the surface of the land during times of revolution. This substance comes up as a thin and very fluent liquid. It may flow for 50 or 60 miles over the ground before congealing. It solidifies to a black and heavy solid—basalt.

There appears to be no doubt—and in this many petrologists are agreed—that basalt is the primary rock-magma upon which the continents float and which buoys up the great oceans of the earth. Just beneath continents and oceans it forms a layer over the whole earth—a layer to which isostasy ascribes a depth of some 60 to 70 miles. This substance, basalt, therefore, plays a very important part in the surface history and physical phenomena of the globe. Primarily, and most important of all, we know that it contains a small quantity of radio-active substances. No basalt ever examined failed to reveal this fact. These radio-active substances continually evolve heat. We know of no conditions which can check, or in any way alter or modify, this ceaseless evolution of thermal energy. Hence we must recognise that in every cubic centimetre of this great magmatic ocean upon which the continents and seas float there is a source of slow thermal evolution.

Keeping in mind that the central problem to be solved with respect to the great land movements affecting the surface of the globe is to account for the great outbreak of igneous activity and crustal disturbance all over the surface of the earth every 25 or 30 million years, we naturally ask if the perennial supply of radio-active heat may not furnish the explanation.

The thermal properties of basalt under ordinary conditions have been fairly well examined. At a temperature of 1150° it softens, at 1225° it flows freely, forming a very mobile but heavy liquid. In passing from one state to the other there is a volume increase of about 10 per cent. of the initial volume. This may be a rather excessive value. It is not less than 6 per cent.

Now, the fact that the basalt in these great floods reached the surface in a fluid state is adequate proof that it was at a high temperature in the regions deep down from which it came. This is its condition generally all the world over during times of revolution. There are many reasons for believing that at the present time it does not and cannot generally exist in the fluid state; although deep pockets of the fluid magma must probably exist at all times throughout the magma-ocean and beneath the continents, there extends for a very long period after a revolution a shallow layer of the melted rock. Generally throughout the deep isostatic layer it possesses the characters of a plastic solid and is yielding enough for the continents to float upon it. The addition of a certain known quantity of heat to each gram of the highly heated basalt will convert it to the liquid state.

We know, as the result of many experiments, the quantity of radio-active substances in basalt. Samples from various great lava flows and volcanoes have been examined. There are certain variations in the quantities observed from one great flow to another. Taking a mean we can calculate the quantity of heat which would be generated, say, in one million years in each gram of the basalt. Briefly stated, the results of our investigation show that the heat accumulated in about 25 million years would suffice to turn the solid basalt, nearly at its melting-point, into a liquid.

The first effect of this change will be a considerable expansion in volume and corresponding loss of density and buoyancy. For, as has been stated, the solid basalt near its melting-point expands some 6 to 10 per cent. of its volume in changing to the liquid state. The result upon the continents is easily inferred. When a ship sails from the salt water of the ocean into a river of fresh water it sinks a little; so also the continents will sink a little. The waters of the ocean will therefore transgress upon the lands, advancing century after century as the basalt changes its state, as we know happens in periods preceding a revolution. Hence the earliest phase of geological change finds an explanation in the melting of the basalt which floats the continents.

But other consecutive consequences follow. For when, all over the earth, beneath continents and oceans, there extends a deep sea of melted lava, it is evident that conditions arise favourable to greatly increased volcanism both on the land and over the floor of the oceans.

The melted basalt will again lose heat and revert to the solid state. It may take 3 to 4 million years for this to happen, but happen it must. For liquids part with heat much more quickly than solids, just because circulation can go on in them. Now the basalt, where it laps against the rocky floor underlying the oceans, loses its heat far more rapidly than radio-activity can supply it. It probably melts away a good deal of the ocean floor in the process of parting with its heat. The ocean floor is very probably, almost certainly, also basalt. Possibly this floor becomes very thin indeed in the course of the long period during which the great ocean of lava is returning to the solid or plastic state.

It will be understood that the change of state has completely altered the conditions of heat-loss, the gain of heat per gram remaining the same at all times. The solid basalt can only lose heat by conductivity—a very slow process. Beneath the continents even this means of escape is almost closed, because the base of the continents possesses a high temperature, arising from the radio-active content of the continental materials themselves. Beneath the ocean, a few miles down, the conditions become much the same. Thus the solidified magma must conserve practically all its heat-gains. When fusion becomes general convection begins, as well as other movements later to be referred to. The escape of heat beneath the oceans becomes then relatively rapid.

But now notice the effect upon the continents of this reversion to the solid condition. When the basalt regains the solid state it also regains its original density; and the land regains its original buoyancy. The continents must now rise again to their former altitude above the sea. They are as ships passing from the river to the ocean. The waters which flowed in upon the continents during the slow process of the melting of the basalt must recede again as the basalt resolidifies. Hence a final great phase of geologic change finds explanation in the physical properties of the basaltic ocean and its inevitable thermal changes.

We can only discuss with any degree of definiteness the events progressing in the upper region of the great basaltic ocean. For the depth of this ocean is probably not less than 60 miles, and the pressures prevailing in such depths greatly modify the behaviour of substances experiencing accession or loss of heat, but there is no reason to believe that any effects to which reference has been made will be seriously modified. On the contrary, the effects, so far as we can infer them, of great pressure in the depths appear to bring events still more into harmony with geological observations and inferences.

From what has been stated we see that the reason for the long time intervals between the epochs of world-wide revolution is to be found in the smallness of the quantity of radio-active substances existing in the great sustaining magma supporting the continents and the oceans. On an average, it takes some 25 millions of years for the change of state to be brought about attending which the continents must sink and the waters transgress upon their surface. Then some 3 to 5 millions of years may be required for the stored radio-active heat to be again dissipated. The cycle is therefore accomplished in, say, 30 millions of years. These figures are given merely as suggestive of what might prevail. Various causes, which cannot be discussed, may modify them.

We live at a period immediately succeeding a very great world-revolution. The lava ocean has lost its heat of fluidity for the most part, and the continents float upon the basalt sea as upon a plastic or viscous body nearly at its melting temperature. These conditions are really very wonderful; but the explanation of our immunity is simple. The melting-point of the continental rocks is from 200° to 500° higher than that of basalt. Again, solid rock conducts heat badly. Hence little or no heat reaches us from the fiery ocean beneath.

We have next to consider if we cannot find an explanation of mountain-building and volcanic phenomena as involved in the changes we have been discussing. We know that the ocean tides are due to lunar and solar gravitational attraction. Oceanic tides are comparatively feeble phenomena; for not only is the ocean shallow and obstructed by land, but also water is a fluid of low density. But during times of revolution, just beneath the continents and oceans, there comes into existence a vast and far deeper ocean, composed for a great part of a highly fluid substance having a density three times that of water. We seem to have, therefore, good and sufficient reason for expecting greatly intensified tidal phenomena to arise during these times. So also a precessional force must act with intensified effect in periods of revolution. Both these forces tend to retard the surface crust of the earth in its diurnal rotation from west to east; that is, they tend to hold it back a little from partaking of the general easterly rotation of the globe. The effect is greatest in equatorial regions.

Fig. 1 shows, to an exaggerated vertical scale, a

Fig. 1.—Diagram of continental border-section W. to E.

portion of a continent seen in section, along with a part of a neighbouring ocean, both floating upon the basaltic magma. West is to left and east is to right. We must imagine that the lower, more viscous part of the magma possesses the full west-to-east angular velocity of the earth; but the continents and oceans and upper layers of the magma are, in virtue of the westerly forces just referred to, not moving quite so fast in that direction. They respond, in fact, to the forces urging them westward. We perceive that this involves, of necessity, an east-going force or pressure acting upon the submerged parts of the continents, and more especially upon the more deeply submerged parts; that is, upon the displacements required by isostasy to float the greater raised features of the continents.

The diagram is intended to illustrate the effect of the magmatic pressure with reference to mountain-building. We have already seen that mountain ranges arise where great depths of sediment collect for long ages. These accumulations may amount to several miles in depth; the sediments pressing down the crust as they collect.

It is well known that this process creates a linear area of weakness in the floating continent. We can picture what happens. The great load bends down the crust, forcing it deep into the hot magma. It becomes seamed with gaping vents and cracks, extending parallel with the axis of the trough into which the magma forces itself.

Now, if a horizontal force acts upon a continent affected with such an area of weakness, this part yields first and the sediments are crushed and forced both upwards and downwards. The part that rises up forms the mountain range; the part that is thrust downwards acts as compensation or buoyancy, which serves to float the mountain. The one adjusts itself to the other. The mountains slowly sink or rise till there is equilibrium. Thus, in course of ages, we get the floating mountain range. It will be perceived that the volume of the downward displacement is much greater than the mountain range. This is because the density of the crust does not differ greatly from that of the sustaining magma.

Such great ranges as the Cordilleras of North and South America rose up out of troughs of sediments in this manner. They were specially favourably oriented to receive the easterly pressure of the underlying magma, and, correspondingly, they are in many respects the greatest mountain developments of the globe.

However, while it seems easy to understand that the formation of mountain ranges directed more or less north and south might arise in this manner, it is more difficult to imagine chains of mountains like the Himalayas or like the Pyrenees originating in the west-to-east force arising from tidal or precessional effects. This brings us to the consideration of the possibility of the continents having shifted their relative positions during geological time.

Many are now weighing evidence for and against such extraordinary possibilities as to whether the Atlantic Ocean is not a comparatively recent innovation; whether New Zealand was not recently detached from Australia, and India from the eastern shores of Africa, and so on. Before this interesting question arose biologists and geologists generally got out of their difficulties by assuming the former existence of land connexions or "bridges" which subsequently "foundered" and disappeared.

Now, according to the present explanation of the surface movements of the earth, the foundering of such "bridges" would be difficult to realise; for they are of lower density than the basaltic magma upon which they at one time floated. So that it becomes very difficult to imagine the former existence of these bridges. Not only is this the case, but also the present theory certainly suggests that differential movements of the continents might quite possibly have taken place. I do not mean to convey that these supposed great movements *necessarily* arise out of our theory, but it is at least remarkable that a theory which appears to explain much—and on a basis which can claim to be more than merely hypothetical—should offer what may be regarded as a *vera causa* for continental drifting if other considerations require it. The continents during times of revolution become acted upon by forces tending to move them towards the east; and, what is even more relevant, these forces must of necessity be different in intensity from one continent to another. In fact, the magmatic drive applied to a continental mass depends upon the depth of its immersion and also on the existence of great displacements extending downwards into the deeper parts of the magma.

Another consideration in favour of continental drifting must be taken into account. The continents become acted upon by these forces only during the period of magmatic fluidity. We saw that this fluidity is ultimately lost, mainly in consequence of heat escaping through the ocean floor; this floor being probably more or less melted away during the process. It may be that the reduction in thickness of the ocean floor is carried so far as to remove what is really the main obstacle to differential continental movement—the existence of a strong and rigid ocean floor, holding the continents immovably fixed to one another.

We return for a moment to the problem of the elevation of such ranges as the Himalayas, which trend more or less east and west. We are now prepared for the possibility that the explanation of these events was due to a certain small amount of continental movement. It is a fact that tidal and precessional forces are greatest in equatorial regions. May it not have been that the great continent of Africa, experiencing the effects of this, rotated just a little, its southern extremity moving eastward; and so also for Peninsular India; so also for the Spanish Peninsula? A small turning movement, crushing the ancient geosynclines, would suffice. For, after all, the greatest mountains are but very tiny wrinkles upon the surface of this huge world.

The outflows of lava on the western coasts of the continents, or to the west of great mountain masses, or brought up by the downward faulting of rift valleys, to which I have already referred, seem to give us direct evidence of the magmatic pressures of which we have been speaking. The injection of lava into the great mountains, or its ejection from lofty volcanoes, finds explanation in the great volumes of included basaltic magma which are taken up in the crushed and shattered sediments of the geosynclines when these are floated up from the depths of the earth's crust.

In the foregoing remarks I have endeavoured to trace, on the basis of isostasy and radio-activity, the existence of cyclical changes, prevailing in the isostatic layer, which are in harmony with the observed recurrent world-revolutions. While a certain grand simplicity in the nature of these events, and the existence of a general resemblance between the character of one revolution and that of the next, permit of this treatment, it would be an erroneous inference that the physical events of historical geology are concentrated in the relatively brief periods of world-wide mountain-building. For in truth an endless succession of minor changes have affected the crust of the earth. Between the great revolutions transgressions of the ocean have occurred over considerable areas. Crustal warping, and even mountain elevation of lesser ranges and batholithic invasion of the crust, as well as renewed volcanism, have not been uncommon. All the events of the greater revolutions may appear locally, and always on a lesser scale.

In point of fact, these lesser, inter-revolutionary events are, probably, part of the primary phenomenon and owe their existence to energy concerned with the genesis of the former. For consider that during millions of years the continental crust, throughout every part of it, has been subjected to those same enormous stresses, vertical and horizontal, that served to uplift the Cordilleras to heights of more than 20,000 feet; and that, at the time when the floor of the ocean congealed around the continents and tidal effects died out, the vast volume of the land was left deformed by these great stresses, strained, often to fracture wherever rigidity prevailed, and with isostatic adjustments profoundly disturbed.

The inter-revolutionary periods of geological history must witness the readjustments necessitated by this accumulation of potential energy. Areas of low resistance—*i.e.* the geosynclines, the volcanic areas, or recently deformed regions—must experience the concentrated results. Moreover, all the conditions for very prolonged continuance of these minor activities exist. For there is no other way in which the accumulated energy may find relief save in crustal disturbance or readjustment. It will be slowly doled out for ages as the effects of denudation call upon it, or as thermal events give it occasion to intervene, for the cooling of the magma beneath the continents must be extremely slow. Sheets of melted lava must underlie them, throughout almost the whole of geological time, although deeper down there may be comparative rigidity.

It will be apparent from all this that there is nothing unaccountable either in the existence or nature of inter-revolutionary events. On the contrary, we may say that their absence would be highly unaccountable. Even more, I think that as we study these events we must conclude that they cannot represent more than a fraction of the stored energy attending a great revolution.

This leads to the energy question at large. Whence does it all come? To answer fully that question would lead us back over much of the ground we have already pursued. But as regards energy other than radioactive we may briefly answer: "From the rotation of the earth." And is it not adequate? Look at the diagram of an earth-sector (Fig. 2); with a floating

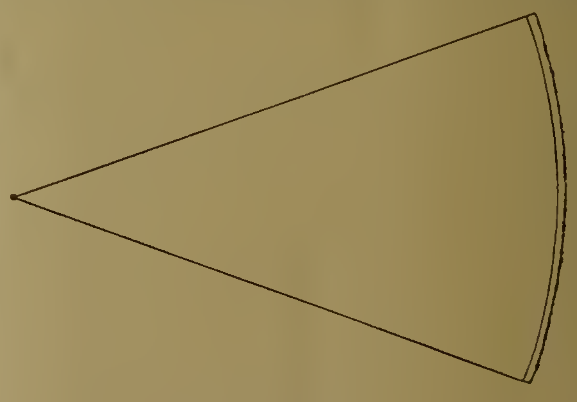

Fig. 2.—Earth-sector showing basaltic layer and continents to scale of radius.

crust 20 miles thick and an isostatic layer 70 miles deep. Consider how petty are the crustal energies contrasted with the stored energy of the globe, built as it is out of materials twice as dense as the continental rocks, and possessed, even to-day, of a surface velocity of 1000 miles an hour.

In its biological aspect how great and wonderful it all is! The living being working out his destiny on this poor raft, unknowing of the fiery ocean upon which his world is floating: unknowing of the inevitable sinking and uplifting which in truth largely control the destinies of his race. Death-dealing forces all around, and yet the light of life shining age after age upon the earth.

Water-Power in the British Empire.[1]

By Theodore Stevens.

The Water-Power Committee of the Conjoint Board of Scientific Societies in its various reports has ably summarised the information on water-power available throughout the British Empire, and the Board of Trade Water-Power Resource Committee and Sub-Committee have dealt with the British Isles in a similar way. Canada has done more measuring of those resources than any other part of the Empire. Canadian water-powers in service, catalogued in Water Resources Paper Number 27, numbered, in 1920, 336 developed water-powers. Of these the summary, arranged by me under the different heights of falls, shows

43 were working with heads of water between 5 and 10 feet;
47 at heads between 11 and 15 feet;
84 ,, ,, ,, 16 ,, 30 ,,
84 ,, ,, ,, 31 ,, 70 ,,

With these figures before us, development of any head of water that may be available can be justified from past experience; but it is a great mistake to conclude that sufficient power can be developed from a stream until all the details of the problem have been fully studied.

There have been, within the last twenty years, water-plants installed in twenty different places, in every one of which after the capital was spent there was a rude awakening to the fact that the quantity of water necessary for the work undertaken was not available. A total of 25,000,000*l*. has been spent in those twenty places, and has proved financially unprofitable. Much more capital has elsewhere been profitably invested. Many other water-powers have proved successful. Enough has been said to show that reasonable caution necessitates efficient preliminary study before capital is invested.

Another note of caution refers to the distance that it is economical to transmit power. For example, it would not pay to generate hydro-electric power to supply a lighting load 75 to 100 miles away, if there is a coal-mine near the consumers' end of the transmission line; nor is it practicable to undertake to supply separate villages and farms on the line of a high-voltage transmission, because it costs many thousands of pounds to tap power from a high-voltage line, and the small consumption in village and farm cannot possibly pay the interest on this expenditure. It would be unnecessary to make such comments if this uneconomical arrangement had not been seriously advised by

Fig. 1.—Victoria Falls, Rhodesia; view from the air.

The river at the fall is 1 mile wide and drops into a narrow gorge 400 feet deep.
The large model of Victoria Falls in the Imperial Institute, South Kensington, London, aids one to visualise this configuration.

[1] Substance of two lectures delivered at the Royal Institution on March 1 and 8, when illustrations of the important waterfalls in each part of the Empire were shown.

engineers whose experience evidently did not include such electrical details.

Seventeen years ago it was suggested that Victoria Falls (Figs. 1 and 2) would supply Johannesburg, and I have preserved a copy of the original prospectus of the company, including a map of the proposed transmission over a distance of 600 miles from the water-power across and into coal-mining districts. The company which was then floated has paid handsomely; but it wisely burns coal and says nothing about water-power. Even the hotel at Victoria Falls is lit by an oil engine. Similarly, if an examination is made of the super power zone in the United States, which embraces the great industrial area in the Eastern States, it will be found that it approaches within 200 miles of Niagara Falls, where many millions of horse-power run to waste, but it is not suggested that power should be derived from Niagara for that super power zone.

FIG. 2.—Victoria Falls; part of main falls. By courtesy of the British South Africa Company.

It is also true that Niagara power is delivered 270 miles from the Falls. The selling price (by Government, without profit) in bulk to the towns at that distance is three times the selling price for similar power near the Falls. There is always an excess of water at Niagara Falls. Under other conditions, for example, where summer flow is limited and cheap coal is available, it might be easy to prove that it is cheaper to generate electricity locally from coal than to transmit water-power so far.

Tidal-power fascinates every one who studies it; and when our coal supplies are much nearer depletion than at present, it may be utilised on a large scale. The Ministry of Transport published a scheme (since withdrawn) for developing tidal power on the river Severn, and said that the power was so vast that it exceeded "all the potential sources of inland water-power in the United Kingdom put together." But two and a half times the power proposed for development in the Severn exists in other parts of the British Isles, where it is free from the irregularity due to the variation in the times of the tides, and it can be developed for 5,000,000*l.* less in first cost than the estimate for that tidal power; the estimate, in my opinion, was not half enough to do the work specified.

We might allow this scheme to rest in peace, since the Geddes axe was first sharpened for use on the promoters of it; but, from time to time, it is brought forward as practicable. If one reads the Interim Report on Tidal Power by the Board of Trade Water-Power Resource Committee, it will be seen that nothing more costly than further investigation and study of the complications involved was recommended by that Committee; and the Electricity Commissioners dissociated themselves from any knowledge of the power-house, two miles long, with railway trains using the power-house as an economical bridge across the river.

We have an example of a corporation electricity supply being changed from a financial burden on the rates to a satisfactorily profitable undertaking in the report of the Chester electrical engineer, Mr. S. E. Britton, by utilising a small head of water (which varies from nothing up to 8·5 feet, because the tide comes up to the water-power plant's discharge). In seven years, on a capital of 56,000*l.* in steam-plant, there has been a relative loss of 15,000*l.*; while 18,000*l.* capital invested in the water-plant has shown 82,000*l.* profit, leaving a net profit of about 67,000*l.*; but it is essential to realise that this water-power cannot be utilised for a satisfactory statutory supply of electricity in Chester without the steam-plant to produce current from coal when the water-power is not available (due to high tide or to insufficient flow in the river).

Shawinigan in Canada is an example of a beautiful waterfall concerning which, I believe, it was an American who wrote:

> At every waterfall two Angels stay,
> One clothed in rainbows, the other veiled in spray.
> The first, the beauty of the scene reveals;
> The last revolves the mighty water-wheels.
> And there those two fair sisters ever stand,
> Utility and Beauty, hand in hand.

To-day, instead of standing to be admired, "Beauty" is to be found voluntarily undertaking some useful work.

The water at Shawinigan Falls now flows down inside pipes. Where, in the days of Beauty, only an occasional sportsman visited the falls, is to be found to-day a town of 12,000 inhabitants, amply provided with work and wages by the water-power which is utilised for various electro-chemical manufactures, as well as for supplying the cities of Montreal and Quebec with electricity.

In Ireland the writer carried out surveys of the power available in the largest rivers, for the Irish Hydro-Electric Syndicate and for the Water-Power Resources of Ireland Sub-Committee under the chairmanship of Sir John Purser Griffith, and has shown that it would be practicable in an average year thus to supply a demand three times as great as the present demand in the whole of Ireland for electricity, and has recommended and shown the economy of linking up this supply to all important towns and cities; utilising existing steam-electric stations to supply current when, owing to drought, one summer's flow of the rivers is too far below the average summer flow. The combination is like that at Chester, but on a much larger scale.

Suppose we allocate part of each of the rivers Shannon and Erne to the manufacture of carbide and of nitrogen fertilisers and operate this plant as fully as the flow of water permits; with an average output we could make in a year fertilisers containing 20,000 tons of nitrogen. Each of these works would be of the size recommended as economical by the Nitrogen Products Committee of the Ministry of Munitions.

It is not definitely known how much nitrogen fertiliser can be utilised within Ireland; but there are markets for carbide and for nitrogen fertilisers outside Ireland, so any excess over home requirements could be exported at a profit.

The nitrogen in various compounds used in a year in the world amounted to 694,600 tons[2] pre-War and 1,219,000 tons post-War (1919). There is nothing excessive in recommending fixation in Ireland of 3 per cent. of the world's annual pre-War consumption of nitrogen.

There would be work throughout the year, but more people employed at the chemical works in winter-time than in summer. It is well known that about 10,000 workers leave Ireland every summer to do farming in Scotland and England and return to their more economical life in Ireland during the winter-time. For some of those there would be thus provided winter work in their own country; while, of course, there would be employment throughout the year for an appreciable number.

There are nitrogen fixation plants near Niagara and at various other places in the world. About half of the pre-War consumption of nitrogen was in the form of native nitrate of soda. Among the many important applications of water-power, the one in Tasmania, where the Electrolytic Zinc Co. of Australasia, Ltd., utilises 30,000 horse-power from the Tasmanian Government Plant for the preparation of high-grade zinc, is worthy of especial mention.

More attention should be paid to the selection of industries that require large amounts of power, and to their establishment at sites where suitable water-power is available. We cannot recall too often the history of Niagara's development. Before electricity was a commercial form of energy, capital was invested (during the years 1853 to 1861) in making provision for direct water-power; in 1861 it was ready, but it ran to waste for ten years before the first consumer arrived in 1871. It was not until 1894 (forty-one years after the commencement referred to) that a profitable amount of power was utilised. Water-power is the cheapest form of energy when fully utilised twenty-four hours in the day.

Obituary.

Prof. J. D. van der Waals.

WITH Johannes Diderik van der Waals, who died on March 8 at Amsterdam, at eighty-five years of age, one of the great figures in the history of modern physics and physical chemistry has passed away. His thesis on the continuity of the liquid and gaseous state was a revelation in the study of fluids, the remembrance of which was to glorify the golden jubilee of his doctorate next June, and after establishing it he continued for some forty years to apply his efforts to the same subject, marking the steps of his success by further brilliant discoveries. When the Nobel Institute honoured this lifework, van der Waals was still occupied rounding off the comprehensive views science owed to him. For about half a century he was in the front of the workers in the domain he had opened. In the ten years which separate us now from then his forces began to give way, and later bodily and mental sufferings, borne with modest resignation, set in. At last, only short visits allowed us to show to the venerated and beloved friend, whose heart we felt remained unchanged, what he had done for us.

Van der Waals was born on November 23, 1837, at Leyden. He was a self-made man who took advantage of the opportunities offered by the University which he later honoured by his curatorship. It was not until he was thirty-six years of age that he wrote his thesis. With it he himself opened the period of Dutch science, which his elder friend Bosscha and he hoped to be one of the results of secondary education. In 1877, van der Waals became a professor at Amsterdam, and began to exert his great influence on the development of Dutch physics. One of the characteristics of his highly admired teaching was the introduction of Gibbs's great work to the chemists. I vividly remember as an example of it how Bakhuis Roozeboom, to whose first experiments the Leyden physical laboratory had been in the position to give some help, obtained results, which were inexplicable until van der Waals came to give him the key to it in Gibbs's doctrine of phases, his deep insight clearing the way for Roozeboom's brilliant work on the phase rule.

Very much was done by van der Waals for the Royal Academy of Sciences at Amsterdam. For twenty-four years he was the soul of the Board, and in 1896 he even accepted the secretaryship of the Academy, a post which he filled until 1912. Here as everywhere else he showed a never-failing unselfishness and high conception of duty. We owe to him the modern form of the Proceedings and their English translation, which he directed, both with an incomparable energy. The great efforts he bestowed on these periodicals have been well rewarded by the effect their stimulating influence had on Dutch science.

The scientific work of van der Waals forms a monumental whole of a special style. Characteristic of it is the intuition by which he introduced happy simplifications and approximations leading to a high degree of qualitative agreement of his theories with Nature, which in the case of the law of corresponding states rose even to a surprising quantitative approximation.

The first idea of the image of the fluid state which was gradually developed by van der Waals came to him when he combined the kinetic theory of gases with the determination of the cohesion in Laplace's theory of capillarity. With the aid of very happy approximations he built up the kinetic theory of the fluid state. Such a simplification gave in the first place the calculation of a molecular pressure which represents the cohesion, and the result of the calculation led him to the profound conception that the molecules of the gaseous and the liquid state are identical and exert identical forces. Secondly, he accepted as by inspiration an exceedingly appropriate form for what would be the outcome of the calculation of the kinetic pressure at higher densities. The simple equation of state which he obtained in this way reproduced the well-known diagram of Andrews-Thomson, as the representation of a series of stable and unstable states of mechanical equilibrium. It gave a deeper insight into the continuity of the liquid and gaseous state as well as a luminous explanation of the critical phenomena. It stood even the crucial test which van der Waals only with apprehension undertook to apply to it; that is, the calculation of the critical data of carbon dioxide of Andrews from the deviations from Boyle's law according to Regnault. Finding correct values for these meant a great discovery. The various thermal properties of fluids treated until then in different chapters of physics proved now to be at least approximatively contained in a single equation with only two specific constants, the volume and the attraction of the molecules, their molecular weights being given by their composition. Later researches have proved, more and more, the greatness of the genius which led van der Waals to his equation of state. Even now it is the most appropriate one to discuss qualitatively the properties of fluids.

Directly from this can be derived the second great discovery of van der Waals, namely, that it is only necessary to introduce the reduced values of volume, temperature, and pressure obtained by dividing the values of these variables by their critical values into the equation of state, to reduce this equation to the same equation for all substances. Simple as this substitution is, it took seven years before it was arrived at, and then only by van der Waals himself, who had been wrestling for a long time with the explanation of the deviations between his equation of state and reality. He had followed many false tracks in order to find some regularity in the deviations of the different substances, and had reached the conviction that to compare substances they have to be considered in corresponding states; that is, at the same values of the reduced variables. At that moment he found the law of corresponding states. Its scope is far wider than that of the equation of state. It involves the bold idea that the thermal properties of all substances can be derived from those of a single one simply by numbers of proportionality; and, what is marvellous, the law approximates more closely to Nature than the equation from which it is derived. How much I was under the influence of its great importance as much as forty years ago may be best judged by my taking it then as a guide for my own researches. It has had a great effect on the work of liquefying the permanent gases (in his thesis van der Waals predicted that air had to be cooled below −158° C. to be liquefied, which has proved nearly correct) and of attaining the *nadir* of temperature.

This cannot be better illustrated than with the words of our deeply mourned Sir James Dewar in a letter to me, expressing that van der Waals was "the master of us all," "whom we cannot honour too much." All substances, except for small differences, appear in the light of the law of corresponding states, as van der Waals expresses it, as individuals of the same kind. He liked to direct attention to the fact that his friend Dewar had proved that, taking temperature as a measure, hydrogen was, according to his prophecy, a dwarf. To read to van der Waals a report of the experiments which proved that helium, though a very small dwarf, was yet well shaped, was a happy moment in my life, especially as the report showed the profit derived from van der Waals' law of corresponding states and at the end referred to his words that "matter would always show attraction."

As all normal substances are almost copies of the same model, van der Waals was anxious to bring his equation of state in closer approximation to this general model and to understand the differences between the various substances. To his pondering on the influence of association into double molecules on the deviations, we owe his theory of binary mixtures, which covers a yet vaster and more varied field than his previous discoveries. It is especially this theory to which, in connexion with the beautiful work of our deeply mourned Kuenen, I owe the strong ties which united me to van der Waals. For many years I went to his study at Amsterdam for a "monthly private course," that is, a consultation on the Leyden work, and I found van der Waals always at his table filled with papers, with the portrait of his wife, who died at an early age, on the chair in front of him. In these hours it often occurred that from an unpublished calculation he could rightly predict some error to be found in the diagrams of the experiments; and it is from them that I have got an idea of the amount of work from which his genius came to his intuitions.

It would occupy too much space here to refer in detail to the work of van der Waals, which groups itself around these three great discoveries. I can only point out that he tried to combine the theory of specific heats with that of the equation of state, and that in the end he was occupied with the very interesting problem of the influence of the conglomeration of greater number of molecules; that of quasi-association. Rounding off in this way the chapter he wrote in the history of science, he gave us, at the same time, a glimpse of that chapter which the next generation has to write, containing a rational application of quantum considerations in van der Waals' theory of the fluid state.

Not less than the extraordinary intellectual gifts which made possible his great life work, his friends admired his severe culture of the ideal and his noble character. We remember the pious heart, in whose friendship we rejoiced, and with a feeling of deep sorrow at the loss of his presence, we give him here the tribute of our profound gratitude.

H. Kamerlingh Onnes.

Dr. Arthur Latham.

The medical profession has lost a somewhat striking personality by the death of Dr. Arthur Latham at the relatively early age of fifty-six. The son of a former Regius professor of medicine at Cambridge, who still survives, Dr. Latham was brought up in a cultured and scientific atmosphere, while his Oxford degree implied the double advantages of the two older English Universities. He was elected assistant physician to St. George's Hospital in 1898, and there soon showed his ability in teaching and his always masterful and dominating personality. A man of precise logical thought and of great determination, he could ill tolerate indefiniteness of view and indecision, and it is not surprising therefore that he had enemies as well as cordial friends.

Whatever Dr. Latham undertook, he made himself thoroughly acquainted with, and it was fortunate that the award to him of a prize for an essay on a tuberculosis sanatorium early determined the chief trend of his work. Although sanatoria for consumptives have not achieved all that was expected of them, this has been largely owing to their misuse under the pressure of the administration of the National (Health) Insurance Act, patients being sent in large numbers to sanatoria, for whom treatment in hospitals was indicated. Dr. Latham contributed other papers and small books on tuberculosis; he was a member of the Departmental Committee on Tuberculosis, which laid down the lines on which the state anti-tuberculosis measures were to be carried out; and in many other ways helped to bring the anti-tuberculosis crusade to its present advanced condition.

Of Dr. Latham's value as a medical politician, of the important work which he did to secure the firm beginning of the Royal Society of Medicine, this is not the place to write; but the memory of his clear and incisive speaking, arising out of logical thinking, of his pertinacious advocacy of great causes, and of his success in advancing the interests of preventive medicine, will not soon die.

We regret to announce the following deaths:

Prof. Gustav Köhler, director of the Mining Academy, Clausthal, for the years 1887–1914, and who had taught there since 1880, at the age of eighty-four.

Sir Shirley Murphy, vice-president of the Royal Sanitary Institute and other scientific societies, and for twenty-two years Medical Officer of Health for London, on April 27, aged seventy-four.

Dr. Alfred Scholl, a director of the Agricultural Experimental Station, Münster, and deputy-editor of the *Zeitschrift für Untersuchung der Nahrungs- und Genussmittel*, on February 12, at the age of forty-six.

Mr. H. J. Seaman, for many years general director of the Atlas Portland Cement Co., New York, who was responsible, with Hurry, for introducing the use of coal dust in rotary tube furnaces for the burning of clinker, on February 9.

Current Topics and Events.

Prof. de Sitter, who is to give a lecture at the Imperial College of Science and Technology on May 7, on "Problems of Fundamental Astronomy," and will lecture also at Manchester on May 9, and at Edinburgh on May 18, was a pupil of Kapteyn's, who was invited by Gill in 1896 to work for a time at the Cape. He made determinations of the parallaxes of several southern stars with the heliometer. For his thesis for doctor of science at Groningen he presented a "Discussion of the Heliometer Observations of Jupiter's Satellites." He has continued these researches and developed a new method for treating the mutual perturbations of the satellites, and is still engaged discussing photographs taken at the Cape and Greenwich for the determination of the necessary constants. After his return to Groningen Prof. de Sitter participated in a number of Kapteyn's investigations dealing with the dimensions and structure of the stellar universe. British men of science owe a debt to Prof. de Sitter for giving during the War, before Einstein's work reached England, three papers in the Monthly Notices of the Royal Astronomical Society which presented to English readers an account of the generalised theory of relativity. Prof. de Sitter has made important contributions to this subject and has examined the various cases where any astronomical verifications may be obtained.

In an article in the April *Quarterly Review*, Lord Ernle writes on "Victorian Memoirs and Memories." His account of Huxley runs as follows: "Mrs. Asquith, who describes a meeting with Huxley at Jowett's, and remarks that he had about him little of the *juste milieu*, does not appear to have been favourably impressed. But Huxley was not always the gladiator. To me he was irresistibly attractive, because I fancied that I had caught a glimpse of his true outlook on life. When I think of his destructive criticism, I see again the arabesque with which he had adorned the side of the first page of his article on 'Lux Mundi.' Up the margin ran a vine-clad trellis: on the top crowed the cock of theology, and towards him crept the fox of science. I remember also discussing with him one of his numerous controversies—I think the Gadarene swine. With the impertinence of comparative youth, I expressed surprise at the quantity of vinegar and mustard which he mixed with the discussion of questions that to many people were matters of life or death. 'My dear young man,' he answered, 'you are not old enough to remember when men like Lyell and Murchison were not considered fit to lick the dust off the boots of a curate. I should like to get my heel into their mouths and scr-r-unch it round.' A wistful smile lit up his plain rugged face, as he added: 'And they never seem to reflect what a miserable position mine is standing on a point of Nothing in an abyss of Nothing.' The world saw much of the first mood, little of the latter."

The council of the Zoological Society of London presented an eminently satisfactory report for the last year at the annual general meeting on April 30. There has been an increase of nearly two hundred in the number of fellows; the additions to the collections are more numerous than in the preceding year, the result chiefly of the receipt of H.R.H. The Prince of Wales's Nepal and Malayan collections; the attendance at the gardens maintains a very high level; and the financial position of the Society is thoroughly sound. The Proceedings have reached their pre-War standard as to bulk, the number of illustrations, and the promptness of publication; but the issue of Transactions has not yet been resumed. An appreciative reference is made to the work of Mr. Pocock, whose resignation of the post of superintendent has lately taken effect. Zoologists will learn with regret, akin to dismay, of the decision of the Society to cease publication of the "Zoological Record," owing to the inadequate support received. The Society has rendered an invaluable service to zoological science throughout the world in having undertaken the responsibility of the Record for so long a period, and it is a matter of grave concern that its efforts have met with so poor a measure of support. The council reports that excellent progress has been made in the construction of the new aquarium, and it is hoped that this will be ready for opening in the autumn of the present year. A favourable report is given of the durability of the coloured labels, painted in fusible enamel on tiles, which were introduced last year on the results of special experiments, and their use is to be extended as rapidly as possible. The scheme for the instruction of school teachers, which has been in operation since 1910, has been suspended for the present, as a large proportion of the London school teachers have now taken advantage of it.

THE results of a conference of veterinary authorities convened by the Government of India at Calcutta in February last were summarised in the *Times* of April 17. Anthrax infection in the case of East Indian wool, hair, and hides is so serious that special attention has been directed to the subject. Yet, according to the official returns, anthrax is a rare disease in India. The cost of disinfecting wool is greater than its present value, and the conference came to the decision that the agencies for notification of the disease in India must be improved, and that much skilled research and inspection are needed among the living animals in the country, if the disease is to be attacked at its seat. Surra, a disease of horses and camels, is now known to be due to a parasite of the group that gives rise to sleeping sickness in Africa. Tuberculosis is proved to be a frequent cause of loss of cattle, but little is known as to its prevalence. In short, "veterinary education, veterinary research, and veterinary legislation and administration in India are wholly unsatisfactory, and it is urgently to be hoped that the Government of India will give immediate and serious attention to the conclusions reached by the Conference."

THE meeting of the Illuminating Engineering Society on April 24 was notable for the large number of representatives of associations concerned with the printing industry which attended to join in the discussion of Mr. L. Gaster's paper on the lighting of printing works. Employers and employees joined in expressing appreciation of the importance of adequate illumination, and the Rt. Hon. C. W. Bowerman, who opened the discussion, contrasted the attention that is now being paid to the subject with the neglect of past years. Mr. Gaster dealt very fully with the lighting of compositors' benches, machine-rooms, etc., showing a number of attractive photographs taken by artificial light, and mentioning the values of illumination recorded in each case. It would appear that recent experience favours the use of general lighting as compared with the "patchy" local lights formerly customary, and pictures were shown of rooms flooded with light up to 10-12-foot candles. It was interesting to learn that the cost of lighting in general forms only about 1 per cent of the wages bill in this industry, which employs highly skilled labour. Mr. Gaster also put in a word for the requirements of the journalist, who is called upon to read manuscripts at high speed, and whose work often demands scrupulous accuracy. Proper lighting, both for proof-readers and in the editorial rooms, is most important, and it is singular that in some large newspaper works this matter is neglected, although the section of the building devoted to the actual printing processes may be relatively well lighted.

PROF. J. A. FLEMING, University College, London, has been asked by the British Broadcasting Company to broadcast an appreciation of the scientific work of Sir James Dewar on Friday evening, May 4, at 9 P.M. The message may be heard by all having a wireless telephone set which can pick up from 2 LO in London.

THE eighth Guthrie lecture of the Physical Society of London will be delivered on Friday, May 11, at 5 o'clock, at the Imperial College of Science and Technology, by Dr. J. H. Jeans, who will take as his subject "The Present Position of the Radiation Problem."

PROF. J. B. LEATHES, professor of physiology in the University of Sheffield, will give the Croonian lectures of the Royal College of Physicians in June; Prof. E. H. Starling, the Harveian oration on St. Luke's Day, October 18; and Dr. John Hay, of the University of Liverpool, the Bradshaw lecture in November.

IT is stated by Dr. Theiler in the *Chemiker-Zeitung* for March 20 that pure methyl alcohol is quite non-poisonous. The poisonous nature of impure wood spirit is due, not to the methyl alcohol it contains, but to the impurities which are present, such as allyl alcohol, allyl acetate, acetone, and their very poisonous homologues.

ACCORDING to the *Chemiker-Zeitung* for March 22, Prof. G. Tammann, of Göttingen, has received the Bakhuis-Roozeboom medal of the Royal Academy of Sciences, Amsterdam. This medal is conferred for researches connected with the phase rule, and was presented, for the first time, to Prof. F. A. H. Schreinemakers of Leyden in 1916. Prof. Tammann will receive the medal personally at the May sitting of the Academy.

The fourth of the series of lectures on physics in industry, being delivered under the auspices of the Institute of Physics, will be given in the hall of the Institution of Electrical Engineers, Victoria Embankment, W.C.2, on Wednesday, May 9, at 5.30 P.M., by Dr. J. W. Mellor, of Stoke-on-Trent, who will deal with "The Application of Physics to the Ceramic Industries." Sir J. J. Thomson will preside. No ticket of admission is required.

At the anniversary meeting of the Royal Society of South Africa, held in Cape Town on March 21, the following officers were elected: *President*: Dr. A. Ogg; *Hon. Treasurer*: Dr. L. Crawford; *Hon. General Secretary*: Dr. W. A. Jolly; *Members of Council*: Mr. K. H. Barnard, Dr. J. W. Bews, Dr. J. P. Dalton, Dr. J. D. F. Gilchrist, Dr. S. H. Haughton, Dr. J. S. v. d. Lingen, Dr. T. J. Mackie, Dr. A. W. Rogers, and Dr. S. Shönland.

An address on "The Worth of Science" will be given at a meeting of the London Branch of the National Union of Scientific Workers on Tuesday, May 8, at 6 P.M., at the Birkbeck College, Bream's Building, E.C., by Sir Richard Gregory. The chair will be taken by Mr. C. S. Garland, M.P. The meeting is intended primarily for members of the Union who are scientific workers in Government departments, but a cordial invitation is extended to non-members interested in the work of the Union, especially those in public employment.

Applications are invited by the Secretaries of the Royal Society for a Moseley research studentship, value 300*l.* per annum, "for the furtherance of experimental research in pathology, physics, and chemistry, or other branches of science, but not in pure mathematics, astronomy, or any branch of science which aims merely at describing, cataloguing, or systematising." The appointment will, in the first instance, be for two years, but it may, in exceptional circumstances, be extended. Further particulars and forms of application are obtainable from the Assistant Secretary of the Royal Society, Burlington House, W.1. The latest date for the receipt of applications is Friday, June 1.

The eleventh International Physiological Congress will be held in Edinburgh, on July 23-27, and the following officers have been appointed: *President*, Sir Edward Sharpey Schafer; *Treasurer*, Prof. A. R. Cushny; *Secretaries*, Prof. G. Barger and Prof. J. C. Meakins; *Assistant Secretary*, Miss Dorothy Charlton. Those who desire to be enrolled as members are requested to forward their names and addresses, together with the amount of their subscription (25*s.*), to Miss Charlton, Department of Physiology, University, Edinburgh, who will send on request particulars of hotels and lodgings, and all other necessary information. Opportunities will be afforded for the exhibition of physiological apparatus.

The Minister of Health has appointed the following committee "To investigate the comparative value, for the therapeutic purposes for which cocaine is at present used, of various possible substitutes, and the evidence as to risk, if any, of such substitutes becoming drugs of addiction": Dr. J. Smith Whitaker, Dr. N. G. Bennett, Dr. R. W. Branthwaite, Dr. T. Carnwath, Dr. J. H. Chaldecott, Dr. H. H. Dale, Mr. T. B. Layton, Dr. G. F. McCleary, Mr. R. Foster Moore, and Sir William Henry Willcox. The secretary is Dr. E. W. Adams, Ministry of Health, to whom all communications relating to the work of the committee should be addressed.

The Postmaster-General has appointed the following committee to consider broadcasting: Major-General Sir F. Sykes (chairman); the Hon. J. J. Astor; Mr. F. J. Brown, Assistant Secretary of the Post Office; Sir Henry Bunbury, Controller and Auditor-General of the Post Office; Viscount Burnham, chairman of the Newspaper Proprietors' Association; Dr. W. H. Eccles, president of the Radio Society of Great Britain; Sir Henry Norman; Mr. J. C. W. Reith, general manager of the British Broadcasting Company; Sir William Robertson; and Mr. C. Trevelyan. The terms of reference of the committee are: "To consider (*a*) broadcasting in all its aspects; (*b*) the contract and licences which have been or may be granted; (*c*) the action which should be taken on the determination of the existing licence of the British Broadcasting Company; (*d*) the uses to which broadcasting may be put; (*e*) the restrictions which should be placed on its user or development."

An article on "Botulism in Scotland" which appeared in Nature of March 24, p. 415, referred to the difficulty, due to breakages, in heating glass containers for potted meats, so as to secure preventive sterilisation. Dr. G. R. Leighton, the author of the report described in our article, says on this subject: "I find it is a common experience in the trade that glass containers cannot be heated above boiling-point without the risk of a good many being broken." Mr. R. L. Frink, director of research of the Glass Research Association, in a letter to us, urges that such statements are scarcely justified, and do not take into account "the strenuous efforts that are being made to establish glass in its proper place as the most suitable container for foodstuffs." He adds: "Within the last month I have received information dealing with those properties and the use of glass as a food-container requiring pasteurisation and sterilisation (the latter being at temperatures of 230°-250° F.). It is shown that of more than 400,000 gross of containers used, there was less than 0·25 per cent. breakage, causing a loss not exceeding two-thirds of that suffered by the use of tins." Also as "the contents of tins are susceptible to fermentation or decomposition there is great danger that ptomaine may be propagated or that soluble salts of lead may exist in the contents."

The Geological Survey of New South Wales is fortunately able to continue the publication of its valuable Records. The last two numbers, vol. x.

pts. 1 and 2, have been received, and contain some important communications, such as:—"Palæontologia Novæ Cambriæ meridionalis; Occasional Descriptions of New South Wales Fossils," No. 8, and presumably the last, from the pen of the late R. Etheridge, junr.; "A Census and Index of the Lower Carboniferous Burindi Fauna," by Dr. W. N. Benson; "Note on the Occurrence of Graptolite-bearing Beds of Ordovician Age at Yalgogrin and Ariah Park," by L. F. Harper; "Materials for the Study of the Devonian Palæontology of Australia," by Dr. W. N. Benson, in which is included a useful bibliography, and a "Census and Index" which will prove invaluable to students.

An article on "The Present Situation in the Radium Industry," by H. E. Bishop, in *Science* of March 23, gives an interesting account of the influence which the discovery of a rich deposit of radium will have on supplies in the future. Rich ore was discovered near Elizabethville in the province of Katanga in 1913, during prospecting work by the Union Minière de Haut Katanga, a Belgian corporation. Before any developments of the find could occur the War broke out. The secret was so well kept that no word reached the outside world until a very large plant for radium extraction had been erected at Oolen in Belgium. In spite of the fact that the ore is transported 2000 miles down the Congo, across the ocean to Antwerp, and then by rail to Oolen, its richness allowed of radium preparations being put on the market in the early part of last year at a considerably lower figure than that at which it has been maintained for some years by the American companies. As a result of conferences between the representatives of the American companies and the Belgian, a joint selling organisation has been formed. We learn from the article that the question of a tariff to protect the radium industry of America has been discussed, and apparently the decision taken that the preferable policy is one by which a lower price of the commodity will lead to its more widespread use.

Circulars Nos. 120 and 121 of the U.S. Bureau of Standards, Washington, are of interest as showing the wide scope of the work of the Bureau and how the interests of various sections of the community are looked after in America. No. 120 describes the "Construction and Operation of a Simple Home-made Radio Receiving Outfit," and No. 121 describes the "Construction and Operation of a Two-circuit Radio Receiving Equipment with Crystal Detector." They are both clearly written, and can be obtained from the Government Printing House at Washington for a few cents. The apparatus described can all be made at home. The movable coil tube, for example, can be made from a round cardboard box which contained table salt, and the outer cardboard cylinder can be an old oatmeal box. For a set which will receive messages from a high-power radio telephonic station up to 75 miles, or from a medium station up to 10 miles distant, the cost varies from 10 to 15 dollars. The simple apparatus described is suitable for every-day work, but mention is made that parts of the apparatus may possibly be covered by existing patents. A test buzzer for finding the most sensitive spots on a galena crystal is regarded as a necessity, and is included in every estimate. As crystals are quite cheap, insensitive crystals should never be used.

We have received the first five parts of the *Japanese Journal of Chemistry*, issued by the National Research Council of Japan, Tokyo, 1922. The president of the Council is Baron K. Furuichi, and the vice-president Prof. J. Sakurai, and there is a committee of publication. As we have already stated in these columns (April 7, p. 478), the Council issues a journal devoted to chemistry and another to physics, each in ten numbers annually, a journal dealing with geology and geography quarterly, and a proceedings and journals covering botany, zoology, medical sciences, astronomy and geophysics, and engineering, occasionally. Communications relating to these publications should be addressed to the Secretary, National Research Council, Department of Education, Japan. The editorial matter, and most of the papers, in the numbers of the *Journal of Chemistry* which have been received are in English. Besides original papers, there are abstracts of papers which have been published in Japanese journals. The standard of the publications is high, and the journals will be useful to European readers in keeping in touch with much first-class work now appearing in Japanese journals.

The Ministry of Public Works, Egypt, has published the report on the work of the physical department for the year ending in March 1922. Dr. H. E. Hurst, controller of the department, records that in spite of an inadequate staff the scope of work has widened in several directions. Rainfall returns were received from thirty stations in Egypt, eighty-nine in the Sudan, forty-five in Uganda, fifty-five in Kenya, five in Abyssinia, and one each in Aden, Somaliland, Zomba, Seychelles, Mauritius, and Cyprus. Arrangements have been made to start a new station at Dangela in north-west Abyssinia. Regular readings of river discharges were made at sixteen stations on the Nile, Atbara, Rahad, and Dinder. The discharges of the White Nile and Main Nile in February 1922 proved to be the lowest on record. The level of the Bahr-el-Gebel and the White Nile fell below the bottom of many of the gauges, and new methods had to be devised quickly to mean the levels. The meteorological service has been active. During the year Egypt had twenty-six and the Sudan twenty-nine meteorological stations. This was an increase of four; new stations have been opened at Suez, Delta barrage, Giza, Makwar, and Bir Abu Tif in the Sinai peninsula. The station at Mansura was closed. Of the Egyptian stations, that at Helwan is of the first order and fourteen are of second order. Investigation of the upper air continues at Helwan and elsewhere in co-operation with the Royal Air Force. The report contains records of other valuable work.

Messrs. W. Heffer and Sons, Ltd., Cambridge, have sent us a copy of their catalogue (No. 223) of 381 publishers' remainders. The copies are as published, *i.e.* not second-hand, and the reductions in many cases are considerable. Several books of scientific interest are included. The list should be seen by all who are in search of book bargains.

The Oxford University Press announces "Race Problems in the New Africa," by the Rev. W. C. Willoughby, in which will be discussed the relation of Bantu and British in the parts of Bantu Africa which are under British control. The same house will also publish "A Practical Hausa Grammar, with exercises, vocabularies, and specimen examination papers," by Capt. F. W. Taylor.

Messrs. A. and C. Black, Ltd., have in preparation new editions of vol. 2 of Dr. D. H. Scott's "Studies in Fossil Botany" (Spermophyta) and vol. 1 (Radiography) of Dr. R. Knox's "Radiography and Radio-therapeutics." In the first-named work the account of the so-called "Seed Ferns" (Pteridosperms) has been completed, rearranged, and for the most part rewritten. A number of families are described more fully than in the previous edition. The systematic position of the Pteridosperms is discussed, and a new view is taken of this question differing widely from that formerly maintained. In the second work the opportunity has been taken to bring the text up-to-date in regard to the progress of radiography, and to include a chapter on the author's recent work on gallstones. The volume also includes some appendices, one consisting of a report of the committee which was appointed to consider the protection of the operator from the effects of over-exposure to X-rays or radium.

Our Astronomical Column.

The Present Condition of the Giant Planets.—Some surprise was created at the meeting of the Royal Astronomical Society on April 13 by a paper from Dr. Harold Jeffreys in which he raised doubts about the generally accepted view that these planets are still at a very high temperature. He made an estimate of the amount of heat that would have been radiated by Jupiter in the course of a period of three hundred million years, on the assumption of a high temperature throughout this period, finding that it exceeded the probable initial supply; he drew a further argument from the low densities both of primaries and satellites, in the case of these four planets, concluding that they are built of less dense materials than the inner planets. While there was some agreement with these views at the meeting, there were several expressions of dissent. The very energetic processes that are obviously going on upon Jupiter can scarcely be ascribed to the very feeble solar radiation, which is only one-twenty-seventh of that received by the earth. Moreover, if Jupiter were formed of material of the same density as that forming its satellites, the much greater force of gravitation upon it would produce a higher density through compression, unless counteracted by heat or some similar agency. A further argument was drawn from the spectra of these planets photographed at Flagstaff; these all showed broad absorption bands, implying dense atmospheres.

It will be remembered that recent studies of Jupiter by the bolometer indicated no sensible heating effect; but this was ascribed at the time to a dense absorbing atmosphere rather than to an actually cool interior. In any case, it is always in the interests of truth for any weighty evidence that can be put forward against accepted results to be considered seriously in an impartial frame of mind.

Nature of the Spiral Nebulæ.—Recent discoveries on the rapid rotational motion of the spiral nebulæ, which has been revealed both by spectroscopic determinations of velocity in the line of sight, and by Dr. Van Maanen's discussion of photographs taken at an interval of some years, has shown that these objects are not directly comparable with the Galactic system. Their distance can be roughly estimated by comparing the angular and linear rotational velocities; it is of the order of a few thousands of light-years, which is far too small to permit us to regard the regions of uniform luminosity as being due to the combined light of millions of stars. Prof. Lindemann read a paper before the Royal Astronomical Society on April 13 in which he put forward the view that they are simply vast collections of cosmical dust, the diameters of the particles being of the order of 10^{-4} cm., that being the size for which light-pressure is most efficient.

In other words, as Prof. Turner expressed it in the discussion which followed, the spirals are regarded as the dustbins of the stellar system, into which all interstellar dust is swept by the light-pressure exerted by the stars. An explanation would thus be afforded of the remarkable freedom from dust of the interstellar spaces, which was brought out by Prof. Harlow Shapley's work on the globular clusters, and by other researches. Prof. Lindemann suggested that the light of the spirals was simply reflected light from the whole stellar system; their spectrum, which seems to be a blend of all the stellar types, is in accord with this view. The case would be analogous to that of the Pleiades nebulæ, which give the same spectra as those of the stars which they surround. Prof. Lindemann showed that on certain assumptions as to the thickness of the spirals, reflected starlight would account for the observed luminosity. The mass of the spirals would still be of the order of thousands of suns, and they might still be regarded as providing the material of future clusters.

Variable with a Remarkable Spectrum.—Dr. Harlow Shapley, in Harvard College Observatory Bulletin No. 783, describes the spectrum and the light variation of the tenth magnitude star H.D. 81137 (R.A. 9^h $18{\cdot}7^m$, Dec. -52° $8'$) as "both of unprecendented types." The spectrum belongs to the type Ma of the Harvard Classification, and contains five well-marked bright lines or bands coinciding with some of the strongest bright lines in the spectrum of η Carinæ, the origins of which are unknown.

The spectrum of η Carinæ is not classified by the Harvard observers but described simply as "peculiar," but it is probably a hot star. H.D. 81137, as it is classed Ma, is comparatively a cool star, so this is an example of a cool star exhibiting bright lines of a hot star nature. Approximate positions of these lines are $\lambda\lambda$ 4244, 4287, 4352 to 4358, 4414 to 4416, and 4452 to 4457.

The light curve showed a steady rise from 9·8 in 1890 to 9·2 in 1901, and has since steadily dropped, reaching 10·1 in May 1922, so the period of variability is long.

Research Items.

THE COIN COLLECTION AT HULL.—The Wilberforce House Museum at Hull contains an interesting collection of local coins and tokens, a catalogue of which by Mr. W. Sykes has now been published. A mint was established in the city by Edward I. in the year 1300, and two silver pennies, the only variety of coin, so far as is known, struck in this mint, are included in the collection. The inscription on the obverse is "Edwardus Rex Angliæ Dominus Hyberniæ," "Edward, King of England, Lord of Ireland," and on the reverse "Vill. Kyngeston," "Town of Kingston-upon-Hull." The collection of seventeenth century tradesmen's tokens is fairly complete, containing 30 out of 34 examples.

THE ROMAN WALLS IN NORTHERN BRITAIN.—The study of the Roman Walls has been considerably advanced by two papers published in the Journal of Roman Studies (vol. xi. part 1, 1921). In the first paper Mr. G. Macdonald discusses the building of the Antonine Wall, with a fresh study of the inscriptions; in the second Mr. R. G. Collingwood enters upon the history of Hadrian's Wall. These two exhaustive papers must form the basis of all later attempts to discuss the problems involved in their construction. Mr. Collingwood suggests that Hadrian's Wall was not, as one is apt at first sight to suppose, a military work intended to give tactical advantage to troops on the defensive, but a police work, intended to facilitate the patrolling of the frontier-line against unauthorised crossing.

THE NORTHMEN IN ENGLAND.—An admirable article in the April issue of the *Quarterly Review*, by Mr. Reginald Lennard, shows that so far from the warrior West Saxon kings like Alfred the Great being the protagonists in this period, it was the intrusion of the Northmen which changed the fabric of Anglo-Saxon society. This view is based partly on the work of sociologist-historians like Maitland and Vinogradoff, but mainly on that of philologists like Mr. Allen Mawer, who have been working at the place-names of northern England. The extent of the Norse vocabulary on place-names is a new and important discovery, and the writer points out that in the early English kingship, taxation, and the judiciary, the Norse influence was great. The explanation suggested is that the Norsemen gained by travel and commerce an experience denied to the home-loving Saxon. They were champions of freedom: the growth of the English manor was largely influenced by them: and in art the Norse spirit is now widely recognised.

OUR TEUTONIC FORBEARS.—Under this title Prof. F. G. Parsons contributes a valuable article, in which, from the point of view of an anatomist, he describes in the *Times* of April 14 the results of the exploration of Saxon burial-grounds at Margate, Mitcham, and Bedford-on-Avon. At Margate the dead are found buried in regular rows, as in a modern cemetery, a habit the Jutes brought with them from the continent, where the so-called "row-graves" or *Reihengraben* have been long recognised in North-West Germany. The Jutes' burials may be always recognised from their habit of burying an earthenware bottle, usually near the face of the dead: it possibly contained ale or mead for the refreshment of the ghost. From the arms and other adornments it is certain that at Mitcham and Bedford-on-Avon the sites were occupied by pagan Saxons, long-headed, long-faced members of the Nordic race, though every now and then a broad head of Mid-European origin turns up, warning us that the Angles, Saxons, and Jutes were not an altogether pure race. The average height 5 ft. 6 in. contrasts with 5 ft. 9 in. of the average Englishman of our day. The well-worn teeth show that much of his food consisted of grain, roughly ground by soft stones; he suffered terribly from chronic rheumatism or osteo-arthritis, and among the men fractures, often wonderfully well set, appear; old head injuries are common, showing the rough, adventurous life they led. Most of them died before 40, and the proportion of adolescents between 15 and 20 was very great.

SOCIOLOGICAL ASPECT OF FATIGUE PROBLEMS.—In *Psyche* (vol. iii. No. 3) Miss Mona Wilson discusses the "Problem of Industrial Fatigue" in Great Britain. She states that she wishes to treat the subject from a sociological, rather than from a technical point of view, because, however valuable the results of scientific research into fatigue may be, they cannot be adequately utilised without a fundamental change in the relations between employer and employed. Until recently no systematic study of industrial fatigue had been undertaken in Great Britain. The War, however, with its urgent demands for maximum output, compelled the Government to consider the problem of fatigue in relation to output, and ultimately the Industrial Fatigue Research Board was established to study the human side of industry. Fatigue showed itself to be a very complicated problem, and already it has had to be considered in relation to problems of vocational selection, training, and motion-study, as well as to the more obvious problems of hours of labour, speed of production, division of the working day. As the problems are too detailed for a single body to undertake them all, the writer suggests that while the Industrial Fatigue Research Board might initiate lines of inquiry, some of the better organised trades might form Joint Research Associations responsible for their own investigations, and that for this purpose they might co-operate with the Institute of Industrial Psychology as well as with the Board. General conditions for working such Associations are given, and in particular there is emphasised the need for giving guarantees to the employees that, should the result of the research work be to employ fewer people, those displaced will be absorbed elsewhere. The article is worthy of careful consideration both by technical researchers, who sometimes tend to become absorbed in a too narrow aspect of their investigations, and also by the student of social problems, who not infrequently tends to neglect the scientific problems inherent in them.

NEW EOCENE MOLLUSCA FROM TEXAS.—Appended to "A geological reconnaissance in the Gulf coastal plain of Texas near the Rio Grande," by A. C. Trowbridge, is an account of the "New species of Mollusca from the Eocene deposits of south-western Texas," by Julia Gardner (U.S. Geol. Surv. Professional Paper 131-D). They are few in number but decidedly interesting. A subspecies of *Ostrea alabamiensis* seems the most abundant form, and Cucullæa one of the more conspicuous. There is a doubtful example of Cerithium, which on the plate has been styled "Melania?" and a handsome nautiloid referred to the genus Enclimatoceras, although as pointed out by Foord in 1891 (Cat. Fossil Cephalop. Brit. Mus., Pt. ii.), this should have borne the prior name of Hercoglossa.

GEOLOGICAL RESEARCH IN SWEDEN.—Volume 18 of the Bulletin of the Geological Institution of the University of Uppsala (1922) bears the name of

Hjalmar Sjögren as its editor; but it also records his death from apoplexy, early in the year. The long list of his papers, from 1877 onwards, and the appreciation so aptly written in English by Prof. A. G. Högbom, show how greatly geological science has lost by the passing of one who did not cease to be an investigator when he could also afford to be a patron. The Bulletin is prefaced by a portrait that will record Sjögren's truly noble personality for friends in every quarter of the globe; it is difficult to realise that he was already well on his way towards his seventieth year. The volume covers even a wider range than usual, from the crystallography of amphibole to Cretaceous mosasaurs from Texas. We may specially note G. Frödin's elaborate study of the highlands of central Sweden, including the Åre district, written in German, and his paper in English "On the analogies between the Scottish and Scandinavian portions of the Caledonian mountain-range." In the latter, as the result of his studies of deep continuous sections in Sweden, the author urges that the Moinian and Dabradian complexes in Scotland received their metamorphic characters during the Caledonian movements, and that they are formed of Torridonian (Sparagmite) and early Palæozoic formations, rather than of a pre-Cambrian series metamorphosed before Palæozoic times. However much this conclusion might simplify the stratigraphy of certain areas, it seems incompatible with the known unconformity of unmetamorphosed Ordovician beds on Dabradian schists and quartzites in western Ireland.

Oil Fields and the Gravity Balance.—The recent use of the Eötvös gravity balance by the oil companies in prospecting for new and exploring old oil fields has brought into prominence an extremely sensitive instrument devised nearly thirty years ago by Baron Eötvös, professor of physics at Budapest, and constructed in 1888 by Süss, then director of the mechanical training workshops of Budapest. The instrument and the measurements made by means of it were described in Hungarian periodicals in 1890 but were not generally known till 1896, when a short account appeared in the *Annalen der Physik*, vol. 59, p. 354. An instrument has now been acquired for the Science Museum at South Kensington, and a paper by Messrs. H. Shaw and E. Lancaster-Jones describing it and giving its theory and some account of tests made by means of it, appears in the April issue of the Proceedings of the Physical Society of London. The instrument consists of a fine fibre which supports a horizontal rod, to one end of which a small mass is directly attached, while from the other an equal mass is suspended by a second fine fibre. The instrument determines the difference of the values of gravity at the two masses, and according to Eötvös will detect a difference of 1×10^{-9} C.G.S. unit.

Magnetic Recording Drum for Electric Relays.—It is now becoming increasingly difficult to differentiate between telegraph, telephone, and radio engineers. The paper read by Dr. N. W. McLachlan to the Radio Section of the Institution of Electrical Engineers on April 11 illustrates this. It is entitled "The Application of a Revolving Magnetic Drum to Electric Relays, Siphon Recorders, and Radio Transmitting Keys," and it is of equal interest to every kind of communication engineer. When the drum is magnetised, part of it is pressed on fixed iron rings with considerable force, and this alters the speed. The author finds that the tangential pull thus obtained is many times greater than the product of pressure due to the product of the magnetic attraction and the coefficient of friction. The ratio of the experimental pull to the calculated pull may exceed 50. It is suggested that the operation of the device depends on some form of cohesive action brought into play by magnetism.

Upper Air Data in America.—Free-air winds at Lansing, Michigan, are dealt with by Mr. C. L. Ray, of the U.S. Weather Bureau, in the U.S. *Monthly Weather Review* for December 1922. Pilot-balloon observations have been carried out at this station daily since June 1919, flights having been made for more than two years at 7 A.M. and 3 P.M., except when impossible through bad weather. Latterly, observations have only been made at 3 P.M. For the three-year period, the results are given for the four seasons of the year for various altitudes from the surface to 6000 metres, and the percentage of the winds from various directions is shown. More than 50 per cent. of the surface winds have a south component and more than 56 per cent. have a west component. At 4000 and 6000 metres the preponderant direction lies between west and north-west. The variation of the winds with altitude for each season is given by tables and graphs. Surface velocities average about three metres per second. At 250 metres the velocities average two and a half times greater than at the surface. Above 1500 metres, winds are consistently west to north-west. Velocities are greater in the winter months, and at the 6000 metre elevation the average reaches 27·7 metres per second as compared with the summer mean of 12 metres per second at that level. In the upper levels the easterly winds do not reach the velocities attained by the westerly winds. Winds with a surface south component all show a clockwise movement with altitude and generally have a west-south-west direction at about 2000 metres. There is a more or less persistent north component to the highest levels. The highest velocity reached at Lansing was 83 metres per second from the north-west at an altitude of about 7000 metres on December 17, 1919.

Ice Patrol Service in North Atlantic.—The U.S. *Monthly Weather Review* for December 1922 contains an article by Lieut. E. H. Smith on "Some Meteorological Aspects of the Ice Patrol Work in the North Atlantic." The disaster to the s.s. *Titanic* on April 14, 1912, when what was then the largest ship afloat was sunk by striking an iceberg off the tail of the Great Bank of Newfoundland, resulted in an ice patrol being established with the object of preventing the recurrence of a similar loss. The patrol was of International origin, the management of the service being undertaken by the U.S. Government. It is now about ten years since the service has been in operation, and much information has been gathered as to the determination of the variable limiting lines of menacing ice, and efforts have been made to determine the causes of the variations as to seasonal and other differences. Glaciers on the west coast of Greenland are said to be the great source of icebergs which appear during March drifting south along the east side of the Great Bank, and during April, May, and June they constitute a menace to steamships. The summer winds in West Greenland, the birthplace of the bergs, have an immense influence on the number of bergs over the North Atlantic in the following season. Off-shore winds drive a great number of bergs westward into the southerly current, while on the other hand, on-shore winds tend to cause a poor ice year. It is said to take approximately five months for a berg passing Cape Dyer to appear south of the 45th parallel. If the dates of the bergs passing Cape Dyer were known, long-range forecasting of ice conditions in the North Atlantic would probably be possible.

The Total Eclipse of the Sun, September 21, 1922.

By Dr. WILLIAM J. S. LOCKYER.

SOME time ago an account was given in these columns (December 29, 1921, vol. 108, p. 570) of the probable expeditions which would go out, and the stations that would be occupied, for the observation of the total eclipse of the sun in September of last year. This programme was very nearly followed, excepting that Mr. Evershed's party from South India, instead of occupying one of the islands of the Maldive group, went to a station, Wallal, on the north-west coast of Australia, thus joining up with other expeditions located there.

The eclipse track, it may be remembered, passed over the Maldive Islands, Christmas Island, and Australia, leaving that continent on its eastern coast.

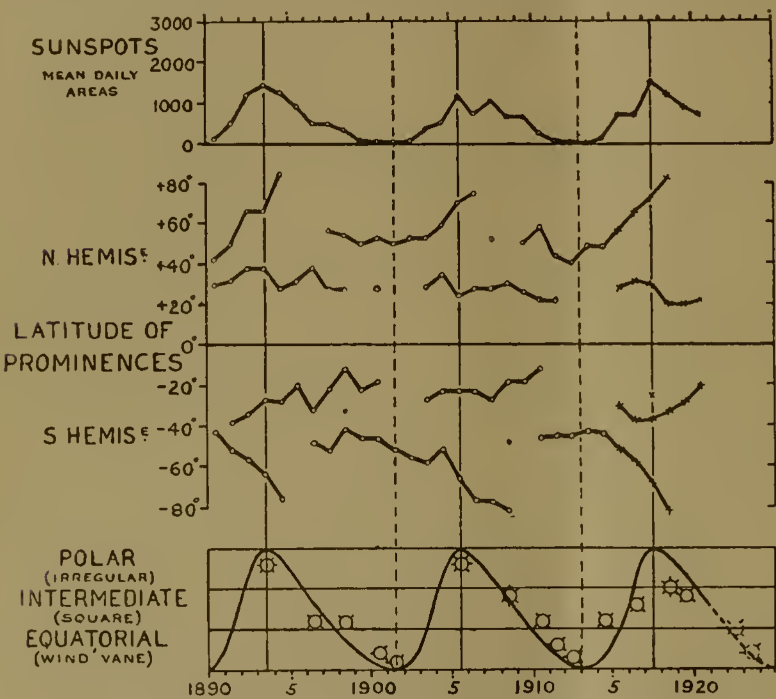

FIG. 1.—Comparison between prominence zones and forms of the corona. From Monthly Notices R.A.S., April 1922, vol. 82, No. 6, p. 324. By permission of the Royal Astronomical Society.

The Maldive Islands seem to have been unoccupied on this occasion, and the British and German expeditions to Christmas Island were so clouded out that no observations could be made. All the stations in Australia were favoured with fine weather, so a valuable series of records may be expected in due course.

The success of the Crocker Eclipse Expedition, which occupied Wallal, is shown by Dr. W. W. Campbell's account of the expedition which appears in the Publications of the Astronomical Society of the Pacific (vol. 35, p. 11). In the first instance, this expedition was organised on a modest scale, owing to the probable great difficulties of transport, etc., at this remote and somewhat inaccessible station in Australia. The generosity of the Australian Government in providing transport from Fremantle, and assistance both in personnel and material, altered the whole aspect of affairs. A much enlarged programme was, therefore, decided upon and was eventually carried out successfully.

The main programme was as follows:

A pair of cameras of 5 inches aperture and 15 feet focal length for application to the Einstein eclipse problem: the Shaeberle camera, aperture 5 inches and focal length 40 feet, for the photography of the solar corona: two cameras of 4-inch quadruplet lenses and 5 feet focus for the Einstein effect and other possible results of the sun's surroundings: several spectrographs for the photography of the coronal spectrum: and a camera of 5-inches aperture and 66 inches focal length for the photography of the form of the corona.

Dr. Campbell's account describes very fully the many and varied experiences of the trip to the station, the landing, the erection of the instruments, and the procedure to prevent the great amount of dust from affecting the mechanisms of the instruments. He pays great tribute to the valuable assistance rendered by Mr. H. A. Hunt, the Government meteorologist, charged with the general organisation of all the expeditions, and to the officers and men of the Royal Australian Navy detailed to accompany the expeditions to Wallal and provide for their needs at transfer points and at Wallal itself. The camp was quite up-to-date, receiving wireless time signals and a weekly aeroplane mail service.

Eclipse day proved ideal and the whole programme was followed successfully.

Owing to the irregularity of the moon's motion, the times of the eclipse were not exactly as forecasted. On this occasion the duration of the total phase for Wallal, assigned by the "Nautical Almanac," was five minutes nineteen seconds. At Wallal the beginning of totality came about sixteen seconds earlier than the predicted time, and the end occurred about twenty seconds earlier. Thus, mid-totality was eighteen seconds early and the whole total duration lasted five minutes fifteen and a half seconds.

The corona appeared visually small and relatively faint, and no large prominences were visible. It is stated that the form of the corona corresponded to that generally associated with sunspot minimum. This verifies the forecast I made in the article in this journal mentioned above, where it was stated that "the corona will most probably be of the 'wind-vane' type, in which the coronal streamers are restricted to the lower solar latitudes, while the regions of both poles will be conspicuous by the presence of the well-known polar rifts." The illustration which accompanies Dr. Campbell's paper indicates a typical form of "wind-vane" corona. (See Fig. 1.)

Dr. Campbell seems to have made supreme efforts to measure, on the spot, some of his plates for the Einstein effect, having previously succeeded in his arrangements for securing night comparison plates in the island of Tahiti. He wished at least to make a preliminary statement concerning the contribution of the expedition to the solution of the Einstein eclipse problem before he left Perth on his homeward journey. In his own words, " it was a severe disappointment to me, that the many delays, wholly beyond our control . . . prevented me from carrying out this plan." (The plates have since been measured, and, as was announced in *Nature* of April 21, p. 541, the results confirm Einstein's prediction.)

It was intended that the large-scale photographs of the corona obtained at Wallal, and by the Adelaide expedition at Cordillo Hills, should be compared for evidence of motion within the coronal streamers, during the interval of 35 minutes between the times of totality at the two stations. The very quiescent solar conditions at the time did not hold out very good prospects, as Dr. Campbell states, but probably the high quality of the negatives will on closer examination lead to positive results.

All the spectroscopic results of the corona indicated also a low activity of the sun, the coronal lines being very much fainter than those recorded in the eclipse of 1918.

The absence of prominences, the smallness of the corona and its faintness, all tended to make the eclipse a dark one, thus favouring ideal conditions for the Einstein plates to secure as many star images as possible.

There is little doubt that when the complete results of the Crocker Eclipse Expedition come to be published they will contain a valuable record of the work accomplished during the brief interval of five minutes fifteen and a half seconds.

Perhaps one may be permitted to take this opportunity of congratulating Dr. Campbell not only on the success of this expedition which he so ably led, but also on his election in January last to the presidency of the University of California. While this position will involve great responsibilities and absorb much of his time, he will still, fortunately, retain his directorship of the Lick Observatory and his residence on Mount Hamilton, and he will return there on all available occasions.

Alloys Resistant to Corrosion.

A GENERAL discussion on the subject of alloys presenting a high resistance to corrosion was held on April 13 at the University of Sheffield, the meeting being arranged jointly by the Faraday Society, the Sheffield Section of the Institute of Metals, and the Manchester Metallurgical Society. Sir Robert Robertson, president of the Faraday Society, occupied the chair. In his opening remarks the chairman referred to the economic loss involved in the corrosion of steel, and to the great step in advance represented by the introduction of stainless steel. In the chemical industry, the use of high-silicon irons had proved to be of great value. It was important to remember that the order of resistance of materials might be quite different towards different reagents, so that in nitration, for example, while iron and steel would resist the action of the concentrated acids, the same solutions after being deprived of their nitric acid would cause attack. The time was ripe for a general survey of the subject.

Prof. C. H. Desch, while noting that no theoretical paper was to be presented at the meeting, remarked that the study of corrosion had undergone a profound change in recent years. Formerly, the usual method of experiment was the determination of loss of weight of specimens under more or less arbitrary conditions, coupled sometimes with measurements of electrolytic potential. The first method gave purely empirical results, whilst the second was difficult to interpret, and the resistance of different metals and alloys often appeared to be quite incompatible with their positions in the electrochemical series. Gradually, investigators had become convinced that the physical character of the products of corrosion was a most important factor in the process. A metal which from its electrochemical position might be expected to corrode rapidly might in the early stages become coated with a protective film, after which the action was negligible. It was not only films of perceptible thickness that exerted such an influence. Recent work had shown the importance of films of oxygen and other substances, one atom or one molecule thick, to which no definite formula could be assigned, but they altered entirely the chemical character of the surface. It is still impossible to predict the composition of highly resistant alloys, and we have to be content with empirical trials, such as have led to the discovery of the alloys to be described. The theory of the subject is still imperfect, and he urged that more attention should be given to the fundamental work of Faraday, the neglect of whose teaching was responsible for much confusion of thought on the subject of corrosion.

Three main classes of alloys were dealt with by the readers of papers, namely, the stainless steels, the alloys of nickel with chromium, and the alloy known as Monel metal. Dr. W. H. Hatfield gave an account of the extensive series of laboratory tests made in the Brown-Firth Laboratory, in which many specimens were exposed to the action of simple and mixed electrolytes, the results being recorded numerically and by means of colour photography. The high resistance of the alloys of iron with chromium and varying amounts of carbon, known as stainless steels, was very evident from these experiments. This class of steels was described in detail by Mr. J. H. G. Monypenny. The greatest resistance to corrosion in these steels is obtained by quenching in such a way as to obtain a homogeneous martensite, while the attack by reagents is greatest when the steels are annealed so as to bring about the greatest separation of the carbide and the ferrite. This is in accordance with the known effects of galvanic action. Tempering at such a temperature that the internal stresses are relieved, but coalescence of the carbide is avoided, does not lessen the resistance. With a very low carbon content, nearly all the chromium is in solid solution, so that the steels are resistant even in the unhardened state, and this property has led to many new uses for the metal. The retarding effect of colloidal substances on corrosion is shown by the fact that while a properly hardened stainless steel is not attacked by vinegar or lemon juice, pure acetic or citric acid of the same concentration produces a marked attack. The same alloys are highly resistant to the action of air at high temperatures or of superheated steam.

It is for their resistance to these agents that the next series of alloys, those containing nickel and chromium as their principal constituents, are specially valued, and these alloys were described by Mr. J. F. Kayser. The technical alloys contain iron, and the useful compositions are limited to a comparatively small area on the ternary equilibrium diagram, although some experiments have been made with alloys outside that range. Copper is occasionally added when resistance to acids is required, but is detrimental when high temperatures are involved. Aluminium has a remarkable hardening effect, owing to the formation of the very hard and infusible compound NiAl. Wires for electric furnaces, case-hardening boxes, and reaction vessels for ammonia synthesis, are among the uses to which this group of alloys has been put. The corroding action of furnace gases containing sulphur compounds is due to the formation of nickel sulphide, which forms a fusible scale.

Mr. J. Arnott gave a short account of the behaviour of Monel metal, which is composed chiefly of nickel and copper, towards various reagents. This alloy is particularly resistant to sea water, to impure waters such as those of many mines, and to steam.

An important point was brought out by Mr. J. H. S. Dickenson, who remarked that for many technical purposes stainlessness as usually understood was not required, freedom from pitting and gross rusting being more important. For example, in submarine work it is not essential that parts should remain quite bright, but it is necessary that they should not become jammed by accumulations of rust. A piece of soft stainless steel, merely sand-blasted, had been exposed in the garden for eighteen months, and, although it had rapidly assumed a yellowish tarnish after the first rain, it had not lost weight, while a mild-steel sample had rusted badly. Mr. Macnaughten remarked that for some purposes a good electrical conductivity was required as well as resistance to corrosion, and that in such cases pure nickel had advantages even over Monel metal.

Some differences of opinion were manifested in regard to the chromium steels. The comparatively recent introduction of alloys so low in carbon as to be available for use without hardening, and in the cold-worked condition, has led to the use of the term "stainless iron" for such alloys, while other authorities prefer to regard the stainless steels as forming a continuous series of varying carbon content. Commercial considerations are involved, but it appears that for practical purposes there is a division, which occurs at the point where the carbon falls so low that the use of an expensive ferro-chrome becomes necessary in the manufacture. Scientifically, there is no break in the series.

Turning to another class of alloys, an interesting announcement was made by Mr. Harold Turner, who exhibited articles made of a new standard silver, free from copper, but containing the 92·5 per cent. of silver required in order to obtain the hall-mark. Although it is not claimed that such an alloy is resistant to acids, experiments had shown that the tarnishing caused by the atmosphere of a town was very greatly less than that of standard silver. Fuller particulars of this interesting alloy will be given at a later date. The working qualities prove to be excellent. No account was given of the alloys of the nickel silver group, some of which have been improved in respect of their resistance to corrosion, particularly by the introduction of tin in place of zinc; but Mr. F. Orme described some acid tests with several alloys of this class, showing little difference between them and the older alloys. It was, however, argued that these alloys are not intended for exposure to acids, and that only a higher resistance to atmospheric action is to be expected from them.

A valuable paper on the mechanism of so-called "dry corrosion" was read by Mr. U. R. Evans, of Cambridge, whose experiments included the examination of a number of metals and alloys when exposed to various gases, either saturated with moisture or in a relatively dry state, excluding the case of the complete absence of moisture. The action was regarded as electrolytic, the formation of a thin liquid film being an essential part of the process. The conductivity of such a film is an important factor. When the product formed is hygroscopic, so that the surface of the metal becomes visibly wet and the liquid may fall off in drops, as in the attack of zinc by hydrogen chloride, nickel by sulphur dioxide, and copper by ammonia, the corrosion is very rapid. Observation of the tarnish colours formed in the early stages of the corrosion seems to indicate that local anodic and cathodic areas are present at the beginning. The formation of temper colours by oxidation at higher temperatures, as in the case of iron above 220°, appears to be a different phenomenon. Dr. R. S. Hutton mentioned that this side of the subject was engaging the attention of the Non-Ferrous Metals Research Association, and that Mr. Vernon was conducting experiments for the Atmospheric Corrosion Committee in this direction. Mr. Vernon, in a written communication, questioned the necessity for the presence of water in such attack by gases, and offered an alternative explanation of the facts.

The discussion undoubtedly served a useful purpose in bringing together data as to the classes of alloys now available when a greater resistance than usual to corroding agents is required. Great progress has been made in this direction, to which the stainless steels and the alloys of the nichrome class, as well as the older silicon irons, bear witness. The new silver alloy is a further indication of the attention being given to the production of alloys which will suffer less by exposure to the atmosphere of towns. Unfortunately, a scientific theory of the phenomena is still lacking, the theory of corrosion, in spite of its very extensive literature, being lamentably imperfect. The process of trial and error, which is at present almost the only method for the discovery of resistant alloys, needs to be replaced by a systematic conception of the process, which will make it possible to predict, with some approach to accuracy, the behaviour of a new combination of metals towards a given environment. The Faraday Society has already performed useful services in regard to this matter, and it is to be hoped that when the next symposium is held it may be possible to review the subject in a less empirical manner.

University and Educational Intelligence.

ABERDEEN.—Sir Robert Horne, who delivered his address as Rector of the University on Thursday, April 26, dealt with the relation of the Universities to post-War problems, and with their increasing responsibility for "cultural" education in an age in which the pressure of business leaves less and less time for the cultivation of the arts. After the address, he announced that he intended to offer a prize of 25*l.* for an essay on "The Function of Universities in the Modern State."

CAMBRIDGE.—Prof. Nuttall and Sir William Pope have been appointed to represent the University at the ceremonies connected with the centenary of the birth of Pasteur to be held in Paris and Strasbourg during the present month.

In connexion with the jubilee celebration of the Local Lectures to be held in Cambridge in July, it is proposed to confer honorary degrees on Sir Michael Sadler, Prof. R. G. Moulton, and Messrs. Albert Mansbridge, G. P. Bailey, J. H. Fisher, and A. Cobham.

Sir Archibald Garrod, Regius professor of medicine, Oxford, will deliver the Linacre Lecture on May 5, the subject being "Glimpses of the Higher Medicine."

LONDON.—A research studentship for post-graduate work at the London School of Economics and Political Science will be awarded in July next. Its value will be 175*l.*, in addition to fees, and it will be tenable for two years. Application forms (which must be returned not later than May 31) can be obtained from the director of the School, Houghton Street, Aldwych, W.C.2.

Manchester.—Prof. de Sitter, of the University of Leyden, will deliver a lecture on "The Theory of Jupiter's Satellites" at the University on May 9, at 5.30 p.m. Visitors will be welcomed.

Oxford.—Sir Michael Sadler has been elected Master of University College, in succession to Dr. R. W. Macan, who retired from the office on April 1. Sir Michael Sadler was well known in Oxford from 1880 to 1895 as scholar of Trinity and steward and senior student of Christ Church. He was president of the Union in 1882, and from 1885 to 1895 he did valuable work as secretary to the then lately-established Oxford University Extension Scheme. He was appointed professor of the history and administration of education at the Victoria University of Manchester in 1903, and became Vice-Chancellor of the University of Leeds in 1911. Sir Michael Sadler is the leading authority upon education in Great Britain, and his return to Oxford is confidently expected to prove a source of increased strength to the educational efficiency of the University.

By the will of Dame Ella Mabel Farrar, the sum of 4000*l.* is bequeathed to such university or university college in the Transvaal as her executors shall select, to found a George Farrar agricultural scholarship for students of European birth.

H.R.H. Princess Mary, Viscountess Lascelles, has consented to present the prizes and certificates to the students of the London (Royal Free Hospital) School of Medicine for Women (University of London), Hunter Street, Brunswick Square, W.C.1, on Saturday, June 2. Scholarships to the total value of 1010*l.* will be awarded for the session beginning in October 1923. Full particulars and forms of entry can be obtained from the warden and secretary of the hospital.

On April 4, the Sterling Chemistry Laboratory of Yale University, the first building to be erected out of the funds provided by the bequest of John W. Sterling to the University, was formally opened, and Sir Joseph Thomson delivered an address on "The Unity of Physics and Chemistry." The date is interesting as being the centenary of the first lecture in chemistry delivered at Yale by the first professor of chemistry, Benjamin Silliman. The building has cost about 400,000*l.*, and according to *Science* of March 23, in which some details of its equipment are given, it is the finest material plant in the world for the teaching of chemistry and for research. There is a laboratory for industrial chemistry, which contains apparatus of factory size, and extends from the foundations of the building to the roof. The centre of the building is devoted to teaching laboratories, all on the same level, and separated from each other by light walls, which can readily be removed should it be necessary to enlarge any laboratory. The building also contains a large number of small private laboratories, two large lecture-halls, class-rooms, and a well-furnished library.

The foundation, recently announced, of six Henry P. Davison scholarships tenable by Oxford and Cambridge men for one year in Harvard, Yale, and Princeton Universities, may perhaps be regarded as significant of a movement in the United States in favour of endowments reciprocal to the Rhodes Scholarship Trust. Each of the Davison scholarships is worth 1500 dollars plus tuition fees, or about 375*l.* in all. According to an announcement by the Oxford selection committee, preference will be given, other things being equal, to undergraduates in their second year proposing to return, on the expiry of the term of tenure of the scholarship, to their own University for a further year of study. Selection will not be by examination. The selection committee will base their choice on a consideration of character, scholarship, and of general fitness to represent the University. It is understood that the scheme is, in its present form, experimental. Compared with the 96 Rhodes scholarships tenable in Oxford by Americans, the number of American university and college scholarships for British students is rather small. A list published in the "Universities Yearbook" gives: the Rose Sidgwick Memorial, 1000 dollars; Choate Memorial (Harvard), 1850 dollars; Bryn Mawr, three of 720 dollars each; Union Theological Seminary, New York, 1200 dollars; Jane Eliza Procter (Princeton), two of 2000 dollars each; and Auchinloss and Dawson (Yale), 2000 dollars. The very magnitude of the Rhodes Scholarship Trust has perhaps hitherto tended to discourage reciprocity.

Education Week in America, December 3-9, was marked by proclamations by the president of the United States and by governors of 42 States, by hundreds of thousands of addresses, sermons, and speeches, by special editions of or editorial support in half of the newspapers of the country and by articles in practically all the others, by special exhibitions in practically all the motion-picture theatres, and by messages from numerous broadcasting stations. What is the justification for such a raging and tearing campaign? The United States Government Commissioner of Education answers this question by saying that no step forward in education can be made except as the result and with the approval of public sentiment, and it is therefore of fundamental importance to arouse the interest of the public generally, and not merely of the educator and educated man, in the needs of education. The Bureau of Education itself made use in Education Week of the Government naval aircraft broadcasting station, and followed this up by establishing a regular service of broadcast messages. The "radio talks" are given on Monday and Thursday evenings, and deal with such subjects as consolidation of rural schools, health work in schools, etc.

The report for 1922 of the Carnegie United Kingdom Trust gives particulars of grants amounting to 106,669*l.*, distributed as follows: Libraries 68,303*l.*, music and the drama 17,320*l.*, physical welfare 10,300*l.*, hostels 6452*l.*, miscellaneous 4294*l.* Of the grants for libraries 36,000*l.* went to rural circulating, 24,000*l.* to urban, and 5000*l.* to special libraries (central libraries for students, Co-operative Library of Dublin, Royal Aeronautical Society, College of Nursing, and Merchant Seamen's), while 1500*l.* was given to the School of Librarianship and 1600*l.* to the "Subject Index to Periodicals." The trustees aim at "providing the initial expenditure necessary for the efficient inauguration" of projects likely to have permanent national value, and especially new projects of a pioneer character, rather than at maintaining indefinitely enterprises which give no promise of becoming self-supporting. Their operations derive from this principle a certain liveliness not commonly associated with the administration of property in mortmain. In connexion with the rural libraries scheme the report comments on the disadvantages of the system under which in England and Wales the Education Committee is only a department of the County Council instead of being an autonomous authority as in Scotland. Among other important benefactions are: a guarantee of 1000*l.* in connexion with the publication of a "World List of Scientific Periodicals," showing libraries in Great Britain where they are on file, and a grant for the National Institute of Industrial Psychology.

Societies and Academies.

London.

Royal Society, April 26.—W. A. Bone, D. M. Newitt, and D. T. A. Townend: Gaseous combustion at high pressures. Pt. III.—The energy-absorbing function and activation of nitrogen in the combustion of carbon monoxide. Nitrogen can no longer be regarded as an inert gas in the combustion of carbon monoxide, because when present as a diluent in a mixture of two volumes of carbon monoxide and one volume of oxygen undergoing combustion in a closed vessel under high pressure, it exerts an energy-absorbing influence which (*a*) retards attainment of maximum pressure, and (*b*) diminishes maximum temperature attained in explosion. The effects are much greater than those due to any other diatomic diluent. The energy so absorbed by nitrogen during the combustion period is slowly liberated as the system cools down after attainment of maximum temperature, and consequently the rate of cooling is greatly retarded. These effects are very marked in the case of a carbon monoxide-air mixture ($2CO + O_2 + 4N_2$). In consequence of such energy-absorption, nitrogen becomes chemically "activated" in such explosions, and while in this condition will combine with oxygen, forming oxides of nitrogen. If no nitrogen be present in a carbon monoxide-oxygen (2 : 1) mixture, carbon monoxide burns in oxygen at high pressures almost as rapidly as does hydrogen. There is no correspondingly large (if any) energy-absorbing effect (other than purely "diluent") when nitrogen is present in hydrogen and oxygen mixtures similarly undergoing combustion, and there is no evidence of nitrogen being then activated. Two or three per cent. of hydrogen in a carbon monoxide-air mixture undergoing combustion prevents any material activation of the nitrogen. It appears that the influence of nitrogen in the carbon monoxide-oxygen explosions is due to its ability to absorb the particular quality of radiation emitted; such radiation is known to be of a different wave-length from that emitted during the flame-combustion of hydrogen. In other words, there seems to be some constitutional correspondence between carbon monoxide and nitrogen molecules, whereby the vibrational energy (radiation) emitted when one reacts with oxygen is of a quality readily absorbed by the other, the two acting in resonance.—R. A. Watson Watt and E. V. Appleton: On the nature of atmospherics. Observations with a cathode ray oscillograph, on the temporal variations of the electric force occurring in radio telegraphic atmospherics are described. The principal constants of six hundred typical atmospherics are examined. A bare majority are quasi-periodic, consisting normally of one complete oscillation, of duration 2000 micro seconds, the mean change of field being 0·128 volts per metre, with no marked unbalanced transport of electricity on the whole group. The second group consists of aperiodic impulses, of duration generally about 1250 micro seconds, but frequently reaching 0·025 of a second, the mean change of field being 0·125 volts per metre, with a seven to one numerical predominance of discharges tending to carry negative electricity to earth in the receiving antenna.—I. Masson and L. G. F. Dolley: The pressures of gaseous mixtures. Measurements have been made at 25° of the compressibilities up to 125 atm. of ethylene, argon, oxygen, and a series of binary mixtures of these. The volume of a compressed mixture usually exceeds the sum of the separate volumes of its two components, the excess depending on the molecular ratio of the two gases chosen and upon the pressure. Thus with an equimolecular mixture of argon and ethylene at 80 atm. the volume is greater than the additive value by 24 per cent. At a given pressure there is an "optimum" composition, and with a given composition there is an optimum pressure. Oxygen-ethylene mixtures behave quantitatively in the same way as argon-ethylene; oxygen and argon when mixed show a negligible volume increase, and are individually equally compressible. The pressure of a mixture at high densities exceeds the sum of those measured for the separate constituents; at moderate densities it is definitely less. The former occurrence is due to the actual space filled by the molecules; the latter is due to a mutual cohesion between each.—T. R. Merton and R. C. Johnson: On spectra associated with carbon. The spectral changes due to the admixture of helium to vacuum tubes containing carbon compounds, and the conditions for isolating the band spectra associated with carbon, have been investigated. The "high pressure CO" bands can be isolated almost completely; the "comet-tail" bands are found in vacuum tubes containing helium and carbon monoxide. In the presence of helium the distribution of intensity in the comet-tail bands differs markedly from that observed by Fowler in tubes containing carbon monoxide at very low pressures. By the admixture of hydrogen the comet-tail bands are replaced by a system of triplet bands, and the wave-lengths of the heads of these bands fall into two distinct band series. In helium containing a small quantity of carbon monoxide a new line-spectrum has been observed under suitable conditions of excitation, which is attributed to carbon.—W. R. Bousfield and C. Elspeth Bousfield: Vapour pressure and density of sodium chloride solutions. A standard set of vapour pressure determinations at 18° C. for aqueous solutions of common salt at all concentrations was required. Water and the solution were introduced into the legs of a V tube surmounting a barometric column of mercury, excluding all air. This necessitated the boiling of the solutions so that they became of unknown concentration. The vapour pressure observations were therefore correlated to the densities of the solutions and the latter with a complete set of density observations at 18° C. made on solutions of known concentration accurate to ± 2 in the fifth place of decimals.—F. A. Lindemann and G. M. B. Dobson: A note on the temperature of the air at great heights. The relatively high temperature of the atmosphere above 60 km. appears to be due to absorption of an appreciable amount of direct solar radiation. Thus there should be a large variation in temperature at these great heights. Some evidence of such variation has been found.—G. H. Hardy and J. E. Littlewood: On Lindelöf's hypothesis concerning the Riemann zeta-function.

Physical Society, March 23.—Dr. A. Russell in the chair.—W. J. H. Moll: (1) A new moving-coil galvanometer of rapid indication. The galvanometer is designed to secure rapid indication and steadiness of reading without unduly sacrificing the sensibility. The coil is long and narrow, and therefore of small moment of inertia; the mirror is supported by the wires forming the coil, between which it is slipped, and the coil is supported between an upper and a lower vertical wire, as distinct from strips, made of silicium bronze and put in tension. (2) A thermopile for measuring radiation. The thermopile is designed to be quick-reading and free from zero-errors, as well as sensitive. The cold junctions are in contact with metal masses, and in order that the hot junctions may have small heat capacity, the bi-metallic strips composing the thermopile are made of plates of constantan and manganin silver-soldered along an edge, rolled in a direction parallel to the edge into thin foil, and then cut into strips perpendicular to the edge.—C. W. **Hume**: A note on aberration and the Döppler effect as treated in the theory of relativity. Aberration has been explained as due to the compounding of the velocity of light with the velocity of the earth relative to the ether; hence it appears to conflict with the principle of relativity. Simple methods are given of treating this problem consistently with the restricted principle, and of finding the Döppler effect. The result differs from the non-relativity result by terms of the second and higher orders in v/c.—C. R. **Darling** and C. W. **Stopford**: Experiments on the production of electromotive forces by heating junctions of single metals. When a circuit is closed through a junction of a cold metal with a hot piece of the same metal, large electromotive forces are often noticed; *e.g.* a bare copper wire connected to the terminals of a galvanometer was cut at the middle, one of the cut ends heated and brought into contact with the cold end, and a large deflexion was obtained. Electromotive forces up to 0·25 volt may thus be produced.—R. H. **Humphry**: The double refraction due to motion of a vanadium pentoxide sol, and some applications. In linear flow the liquid behaves in the same way as a plate of uniaxial crystal cut parallel to the axis and placed with axis parallel to the direction of flow. The field between crossed nicols lights up near an obstacle interposed in a stream of the liquid. Similar effects due to efflux of the sol from a jet, to the convective stream from an electrically-heated wire, etc., were also described.

Optical Society, April 12.—Prof. A. Barr, president, in the chair.—F. **Twyman**: The Hilger microscope interferometer. The instrument is used for measuring the aberrations of microscope objectives. A collimated beam of monochromatic light is separated into two beams at the transmissively silvered surface of a plate of plane parallel glass. The transmitted beam passes through the lens under test, and is reflected back from the surface of a convex mirror, which coincides nearly with the approximately spherical wave front of the light as it converges after passage through the lens. The second beam is reflected back along its own path by a mirror so that the two beams recombine at the silvered surface of the plane parallel plate. Portions of each beam then pass on together through a lens to the observer, who sees an interference pattern apparently located on the surface of the lens under test, which is a contour map, to a scale of half wave-lengths of the light used, of the aberrations of wave-surface caused in a plane wave.—A. **Whitwell**: On the form of the wave-surface of refraction. A series of wave-surfaces is drawn for each of a number of refracting surfaces or lenses. Each series consists of the following forms, which always follow each other in the same order. (1) Saucer type; convex to the incident light when the refracted pencil is converging, and concave when the pencil is diverging. (2) Saucer with inturned edges; like (1), but the edges of the wave-surface which have passed through the primary focus are concave towards the incident light when the refracted pencil is converging. (3) Closed surface type; the wave-surface is completely closed like a cone with a dished bottom, the axis of the cone being coincident with the optic axis. (4) Goblet type; somewhat like a champagne glass set sideways, the bowl being towards the incident light and the base towards the secondary focus. (5) Basin type; the base of the goblet has disappeared and just beyond the focus the surface is like a basin concave towards the incident light. The diffraction spectra are found in the neighbourhood of the edges of the saucers, of the apex of the closed surface type, and of the rims of the goblet and basin type. Interference patterns occur in the region bounded by the caustic and by the extreme marginal rays. By drawing wave-surfaces half a wave-length apart lines of maximum and minimum intensity are found which are the sections of surfaces of revolution on which the intensity is a maximum or minimum. Sections of these surfaces by a plane at right angles to the axis show interference rings. The goblet type of wave-surface always occurs between the focus for marginal rays and that for paraxial rays, and may be called the characteristic of the focus.

Linnean Society, April 19.—Dr. A. Smith Woodward, president, in the chair.—A. B. **Rendle**: The structure of the fruit of the mare's-tail (*Hippuris vulgaris* Linn.). The fruit is a drupe, the upper portion of which around the persistent base of the style, with the seedcoat, is developed in the form of a stopper which is easily withdrawn on soaking the ripe fruit. The embryo ultimately fills the seed, and has the large radicle and hypocotyl so often found in water plants. The radicle is placed directly beneath the stopper which provides a place of exit on germination.—B. Daydon **Jackson**: History of botanic illustration during four centuries (Colour). In the early years of printing, copper-plate engraving was employed in providing outlines for hand-colouring and was in use until the last century, when it was ousted by lithography. In Redouté's method of semi-stipple for coloured prints each colour was separately applied to the plate and cleaned off, before finally heating the plate and pulling the print. Chromo-lithography has greater permanence, if lasting colours are employed, than hand-coloured plates. In the three-colour process three (or four) half-tone blocks are prepared, each to print its own colour, to give a complete colour scheme. The weakness of the process lay in this, that it almost demanded a paper coated with baryta or china-clay, which could not be guaranteed as permanent: in addition was the temptation to use inks, made from aniline dyes, which were fugitive.

Cape Town.

Royal Society of South Africa, March 21.—Dr. A. Ogg, president, in the chair.—B. T. **Schönland**: On the passage of cathode rays through matter. The absorption, reflexion, and secondary emission involved in the passage of fast cathode rays through thin foils of various metals, and their variation with the velocity of the rays, were examined. Accurate measurements were possible up to 0·4 of the velocity of light. The results show that Lenard's Law is only an approximation. The existence of a "range" for these particles appears to be established, two independent methods of measuring it agreeing very satisfactorily. The values obtained are in agreement with the theory of absorption due to Bohr.—T. **Stewart**: Holtzhuisbaaken Spring, Cradock. The spring is a typical Karroo spring. Measurements of the flow have been taken over a period of 38 years. The rainfall of a particular season is found to be reflected in the flow, but is not necessarily proportional to it; regard must be had as well to the rainfalls of previous seasons and the "tail" of the flow produced by them.—Gertrud **Theiler**: Two new species of nematodes from the zebra. *Cylindro-*

pharynx intermedia inhabits the pelvic flexure and dorsal colon of the host, of which it is one of the commonest parasites, and *Habronema zebræ* occurs in fairly large numbers in the stomach.—Sir Thomas Muir: Note on Zeipel's condensation-theorem and related results. Both Zeipel's papers on determinants are now over fifty years old and have been somewhat neglected. One or two of the basic results of Zeipel's first paper are discussed and a number of deductions that cluster somewhat picturesquely round them.

Official Publications Received.

Mysore Agricultural Calendar, 1923. Pp. iii+54. (Bangalore: Government Press.) 1 anna.

The Journal of the Royal Agricultural Society of England. Vol. 83. Pp. 8+260+cxlviii+24. (London: J. Murray.) 15s.

Thirty-fourth Annual Report of the Bureau of American Ethnology to the Secretary of the Smithsonian Institution, 1912-13. (With accompanying paper, "A Prehistoric Island Culture Area of America," by J. Walter Fewkes.) Pp. 281+120 plates. (Washington: Government Printing Office.)

Report of the Board of Commissioners of Agriculture and Forestry of the Territory of Hawaii for the Biennial Period ended December 31, 1922. Pp. vi+102+16 plates. (Honolulu, Hawaii.)

SATURDAY, MAY 5.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. L. L. B. Williams: The Physical and Physiological Foundations of Character (2).

MONDAY, MAY 7.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

SOCIETY OF ENGINEERS, INC. (at Geological Society), at 5.30.—P. Mauclère: Pneumatic Handling of Petrol and other Inflammable Liquids.

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street), at 8.—L. J. Russell: Some Points in the Philosophy of Leibniz.

ROYAL SOCIETY OF ARTS, at 8.—S. S. Cook: The Development of the Steam Turbine (2). (Howard Lecture.)

SURVEYORS' INSTITUTION, at 8.—C. H. Bedells: Some Functions of a Surveyor under the Settled Land Acts 1882-1890, and Part II. of the Law of Property Act, 1922.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—F. Kingdon Ward: The Tibetan Border; Yangtse to Irrawaddy.

ROYAL SOCIETY OF MEDICINE (Tropical Diseases and Parasitology Section) (Annual General Meeting), at 8.30.—Lt.-Col. A. E. Hamerton: The Establishment of an Anti-rabic Institute in the Tropics.

TUESDAY, MAY 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. C. Seward: The Ice and Flowers of Greenland.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—W. A. Guthrie: Heavy Grade Egyptian Crude Petroleum.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—The Secretary: Exhibition of Photographs of Big Game from Choma, Northern Rhodesia.—Miss L. E. Cheesman: (1) Exhibition of Living Specimens of *Peripatus* from Trinidad. (2) Exhibition of Section of a Nest of the Stingless Bee from Australia.—H. Burrell: Note on a Hibernating Female Specimen of the Marsupial *Acrobates pygmæus*.—F. Martin Duncan: The Microscopic Structure of Mammalian Hairs.—I. The Hairs of the Primates.

ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 5.30.—Annual General Meeting.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—R. R. Dobson: Mental Tests.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—E. Kilburn Scott: The Pioneer Work of Le Prince in Moving Pictures.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—R. Paulson: Fungi and Birch Trees.

WEDNESDAY, MAY 9.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. G. Keynes: Chronic Mastitis.

ROYAL SOCIETY OF MEDICINE (Surgery: Sub-section of Proctology) (Annual General Meeting), at 5.30.—Sir Humphry Rolleston, Sir Thomas Horder, W. E. Miles, P. Lockhart-Mummery, Prof. L. S. Dudgeon, Dr. W. E. Carnegie Dickson, and Dr. A. F. Hurst: Discussion on Ulcerative Colitis.

INSTITUTE OF PHYSICS (at Institution of Electrical Engineers), at 5.30.—Dr. J. W. Mellor: The Application of Physics to the Ceramic Industry.

INSTITUTION OF AUTOMOBILE ENGINEERS, at 7.30.—Col. R. E. Crompton: The Effect of Motors on Roads.

ROYAL SOCIETY OF ARTS, at 8.—Prof. W. A. Bone: Recent Developments in Surface Combustion, with Special Reference to Recent Developments in Radiophragm Heating.

THURSDAY, MAY 10.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers), at 10 a.m.—Report.—Presentation of Bessemer Medal to Dr. W. H. Maw.—E. R. Sutcliffe and E. C. Evans: The Reactivity of Coke as a Factor in the Fuel Economy of the Blast Furnace.—F. Clements: British Steel Works Gas Producer Practice.—J. E. Fletcher: Some Characteristics of Moulding Sands and their Graphical Representation.—J. H. Whiteley and A. Braithwaite: Some Observations on the Effect of Small Quantities of Tin in Steel.—L. Northcott: Note on Temper Carbon.—J. W. Landon: Change of Density of Iron due to Overstrain.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers), at 2.30.—Prof. H. C. H. Carpenter: The Production of Single Metallic Crystals and some of their Properties.—Prof. J. O. Arnold: The Co-relation of the Chemical Constitutions of "True Steels" to their Micrographic Structures.—D. Hanson and J. R. Freeman: The Constitution of the Alloys of Iron and Steel.—T. F. Russell: The Potential Energy of Cold Worked Steel.—F. C. Thompson and A. Goffey: The Changes in Iron and Steel below 400° C.—L. E. Benson and F. C. Thompson: Some Experiments on Grain-growth in Iron and Steel.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. J. T. MacGregor-Morris: Modern Electric Lamps (3): Glowing Gases (Neon Lamps).

ROYAL SOCIETY, at 4.30.—Prof. A. Fowler: The Series Spectrum of Trebly-ionised Silicon (Si IV).—Sir Robert Robertson and W. E. Garner: Calorimetry of High Explosives.—Dr. H. S. Hele-Shaw: Stream Line Filter.—Dr. F. W. Aston: A Critical Search for a Heavier Constituent of the Atmosphere by means of the Mass-Spectrograph.—Prof. H. E. Armstrong: Electrolytic Conduction; sequel to an attempt (1886) to apply a Theory of Residual Affinity.—Prof. H. E. Armstrong: The Origin of Osmotic Effects. IV. Hydrodynamic Change in Aqueous Solutions.—Prof. R. W. Wood and A. Ellett: The Influence of Magnetic Fields on the Polarisation of Resonance Radiation.—W. G. Palmer: A Study of the Oxidation of Copper and the Reduction of Copper Oxide by a new Method.—E. A. Fisher: Some Moisture Relations of Colloids. II. Further Observations on the Evaporation of Water from Clay and Wool.

ROYAL SOCIETY OF MEDICINE (Neurology Section), at 5.—Annual General Meeting, to be followed by a Clinical Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—Dr. J. A. Fleming: Problems in Telephony, Solved and Unsolved (Fourteenth Kelvin Lecture).

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—Dr. J. W. French: Stereoscopy restated.

CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 8.—Prof. W. H. Perkin: Adolph von Baeyer Memorial Lecture.

FRIDAY, MAY 11.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers), at 10.—Announcement of award of the Andrew Carnegie Research Scholarship.—C. A. Ablett: Economic Principles governing the Use of Electrical Power in Iron and Steel Works.—T. P. Colclough: The Constitution of Basic Slags—its Relation to Furnace Reactions.—Prof. C. H. Desch and A. T. Roberts: Some Properties of Steels containing Globular Cementite.—K. Honda and T. Murakami: The Structural Constitution of Iron-Carbon-Silicon Alloys.—T. Matsushita: Some Investigations on the Quenching of Carbon Steels.—E. J. L. Holman: Note on a Value for the Surface Tension of Iron Sulphide.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers), at 2.30.—C. A. Edwards and C. R. Austin: A Contribution to the Study of Hardness.—F. C. Langenberg: An Investigation of the Behaviour of Certain Steels under Impact at Different Temperatures.—J. Stead: The Cold Working of Steel with Reference to the Tensile Test.—J. J. A. Jones: The Acl Range in Alloy Steels.—C. R. Austin: Some Mechanical Properties of a Series of Chromium Steels.—H. O'Neill: Variation of Brinell Hardness Number with Testing Load.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—J. H. Jeans: The Present Position of the Radiation Problem (Eighth Guthrie Lecture).

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5.30.—Annual General Meeting.

BRITISH PSYCHOLOGICAL SOCIETY (Æsthetics Section) (at Bedford College), at 5.30.—Prof. C. W. Valentine: The Place of Imagery in the Appreciation of Poetry.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—W. F. C. Cooper: The Theory of Resistance to the Flow of Gases and Fluids in Pipes (Durham Bursar's Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. W. A. Bone: Gaseous Combustion at High Pressures.

PUBLIC LECTURES.

MONDAY, MAY 7.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, at 5.15.—Prof. W. de Sitter: Problems of Fundamental Astronomy.

TUESDAY, MAY 8.

UNIVERSITY COLLEGE, at 5.—Prof. H. R. Kruyt: The Electric Charge of Colloids.—At 5.30.—J. H. Helweg: Danish Scenery.

KING'S COLLEGE, at 5.30.—Prof. H. Wildon Carr: Blaise Pascal: Tercentenary of his Birth, June 19, 1923 (1) (succeeding Lectures on May 15, 22, and 29).

BIRKBECK COLLEGE, at 6.—Sir Richard Gregory: The Worth of Science.

WEDNESDAY, MAY 9.

UNIVERSITY COLLEGE, at 5.15.—Sir Thomas H. Holland: Phases of Indian Geology (succeeding Lectures on May 23 and 30).

THURSDAY, MAY 10.

ST. MARY'S HOSPITAL (Institute of Pathology and Research), at 4.30.—Dr. H. H. Dale: The Physiology of Insulin.

KING'S COLLEGE, at 5.30.—Principal L. P. Jacks: Reality in Religion and Education (Hibbert Lecture).

FRIDAY, MAY 11.

SCHOOL OF ORIENTAL STUDIES, at 5.—Dr. P. Giles: The Aryans (succeeding Lectures on May 25 and June 8.

The Zoological Record.

THE decision of the Zoological Society's council to discontinue the publication of the "Zoological Record" on the grounds of expense suggests somewhat opposing thoughts. It is generally admitted, or even strongly urged, by most workers in every branch of science that some guide to the ever-increasing flood of literature is a necessity. If this was true in 1865, when the "Zoological Record" was started, it is no less true to-day. The need, in fact, must have increased in at least the same direct ratio as the number of publications. Yet in zoology, as in geology and other sciences, these guides, records, and indexes have had a perpetual and severe struggle for life, in the course of which many have from time to time succumbed, been revived under another form, and too often again collapsed.

The "Zoological Record" itself was begun in 1865 as a publication by Van Voorst, under the editorship of Dr. Albert Günther, with a distinguished staff of recorders. The publisher paid for the printing, but the manuscript, we believe, was compiled for nothing. Mr. Van Voorst soon found the loss too great, and, though he continued as publisher, an association was founded in 1871 to guarantee the expenses. This carried on till 1887, when the Record was saved from extinction by the Zoological Society, which generously shouldered the burden and bore it unaided until the establishment of the International Catalogue of Scientific Literature. The question then arose whether the record of zoology should merely become one part in that vast scheme. Fortunately the secretary of the Zoological Society was far-sighted enough to preserve the continuity and title of the Record and the control of the Society, by inducing his council to contribute largely to the expense and to maintain its Record Committee. Consequently, when the International Catalogue failed, and when the Royal Society declined to undertake the huge expenditure on what had virtually become its sole responsibility, then zoologists still found their Record appearing—retarded and weakened, but in being and ready to resume its old strength and value whenever they themselves would provide the necessary sustenance. Unfortunately, the increased costs of production have coincided with the loss of a number of subscribers owing to the effects of war and its sequelæ. The secretary of the Zoological Society has over and over again sought in various directions to supply this loss, but has not met with any cheering response. All these facts must be remembered before we venture to blame the Society for its present decision.

When, now, we see the "Zoological Record" threatened with the fate that has overtaken so many similar publications, it is time to inquire more closely into the causes. For one thing, we note that the editorial and recording work is no longer done for the love of the science. For many years, indeed, the editor and recorders have been paid, but of late the appropriation for this purpose has grown enormously. Times, no doubt, have suffered an economic change; there are fewer people with money and leisure enabling them to work for nothing. But more of our younger workers should be inspired by the thought of service to their science, and should realise the experience and knowledge they themselves could gain by compiling a good Record. The work, too, is lightened for them. The International Catalogue introduced the system of furnishing the recorders with slips ready written, and to a certain extent this system is continued by the payment of searchers. We ought, therefore, to be getting an even better Record than we are, and we were hoping that it would have been possible before long to restore some details eliminated by the need for economy. Clearly, the greater the value the better is the prospect of selling.

So we pass from the producers to the purchasers. Here there are two points to be made. First, every worker should consider seriously whether he is prepared to devote a large proportion of his time to ransacking literature, at least that part of it which alone is accessible to him, or in default to work in a state of haphazard half-knowledge, or whether he is prepared to save his time by paying some one else a trifling wage (about a shilling a week) to furnish him with a complete analytical index to the yearly harvest of his science. Put thus, can he remain in doubt? If he is not stirred by conscience to pay himself, he can at least insist that the institution for which he works shall find the money and provide the book. But there is a second point. Admitting that there exist a few workers so exceedingly distinguished that they are furnished with complimentary copies of every paper on their subject that appears from China to Peru, this can scarcely affect the fact that most workers in pure or applied zoology are not in that easy position. The trouble with them is that, for the most part, they have never heard of the Record. We believe this statement to be no exaggeration, and we would urge the advisability of some real advertising. The occasion is favourable, for such competitors as there have been are nearly all now out of the running. One good way would be to induce university professors to instruct their pupils in the craft of bibliographic research.

What, then, is the conclusion? For thirty-six years the Zoological Society has earned the thanks and praise of zoologists for its support of this indispensable aid. But zoologists at large must now do their share if they wish this support to continue. On their side, as well as on that of the recorders, there must be a little more enthusiasm and self-sacrifice. The vessel is stranded, but with good will from all hands she can be kept afloat till the high tide returns. If the workers will give some real earnest of this good will, we cannot believe that the Society which has so long served as pilot will leave her to be broken up.

Hygiene of the Great War.

History of the Great War: Based on Official Documents. Medical Services: Hygiene of the War. Edited by Major-Gen. Sir W. G. Macpherson, Colonel Sir W. H. Horrocks, and Major-Gen. W. W. O. Beveridge. Vol. 1, pp. xii + 400. Vol. 2, pp. vi + 506. (London: H.M. Stationery Office. 1923.) 21*s*. net each.

THE two volumes dealing with that part of the Medical Services of the War which was concerned with preventive medicine possess great historical interest and high current value; they form an admirable example of the excellent results achievable when science is applied to practical life.

The first volume deals with general administrative problems, and comprises chapters on sanitary administration in the field, on the schools of sanitation and instruction organised to secure sanitary practice, on methods of water purification and of disposal of waste products in different countries, and on the housing and the clothing of the soldier. The second volume is concerned with food rations, with the physical test stations, the base hygienic laboratories, and with prisoners of war; these chapters being followed by special discussions on the prevention of malaria, of trench foot, of bilharziasis, of trachoma, of smallpox, and of plague, which present more vividly than the other chapters the successful conquest of science over disease.

The prevention of typhoid and paratyphoid, of typhus and of trench fever, are not included in the discussions in these volumes; but as the prevention and cure of pediculosis forms the essential element in the elimination of the last two of these diseases, the very full discussion given to the methods of disinfestation found most useful in the War fulfils the main need from the point of view of health, the clinical accounts of these diseases being given in other volumes of the history of the War. Similar remarks apply as regards scurvy and beri-beri, but on p. 73 of the second volume is an interesting statement as to the means taken to supply British and Indian troops with fresh fruit juice in Mesopotamia. In the prevention of beri-beri the addition of oatmeal and dhall to the British ration, the addition of marmite, and later, the issue of bread containing 25 per cent. of atta, were found valuable. After May 1917, following the report of Misses Chick and Hume, germinated dhall was used in outlying districts, when fresh vegetables or fruit could not be obtained.

A remarkable feature of medicine in the War was the stimulus given by war to scientific investigation. The instance already given is in point; and many other investigations were successfully carried out under the compulsion of urgent necessity. The pathogenesis of trench fever unfortunately was only fully revealed towards the end of the War; otherwise disinfestation of soldiers would have formed an even larger part of army sanitary work than it did. For details of a valuable investigation of energy expenditure in relation to food by Dr. E. P. Cathcart, chap. iv. in the second volume should be consulted. In the prevention of trench foot, success was at once attained so soon as compliance was secured with the army routine order that every man should remove his boots at least once in twenty-four hours, drying and rubbing his feet and putting on dry socks in place of those discarded.

In view of the large part borne by flies in conveying infection in the South African War, the prevention of flies in all divisions of the Army was vigorously promoted in the Great War, and the chapter devoted to this is a useful summary of the subject. The chapter on the prevention of infestation by lice, which is written by Sir W. H. Horrocks, is a masterly presentation of this important subject, including the biological facts, on knowledge of which efficient preventive measures must be based. The sixty-one pages devoted to this subject do no more than represent its relative importance in military hygiene, when we recall that Colonel Horrocks estimates that in the War 50 per cent. of the admissions to hospital from troops in the field armies were attributable to lack of personal cleanliness and to vermin. The great sanitary lesson of the South African War was that of fly prevention and satisfactory conservancy methods; the great sanitary lesson of the Great War has been that probably one-half of the disablement of our armies in the field is due to pediculosis and scabies.

Scabies was made the subject of accurate investigation at Cambridge, civilians volunteering for this purpose. These investigations showed that the infection of scabies could be conveyed by sleeping in beds previously occupied by heavily infested soldiers or by wearing their clothing. Perhaps the least satisfactory disease prevailing among soldiers, from the point of view of control, was cerebro-spinal fever; and although very specialised efforts were made to prevent its dissemination, it may be doubted whether these were successful, apart from the diminished prevalence which was secured when barracks became less crowded and an approximation towards open-air conditions became possible. There does not appear to be any justification for the belief that the segregation of contacts with cases of the disease or the chemical spraying of the throats of contacts, which was practised on a large scale, greatly influenced the course of events.

There are but few statistics of disease in these two volumes; but it is significant that whereas in the South African War, with an aggregate personnel of 530,000, 8000 men died of typhoid fever, only 266 deaths from this disease occurred in the Great War in the Western Front among British and Dominion troops, with an average strength of 1¼ millions and an aggregate of three or four times that number. The relative share of prophylactic vaccines, of purification of water, and of the sanitary disposal of waste-products in securing the remarkably low incidence of typhoid and of dysentery in the War is not discussed in these volumes; but we hope that in some other volume of the history of the War it will be possible to give details of any experiences in which one or other of these factors of prevention was absent, with the view of assessing their relative value in actual experience.

Attention is directed in Sir W. G. Macpherson's preface to the fallacious illogicality of estimating the healthiness or otherwise of troops by the ratio of deaths from disease to deaths from wounds. This ratio is evidently one between two variables: in particular the number and extent of the battles may vary. As a permissible limit of inefficiency due to sickness in an army in the field, 0·3 per cent. of strength had been accepted as a permissible limit; and this empirical standard was found in experience to be most useful in directing attention to the need for special inquiry in any unit.

The details of sanitary organisation given in vol. 1 are of importance to all practical workers, and this volume will for years form a valuable source of information. The success of the sanitary work of the Army in circumstances involving a manifold multiplication of existent machinery is one of the most striking features of the War. Some of the factors rendering this rapid addition to sanitary staffs practicable are not stated in these volumes; but it is noteworthy that the health of the troops sent abroad depended primarily on the condition of the rapidly improvised camps which were scattered throughout this country; and that the sanitary safety of these camps depended in large measure on the sanitary provisions in the districts in which they were placed, and on the active co-operation between local and central sanitary authorities and the Army authorities. The records of the Local Government Board and of local authorities show that their assistance was given whole-heartedly, and that the soldiers had the full advantage of the high general standard of civil sanitary administration in this country. Furthermore, the Army Sanitary Officers were recruited from the ranks of medical officers of health. To these facts, to the excellent Army medical organisation, to the Army schools of instruction in hygiene, and to the fact that the sanitary lessons of the South African War had been learnt, we must attribute the relative freedom from intestinal infections during the Great War. The investigations made during the War have advanced our medical and hygienic knowledge, and thus the Army will be able to repay its indebtedness to civilian sanitarians by adding to our means of preventing disease in the ordinary course of civilian life.

Radiophones.

(7) *The Perry Auto-Time Morse System: an Aid to the Rapid Acquirement of Speed in the Transmission and Reception of the Morse Code.* By F. W. Perry. Pp. 16. (London: The Wireless Press, Ltd.; New York: Wireless Press, Inc., 1922.) 6*d.*

A CONSTANT struggle has been going on for the last ten years between the users of the adjectives "wireless" and "radio." It is hoped that the question will be solved by international agreement. In America "radio" is in general use, but in this country it is probable that "wireless" will be used by many experts for several years to come. It is easily understood why authors who have written books on "wireless" should be loath to change, but that they should have a strong following seems odd. In our opinion, "radiophone" is a suitable contraction for "radio-telephone," and "radiophone communication" is better than "wireless telephone communication."

Whether we like it or not, there is no doubt that listening to radio broadcasting has become an everyday incident in many households. Until about November 1920 practically the only use of radio-communication was for signalling between pairs of stations. That a message sent out from a station could be heard simultaneously at many others was generally regarded as an inherent drawback to this system of communication, except in the case of a ship in distress on the sea. In the United States radiophone broadcasting began with news items and phonograph music. The latter item was not so good as having your own phonograph. You had to be content with a record chosen by somebody else, at a time which he thought best. The stations now send out vocal and instrumental music, time-signals, accounts of sporting contests, weather and stock-exchange reports, and so on. If broadcasting is to be a success, the programmes have to be good from both the recreational and educational points of view. The quality of the speech and music reproduced by the radiophones or the loud-speaking telephone must surpass the performance of a gramophone. The programmes must be sent out daily at definite times and with absolute punctuality. Lastly, inexpensive and easily operated receiving apparatus must be readily procurable.

A development which will probably take place in the immediate future is the simultaneous transmission of different programmes. This can easily be done by using different wave-lengths. The element of choice will certainly make the broadcasting more attractive. From the programmes published in America we learn that the radiophone "cheers the hospitals," brings "church services to the home-bound" and "entertainment and news to the isolated." A claim is also made that radio broadcasting tends towards greater national and international harmony.

On the other hand, Mr. Perry in the preface to (7) advises every one to learn the Morse Code so as to listen-in to radio-telegraphic messages, which, he says, is far more interesting than broadcast radiophone concerts. In his opinion the constantly changing personal messages sent out "open up a vast field of interest, amusement, and knowledge." His book is to help the reader "to maintain a healthy interest in such a wonderful subject." It seems to us that there is room for a book on the subject of the ethics of "listening-in" to urgent personal and farewell messages from, for example, passengers on board ship. This method of obtaining interesting and amusing knowledge would not appeal to every one.

(1) Prof. Hausmann's book describes in an excellent and simple way the methods and apparatus used for receiving radiophone speech and music. Nine of the most eminent experts in America have co-operated to produce a thoroughly good book which can be readily understood without special technical knowledge.

(2) Mr. Keen's book deals not only with the general principles of direction-finding, but also with the constructional details of the installations required for shore service and for the navigation of ships and aircraft. It will be appreciated by the expert, for, although the discussion of problems is usually rather elementary, it is very thorough. The nomenclature of the subject is not yet fixed and so the author occasionally uses alternative words. We thus find the "cardioid," the "heart-shape," and the "apple" diagram of reception. Occasionally the author gets tired of writing about the "Marconi-Bellini-Tosi" system and refers to it simply as the M.B.T. system. The notes on field and nautical astronomy given in the appendix are good and will be helpful to the engineer.

(3) Colonel Crawley's little book on wireless is popular and interesting. He points out that the enthusiasm for broadcasting may have drawbacks. In the United States it is sometimes called "radio-flu." The purchase of a cheap set may lead to grievous disappointment. He gives a thoughtful discussion of the Imperial Wireless Chain.

(4) Mr. Coursey discusses the essentials of a radiophone and how it operates. He uses "wireless" and "radio" indiscriminately. The book is nicely got up and will be useful to beginners.

(5) The fifth book on our list will meet the requirements of those who desire to construct their own apparatus. A detailed description is given of a high-grade crystal receiver suitable for the reception of the broadcast concerts and radio time-signals sent out by the Eiffel Tower station in Paris. It must be remembered, however, that the concerts broadcasted by the Hague are quite inaudible in even a good crystal receiver connected with a large aerial. They can be heard only by suitable valve apparatus.

(6) Full particulars are give in Mr. Ainsley's little book for erecting various kinds of masts and aerials. Although it is not essential to possess an outside aerial with every receiving set, yet, when economy is a consideration, it is an advantage to have one. A strong 36-foot mast is shown the cost of the material for which was only 25*s*.

(7) In the last book on our list the author describes an ingenious method of learning the Morse system rapidly. This book should prove very helpful to many amateur radio-telegraphists.

Those intending to listen-in to the broadcasting must remember that even the best loud-speaking telephones appreciably distort speech and music. They cannot be used, also, unless the signals be so strong that they are uncomfortably loud on the radiophones. As a general rule, if it is desired to make signals audible in a room by means of a "loud speaker" it is necessary to add a two-valve magnifier to a set which would give comfortable hearing when used with radiophones. The two-valve magnifier itself appreciably distorts speech, thus adding to the troubles of those who listen-in.

The "Chemical" Sense.

Smell, Taste, and Allied Senses in the Vertebrates. By Prof. G. H. Parker. (Monographs on Experimental Biology.) Pp. 192. (Philadelphia and London: J. B. Lippincott Co., 1922.) 10*s*. 6*d*. net.

THE mechanism of the senses of smell and taste is apt to be unduly neglected, probably on account of the fact that in civilised man these senses do not play a large part in intellectual processes. But they bring before us some interesting problems as to the nature of receptor organs in general. It will be remembered that the object of such organs is to excite a set of nerve fibres on the incidence of some external agency of such a kind or intensity as to be unable to affect these nerve fibres directly. This is done by the production of some powerfully stimulating agent in the receptor mechanism at the terminations of these nerve fibres.

It is difficult to define satisfactorily the difference between taste and smell. If it be said that the former relates to substances in solution, whereas the latter relates to vapours, we are met with the fact that even vapours must be dissolved in the watery layer covering the olfactory cells. Moreover, the presence in fishes of a mechanism which appears to be the same as that of smell in air-breathing organisms suggests the need of some other criterion. Prof. Parker directs attention to the lipoid solubility of odorous substances and to the existence of hairs composed of lipoid material on the olfactory cells. The relation of surface tension and adsorption has also been brought into connexion with odorous properties. When we come to attempt to correlate either smell or taste with chemical composition we are met with serious difficulties.

The sense of taste is shown to include at least four distinct senses—sour, saline, bitter, and sweet. Some interesting experiments are given on p. 161, which show that the catfish, Amiurus, responds to meat juice by means of taste-buds situated on the sides of the animal. What is also significant is that the response is accompanied by "local sign," just as touch is in ourselves. The fish is aware of the position of the stimulus, turns to it, and swallows the meat. The response is absent when the nerves to the taste-buds are cut.

Prof. Parker holds that the sensations produced by various chemical irritants are to be distinguished from those of pain, although both are devoid of differentiated receptor organs and are mediated by free nerve endings. The chemical sense is said to be abolished by a smaller dose of cocaine than is the sense of pain. They have in common, however, a high threshold value, as would be expected from the nature of the structures stimulated. As the object of the sensibility is mainly to avoid injury, too great a delicacy would clearly be a disadvantage. The last chapter of the volume contains an interesting discussion on the relations between the common chemical sense and those of smell and taste. Of the three the olfactory sense is regarded as the most primitive, that of taste the most highly developed, with the common chemical sense as intermediate in evolution.

The volume is a very useful summary of our knowledge on the subject of the "chemical" senses as a whole.

W. M. B.

Our Bookshelf.

Geologie in Tabellen für Studierende der Geologie, Mineralogie, und des Bergfachs, der Geographie und der Landwirtschaft. Von Prof. Dr. K. Andrée. Erster Teil. Pp. xv + 96. Zweiter Teil. Pp. 97-134. Dritter Teil. Pp. 135-228. (Berlin: Gebrüder Borntraeger. 1921–1922.) Three parts, 8*s*.

The most remarkable things about this representation in tables of matters with which the geologist has to deal are the ingenious industry of the author and the very moderate price at which the book has been so excellently produced. Whether it will appeal to students depends much on the individual frame of mind. We incline to think that the "Tabellen"—we had almost written "tabloids"—will be of most, and indeed of considerable, service in the private library, as reminding the worker of what to look for in larger and descriptive treatises. It is to be regretted that there is no index to the mass of information of an expected or unexpected nature here assembled.

The author, in view of the abundance of material, has wisely kept the classification of igneous rocks on very simple lines. The customary grading of the "fine earth" of soils is given in section B of Table 49. Prof. Andrée has directed attention to his use of graptolites and ammonites in the stratigraphical tables, and here the succession of strata in various regions is set forth under the several systems. The columns dealing with the later series naturally show far more detail than those relating to the Carboniferous and older systems. The full treatment of Cainozoic strata should go far to correct the notion of their relative unimportance that still prevails among geologists in the British Isles. This is, we fancy, the portion of Prof. Andrée's work that will be referred to most often.

Prof. Andrée in his last ten pages generously provides a list of authoritative modern works on geology, which will guide the student into more arcadian fields. With two exceptions in favour of the United States, and three of an international character, the books named are all in German, so that we miss Geikie's "Text Book," Haug's "Traité," and De Margerie's translation, virtually a revised and extra-illustrated edition, of Suess's "Antlitz der Erde."

Reinforced Concrete: A Practical Handbook for Use in Design and Construction. By R. J. Harrington Hudson. Pp. xxiv + 318. (London: Chapman and Hall, Ltd., 1922.) 16*s*. net.

This volume is one of the very few treatises on reinforced concrete in which the properties of the materials employed, and the methods of working these materials so as to produce the finished results, receive adequate treatment. The matter is of great importance from the student's point of view; in too many instances, after a course in reinforced concrete, the impressions left in his mind are somewhat hazy, and he is apt to think that the subject is one consisting only of complex calculations. The early chapters in the book before us will go far to remove this impression. Most of the space is taken up with questions of design, both in theory and practice; the plan generally followed has been to give a general discussion of the particular problem, and then to throw the results into the form of tables and graphs so as to simplify so far as possible the practical work of the designer. The reader will find the numerous worked-out examples very helpful in gaining a knowledge of the methods of practical design. The portions dealing with monolithic design are good, and include discussions on secondary stresses and on continuous beams monolithic with columns. In developing this part of the subject the author successfully employs the equation of three moments. The London County Council reinforced concrete regulations are included in the volume, as also are extracts from the British standard specifications relating to Portland cement, and structural steel. The author is to be congratulated on his volume, which cannot fail to be of value both to engineering students and to those engaged on the practical side of structural engineering.

The Topography of Stane Street: a Critical Review of "The Stane Street," by Hilaire Belloc. By Capt. W. A. Grant. Pp. 95. (London: John Long, Ltd., 1922.) 5*s*. net.

In his critical review of Mr. Belloc's "Stane Street," Capt. Grant has produced a valuable study of this Roman way, which, although the author pretends to offer no opinion on historical or archæological points and confines himself to questions of topography, is of no inconsiderable interest to archæologists and students of Roman Britain. His criticism of Mr. Belloc is that, while an adept in map reading, his lack of familiarity with the principles of surveying for map construction has led him into numerous errors in tracing the alignments of Stane Street from Chichester to the site of Old London Bridge, sixty yards east of the modern bridge.

Mr. Belloc's theory is that there were four great limbs or sections covering respectively the ground from Chichester (east gate) to Pulborough Bridge, from Borough Hill to Leith Hill, from Leith Hill to Juniper Hill, and from Juniper Hill to the southern end of London Bridge. Capt. Grant examines each of these in detail and demonstrates the errors, while in a further chapter he indicates the true alignments and discusses the general principles upon which Stane Street would appear to have been planned. Capt. Grant is commendably precise in his criticisms, and in two appendices gives long lists, with references, of "Errors due to carelessness or Printers' Errors," and "Errors due to Miscalculation and mis-statements arising therefrom."

British Museum. Guide to the Maudslay Collection of Maya Sculptures (Casts and Originals) from Central America. Pp. 94+8 plates. (London: British Museum, 1923.) 1s. 6d. net.

To the small but select band of Americanists in this country it has always seemed little short of a scandal that the Maudslay Collection of Maya Sculptures, after being on exhibition for a short time at the Victoria and Albert Museum, should have been consigned to store, where it has remained for thirty years. Its rescue and display in the galleries of the British Museum pays a tardy tribute to Dr. A. P. Maudslay's pioneer researches and his enthusiastic efforts to preserve a faithful record of the remarkable artistic skill and culture of the ancient inhabitants of Central America. This collection of casts and originals was made by Dr. Maudslay, entirely at his own expense, between the years 1881 and 1894, when he made no less than seven journeys to Central America, visiting the principal sites in Yucatan, Honduras, and Guatemala.

The preparation of the guide to the collection has been in the competent hands of Mr. T. A. Joyce, who, in addition to a detailed description of the exhibits, has written an introduction dealing with the main characteristics of Maya culture and, in particular, with their hieroglyphic and chronological systems. It contains exactly the information necessary to enable the uninstructed visitor to the gallery to appreciate the most striking features of this ancient semi-civilisation.

Flora of the Presidency of Madras. By J. S. Gamble. Part 5: Ebenaceæ to Scrophulariaceæ. (Published under the authority of the Secretary of State for India in Council.) Pp. 769–962. (London: Adlard and Son and West Newman, Ltd., 1923.) 10s. net.

The present part of Mr. Gamble's Madras flora is on the same lines as previously issued parts. The family Ebenaceæ is completed, with an enumeration of the 24 species of Diospyros, several of which are large trees yielding a black heartwood, or ebony; and the treatment of the families of gamopetalous dicotyledons follows in the sequence usually adopted in the British Colonial floras. The principal families are Apocynaceæ, Asclepiadaceæ, and Convolvulaceæ, and the part concludes about half-way through Scrophulariaceæ. Solanaceæ is poorly represented, but in this family, as in Apocynaceæ, several South American genera, introduced in cultivation, have run wild. Mr. Gamble enumerates eight species of Strychnos, including *Nux vomica*, the source of strychnine, and another species, the seeds of which yield the alkaloid brucine; a third species, *S. potatorum*, derives its name from the fact that the seeds are used to clear muddy water. Of the Convolvulaceæ, the genera Argyreia and Ipomœa supply many showy-flowered climbers; *I. Batatas*, sweet potato, is in common cultivation as a vegetable.

Coal and Allied Subjects: a Compendium of the First Ten Bulletins issued by the Lancashire and Cheshire Coal Research Association. By F. S. Sinnatt. Pp. v+205. (London: H. F. and G. Witherby, n.d.) 15s. net.

Mr. Sinnatt and his collaborators have prepared a compendium of the first ten bulletins issued by the Lancashire and Cheshire Coal Research Association, and the intention of the publication is "to enable those engaged in the Coal Industry and others to share the knowledge gained in carrying out the work." The bulletins have been well worth collecting and issuing together in this form, which will facilitate ready reference. They vary in content from such a general subject as "Notes of Ten Introductory Lectures on Organic Chemistry, with Special Reference to Coal" (condensed into 32 pages) to the highly specialised brief bulletin on "Hoo Cannel." One of the most interesting describes the examination of the inorganic constituents of coal which deals with those ash inclusions known as ankerites, while "Coal Dust and Fusain" indicates another line of work with which Mr. Sinnatt has identified himself. No very fundamental problems of fuel technology have been attacked, and some of the matter is not original, being simply collected in the bulletins for the convenience of the Research Association, but it is a record of useful work. J. W. C.

The Phase Rule and its Applications. By Prof. Alexander Findlay. (Text-books on Physical Chemistry.) Fifth edition. Pp. xvi+298. (London: Longmans, Green and Co., 1923.) 10s. 6d. net.

The fifth edition of Prof. Findlay's book on the phase rule differs from previous editions in that the whole volume has been re-set, so that in spite of containing additional matter there is a substantial reduction in the number of pages. In the new edition the iron-carbon diagram has been altered in order to include the δ form of iron which appears when the pure metal is heated to 1400° or to a somewhat higher temperature in presence of carbon; the β form of iron has also been eliminated as differing only in magnetic properties from α-iron or ferrite. New material has also been introduced in connexion with the allotropy of sulphur and phosphorus, in view of the fact that these elements can give rise to pseudo-binary systems. In the later chapters of the book, additional space has been devoted to the mineral-forming systems, including both the aqueous deposits of the Stassfurt salt beds and the igneous calcium aluminium silicates.

Letters to the Editor.

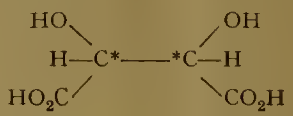
Molecular and Crystal Symmetry.

THE relation between the symmetry of a crystal and that of the component molecules has been recently discussed by G. Shearer (Proc. Phys. Soc., 1923, vol. 35, p. 81), who, unknowingly following the same train of thought, has arrived at the conclusion, previously stated by Fedorov (*Zeits. Kryst.*, 1912, vol. 52, p. 22), that a crystal obeys what may be termed a principle of conservation of symmetry. Thus, if n be the "symmetry number" of the structural unit or parallelepipedal brick (the number of identical or enantiomorphously related asymmetric parts into which it is subdivisible), m the number of molecules it contains, and p the symmetry number of each molecule, then $n/m = p$, or alternatively $pm = n$, *i.e.* the symmetry of the individual molecules multiplied by their number gives the symmetry of the crystal. If the formula be correct no symmetry is dissipated, the whole of the molecular symmetry being taken up by the crystal. Now, so far as Fedorov was concerned, the matter was purely speculative, for the X-ray method had only just been discovered and its exact meaning was still obscure, but Shearer has gone a step further by collecting X-ray data in support of the principle (or "Shearer's rules"), with the result that it has been provisionally adopted by Sir W. H. Bragg (Journ. Chem. Soc., 1922, vol. 121, p. 2766) as a working hypothesis in the interpretation of X-ray measurements. As I think the various considerations advanced by Shearer are inconclusive, and are already leading to very questionable conclusions concerning the stereochemical formulæ of certain aromatic compounds, I would here submit the Fedorov-Shearer principle to a brief discussion.

It is self-evident that any real vindication of the principle involves a knowledge of all the three terms p, m, and n of the formula. Now the last two quantities are relatively easily determined, but the molecular symmetry p is a much more difficult matter, for it implies a determination with a tolerable degree of accuracy of the position of every atom in the structure, and as such difficulties have not yet been overcome in the case of such complicated compounds as the benzene, naphthalene, and anthracene derivatives investigated by Sir W. H. Bragg, it is evident that the field for testing the principle is very restricted. As a matter of fact, the evidence adduced by Shearer is very scanty, consisting as it does of the demonstration that in no known case is $m > n$, followed by the statement that if certain values of p be allowed, then all the crystals can be brought into line with the principle. It must be noted that there is no experimental evidence in favour of these special p-values (which are, then, really postulated), and that most of them are not what one would expect from chemical knowledge (unless, of course, the molecular configuration in the crystal has not the same symmetry as it has in solution). Thus, crystal molecules of α- and β-naphthol, resorcin, benzoic, salicylic, and phthalic acids are all held to be asymmetric, from which it is to be inferred that the crystals contain two kinds of molecules in the manner of racemic acid. Then, again, naphthalene is held to have no plane of symmetry, and so on.

There is, however, one organic compound for which all the three terms p, m, and n have been reasonably well established, namely, the ordinary tartaric acid recently investigated by W. T. Astbury (Proc. Roy. Soc., 1923, vol. 102, p. 506). This is apparently held to conform with the principle, but as I do not agree with Messrs. Shearer and Astbury that the molecule is asymmetric, the case calls for a brief examination. The acid has long been known to have the formula



in which the two carbon atoms marked out by asterisks are the so-called asymmetric carbon atoms, *i.e.* atoms surrounded by four different groups in an asymmetric tetrahedral manner (the four groups being in each case H, OH, CO_2H, and CHOH . CO_2H). If a three-dimensional model be constructed according to the above scheme, it will be found to take three forms, depending on the way in which the duplicated groups H, OH, CO_2H are arranged about the main stem, C*——*C. One form is identical with its mirror-image (Pasteur's *meso* acid); the other two are non-identical mirror-images of each other (enantiomorphous) and represent the ordinary *dextro* acid of commerce and Pasteur's rare *laevo* acid respectively. It is the *d*-acid that is under examination, but the same will hold for the *l*-acid. If we inspect the model for symmetry we shall find a twofold (digonal) axis somewhere or other in the plane normal to the central stem, no matter how we may have previously affected the relative positions of the two ends by rotating one against the other (about the main stem). It may be added, parenthetically, that Astbury arbitrarily limits his discussion of the stereochemical model to six such positions, but in every case the molecular configuration of tartaric acid in the liquid or dissolved condition is not asymmetric (as generally described).

With regard to the state of the molecule in the crystal; a study of Astbury's paper leads me to the conclusion that the molecule is still symmetrical. The statement that "one-half of the ordinary tartaric molecule behaves exactly like the other half and is indistinguishable from it"; the pains that seem to have been taken to preserve this parity in allocating the various atoms within the structure; and, finally, the evidence of the numerous figures, all go far to counteract the impression created by Astbury's use of the term "asymmetric molecule." It seems as if the unobtrusive molecular twofold axis (normal to Astbury's "dumb-bell axis") has been overlooked. If this is so, then the state of affairs in a crystal of tartaric acid can be described as follows. The structure is not simply built up of a single space-lattice arrangement, with the molecular axes uniting to create the symmetry axis of the crystal, but is constructed of a pair of molecular lattices, mutually interpenetrating, the office of the second being to restore the symmetry lost by a refusal of the crystal to recognise molecular symmetry. As all the molecular symmetry is wasted, the Fedorov-Shearer principle is infringed to the utmost possible limit.

The above exhausts the material at present available for any practical discussion of the symmetry principle; for the numerous inorganic crystals reviewed by Shearer are evidently not put forward as proofs, but rather as contingent illustrations of the way in which the principle serves to limit the positions of the electrons in certain atoms. The conclusion must therefore be drawn that the principle has not been established. On the other hand, I am not disposed to attach too much weight to the evidence against the principle furnished by tartaric acid for the following reason. The object of Astbury's investigation was to explore the connexion between optical activity and enantiomorphism, and it was therefore necessary to choose a substance of relatively complicated composition. The crystals of tartaric acid are much too involved for any effective test of the symmetry principle. It is, for example, by no means certain that a slight deformation of the symmetrical crystal molecule into an asymmetric form could be detected by the X-ray method, and yet this deformation would be enough to substantiate the principle so far as tartaric acid is concerned.

It seems to me, therefore, that the whole question is still open, and that the suitable choice of material for an eventual test is worthy of a careful consideration. Such aromatic compounds as those under investigation for other purposes by Sir W. H. Bragg would seem to be unsuitable, for they are so complicated that the positions of the individual atoms cannot at present be deduced from the measurements; consequently, the shape and symmetry of the molecule have to be assumed. The compounds should rather belong to the simplest order of molecular structure; a molecule containing one atom of carbon is much better than one containing two. Hydrogen should be avoided, as it cannot be placed by the X-ray method. There should be as few kinds of atom as possible, for the quantitative connexion between atomic weight or number and reflection intensity is, perhaps, not too well known. The symmetry of the crystal should be beyond reproach, and it should be part of the investigation to assure it, since as a rule the crystallographer does not take the necessary trouble to determine the class of symmetry. Perhaps a suitable commencement might be made on carbon tetrabromide, CBr_4, the corresponding iodide and possibly hexachloro- and hexabromo-ethane (if these are not already too complicated). Such compounds have the advantage that the carbon content is almost negligible (being much less than the average percentage of hydrogen in organic compounds), and the X-ray effect of the carbon atom might therefore be neglected as a first approximation, the investigation being, as it were, simplified to that of a solidified bromine (or iodine) in which the halogen atoms are limited stereochemically by the insignificant carbon atom. Moreover, the dimorphism of the tetrabromide (monoclinic at ordinary temperatures and cubic above 49°) might afford information on the extent to which the molecular configuration changes with change of crystal structure.

Closely related with the above compounds are others of the same simple chemical type. Tin tetraiodide, SnI_4, for example, might give interesting results, since from the X-ray point of view the investigation might be regarded as that of an element (by virtue of the approximate equality in atomic number of tin and iodine), while from the chemical point of view one can be quite certain it is a compound (though whether the grouping of iodine atoms is tetrahedral is not so well grounded as in the case of a carbon compound). Work on such simple compounds as these might possibly establish the Fedorov-Shearer principle, and so be of assistance in the study of more highly developed carbon compounds.

Martini's Equations for the Epidemiology of Immunising Diseases.

E. MARTINI, in his "Berechnungen und Beobachtungen zur Epidemiologie und Bekämpfung der Malaria" (Gente, Hamburg, 1921), sets up a system of differential equations to represent the presumptive course of events in the development of an endemic in which recovery is accompanied by acquired immunity. He adopts the notation:

u = fraction of population affected with the disease, and infective.

i = fraction of population *not* available for new infection (immune or already affected).

$(1-i)$ = fraction of population *available* for new infection.

p = fraction of population newly affected, per unit of time.

q = fraction of affected population that ceases to be so, per unit of time, by recovery or by death.

m = fraction of immune population which loses immunity or dies, per unit of time.

α = infectivity (a proportionality factor).

Martini puts the new infections, p per unit of time, per head of population, proportional both to the infective fraction u of the population, and also to the fraction $(1-i)$ of the population *available* for new infection, so that $p=\alpha u(1-i)$, and accordingly writes his equations:

$$\frac{du}{dt}=\alpha u(1-i)-qu=(\alpha-q)u-\alpha ui, \quad . \quad . \quad (1)$$

$$\frac{di}{dt}=\alpha u(1-i)-mi=\alpha u-mi-\alpha ui. \quad . \quad . \quad (2)$$

Martini remarks that these equations cannot be integrated in finite terms. They are of a type discussed by the writer elsewhere (*American Journal of Hygiene*, January Supplement, 1923). Their solution in series is

$$u=P_1e^{(\alpha-q)t}+P_2e^{-mt}+P_{11}e^{2(\alpha-q)t}+P_{22}e^{-2mt}+\ldots \quad (3)$$

$$i=Q_1e^{(\alpha-q)t}+Q_2e^{-mt}+Q_{11}e^{2(\alpha-q)t}+Q_{22}e^{-2mt}+\ldots \quad (4)$$

From this it is seen that:

(1) The equilibrium at the origin ($u=i=0$) is stable if, and only if, $\alpha<q$. When this condition is satisfied, the disease will die out.

(2) The solution near the origin cannot take on oscillatory form, since $(\alpha-q)$ and m are necessarily real quantities.

There is, however, another equilibrium (as pointed out by Dr. Martini), namely, at

$$u=\frac{m(\alpha-q)}{\alpha q}=\mathrm{U}, \text{ say}, \quad . \quad . \quad . \quad (5)$$

$$i=\frac{\alpha-q}{\alpha}=\mathrm{I}, \text{ say}. \quad . \quad . \quad . \quad . \quad (6)$$

This has a real meaning if and only if $\alpha>q$, that is to say, just in that case in which the equilibrium at the origin is unstable; at the same time, in the neighbourhood of $u=\mathrm{U}$, $i=\mathrm{I}$, we have again a solution—

$$(u-\mathrm{U})=P'_1e^{\lambda_1t}+P'_2e^{\lambda_2t}+P'_{11}e^{2\lambda_1t}+\ldots \quad (7)$$

$$(i-\mathrm{I})=Q'_1e^{\lambda_1t}+Q'_2e^{\lambda_2t}+Q'_{11}e^{2\lambda_1t}+\ldots \quad (8)$$

where

$$\lambda=-\tfrac{1}{2}\left\{\frac{\alpha m}{q}\pm\sqrt{\frac{\alpha^2m^2}{q^2}-4(\alpha-q)m}\right\}. \quad . \quad (9)$$

We need here give no further consideration to the case $\alpha<q$, since the second equilibrium has no real existence in this case, and the first equilibrum was found to be stable, the disease dying out.

In the other alternative, namely, $\alpha > q$, we have two cases to distinguish :

$$(1) \quad . \quad . \quad . \quad . \quad . \quad (\alpha - q) < \frac{\alpha^2 m}{4q^2}.$$

In this case λ_1 and λ_2 are both real and negative. The equilibrium at U, I is stable, the disease will become definitely established, if once started. The approach to equilibrium is aperiodic, asymptotic.

$$(2) \quad . \quad . \quad (\alpha - q) > \frac{\alpha^2 m}{4q^2}, \quad \text{or} \quad \frac{m}{q} < 4\frac{q}{\alpha}\left(1 - \frac{q}{\alpha}\right).$$

In this case λ_1 and λ_2 are complex, with negative real parts. The equilibrium at U, I is still stable, but will be approached by a periodic process of damped oscillations.

It may be remarked that a solution can still be given if the coefficients α, m, q, which have here been treated as constants, are regarded as periodic or even as general functions of the time. However, the numerical evaluation of the coefficients appearing in the solution then becomes very onerous. It will suffice, on this point, to refer to the pertinent mathematical literature, as, for example, Picard, "Traité d'Analyse," 1908, vol. 3, pp. 187, 188, 194, 197; Goursat, "Traité d'Analyse," vol. 2, 1918, pp. 482, 498.

ALFRED J. LOTKA.

Johns Hopkins University.

The Cause of Anticyclones.

IF space permits, I should like to reply to one or two points in the letter contributed by Mr. W. H. Dines to NATURE of April 14, p. 495.

(1) In the first place, when one is dealing with two different sorts of air, probably of unequal frequency of occurrence, it appears to me to be unsafe to depend very greatly on comparison with mean values derived from all cases considered *en masse*. Has not the Bjerknes theory been elaborated as the result of an attempt to deal with the problem of atmospheric circulation on the assumption that discontinuities might exist, and that therefore—as other methods would probably fail to reveal them—only close study of individual cases could hope to succeed?

Apart from this, Mr. Dines deals with departure of temperature from the mean for the *height* and date. In the paper (Q.J.R. Met. Soc., Jan. 1923) to which reference was made in my earlier letter (NATURE of March 31, p. 429) temperature is dealt with throughout in relation to given *isobaric surfaces*. This seemed particularly desirable in the case of polar air, for a mass of such air, leaving polar regions with high velocity and low barometric pressure, may eventually find itself, with much reduced velocity and with a pressure increased by some 20 to 30 millibars, forming the surface layers of an anticyclone in temperate regions. The corresponding adiabatic increase of temperature (communication of heat from warmer seas, etc., being left out of account as being more or less common to all polar air moving southward) would be 3° to 5° F., or enough to bring the temperature at a fixed *height* up to about the mean temperature for that height. If the fifty-two cases of anticyclones referred to by Mr. Dines are considered from the point of view of normal temperature for a given pressure it will be evident that about half must be of polar air up to 1 km., and I think this is about as large a proportion as I should claim for that level. Rather more than one-fifth would then be polar up to 3 km., and so on.

(2) The question in regard to humidity is very complex; but I have always taken exception to the view that humidity (either relative or absolute) would be of much value in distinguishing between polar and equatorial air apart, that is, from its value for locating the discontinuity. In particular, polar air, in its passage over warmer seas, should have its humidity at all heights affected quite as greatly as its temperature. Equatorial air, on the other hand, is being cooled in its surface layers in the course of its northward journey, and the cooling effect does not tend to be propagated upward to any comparable extent; such factors as are at work within equatorial air tend rather to rob it of its water vapour without renewing the supply.

I do not, therefore, consider that where polar air lies under equatorial air the inversion of temperature need necessarily be associated with any particular peculiarity as to relative humidity. At the same time, the conspicuous decrease of relative humidity is well known and appears to be common, at least to all inversions in anticyclones. It may, therefore, be a natural sequel to the inversion itself, and I offer an explanation which seems to me not altogether impossible. It is that the inversion of temperature once formed acts as a non-return valve to moisture (in the same way that it almost certainly does to dust and haze in the atmosphere), and that very soon the "convectional lid" accumulates a concentration of water vapour just beneath it; the layer of air just above, on the other hand, succeeds in passing on upward or allowing to drop below the greater part of both its dust and its moisture while replenishment of these from below has ceased.

A. H. R. GOLDIE.

Wimbledon, S.W.19,
April 26.

THE reply of Mr. W. H. Dines, in NATURE, April 14, p. 495, to Major Goldie's letter, brings out very convincingly the peculiar fact that the temperature conditions of the troposphere, both in cyclones and anticyclones, are such as would rather obliterate than maintain them. Indeed, when we consider the problem of pressure distribution, we find that the conditions are generally exactly the reverse of those required by the ordinary accepted theory, except in latitudes within the tropics of Capricorn and Cancer. We are thus faced with a very striking theoretical difficulty; for the winds of the earth do not appear, in the main, to derive their force and direction from the temperature conditions at or near the earth's surface.

One of the most marked effects of surface temperature on the pressure distribution, other than the phenomena of the trade winds, is the fact that along the high-pressure belts of the tropics the pressure is greatest over the cold land masses during the winter and lowest over the heated land masses during the summer. Another clear effect of surface temperature is the fact that the North Pacific cyclone and the North Atlantic cyclone (the eyes of the North Polar cyclone) are more powerful during the summer than they are during the winter. However, we have to set against these considerations the striking facts that throughout the year the great low-pressure areas are over the frigid poles, which are not even exposed to the sun's rays during the winter, and that the high-pressure belts are near the tropics of Cancer and Capricorn, and cover the intensely-heated desert lands of the continents. To surface temperatures, on the other hand, must be ascribed the great seasonal changes of pressure and temperature which occur over the elevated areas of Asia.

When considering the theory of anticyclones and cyclones, it is better to pay attention to the great permanent features shown by the distribution of atmospheric pressure over the earth's surface. It is to these that the prevalent winds of the atmosphere are due. Small travelling cyclones are of course interesting; and, strange to say, they show the same peculiarities of pressure and temperature distribution as do the much larger permanent cyclones. Everything points to the conclusion that there is some other force at work more potent than the temperature conditions in the troposphere; and I have suggested that this force arises from differences of temperature in the upper stratosphere.

It is true that many registering balloon ascents show an isothermal condition in the lower stratosphere; but others show quite a rapid rise of temperature with increasing height. A study of these curves led me to conclude that at a height of 60 km. the temperature approaches very nearly that of the earth's surface. That such is the case a study of meteoric phenomena has demonstrated. Now if the distribution of temperature near the limits of the upper atmosphere varied with the latitude, the pressure distribution at the earth's surface would be affected. It seemed natural to suppose that such heating would be greater over the equatorial than the polar regions; but if this were so, the low-pressure areas would be in low latitudes and the high-pressure areas in high latitudes; which is not the case.

The above considerations suggested that the upper atmosphere must be hotter over the poles than it is over the equator; for, if such were the case, all our difficulties in trying to account for the pressure distribution and directions of the winds would vanish. However, there are several peculiar phenomena of the polar areas, such as the aurora borealis, which require explanation as well. This is a matter which cannot be adequately discussed in a short letter; but it is probably due to the deflexion of electrons, etc. (shot out by the sun), towards the polar areas by the earth's magnetic field.

It has been objected that my theory necessitates vertical currents in the stratosphere, which the temperature conditions would not permit. The actual temperature conditions would certainly retard the equalisation of pressure by vertical movements in the stratosphere, and this would cause it to take place mainly in the troposphere. It may be that it is this that makes it appear as though the force maintaining cyclones resided at the upper surface of the troposphere, as Mr. W. H. Dines points out in one of his papers. Indeed, the inrush due to the friction of the air with the earth's surface in a cyclone would lead to an outrush at the top of the troposphere.

It is admitted that there are difficulties in the theory which remain to be explained; but they seem less than those met with when other theories are considered.

R. M. Deeley.

Tintagil, Kew Gardens Road, Kew, Surrey.

Physical Literature on the Continent.

During the last few years it has become increasingly difficult for the universities of Central Europe to procure the scientific journals of other countries, in consequence of the calamitous depreciation of German and Austrian currencies. Such a state of things acts as a deterrent to scientific advancement in that the knowledge of work done outside only slowly and imperfectly permeates into these countries through indirect channels. Quite recently I have had two letters from continental physicists in reference to this matter, and I am anxious to bring the facts to the notice of the readers of Nature, in the hope that something may be done to remove to some extent the difficulty which at present exists.

Prof. Benndorf, of the Physical Institute of the University of Graz, Austria, informs me that the last number of the *Philosophical Magazine* available in that city is that of July 1914. In view of the expense, it has been quite impossible for them to procure back numbers of this and other English scientific journals, or to maintain them at present, as will be realised from the fact that the equivalent in our money of the annual grant to the Physical Institute of that University amounts only to 23*s*. The unsatisfactoriness of such conditions is obvious.

As it is not difficult in the libraries of most of our university towns to procure at least one copy of the *Philosophical Magazine*, it has occurred to me that perhaps some reader of Nature might be prepared to assist the Graz Physical Institute, by handing over his copy of the *Philosophical Magazine* to that institution say at the end of each month of issue. Such a donation would be most acceptable, and the donor may be sure of the sincere gratitude of the recipients, some of them well known in physics, such as Benndorf, Kohlrausch, and Hess.

The second letter has reference to the Physical Institute of the University of Berlin, which, for like financial reasons, is no longer in a position to purchase the *Philosophical Magazine*. Several members of this Institute, including Prof. Pringsheim, Dr. Hettner, and Dr. Laski, have suggested to me the possibility of surmounting the difficulty by an exchange of periodicals such as has already been arranged with America. They propose an exchange of the *Philosophical Magazine* as issued for either the *Zeitschrift für Physik*, *Die Naturwissenschaften*, or some other journal to be arranged upon.

If any reader of Nature feels disposed to assist in respect of either of the above suggestions, I shall be glad if he will acquaint me of the fact, so that I may put him in touch with the Institutes referred to.
